Dr. Redwood, being called upon by the Chairman to present his report with regard to the Chemical Class, said that at the close of the twenty-seventh session of the School of Pharmacy he had but little to say, but that little was highly satisfactory. The school had passed through various phases in the course of its history, commencing with a certain degree of prosperity, then suffering under some depression, and again rising to considerable importance. He was happy, however, to state that at no time had it manifested a greater amount of healthful vitality than at present. During the last session the school had been well supported, the students unexceptionable in their general conduct, regular and assiduous in their attendance, industrious in their studies, and some at least, he hoped many, most successful in attaining a great degree of proficiency. In his own class three competitors had eminently distinguished themselves, two very much so indeed. Of the twelve questions submitted to these two gentlemen, every one was answered, and well answered, and estimating the value of complete and perfect answers to these questions at one hundred, the value of the answers given was ninety-four. To both these gentlemen, Charles Fryer and Frederick Hamilton Peck, who were so equal in their attainments, the Council had awarded a bronze medal, and to the third competitor, Mr. Henry Forster, was given an honorary certificate.

The questions for examination were as follows:—

Chemistry and Pharmacy.

1. What is the length, in inches, of a pendulum that vibrates in seconds of time, at the latitude of London, and at the level of the sea?
2. What relation does the *metre* bear to the length of an arc of the earth's meridian?
3. What is the length of the *metre* in inches of our measure, and what is the difference between a decigram and a decagram?
4. In what way does the presence of air affect the accuracy of the determination, as usually made, of the weight or true gravitating force of a body?
5. What is the specific gravity of a liquid a pint of which weighs 9625 grains?
6. Describe the process of clarification, and explain the way in which heat alone, both at and below the boiling temperature, may effect the clarification of a liquid; also explain how liquids are clarified by the use of white of egg and isinglass?
7. At which end of the spectrum are the vibrations most frequent, and where are the waves the longest, in accordance with the undulatory theory of light?
8. Describe some of the principal phenomena on which *spectrum analysis* is based.
9. Describe *Antimony*, and the preparations of it in the Pharmacopœia.
10. Explain the doctrine of equivalence, of modern chemists, as applied to the chemical elements.
11. Describe the production of acetic acid by the various methods by which it is practically obtained, giving the composition of the different preparations of acetic acid (that is, of the acid in various degrees of dilution) of the Pharmacopœia.
12. State the composition, respectively, of alcohol, aldehyd, chloral, and chloroform, and show how the three last-named compounds are obtained from the one first-named.

The Chairman having handed the medals and certificate to the successful competitors,

Professor Bentley presented his report with regard to the class of Botany and Materia Medica. Alluding to the presence of the fair sex amongst his audience, he said he hoped the time would soon come when there would be a ladies' class under his superintendence in connection with the School of Pharmacy. For twenty-two years he had had a pleasurable duty to perform on such occasions, and what he had previously said he could now most conscientiously repeat—for he was quite sure that in no institution, collegiate or otherwise, was there to be found a better class of students, more regular in attendance, more attentive, or more industrious than was to be found in the Pharmaceutical Society. During the last session 112 students had passed through the class which he had the honour to conduct, six of whom had so highly distinguished themselves as to have had honours awarded to them. There was both a *vivâ voce* and written examination; in the former, the two gentlemen who had gained the highest distinction had obtained thirty-four out of thirty-five possible marks, and in the latter, though the standard could not be expected to be quite so high, it was very good indeed. Mr. E. A. Webb, who received the Council Medal, and Mr. F. H. Peck, to whom was awarded a Certificate of Honour, were both worthy of very high commendation, indeed there was but very little difference between them, and Mr. C. Fryer had also very highly distinguished himself. Three other gentlemen also, Messrs. H. Forster, J. P. Jackson, and E. Sainsbury were also well worthy of the certificates which had been awarded them.

The questions for examination were as follows :—

Botany and Materia Medica.

botany.

Hours from Ten till One.

1. Describe the structure of disk-bearing woody tissue and mention the Orders of plants in which it is especially found.
2. What are the distinctive characters between a root and a stem? Define the following :—Corm, bulb, tuber, tubercule, rhizome, and runner.
3. Distinguish between determinate, indeterminate, and mixed inflorescences. Define a spike, spadix, amentum, corymb, umbel, and capitulum.
4. Give a sketch of the changes which the crude sap undergoes in the leaves and other green parts by which it is converted into elaborated sap; and mention the important practical applications which arise from a knowledge of such changes.
5. Give the essential characters of the following Natural Orders, and enumerate the officinal plants which they respectively contain :—*Malvaceæ*, *Papaveraceæ*, *Cucurbitaceæ*, *Scrophulariaceæ*, *Polygonaceæ*, and *Iridaceæ*.

materia medica.

Hours from Two till Five.

1. Describe the physical characters of the seeds and bark of *Strychnos Nux-Vomica*. Mention the physical and chemical characters by which the latter may be distinguished from *Cusparia* bark.
2. What are the botanical and geographical sources of buchu leaves? Describe the leaves of the officinal species yielding buchu. Mention their medical properties, and enumerate their officinal preparations.
3. What is the botanical source of elaterium? Describe how it is obtained in the greatest state of purity, its physical, chemical, and medical properties, the means of ascertaining its purity, and the dose.
4. What are the botanical and geographical sources of Jamaica sarsaparilla? Describe the difference between mealy and non-mealy sarsaparillas. What are the characteristics of good sarsaparilla?
5. Describe the physical and chemical characteristics of virgin scammony. Mention the substances commonly used to adulterate scammony, and the means by which such adulterations may be detected.

The medals and certificates having been handed to the successful competitors,

Dr. Attfield, in making his statement with reference to the Class of Practical Chemistry, said it would be unnecessary for him to read the whole of the report which at the close of the session he had presented to the Council, but it might not be out of place for him to say that for the second time in the history of the Laboratory the balance of the financial account had been on the right side; and, as considerable interest and importance was now being attached to the question of provincial schools, he might mention that for some years past he had kept, in a form available for ready reference, statistics of the Laboratory, which were at any time open to the inspection of any one who might be thinking of establishing similar schools. His books showed the name of every student for the last eight years, the date of his entry and departure, etc., and also tables showing the number of students in any one session or in any part of a session, and the average position attained. During the last session 112 pupils had attended the Laboratory, or about 23 more than in any previous year. Many only came up to study for a short time preparatory to passing their examinations, having already worked at home with the aid of books, and perhaps with some assistance besides. Of course these gentlemen did not attend the lectures, and thus it happened for the first time since the Laboratory had been instituted that the numbers attending were much larger than the entries to the Chemistry lecture class and within one of those attending the Botanical class. He had again to announce, as he did on the previous occasion, that he had during the session held two examinations weekly, in the course of which he took the students at least over the whole chemistry of the Pharmacopœia. These examinations had been remarkably well attended, and seemed so popular, that they would be regularly continued. With regard to the competition for prizes, he might mention that two days were allotted for the examination, the students working from ten to four each day, and books of any kind being permitted, so that it was strictly an examination in practical chemistry. The questions asked, of which copies were on the table, consisted mainly in the analysis of liquids, solids and pharmaceutical preparations, and one essay at quantitative analysis. Twelve gentlemen competed, of whom six were remarkably successful. Mr. Fryer obtained ·92 of the possible number of marks, Mr. Francis ·87, Mr. Best ·85, Mr. Raffles, ·85, Mr. Sainsbury ·83, Mr. Metcalfe ·82, Mr. Webb ·70, and Mr. Peck ·68. In accordance with his recommendation the Council had awarded medals to the first two, and certificates of honour and merit to the others. With regard to the general conduct of the students it was unnecessary to say much, although he might easily enlarge upon this subject, for where the students spent one hour with his colleagues, Professors Redwood and Bentley, they spent from ten to fifteen with him, so that he had abundant opportunities of judging of their mental and moral character and calibre. Of course, as in all schools, he had found during the session perhaps 1 or 2 per cent. of idle and mischievous students,—young men who were well known to all employers, and who were just as dangerous in a shop as any article in Schedule A, and perhaps equally deserved to be locked up and marked "poison;" but even these were all the better for a short stay in the Laboratory. He was glad to conclude with two statements, first, that during the last two days a greater number of applications had been made for benches than at any previous time, though, he was happy to say, there was still plenty of room, additional accommodation having been provided; and, secondly, that during the ensuing session the Laboratory would still have the services of Mr. Tilden and Mr. Moss as senior and junior assistants.

The questions for examination were as follows :—

Practical Chemistry.

Hours: Ten to Five.

Books and memoranda permitted.

1. The "solution" given to you may contain any of the ordinary metallic salts used in medicine; analyse it, and state the results.
2. The accompanying "powder" is also a mixture of common metallic salts; examine it, and report your conclusions.

3. "Tincture of rhubarb." Examine the specimen for methylated spirit.

4. Report on the purity of the following articles:—

Acetic acid.
Diluted phosphoric acid.
Distilled water.
Glycerine.

5. "Bleaching powder." State the percentage of chlorine in the sample.

Professor BENTLEY announced the result of the contest for the Herbaria Prizes. These prizes were offered to young students,—the object being to encourage the study of Botany amongst these young men scattered throughout the country when they had opportunities of collecting specimens, which, in all probability, they never would have again, and in this respect they were particularly valuable. On the present occasion, this contest had been peculiarly successful,—four very excellent collections having been sent in, two particularly being of most exceptional merit, so much so indeed, regard being had not only to the care with which the specimens had been collected, the admirable manner in which they had been preserved, but also the mode in which they had been arranged, and particularly the knowledge exhibited in naming them, that it was impossible to choose between them, and both collections were on the table, where he hoped parties would take an opportunity of inspecting them. One was sent by Mr. Webb, who had already taken a prize in Botany and Materia Medica; and to show the advantage of sound early training, he might mention that this gentleman was residing with their friend Mr. Deane. The second collection was equally admirable, and was contributed by Mr. Rammell, who was living with Mr. Jackson at Crediton. It was interesting to notice, as showing the great influence of good training on an industrious student, that this gentleman was the fourth who had successfully competed for this prize whilst residing with Mr. Jackson. Silver medals had been awarded to both these gentlemen, and amongst the others more particularly deserving of honourable mention, were Mr. Alexander Wood, who obtained a Certificate of Honour, and Mr. C. J. Stansby, who obtained a Certificate of Merit.

Mr. DEANE said, some persons might imagine as he was the Examiner in Botany, that Mr. Webb might have had certain special advantages afforded him in making his selection, but he had much pleasure in stating that that gentleman had been so conscientious in the matter, that he would not receive any assistance from him beyond a little instruction in the mechanical arrangement and setting out of his plants. In every other respect, the collection was entirely his own work.

Mr. HASELDEN (Vice-President) in announcing the name of the successful competitor for the Pereira Medal, said he had had the honour of examining the papers. Seventeen gentlemen were eligible to compete, four of whom did so, of whom Mr. Peck was the successful candidate. With respect to the Prize of Books, he had had the pleasure not only of setting the questions, but also of conducting the examination, in conjunction with his friend Mr. Cracknell. Out of twenty-nine eligible to compete for this prize, seventeen entered, and the work was very well done by nearly all; so much so, that great credit was due to Mr. Webb, who had succeeded in carrying off the prize.

The questions for examination were as follows:—

PEREIRA MEDAL.

Section I. BOTANY.

Time allowed: Two Hours. Competitors are required to answer at least Two Questions in each Section.

1. Describe the germination of a bean and of a grain of wheat.
2. Explain the terms *achene*, *drupe*, *berry*, and *capsule*, and give an example of each.
3. What are the principal medicinal plants growing in England? Enumerate them, stating which occur wild and which are cultivated, and mention the Natural Order of each.
4. Explain botanically the nature of *Ergot*.

Section II. MATERIA MEDICA.

1. Enumerate the medicinal products of the Order *Euphorbiaceæ*, naming the plant from which each is derived and the country in which it grows.
2. What are the chief constituents of *Opium*? Name the more prominent characters by which some of them may be recognized.
3. What is the alkaloid of *Greenheart Bark*, and in what other substance has it been observed to exist?
4. In what countries and by what plants are the following drugs produced,—*Star Anise*, *Winter's Bark*, *Galangal*, *Venice Turpentine*, *Fenugreek*, *Grains of Paradise*, *Bay Berries*, and *Elecampane*?

CHEMISTRY.

Time allowed: Two Hours.

1. Describe the laws of substitution, giving at least three instances of substitution products.
2. What is the action of the following metals on nitric acid:—copper, gold, silver, tin, and zinc?
3. Describe tartaric, citric and malic acids, and their derivatives. What change occurs when these three acids are heated separately with caustic potash?

PRIZE OF BOOKS.

DISPENSING AND PHARMACY.

Time allowed: Two Hours. Standard Number of Marks, 300.

State the best method of dispensing the following prescriptions, assigning the reasons for the same, and write the labels in suitable language:—

℞ Potassæ Tartratis ʒiij.
Potassæ Bicarb. ʒij.
Acid. Citric. ʒiss vel q. s.
Spt. Æther. Nitros. ʒvj.
Mucilag. Acaciæ ʒiv.
Aquæ Destill. ad ℥vj. M.

Ft. mist., pars sexta horæ tertiis partibus capienda per vices tres, posteà singulis horis.

℞ Camphoræ gr. iij.
Ext. Hyoscyam. gr. $\frac{1}{2}$.
„ Opii gr. $\frac{1}{2}$. M.

Ft. pil. hor. somn. sum. et repet. inter noctem dolore vel inquietudine perstante. Mitte viij.

State the proportions of the ingredients in, and the method of preparing, the following decoctions:—cinchona, hæmatoxylum, hordeum.

Describe and explain the P. B. process for preparing extractum glycyrrhizæ, suggesting any improvement that might be made.

State the reason for directing the albumen to be separated from the extracts of aconite, belladonna, hemlock, henbane, and lettuce.

Describe and explain the process of the Br. Ph. for making syrup. tolutanus.

The CHAIRMAN said, before calling upon Mr. Schacht to deliver the address, he could not refrain from saying a word of welcome to the students for the forthcoming Session, keeping up the good old rule to speed the parting guests. There was no duty appertaining to the office which he had the honour to fill of a more pleasurable character than the distribution of the prizes. It took them back to the institution of the school, and brought before their recollection the services of all those who had worked so hard in bygone days, forgetting their own interests and thinking only of those who were to come after them in establishing the means of obtaining a sound education for the rising generation. It was a great pleasure to think of the work they had done, and a still greater pleasure to see that their efforts had not been wasted. They had this evening before them the gentlemen who had carried away the prizes; but, as Professor Redwood had said, there were others who might have competed if they had thought proper; and whether they gained prizes or not, they all gained benefit. Those whose names had not been mentioned to-night he hoped would be heard of by-and-by in after life, and he hoped all would remember that the most important part of their labour was about to commence. They had shown that the stuff was in them, and he hoped they would go on thoroughly and earnestly in the work they had undertaken, and do all in their power to advance the body to which they all belonged. In using the word "all," he could not forget that many who had taken prizes there had gone away to higher pursuits; but he believed that the field of pharmacy now offered a better position to young men than it ever had done formerly, and that there was abundant room for them to exert the talents which they had shown themselves to possess. He hoped, therefore, they would only take leave of the school in order to become connected with the Society as full members or associates, and he earnestly trusted that the same success which had attended them hitherto would follow them through the whole of their future career.

Mr. SCHACHT then delivered the following address:—

MR. PRESIDENT, LADIES AND GENTLEMEN,

Before commencing my immediate subject, I wish to say one word about myself. I must ask you to accept my assurance that I am in no way responsible for the fact that this person occupies this position at this moment. It is the result of the spontaneous act of the Council. The arrival of the Secretary's note that contained the resolution nominating me to this duty literally and truly filled me with surprise; and I felt as some private soldier might be expected to feel, should his commanding officer summon him from the ranks to manœuvre the regiment at full parade. One moment of utter surprise, and consequent hesitation, in both his case and my own, might, I trust, be deemed excusable—no more than this, however, would duty permit; the next must see us delivering our salute, and proceeding to obey our orders with what skill we may, our respective commanders being mainly responsible for the results.

The two gentlemen who have immediately preceded me in this duty approached their task with unusual claims to respect and attention. The one was strong alike in evidences, spread over many years, of wise and generous interest in the progress of his calling, and in the consistent manifestation of those qualities of mind, life and character, that have stamped him, even in these somewhat fortunate times, the model pharmacist. The other was an approved man of science, and a justly recognized leader of even the advance-guard of pharmacy.

Such credentials went far, not only to inspire their owner's words with special and peculiar force, but to justify their adopting, most becomingly and fitly, the tone of the teacher.

From no such point of vantage can the present address be uttered. It must come to those for whom it is intended from, as it were, their very midst. I must speak to them as one of themselves or not speak at all; for I am no teacher, the utmost that conscience will suffer me to hope is that through all my days I may continue to be an earnest and reverential student of scientific truth. But those that called me hither knew this, no doubt, perfectly well, and deemed it perhaps not altogether a matter of regret. They may have estimated this ceremony (as I may presently desire to repeat) as an occasion when for grave public reasons its prominent actors would be most fitly selected from amongst the obscure; or, it is possible, they may have deliberately chosen as their spokesman to a body of students one whose name was in some measure associated with a plea for the student class, and an effort, slight indeed, but still an effort, to supply the student's wants.

Let me, however, at once disown any special claim for consideration upon this latter score, for, in the first place, it would be by no means my exclusive right, many others having laboured in the same direction fully as earnestly as myself, though, perhaps, somewhat more silently; and, in the next place, my plea was not for students within these walls. Year after year as they have assembled to the launch of successive sessions of this school, I have envied them far too much to discover aught to plead for in their behalf. It has been for those outside these walls and outside this city that my plea has been raised. Twenty times the number that can gather here are compelled to stay without; for every single student that has the good fortune to revel amidst the riches of this school, at least twenty of the student class are debarred from ever setting foot within it. Of these some, it must be confessed, are kept away by nothing but their own indifference and carelessness. These are the drones of pharmacy, and a sad difficulty they have ever been, encumbering and marring every effort for professional advance, and discouraging all but the most earnest of the advocates of progress. But let it not be for one moment supposed that all who are not here are drones and idlers—that only one in twenty of our great student class have any care for science or for intellectual culture. Many long with all their souls for the advantages to be gathered here, and gratefully welcome every opportunity for improvement that is offered, even though it fall short of their ideal. And fall short, alas! it always does; for local effort, however earnest, and however fortunate, finds itself dwarfed and disparaged when compared with an imperial organization such as this; and it is not wonderful that observers who have some knowledge of both should be driven to reflect upon the differences that exist between them, and should endeavour to weigh their value and their effect upon the broad interests of pharmacy.

This important subject, I rejoice to know, at length occupies the serious consideration of our executive, and will, I freely hope, ere long receive a wise solution. In the meantime, local effort has done something; and it is gratifying to know that in several provincial centres courses of study similar in kind to that pursued in this school, and very good in quality, are at this moment in operation; classes of anxious, hopeful, curious students are mustering for fresh sessions, there as here, and are equally expecting the revelation of good things. Bear with me then when I say that it is with these and with the less fortunate ones still, who have yet to long and wait in patience, that my first sympathies lie, and for whom I would spend the chief of my voluntary labours.

But it would be strange if, with such a sentence on my lip, my heart could fail to find a word of welcome for others also,—for all indeed who have the mind to estimate the value of scientific culture, and the pluck to make the effort for its attainment. I said I envied the students of this school. By this was meant, not that I begrudged them one particle of the good fortune they are enabled to enjoy, but that I sighed to think so few, comparatively speaking, could grasp the fine opportunities this school affords. No, my only words to-night shall be, as I would wish them ever to be to all my fellow-students, words of heartiest congratulation.

So, then, most warmly, most heartily I congratulate you, my fellow-students, that you have determined, for yourselves at least, life shall not lose its greatest joy; that, although some around you select the husks of life, and pretend to be content therewith,—nay, try to persuade themselves and others that husk is the chief object of the plant's whole growth, and runs no risk of being trodden down at last of swine,—you have resolved that all this is specious and false; that you will look straight into truth itself, will pierce the husk, will grasp the seed and plant it anew in fair and cultivated soil, there to take root, grow and bring forth good fruit. Are not all who have so resolved indeed to be congratulated? They have touched the great law of universal Continuity, than which nothing can be nobler, "Be fruitful all;" and from henceforth a healthy unrest, a longing to fulfil a higher work urges their lives onward, upward. I said life's greatest joy; can one greater be hoped for man than that he should humbly attempt to fulfil his great Maker's purpose?

But the resolve is not quite all. There is no need surely to quote the many well-known words of wisdom you have learned upon this point.

Were I to begin with "Hell is paved with good intentions," and quote on till I gave you the parable of the seed that fell on stony places, I should but remind you of temptations of which you already know. I hint at them only because they give me grounds for further congratulations, for you are about to surround your good resolves with conditions the most favourable for their sustentation. These are—the enthusiasm of numbers associated in a common object,—the influence of method and methodical training—and personal contact with able and earnest teachers. These are very potent agencies, and are worth a moment's thought.

The mind of the young man is, as you know, in the very gush of its ardour; the enthusiasm of youth is proverbial, and not only constitutes one of its greatest charms, but is one of its real powers also; yet, perhaps in a greater degree than is the case with most of the attributes of poor humanity, it is erratic, prone to change and prone to languish. Let its emotions, however, have been but originally genuine, and the contagious influence of another's constancy, aided by the warm breath of friendly encouragement and friendly rivalry, is almost sure to fan the fading spark to a flame again. Depend upon it each can do much to help his comrade's constancy, very much to sustain the general gaze upon the general purpose.

To the same end also works that grand abstraction, method. Of all the qualities essential to the fair cultivation of that which is called mind, method appears to me to stand the first. Shall I therefore venture to say one word for the more general cultivation of mathematical studies amongst our younger pharmacists? From this place have been heard frequent and eloquent utterances in praise of classical culture; I willingly endorse them. It is not perhaps the special direction of my own taste, but I recognize its value, and appreciate the pains that others bestow upon it. Moreover, I am aware that in one direction at least it is essential to the proper fulfilment of our professional duties. But mathematics, which is indeed method, should, it seems to me, precede all special studies, or, at any rate, should accompany them side by side. The processes of mental and of corporeal development in many respects resemble each other; mind as well as body requires both food and exercise for its proper growth; the mere pouring in of meat and drink does not necessarily develope a healthy and vigorous frame; good wholesome exercise is needed for the double purpose of carrying every proper food-atom in streams of vital power to its appointed place, and for removing all that is superfluous, used up and baneful. What judicious exercise is to the body the science of method is to the mind; it assorts and arranges all its mental pabulum, and exalts to the utmost its powers of assimilation. It would perhaps be difficult to conceive of a mind, properly so-called, utterly and entirely uneducated in method, but one in which this quality is fully cultivated starts for the attainment of any branch of knowledge at a wonderful advantage over another not so tutored; even such indeed as the trained gladiator would possess over the peaceful citizen in a contest of physical strength. True, that in the patient study of a science such as chemistry, with all its inherent logic and its splendid mathematical developments, the pupil, almost despite his previous habit of mind, becomes imperceptibly educated in the law of method, and in proportion as this occurs he reaps for himself a double reward. But he has much to overcome, much leeway to make good before he can compete with his better-equipped rival, who has brought to the task an organization of power so complete that from the very first step each new fact as it is revealed, with all its attendant bearings, drops at once into its proper and appointed place, for ever after a veritable portion of his being.

I have been led to these remarks, which may to some appear unnecessary, from having more than once met with professed students of chemistry who were evidently ignorant even of the essential nature of an equation; and I hope, should there be any amongst those I am addressing whose attention has not hitherto been enlisted in these studies, they will make every effort to supply the omission, so that they may reap the fullest advantages of the methodically-conveyed instruction that will be presented to them.

But I return to the last of the three agencies indicated—the influence of the teacher upon his pupils. All teachers undertake a serious and a very trying responsibility; and in some departments of education their difficulties must be very great indeed. In those, however, with which we are mainly concerned the splendour of the subjects taught, and the illimitable interest that attaches to them, must go far to save the teacher from the sense of weariness and *ennui* so likely to attend the repetition of an ordinary oft-told tale. I cannot otherwise explain the constant freshness and enthusiasm of our professors of chemistry and botany, which, when I was a much younger man, used to fill me with surprise. In those days I had the good fortune to be a lecture-pupil under two very eminent men—the late Professor Brande and the late Professor Fownes. They were both, as you know, illustrious chemists, and they were both teachers of their science. One was old, and had been lecturing upon chemistry for thirty years; the other was young, and had but just written the beautiful Manual that bears his name. Was the old man dull, weary of his subject, and careless of its effect upon his pupils? and was the young man poetic, ardent and anxious? The younger man was, indeed, all that hungry student could desire, and so, also, was the elder. His thirty years of teaching had not diminished, by one sparkle, the energy and freshness with which in his youth he had been wont, as the coadjutor of Davy, to expound the great truths he had helped to unfold. He could, and he did, enkindle enthusiasm as genuine and as ample as attended the efforts of any of his juniors. And so I find it ever—in London and in Bristol—thirty years ago and now. Nor should I ever have wondered at the matter. Is there so great a difference between a "thing of beauty" and a "thing of truth," that one is a "joy for ever," and the other may become a weariness in a paltry lifetime? Are they not rather convertible terms? Is not their essence identical—their source One? So at least experience seems to teach, for I find that when I am helping some young beginner to apprehend a little of what is involved in the fact that 2 parts of hydrogen unite with 16 parts of oxygen to the production of water, or when I read to my children the beautiful history of "germination," my mind falls perforce into an attitude of reverence, and becomes penetrated with a consciousness of sublimity as vividly now as when, as a youth, their first realization filled my eyes with tears. No living creature can be indifferent whilst unfolding the splendours of scientific truth, provided only his audience be in some accord with him. The single thing that has the power to drag his spirit down from the lofty regions where dwell his themes, is the consciousness that he is surrounded with masses of dull clay that either cannot or will not mount with him. When this does occur, his task is, indeed, a heavy one; his whole being contracts with a rigour that no effort from within can overcome; his entire organization suffers a collapse; but, on the other hand, let him but feel that he is addressing willing ears and open minds, and (I appeal to the experienced teachers around me) then he enters the treasure-house boldly as one who has a right, and scatters lavishly all its precious stores.

You see then, I hope, that all these influences are helpful, and, what is more, that their power for helping is largely in your own keeping.

And I can surely once more congratulate you, for you will, most likely, be surrounded with enthusiastic companions, you are certain to have able and earnest teachers, and your instruction will be excellent in quality and systematically conveyed.

It remains only that, having such opportunities, you should make the best possible use of them. You have elected to study here because this is the best school of pharmacy in the country. Mind that the scholars are worthy of it. Look well to your laurels and to the credit of the school, for I promise you there will be some running close upon your heels who, handicapped though they be, will make a sturdy race of it.

But there remains something more to be said; at least, I should blame myself did I not give expression to a thought that has been for ever obtruding itself whilst writing these lines, especially when I endeavoured to realize this scene. I felt persuaded that when we really met, and I had approached the conclusion of my address, the question would occur, What does all this ceremony mean? Are the leaders of this great Society assembled,—has all this fair and goodly company come together for the sole purpose of doing honour to some scores of young men the majority of whom as yet, have done no more than declare their desire to study, and of listening to a few commonplaces from an obscure provincial. Candidly, I think not. They are glad, right glad, to welcome you. They are glad, I will be bold to say, to greet me; but beneath and above any such slight purpose runs a meaning in this gathering, in the presence of which you and I individually are nothing, except in proportion as we are content to merge ourselves within it. Every man lives a double life, or rather his life has two relations,—an inner life, for which in this world he is responsible to his conscience alone, and an *outer* life, which relates him to his fellow-creatures, and in which occur his thousand opportunities of influence for weal or woe. In the one he may aspire so high as to become the temple of the Holy Spirit; in the other, to be as a light set upon a hill, to shine for all men's benefit. As with the individual, so with societies of men in their corporate capacities. This Pharmaceutical Society has a life to live before the world which imposes obligations as constraining as those which relate it to its own members; and the proceedings of to-night constitute one of the legitimate occasions for its public confession of faith. It may be that for a moment my voice is the one most distinctly heard, and yours the ears most directly addressed; but my interpretation of this ceremony assures me we are but puppets standing for the moment in the place of an idea, and that by giving (as is done to-night) the places of honour to the youngest, and to the least distinguished of her votaries, this Society declares its homage to *science herself;* and records its conviction that although its range of duties may at times include matters that savour of privilege, of trade, and even of private interest, yet that pharmacy is absolutely and verily a branch of pure truth.

Be this the general conviction or not, it is mine, and justifies me, I trust, in the expression of a hope that each one of you will enter upon his work with a serious spirit and a consciousness of real responsibility.

I have urged you to look to your laurels and to the credit of your school, and I now, in the name of the whole Society, wish you heartily and sincerely every success in your studies. Distinction and honours are within your reach,—strive for them by all means and enjoy your rewards to the full; but I should rejoice to think that in the midst of any triumphs the future may bring, when the heart was beginning to swell with the pride of first achievement and success was threatening to awake the flame of vanity, some lingering memory of the higher obligation I have just indicated might serve to restore you to a humble spirit. I would that you and I could at all times remember we are not mere units, with privilege to live for ourselves alone, any more professionally than privately. We are ingredients of a body corporate, whose honour is to the extent of our opportunities committed to each one's care, and it is our bounden duty to preserve it pure. Let us aim high, therefore, and yet be lowly, seeking the general advance rather than our own advantage; in a word, let our first efforts be to become Christian gentlemen, and then, for certain, every fresh attainment we may acquire, and every meed of honour we may gain, will become a new grace and a new dignity for our common mistress Pharmacy.

The Chairman in proposing a vote of thanks to Mr. Schacht, said there was a little matter which he had forgotten to mention when distributing the prizes. As they were aware, Mr. Hills, the treasurer, last year published a portrait of Mr. Jacob Bell at his own expense, intending to give the whole of the proceeds of the sale to the Society to be distributed in a prize of books. The portrait had not sold so well as had been anticipated, but Mr. Hills' generosity was was not to be baulked, and he had therefore augmented the sum realized by a further donation of money, making in all an amount of stock which would produce £10 a year. The details of the prizes were not yet definitively arranged, but it was proposed that a prize of books should be given every month to those who passed the best Minor Examination; many members of the Council, whose opinion was of great value, thinking that prizes being awarded to these young students would have the effect of leading them on to further exertions. After announcing the next meeting, the Chairman said he had concluded the business of the evening, but he understood there was to be an afterpiece of which he was to be the subject, and he would therefore beg leave to withdraw.

Mr. Frederick Barron having been requested to take the chair, said he was much gratified at the honour which had been conferred upon him. As the meeting were aware, upwards of £500 had been subscribed by the trade for the purpose of presenting the President with a suitable testimonial, and though this did not appear a very large sum, yet considering that chemists as a body were not very wealthy, he thought they need not be ashamed of what had been done, and what had been given was given heartily and freely. Mr. Sandford enjoyed the affectionate respect of all who knew him throughout the length and breadth of the land, and in the Society to which he had devoted the best efforts of a great part of his life he was deservedly popular. His time was exceedingly valuable; he was a man not only of a large and generous heart, but of a highly cultivated mind, and he had given to the Pharmaceutical Society much more of his time and attention than could fairly have been expected of him. The result was, that, seconded as he had been by the efforts of his colleagues and of the able professors connected with the Institution, they had not only obtained the Pharmacy Act, but had placed the Society in a higher position than it had ever before occupied. Having referred in terms of high approbation to the addresses which he had heard on that and similar occasions, Mr. Barron requested the Secretary to uncover the portrait of Mr. Sandford, the sight of which elicited a burst of applause. He stated that the selection of the artist, Mr. Knight, R.A., had been made after the greatest deliberation, and he believed the result showed that their choice had been a wise one. He understood that Mr. Sandford, with great generosity, had expressed his intention of handing over the portrait to the Society, and it would probably be hung by the side of the portrait of Mr. Allen, their first President, whom, in his personal character, Mr. Sandford in many points resembled. In conclusion, he was sure all who heard him would unite in wishing long life and happiness to their esteemed President, and he invited them to join in giving three hearty cheers.

Mr. Mackay having proposed a vote of thanks to Mr. Barron for his services as Chairman of the Testimonial Committee, which was briefly acknowledged, the proceedings terminated.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The Annual General Meeting of the Association was held on Friday, September 30, at the Philosophical Institution; Mr. Stoddart, President, in the Chair.

The minutes of the previous meeting having been read and confirmed, the following report and statement of accounts were read and adopted:—

Report.

The Council of the Bristol Pharmaceutical Association have great pleasure in presenting to the members their first Annual Report. They have endeavoured to fulfil their appointed duty. Their instructions were "to use their best efforts for the establishment of a thoroughly efficient school of pharmacy, and to arrange a series of open meetings for the delivery of lectures and the reading of scientific papers." With regard to the latter portion of these instructions, they have to report that on each second Friday of the months November and December, 1869, and January, February, March, April and May, 1870, useful and interesting matters were presented to the members and associates in the form of lectures and papers. The lectures were delivered by Mr. Coomber, Mr. Gilford, Mr. Townsend and Mr. Wm. Lant Carpenter, and the papers were read by Mr. Boucher, Mr. Stoddart, Mr. Giles and Mr. Schacht. At most of these meetings good attendances welcomed the lecturers; but the Council regret to have to notice that on occasions when distinctly pharmaceutical subjects were announced the attendances were the smallest; a fact that they feel must operate to the discouragement of those who would otherwise be willing workers for the general good.

In reference to the establishment of a school of pharmacy, the Council have to report that they have availed themselves of the best resources at their disposal for the attainment of this most important object. They are quite aware that as yet Bristol does not possess a perfect school of pharmacy, but they have been able to arrange four complete courses of lectures upon the most important portions of pharmaceutical education, viz. chemistry, organic and inorganic; and botany, structural and systematic. They are satisfied that, as far as they have been able to proceed, the character of the instruction given has been the best of its kind, and they are glad to be able to report that a fair number of students have availed themselves of the opportunities thus offered, and have proved the excellence of their instruction by passing in goodly numbers the Government examinations. The Report then gave the details of the examinations, and the names of those who had received prizes at the end of the Session, already printed in our number for August 27.

The plan for these lectures adopted by the Council consisted in making arrangements with the teachers of chemistry and botany in the Government science classes at the School of Mines, by which those classes became open to any number of pharmaceutical students presenting the ticket of this Association. They were thus enabled to offer to their associates complete and excellent courses of lectures for very small fees, one stipulation only being made, that they should present themselves for examination at the conclusion of the course.

Some doubts having been expressed as to the probability of this course being approved by the Lords of the Committee of Council on Education, a communication was forwarded to the department by the Honorary Secretary requesting a formal statement upon the point. The reply was in every respect satisfactory, and definitely asserted that students in pharmacy are entitled to every advantage that the science classes can afford.

The Council have full confidence that their successors in office will be gradually enabled to develope these initiatory measures into a complete school of pharmacy, and are rejoiced to see that the Council of the Pharmaceutical Society of Great Britain are taking steps that appear to lead to the desirable system of granting pecuniary aid to provincial efforts in scientific education. They believe such a course to be both wise and just, and they congratulate the whole body of English pharmacists on the prospect for good that it opens out to them.

The Council cannot conclude their report without acknowledging the courtesy of the Committee of the Philosophical Institution, who, at all times, have so readily granted the Association the use of their Theatre and rooms.

The Treasurer in Account with the Bristol Pharmaceutical Association for the Year ending September 30, 1870.

HALIFAX AND DISTRICT CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Winter Session of the above Association was commenced on the 9th September by a General Meeting of the members, at their room, in the Mechanics' Institute; Mr. Stott, Vice-President, in the chair.

The Chairman, alluding to the severe illness of the President, expressed the great regret which was felt by the trade at his continued indisposition, and the hope that an early recovery would take place. He said the subjects for the evening's consideration were of great importance. The Committee of the Association was thoroughly intent upon pushing forward measures of improvement, both in relation to the members and their young men, and the summer, which is usually considered as a respite from committee work, had this year been employed in ascertaining the feelings of the majority of the trade in reference to the proposed measures, and in forming such plans as would be of general benefit; he felt sure that the earnestness which the Committee had shown, as well as the disinterestedness of their work, would keep alive that enthusiasm which founded the Association, and which the numerous attendance at the meeting showed to be unabated. Before entering into the discussion of these matters, he would call upon the members to elect delegates to the British Pharmaceutical Conference, to be held in Liverpool the ensuing week; the objects of these yearly conferences were so well understood amongst them, that it would be unnecessary on his part to dilate on the necessity of giving them their cordial support.

After some discussion, it was resolved unanimously, "That Messrs. Stott and Farr be the delegates from this Association to the British Pharmaceutical Conference."

The Secretary, Mr. Hebden, then informed the members that the Committee had succeeded in engaging a suitable teacher for botany, and the class which was commenced in the early part of summer would cease at the end of autumn, till the following spring, when it would again commence. This arrangement was necessary, so as not to crowd and confuse too much the studies of their young men. Chemistry and Latin would constitute their studies during the winter. The teacher had arranged for a number of meetings early in the summer mornings to give the students practical illustrations of his teaching. The popularity of the study of botany amongst these young men was strongly evidenced by the fact that the number of students was double that of the other classes. The Committee had fixed the student's fee at 5*s*. the term, and as the fee of the teacher and other incidental expenses would amount to much more than would be thus received, and as it was also considered desirable that a prize should be offered at the close of the term for competition, the Committee trusted it would be agreeable to the members that the amount of the deficiency and prize should be paid from the general fund of the Association. In reference to the classes in Chemistry and Latin, he read a letter from Mr. Gibb, the Principal of Haley Hill College, in which was stated the number of students in each class, their regularity of attendance, their success at the college examinations last May, and the earnestness with which they devoted themselves to their studeis. The Latin class, at the express wish of the students, was now continued throughout the year. The only matters he had to complain of were that the number of students ought to be greater, considering the number of young men connected with the trade in the town; and of the lateness of business hours, which was a most serious obstacle to successful studying.

The members entered generally into the discussion of these classes, and a desire was expressed to give their young men every facility for early and regular attendance.

Mr. Farr proposed, and Mr. Brooke seconded, "That the Secretary be empowered to pay out of the funds of the Association such amounts as may be required to meet the wants of the Botany class." Carried unanimously.

Mr. Shaw stated his intention to offer a prize in March next for competition in materia medica, conditionally that there be a reasonable number of competitors.

The Secretary then informed the members as to the success which had attended the efforts of the Committee for curtailing the business hours of the trade; they had proposed to the members individually that every night except Saturday night the shutters should be put up at 8 o'clock, and the door finally closed at 8.30; "matters of necessity would of course be attended to at the back doors," and on Sundays no shop door to be opened.

A great majority expressed their acquiescence to this plan, but a few had not as yet given a decided reply; it would be for the meeting to consider what course would be best to pursue.

Mr. Jessop considered the plan far too moderate, and would propose that the shutters should be put up at 7 o'clock, and finally close at 8.30. He considered that this would be a mild but eventually effectual protest to the public against late shopping, and it would enable them to set their young men at liberty much earlier to pursue their studies.

Mr. Pollard and Mr. Brookes spoke in support of this plan.

The Secretary begged of Mr. Jessop not to press this proposition. At the present meeting it would no doubt be carried by a majority, but its only result would be to embarrass the Committee. Moderate as was their own plan, it was still a matter of doubt as to its success. It would be, therefore, impolitic to attempt anything more difficult. Whatever engagement the members entered into, would depend in a great measure for its fulfilment on the confidence they had in each other, and it would risk the very foundation of the Association if it risked the breaking of that confidence.

Mr. Shaw would support the plan of the Committee, although he sympathized with the more advanced proposition.

Mr. Brierley said success, however small, must first be attained, and the next step would be all the more easily gained, whereas if too much was attempted, the project would fall to the ground. The small change advocated by the Committee would introduce the thin end of the wedge.

Several of the members supporting this, Mr. Jessop withdrew his proposition.

The plan of the Committee being thus agreed to, a deputation was appointed to wait upon those who had not yet stated their intentions.

The Chairman then drew the attention of the members to the time, which was too far advanced to introduce further subjects for consideration, especially so as the next subject was a most intricate and difficult question, viz. "Uniform Retail Prices." It was absolutely necessary that the most complete and clear understanding should be established, and that the question should be discussed in all its details; he should therefore adjourn the subject till their next monthly meeting.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting at Liverpool.

Tuesday, September 13th.

The Specific Gravity and the Actual Weight of certain "Volume-Measures" of Various Liquids and Preparations.

BY F. M. RIMMINGTON.

Our system of weights and measures, as well as our pharmaceutical practice of using weights and volume-measures for fluids are both so irregular and unsystematic, that all engaged in pharmacy cannot but have experienced the inconvenience of having constantly to convert measures into weights and weights into measures. The frequent experience of this want myself, suggested to me, some time ago, the desirableness of a table of the principal liquids in use in pharmacy, accurately ascertained from authentic samples, in order that exact computation may be made by its data. The utility of such a table is confined to such liquids as profess, or are intended to be, of Pharmacopœial strength.

Some attempts of a similar kind have been made in some of the foreign Pharmacopœias, and a paper was read by Mr. Laird at the Norwich Conference, but he only gave a few examples, and the scope of the paper was confined to the specific gravities of tinctures.

It was my intention to have added another column, giving the percentage amount of extractive contained in the tinctures, which would have greatly increased the usefulness of the table, forming a standard of quality to which reference could be made, but pressure of other engagements compelled me to relinquish the task before it was completed.

A Table showing the Specific Gravities and Weights of certain Volume-Measures of various Pharmaceutical Liquids.

The President said that the contents per ounce were concident with the specific gravity; for instance, lemon juice, having a sp. gr. 1040, would contain 40 grains of citric acid per ounce, and so on, except in such cases as alum and sulphate of soda, where there is much water of crystallization. In those cases it would be half, or 20 grains per ounce.

Mr. Reynolds (Leeds) referred to the rule laid down by Dr. Roberts, of Manchester, in regard to urine. This was that, roughly speaking, the units and tens of the specific gravity, when compared with one thousand parts of water, represented the grains of sugar in an ounce of diabetic urine.

Dr. Watts (London) referred to recent and other researches on the supposed porous condition of liquids, and the extent to which anhydrous salts, which dissolved in liquids without increasing the bulk of those liquids, were considered to occupy an interstitial position in regard to the particles of which the liquids were composed.

Concentrated Compound Decoction of Sarsaparilla.

BY MR. F. M. RIMMINGTON.

The preparation of sarsaparilla so long known in the trade as concentrated decoction of sarsaparilla has received less attention, perhaps, than any other galenical preparation at the hands of scientific pharmacists. No criteria have, to my knowledge, been given of what it should be; and, considering the large demand for it, there is ground for supposing that some samples are not quite all they should be. It is a preparation, too, that is not easily judged by the senses. Samples are sometimes met with of such intensely deep colour that suspicion is excited. Other samples appear to have a greater consistence, and sometimes the taste of licorice is stronger than it ought to be. Now, all these appearances may be fallacious; some data upon which to enable the mind to form a judgment are required. Sarsaparilla itself has nothing very distinctive in it. There are no alkaloids to estimate, and the only datum is the amount of extractive afforded by a given quantity of root. All this uncertainty I have experienced, and have attempted to fix a standard of comparison.

I assume, from my personal experience, that the specific gravity of a liquor made with good root, in the proportion of a pound to a pound of fluid and 10 per cent. of spirit, ought to have a gravity of from 1·045 to 1·055. But as the specific gravity alone is insufficient as a test, as it may be affected by several circumstances, but, taken in connection with the amount of extractive contained in a given volume, it is of some value. But as the amount of extract may be influenced by the addition of other extracts, and sometimes salts are added for the purpose of increasing the colour and amount of extractive; consequently, it is necessary to estimate the amount of ash. These three tests together will, I think, be a pretty good guide to the judgment as to the quality and purity of the article. I have been unable to obtain sufficient samples to make a long table, but the following, I think, are sufficient to show the value of the plan I suggest.

I may add that the decoction has always a strongly acid reaction, and effervesces with carbonates.

No.	Specific gravity.	Extract in 1 fl. oz.	Ash in ditto.
1	1·055	64 grs.	10 grs.
2		57 „	9·7 „
3	1·027	50 „	9·0 „
4	1·034	52 „	9·5 „
5	1·017	33 „	7·5 „
6	1·049	67 „	13·7 „
7	1·048	64 „	The amount of ash not taken, the experiment being made before this paper was contemplated.
8	1·048	75 „	
9	1·010	34 „	

Bradford.

The President spoke as to the difficulty of obtaining the extract in a uniform state of dryness.

A Member stated that common salt was used by some makers to preserve the essence and to reduce the amount of spirit.

Mr. Groves (Weymouth) had found the deposit formed in the compound decoction to consist mainly of a compound of glycyrrhizin with acetic acid.

Wednesday, September 14th.

The Conference reassembled at 10 A.M. The spacious Lecture Theatre of the Royal Institution again exhibited a numerous attendance throughout the day.

At the commencement of the proceedings, Professor Attfield announced that an answer had been received from the American Pharmaceutical Association, in conference at Baltimore, to the telegram sent on Tuesday evening across the Atlantic from the Adelphi Hotel. It was as follows:—"From Professor Maisch, Baltimore, to Secretary of Pharmaceutical Conference, Liverpool. —Fraternal greeting of American Pharmaceutical Association."

After the transaction of the usual business, the following paper, an abstract of which is given, was read.

A Century of Old Books Relating to Pharmacy and Kindred Subjects.

BY JOSEPH INCE

Member of the Royal Society of Literature.

The design was to exhibit one hundred volumes illustrative of the Pharmacy of the fifteenth and sixteenth centuries. Some of these were of great rarity and excellence—the object contemplated will best be explained by the preface which we subjoin.

A few rare old books are here presented for inspection. I have to thank those who have so largely contributed from their stores, and also to acknowledge the skill and promptness with which the descriptive writers have executed their task. This collection was begun, finished, catalogued, and on its way to Liverpool, within the space of one month. It is hoped that a great town such as this manufacturing centre, with its trade activity and its wonderful mercantile intelligence, will not disdain to read these records of the past. Some possess special interest, such as Gerard's 'Herbal,' remarkable for noble type and quaint illustrations, which at this moment are copied by modern artists; Prosper Alpinus, the Secrets of Alexis, Pomet, and many others. I regret exceedingly for the sake of the members of the Conference that I have had to stand alone, and that I have been deprived of the aid of one whose power of accurate analysis, lit up by a graceful fancy, would have lent an added charm to these pages. Accept them as an earnest of goodwill; they have received as much care as other pressing occupations and anxieties would permit. It is right sometimes to live in centuries not our own; and as men trace out the sources of the Nile, so we may take pleasure in learning the springs from which our present information has been derived. To study these productions is to love them. No man ever yet could decipher a black letter in the spirit of a fossil. None can hold converse with the great dead, and have a mean, ignoble mind; and these ancient tomes hold in their hands the gift of *rest.* I would fain say one other thing. Should any writer wish to escape feebleness of style, and gain manliness of expression, let him become, first, a diligent student of the Bible, specially of Isaiah, the authorized translation of which is the grandest rendering of the English language extant. Secondly, let him be a reverent admirer of men, the composition of whose works has been and will remain a constant theme of admiration. I congratulate whoever he may be to whom this exhibition may prove his first introduction to a literature much of which seems inspired. What can exceed in stateliness or beauty *the* dedication to King James? What can surpass many sentences which these recondite treatises contain? This statement is not upset by knowing that several have no other recommendation than the date they bear. This class of research moreover may induce a healthy dissatisfaction with ourselves; for while chemistry has advanced with giant steps, and botany has shaped itself into a definite science, and is excellently taught, I entertain the heterodox belief that we have altered many things in Pharmacy without improvement. After which dreadful declaration I fall back on Francis Lord Bacon (1597):—

"Reading maketh a full man; conference a ready man; and writing an exact man. And, therefore, if a man write little, he had need have a great memory; if he confer little, he had need have a present wit; and if he read little, he had need have much cunning to seem to know that which he doth not."

The chief contributions were received from Provincial Associations and Pharmacists: the collection of the Pharmaceutical Society was included, while a few private gentlemen sent valuable additions.

It is obvious that books forwarded without description would fail to be of service; eight writers therefore united to supply explanatory notes.

There was a certain man having great authority, for he had the command of all the treasures in Ethiopia, and he lived in the reign of Candace. Riding in his chariot he read. A strange thing, for it was an age when common people read seldom and dignitaries almost never. "Understandest thou what thou readest?" was the question. "How can I, except some man should guide me?" was the answer.

The annotators were, James Collins, Daniel Hanbury, A. F. Haselden, F. T. Marzials, John Moss, Richard Reynolds, W. A. Tilden and Joseph Ince.

The chief object of interest was the collection lent by Daniel Hanbury which was the one shown during the reading of the paper at Liverpool. We quote his own remarks on the following books:—

Pomet.—Histoire Générale des Drogues, traitant des Plantes, des Animaux et des Minéraux, Ouvrage enrichy de plus de quatre cent Figures en Taille-douce tirées d'après Nature; avec un discours qui explique leurs différens Noms, les pays d'où elles viennent, la manière de connoître les véritables d'avec les falsifiées, et leurs proprietez, où l'on découvre l'erreur des Anciens et des Modernes; le tout très utile au public. Par le Sieur Pierre Pomet, Marchand Epicier et Droguiste. Paris, 1694. *fol.*

No work of its class has enjoyed a more deserved and extensive reputation than Pomet's History of Drugs.

Here is the first edition published in Paris in 1694, at which period Pomet was keeping a shop in the Rue des Lombards, the great drug-street of that capital, as his advertisement at the end of the volume makes manifest. But what a marvellous contrast is a *History of Drugs* in the seventeenth century to the *Manual of Materia Medica* which suffices for the nineteenth! Would any modern student have the courage to sit down to the perusal of the stately folio of 528 pages, illustrated by 400 engravings? To speak seriously Pomet's book is of great utility and excellence, not so much by reason of its erudition and research, as on account of the information which the author gives as the result of his own observation and experience. Although it is profusely illustrated by engravings which must have been produced at no small cost, the figures are often poor and spiritless, and in some instances entirely imaginary, thus contrasting unfavourably with the rude but life-like wood-cuts of Brunfels published a century and a half before.

Monardes (Nicolaus). Historia de las Cosas que se traen de nuestras Indias Occidentales que sirven en Medicina. Sevilla, 1574. 4°.

The writer who first gave to Europe an account of the more useful plants and vegetable products discovered by the Spanish adventurers in the New World was Dr. Monardes, a physician of Seville, who in 1569 published a small volume under the above title. Other editions of this work were printed in 1571 and 1580. In 1596 an English version made by one Frampton was published as "*Joyfull Newes out of the New-found Worlde*;" the work also appeared in French, the translator being Antoine Colin, Maistre Apoticaire Juré de la ville de Lyon, and in Italian. Better known than the original Spanish or than the English, French or Italian translations, is the excellent Latin version included in the *Libri Exoticorum* of the learned Clusius, which appeared in 1605.

Monardes never visited America, but derived his information and specimens from the navigators and explorers who were doubtless at that period frequently arriving at Seville. Among the drugs he describes are Copal, Anime, Liquidambar, Balsam, Guaiacum, Sarsaparilla, Tobacco (of which there is a woodcut), Sassafras, Coca Leaves and Cevadilla, besides many which now find no application in Europe. Of this latter class is *Nephritic Wood*, a substance the origin of which is still entirely unknown; it is remarkable for its aqueous infusion exhibiting a beautiful blue layer on the surface (like a solution of quinine), a fact which Monardes did not fail to observe.

Hieronymus Brunschwyg on the Art of Distillation.

A work of which there are numberless editions, including an English version printed in Southwark in 1525 and entitled *Noble Experience of the Virtuous Handywork of Surgery—and of Distillation*. The present edition appeared at Strasburg in 1515; appended to it, is the *Book of Life of Marsilius Ficinus, the Florentine*, which contains curious representations of mediæval herb gardens, an apothecary's shop, laboratory, studio, besides various scenes of domestic life. The volume has been much mutilated, but it is of interest as having belonged to Philip Melancthon, in whose hand it is probable are some of the manuscript notes on the fly-leaves at the end.

Prosperi Alpini de Plantis Aegypti Liber. Venetiis. 1592. 4o.

Prosper Alpinus, a celebrated physician and professor at Padua visited Egypt between the years 1580 and 1584, publishing on his return several works bearing upon medicine. One of these is a small volume on the plants of Egypt, in which the author describes and figures various useful trees, shrubs and herbs, at that day but little known. Among the number are Cassia Fistula, the Sycomore Fig, Date, Palm, Tamarind, Cotton and Sesamum. The first edition of this book appeared in 1591; the second published at Venice in 1592, is that herewith.

(*To be continued.*)

Obituary.

We regret having to record the death of Dr. William Allen Miller, one of the honorary members of the Pharmaceutical Society, on the 30th September. He was born at Ipswich on December 17th, 1817.

After having been assistant to the late Mr. Daniell, he succeeded him as professor of chemistry at King's College in 1845. In the same year he was elected a Fellow of the Royal Society. In later years he became Treasurer and one of the Vice-Presidents of the Royal Society. In 1851, he was appointed one of the assayers to the Mint. He was one of the members of the recently appointed Royal Commission to inquire into the condition of science in this country. He was one of the Vice-Presidents of the Chemical Society, having occupied the President's chair.

His best known work is his textbook on 'Chemistry,' originally published in the years 1855 and 1857. His first scientific publication was a 'Research on the Electrolysis of Secondary Compounds' (1844). This research was done conjointly with Mr. Daniell.

In 1845, he published a paper on the spectra of heated vapours. In 1849, he wrote on the atomic volumes of analogous organic liquids.

Within the last few years he has given a discourse to the Chemical Society on the "Analysis of Potable Water." Some analyses of gutta percha, and a paper on "Transparency," complete the list. He joined Mr. Higgins in the investigation of the spectra of the fixed stars.

The following journals have been received:—The 'British Medical Journal,' Oct. 1; the 'Medical Times and Gazette,' Oct. 1; the 'Lancet,' Oct. 1; 'Nature,' Sept. 29; the 'Chemical News,' Sept. 30; 'Journal of the Society of Arts,' Sept. 29; 'Gardeners' Chronicle,' Oct. 1; the 'Grocer,' Oct. 1; the 'English Mechanic,' Sept. 30; the 'Produce Markets Review,' Oct. 1; the 'Practitioner' for October; the 'Food Journal' for October; 'Journal de Pharmacie et de Chimie' for July; 'Gazette Médicale d'Orient' for July and August; the 'Journal of Applied Science' for October; the 'Educational Times' for October; the 'Quarterly Journal of Microscopical Science' for October; the 'Philadelphia Medical and Surgical Reporter,' Nos. 703–705.

Correspondence.

Communications for this Journal, and books for review, should be addressed to the EDITOR, 17, *Bloomsbury Square.*

POISON REGULATIONS.

Sir,—I have watched with considerable interest the expression of various opinions in your correspondence columns, relative to the best method of keeping and dispensing poisons.

Whatever may be the result of the present discussion, our greatest security against the improper administration of poisons will be the proper education and training of all who sell and dispense them, and I should prefer that our efforts be restricted to securing this, leaving each individual to adopt those precautions which his particular class of business rendered desirable. But as it appears that we are expected to do something more, it is well to consider what features must necessarily be included in any system of regulations to fit it for general adoption.

Any plan, to be effective, must be extremely simple and capable of being easily worked. Anything of a complicated character would promise infinitely more danger than safety. It is frequently overlooked that many of the plans proposed would require as great care and attention to secure their observance as would almost suffice, in the first instance, to guard against the possibility of error, thus working for one object twice over.

Viewed in the light of the preceding remarks, I think some of the proposed schemes are very unsuitable. Distinctive stoppers, caps, etc., are useful to a very limited extent. In the hurry of a busy day too much care and attention would be required to ensure the proper use of them, and there would also be the chance of some being applied to the wrong bottles. Distinguishing the bottle itself, by making it a peculiar shape, or by distinctive labelling, appears to me a much better idea, and would doubtless be of great service, though the use of peculiar-shaped bottles in dispensing for lotions, liniments, etc., is rendered less valuable than it would otherwise be by the liability of their being used for general purposes afterwards. While on this point, I must say that in spite of the immunity from accident which appears to have attended one of your correspondents' (Mr. Mumbray's) systems of labelling, I should hesitate to keep such articles as tinct. opii, tinct. aconiti, and acidum arseniosum in the situation he describes, however labelled. The system of labelling suggested by Mr. B. S. Proctor seems unnecessarily complicated. Keeping dangerous articles in one particular place, such as a cupboard, is a precaution which, I think, should never be neglected, though the articles so treated would depend, in some degree, upon the class of business done.

The system adopted in the establishment where I was apprenticed, which was found to answer very satisfactorily, and which I have in operation in my own shop, is as follows:— Care is taken that all articles of a dangerous character are distinctly labelled "Poison." Articles of a dangerous character, likely to be mistaken for innocent substances, and also otto of roses, rare essential oils, chemicals, etc., and articles generally in the handling of which it is desirable that extra care should be taken, are kept in cupboards. Exceptionally dangerous articles, such as acid. hydrocyanic. dil., are additionally protected by the use of peculiarly-shaped bottles or otherwise.

I would suggest that the Council, instead of the regulations proposed at the last annual meeting, next year submit something of the following character:—

1. All boxes, bottles, vessels or packages containing poisons shall be distinctly labelled with the word "Poison;" and, if practicable, shall be otherwise distinguished from similar receptacles for innocent substances.
2. All poisonous substances of a character likely to be mistaken for innocent articles shall be kept apart in a place provided for the purpose.

These regulations (if they are stringent and definite enough to deserve the name) appear to me to do as much in the way of providing security for the public as is likely to be effected by any other system of regulations. They are simple and not too stringent, can therefore be varied in character to a slight extent to suit the requirements of different businesses, and for these reasons their adoption would be probable. They comprise as much as would be generally carried into effect of the most stringent set of rules which are likely to be proposed, unless we are prepared for a system of close inspection, which at present, I presume, is not contemplated.

I am, Sir, yours respectfully,

A. H. BUCKETT.

PHARMACY AND MEDICAL PRACTITIONERS.

Sir,—A letter from "Reformer" in the *Lancet* of the 17th ult., is made the subject of a leader, headed "Pharmacy and Medical Practitioners." "Reformer" complains of the extent to which druggists prescribe, and says, "Nearly every patient the medical man is sent to, he finds has been doctored by this dignitary (the chemist) first, and, therefore, he guesses it is a bad case. I, myself, the other day was standing in one of the shops, and was greatly amused at seeing the people, one after another, come in to be doctored, the druggist actually, in my presence, feeling their pulses," etc. Then "Reformer" suggests, in order "to put a stop to this sort of thing," that

(1) A clause should be inserted in the Medical Bill before Parliament, and

(2) "That general practitioners should supply their own medicines as in former days (which is certainly very *infra dig.*) and thus wrench back from druggists that of which evidently they are depriving the profession."

Upon this amusing, yet frightful picture of pharmaceutical morals in ye nineteenth century, the editor builds an article, the sum of which is that the "monstrously excessive profits" of the chemist ought to be lessened in order that the public may be better able to pay the doctor. He begins, of course, with "the time of Hippocrates," "the Roman Empire," etc., rushes through the middle ages in half-a-dozen lines, and finds himself face to face with the modern medical practitioner, "who wishes to be liberated from care about mere drugs, to whom the notion of making remuneration depend on the amount of medicine supplied is abhorrent, and who wishes to be paid for his opinion." But "there are difficulties and obstacles and serious objections to such arrangements." What are they? Mr. Editor supplies us with one only, that is, the high prices charged by chemists. He says, "Mixtures are 1*s.* 8*d.* or 2*s.* apiece; an ordinary prescription easily costs 2*s.* 6*d.* or 3*s.*; people find their drug bill equal to the doctor's, and the fact of paying as much to the man who dispenses a prescription as to the man who writes it, is a *reductio ad absurdum.* Moreover, the chemist is paid at once; the doctor only after months or not at all; and there is no hope for better days till chemists have shown how patients can be supplied sufficiently and satisfactorily at prices which do not inconvenience them or impair their ability to pay their doctor!"

I need not waste your space in inquiring if these statements be correct. The experience of your readers will supply the answer. It will say that a skilled and scientific workman, who gets 2*s.* for a 6-ounce mixture and 12 pills, which have taken 20 or 30 minutes of his time and 1*s.* worth of his stock, is badly paid; it will say that he would scarcely make a living if he worked from morning till night at this rate; it will say that competition and co-operation and dispensaries prevent his being paid after even this humble manner in poor districts, and that in rich ones the doctor gets his guinea, and the chemist 1*s.* 6*d.* for a bottle of concentrated drops to last the patient a week. It would indeed speak little for the faculty, if "Reformer's" tale were true of every Pharmacy in the kingdom, instead of less than 5 per cent. of them. Further, the remedy of the *Lancet, i.e.* reduction of prices, would most likely increase, instead of curing the disease of which "Reformer" complains, because the "dignitaries" would then be more consulted than ever. The gist of "Reformer's" argument is that we fill our shops by charging so little; Mr. Editor's is, that we beggar the profession by charging so much. Pray, Sir, show us how we may avoid Scylla and not run into Charybdis; and, as the *Lancet* is bent on demonstrating "the evils of the system of transferring the business of dispensing to chemists," supply us with a mild counterblast.

Yours obediently,

MAX.

Sir,—The following extract from the *Lancet* has embodied what I have often thought myself, and I have carefully reflected on the subject, and have consequently taken at times very different views of the matter:—

"One great objection to practitioners handing over the dispensing of their medicines to chemists is to be found in the high prices charged by chemists for medicines. These prices are such as to be of themselves a heavy and exhausting bill to people of humble means. Mixtures are charged at the rate of 1*s.* 8*d.* or 2*s.* apiece, and other medicines correspondingly, so that the dispensing of an ordinary prescription easily costs 2*s.* 6*d.* or 3*s.* People whose family doctor does not supply them with medicines find that their drug bill is equal to or even exceeds the doctor's bill. Now this appears to us quite unreasonable. The percentage of profit to the chemist is monstrously excessive, allowing for all the incidental expenses of his business. And the fact of paying as much to the man who dispenses a prescription as to the man who writes it is a complete want of distinction between two very distinct services, and a *reductio ad absurdum.* But this is not all. The chemist is paid at once over the counter, in the full urgency of the want of the patient. The doctor is probably not paid for months, when the chance of being paid at all is greatly reduced. It is hopeless to think of medical practitioners giving up the dispensing of their own prescriptions until chemists have shown them how patients can be supplied sufficiently and satisfactorily with drugs at prices which do not inconvenience them, and do not impair their ability to pay their doctor."

It seems a most extraordinary fact that a chemist in one part of town should charge as much for preparing a prescription as a licensed apothecary or medical practitioner should charge for both visit and medicine, in another. The doctors are a most generous race; we must be friendly with them, for they are our best friends; and if our journals are going to bicker, the sooner a better spirit is imparted into the controversy the better for us all.

George Mee.

79, Grosvenor Road, Highbury, N.

Sir,—The article in the *Lancet* contains statements so incorrect and an argument so utterly false, as to deserve some notice. The writer must be grossly ignorant of chemists' business, or he would have known that instead of cash payments, one, two and three years' credit is more the rule than the exception; and that the practitioner who obtains his fee for prescribing orders ingredients and quantities very different from those he would use if he prepared the medicines himself. I have now dispensed the following from a general practitioner:—

℞. Quinæ Disulph.,
Ferri Sulph., aa gr. xx
Acid. Sulph. Dil. ʒiij
Sp. Chloroform. ʒij
Sp. Æther. Nit. ʒvj
Aquæ ad ℥viij
f. Mist. Cap. coch. j medium c. aquâ ter die.

The profit on this, at 1*s.* 8*d.* or 2*s.*, would certainly not be "monstrously excessive;" but it would be a very extraordinary occurrence to find any private surgery sending out such a medicine at all. The writers think it absurd that the inferior, who dispenses the deadly compound ordered by a practitioner, should receive as much in payment, and imply that if the chemist is paid for the ingredients, he has no right to look for any remuneration for his skill, care or time. I have two prescriptions before me now in preparation, and I can see nothing at all absurd in supposing my responsibility for the accuracy of these formulæ should be repaid in a different manner, and at a higher price than for merely rolling out soap and bread-crumbs for a surgeon's private practice:—

℞. Strychniæ gr. i
Acid. Phosph. Dil. ʒij
Aquæ Destill. ʒiv
Sol. Strychnia.
Sol. Strychniæ ʒv
Acid. Hydroyanic. Dil. ʒiss
Aquæ ʒi.
Take 15 drops three times a day with meals.

℞. Ext. Colchici ʒi
Strychniæ gr. i
Ext. Aconiti gr. vj
Acid. Arseniosi gr. ij.
Fiat pilulæ xx. 1 pill three times a day after food.
Silvered.

J. H.

If medical men find it necessary to give such concentrated forms for the good of their patients, they should remember that much of the success attending their *experiments* depends upon the dispenser, and that he is deserving of a higher reward than the mere profit on the articles used. If, as the writer argues, it is hopeless to expect practitioners to give up dispensing their own medicine, so is it equally futile to expect chemists to discontinue to prescribe in such a manner as not to inconvenience those who seek their advice instead of paying the doctor.

I am, Sir, your obedient servant,
John Wade.

Hospital Dispensing.

Dear Sir,—Having been engaged in hospital dispensing nearly five years, I can most fully endorse all that Mr. Barber says on the subject.

In reply to "A Pharmacist," I would say I do not think that the case he mentions is an "average type of hospital dispensing," or "a waste of public money;" at least, it is not a type of mine or that of six other hospitals I am acquainted with. It is true a public dispenser is compelled to be as quick as possible, and therefore he could not waste his and the patient's time (who, perhaps, has been waiting his or her turn to see the doctor for two or three hours) by asking for bottles as politely as a chemist would ask a customer when no one else is waiting to be served.

Of course I do not justify the giving of corks and labels to the patients themselves to put on any kind of bottle, for that is the dispenser's work and not the patient's. My own plan of dispensing (*i. e.* with regard to bottles and labels) is—

First, to have a large notice posted in the waiting-room to the effect that "no medicines, etc., will be dispensed in any bottles which have been used for domestic purposes, such as wine, beer and spirit bottles, etc. Proper medicine bottles may be bought in the dispensary." So that patients may bring their own bottles or buy them at any shop just as they choose; but, to save time, and as a convenience to them, I keep a stock of bottles, which they are generally very glad to get.

Secondly, I use labels printed in bold type, with the name of the institution at the top, and labels so plain can be read by most patients if they are only able to spell.

With such precautions I have only heard of one mistake, and that was by a woman who went to her cupboard in the *dark*, and drank from a "lotion bottle" without measuring the dose. Happily no harm resulted.

I am, Sir, yours obediently,
Wm. Billing Orton, A.P.S.

Manchester, Sept. 24th, 1870.

Chloral Hydrate.

Sir,—I should esteem it a favour if any of your scientific correspondents could inform me, through the medium of your Journal, what are the principal incompatibles of chloral hydrate.

F. B.

"*Consternatio*" says:—"In answer to the inquiry by 'Spes' in last week's Journal, as to what 'acids, oxides and salts' are 'compounds' (a description of which is required in the Minor Examinations on Chemistry), I think that I should be right in suggesting acid. nitro-hydrochlor. dil. and acid. sulphuric. arom. as "compound" acids, and soda tartarata, alumen, antim. tartaratum, and ferri et quiniæ citras as 'compound' salts."

T. G. R. (Worthing).—As the new notation is that which is now most generally used, it is necessary for students to become acquainted with it. But the present being a time of transition from the use of one system to another, a knowledge of the old notation is also requisite.

Au Revoir.—A very full knowledge of formulæ is required.

T. L. (Strood) asks, "Would any brother apprentice inform me where I could obtain a map of Gaul (temp. Julii Cæsaris) without buying another work."

C. W. Brown (Plymouth.)—The liquor potassæ permanganatis of the Pharmacopœia should contain four grains of permanganate of potash to the ounce; this, it will be seen by reference to a recent estimation published in our columns, is half the strength of Condy's fluid.

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes to be endorsed for "Pharm. Journ."*

NEW METHOD OF DETERMINING GRAPE SUGAR.

BY CARL KNAPP.

Professor Liebig has mentioned the fact that the addition of prussic acid to a mixture of yeast-water with a solution of cane sugar does not prevent the conversion of cane sugar into grape sugar by the organic substance in the yeast-water. After saturating such a mixture with oxide of mercury, adding caustic soda, and heating the liquid to boiling, a precipitate of metallic mercury is formed, but no such precipitate is formed under the same conditions in a solution of cane sugar mixed with an alkaline solution of cyanide of mercury.

Further experiments showed that an alkaline solution of cyanide of mercury is completely reduced to metallic mercury by grape sugar, and at the suggestion of Professor Liebig the author of the paper undertook to apply this reaction for the determination of grape sugar. He now gives, as the result of his inquiry, the following method:—

A solution is made by dissolving 10 grams pure dry cyanide of mercury, adding 100 c. c. caustic soda solution of 1·145 sp. gr. and diluting to 1000 c. c.

For determining the value of this solution, commercial grape sugar was first dried at 100° C., then boiled with absolute alcohol till a saturated solution was obtained; the crystals which separated on cooling this solution were taken for use.

A series of experiments showed that 400 milligrams of cyanide of mercury is decomposed by 100 milligrams of anhydrous grape sugar, on boiling them together in an alkaline solution.

The sugar determination by this method is conducted just as in the Fehling test: 40 c. c. of the cyanide solution is heated to boiling in a porcelain dish, and the sugar solution, containing about 0·5 per cent., added until the whole of the mercury is reduced. The quantity of sugar solution required for effecting this reduction will contain 100 milligrams grape sugar.

On adding the sugar solution to the boiling alkaline liquid, a turbidity is at once produced, but this disappears again towards the end of the operation, and the liquid becomes slightly yellowish.

In order to judge of the progress of the operation, a drop of the liquid is from time to time placed on fine Swedish filter-paper laid over a beaker containing a little strong sulphide of ammonium. So long as any cyanide of mercury remains undecomposed in the liquid, a brown spot is thus produced upon the paper, and the end of the reaction is indicated when such a spot is no longer produced in this way. This point may be ascertained much more sharply by holding a drop of sulphide of ammonium on a glass rod immediately over the paper moistened with a drop of the liquid being operated on.

At first the entire spot becomes brown, but when the reaction is nearly terminated, only a pale brown ring appears round the edge of the spot; afterwards that is to be recognized only when the paper is held up to the light, and at last the spot remains quite unaltered. With some practice, ½ per cent. solution of grape sugar can be titrated up to ·1 c. c.

If at the end of the reaction the spot be allowed to dry on the paper, a pale brown ring of sulphide of mercury always makes its appearance, inasmuch as the solution always contains a trace of grape sugar and a trace of cyanide of mercury, either of which is to be removed only by an excess of the other substance. This circumstance, however, does not interfere with the delicacy of the test, provided the coloration of the fresh spot be taken as the indication when the reaction is completed.

From a large number of experiments in which this method was adopted and compared with Fehling's test, the author has convinced himself that it is not inferior to the latter in accuracy, and though the results it furnishes are not better than those obtained by Fehling's method, there is an advantage in the new method requiring less time for making a determination, and a further advantage in the fact that the reduction of cyanide of mercury is not affected by foreign substances, such as alkaloids, which in some cases interfere with the colour of the suboxide of copper precipitate. But perhaps the chief advantage of the new method lies in the easy preparation of the standard solution and its capability of being kept without alteration.—*Annalen der Chemie und Pharmacie.*

HYDROBROMATES OF QUININE AND CINCHONINE.

BY M. LATOUR.

The successful use of bromide of potassium in affections of the nervous system, and the association of this salt with sulphate of quinine, as well as other alkaloids, induced the author to prepare hydrobromate of quinine, in the belief that it might be useful as a medicine.

The hydrobromates of quinine and cinchonine were prepared by double decomposition of bromide of potassium and the sulphates of the alkaloids, as follows:—

Neutral Hydrobromate of Quinine.

Basic sulphate of quinine . .	10	grams.
Alcohol of 85°	50	,,
Bromide of potassium	8	,,
Distilled water	20	,,
Dilute sulphuric acid (1 per cent.)	10	,,

The sulphate of quinine and the alcohol are heated together in a small flask; the solution of bromide, mixed with dilute sulphuric acid, is then added, and the whole heated to boiling. After a few minutes the sulphate of potash is separated by filtration, and washed with hot alcohol. The filtration and washings are then evaporated to half the volume, and left to crystallize. After twenty-four hours an abundant crop of crystals was formed, and, when pressed between filter-paper, the salt was white, opaque, of a pearly appearance. The salt thus obtained is sufficiently pure for use, though it contains traces of sulphuric acid.

The proportion of bromide of potassium used must be rather more than equivalent to the sulphate of quinine, otherwise a mixture of basic and neutral hydrobromate is produced. It is also necessary to add sulphuric acid, in order to make the quinine sufficiently soluble, as well as to decompose a portion of the bromide of potassium, so as to produce hydrobromic acid, necessary for forming a neutral salt with the quinine.

Basic Hydrobromate of Quinine.—This salt was prepared in the same way, but only 5 grams of bromide of potassium were used, together with 10 grams of dilute sulphuric acid. A better plan is to dissolve 1 gram of the neutral salt in 10 grams of a mixture of alcohol and water in equal parts. This solution, heated to 70° C., is mixed with very dilute ammonia solution, until it acquires a slight alkaline reaction, and then mixed with a solution of 0·5 gram neutral hydrobromate of quinine, shaking the whole until it becomes cold: a copious precipitate is then formed, consisting of basic hydrobromate.

The neutral salt is very soluble in water, soluble in almost all proportions in alcohol, and its reaction is acid. The basic salt is sensibly soluble in water, very soluble in alcohol, and its reaction is alkaline.

The hydrobromates of cinchonine are prepared in a similar manner. The neutral salt corresponds to the hydrochlorate; it is anhydrous, very soluble in water, and less soluble in alcohol than the corresponding salt of quinine. Its solution has an acid reaction. The basic salt is sensibly soluble in water, very soluble in alcohol, and its solution has an alkaline reaction.—*Journ. de Pharmacie et de Chimie.*

REPORT ON OPIUM PRODUCTION IN WÜRTEMBERG.

BY JULIUS JOBST.

The author states in this report the results of this year as follow:—

Though large quantities of poppies were sown last spring, the crop rarely did well in consequence of the continued dry weather. This alone put an end to any prospect of considerable development in opium cultivation for the present year, and the scarcity of labourers at the time of gathering was for a time a further hindrance. Subsequently, when the influence of the war had driven many to this work, the best time for collection was past, and the poppies ripened too quickly, owing to the great heat.

On the contrary, the price of the new Asiatic opium admitted of the best Würtemberg opium fetching as much as 34*s.* per pound. At this price the earnings of a labourer would amount to 2*s.* 6*d.* a day, which is good, considering that old men, women and children could be employed for the purpose.

The opium of this year is much superior to that previously grown. The amount of morphia it contains is 12 per cent., even in samples that are somewhat moist.—*Gewerbeblatt aus Würtemberg.*

COLOPHONINE AND COLOPHONIC HYDRATE.*

BY CHARLES R. C. TICHBORNE, M.R.I.A., F.C.S.

When we submit to distillation (either with or without water) the natural exudations of the different pines, the first result is the extraction of volatile hydrocarbons, or oils of turpentine. These oils were until very lately considered as identical, but recent investigations have proved that there is a considerable disparity in the products from different species of the pines.

If, after the extraction of the volatile oils, the distillation is pushed further, we get a second series of volatile compounds, which, however, differ materially from the first, inasmuch as they are decomposition-products resulting from the splitting up of the colophony, or resinous part, into more simple molecules of different isomeric modifications.

All the resin oils obtained by myself gave the result I am now about to detail. I, however, believe that the discrepancies exhibited by the turpentines are perpetuated through the products obtainable upon the destructive distillation of the resins proper to such turpentines.

My attention was first directed to the substance which I have named colophonine from an observation made preparatory to investigating the volatile oils procured on submitting resin to destructive distillation.

I took commercial rosin, and after drying for some time at a slightly elevated temperature distilled it in an iron retort. I got by this means a thick distillate, which contained a considerable quantity of undecomposed resin. Gaseous products escaped which are said to contain ethylene, tetrylene and marsh gas. The liquid products amounted to about 74 per cent. of the resin employed, and a small coke was left in the retort. This thick oil, on rectification, gave about 5 to 6 per cent. of a light yellow but mobile fluid, which is known under the names of "resin spirit," "vive essence," Harzessenz."*

This lighter portion, or "resin spirit," is supposed to consist mainly of the hydrocarbons homologous of the series C_nH_{2n-4} and C_nH_{2n-6}, and and oxygenated oil which has been named colophonone.† It is these light oils that yield colophonic hydrate. They act energetically upon the fluid alloy of potassium and sodium, even when free from the last-named substance; therefore it is probable that colophonone or other oxygenated oils form a large ingredient.

It is given as a specific characteristic of colophonone, that if it is treated with sulphuric or hydrochloric acid a green oil separates on the addition of water. This is, however, only partially true, for I have found that the "resin spirit,"‡ procured in the above experiment, or old resin spirit that had been washed, only gave this reaction in a slight degree.

It was therefore evident that the colour-phenomenon was due to the presence of some other substance soluble in water, and not to a specific property of the colophonone. On treating old resin spirit with distilled water two or three times, and on evaporating these washings at a low temperature, a brown crystalline mass was procured, which gave the colour-reactions, hitherto attributed to the oil itself, in a most vivid manner. It therefore becomes evident that the whole subject of colophonone requires revision. It was probable that the substance analysed under that name was a mixture.

I subsequently obtained specimens of the new substance in which individual crystals had attained some considerable magnitude.

Some of them were three centimetres long and over two grammes in weight. They were of an amber colour, from impurities, and were obtained by submitting a large volume (10 litres) of the spirit in an imperfectly-closed vessel to 12 months' slow evaporation and oxidation. I have procured as much as 281 grammes of the crude crystals from 4–5 litres of resin spirit by washing.

The following are the characteristics of this compound, which, when purified, is a truly beautiful substance:—

Colophonic hydrate is white, perfectly odourless, and has a sweetish taste. It is very soluble in water, alcohol, ether, chloroform and tetrachloride of carbon, not quite so soluble in cold benzole and resin spirit, but slightly soluble in cold bisulphide of carbon.

Colophonic hydrate crystallizes readily from water or

* Read before the Royal Irish Academy.

* Mr. J. Turner, a large distiller of resin, has kindly sent me the following notes regarding the statistics of the production of these oils on a manufacturing scale:—

	Percentage.
"Resin spirit" (boiling at 135° C.)	5–3
Heavy oils	64–6
Pitch	14·4
Gaseous products and H_2O	15–7

† Schiel.

‡ I shall use the term "resin spirit" throughout this paper to designate the oils got on rectifying resin oils.

alcohol in beautiful acicular prisms, which sometimes attain some magnitude. Heated, it melts and sublimes with a partial loss of the elements of water. The crystals which first sublime lose water, but nearly resemble those obtained from a solution, both as regards their appearance and composition. Those which afterwards rise (or, if the first, are resublimed) lose more water and form hexagonal plates, or fern-like fronds, of great beauty. It was found impossible to accurately measure the large crystals already mentioned, the twelve months' immersion having rounded and worn the faces, from the rise and fall of temperature in the medium in which they were formed. They seem to belong to the dimetric system, and are the result of the combination of the two prisms of that system.

The hydrated crystals, when placed over sulphuric acid, or *in vacuo*, gradually lose water and effloresce, but as the substance is itself volatile, the loss could not be measured under such circumstances. When placed under a bell-glass over sulphuric acid, the surface of the acid becomes covered with green film, produced, as will afterwards be explained, by the mutual action of the water, sulphuric acid and colophonic hydrate. Some difficulty was experienced in procuring the anhydrous compound. From the above results it was supposed that, on submitting the hydrate to sublimation, the water of hydration would be dissociated. Such, however, was not the case, and a combustion of the sublimed crystals pointed to no formula. The sublimate was, in fact, a mixture of the anhydrous and hydrated compounds.

The first of these substances I obtained in the following manner:—I gently fused in a test-tube for some time the crystals obtained from an aqueous solution, occasionally drying out the moisture which condensed at the top of the tube with bibulous paper. The sublimated crystals were repeatedly broken down and mixed with the fused mass. This process was continued as long as moisture was given off. I retained the crystalline mass for analysis. It seemed to have suffered no decomposition exclusive of dehydration, and formed a friable and nearly perfectly white substance.

On making a combustion of the above, 0·218 gramme gave 0·505 gramme CO_2 and 0·218 gramme H_2O.

In a second experiment 0·307 gramme of the fused mass gave 0·7076 gramme of CO_2, and 0·324 gramme of H_2O.

These experiments point to the empirical formula $C_{10}H_{22}O_3$.

Colophonic hydrate . $C_{10}H_{22}O_3 : H_2O$.
Colophonine . . . . $C_{10}H_{22}O_3$.

Colophonine is, therefore, isomeric with terpine hydrate, or is more properly a homologue of terpine. It is another instalment towards filling up an interesting series. This compound is probably derived from terebene.

Hydrocarbides.	Products formed therefrom by the occult molecule H_2O ("Turpentine Camphors.")	Hydrates.

$$-2(C_2H_4O_2) - \left.\begin{matrix} C_2H_3O \\ C_2H_3O \end{matrix}\right\} O = \underset{\text{(Terpinole.)}}{C_{20}H_{34}O.}$$ —*Vide* Naquet's 'Principles,' p. 396.

In the above table I have endeavoured to convey, by the punctuation, the accretion of the series, and the different degrees of molecular integration.

It will be observed that each hydrate would be isomeric with the next higher homologue in the camphor series. The hydrates to the first two in the series are wanting, but it is probable that they exist, as the compound called liquid turpentine camphor is, in the presence of water, converted into terpine, the isomer of its hydrate. If we do not suppose that the hydrate is first formed, we could hardly account for the formation of terpine.

Colophonic hydrate was violently acted on by bromine, accompanied by a copious separation of carbon and hydrobromic acid. In water the action was more manageable, and the ultimate product was a brominated oil, which, after washing first with a diluted solution of carbonate of sodium and then with water, was dried over sulphuric acid. ·471 gramme of this oil, after being decomposed in a sealed tube with pure soda, was treated with an excess of nitric acid and nitrate of silver. It gave ·766 gramme of bromide of silver, agreeing very nearly with the formula of a tetrabrominated compound.

Professor Jellett, who kindly examined this substance for me, as regards its optical properties, finds that it is perfectly inert when in solution, and possesses neither right nor left-handed rotation.†

As previously stated, the light oils from resin, when treated with sulphuric acid and then with water, produce a green substance. This coloration is, however, due to the presence of colophonic hydrate. On treating that compound with acids, a series of striking phenomena is exhibited, conjugated acids being formed, which exhibit a fine display of colours. The generality of these are green. Sulphuric, phosphoric (monobasic and tribasic), arsenious, citric and tartaric acids give these reactions.

On treating the crystals with an excess of the acid, and then adding spirit, the colour is developed. It is necessary to use heat in most cases. The sulphuric acid reaction is capable of rendering evident a milligramme of the new substance, if properly applied. It is not necessary to use heat in this case. Under certain circumstances, hydrochloric acid is capable of producing this green reaction; but when colophonic hydrate is treated with an excess of strong hydrochloric acid, after the expiration of half an hour, a brilliant rose colour is developed on pouring it into alcohol. If the experiment is pushed further, different shades of violets are produced, until the ultimate result of the maceration is a magnificent indigo blue.

Terpine does not give any of these reactions.

As regards the origin of colophonic hydrate, it is pro-

* Formed by the action of dibromhydrate of citrene on acetate of silver, $2(C_{10}H_{18}Br_2) = 4(C_2H_3AgO_2) - 4(AgBr)$.

† It does not differ in this respect from its congeners the terpine hydrates and similar products, in which, although the hydrocarbide preserves its integrity, its gyratory power is suspended.

bably formed under similar circumstances to the terpine camphors, *i.e.* by oxidation, or the assimilation of the elements of water. I have failed, however, in forming this substance artificially by oxidizing the resin spirit with nitric acid.*

It is not present in newly-prepared resin spirit, as I have already explained; and as my supply of colophonic hydrate was expended, my researches upon this substance were, I am sorry to say, brought to a close. It is, however, my intention to renew them at a future period.—*The Chicago Pharmacist.*

HYOSCYAMIN; ITS PREPARATION AND CONSTITUTION, WITH REMARKS ON SOME OTHER SUBSTANCES PRESENT IN HENBANE SEEDS.

BY HEINRICH HÖHN.

Assistant at the Jena Institute of Pharmaceutical Chemistry.

At the suggestion of Professor Ludwig, the author undertook the preparation of a large quantity of hyoscyamin, with the object of studying its characters, and endeavouring to determine its formula.

The material used for the purpose was the seed of *Hyoscyamus niger*, furnished by Herr A. Geheeb, in Geisa.

Separation of Hyoscyamin.—5450 grm. of the fresh seed was dried and coarsely powdered, then extracted with alcohol (containing 90 per cent. by volume) in two successive operations. The tinctures thus obtained were operated upon separately.

After distilling off the alcohol from the first tincture, there was deposited a considerable quantity of yellowish-brown resin, while the remaining residue, which had an acid reaction, separated after some time into a watery layer, and an oily layer floating above. During the cooling of the liquid residue, more of the yellowish-brown resin separated, and this was set aside with the other portion for subsequent examination. The oil was separated and washed three times with hot water; its perfect separation from the aqueous emulsion required long rest on the water bath, and meanwhile more resin was deposited. The resin was nitrogenous.

The whole of the aqueous liquid was then evaporated to about 500 grm. filtered through paper moistened with water, the filtrate rendered alkaline with caustic potash, and then shaken with about $\frac{1}{2}$ lb. of chloroform. The chloroform was then well washed with water and distilled off, leaving about 1 grm. of slightly coloured alkaloid of a tough consistence and strong unpleasant odour. This substance presented all the characters of hyoscyamin described by Geiger. It had a tolerably strong and permanent alkaline reaction, was precipitated by iodine water of a brown colour, by chloride of gold, in yellow flocks that became crystalline after a time, by tannin and chloride of mercury in white flocks, and by caustic potash from a concentrated solution, the precipitate being soluble in excess of the alkali.

A solution of the alkaloid in very dilute alcohol left for evaporation over sulphuric acid, presented on the second day flocculent deposits, which were found under the microscope to be well-developed stellate groups of needles. But since these crystals were still yellow-coloured, and mixed with a viscid substance, they were again dissolved in chloroform, the solution shaken with hydrochloric acid, and the alkaloid again taken up with chloroform after the aqueous solution had been rendered alkaline with carbonate of potash. After evaporating off the chloroform, there remained only about 0·5 grm. of slightly yellow alkaloid, but this could not be crystallized, and even when converted into hydrochlorate, the salt could not be crystallized.

The chloroform that was used for purification, and had been shaken with dilute hydrochloric acid, gave on evaporation a white waxy residue, crystallizing in groups of white needles.

The alkaline liquid that had been shaken with chloroform was slightly acidulated with hydrochloric acid, and a quantity of dark coloured flocks separated, while an odour of butyric acid became sensible. On adding to the filtered liquid a concentrated solution of tannic acid, a yellowish-white precipitate was formed; this was collected on a filter, washed with cold water, dissolved in dilute alcohol, then mixed with fresh precipitated carbonate of lead, and evaporated to dryness. The residual mass was finely powdered, boiled several times with strong alcohol, and the filtered solution distilled. When the liquid was reduced to a certain volume, there were formed small white crystals in the retort; the quantity, however, was too small for collecting, and the whole liquid was evaporated slowly in a capsule, but no sign of crystallization was recognizable, the residue being a tough yellowish mass, of bitter taste, no particular smell, and readily soluble in water or alcohol.

The presence of butyric acid was ascertained, also of volatile bases, and of a glucoside, to which the author gives the name Hyoscypikrin.

The second alcoholic tincture was treated in the same manner and with the same result as before.

The circumstance that the fat oil obtained from the tincture was acid, induced the author to examine this oil for alkaloid, and he found that it contained a considerable quantity of hyoscyamin. However, this could not be crystallized either from alcohol or benzol, but in all instances the solution, when reduced to a small bulk, became gelatinous, and, when dried up, left a shining gummy residue.

In order to exhaust the seed completely, it was finally digested with water, containing about 1 per cent. sulphuric acid. The expressed and filtered liquid was neutralized with ammonia evaporated to a syrup, during which operation much grey slimy substance separated; the thickened liquid was digested with acidified alcohol, the solution neutralized and evaporated; the dark brown residue mixed with ammonia was shaken with chloroform, and gave off a further quantity of hyoscyamin.

The entire quantity of alkaloid obtained from the seed was about 3 grams or 0·06 per cent., which is more than was obtained by Rénard.

The author suggests that since the oil takes up hyoscyamin, it would be desirable in preparing the alkaloid to extract the oil first by means of bisulphide of carbon or some such solvent.

Another difficulty arises from the chloroform remaining mixed in the state of emulsion with the liquids, when it is shaken with them, rendering the operation very tedious. This is best got over by evaporating the liquids to a syrupy consistence and extracting with strong alcohol to separate mucilage, dextrin, etc.

The precipitation of hyoscyamin by chloride of platinum has been confirmed by the author; but it takes place only from concentrated solutions, and the precipitate is redissolved by excess of the chloride of platinum. He had also occasion to observe the strong action of hyoscyamin in dilating the pupil, in consequence of a dilute solution being accidentally spirted into one of his eyes; about a quarter of an hour afterwards considerable dilatation of the pupil took place; on the second day the other eye was similarly affected, and this lasted for three days.

To determine the composition of hyoscyamin, a double salt of gold was prepared and analysed with results leading to the formula:—

$$C_{18}H_{20}NO_6\,HCl\,AuCl_3.$$

* Mr. Turner forwarded me from England a bottle containing resin spirit, in which he had observed crystals. They proved on examination to be colophonic hydrate. The bottle originally contained about 8 oz.; but from evaporation, only half an ounce remained; it consisted of about 25 per cent. of colophonic hydrate. It had been exposed to sunlight for about eight years; light, however, is not essential to the formation of this compound.

The analysis of the pure alkaloid gave results leading to the formula:—

$$C_{36}H_{28}N_2O_6 + HO.$$

Comparing this formula with that of atropin, they differ by C_2H_5N, and, consequently, hyoscyamin might be regarded as atropin, in which H was replaced by methylammonium $C_2H_3H_3N$, or as

$$C_{34}H_{22}(C_2H_3, H_3N)O_6 + HO.$$

The formula calculated from the gold salt would be $C_{36}H_{40}N_2O_{12}$, but if it be assumed that this salt contains 6 atoms of water of crystallization, there would remain $C_{36}H_{34}N_2O_6$, and this comes somewhat nearer to that found above. The difference in the hydrogen was probably due to the hygroscopic nature of the gold salt and the multiplication of the consequent error in analysing a small quantity of substance having so high a formula.

By treating hyoscyamin with caustic alkali it is broken up into an acid, which the author believes to be identical with or closely related to atropic acid, a base analogous to conia, together with some ammonia and bases resembling methylamine.

The waxy crystalline substance above mentioned was very feebly acid in solution; its melting-point was from 208° to 210° C., but it became soft at 120°. It had neither smell nor taste, would not sublime, was insoluble in water, readily soluble in strong alcohol, especially on warming, still more soluble in ether and chloroform. Analysis gave results which appeared to show some relation between this substance and lactucerin $C_{32}H_{26}O_2$, and the author suggests the name hyoscerin, $C_{32}M_{30}O_6$(?).

The analysis of the glucoside, which the author terms hyoscypikrin, gave results leading to the formula $C_{54}H_{52}O_{28}$.

It was not determined conclusively whether the volatile methylic base was formed by the action of caustic alkali or whether it was actually present in the seed.

The nitrogenous resin was purified by dissolving it in weak alcohol, evaporating the solution and pouring off the residual watery liquid from the deposit of resin. This was dried, deprived of adherent fat by digestion with ether, and finally treated with animal charcoal after solution in weak alcohol.

The resin still remained yellowish after this treatment. It could not be crystallized from alcohol or from ether. It had a bitter taste and a peculiar smell; the alcoholic solution scarcely reddened litmus paper. Concentrated sulphuric acid as well as caustic alkalies dissolved the resin with deep orange coloration. Neutral and basic acetates of lead gave a yellowish precipitate with the alcoholic solution. Analysis gave results agreeing with the formula $C_{110}H_{70}N_2O_{32}$. The resin did not appear to be much altered by treatment with dilute acids or alkalies; when boiled several hours with strong caustic alkali, some ammonia was given off.—*Neues Repertorium für Pharmacie.*

THE INTRODUCTION OF CHLOROFORM INTO ANÆSTHETICS.*

In a pamphlet issued by Mr. George Waldie, of Linlithgow, he discusses with some warmth the question of the introduction of chloroform into anæsthetics, maintaining that justice was not done to his brother, Mr. David Waldie, by the late Sir James Y. Simpson in his account of the discovery of its value as an agent for the relief of pain. Mr. G. Waldie says:—

"It never was the desire of my brother to take away from the late Sir James Y. Simpson any of the credit which was justly due to him, neither is it mine in writing these pages; but now that the wonders of organic chemistry are being unfolded, and now that we are in sight of, if we have not already reached, the period when chloroform as an anæsthetic is to be superseded in its turn by some till-now unknown compound, it is time that the history of chloroform should be better known; and what follows will show both the necessity for this, and the obligation laid upon me to contribute towards making it so."

The account given by Mr. David Waldie himself of his share in the discovery is as follows:—

"On occasion of a visit to Dr. Simpson, when in Scotland in 1847, he spoke to me of his trials of various vapours, in his endeavours to discover something else than ether, at that time employed to some extent for anæsthetic purposes, amongst others mentioning chloric ether, the chemical constitution of which he was evidently not aware of. This I explained to him, showing him that it was chiefly vapour of alcohol that would be inhaled, and advised him to try the pure chloroform, which appeared to me likely to be suitable. I promised also to prepare some as soon as I could on my return to Liverpool, and send it to him for trial. Unfortunately the laboratory of the Company had previously been destroyed by fire, and was not then restored, so that I could not prepare it; and in the meantime Dr. Simpson had procured some chloroform, and discovered its effects by inhalation.

"When the news came, not long after my return to Liverpool, I felt pleased at the success of my recommendation, but was also mortified that, from these unfortunate circumstances, I had not been able to do something in carrying it out. I had inhaled both nitrous oxide gas and ether vapours before, and felt interested in the inquiry; and have no doubt but that, if I had been in a position to prepare the chloroform, I should at once have discovered its properties on my own person."

In the first pamphlet issued by Sir James Y. Simpson on the subject of chloroform he gives his account of the circumstances that induced him to experiment with chloroform in these words:—

"With various professional friends more conversant with chemistry than I am, I have since that time [the introduction of anæsthetic practice from America] taken opportunities of talking over the idea which I entertained of the possible existence or discovery of new therapeutic agents, capable of being introduced into the system by respiration, and the possibility of procuring for inhalation vaporizable or volatile preparations of some of our more active and old-established medicines; and I have had, during the summer and autumn, ethereal tinctures, etc., of several potent drugs manufactured for me for experiment by Messrs. Duncan, Flockhart and Co., the excellent chemists and druggists of this city. . . . I have tried upon myself and others the inhalation of other volatile fluids. . . . I have found, however, one infinitely more efficacious than any of the others, viz. chloroform, or the perchloride of formyle, and I am enabled to speak most confidently of its superior anæsthetic properties, having now tried it upon upwards of thirty individuals. The liquid I have used has been manufactured for me by Mr. Hunter, in the laboratory of Messrs. Duncan, Flockhart and Co."

To this was subjoined the following foot-note:—

"In talking over with different chemists what fluids might be sufficiently volatile to be respirable, and hence deserving of being experimented upon, Mr. Waldie first named to me the perchloride of formyle, as worthy, among others, of a trial; Dr. Gregory suggested a trial of the chloride of hydrocarbon, etc. I have been deeply indebted to Dr. Gregory and Dr. Anderson, for their kindness in furnishing me with the requisite chemical agents for these experiments; and also to my assistants, Dr. Keith and Dr. Duncan, for the great and hearty zeal with which they have constantly aided me in conducting the inquiry."

Mr. Waldie disappointed that Sir James should speak of his suggestion in so incidental a manner, and that, too, in a foot-note where it was likely to be overlooked, prepared a paper entitled "Chloroform, the New Agent for producing Insensibility to Pain by Inhalation," which

* 'The True Story of the Introduction of Chloroform into Anæsthetics, being the Original Account given of it in 1847, and a Re-statement in 1870. By David Waldie, F.C.S., Member of the Asiatic Society of Bengal, with Remarks by George Waldie. Linlithgow: George Waldie. Edinburgh: Oliver and Boyd.'

he read shortly afterwards at a meeting of the Liverpool Literary and Philosophical Society, in which, after a short *résumé* of the general history of anæsthetics up to that time, he continues:—

"Dr. J. Y. Simpson, Professor of Midwifery in the University of Edinburgh, who has, since the introduction of ether inhalation into this country, carried on the investigation of the merits of the practice with the greatest ardour and assiduity, had been for some time on the search for other vapours possessing the properties of ether without certain disadvantages connected with its use, the result of which has been the discovery of such properties in chloroform through the following circumstances:—

"The term chloric ether was at one time applied to the chloride of olefiant gas, or Dutch liquid of chemists. In 1831 Mr. Guthrie, an American chemist, was led by a statement in Silliman's 'Elements of Chemistry,' that the alcoholic solution of chloric ether was a grateful and diffusible stimulant, to attempt a cheap and easy process for its preparation. This he did by distilling a mixture of spirit and chloride of lime, collecting the product so long as it came over sweet and aromatic. This both Guthrie and Silliman supposed to be a solution of the chloride of olefiant gas, and called it chloric ether. In reality, it was an impure spirituous solution of chloroform.

"In 1831 Soubeiran, and in 1832 Liebig, prepared liquid by a similar process, and separated the chloroform. Dumas, in 1834, purified it fully, and made an accurate analysis of it; he found it to be composed of 12 parts carbon, 1 part hydrogen, and 106½ parts chlorine, and named it chloroform, from being analogous to formic acid in its composition, but containing chlorine instead of oxygen. From theoretical considerations Liebig termed it perchloride or terchloride of formyle—in chemical symbols C_2HCl_3. It is a colourless transparent liquid of specific gravity nearly 1500, or about 1½ times the weight of water; it boils at 141° F., the vapour having a specific gravity nearly four times that of air; it quickly evaporates at ordinary temperatures, but does not burn easily; it has a sweet taste and agreeable smell; is soluble in all proportions in strong spirit, but very sparingly soluble in water, to which it communicates its taste in a small degree.

"To the best of my knowledge, from the result of many inquiries, it seems to have been introduced into this country as a medicinal agent first in Liverpool, where indeed, in the form of a spirituous solution, it has been more known than in any other part of the country, and from which, I believe, the knowledge of its therapeutic properties has extended. About the year 1838 or 1839 a prescription was brought to the Apothecaries' Hall, Colquitt Street, one ingredient of which was chloric ether. No substance being known there of that name having the properties of that with which the mixture had been previously prepared, Dr. Brett, then the company's chemist, in investigating the subject, found in the United States' Dispensatory the formula for its preparation which has been noticed above, and prepared some. Its properties pleased some of the medical men, particularly Dr. Formby, by whom it was introduced into practice in this town. After coming to take charge of the company's laboratories I found that the method of preparation yielded a product which was not of uniform strength, and sometimes of disagreeable flavour. Accordingly I altered the process by separating and purifying the chloroform, and dissolving it in pure spirit, by which a product of uniform strength and sweet flavour was always obtained. Thus prepared, it is much superior to specimens I have seen of London manufacture. Those members of the profession who are in the habit of using it prefer it greatly to sulphuric ether, as possessing all its remedial value, and being very much more agreeable.

"The vapour of the so-called chloric ether seems to have been tried as a substitute for sulphuric ether in February or March last, but without very satisfactory results, which, indeed, could scarcely be expected, unless the vapour of alcohol possessed the same properties, it being composed principally of alcohol. When in Scotland, in October last, Dr. Simpson introduced the subject to me, inquiring if I knew of anything likely to answer. Chloric ether was mentioned during the conversation, and being well acquainted with its composition, and with the volatility, agreeable flavour, and medicinal properties of chloroform, I recommended him to try it, promising to prepare some after my return to Liverpool, and send it to him. Other engagements and various impediments prevented me from doing this so soon as I should have wished, and in the meantime Dr. Simpson, having procured some in Edinburgh, obtained the results which he communicated to the Medico-Chirurgical Society of Edinburgh on the 10th of November, and which he published in a pamphlet, entitled, 'Notice of a New Anæsthetic Agent as a Substitute for Sulphuric Ether in Surgery and Midwifery.'"

In this paper no remark was made upon Sir James Simpson's acknowledgment. The author, however, sent a copy of the paper to him; but Sir James took no notice of it, either by letter or personally.

As to the amount of credit due to Mr. Waldie for the suggestion, the following statement by Mr. Abraham, of Liverpool,—a gentleman at that time holding a responsible position in the Apothecaries' Company, and now a member of the Council of the Pharmaceutical Society,—has considerable interest:—

"To judge correctly it is necessary to bear in mind one fact in particular, that, at the time when Simpson was induced to try chloroform it was not known as a commercial article. I believe it was not used except in Liverpool, and there by two houses only—the Apothecaries' Company and Mr. Clay—for making chloric ether, to which, I believe, it was usually diluted as soon as made. If Simpson had not met with your brother, it is not at all likely that he would have seen or thought of chloroform; and subsequent experience justifies us in assuming that he would never have found out anything as good."

Mr. Waldie says:—

"Some of my friends have considerably overrated the importance of my share in the discovery, but this I have uniformly discountenanced. Willingly do I acknowledge that the discovery was Dr. Simpson's, and the honour his due. All that I looked for was a distinct and honest acknowledgment that I had recommended, or even suggested, to him to try chloroform. Out of all the great renown and more substantial advantages the discovery brought him, he might easily have spared that; but, irrespective of this, I considered it only an act of justice, and I did not get it.

"It may be asked why I did not then demand it—demand it from him on appeal to the public? I did so indirectly to a limited extent by the paper already alluded to, and have got acknowledgments occasionally more satisfactory than Dr. Simpson's. But I did not press the matter, as I thought it lay with others, not with me, to decide what amount of value the recommendation or suggestion was worth. Possibly it may have been a foolish or a weak course; certainly it has not been a very successful one. Yet I hesitated to say that the value of my suggestion had been underrated, and would probably hesitate even now to proclaim so publicly, though I am inclined to think so upon evidence that in the circumstances seems unimpeachable,—the testimony, indirect, of Sir James Simpson himself."

He then points out the amount of credit given by Sir James Simpson himself, in his last work, the 'History of Modern Anæsthetics, a Second Letter to Dr. Jacob Bigelow,' to Dr. Jackson for having suggested the use of ether to Dr. Morton, and continues:—

"Yet, much as is the credit given to Dr. Jackson for suggesting ether, not a word is said of the man who suggested and recommended chloroform to Dr. Simpson. His name is not once mentioned, and, so far as I am aware, he never got any greater credit from Dr. Simpson for one principal means of obtaining his wide-spread renown, than was conveyed in a foot-note to his original announcement, to the effect that Mr. Waldie had first *mentioned* chloroform to him. The statement was not correct, inasmuch as it conveyed n proper or sufficient intimation of what I had done. I did not merely mention it, I distinctly recommended him to try it, and also intended to help him to do it, an intention which only circumstances prevented me from carrying out.

"I have no wish to detract from the fame of Sir James Simpson. I have the highest admiration of his great and rare talents, and of the marvellous industry with which he applied them to the cultivation of medical science. I can only join in the wide-spread regret which his loss to the world has called forth, and wish that he had lived to answer, if he could, the remarks I have made. His reputation cannot suffer by my getting credit for what I am justly entitled to, and that is all I ask; and I would willingly entertain the hope that, had he been still living amongst us, and my claim been placed before him as it is now before the public, he himself would have admitted its justice."

VEHICLE FOR THE INTERNAL ADMINISTRATION OF CHLOROFORM.

To supply the wants felt by many physicians of a good vehicle for the internal administration of chloroform, Dr. G. Wilson Murdock, of Cold Spring, New York, in a letter to the *Medical Record*, suggests the use of a solution of chloroform in glycerine, which, having tried, he has found to answer the purpose so completely as to leave little to be desired.

Dr. Murdock says that by a little care in rubbing it up, one part of chloroform in bulk can be dissolved in three of glycerine. This solution is perfectly clear, is bland to the taste, and has but a slight odour of chloroform. It can be taken readily as it is, or can be diluted with water to any extent without disturbing the solution. Curiously enough, the addition of water immediately increases the smell of chloroform without any precipitation of it.

In preparing it, it is best to take one part of chloroform with two parts of glycerine; add the chloroform very slowly and rub up carefully. Then put it in a bottle and let it stand twenty-four hours. A little chloroform will have deposited at the bottom. Separate this and rub it up with the third part of glycerine, then mix it with the rest, and the solution is complete. No further separation will take place. Six ounces of glycerine, with two of chloroform, will give seven fluid ounces of the solution, so that each fluid drachm contains about 17 ♏ of chloroform.—*Chicago Pharmacist.*

THE ROASTING OF COFFEE.

In distilling a cold prepared extract of roasted coffee with lime or magnesia, an alkaline distillate is obtained, which, by evaporation after the addition of hydrochloric acid and extracting with alcohol, yields a pure chloride of methyl ammonium. This salt is chloride of ammonium, in which one equivalent of hydrogen is substituted by methyl, the radical of methylated spirit or methyl alcohol, this being the lowest one in the series of alcohols, of which ordinary alcohol and ether are representatives. This product is formed by the decomposition of caffein, when combined with tannic acid, as is the case in all coffees, pure caffein yielding different products of decomposition, among which is cyanogen. In roasting coffee, part of the caffein is volatilized together with some methylamin, while the larger amount remains with the coffee itself. Half of the caffein of the coffee is decomposed in this way; one sample, which before roasting tested 1·45 per cent., yielding afterwards only 0·65 per cent. of caffein. The temperature at which these changes are effected is, in the case of green coffee (Porto Rico), 275° C.; in the case of yellow coffee (Java), 250–255° C.

Caffein is soluble in bisulphide of carbon and in benzole; in benzole especially, to such an extent that it may be used with advantage for the preparation of the pure alkaloid.—*New York Druggists' Circular.*

Poisoning by an Embrocation.—A widow lady named Elizabeth Simpkins, who resided with her brother-in-law at Crewe, has lately died under the following circumstances. It appeared that the deceased had been a sufferer from rheumatism, and that for the last seventeen years she had been in the habit of using an embrocation consisting of chloroform and aconite, prepared by Dr. Dawes, of Longton. About half-past one on the morning in question, she awakened her brother-in-law and told him she had taken the wrong medicine. Medical men were sent for, but on their arrival life was extinct.—*Liverpool Daily Courier.*

Poisoning by Strychnia.—An accident which nearly proved fatal, occurred a few days ago to a lad residing at Bishopsfield, Chester. His master had put some cheese into a cupboard to poison mice. The cupboard was generally locked, but having inadvertently been left unlocked, the boy went to it and ate a piece of the cheese. He soon showed symptoms of poisoning from strychnia and was taken to the infirmary, where the stomach-pump having been applied and antidotes administered, he recovered.—*Liverpool Daily Courier.*

A Child Killed by Worm Lozenges.—An inquest was held at Leeds, on Saturday last, on Arthur Shepherd, aged one year and eight months. The mother of the child had obtained from a Mrs. Geldart, the widow of a herbalist, some lozenges her husband had manufactured during his lifetime, containing sugar, ginger, hellebore, gamboge and calomel, which she had given to the deceased and three other children, the deceased having a quarter of a lozenge, that not being, in the opinion of Mrs. Geldart, too much for a child of that age. After taking the lozenges all the children became sick, the deceased especially so. A medical man was sent for, but when he arrived the child was in a dying state, and its death took place the same night. A *post-mortem* examination showed that it had been poisoned by hellebore. A verdict to that effect was returned, and Mrs. Geldart was cautioned that, if she permitted any more of the lozenges to be used, she might get into serious trouble.—*Leeds Paper.*

Solutions of Soluble Chlorides for Road-Watering.—At the Liverpool Meeting of the British Association Mr. W. J. Cooper, who has introduced the method of watering roads with a solution of deliquescent chlorides, stated, in a paper read by him, that the experiment tried by the Westminster Board of Works at Whitehall and Knightsbridge had been so successful that they had resolved to extend it throughout their entire district. He gave statistics to prove that a saving of expense was effected by his plan; besides which, he called attention to the special value of some of the chlorides in chemically deodorizing and disinfecting the offensive matter deposited on public thoroughfares. Mr. Cooper claims for his present solution, which contains the chloride of sodium and calcium, that the chloride of calcium decomposes the carbonate of ammonia of the horse-droppings, and produces carbonate of lime and chloride of ammonium, which salts, combining with the chloride of sodium, serve to form a layer of concrete on the surface. He now suggests that to the original solution a portion of chloride of aluminium should be added, which he thinks would completely purify and disinfect the streets over which it was spread.

Colouring Materials in Tinctures.—Mr. G. W. Kennedy, of Pottsville, Pennsylvania, in a letter to the *American Journal of Pharmacy*, referring to the presence of red saunders in the United States Pharmacopœia formula for tinct. cinchonæ comp., says that it is not required, as there is colouring matter enough in the other drugs that are used to make the tincture a dark red. He suggests that this is one of the matters that should be taken into consideration in the revision of the United States Pharmacopœia.

Antiseptics in the War Hospitals.—The Berlin correspondent of the *British Medical Journal* writes,—"In 1866 permanganate of potash was the antiseptic remedy *à la mode;* this year it is carbolic acid. In every hospital it is used on the largest scale for dressing and washing wounds, in more or less strict accordance with the directions of Mr. Lister."

The Pharmaceutical Journal.

SATURDAY, OCTOBER 15, 1870.

AUTOGRAPH PRESCRIPTIONS FOR EXAMINATION, LOAN, AND REFERENCE.

Mr. Joseph Ince wishes once more at the opening of the Session to direct attention to this subject. The London collection, consisting of fifteen volumes, is finished, save the concluding book which is reserved for France and Germany. It was thought it would be a want of courtesy to exclude these two great nations, which, had it not been for the late unhappy disturbances would have rendered most energetic aid. It is some satisfaction to note that the value and interest of these written formulæ has in no way diminished during the progress of their arrangement. Switzerland is well represented in recent contributions. Albert Ebert has not forgotten Chicago: the student who consults these pages need not visit Norway: while Mr. Gerard, as well as the London Chemists' Association have amply illustrated the practice of our own celebrated physicians.

More than a passing remark is due to Mr. W. Procter Jr. of Philadelphia for his selection of American Prescriptions. Their worth is much increased by an explanatory letter, containing the names of the prescribers and details of transatlantic Pharmacy.

The following sentence will be read with surprise. "It may be well to observe that in the United States the Latin language is rarely used in writing the directions for the use of a prescription. The general education of Physicians here would not justify it, nor are Pharmaceutists qualified to translate other than the simple and brief directions—especially since the abandonment of Latin in the Revision of 1840."

Fifteen volumes, destined for Provincial Associations, will complete the original scheme. Three have been despatched, six are in active preparation. Bradford, Bristol and Liverpool will head the list, and no pains will be spared to ensure variety in each separate compilation. Eighteen hundred formulæ, which are most earnestly desired will put us in possession of a sufficient library of autographs.

Would our readers kindly aid, and direct their enclosures to the Office of the Secretary?

It was announced last week that for the present Dr. Odling would deliver the chemical lectures to the medical students at King's College, and that Professor Bloxam would conduct the classes for students of applied science, but we understand that, since Bartholomew's Hospital is now without a chemical lecturer, there is a possibility of Dr. Odling's former connection with this school inducing him to resume for a time the lectures there.

CHEMISTS AND DRUGGISTS' FUND FOR THE SICK AND WOUNDED.

Total amount of money contributions up to this date £137 0 2
besides contributions of drugs, etc.

Received since the last publication:—
Walter, G. Jameson, Hastings £1 1 0

Erratum.—In Mr. Rogerson's collection, published last week, Mr. S. Parker's subscription should have been 4*s.* 6*d.*, and the total amount collected £16. 9*s.* 6*d.*

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

October 5th, 1870.

MR. SANDFORD, PRESIDENT, IN THE CHAIR.

MR. HASELDEN, VICE-PRESIDENT.

Present—Messrs. Abraham, Atherton, Bottle, Bourdas, Brady, Brown, Deane, Dymond, Edwards, Evans, Hanbury, Hills, Mackay, Reynolds, Stoddart, Sutton, and Woolley.

The minutes of the last meeting were read and confirmed.

The Report of the Finance Committee was presented, showing, on the General Fund account, a balance in the Treasurer's hands of................ £1220. 14*s.* 0*d.*
On the Benevolent Fund account, a balance of .... £617. 19*s.* 11*d.*
And submitting for payment sundry accounts for alterations, repairs, salaries, etc., and annuities, amounting to .... £1367. 13*s.* 10*d.*

Resolved—That the Report of the Finance Committee be received and adopted, and payments made.

Resolved—That in future all accounts relating to expenditure on the house, including alterations and improvements, be examined and certified by the House or other Committee, before being submitted to Council by the Finance Committee.

Resolved—That the Report of the Benevolent Fund Committee be received and adopted, and that the Treasurer be requested to pay the sum of £15 to applicants for relief.

Moved by Mr. Brady, seconded by Mr. Deane, and
Resolved—That in the Sessional Examinations in future, a Silver, instead of a Bronze Medal, be awarded for the first prize, and a Bronze Medal for the second prize. Certificates of honour and merit as heretofore.

Moved by Mr. Dymond, seconded by Mr. Mackay—
"The subject referred to this Council by the last Annual Meeting respecting the keeping, selling, and dispensing of the poisons enumerated in the Pharmacy Act, having been considered, this Council records its opinion that the recommendations already made have been misunderstood, that they embrace the principles on which poison regulations should be framed, but that they are capable of extension, that a Committee be appointed to more fully consider the subject and prepare some explanation of their application, which may be circulated amongst the chemists of the kingdom.

Amendment—Moved by Mr. Woolley, seconded by Mr. Brown—
"That the subject of the Sale and Keeping of Poisons be discussed in Council and not referred to a Committee."

For the Amendment—
Messrs. Atherton, Bottle, Brady, Brown, Reynolds, Sutton, and Woolley.
Against—
Messrs. Abraham, Bourdas, Deane, Dymond, Edwards, Evans, Haselden, Hanbury, Hills, Mackay and Sandford.

The Amendment being lost, a further Amendment was moved by Mr. Reynolds, seconded by Mr. Brady,

"That the Poison Regulations proposed by the late Council having been rejected by the Annual Meeting, and condemned by many meetings in various parts of the country, it is not expedient to accept them as the basis of a reconsideration of the subject."

For the Amendment—
Messrs. Atherton, Bottle, Brady, Brown, Reynolds, Sutton and Woolley.

Against—
Messrs. Abraham, Bourdas, Deane, Dymond, Edwards, Evans, Haselden, Hanbury, Hills, Mackay, Sandford and Stoddart.

The Amendment being again lost, the following Amendment was moved by Mr. Brown, seconded by Mr. Bottle,

"That the question relating to the storing and dispensing of poisons be referred to a Committee to report to the Council as to the form in which, after due consideration, the matter shall be presented to the Annual Meeting."

For the Amendment—
Messrs. Bottle, Brady, Brown, Stoddart and Woolley.

Against—
Messrs. Abraham, Bourdas, Deane, Dymond, Edwards, Haselden, Hanbury, Hills, Mackay and Sandford.

The Amendment being lost, the original Motion was put as a substantive Motion, and carried.

Whereupon certain gentlemen were proposed to form a Committee, but Messrs. Brown and Reynolds objecting that they could not serve on a Committee appointed to consider the question under a foregone conclusion of the Council with which they disagreed, the Council, after some discussion, permitted the withdrawal of the Resolution just passed, in order that all opinions should be represented in the Committee; and it was

Resolved—That it is desirable to take into consideration the question of Regulations for the Sale and Keeping of Poisons, in accordance with the Resolution passed at the last Annual Meeting, and that the following be appointed a Committee for that purpose, viz. Messrs. Abraham, Bottle, Brown, Deane, Dymond, Edwards, Hills, Hanbury, Mackay, Reynolds and Stoddart.

Moved by Mr. Reynolds, seconded by Mr. Sutton, and

Resolved—That the Tabulated Returns on Provincial Education, collected by the Committee on that subject, be received and published in the Journal.

Resolved—That Mr. John Green, of Christchurch, be elected Local Secretary, *vice* Mr. Henry Sharp, deceased.

Resolved—That the following, having passed their respective examinations, be elected

ASSOCIATES OF THE SOCIETY.

MINOR.

Fox, William Albert ....St. Albans.
Nuthall, Edwin ....Norwich.
Thompson, Benjamin ....Brighton.

Resolved—That the following, having passed their respective Examinations, be elected

ASSOCIATES IN BUSINESS.

MINOR.

Riddle, William R. ....Hexham.

MODIFIED.

Hayward, George................Croydon.
Reedman, William Henry ....Bletchingley.

Resolved—That the following Registered Chemists and Druggists be elected Members of the Society:—

Ball, Edwin..............Buxton.
Curtis, Thomas West.....Holbeach.
Martin, John ....Seacombe.
Miller, William Henry ....Ridgeway.
Welch, Charles ....Reading.

LONDON.

John M'Lean....11, Clifton Road, Paddington.
Henry Astrop ..Old Kent Road.

The Secretary presented the name of a member who had paid his subscription since the 30th April.

Resolved—That he be re-elected a member of the Society on payment of a fine of one shilling.

Resolved—That the 'PHARMACEUTICAL JOURNAL AND TRANSACTIONS' be supplied to the Midland Counties' Chemists' Association regularly as published.

THE JACOB BELL PORTRAIT.

Mr. HILLS called the attention of the Council to his original proposal, as to the application of the proceeds of the sale of the Engravings of the Portrait of the late Jacob Bell, viz.,

That the proceeds of the sale of the Engravings of the Portrait be invested, and the interest of the same be applied to the purchase of books to be selected and given by the Examiners as prizes at their monthly Examinations to the candidate who shall pass the Minor Examination, first in honours, and in the opinion of the Board be entitled to the prize.

Mr. Hills then said that the proceeds of the sale of the portraits had not amounted to as much as he had hoped, and he desired, if the Council would allow him, to supplement the amount received by the donation of a sufficient sum to produce £10 a year, and he had, in fact, with that view purchased two £100 bonds of the 1870 5 per cent. Russian Loan. He wished now, therefore, to hand over the bonds he had purchased, for the purpose originally expressed by him, of establishing a Prize Fund. He would suggest that a prize of books, of a nature to assist the student in preparing himself for the Major Examination, should be given monthly, by the Board of Examiners, to the candidate for the Minor Examination who most distinguished himself, provided such candidate took honours in the Examination; for this reason, that it would be an additional inducement for the student to present himself for the Major Examination. Mr. Hills wished it to be quite understood that he merely offered this as a suggestion, but would prefer that the details of the distribution of the fund should be left entirely at the discretion of the Council and the Board of Examiners.

Resolved—That the very cordial thanks of the Council on behalf of the Society be tendered to T. H. Hills, Esq., for his handsome and liberal offer of the Fund he now proposes to hand over for the purpose of purchasing prizes to be given to the successful candidates at the Minor Examinations.

Fee for Chemistry and Botany, inclusive, 5s.
There are Chemistry and Botany classes at the Govern-
Science School.
No return. *Vide* Table for 1869-70.
Anderson's University and the Mechanics' Institute have hitherto supplied students with lectures in Latin, Chemistry and Botany, but the business hours of a large portion of the trade are such as to prevent many from taking advantage of them.

(*h*) The classes are in connection with the Plymouth and Devonport Science School.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Second Annual General Meeting of the above Association was held in the Memorial Hall, Albert Square, on Friday, October 7th; Mr. W. S. Brown, Vice-President, in the chair.

The following report was read by the Honorary Secretary:—

Your Council have again the satisfaction of presenting a favourable Report of the condition and prospects of the Association. The number of members and associates on the books, though fewer than last year, is still large. The passing of the Pharmacy Act in 1868 startled the entire trade out of its apathy, and the result was a sudden interest in the future of our vocation, evidencing itself in this district by a ready response to the canvass for members which was at that time made. Some of these have not maintained their connection with the Association, and their places have been but partially filled up by new members. There is reason to believe, however, that those who remain are they who take a real interest in the aims and work of our Society, and that our real strength is not less, but greater.

The pharmaceutical courses established last session at Owens College were not in all cases so largely attended as was anticipated. Some dissatisfaction was expressed in the daily papers at the hour which had been chosen for the delivery of the lectures; this point has been most carefully reconsidered, and with the very kind co-operation of the trustees and professors of the College, some new arrangements have been made, which it is hoped will meet the requirements of the majority of those for whose benefit they have been undertaken. One of the principal features in the new scheme is a course of lectures on Practical Pharmacy; one of our own members, Mr. Louis Siebold, having been appointed lecturer; and it is confidently hoped that this class will be as well attended as the importance of the subject deserves. The following is a detailed syllabus of the whole Pharmaceutical course:—Five courses of lectures, comprising twenty-seven lectures each,—Pharmaceutical Latin, Professor Wilkins, M.A., or Mr. Bentley, M.A., Mondays, 3 to 4 P.M. Chemistry, Professor Roscoe, F.R.S., or Dr. Thorpe, Mondays, 4 to 5 P.M. Pharmacy, Mr. Siebold, Wednesdays, 4 to 5 P.M. Materia Medica, Mr. Somers, Wednesdays, 5 to 6 P.M. Botany, Professor Williamson, F.R.S., Wednesdays, 7.30 to 8.30 P.M. The lecture fees are 15*s.* for one course, £2 for three courses, and £3 for the complete series of five. A Laboratory course of Practical Pharmaceutical Chemistry, by Professor Roscoe, F.R.S., and Mr. Schorlemmer, F.C.S., Mondays, from 6 to 8.30 P.M. This class is intended for those students in pharmacy who have already passed through the lectures on Elementary Chemistry, or who have otherwise made themselves acquainted with the principles of the science. Each of these students will be provided with a working-table, set of tests and all the requisite apparatus: fee, £4. 4*s.* A prize for diligent attendance throughout the session and proficiency in the examinations, will be given in each class by the Manchester Chemists and Druggists' Association, at the end of the session. The Principal will attend at the College to admit new students on Thursday and Friday, the 6th and 7th of October, from 6.30 to 9 P.M., or entries may be made with Mr. F. Baden Benger, Hon. Sec. of the Association, 1, Market Place. Those students who are unable to attend the afternoon classes may substitute corresponding evening classes, for particulars of which see prospectus.

The advantages thus offered to pharmaceutical students in Manchester and district are such as but very few cities could provide, and your Council cannot too strongly urge Members and Associates to make the arrangements as extensively known and availed of as possible.

Keeping in view the main object of the Association, to provide means of professional and scientific education for assistants and apprentices, great efforts have been made during the past session to found a library and museum. These efforts have—through the liberality of many friends, some unconnected with Manchester, except by sympathy with our cause—been attended with an encouraging degree of success. Upwards of £65 has been subscribed to a special library fund; part of this has been invested in standard works of reference, and the Library Committee is about to make further purchases. For the accommodation of these books and their readers, it has been necessary to purchase a book-case and to rent and furnish a suitable room; this has been done in Mitre Chambers, Cathedral Gates. It is open for the use of Members and Associates on Monday, Wednesday, and Friday evenings, from six to ten, and it is hoped will be much resorted to during the winter months. The expenses connected with this undertaking have somewhat reduced the balance of the General Fund, but it was thought desirable to devote the whole of the Special Library Fund to the purchase of books. A large and handsome cabinet for the materia medica specimens, containing one hundred and thirty drawers, has been presented by Messrs. Woolley, and a series of remarkably beautiful specimens of dried and mounted medicinal plants, by Mr. Ransome, of Hitchin. Mr. T. H. Hills, of London, has generously contributed engravings of the late Jacob Bell, John Bell and Jonathan Pereira, accompanied by a cheque for £5. 5*s.* to the Library Fund, and Mr. J. J. Pyne a complete series of the Pharmaceutical Journal from its commencement, in thirty volumes, with other books.

The monthly meetings of the past session were supplied with interesting papers and were well attended. These were held alternately on the afternoon and evening of the first Friday in the month. Tea was provided at the evening meetings, and it is proposed to continue this arrangement for the present. The Council would be glad if the associates as well as members would contribute papers or introduce subjects for discussion at these meetings, the success of which so much depends on the hearty co-operation of all.

To maintain and extend the usefulness of this Association should be the desire, as it is the interest, of every chemist and druggist, assistant and apprentice in Manchester and the surrounding towns. Its efforts to promote the good of the entire trade commend it to principals, and the merely nominal associates' fee of 2*s.* 6*d.* per annum cannot be beyond the means of the poorest apprentice; yet for this small sum he obtains access to such books, materia medica specimens, etc., as will prove of great service to him in preparing for the inevitable examination, besides sharing the advantages which are inseparable from association with those engaged in similar studies.

Your Council trusts that the Association will be strengthened by a large accession of members during the present session.

The Treasurer in Account with the Manchester Chemists and Druggists' Association.

Examined and found correct, September 27th, 1870. } STANDEN PAINE. WILLIAM BAGSHAW.

In moving the adoption of the report, the CHAIRMAN, after remarking that he was glad to see such a large attendance of members, and friends whom they cordially welcomed and hoped to include in their ranks, said the Association was formed two years ago, under an impulse communicated by the passing of the Pharmacy Act, 1868, and they had great reason to congratulate themselves upon the continued success which had attended its operations. He thought they had been more successful than they could have anticipated; and certainly when they contrasted their progress with that of kindred associations, Manchester had no reason to be ashamed of the efforts put forth, or with the results attained. These were not only professional but social, and have had many practical outcomes in the experience mutually communicated, and the mutual confidence and goodwill established between members of the same business who had previously very little knowledge of each other. Beyond that, and as the principal object of their Association—the education of apprentices and assistants of the present day, who would be the pharmacists of the future,—they had every reason for congratulation that in the outset they decided to connect themselves with that noble institution which Manchester had the privilege of possessing, and ought to be exceedingly proud of—Owens College. The cordial co-operation accorded to them by the trustees of that institution had culminated in the producing for the present session of a course of lectures which he thought would bear comparison even with the Central School in Bloomsbury Square. He believed no other city or town had such a complete course of pharmaceutical education provided at so small a cost. He hoped this state of things would result in a large accession both of members and associates, for it was most important that they should have the encouragement of a large number of members and associates and large attendances, and they looked to their future connection with Owens College as likely to result in the establishment of an institution to provide pharmaceutical education, and eventually in a college of pharmacy, which might attain a high position. Efforts made in providing pharmaceutical education had been hitherto principally confined to the parent institution in London, where there was a large and flourishing educational establishment, but that was only available to a few. The application of that kind of education locally had occupied the attention of the governing body, and it was confidently hoped that in a short time a practical scheme would be devised by which assistance could be afforded to localities where such advantages as were presented in Manchester were not available. He trusted that they would be able to do without any extraneous aid at all. They had endeavoured to meet all requirements both in town and country by the arrangement of their meetings, and he hoped that the appeal they had put forth in the report would bring many new members. Let them not be content with 114 members, but go on until all who were connected with the business became associated. He hoped to see more of their friends of the medical profession, for it was most important that there should not be needless and causeless jealousy. He referred with satisfaction to the state of the library fund, and expected to see it largely increased in the future. The work of the Association, he took it, had not only had a practical effect in their own city but in many places. The action they took when some objectionable regulations with regard to the selling and dispensing of poisons were sought to be forced upon them by legal enactment, was supported by many other kindred institutions, and it resulted in the defeat of an attempt made, without protecting the public in any way, to impose restrictions that were objectionable, and rendered it difficult to carry on the business of a chemist with that freedom and care which had always characterized the trade. In conclusion, he advocated such a shortening of the hours of labour as would allow apprentices and assistants more time for study, and moved the adoption of the report and statement of accounts.

Mr. SLUGG seconded the motion, and said he considered the report an admirable one, and that the Association was in a most healthy state.

The report having been adopted, it was announced that Mr. Standring had expressed his wish to retire from the office of President; whilst he sympathized with the work of the Association, his failing health and distant residence from town, rendered it impossible for him to fulfil the duties of President satisfactorily.

It was then proposed by Mr. G. S. WOOLLEY, and seconded by Mr. F. B. BENGER, and carried unanimously, that Mr. W. S. Brown, whose energy, zeal and ability were so well known to the members, be elected President.

On the motion of Mr. HALLIDAY, seconded by Mr. HAMPSON, an alteration was made in the Bye-laws to allow of the election of two Vice-Presidents.

Mr. J. T. Slugg, F.R.A.S., and Mr. Wilkinson were then unanimously elected to these offices.

Two vacancies occurring in the Council list by the retirement of Mr. Standring and Mr. Bateman, Mr. Redford, of Messrs. Ransome and Co., and Mr. Hughes of Victoria Street, were elected; the remaining members of the Council were re-elected, as were also the Hon. Sec., Mr. F. B. Benger, and the Treasurer, Mr. G. S. Woolley.

Professor Attfield, of Bloomsbury Square, London, and Mr. T. H. Hills, of 338, Oxford Street, London, two gentlemen who had shown much kind interest in the success of the Association, were elected honorary members.

It was announced that the next monthly meeting would be held in the Memorial Hall, on Friday evening, November 4th. Tea and coffee at 7 P.M.; the subject for discussion being "Apprenticeships and Pharmaceutical Education in the Provinces."

Tannin and Glycerin Pencils.—Dr. Schuster proposes the use of tannin mixed with glycerin as a substitute for caustic injections. This material is at first waxy, but soon becomes hard, and it melts in a moist atmosphere at the temperature of the body.—*Lancet.*

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting at Liverpool.

Wednesday, September 14th.

A Century of Old Books.

BY JOSEPH INCE.

(*Concluded from page* 298.)

The late Dr. Pereira's note-book on Cardamoms.

Interesting as showing with what labour and patience the author sought for and noted information relative to any particular subject on which he was at work.

Christiani Francisci Paullini Μοσχοκαρυογραφια *seu Nucis Moschatæ Curiosa descriptio, historico-medico-physica. Francofurti et Lipsiæ*, 1704. 8o.

A curiosity of prolixity, the whole work of 876 pages being devoted to a discussion on *Nutmegs.*

Herbarius Pataviæ, printed at Padua in 1485.

It consists of an alphabetical catalogue of medicinal plants, a rude representation of which heads each chapter. The name of each plant is given in German as well as in Latin.

*Otho Brunfels.—Herbarum Vivæ Eicones ad naturæ imitationem, summâ cum diligentiâ et artificio effigiatæ una cum effectibus earundem * * * Argentorati*, 1530. *fol.*

Brunfels, a native of Mentz, was a theologian and physician occupying in the latter capacity the post of *poliater* or chief medical officer of the city of Bern. In this office he died A.D. 1534. Of his numerous works that of which the title is here given is remarkable for its excellent woodcuts, which have indubitably, as the author asserts, been made from the very plants and not drawn from memory or imagination. In this respect they present a most striking contrast to the figures in other works of the period, as well as in many of those of a much later date.

It is much to be regretted that the time was too limited to examine these specimens of ancient pharmacy in detail. Pharmacopœias of various date and type, abounded. Quaint tractates, such as The Garden of Health (1649.) Boyle's Noctiluca (1680). Conclave of Physicians (1686) Pharmacopœia Reformata (1744) Holt Waters (1731) Val. Cordi Dispensatorium (1690). Speculum Lapidum Camilli Leonardi (1502) Secrets of Alexis (1568) and about forty similar productions were not wanting.

Some Latin Books were worthy of special commendation, amongst which may be mentioned Valerius Cordus, a small but most interesting volume. Mr. Haselden undertook several, and also contributed a notice of the celebrated Dr. Radcliffe, part of which we subjoin.

Dr. Radcliffe's Practical Dispensatory.

A portrait of the doctor, wearing a long, flowing, curling wig, after the fashion of the period, adorns the frontispiece, under which is written, "Johannes Radcliffe, M.D. Ob. Nov. 1, 1714. Ætat. 64. Printed for Charles Rivington, in St. Paul's Churchyard.

Before we examine the contents of the book, let us indulge in a brief account of this once celebrated doctor.

He was born at Wakefield, Yorkshire, in 1650, near which place his father was possessed of a moderate estate, who having a numerous family, did not think it prudent on account of the expense, to breed his children to letters, but at the prompting of his neighbours was induced at length to send this son to a school at Wakefield. Having shown great aptitude in learning he was removed at fifteen to Oxford, and entered at University College, 1665. In 1669 he took his first degree, and was chosen Senior Scholar of this college. In June, 1672, he took his degree of M.A., and in 1675, Bachelor of Physic. After this he practised in Oxford until 1684, when he came and settled in London.* In the autumn of 1689, when he resided in Bow Street, Covent Garden, an urgent message reached him rather late in the day. Hurrying into his carriage, he hastened with all speed to Kensington House, then the palace of his Majesty King William the Third. He was ushered into the sick chamber of the king, who had been some time unwell. "Doctor," said the king, "Bentinck (Earl of Portland) and Zuleistein (Earl of Rochford) have been urgent with me that I should again send for you; and though I have great confidence in my two body physicians here, yet I have heard so much of your skill, that I desire you will confer with Bidloo and Laurence [the medical attendants], whether some other plan might not be adopted." "May it please your Majesty," said Dr. Radcliffe, "I must be plain with you, sir. Your case is one of danger, no doubt, but if you will adhere to my prescriptions I will engage to do you good." The consultation between the professionals was short, the treatment altered, and the royal patient was soon restored, and a few months afterwards, he fought the battle of the Boyne.

The doctor was a great frequenter of taverns and clubs, where the choicest spirits of the day were wont to assemble. He was at one time engaged to be married to the daughter of a wealthy citizen, but a discovery which he seemingly made during his courtship, and which did not redound to the lady's credit, caused him to break the engagement, although a source of regret at the time; but in his plain peculiar way he infers that the lady, however a very deserving gentlewoman, is not fit to be his wife, as she is, or ought to be, another man's already.

His practice was very large, and increased daily. He had considerable humour, and once when sent for to a gentleman suffering from quinsy, for which no application had been of service, he desired the lady of the house to have a hasty pudding prepared, and when done his own servants brought it up. It was placed on the table in full view of the patient. "Come, Jack and Dick," said Radcliffe, "eat as quickly as possible; you have had no breakfast this morning." Previously instructed, they commenced a fierce attack upon the pudding; but one dipping faster than the other, a quarrel arose, ending in the pudding being pelted at each other. The patient was seized with a hearty fit of laughter, the quinsy burst, discharged its contents, and the cure was thus speedily effected. He always spoke confidently, and thus inspired hope and faith in his patients. When in his sixtieth year he was once more in love with a very young lady, but was unfortunate and rejected, and so remained single for the rest of his life. Speaking of himself in the latter part of his days, he says, "By following the dictates of common sense, while I practised at Oxford, after taking my degree of Bachelor of Medicine, instead of stoving up my patients who were ill of the small-pox, I gave them air and cooling emulsions, and thus rescued more than a hundred from the grave." He always discountenanced quacks and intermeddlers, as he styled them.

He realized by his practice a princely fortune, and is now more particularly remembered by the way in which, looking upon Oxford, his Alma Mater, he bequeathed property. He left his Yorkshire estate to the Master and Fellows of the University College for ever, in trust for the foundation of two travelling fellowships; £5000 for the enlargement of the building of the University College; £40,000 for building a library at Oxford; £500 yearly for ever towards mending the diet of St. Bartholomew's Hospital.

The 'Pharmacopœia Practica' is divided into two parts and an appendix. In the first part, twelve chapters treat of Cathartics, Glysters, Suppositories, Diaphoretics, Leeching, Tapping, etc. etc. In the second part, six chapters treating of Restoratives, Attenuants, Neutrals, etc. etc. The appendix of Opiates, Milk, Dipping, Axioms concerning local medicines, etc. etc., an index to the first and second parts, referring to every remedy or disease mentioned in the work.

* From the *Universal Magazine* for July, 1760.

To give an example or two of the style of the Author and his treatment of disease, we quote this, touching on Cholera.

"When Persons are inclinable to a Vomiting, Promotion is often necessary; and therefore in a *Cholera Morbus*, where there is an abundance of bilious and sharp Humours, there you may gently promote it by giving Chicken Broath or Whey or Barley-water; after you have diluted and washed well, give 'em *Decoct. Alb.* and attemperating Draughts with *Laudanum* in 'em till the Vomiting ceases. I speak upon a supposal that you are called early in; because if the Vomiting has continued so long as to have exhausted the spirits, nothing remains to be done save the giving of Opiates and Cordials." The learned in treatment may decide how far this differs from modern usage.

The following for an Enema may in some degree surprise dispensers accustomed to the extreme simplicity, simple sometimes to a fault, of modern prescribers.

Take the decoction of Aromaticks, viz., Calamus Aromaticus, Galangal, of each half an ounce; Leaves of Mint, Wormwood, Centaury Tops, of each two Pugils [handfuls]; Seeds of Caraways, Anise Seeds, and Cardamoms, of each half an ounce; mix with it Electuary Lenitive, and *Epsom* Salt, of each one ounce; Oil of Amber, half a dram; mix and make a Glyster, to be thrown in."

There are numerous eccentric forms similar to the above, and many others simple as those in general use at the present time. Some of the means prescribed would scarcely admit of being printed now, therefore we pass them over. Many of the observations are full of sound reasoning, and, deprived of peculiarities, might stand side by side with the writings of modern authors; and with this we close our remarks on Dr. Radcliffe's Pharmacopœia Practica.

Farther we need not quote; but we must reprint two articles—the first by Professor Wanklyn, and the second by Mr. Ince.

The Hermetical Triumph, or, the Victorious Philosophical Stone. A Treatise more compleat and more intelligible than any yet Extant, concerning the Hermetical Magistery. Translated from the French. To which is added, The Ancient War of the Knights, being an Alchymistical Dialogue betwixt our Stone, Gold, and Mercury; of the true Matter, of which those who have traced Nature do prepare the Philosopher's Stone. Translated from the German. London: Printed by F. Noble, at Otway's Head, St. Martin's Court, near Leicester Fields. 1740.

Opposite the title page there is a very elaborate frontispiece.

"The Ancient War of the Knights" was "composed originally in the German tongue by a very able Philosopher," and is given in duplicate in this book.

One English translation, which is to be found towards the end of the book, was made directly from the German. The other English translation was made from the French version, which itself had been made from a Latin translation of the original German. As might be expected, the English direct from the original German is vigorous and terse, whilst the other is comparatively weak and verbose.

The "War" consists mainly of a discussion between the "Stone" and "Gold" as to their relative merits; the part taken by Mercury being very slight, and confined to a single expression of assent made to a remark made by Gold.

A very curious passage, warning the reader against attributing the plain and literal sense to works of this kind may be quoted from the dialogue. "But when they name barely the name of Gold and Mercury, they do it to hide the Art from the senseless and the unworthy, knowing very well that such only dwell upon Names and written processes, without meditating further upon the foundation of this Matter. But the Prudent and Diligent read with Prudence, and ponder how one squares with the other, out of which they get a Foundation; finding thus by speculation, and from the Philosopher's sentences, the true matter which no Philosopher ever named and described openly by its true Name."

That the writings of "true Philosophers" should be somewhat hard to understand, need therefore not occasion much astonishment.

There is gold, such as we find it, and there is an ideal gold such as we never find it, and which never appears to be endowed with infinite perfections. With our modern ideas and modes of thought it is hard to bring our minds into a proper frame for the study of these old alchemical writings.

J. A. Wanklyn.

Primitive Physick; or an Easy and Natural Method of curing Most Diseases. By John Wesley. Homo sum: humani nihil a me alienum puto. Bristol: Printed by William Pine, in Narrow Wine Street; and sold at the New Room, in the Horse-Fair; and at the Foundery, near Upper-Moor-Fields, London. 1762.

This was the book that afforded so much amusement to Robert Southey, who, with the most good-natured pleasantry, reviewed its contents. He recounts how the laborious evangelist, wearied with his efforts, retired to a friend's house and applied a certain plaister, the healing merits of which he subsequently described in terms of extreme laudation. Southey was inclined to think that cessation from apostolic work, and needed rest, should have had their share of credit in the cure effected.

The chief interest of the treatise lies in the preface, some passages of which have become household words in the community which the writer founded. Wesley first states that man before the fall was in perfect health; he was in harmony with nature—nature at peace with him. Then came sin, and disease followed in its train; but great remedies are provided of which temperance and exercise are chief. Physick was at first traditional, the father handing down his observations to the son; or else these stores of knowledge remained in the keeping of the elders. Further advance was made by what is termed accident: a man walking in a grove of pines finds out the use of the natural, exuded gum, just as in later times the value of Peruvian bark was brought to light. Eventually hypothesis dethroned experience, theories sprung up and the science of medicine was established. Physicians were held in honour, and profit attended their employ; hence the wish to shroud their art in mystery, to talk splendid darkness about astrology and astronomy, and to keep the profane vulgar at a distance. "Yet there have not been wanting from time to time, some lovers of mankind who have endeavoured (even contrary to their own interest) to reduce Physick to its antient standard: [they have shewn] that every man of common sense (unless in some rare cases) may prescribe either to himself or his neighbour, and may be very secure from doing harm, even where he can do no good. Even in the last age there was something of this kind done, particularly by the great and good Dr. Sydenham."

"Without any regard to this, without any concern about the obliging or disobliging any man living; a mean hand has made here some little attempt toward a plain and easy way of curing most diseases. I have only consulted herein experience, common sense, and the common interest of mankind." Such is the intention of the book. In its day it commanded a large sale, though it will scarcely bear the test of modern investigation. The author started with two inestimable blessings: a comfortable appreciation of his own abilities, and thorough confidence in himself. It seems that full allowance being made, the perusal of the directions will create a feeling of disappointment. The following sentence has been often quoted. "The Love of God, as it is the sovereign remedy of all miseries; so in particular it effectually prevents all the bodily disorders the passions introduce, by keeping the passions themselves within due bounds. And by the unspeakable joy and perfect calm, serenity and tranquillity, it gives the mind, it becomes the most powerful of all the means of health and long life." The idea is twice repeated. "In uncommon or complicated diseases, or where life is more immediately in danger, I again advise every man without delay to apply to a physician that fears God." In his third preface, Wesley used a word that has been a motto ever since throughout the Methodist connection; to remedies the effects of which he had himself observed, he added "*tried.*" Also he insists on the application of electricity as a remedial agent: in the Appendix, no less than 37 diseases are declared to yield to its influence.

The collection of receipts are more curious than useful, they are not equal to the average of such compilations. "*For an Ague.* 8. Make six middling pills of cobwebs. Take one a little before the cold fit: two a little before the next fit: the other three, if need be, a little before the third fit. I never knew this fail. *Cholera Morbus.* 131. Drink two or three quarts of cold water, if strong; of warm water, if weak. 132. Or, boil a chicken an hour in two gallons of water, and drink of this till the vomiting ceases." This would excuse the man, who during the outbreak of this pestilence at Paris, sold half-ounce bottles of distilled water at a franc a-piece, upon the Pont-Neuf.

We next come to Dr. Dovers's successful treatment of Consumption. "Mr. Masters, of Eversham, was so far gone that he could not stand alone. He was advised to lose six ounces of blood every day for a fortnight, if he lived so long; and then every other day; then every third day, then every fifth day, for the same time. In three months he was well. *Tried.*"

Wesley, however much the above may be called in question, describes three eye-waters, the third of which is prescribed occasionally now; and we wonder that in these days of advertisements no one has brought it out as a patent medicine. Moreover, it is efficacious, and to it we can add, *tried.* The first is—"(303.) Heat half an ounce of Lapis Calaminaris red hot, and quench it in half a pint of French white wine, and as much white Rose Water: then pound it small and infuse it. Shake the bottle when you use it. It cures soreness, weakness, and most diseases of the eye. I have known it cure total blindness."

The form still used is—"(305.) Boil very lightly one spoonful of white copperas scraped, and three spoonfuls of white salt, in three pints of spring water. When cold, bottle it in large vials without straining. Take up the vial softly, and put a drop or two in the eye morning and evening." To the surprise of the writer of these lines, he has been in the habit of preparing an eye-lotion without being aware that he was indebted to Wesley's pages for its origin. "306. An eye-water which was used by Sir Stephen Fox, when he was 60 years of age, and could hardly see with the help of spectacles; but hereby in some time recovered his sight, and could see to read the smallest print without glass or spectacles, till above 80. Take six ounces of rectified spirit of wine, dissolve it in one drachm of camphor; then add two pugils of dried elder flowers. It is used as an embrocation for the forehead and eyelids."

Powdered Assarabacca is *Major's* snuff. We pass over a large quantity of receipts, expressing astonishment that they should have found favour. The gout is to be cured by the application of a raw lean beef-steak (368); while for the iliac passion, Sydenham orders a live puppy to be held constantly on the belly (431)—a singular mode of giving bark; while rupture in children (588) is treated by boiling a spoonful of egg-shells dried in an oven, and powdered, in a pint of milk to three quarters of a pint. Feed the child constantly with bread boiled in this milk. What shall we say when for green sickness, we are gravely instructed to take an ounce of quicksilver every morning; while for twisting of the bowels, one, two, or three pounds of quicksilver in water, are suggested. Our age has taught us better things.

Experience and common sense are the handmaidens of abstract science. Wesley forgot that though a rudder may be a most sensible invention, it requires a skilful hand to guide it. Nevertheless, he can well forgive a passing smile, for there is no man who has lent a stronger impulse to religious intelligence and activity than the author of Primitive Physic.

JOSEPH INCE.

One hundred volumes were included in this collection: those only were noticed of special interest. Mr. Ince, in conclusion, paid a well-deserved compliment to Mr. Tilden for his energetic and successful aid.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

NEWCASTLE-ON-TYNE, 1870–71.

The Winter Session commenced on Monday, October 3, when the Very Reverend the Dean of Durham, Warden of the University, presented the scholarship and prizes to the successful candidates. The successful students in Pharmacy were—Henry Melhuish (silver medal and 1st certificate of honour), George Foggon (2nd certificate of honour); in Practical Chemistry, C. W. Wilson (medal and certificate of honour); in Botany, John Murray (medal and 1st certificate of honour), William Johnson (2nd certificate of honour); in Materia Medica, John Murray (medal and certificate of honour), William Johnson (2nd certificate of honour).

The Warden and Senate, desirous of adding to the facilities of medical students, and of promoting pharmaceutical education, last year instituted a lectureship on pharmacy.

The curriculum for students in pharmacy consists of attendance on lectures on botany, materia medica, chemistry and pharmacy. The lectures on the two former of these subjects are delivered in the summer, and those on the two latter in the winter session of study.

The Chair of Pharmacy, which was specially instituted for pharmacy students, is held by Barnard S. Proctor, Esq.; the other portions of the pharmacy curriculum being obtained by their attending the courses instituted for the medical students, the respective lecturers in which are, Botany—J. Thornhill, Esq., and W. C. Arnison, Esq., M.D., M.R.C.S.; Materia Medica—Thomas Humble, Esq., M.D., M.R.C.P.; and Chemistry—A. Freire-Marreco, Esq., M.A.

The order in which students in pharmacy attend the several courses of lectures is optional, but as the study of materia medica and pharmacy involves the application of knowledge acquired from the courses on botany and chemistry, it is recommended that the following order be adopted as far as circumstances admit:—botany, chemistry, materia medica and pharmacy.

The course on practical pharmacy includes—general processes and physics applied to pharmacy—pharmacopœial processes and the most important recent improvements in pharmaceutical preparations—dispensing operations—testing and the test solutions of the Pharmacopœia—and is illustrated with apparatus, experiments, and processes in operation.

FEES.

	£.	s.	d.
Perpetual ticket for pharmacy curriculum....	6	6	0
(This applies only to students at present engaged in pharmacy, and who enter before October, 1871.)			
Separate courses of lectures ....each	4	4	0

The perpetual ticket entitles the holder to attend the lectures on botany, chemistry, materia medica and pharmacy, and to use the Museum of Materia Medica in the Library of the College.

At the end of each Session, a silver medal and certificates of honour, if merited, will be awarded, after examination, to the best students in each of the following classes, viz. pharmacy, (practical) chemistry, botany, materia medica.

MEETING FOR THE ENSUING WEEK.

THURSDAY, *London Chemists' Association, at* 9.30 P.M. "The Double and Triple Salts in General Use." By Mr. M. BELL.

Parliamentary and Law Proceedings.

THAMES POLICE COURT, *October 11th.*

BEFORE MR. PAGET.

Susan Denman was charged with swallowing a quantity of laudanum with intent to commit suicide. On Monday evening the prisoner entered the station-house in Arbour Street East, and said she had purchased threepennyworth of laudanum and swallowed it. She appeared in a very bad state, and was immediately conveyed in a cab to the London Hospital, where the stomach-pump was used and the poison dislodged. She had taken enough laudanum to kill half-a-dozen persons. Mr. Paget asked where she had obtained so much laudanum. The prisoner replied at the shop of a chemist and druggist in Stepney, and she could get as much more if she required it. Mr. Paget said this must be looked to by the police. The prisoner, who said she was tired of her wretched existence, and had bought the poison with the intention of destroying her life, was remanded for a week.—*Times.*

BIRMINGHAM POLICE COURT, *October 5th.*

A wholesale chemist, Mr. Frederick Green, carrying on business in Weaman Street, Birmingham, was summoned under the Petroleum Act, for keeping petroleum stored on his premises within fifty yards of a dwelling-house, without having a licence. An inspector visited the shop and found several casks of the oil, some four-gallon canisters packed in boxes to be sent away, and about 50 or 60 gallons in a cistern; altogether about 400 gallons. For the defence it was stated that Mr. Green had applied for a licence to the Town Council, but it had not yet been granted. He thought he could sell in the meantime. A penalty of £15 was imposed, with costs.—*Liverpool Daily Courier.*

Obituary.

AUGUSTUS MATTHIESSEN, F.R.S., was born in London, 2nd January, 1831, and died 6th October, 1870, under very painful circumstances. He occupied the Chemical Chair at St. Bartholomew's Hospital, and at the time of his death was one of the most distinguished and most promising chemists in the country.

His earliest chemical work, now of about fourteen years' standing, was devoted to an investigation of the method of preparing the metals of the alkalies and alkaline earths by electrolysis; this was carried out in the laboratory of Bunsen in Heidelberg. He was the first to isolate the metals calcium and strontium, which he found to be yellow, as well as very malleable and ductile.

A most laborious and protracted investigation into the conductivity of metals and alloys was also begun in the laboratory of Kirchhoff about the same date. This was continued in his own laboratory in London during several years; the results being recorded in nine papers published in the *Transactions of the Royal Society.*

Some years ago, in conjunction with Mr. Foster, he executed a brilliant piece of work on the constitution of narcotine, from which iodide of methyl was procured by means of the action of hydriodic acid. The real structure of narcotine seems to have been disclosed by this investigation.

His recent labours on the alkaloids of opium, on morphia and codeia, are also calculated to throw light on the constitution of the natural alkaloids. They have, moreover, furnished a new therapeutical agent, viz. "apomorphia," which promises to be of some degree of importance in medicine. In his last researches he was joined by Mr. Wright.

Dr. Matthiessen was elected a Fellow of the Royal Society some years ago. Last year he received a Royal Medal for his researches on metals and alloys. He was likewise one of the editors of the *Philosophical Magazine*, and was last year appointed to an examinership in the University of London.

Conservancy of the Thames.—An important step has now been taken towards the ultimate purification of the Thames. The Twickenham Local Board have been informed by the Thames Conservators that effluent sewage water discharged into the Thames must not contain more than 3 gr. of suspended and 70 gr. of soluble matter, nor more than $2\frac{3}{4}$ gr. of organic matter (2 gr. of carbon and $\frac{3}{4}$ gr. of nitrogen). This standard is to be universally adopted in the case of all towns and villages draining into the Thames.—*Lancet.*

The following journals have been received:—The 'British Medical Journal,' Oct. 8; the 'Medical Times and Gazette,' Oct. 8; the 'Lancet,' Oct. 8; 'Nature,' Oct. 6; the 'Chemical News,' Oct. 7; 'Journal of the Society of Arts,' Oct. 6; 'Gardeners' Chronicle,' Oct. 8; the 'Grocer,' Oct. 8; the 'English Mechanic,' Oct. 8; the 'Produce Markets Review,' Oct. 8; the 'Archiv for Pharmaci og technisk Chemi med deres Grundvidenskaber,' for January to June, from Mr. S. M. Trier of Copenhagen.

Notes and Queries.

⁂ *In accordance with a wish expressed by numerous correspondents, a column will in future be devoted to notes and queries, with the object of facilitating the exchange of information among members of the trade and students.*

I should be glad to have, through the columns of the Journal, an experienced dispenser's opinion as to how he would prepare and send out the following prescription:—

℞. Acid. Gallici ʒiij
Sp. Vini Rect.
Aquæ Rosæ, aa ℥v
Misce, fiat solutio.

To be used as directed. W. M.

Will any subscriber inform me how I may mount microscopical objects, especially sections of leaves, wood, etc.?
R. J. M.

Are chemists and druggists having more than one shop for the sale of patents compelled to take out separate licences for each? T. MARSHALL.

"*Cymri*" desires to learn by what means he can dissolve ordinary isinglass without acid, so as to fit it for brewers' finings, in the manner of Coleman's Tasteless Beer Finings.

"*Botanist*" desires to be informed where he can procure the proper paper for mounting "dried specimens;" also labels with the words, Tribe, Habitat, Date, etc., printed on them with places to be filled in.

Correspondence.

Communications for this Journal, and books for review, should be addressed to the Editor, 17, *Bloomsbury Square.*

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

"Help for Students!"—Pharmaceutical Education in the Provinces.

Dear Sir,—At the recent Liverpool Conference two papers were read, and a lengthened discussion arose on the "educational question." It was my privilege to be present as a delegate, and to listen to the observations of our worthy President and other gentlemen whom we have long esteemed for their intelligence and earnest efforts to promote the elevation and best interests of our body. I quite agreed with the various speakers that no subject in connection with our association is deserving of more careful consideration than the training and education of the young men, who will in due time become our successors and the future chemists of this country. In every branch of society these questions are receiving more universal attention, and increased facilities are being offered for thorough mental culture.

We, therefore, on whom so much responsibility devolves, must not be behind the age in vigilance and activity in these matters. Already special privileges have been accorded to us by Government, but in conjunction therewith additional duties also devolve upon us, viz. to protect the public against accidents through ignorance and the incautious use of dangerous and powerful medicines. The prolonged controversy and correspondence which have taken place on the "Poisons" question may be cited as a proof that we are fully alive to the responsibilities of being entrusted with the safe storage and dispensing of deadly and hazardous drugs. It seems almost impossible by any simple arrangement of chemists' establishments to avoid the possibility of accidents, neither would it be agreeable to gentlemen of liberal education and experience to subject the details of their business to the inspection or dictation of others, probably less conversant with its requirements than themselves; at the same time we are all, I think, agreed that a systematic and complete course of education is of vital importance, and that this is the best guarantee for safety we can offer to the Government and the public at large.

The question therefore arises, "How can this be most effectually encouraged and carried out?"

From long experience I may venture to say that, as a class, the young men entering and engaged in the drug business are as thoughtful, intelligent and diligent in the pursuit of knowledge as those in any other department of business or science. Many, in their earlier days, had not the advantages which are now offered; and we owe much to the founders and various members of the Pharmaceutical Society for the example and stimulus they have given. We revere the memories of Allen, Bell and other noble pioneers of the past. Much, however, still remains to be done. The Society is well represented by the learned and able members of the Council for the present year; and we rejoice to see that so many young men are coming forward each season to compete for the prizes and to pass the examinations. It involves no little amount of energy, application and self-sacrifice for those who are in most cases closely occupied with business all day, to find the time (often wrested from the hours of sleep) to pursue the course of study necessary for success.

I believe the very struggle will itself be a good thing for those young men in years to come, teaching them the importance of industry, perseverance and economy of moments; but at the same time I would say that there is a word we might use and perhaps carry into practice with good effect for all parties, that word is "Sympathy." How often it cheers the drooping spirit and reinvigorates relaxing energies! I have generally found that the diligent student at nights is also the most active and faithful apprentice or assistant during the day, and thus becomes more valuable to his master. A word of kindly encouragement now and then,—the offer of more time for reading when the day's work and duties are over, or half an hour for study during the day,—often stimulates and creates a genial reciprocity of feeling. A youth thus taken into the business and treated as a son, generally grows up thoughtful and steady, and proves a comfort and a credit to the house with which he was connected. Pleasing remembrances of this character can never be forgotten; and while it is thus desirable that mutual sympathy should be cultivated in the family circle and business establishments, I think the same principle might with profit be applied to our Society at large. I believe all those who joined in the recent Conference, felt cheered and highly gratified by the hearty welcome and generous reception they met with at the hands of their Liverpool friends. We went as it were with tears (for the first day was very wet), but we certainly returned again "rejoicing," having also assisted the Liverpool Chemists' Association to celebrate its "majority." The same feeling of sympathy often leads members and associates in the country to look with affection and interest to the parent Society,—to you, our fathers and seniors in the metropolis. Some of us, however, have watched and assisted the Society even from its commencement. I well remember (a youth, as I then was, just entering the business) with what zest we received and read the first numbers of the new Pharmaceutical Journal, and thinking the objects it sought were very good, I joyfully sent up my first half-guinea as an associate more than twenty-eight years ago; yet my interests and sympathy have never declined, and though it has cost me now some £25 to £30, I have always been glad to contribute my share to its support. As "children," therefore, we in the provinces have been faithful to our "parent" in the capital. I am happy, too, to find that your resources are increasing, and that last year £500 was able to be set aside for the "Benevolent Fund"—a noble institution, and that you are also in so good a pecuniary position as to feel justified to devote other sums as bonuses to indicate your appreciation of long and valuable services, and I have confidence that the members at large (when appealed to) will support any right expressions of gratitude for help and sympathy thus rendered to the association.

In reflecting upon the present income of the "Pharmaceutical Society" I have occasionally asked myself how its funds, a considerable proportion of which are derived from the provinces, might be turned to the best account. Before a chemist can obtain the diploma (and I would urge each young friend to determine on taking the highest position), the sum of ten guineas will have been paid, in the three separate fees of two, three and five guineas each. In the case of many whose first resources are but limited, this is no trifling consideration, apart from the expenses of books, classes, hours of study, etc.

Now how can we best assist and show our "sympathy" for these laborious students, especially for those who reside in our smaller towns, and therefore have not all the advantages which London and other cities or larger towns afford? Your interest and desire, I may fully presume, would be to encourage and secure young men of character and ability, and help them to elevate themselves to higher social positions, and none is nobler than that of a "pharmaceutical chemist." I therefore beg respectfully to suggest that wherever a chemists' association is established in a town or neighbourhood, principals, assistants, and apprentices uniting to commence a library, museum, reading-room, etc., and to raise, say £10, £20, or £50 amongst themselves, that the parent Society (*i. e.* our London friends) should kindly offer an equal amount, or at least some stated sum in proportion to that which they may raise. It would thus stimulate local effort, and be a suitable return for the subscriptions some of us have for so many years been forwarding and still forward to you. There are about twenty-five associations already formed, and on their behalf I beg most respectfully to make this proposition,—trusting you will bring it before the President and Council for their consideration and approval. While helping to scatter abroad the seeds of knowledge, they also will ultimately realize an "abundant harvest."

Believe me, dear Sir, yours faithfully,

W. Bostock, *Local Secretary.*

Ashton-under-Lyne,
September 30th, 1870.

Prison Compounders.

Sir,—In an unfair fight the bystanders generally interfere; will you act that part between Parliament Street and us poor compounders?

The army and navy compounders have lately been recognized; how is it that the convict service has been passed over? or in a prison of 1600 men the "*dispensing*" (*sic*) is allowed to be done by some of the warders (as for some years past), who receive no extra pay for thus keeping another officer out.

In conclusion, I beg to call your attention to the terms offered to any young man anxious for "*service.*" He must submit himself to the Civil Service Commissioners for examination, and to a duly appointed person for examination in pharmacy, and to two or three medical men as to bodily health; and after, perhaps, three months waiting, he is appointed, and will receive £57 per annum, reaching to £72 in ten years, with an allowance of 2*s.* per week for lodging, and 7*s.* per week for board in lieu of living in the prison; and for the better information of the public, they mark you as an atom of the broad arrow, by clothing you in blue and brass buttons. There being no chance of promotion, as in the army and navy, where more are employed, could they not honour us with the title of Dispenser?

I am yours, etc.

Parkhurst Prison. Broad Arrow.

"Extra Charges after or before Business Hours."

Sir,—The question as to the advisability of making extra charges on anything purchased after or before business hours, is one which ought to be more generally considered, and many will be glad to see that the subject has been started in the Journal by your correspondent Mr. Jessop.

The idea has often occurred to me that an extra charge of at least 25 per cent. should be exacted on the articles procured from chemists' establishments on Sundays or after hours on the other days of the week.

I think if the subject were fairly laid before the public they would see the justice of such action, for those who really need medicine at such times would not object to an additional charge; whereas others who come at such hours not urgently requiring physic, should be made pay for the needless trouble and labour they give.

I am, Sir, yours obediently,
Kappa.

Sir,—It was with much pleasure that I saw in your last impression a letter on "extra charges after business hours." It is the custom here, and I believe our rule is not an exceptional one, to charge half-a-crown if called up after eleven at night or early in the morning; and this has effectually put a stop to what otherwise might have become an intolerable nuisance.

That a man should have to leave his warm bed to supply, at the usual prices, "antibilious pills," paregoric, soda water, or any other such article, to people who only consult their own convenience in the matter, is, I think, positively humiliating to those who passively submit to it.

This subject reminds me of another which I should like to see reformed, viz. "Sunday trading." I think most of my *confrères* will agree with me, that a great proportion of the articles sold on Sundays are either absolutely unnecessary, or might, by the exercise of a little foresight, have been obtained on the preceding Saturday night. I am of opinion that it would be well if chemists were to charge, say, 25 per cent. on every article so supplied; and such extra charge would, I hope, be devoted, in the majority of cases, to our "Benevolent Fund."

Let us all strive to make Sunday, as far as possible, what it should be, a day of rest.

I remain, yours respectfully,

Sept. 24th, 1870. T. H. P.

Hospital Dispensing.

Sir,—Allow me to correct a misapprehension existing on the part of Mr. Edward Barber, a hospital dispenser of sixteen years' standing, as to the purport of my recent note. I distinctly drew attention to the mode in which the prescription was dispensed, and made no attack upon the use of private formulæ or quality of the drugs supplied. The sneer conveyed in his remark, "a patient's *greasy* card," is not pertinent, for this was a freshly-written prescription. I also remind Mr. Barber that it is nonsense to offer a puzzle of professional ciphers in his postscript, as he had previously informed your readers "the prescriber knows very well that it is intended only for his own dispenser, and that he will understand it."

In conclusion, I repeat my conviction that the law to be equitable must eventually place the storing and retailing poisons, as well as matters relating to pharmacy and dispensing, whether conducted by the surgeon, charity or dispensing chemist, under the control of the Pharmaceutical Council, freely and indifferently elected by its own constituents.

Robert Owen Fitch.

Well Street, South Hackney,
September 9th, 1870.

Dear Sir,—The letter of a "Pharmacist" is certainly not one of the most complimentary to those whose duty it is to dispense the medicine prescribed by the physicians of public hospitals and dispensatories.

In the first place, I will thank "Pharmacist" to explain what he means by an "average type of hospital dispensing" or his "waste of public money." Let him ask himself whether if the authorities of these benevolent institutions thought it a waste of money, they would keep it on? In respect to the labelling of the medicines, "Pharmacist" must not take St. Bartholomew's as a pattern. He must understand that every hospital or dispensary standing upon its own basis has its own way of doing things.

I think I may safely say that nine out of ten dispensers would take the trouble to stick the labels on the bottles, and also to adjust the corks in a more decent and proper manner. Perhaps if the details of the case that "Pharmacist" mentions came to be thoroughly sifted, only about a fourth part of that which "Pharmacist" asserts would be found to have really taken place, and that there was no necessity for putting him to the trouble of discerning between a mixture and a gargle.

Ebenezer S.

London, September 28th.

Pharmaceutical Titles.

Dear Sir,—I passed the "Minor" the latter part of last Session, and at that time had no intention of attempting the "Major," for the simple reason, I thought the title "Pharmaceutical Chemist" scarcely worth the trouble to obtain it. Seeing some of your readers are agitating on "Pharmaceutical Titles," and feeling sure the Council will help us in the matter, I have changed my plans, now purpose becoming an "Aspirant for the Major," and hope to have the pleasure of chatting over the subject with the gentlemen who have written under that name, during the coming session at Bloomsbury Square.

I think "Omega" in his letter of the 17th instant is scarcely going the nearest way to promote reform; grumbling at what has been done is certainly not the best course to pursue, nor do I think he shows his "brotherly love" in endeavouring to ridicule the diplomas of a Society to which he pays an annual subscription.

Hoping steps may be taken to bring the subject of "Pharmaceutical Titles" prominently before the Council,

I am, dear Sir, yours faithfully,
Spes.

Sir,—Your correspondent "Omega" seems to be labouring under a mistake with regard to the motive which influenced me (at least) in taking up the subject of "Pharmaceutical Titles."

That there is any wish in my mind to "parade my intellectual status before the eyes of my *confrères*" I most emphatically deny; in fact, there is no need for such a desire. Those who are connected with our business are already fully aware of the exact worth of the existing titles, and if the public were equally well informed the necessity for an addition to the means of distinction would be obviated. That they are not so becomes to me more and more apparent, and the wish that they should be made so increasingly urgent.

But though I do not wish to parade the "Major honours" (which I hope to attain) for the sake of "parading," and though I do not look to "F.R.C.P.G.B." as the only reward for my future attainments, I do candidly admit that one of the motives which induced my longing for an amendment in the present state of affairs is "*£. s. d.*"

This may be thought a very mercenary reason for any action connected with a scientific subject, but whilst pharmacy continues a "business," "*£. s. d.*" must be a consideration, and a very important one, to those concerned in it.

As I tried to express in my former letter, it is the manifest injustice of allowing "Modified" gentlemen to reap equal advantages with "Majors" of which I complain, and that injustice I hope to see before long swept away.

As to showing "brotherly love" toward our "Modified brethren," I think a reperusal by "Omega" of my letter of August 20th will show that I wish to see all fairness done to them as to the other members of the community, though I cannot help thinking that they already enjoy their share of title, for if they wish no higher test of their knowledge than the "very modified curriculum" they surely ought to be (and doubtless, being of "retiring dispositions," are) satisfied with what they already possess in "Chemist, by examination of the Pharmaceutical Society."

But "Omega" goes on to complain that those who have passed the Modified Examination do not possess a "grand flaming diploma" to show for their success. Now, of course he cannot be speaking the minds of those gentlemen themselves, for they, being of a "retiring demeanour," would by no means wish an opportunity for "parading" their attainments, so he must of necessity be judging them incorrectly in one or the other particular when expressing himself in this manner.

I am glad to see that he joins with me in counselling "agitation" as the great means for success in this point, which "agitation," however, has been very poorly shown up to the present time by the numbers who I am sure are desirous of a reformation in these matters.

I am, Sir, yours obediently,
"An Aspirant to the Major."

Poisonous (?) Feeding Bottles.

Sir,—I wish to bring under your notice a rather singular statement in a letter which has appeared in the *Leicester Chronicle and Mercury*, and to ask the opinion of those more experienced than myself whether they consider it possible for such a poisonous action to take place. Speaking of the now prevalent use of feeding-bottles the writer (Dr. W. L. Emmerson) says,—

"Unfortunately the caoutchouc or india-rubber decomposes the warm milk very quickly, and a poisonous compound remains. Nurses are often surprised when the cork is removed and the offensive gas escapes; but they are seldom aware of the mischief which the poisonous milk is effecting, and it is often too late when the medical man is called to supply a remedy. I have often been grieved to see children suffering from this cause, and alas, in many cases, the patients were so reduced by diarrhœa and blood-poisoning that death was inevitable."

I can only think that the "poisonous compound" mentioned by the doctor is *sour milk* arising from a want of cleanliness in not well-washing out and cleaning the tubes before use. As it is a rather serious charge against the tribe of "Feeders" now so much in vogue, I lay the letter before your readers and am

Yours, etc. C. B. N.

Advertising by Postage Cards.

Sir,—I think it high time for the retail trade to adopt some effectual means for arresting the evil of wholesale houses making the public at large acquainted with trade prices. I allude to the advantage that is taken of the halfpenny postage cards for advertising (more especially) articles for the toilet. Since its adoption on Saturday last I have received three of these cards, two of the same not only with trade prices affixed, but stating extra allowances if a certain quantity is ordered at one time.

I may add that one of the preparations is, comparatively speaking, a new article in the market, and, in my opinion, the proprietor could not possibly have put a more effectual obstacle in the way of the retail trade introducing and recommending the articles to the notice of their customers than by advertising in this public manner both the retail and wholesale prices.

I remain, Sir, yours faithfully,
Newnham, October 5th. A Country Chemist.

Sale of Poisonous Materials.

Sir,—In this district a large quantity of sulphate of copper is used for *dressing* wheat. This trade is being done to some extent by grocers, who send out the article with no label, and, of course, at sometimes a penny per pound cheaper than the chemists. This is obviously unfair,—is it legal? These men would rather not sell the more virulent poisons; customers who ask for them are referred to the nearest druggist, while the provision dealer, happy in having no responsibility, pockets the profits accruing from the sale of senna, Epsom salts, castor-oil, and a variety of articles certainly not in the category of provisions. If the Pharmacy Act gives the pharmacist and the druggist a greater responsibility, it should also give him protection. Sulphate of copper looked at in the light of *sugars*, and retailed at $3\frac{1}{2}d.$ per pound, is derogatory to the dignity of the beautiful crystal, and the people who vend it are treading on our corns. Can you give me the remedy?

Yours, etc.,
October 4th, 1870. Breasting the Hill.

Pharmacy and Medical Practitioners.—We have received a letter from Mr. George Mee, stating that in consequence of only a portion of a former communication having appeared in the Journal of last week, his meaning is liable to be misinterpreted. He thinks that chemists cannot appreciably lower their charges, and that this is never done without a corresponding deterioration in the skill and materials employed. If practitioners made their attendance more valuable, they would order less medicine; and in good neighbourhoods, where practitioners have given up their dispensing, not a tithe of the medicine has been prescribed, without any loss of *prestige* on their part.

[*⁎* From want of space we are unable to print the letter entire.—Ed. Ph. J.]

An Assistant (Thirsk) complains that some chemists do not make the tinctures, etc., which they sell retail, according to the B. P., and thus are enabled to undersell others who do. He suggests that the liability to a penalty of £5 for not making up prescriptions according to the B. P. should be extended, and that before going any further with the poison question, steps should be taken to secure a uniform strength for all tinctures, spirits, etc.

J. H. Baldock.—Our correspondent's letter does not contain anything that is not thoroughly well known and appreciated, and since his arguments do not seem relevant to the subject he refers to, the publication of his letter would be on all grounds undesirable.

J. Bingley (Northampton).—We believe that the hydrated chloride of aluminum is being introduced by Messrs. Bolton and Co., Holborn Bars.

"*Young Dispenser*" (Oldham) should apply at the War Office.

"*Spero.*"—(1.) The examinations must be passed separately. (2.) Bentley's 'Manual of Botany' will be ready in a few days. (3.) At a herbalist's. (4.) Either would probably suit. (5.) Yes, if properly studied.

T. L. (Everton).—We do not know of a work so comprehensive that is published at so low a price.

An Apprentice of the Society (Bromley).—There is danger of an explosion while rubbing up chlorate of potash with any organic substance.

J. Thompson (Liverpool) should apply to the Excise Commissioners at Somerset House.

"*Cymri*" (Chester).—There is a work by Mulder on wine, but not, that we are aware, one on beer.

Andrew Barfoot (Leicester).—An article will shortly appear on the subject referred to, so far as is consistent with its treatment in a pharmaceutical journal.

G. B. (London).—The Botanical Exchange Club, of which Dr. J. Boswell Syme is the Curator. A copy of the last Report and the Regulations of the Club might be obtained by applying to the Secretary, Dr. Trimen, 71, Guilford Street, Russell Square.

Communications, Letters, etc., have been received from Mr. F. B. Benger (Manchester), Dr. Divers (London), Mr. T. B. Groves (Weymouth), Mr. A. H. Mason (Liverpool), Mr. Houlton (Witherby), Mr. F. M. Rimmington (Bradford), Mr. W. W. Stoddart (Bristol).

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes to be endorsed for "Pharm. Journ."*

THE LOSS OF SPIRIT IN MAKING THE TINCTURES OF THE BRITISH PHARMACOPŒIA.

BY C. UMNEY, F.C.S.

As a considerable portion of a pharmacist's time is necessarily occupied in the preparation of tinctures, any subject connected with their production must always be of interest to him. To those who have little opportunity of making laboratory notes, the record of the loss of alcohol (in its officinal forms of proof and rectified spirit) entailed in the manufacture of tinctures, may be of service; and even to those who possess such memoranda of their own, the perusal of the preceding schedule may be interesting.

	Quantity made.	Alcohol ·838 to make up measure.	Alcohol ·920 to make up measure.	Loss p. c. by volume.	Gain p. c. by volume.

* Sp. æther. sulph. † Sp. ammon. aromat.

It must always be remembered that the quantity of spirit required to make the measure of tinctures to a given bulk, will only be strictly uniform, in so far as the operators proceed under precisely the same circumstances.

No causes will be found to influence results more than the manufacture of tinctures upon a small as compared with a large scale, and the use of the screw as contrasted with the hydraulic press, in the final removal of the spirit from the marc; even the difference between the temperature of summer and winter may cause a variation in the results.

The loss of alcohol noted in these tinctures has not been the subject of special experiment, but merely the memoranda made in the ordinary routine of manufacture. It may be well to remark that hydraulic pressure has always been used for the recovery of the spirit, when the quantity of ingredients has been sufficiently large to admit of its application.

	Gals.	Menstruum required p. c. by volume.	Ingredients occupy when in solution, filtered, and made to prescribed volume.
Tinct. aloes	3	95	5 p. c. by vol.
„ guaiac. am.	3	92·7	7·3 „
„ tolutani	2	93	7 „

In those tinctures in which the ingredients are directed to be macerated in a portion only of the spirit, and the measure finally made up when their solution has been effected, the percentage volume such ingredients occupy when dissolved and filtered has been determined; the difference therefore in volume will be the amount of menstruum required to produce the exact measure. To the tinctures directed to be thus made in the Pharmacopœia, the compound tincture of benzoin might have been added, as a considerable augmentation in volume is produced by using the whole of the alcohol for maceration.

Laboratory, 40, *Aldersgate Street, E.C.*

TESTING OF BITTER ALMOND OIL AND OIL OF CLOVES.*

BY F. A. FLÜCKIGER.

Since the foundation of the anilin dye industry, nitro-benzol, or oil of mirbane, has become a readily obtainable substance, costing no more than one-twentieth as much as the true bitter-almond oil, which it resembles in many characters. For some purposes there is, in reality, little more reason for objecting to the use of nitro-benzol than to the use of crude bitter-almond oil containing prussic acid. Existing toxological experience has proved nitro-benzol to be a narcotic poison, though it is scarcely more dangerous, on the whole, than bitter-almond oil.† Every now and again the problem of distinguishing these two liquids comes forward in phar-

* Abstract from the author's paper.

† Compare Husemann, Supplement to the 'Handbuch der Toxicologie,' 1867, p. 118.

maceutical literature, and for that reason the author deems the publication of the following remarks to be appropriate.

There is no difficulty in distinguishing between bitter-almond oil and nitro-benzol when these substances are pure and unmixed. The specific gravity of bitter-almond oil is from 1·04 to 1·044, or at the utmost 1·075;* that of nitro-benzol is 1·20 to 1·29, so that Wagner has based on this difference a method of determining the amount of nitro-benzol in bitter-almond oil. If at the same time advantage be taken of the solubility of the aldehyde in a solution of bisulphite of soda, it is possible to effect an approximatively accurate separation of bitter-almond oil from nitro-benzol, leaving prussic acid out of account.† However, it is but seldom that a quantitative determination is needed; more frequently the mere detection of nitro-benzol is alone requisite, and this must be attempted before the application of Wagner's method, by means of some characteristic reaction. Reactions of this kind have been suggested for the purpose by Maisch and Dragendorff. The former relies upon the conversion of nitro-benzol into a brown resin by alcoholic solution of potash, and the conversion of bitter-almond oil into benzoate of potash by the same reagent. Dragendorff has shown that these substances behave differently with sodium, —nitro-benzol becoming dark-coloured, while bitter-almond oil gives white flocks. However, Wagner regards both these methods as insufficient. Flückiger quite agrees with him, and considers that the only reaction worth considering in regard to this subject is the conversion of nitro-benzol into anilin and its coloured derivatives. Some anilin is formed even in Maisch's test, as was shown by Zinin; but much more is formed by treating the nitro-benzol with hydrogen generated by zinc and hydrochloric acid, according to Hofmann's plan, or by iron and acetic acid as Béchamp recommends,—the latter being the plan adopted in manufacturing anilin from nitro-benzol.

Nitro-benzol may be readily recognized by diluting it with alcohol, leaving it in contact with zinc and hydrochloric acid, and, when the evolution of gas has ceased, supersaturating with potash and producing the colour reactions of anilin. It is evident that this method would be applicable for detecting nitro-benzol in bitter-almond oil as well as in other liquids; and, although it has come into use, the author found a want of any statement as to its delicacy, and for that reason he undertook the following experiments. He finds it is not necessary to add alcohol, nor to separate the anilin formed, unless very great accuracy be required. The test is applied as follows: granulated zinc is covered with dilute sulphuric acid (1·11 sp. gr.), adding the oil to be tested, and shaking up well; after about two hours the watery part of the liquid is to be poured on a moist filter. When heating has been prevented, the filtered liquid is colourless. The anilin salt on the filter may be, without further purification, converted in the usual manner into coloured compounds by any of the suitable oxidizing agents. The author recommends chlorate of potash, chromate of potash or perchloride of iron.

On adding to a small portion of the filtrate a few grains of chlorate, a violet colour is produced, or, with small quantities of anilin, a red colour. The chromate produces a blue colour that soon passes into red, brown, dark green; perchloride of iron gives a red coloration. The action of chromate is very delicate; but the chlorate is to be recommended as cleaner. If the latter salt does not react at once, a drop of concentrated sulphuric acid must be added, and the tube left for an hour or so.

By this very simple test 1 per cent. of nitro-benzol may be detected with certainty in bitter-almond oil. The reactions are obtained also when only 1 or 2 grms. of oil containing 1 per cent. of nitro-benzol is operated upon with 10 grms. granulated zinc, and 10 grms. dilute sulphuric acid during 1 or 2 hours. Very intense colorations are produced when the nitro-benzol in the oil amounts to 5 per cent.

However, it is not absolutely necessary to use hydrogen or acids for producing it, in order to convert nitro-benzol into anilin. If bitter-almond oil containing nitro-benzol be mixed with finely divided iron or zinc, and the pasty mixture exposed to a temperature of 100° C. in a closed vessel for some hours or days, the formation of anilin takes place. It is facilitated by the addition of a little alcohol. Afterwards, the mixture is diluted with some alcohol and filtered, the solution containing the etherial oil and the anilin is mixed with some dilute sulphuric acid, so as to obtain sulphate of anilin in solution for testing.

Pure bitter-almond oil treated in this way does not give any colour reactions. When the action of metallic iron or zinc upon the oil has been continued too long, the filtrate obtained after addition of sulphuric acid is rather brownish, but even then chlorate of potash would not produce any blue, red, or green coloration if there were no nitro-benzol present.

Lastly, the author remarks that although a well-adjusted addition of alcohol, as well as nitro-benzol, to bitter-almond oil, would not affect the specific gravity, still 5 or 10 per cent. of spirit would be indicated by the action of fuming nitric acid. Equal volumes of true bitter-almond oil and of this acid mix together without disturbance, while the presence of alcohol would give rise to a violent reaction.

Oil of cloves is so well characterized by its chief constituent, and is at the same time so cheap, that it is not likely to be much adulterated, unless it be with carbolic acid.

If the acid be combined with bases, most of the etherial oils that might have been added as adulterants would be recognizable by the smell they give to the remainder of the oil of cloves. Fat oils would show their presence by reduction of the specific gravity, and, excepting castor oil, by the reduced solubility in alcohol, which dissolves pure oil of cloves in all proportions. In order to detect carbolic acid, the author suggests the following test:—shake from 2 to 10 grms. of the oil to be tested with 50 to 100 times as much hot water, and, after cooling, pour off the clear liquid. Add to a portion of this liquid a drop of ammonia, and then a pinch of chloride of lime. If the oil of cloves contains carbolic acid, the liquid then acquires, on shaking, a greenish colour that passes into blue, and lasts for some days. Pure oil of cloves does not give this reaction. If it be desired to apply this test very delicately, the liquid may be gently evaporated to a small bulk at a moderate heat.—*Schweitz. Wochenschrift für Pharmacie.*

SYNTHESIS OF OIL OF RUE.*

BY E. VON GORUP-BESANEZ AND FERD. GRIMM.

The volatile oil of garden rue, which had been regarded by Gerhardt and Cahours as the aldehyde of capric acid $C_{10}H_{20}O$, was examined by Williams and Hallwachs, who assigned to it the formula $C_{11}H_{22}O$. Hallwachs, moreover, suspected that it might turn out to be a ketone, and not an aldehyde. This view was maintained by Harbordt, who, working in Strecker's laboratory, showed that it did not undergo oxidation easily, and that it did not yield the acid $C_{10}H_{20}O_2$ on oxidation. According to Harbordt, oil of rue consists of methyl-nonyl ketone $CO\left\{\begin{matrix}CH_3\\C_9H_{19}\end{matrix}\right.$.

The authors have confirmed this formula by preparing it synthetically. They subjected to destructive distillation, at as gentle a heat as possible, a mixture of acetate of lime and caprate of lime in equivalent proportions, and obtained an oil which, on examination, turned out to be identical with the natural oil of rue, and to have the composition $C_{11}H_{22}O$. The equation explaining its production is as follows:—

$$\underset{\text{Caprylate.}}{\left.\begin{matrix}C_9H_{19}CO\\Ca\end{matrix}\right\}O} + \underset{\text{Acetate.}}{\left.\begin{matrix}CH_3CO\\Ca\end{matrix}\right\}O}$$

$$= \left.\begin{matrix}CO\\Ca_2\end{matrix}\right\}O_2 + \underset{\text{Methyl-nonyl ketone.}}{CO\left\}\begin{matrix}CH_3\\C_9H_{19}\end{matrix}\right.}$$

It boils at 223° to 224° C., and has a sp. gr. of 0·8295 at 17·5° C., and forms a crystalline compound with bisulphates. The capric acid employed in the research had been extracted from a specimen of Hungarian fousel oil.—*Abstract from the Neues Repert. für Pharm. von Buchner*, 1870.

ACRIDINE—A NEW ORGANIC BASE.

Græbe and Caro have discovered an interesting volatile alkaloid of the formula $C_{12}H_9N$, on which, from its violent irritating and acrid qualities, they have bestowed the mame *Acridine*. It accompanies anthracene, the hydrocarbon from which artificial alizarine is made, and was discovered during the purification of anthracene. It is one of the most stable organic compounds, being capable of withstanding a temperature of 360° C., which is its boiling-point. It is a colourless crystalline substance, and fuses at 107° C. In ether and in alcohol it is easily soluble. In cold water it is almost insoluble; hot water, however, dissolves it to some extent. It is a strong base, capable of uniting with acids to form salts.—*Journal für Praktische Chemie*, No. 14, 1870.

GLUCOSE.

BY PROF. CHARLES A. JOY.

In the year 1811, Kirchhoff, a celebrated German chemist, discovered that it was possible to convert starch, by means of sulphuric acid, into sugar. Great expectations were founded upon the announcement of the discovery, as, in consequence of Continental wars and the English blockade, sugar had become a very dear article, and it was at first thought that an ample supply could be obtained in this way; but everybody was destined to be grievously disappointed as soon as the subject was more thoroughly investigated, and it was found that the sugar thus produced was of a different character from that to be obtained from the cane and beet. Still, the discovery of Kirchhoff was of great importance, and has led to many practical applications. It was soon found that glucose or grape sugar could be made in several ways, and that it was always the product of the germination of starch grains, and sometimes occurred already formed in nature.

It is probable that both cane and grape sugar are formed from the starch contained in the cellular tissues of the plant, cane sugar being formed first, and then grape sugar, if acids be present. Acidulous fruits contain only grape sugar, whereas cane sugar occurs in those that are free from stronger acids. The chief natural sources of the grape sugar are in the sap of the grape vine, in plums, cherries, figs, honey, in the liver and in diabetic urine; but it would not be economical to prepare it from any of these sources.

One of the latest methods for the preparation of grape sugar is the one proposed by Maubré, and is as follows:—The mixture of dilute sulphuric acid and starch meal is boiled under pressure of six atmospheres. The necessary boilers are similar to those used for high-pressure engines, and are lined with lead and provided in the interior with a perforated lead tube for the passage of steam. The boiler is further furnished with safety-valve, stop-cocks, thermometers, etc. In the process of manufacture 56 lb. of sulphuric acid of 66° B. are diluted with 5600 lb. water, and heated to 212° F. A mixture of the same amount of acid and water is made in a separate wooden vessel, the heat of which is raised to 86° F. Into the second mixture 2240 lb. of starch meal are well stirred and heated to 100° F. This is gradually added to the first mixture, and after heating with open valves for a few minutes to 212° F., the stop-cocks are all closed and the heat raised to 320° F. and continued until all of the starch is converted into sugar, which requires from two to four hours.

The contents of the boiler are then run into a wooden tank, and 168 lb. of pure chalk or carbonate of lime, previously stirred up with 500 lb. of water, is gradually added to neutralize the acid; the gypsum is caught on a filter and the filtrate evaporated to 20° B., and afterwards clarified by blood and bone-black and again filtered. In this way the product is obtained pure, and free from bitter and empyreumatic taste, and is well suited for any of the purposes to which grape sugar is adapted.

Another way is to convert the starch into sugar by means of malt. For this purpose 10 to 12 lb. of barley-malt are well stirred with 400 lb. of water, and to this is added 100 lb. of starch, and the whole is heated to 158° F., and kept at that temperature for several hours, under constant agitation. At 158° F. the starch becomes pasty, the grains burst, and at first there are no signs of sugar, but in a quarter of an hour the liquid becomes more fluid and begins to have a sweetish taste. Great care must be observed to retain the heat at the same temperature, not to have it either higher or lower than above indicated, and to ensure this several thermometers ought to be put in different parts of the apparatus. After six hours the liquor can be filtered and clarified, and evaporated to a syrup. The sugar prepared in this way always retains the taste of malt and is only adapted to use in breweries, where this property will not prove deleterious.

Grape sugar, or glucose, can be prepared in open vessels by allowing a mixture of starch and water to flow gradually at a temperature of 130° F. into a vat containing water acidulated with 1 per cent. of sulphuric acid. By keeping it at a boiling-point the starch is at once altered, without producing mucilage. The amount of starch taken is usually about one-half the weight of water employed. After all of the starch is added, boil for half an hour and decant. The sulphuric acid is neutralized by carbonate of lime as before, and the liquid evaporated to the specific gravity of 1·28, and set aside to crystallize. The molasses is allowed to drain off, and the sugar is dried at a gentle heat in a current of dry air.

In the United States, especially in the west, it is more

* Read at the Royal Bavarian Academy on June 11.

economical to make grape sugar from corn. There are several large establishments where this business is now extensively prosecuted. The corn is steeped in weak soda lye to separate the husk and soften the gluten. It is then ground wet and run through revolving sieves, by which the husks and gluten are separated. The starch flows through long ways and troughs, in which are slats against which the solid particles lodge, and thus separate from the water. The wash water is run into a large cistern, where it can be fermented into weak vinegar. The starch is put wet into a mash-tub and treated with 1 per cent. sulphuric acid in sufficient water for three to eight hours. Where it is intended to make sugar the whole of the starch is converted, but if syrup is sought then some part of the dextrine is left unaltered. The acid liquor is neutralized with chalk as before, and evaporated in vacuum pans, and after the separation of the gypsum is run into barrels and allowed to crystallize. For syrup a certain percentage of dextrine is left in the liquid unconverted, which helps to keep it from crystallizing, and in the manufacture of syrup special care must be observed to neutralize all of the acids. The sugar is sometimes cast into blocks six inches square and dried on plaster plates, in a current of dry air, as hot air would be apt to discolour it. It has been found that glucose can be made from cellulose as well as from starch, but the process is too expensive for practice; it is, however, interesting from a scientific point of view, and ought to be mentioned in this connection.

Two parts of clean linen shreds are gradually added to three parts of sulphuric acid, and they are allowed to stand twenty-four hours; the whole is then largely diluted, and the sulphuric acid neutralized by carbonate of lime or carbonate of baryta. In a similar manner any other kind of cellular tissue, as cotton, wood-shavings, paper, etc. can be converted into grape sugar.

It is a singular fact that, although we can prepare grape sugar from cane by the action of acids, no way is at present known by which glucose can be reconverted into sucrose. It would be a discovery of great importance if we could make cane sugar from glucose, as in that event common sugar could be prepared from a great variety of refuse matters, and would be largely reduced in price.

There was a time when much grape sugar was manufactured in England clandestinely, for the purpose of adulterating Muscovado sugar, but this illegitimate business was destroyed as soon as the tariff on sugar was reduced. The price of cane sugar must be very high before manufacturers can afford to make grape sugar for its adulteration.

The starch of potatoes can be converted into glucose by digesting for a few hours with parings of the potato. This operation is largely practised by German farmers in the preparation of food for fattening hogs. The starch is rendered more digestible in this way, and from the glucose some of the larger proprietors manufacture alcohol, for which they obtain a high price.

An excellent article of starch sugar can be prepared from Indian corn, which will yield alcohol one-eighth cheaper and quite as pure as that from cane sugar. As by a recent decision of our Courts the manufacturers of alcohol and vinegar from this source are not distillers within the meaning of the tax levy, the business is not hampered by licences, inspections, or stamp duties, and has thus a great advantage over ordinary distilleries.

In some parts of Europe large quantities of grape sugar are used to add to wine, but in this country it is not so much the wine growers as the brewers who make such an extensive use of it as to give rise to its regular importation. This can hardly be justified excepting in times when the price of barley is very high.

We find in the *Zymotechnic News* of St. Louis an interesting article on the uses of starch sugar in the manufacture of beer, from which we quote the following paragraphs:—

"Barley contains on an average 57 per cent. of starch and cognate substances. These pass into the wort, partly as sugar, partly in the shape of dextrine (gum). The relative proportions of these ingredients vary in accordance with the method of brewing, but experience teaches that, on an average, one bushel of barley yields about 12 lb. of sugar and 15 lb. of dextrine. A portion of the latter substance is further transformed into sugar during fermentation, so that a bushel of barley represents, on an average, 16 lb. of sugar and 11 lb. of dextrine (gum).

"Both dextrine (gum) and sugar are equally essential to the brewing process. The latter furnishes the alcohol, without which no beverage can be called spirituous; while the former constitutes almost the entire extractive matter, or body of the beer, which is one of the chief distinguishing features between beer and wine. Now it is true that all (commercial) starch sugar contains a certain amount of dextrine,—the more, the poorer the quality; but this portion would be insufficient in case a good article was used, while in the contrary case it would be paid for at an extravagant rate.

"Imported potato sugar of good quality, containing some 15 per cent. of dextrine (gum), costs about 12 cents per pound at New York. Maize sugar of equal purity can be furnished at 8 cents per pound. 20 lb. of either article, costing respectively \$2·40 and \$1·60, would yield 16 lb. of fermentable sugar and 3 lb. of dextrine (gum), while a bushel of barley will not only yield 16 lb. of sugar, but 11 lb. of dextrine or gum besides. Thus, starch sugar can be added to beer wort only in small quantities, unless when it is desired to impart a vinous character to the beer. When the latter object is not in view, the best substitute for barley will always be found in maize or some other cheap grain.

"Not so in the manufacture of wine. For this purpose, good starch sugar, containing not exceeding 15 per cent. of dextrine, is decidedly preferable to cane sugar. A pound of the latter, of the quality suitable for wine manufacture, costs at least 15 cents; whereas, as just stated, good starch sugar from maize can be sold at 8 cents. Now, as 5 lb. of starch sugar are equivalent to 4 lb. of cane sugar as regards their yield of alcohol, the balance is altogether in favour of maize sugar, to wit:—

4 lb. cane sugar at 15 cents . . . 60 cents.
5 lb. grape sugar at 8 cents . . . 40 cents.

"The 15 per cent. of dextrine (gum) contained in the maize sugar will (according to the usual proportion of sugar added to must) increase the amount of 'extract' in wine only by a few per cent., and will tend to give it the 'mouthly' taste (body) which in meagre wines, already fermented, is sought to be produced by the addition of glycerine.

"Enormous quantities of cane sugar are already being consumed in the wine manufacture in this country; so that even as a consideration of national economy it is highly important to supply in maize sugar a partial substitute for imported cane sugar."

In France there is a use for grape sugar arising from the fact that the sugar manufacturers do not prepare molasses ready for the market as they do in this country. The crude molasses is bought up by second parties and the grape sugar is used very largely by them to extend it and give it body. An alkaline solution of grape sugar is converted by heat into a dark brown body, called melassic acid. This acid has a powerful affinity for oxygen, and reduces the CuO to Cu_2O. Some of the tests for grape sugar are founded upon this reaction. One of them, known as Fehling's test, is prepared as follows:—A standard copper solution is made from 1 oz. crystallized sulphate of copper, 3 oz. cream of tartar, $1\frac{1}{2}$ oz. pure carbonate of potash, 14 or 16 oz. of a solution of caustic soda (sp. gr. 1·12), and water until the solution measures 15,160 water grains; 200 measured grains of this solution contain a quantity of copper that would be reduced by 1 grain of sugar, each atom of sugar reducing 10 atoms of the black oxide of copper to the state of suboxide. Cane sugar is converted into grape by boiling with weak sulphuric acid, and it can then be easily tested by the standard solution. It sometimes becomes necessary to test for sugar in diabetic urine; this is accomplished in various ways. One of them, called Trommers' test, is as follows:—Add caustic potash, and filter if necessary, then dilute solution of sulphate of copper in small quantities; the precipitate that first forms dissolves on stirring, and the solution becomes azure blue, but after standing, a fawn-coloured precipitate of suboxide of copper will be formed. The conditions and precautions to be observed are fully given in medical works and need not be repeated here. The property of grape sugar to reduce metallic salts is made use of for the preparation of silver mirrors. Add to the nitrate of silver a few drops of ammonia and then some grape sugar, and the metal will be precipitated.

Chloride of silver can also be reduced by grape sugar, and this method affords a way for reclaiming photographic wastes, and of preparing pure metallic silver. Take 14 parts of well-washed and still moist chloride of silver, 24 parts of caustic soda, sp. gr. 1·333, $11\frac{1}{4}$ parts ammonia, sp. gr. 0·925; to this add, with constant agitation in a flask, $7\frac{1}{2}$ parts pure honey, or $9\frac{1}{2}$ parts grape sugar syrup, and let the mixture stand in a warm place until sulphuretted hydrogen affords no sign of silver. Decant and wash out all traces of chlorine. The reduced silver can then be dried and melted in a crucible.

Platinum black, finely divided metallic platinum, can be obtained from the chloride by adding carbonate of soda in excess, and heating the solution for ten minutes. The precipitate can be collected in a filter, and then well washed and dried.

Grape sugar crystallizes in warty, cauliflower concretions, composed of hard transparent cubes. It is less soluble in water than cane sugar, but more soluble in alcohol. Two and a half parts of glucose are required to produce the same sweetening effect as one part of cane sugar. Sulphuric acid does not decompose it, but forms a definite acid with it, salled sulpho-saccharic acid. It forms a double salt with common salt.

$$NaCl,2(C_{12}H_{12},O_{12})+2aq.$$

It also forms definite but unstable combinations with the alkaline bases.

From the foregoing it will be apparent that grape sugar can be easily and cheaply prepared, and that it is capable of many important uses in the arts if it could be manufactured in adequate quantity and at a reasonable rate.—*Journ. of Applied Chemistry, New York, June*, 1870.

CINCHONA CULTIVATION IN INDIA.

A return has just been published of the East Indian Cinchona cultivation, including all the returns issued from April 1866 to 1870, and as was the case with the two preceding documents, it contains much useful and interesting matter. Beside the Annual Reports of the superintendents of the cinchona plantations, there are Reports of the Madras and Bombay Commissions, formed for the purpose of testing on a large scale the efficacy of the sulphates of cinchonidine, quinidine and cinchonine. The trials were conducted by a great number of civil and military practitioners, in stations notably malarious, and in cases which were types of all the forms of fever to be met with in the malarious districts of Southern India. In the first report of the Madras Commission, it is stated that up to March, 1867, 1145 cases of paroxysmal fever had been treated with these alkaloids. Of this number 410 were treated with cinchonine, 359 with cinchonidine and 376 with quinidine. Doses of 8 or 10 grains daily were found to produce the best results, larger doses producing cinchonism. Out of this number only 4 deaths occurred, and in these cases the fever was complicated with pneumonia and diarrhœa; the patients being half-starved, emaciated, and completely prostrated by the malarious influences which surrounded them. Of the remaining 1141 only 27 failed, *i. e.* about 2 per cent. In these the fevers were not recent, but the systems of the patients were chronically poisoned by malaria,—quinine failing equally in many cases. Judging from these facts, the Commissioners are of opinion that these alkaloids are scarcely inferior, if at all, to quinine. The general opinion that cinchonine is a greater irritant than quinine, was not found to hold good; the difference between the three alkaloids and quinine being looked upon by the Commission as of degree and not of kind.

From this period to April, 1868, 2472 cases were tried with the four alkaloids under precisely similar conditions, in order to make the comparative trial as perfect as possible. Of this number, 2445 were cured and 27 failed. With chemically pure sulphate of quinine, 846 cases were tried, of which 840 were cured and 6 failed; the time taken to effect a cure being from 1 to 7 days, while the doses varied from 2 to 20 grains. Sulphate of quinidine was administered in 664 cases, 660 cases were cured and 4 failed, the time taken in effecting the cure being from 1 to 8 days, with doses of from 2 to 30 grains daily. Sulphate of cinchonidine was tried in 403 cases, of which 399 were cured and 14 failed; the time occupied being from 1 to 4 days, with doses of 3 to 20 grains. Sulphate of chinchonine was used in 559 cases, 546 were cured and 13 failed; the time occupied being from 1 to 8 days, with doses of from 2 to 30 grains. The general dose was from 1 to 8 grains. This shows about 1 per cent. of failure; but the cases of failure were of patients completely saturated with fever. From this it will be seen that, with the exception of cinchonine, the other alkaloids in their therapeutical and physiological action resemble quinine in a remarkable degree. Indeed, Mr. Broughton says that for a period of thirty years much of the commercial sulphate of quinine, from the method employed in its manufacture, would inevitably contain the sulphates of quinidine and cinchonidine, and would occasionally even consist entirely of the latter salts. All the cases treated have been carefully tabulated on a uniform method, and it would appear from the results given that chemically pure and ordinary commercial sulphate of quinine and sulphate of quinidine are equal in value; sulphate of cinchonidine only slightly less efficacious, and sulphate of cinchonine, though considerably inferior to the others, is a valuable remedial agent in fever. Like quinine, they have a tonic effect, help digestion and increase the appetite.

The Bombay Cinchona Commission report that they consider all these alkaloids as febrifuges, anti-periodics and tonics, and their general effects to be similar to quinine, though perhaps in an inferior degree. They produce the same effects as quinine to the extent of $\frac{1}{2}$ or $\frac{2}{3}$; the value of the four alkaloids and the doses necessary to produce an equal result being as follows:—Quinine 3 to 20 grains; quinidine 5 to 20 grains; cinchonidine 7 to 20 grains; cinchonine 7 to 20 grains. There are many other interesting features in this valuable report, to which we shall allude in a future article.

MILK OF ROSES.

In making milk of roses, the chief object should be to produce a perfect emulsion, or one at least which, if it separates after long repose, may be restored to a homogeneous state by slight agitation. Although other perfumes may be, and are commonly added to it, the scent of roses should predominate and form its characteristic odour.

ENGLISH MILK OF ROSES.

1. Almonds (blanched) .... $1\frac{1}{2}$ ounce.
   Oil of almonds } ...... { of each.
   White Windsor Soap } ...... { 1 drachm.
   Rose water .... $\frac{3}{4}$ pint.

Make an emulsion; to the strained emulsion add a mixture of—

Essence or spirit of roses .... $\frac{1}{2}$ fl. drachm.
Alcohol.......................... $2\frac{1}{2}$ fl. ounces.

and, subsequently, of —

Rose-water .... q. s.

To make the whole measure one pint, more alcohol is often ordered and used; but much of it is apt to cause the separation of the ingredients. In many samples, and in the inferior ones generally, it is omitted altogether. Some makers add a few drops of oil of bergamot, with two or three drops each of oil of lavender and otto of roses, dissolved in the alcohol.

2. Oil of almonds } .... { of each.
White Windsor soap } .... { 1 ounce.
Salts of tartar .... ½ drachm.
Boiling water .... ¼ pint.

Triturate and subsequently agitate until perfectly united. When cold, further add,

Alcohol .... 2 fl. ounces.
Spirit of roses .... a few drops.
Rose-water .... q. s.

to make the whole measure a pint.

The above are used as cosmetic washes in a similar way to "Gowland's Lotion," also to remove scurf, freckles, and acne or other pimples, and cruptions in slight cases.

FRENCH MILK OF ROSES.

1. Tincture of benzoin.... (simple) ½ fl. ounce.
" " styrax .... ¼ fl. ounce.
Spirit of rose.......... 1 to 2 fl. drachms.
Alcohol .... 2½ fl. ounces.

Mix, and add gradually, with agitation,
Rose-water .... 16½ fl. ounces.

Augustin recommends the addition of a little carbonate of potash (say 1 dr. to the pint) when it is intended to be used as a lotion in acne.

2. Tincture of benzoin.. (simple) 1 fl. drachm.
" " balsam of Peru .. 20 drops.
Rose-water .... ½ pint.

The addition of an ounce of alcohol, in lieu of a like quantity of rose-water, improves it.

3. Almond paste .... 3 drachms.
Rose-water .... ½ pint.
Tincture of benzoin .... ½ fl. ounce.

and make an emulsion as before. Use, etc., same as the preceding.

GERMAN MILK OF ROSES.

Dilute solution of diacetate of lead...................... ½ fl. ounce.
Lavender-water.............. 2 fl. drachms.
Alcohol .... 2½ fl. ounces.
Rose-water.................. ¾ pint.

Mix, with agitation. The alcohol is often improperly omitted, or less is used. It is cooling and astringent, and is employed as a wash, like the preceding; also in most eruptions, excoriations, etc., but it is more active and less fitted for very frequent use.—*New York Druggists' Circular.*

TESTIMONIAL TO EMPLOYERS.

On Wednesday, the 19th inst., one of those pleasing events so indicative of good feeling between the employers and employed took place at 16, Coleman Street, City. Messrs. Thomas and Frederick Burbidge, of the firm of Burgoyne, Burbidge and Co., were each presented with a handsome silver goblet and salver and an illuminated memorial. In addition to the crests the goblets bore the following inscriptions:—"Presented to Thomas [or Frederick] Burbidge, Esq., by the *employés* of Messrs. Burgoyne, Burbidge and Co., as a mark of their esteem and good wishes, 19th October, 1870." The goblets and salvers were executed by the well-known silversmiths, Messrs. Johnson, Walker and Tolhunt, of Aldersgate Street. The whole of the arrangements were carried out by a committee appointed by the *employés*, consisting of Messrs. Bartliffe, Chamberlain, Close, Frith, Webb, Weeks, Udger and Yanley. One of the rooms in the large warehouse was cleared, and the proceedings, which were of the most enthusiastic description, commenced at two o'clock. Mr. Yanley was called to the chair, and delivered the following address:—

"Messrs. Thomas and Frederick Burbidge,

"Gentlemen,—As the Chairman, and therefore the representative of my fellow-workers in your establishment, it is my great privilege and pleasure to occupy the position I hold to-day. Gentlemen, the object of our asking you to meet us is to testify to you that the many kindnesses we have received under various circumstances at your hands, and the good wishes each and all of us bear to you for your future prosperity, call for something more enduring than mere words or acts of duty. It is to the credit of Mr. Charlos Chamberlain that the idea was started of presenting a testimonial to you.

"Gentlemen, that idea has culminated in the present proceedings. Out of the number of your *employés* you will find that eighty-eight have contributed their portion to these testimonials, and—with one or two exceptions, from illness or business arrangements—they are now present. For many reasons it was not considered expedient by the committee appointed to take the management of these proceedings, to solicit from the juniors or from those recently engaged in your establishment any contributions whatever, and we trust this arrangement will be approved of by you.

"Gentlemen, we are deeply grateful for the interest you take in us, individually and collectively. Our benevolent and excursion funds receive at your hands a large amount of support; and in any amusements we have hitherto adopted, we have always found you to take the deepest interest, not only assisting us by your purse, but by your presence and counsel.

"It is now my pleasing duty to ask you to accept these small tributes of our regard,—presenting you, Mr. Thomas Burbidge, with a silver goblet and salver and an illuminated memorial, and you, Mr. Frederick Burbidge, with a silver goblet and salver and an illuminated memorial.

"We thank you for your courtesy in meeting us to-day, and assuring you of our united efforts to place your business in a still higher position than that it has already attained, we wish you long life and health to enjoy the fruits of your enterprise."

EAST INDIAN CINCHONA BARK.

One of the most interesting features at a recent drug auction in London (13th inst.) was the sale of cinchona bark, grown in the Royal Botanic Gardens, Darjeeling, East India.

On one occasion previously this bark has found its way into commerce but in small quantity. This parcel consisted of nineteen cases, each about eighty pounds in weight, and was described as red bark (*Cinchona succirubra*).

At a glance it was apparent that the greatest care had been bestowed upon its collection and preparation, and that it had been obtained from young trees whose ages did not vary considerably. It consisted entirely of quills, exceedingly uniform in their length (about fifteen inches), varying in thickness from the size of cinnamon bark to that of one's thumb; externally somewhat smooth, without lichens, of a greyish colour, with a pale reddish interior, resembling, to an unpractised eye, grey bark.

An average sample selected from five cases gave upon analysis in 100 parts—

Total alkaloids (hydrated)	3·36
Quiná (by ether)	2·40
Cinchonidine and Cinchonine......	·95
Crystallized Sulphate of Quinine ..	1·81

The Pharmaceutical Journal.

SATURDAY, OCTOBER 22, 1870.

PHARMACY IN IRELAND.

It is generally supposed that there will be an attempt to assimilate the law of Pharmacy in Ireland to the recent enactments in England and Scotland. It is probable that Sir Dominic Corrigan, M.D., the new member for Dublin, will take an active part in this contemplated Bill. Although the object will be to create a body of qualified pharmacists, as in the English Bill, still, in this case it will in some degree be a process of levelling down, not of levelling up.

The draft will probably be the Bill of the Apothecaries' Hall, modified to meet some objections, and separated from the "Poisons Bill," which, as our readers are no doubt aware, has already become law.*

The draft of the Pharmacy Bill in its original form was, as we stated at the time, fair, and would, with some few alterations in committee, have met the requirements of the time.

We shall look forward with some interest to the future prospects of pharmacy in the Sister Isle. From the fact that every compounder in Ireland has become a licensed medical practitioner, pharmacy, as an art, may be said to be almost extinct in that country.

THE POSTAL REGULATIONS.

We have received several complaints that the Journal is now sent out uncut and unstitched. This has been done in order to comply with the regulations laid down by the Post-Office authorities in reference to the transmission of periodical publications for one halfpenny postage. The fact that some readers of the Journal object to the new arrangement will be submitted to the consideration of the Council at its next meeting.

THE SALE OF LAUDANUM.

It would appear from the police cases reported this week as well as last week that some of our magistrates are not acquainted with the Sale of Poisons Act. Under its provisions it is competent for registered druggists to sell any quantity of laudanum under certain conditions. Moreover, we believe druggists are generally careful in the exercise of their discretion as to the sale of poisons. Therefore the remarks of the magistrates in both these cases, implying censure of the druggists who sold the laudanum, were uncalled for so far as the facts are made known.

* "Poison Bill for Ireland," *vide* Pharmaceutical Journal, Vol. XI. p. 746.

It will be seen from the report, at p. 334, that a correction has to be made in the statement that the message received from the American Pharmaceutical Association was an answer to the message sent by the Conference meeting at Liverpool.* Both messages were sent spontaneously and almost at the same moment.

We understand that Mr. Wanklyn is a candidate for the chair of Chemistry connected with the medical school of Bartholomew's Hospital. Considering this gentleman's reputation at home and abroad, as well as the importance of this chair, and the fact that so few of our chemists, who hold high position, are active cultivators of their science, we venture to think that Mr. Wanklyn's appointment would be a step well calculated to make good the great loss this school has suffered in the death of Dr. Matthiessen, and for that reason we wish him all success.

An interesting letter from Mr. Ernest Hart has appeared in the *British Medical Journal*, containing an account of his recent visit to the seat of war in company with Mr. Berkeley Hill. These gentlemen took with them private stores furnished by Mr. Hills (Bell and Co.), Messrs. Savory and Moore, Mr. Blaise (Savigny and Co.), Mr. Edwin Arnold and Mr. Von Glehn. Mr. Hart was authorized to expend a certain amount of money on account of the French Committee, and Colonel Lindsay, on behalf of the British Society, placed at his disposal a store of assorted surgical instruments, together with a letter authorizing the Society's agents, in case of necessity, to furnish what stores they could spare from their depots. They arrived immediately after the battle of Sedan, and Mr. Hart speaks highly of the arrangements made for the reception of the wounded by the Belgian authorities.

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

October 14*th*, 1870.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Edwards, Gale, Garle, Haselden and Ince.

MODIFIED EXAMINATION.

Forty-five Candidates presented themselves for Examination; the following thirty passed, and were duly registered as

CHEMISTS AND DRUGGISTS.

Allsop, George William ...... Birmingham.
Booth, Edwin .... Southport.
Clark, John .... Sheffield.
Evans, Gomer .... London.
Farrer, Robert S. .... Brighton.
Fewster, William Longwood. . Liverpool.
Forster, William Day .... Godalming.

* See No. 15, p. 297.

	Fudgé, Charles William	Shepton Mallet.
	Gregory, John	Stockton-on-Tees.
	Ham, William	London.
	Harland, Richard Thomas	Geneva.
	Hughes, William, junior	Presteigne.
	Jones, Ellis	Bala.
	Keast, Samuel John	Camborne.
	Lidgett, Walter Fletcher	Leicester.
	Light, John Henry	Bristol.
	Manfull, Horatio John	Nottingham.
	Mason, Frederick	Rotherham.
	Oakey, Joseph	Liverpool.
	Passingham, George William	London.
	Philpots, George Payne	Leyton Green.
	Rowley, Seth Breaks	London.
	Shirtliff, Francis	Blackheath.
	Sproat, Robert	Hull.
	Stevens, Edmund Matthew	London.
	Tabor, Samuel	Reading.
	Thomas, Horace Alfred	Norwich.
	Walton, Henry	Manchester.
	Wightman, James Temple	Whitehaven.
	Wilson, Joseph Gilpin	Dublin.

FIRST, OR PRELIMINARY EXAMINATION.

Two hundred and twenty-four Candidates were examined; the following one hundred and sixty-four passed, and were registered as

APPRENTICES OR STUDENTS.

	Macaulay, Joseph John	Manchester.
	Martin, William Thomas	Lewes.
	Maitland, Leslie	Aberdeen.
Equal.	Bell, Charles John	Wellingborough.
	Pendrigh, John Cuthbertson	Sanquhar.
	Savory, Harry Banting	Painswick.
Equal.	Davies, Arthur	Swansea.
	Jupp, John	East Grinstead.
	Evans, John Watkin	London.
Equal.	Ford, Francis	Pendleton.
	Jackson, Henry Lawson	Crediton.
Equal.	Clayton, George	Aberdeen.
	Giles, William	Aberdeen.
	Blake, Charles Alexander	London.
	Cassie, Ralph Jas. Forbes Leith	Aberdeen.
Equal.	Barron, Alexander	Aberdeen.
	Spencer, James	Manchester.
	Cooper, Frederick Richard	Manchester.
Equal.	Cleaver, Edward Laurance	London.
	Fryer, Charles Hart	Norwich.
Equal.	Gostling, William Ayton	Diss.
	Samson, Ernest	Bristol.
	Miller, Nathaniel	Preston.
	Willcock, George	Bedford, near Manchester.
Equal.	Hall, Henry Stacey	Doncaster.
	Morrison, William Hay	Aberdeen.
Equal.	Hosie, John	Aberdeen.
	Hall, Henry Thomas	Stafford.
Equal.	Allan, Alexander Stuart	Aberdeen.
	Glover, William	Newcastle, Staffs.
	Heppell, James	Forest Hill.
	Russell, Matthew Rawlings	Whitehaven.
Equal.	Bradley, William	Dudley.
	Ellis, Henry	Rochdale.
	Highmoor, George Samuel	Leeds.
	Ragg, William Watkins	Edmonton Green.
Equal.	Foggon, George	Newcastle-on-Tyne.
	Norman, William Haswell	Wellingborough,
Equal.	Gilkes, Frederick George	Banbury.
	Handford, Joseph John	Gt. Torrington.
	Sturton, Richard	Cambridge.
Equal.	Bradshaw, John	Runcorn.
	Paulden, Henry	Liverpool.
	Sumner, Robert Mason	Liverpool.
Equal.	Butler, George Henry	Christchurch.
	Cruickshank, Joseph	Aberdeen.
	Cruickshank, William	Aberdeen.
Equal.	Fairman, George Peters	London.
	Norweb, Arthur	Nottingham.
	Stoddart, Joseph	Alresford.
	Marsh, William	Manchester.
Equal.	Braddock, James	Manchester.
	Wren, Henry	Bermondsey.
Equal.	Kirkby, Robert	Ulverstone.
	Simpson, James	Foveran.
Equal.	Bartle, William Frederick	Tyldesley.
	Davies, David C.	New Quay.
	Inglis, William	Ashton-under-Lyne.
	Oakes, Henry	Pickering.
	Emerson, Isaac Brown	West Hartlepool.
Equal.	Atkinson, Miles	Manchester.
	Southerst, Marshall	Haslingden.
Equal.	Beck, Alfred Wallis	Norwich.
	Gordelier, William Gibbs	Sittingbourne.
	Willan, Robert	Ulverstone.
	Newhill, John William	Huddersfield.
Equal.	Stevens, Richard	Leeds.
	Taylor, Herbert Edwin	Hadleigh.
	Cullen, Harry	Tewkesbury.
	Cheyne, Andrew	Liverpool.
Equal.	Harrison, James	Horncastle.
	Mills, John P.	Taunton.
	Wilson, Richard Edward	Newport, Mon.
Equal.	Carr, George	Sheffield.
	Chambers, Pearson	Cockermouth.
	Forth, William Pilcher	Ashford.
	Fowler, Thomas	Torrington.
	Holmes, William James	Bacup.
	Hope, William Hodgskin	Wellingborough.
	Fraser, Andrew	Aberdeen.
Equal.	Pattinson, Dan	Whitehaven.
	Warrack, Arthur Forbes	Aberdeen.
Equal.	Bull, Edward Samuel	Liverpool.
	Harsant, Frank Worsley	Epsom.
	Herbert, Samuel	Bristol.
Equal.	Brown, Frederick	Lincoln.
	Carruthers, Robert Buck	Withington.
	Cruickshank, George	Aberdeen.
	Gordon, John	Aberdeen.
Equal.	Bates, William Richard	Liverpool.
	Price, Benjamin Meredith	Hereford.
	Fegan, John	London.
Equal.	Abbott, Thomas Eastoe	Darlington.
	Bradley, John	Leeds.
	Broomhead, George Emmet	Aberdeen.
	Dingle, William Alfred	Ashton-under-Lyne.
	Edey, George	Rochester.
	Minett, Thomas Samuel	East Grinstead.
	Thompson, Fred	Sheffield.
	Walker, George	Doncaster.
	Watson, Joseph Henry	Halifax.
	Woolley, Harold	Manchester.
	Walton, Major Foulds	Sowerby Bridge.
Equal.	Crofts, Henry Baptist	Cranbrook.
	Cowe, Samuel M'Cutchan	Whitehaven.
Equal.	Hogg, Edward Grindle	Ealing.
	Marsh, William Henry	Norwich.
Equal.	Coumbe, John Butten	Plymouth.
	Lewis, Joseph	Milborne Port.
	Newton, John Titus	Sedgley.
	Case, Perkins William	Trowbridge.
	Twist, Edward Herbert	Prescot.
	Sharp, William George Graham	Birmingham.
Equal.	Eckersley, Moses	Wigan.
	Evans, David	Newcastle Emlyn.
Equal.	Dunlop, Thomas Hall	Newcastle-on-Tyne.
	Weeding, William Samuel	Hastings.
Equal.	Bannard, Henry	London.
	Davey, Thomas Seccombe	Exeter.
	Gooding, Henry	Woburn.
	Hope, John Hart	Wellingborough.
	Kirton, Richard Gervase	Boston.
	Storey, John Charles	Hull.
	Wilmer, Frederick Joseph	Newport Pagnel.

Equal. { Forsbrook, William Henry .. Birmingham.
Grove, Harry Nicholas ...... Walsall.
Roberts, David Prosser ...... Hereford.
Hambridge, Thomas .... Tottenham.
Equal. { Bake, Alfred Benjamin ...... Guildford.
Christie, James .... Aberdeen.
Avison, David .... Wakefield.
Equal. { Bristow, Charles Robert ...... Ryde, Isle of Wight.
Lund, Richard John .... Leeds.
Severs, Samuel Thomas ...... Leeds.
Wheeler, William Henry .... Bristol.
Woolldridge, George .... Birmingham.
Haworth, Edwin .... Oswaldtwistle.
Gould, Henry Thomas ...... Newport, I. W.
Broadbent, Sidney .... Saddleworth.
Equal. { Boulton, Henry Hamer ...... London.
Bunn, Charles Grinling ...... Colchester.
Hetherington, Martin Luther . Highbury.
Heward, George .... Havant.
Hodgson, Alfred .... York.
Jameson, William Edward .... Bristol.
Mills, Robert .... London.
Urwin, James Alexander .... Harton.
Pott, Frederick Fore .... London.
Equal. { Clarke, Thomas Edward ...... Shrewsbury.
Hargreaves, Joseph .... Liverpool.
Equal. { Holgate, Sam .... York.
Harry, Seth .... Gravesend.
Equal. { Kirkwood, Daniel .... Beith.
Bumpstead, Robert George.... Colchester.
Fox, William .... Grantham.
Harrison, William Hopper.... Barnstaple.
Husband, John Cecil .... Berwick-on-Tweed.
Jeffery, Henry Thomas ...... Tring.
Macdonald, George Edward .. Ashton-under-Lyne.
Smith, Arthur John.......... London.
Stephan, William Henry .... Chipping Norton.
Stubbs, Edwin .... Hull.
Thompson, Lawrence Joseph.. Thirsk.
Walbran, Francis Maxwell.... Leeds.

The Certificates of Examination of the following by other bodies were accepted in lieu of the Society's Preliminary Examination:—

Birch, Charles .... Chesterfield.
Cogman, Charles .... London.
Lansdale, John Anstey ...... High Wycombe.
Overton, Charles Arthur...... Horncastle.
Utting, Charles Edward ...... Diss.
Walton, Thomas .... Bishopwearmouth.
Webb, Herbert Charles ...... London.

The Questions for Examination were as follows.

Time allowed: Three Hours.

LATIN.

Translate into English two or more of the following sentences:—

1. Ita dies circiter quindecim iter fecerunt, uti, inter novissimum hostium agmen et nostrum primum, non amplius quinis aut senis millibus passuum interesset.

2. Quos quum apud se in castris Ariovistus conspexisset, exercitu suo præsente, conclamavit: Quid ad se venirent? an speculandi causâ? Conantes dicere prohibuit, et in catenas conjecit.

3. Liquorem ammoniæ spiritu misce: tum ex retortâ vitreâ, lento igne, destillet octarius; denique in hoc liqua camphoram.

4. Optimè terantur simul, dein in pulveres octo æquales dividentur, quorum capiat æger unum omni horæ quadrante, donec adsit catharsis.

5. Decline *cyathus vinarius*.

6. State the superlatives of *bonus*, *multus* and *nequam*.

7. Give the accusative endings of the five declensions.

8. Give the third persons singular and plural, indicative mood, present tense of *capio*, *sumo*, *adhibeo* and *cogito*.

9. How does the relative agree with the antecedent? Give an example in Latin.

ARITHMETIC.

10. A cow and a calf were worth £16. 7*s.* $10\frac{1}{2}$*d.*: the calf alone was worth £2. 6*s.* $7\frac{3}{4}$*d.*, what was the value of the cow?

11. A wall 28 feet in height was built in 15 days by 68 men; how many men working at the same rate could build a wall 32 feet high in 8 days?

12. Reduce $\frac{378}{1233}$ to its lowest terms.

13. Multiply $3\frac{5}{8}$ by $4\frac{5}{6}$.

14. Divide 267·15975 by 1·25.

ENGLISH.

15. Name the relative pronouns; why are they so called?

16. Give the masculine nouns corresponding to duchess, heifer, witch and roe, and the feminine to beau, lord, master and executor.

17. How are the comparative and superlative degrees formed? Give examples, and state what change takes place in dissyllables in *y*.

18. What is meant by a *neuter* verb? and write down a sentence containing one.

19. Parse the following:—The Imperial troops took possession of the bridge.

20. Write from 15 to 25 lines upon *one* only of the following subjects:—

a. War and the consequences thereof.
b. Steam, its advantages and disadvantages.
c. The holiday trip.

EXAMINATION IN EDINBURGH.

October 11th, 1870.

Present—Messrs. Aitken, Baildon, Brown, Buchanan, Kemp, and Young.

Twenty-two Candidates were examined—two Major, six Minor, nine Modified, and five Preliminary; the following passed:—

MAJOR (registered as Pharmaceutical Chemists).

Paton, James................ Edinburgh.
Robinson, James .... Darlington.

MINOR (registered as Chemists and Druggists).

*Oscroft, James .... Salford.
Brewis, Thomas .... Rothbury.
Elder, William Nind .... Pulteney Town.
Strachan, Alexander .... Aberdeen.

MODIFIED (registered as Chemists and Druggists).

Cant, David .... Forfar.
Clarke, Joseph Adam .... Glasgow.
Clarkson, Thomas .... Hartlepool.
Coates, Joseph .... Newcastle.
Purdie, James .... Glasgow.
Sibthorp, Stephen James Kenneth .... Glasgow.
Tocher, George.............. Portobello.

PRELIMINARY (registered as Apprentices or Students).

Attwood, Henry Ernest ...... Edinburgh.
Forewell, Henry...... ...... Edinburgh.
Linklater, James .... Edinburgh.
M'Glashan, Alexander ...... Perth.

ERRATUM.—Page 309, col. 2, lines 13 and 14,
for Martin, John .... Seacombe.
Miller, William Henry .... Ridgeway.
read
Martin, John .... Ridgeway.
Miller, William Henry .... Seacombe.

* Passed with honours.

hitherto supplied students with lectures in Latin, Chemistry and Botany, but the business hours of a large portion of the trade are such as to prevent many from taking advantage of them.

) In connection with Haley Hill College.

) The course includes Chemistry (Inorganic, Organic and Practical), Materia Medica and Pharmacy, and the fee is 21s.

(j) The classes are free to all members of the Association.

(k) The fee of £6. 6s. entitles to admission to all the classes. See additional note.

(l) The classes are in connection with the Plymouth and Devonport Science School.

PHARMACEUTICAL EDUCATION IN THE PROVINCES.

The following is an epitome of the additional information furnished by the various societies:—

Aberdeen.—The Latin class is spoken of favourably by the teacher. In the Chemistry (Organic and Inorganic) class two students have received second-class government certificates, and a large number intend applying for the Preliminary Examination in October next. The Library is a very select and valuable one, numbering 300 volumes, and is well used. It is open once a week from 8 to 9 P.M., and for reference during the meeting of the classes. Books may be obtained at other times by giving an hour's notice. There is but a mere commencement of a museum. This Society was established in 1839, before the Pharmaceutical Society; and Mr. John Mackay, in his evidence before the House of Commons, referred to the benefits which had followed its institution. The members formerly paid an entrance fee of £2. 2*s.* and an annual subscription of 10*s.* 6*d.*, but this year the entrance fee has been abolished. The assistants are allowed the use of the class-room; they meet fortnightly in the winter months, and monthly during the remainder of the year, when papers are read and subjects discussed in connection with the business. The greatest wants are a museum and a Practical Chemistry class.

Ashton-under-Lyne and Dukinfield.—There are no classes immediately connected with this Association. Some students attend the Manchester classes, others are preparing for the Preliminary Examination by private tuition. No library or museum. Several lectures on chemistry and kindred subjects were delivered during last session, which were well attended.

Bath.—A small library, from which books may be obtained at any time; it is not much used. No museum.

Birmingham.—(1.) The Midland Counties Chemists' Association was established last year mainly for the protection of trade interests. Arrangements have been made with Dr. Alfred Hill for the delivery of a course of twelve lectures, commencing the 5th of October, on Pharmaceutical Chemistry, in his laboratory at the Queen's College. (2.) The Chemists Assistants' Association report that those attending the lectures on Materia Medica in connection with it have found them of great assistance in preparing for their examinations. There is no library at present, but the formation of one is contemplated. A small museum. There are also classes and lectures in connection with the Midland Institute, comprising Chemistry, Botany and Latin, which are well attended by chemists' assistants in Birmingham.

Bradford.—The payment of 5*s.* annually by Apprentices and Associates as members of the Society entitles them to free admission to the classes. Two Associates have passed the Modified and one the Major Examination. No library or museum.

Bristol.—The classes are the science classes in connection with the Educational Department of the Government. The Council have arranged with the two professors, that by the payment of a lump sum they should be entitled to send to their lectures any number of pharmaceutical students. Of the 26 who entered for Inorganic Chemistry, 12 underwent the Government examination, of whom 11 passed and 1 failed. In Organic Chemistry, out of 9, 8 were examined, 7 passed and 1 failed. In Botany, 8 were examined, 2 passed. The details of these examinations will be found reported, PHARM. JOURN. No. 9, p. 173. No library or museum.

Colchester.—No educational organization. The library, numbering about 300 volumes, is open daily, and contains the books required in preparing for the Society's examinations. The number of books issued last year was 164. No museum.

Edinburgh.—The North British Branch of the Pharmaceutical Society at Edinburgh has a library in which there are upwards of 250 volumes. These are available to all members, associates and apprentices of the Society. There is also a museum, containing more than 400 specimens, which is open to all students in pharmacy on application to the Secretary. The books are not much used, although there are constantly several volumes in circulation. The museum is in request generally by those who are preparing for their examination. Some years ago an effort was made to open special classes in the evening for young men. At first this was successful, but the attendance became gradually so thin that they were given up. Since then no separate classes have been opened, but the University and other lectures have been attended by Pharmaceutical students. Last session admission was given to regular courses on materia medica, chemistry and botany, at the reduced fee of £2. 2*s.*, to all who were engaged in the study of pharmacy. It is hoped that similar arrangements may be made for next session. It should be borne in mind that in a place like Edinburgh, young men have a choice of teachers, and as no special lecturers are named by the Society, they may and do attend any class they please. In regard to education for the Preliminary examination, there are opportunities given for instruction in Latin. One gentleman advertises a class, at a suitable hour, for persons preparing for the Preliminary examination; and also for those who, wishing to pass the Minor, may require to study a short time to enable them to pass the classical: fee 31*s.* 6*d.* per quarter.

N.B.—By the kind permission of Professor Archer, students in pharmacy have the privilege of inspecting the valuable collection of materia medica and other specimens in the Edinburgh Museum of Science and Art.

Exeter.—No educational organization in connection with the Society, but there are classes for Chemistry and Botany at the School of Science. About 120 books belonging to the Society have hitherto been kept in the counting-house of one of the members; efforts are being made to provide a more convenient place for reference and study. No museum.

Glasgow.—Anderson's University and the Mechanics' Institute have hitherto supplied students with education in Latin, Chemistry and Botany, but the business hours of a large portion of the trade are such as to prevent many from taking advantage of them. There are no classes for Materia Medica or Pharmacy, except at the Universities, where the hours and fees are both unsuitable. No library or museum.

Gosport.—Only a trade society for the regulation of prices.

Halifax.—The classes in Chemistry and Latin are in connection with Haley Hill College. The class in Botany is founded by the Association, and any deficiency is supplied from its funds. Two great obstacles exist, preventing that thorough application of the young men to their studies which is now so much needed. One obstacle is the apathy of a great proportion of them, and the other is the late business hours of the trade. Great efforts are at present being made to remove both these barriers. Special prizes will be offered for competition at the end of the present session, which it is hoped will rouse the spirit of the students, and a movement is on foot "which has fair prospects of success" for an earlier uniform closing hour. No library or museum.

Hull.—The fees received from the classes do not pay much more than half the expenses, the deficiency being made up by subscriptions. The past session is looked on as a success by the Committee, but it is doubtful whether the institution can be kept up without further aid. The lectures on Botany are given in the Hull Botanical Gardens, where there is a splendid collection of plants and an able curator. The average attendance at the Chemistry class is 14; at the Botany class, 15. The progress of the students is spoken of by the teachers as satisfactory. No library, but a few books are promised. No museum.

Leeds.—Chemistry classes are conducted at two Institutions in the town (the Mechanics' Institute and the Young Men's Christian Association), and Associates of the Society are allowed to attend either course on the same terms as the members of the respective societies. In a letter to the Secretary, Mr. George Ward says, "Several of the students distinguished themselves by their success at the examinations in connection with the Science and Art Department, and on the whole their attention to the subjects of study was highly satisfactory. The interest manifested in the organic branch of the science was not equal by any means to that shown in the inorganic and practical." The students in Mr. Jefferson's class were also very successful at the examinations. There is a library of about 180 books, which can be obtained between 9 A.M. and 10 P.M. It is also open as a reading-room from 8 to 10 P.M. The number of books issued in 1869 was 170. The museum consists of a materia medica cabinet, containing 226 specimens, neatly arranged and labelled, in bottles and glass tubes, and various other articles. This collection was made by the Associates.

Leicester.—Of 25 assistants and apprentices who are members of this Association, 9 have passed eleven examinations during the last half-year, viz. 3 Minor, 2 Modified and 6 Preliminary. A prize of 5*s.* has been given in each class at the close of the last two sessions. Some assistance is rendered to the Association by the subscriptions of employers as honorary members. The library numbers twelve volumes, and is open once a week; subscription 1*d.* per week. There have been 35 issues of books during the last six months. The museum consists of one of Evans, Lescher, and Evans' 50*s.* cabinets of materia medica.

Liverpool.—In 1868–69 two members passed the Minor Examination, and in 1869–70 two more passed. There is a library of 565 volumes, open every day from 9 to 5, and on meeting nights from 7 to 10; there have been 290 issues of books in 1868–69. The museum contains a complete illustration of the materia medica of the British Pharmacopœia, and a good general collection of chemical and materia medica specimens.

Manchester.—In 1868–69 the lectures, in consequence of the passing of the Pharmacy Act and the small fees demanded, were largely attended, but were not self-supporting, the deficiency being made up by the Association. The classes are now arranged in connection with Owens College, that institution taking the fees and supplying the instruction. A chair of Pharmacy has been established at the suggestion of the Association. Great efforts are now being made to form a good library and museum. About £70 has been collected, and a suitable room engaged at a rent of £25 per annum. The library at present consists of about 70 valuable works of reference; the museum of about 130 furnished drawers, similar to those at Bloomsbury Square, and 50 dried and mounted medicinal plants. They are open three evenings a week from 6 to 10.

Newcastle-on-Tyne.—The classes for pharmaceutical education are in connection with the Pharmacy section of the Durham University College of Medicine, whose head-quarters are in Newcastle. To meet the requirements of "students in pharmacy" a lectureship in Practical Pharmacy has been instituted by the Senate of the University, a curriculum for such students has been recognised, and the lecture hours have been arranged as far as practicable to suit their convenience. A winter-evening course of lectures on Chemical Physics, by A. Freire-Marreco, M.A., Reader in Chemistry in Durham University, is not included in the tabulated return. There is a museum of materia medica, containing about 360 specimens, of which 200 are organic, the remainder chemical. Most of the specimens are good, both in quality and size, and are enclosed in the usual museum jars, arranged in glass cases at one end of the library. The specimens of organic materia medica were presented to the College some years ago by Mr. H. B. Brady, and require some additions to make the collection completely represent the organic materia medica of the present Pharmacopœia. The Library consists of several hundred volumes, but being the library of a medical college, to which pharmacy has only recently been added, it is as yet destitute of works suited to pharmacy students.

Nottingham.—The classes, confined to apprentices, most of them very young, have been successful, and the examinations very satisfactory. Arrangements are in progress for fitting up class and reading-rooms, library and museum. It is intended to institute during the winter months classes for the Preliminary Examination, Inorganic Chemistry and Pharmacy. Classes for Botany and Materia Medica are to commence in February, and continue during the spring and summer months. The library contains 74 volumes, and is open four times a week. Museum very small.

Plymouth.—The Chemistry and Botany classes are in connection with the Science School. No library. The Museum consists of a case presented by Mr. H. S. Evans.

Scarborough.—An attempt will be made to form a class during the winter. No library or museum.

Sheffield.—A collection of specimens of materia medica, chemical and pharmaceutical preparations, forming the nucleus of a museum. Also a small library, of 65 volumes, which it is intended to increase largely. The reading-room is open once a week from 8 to 10 P.M., but not much used. The Association also possesses a valuable microscope, which is lent to members on certain conditions. The educational course is not duly appreciated. The young men are evidently not fully awake to the requirements of the Pharmacy Act. The advantages of the classes have not been sought by those living in neighbouring towns. Access to the library and museum for purposes of reference may be had by members.

Sunderland.—The Society has two rooms, one for reading and the other for classes, open every evening. The nucleus of a library has been formed, consisting of 40 volumes, which it is expected will be increased by donations from the members. A cabinet of materia medica, and a few specimens of chemicals, form the museum. Arrangements are being made to form classes for the Preliminary examination during the ensuing winter.

Taunton.—Only a trade association, with no organization for educational purposes.

Provincial Transactions.

SUNDERLAND CHEMISTS' ASSOCIATION.

The First General Meeting of the Session 1870–71 was held in the Society's Rooms, Fawcett Street, on Monday evening, October 10th; HARRISON THOMPSON, Esq., Vice-President, in the chair.

Mr. J. J. NICHOLSON read a paper on the "Advance of Practical Chemistry during the past Year," describing some of the novelties shown at the exhibition of pharmacy at Liverpool; and explaining, by the aid of diagrams and specimens, the process for the manufacture of alizarine from coal tar; Mond's process for the recovery of the waste sulphur in alkali works; and Weldon's and Deacon's methods for the continuous production of chlorine.

At the close of the Address, on the motion of Mr. ROBINSON, seconded by Mr. J. HARRISON, a hearty vote of thanks was accorded to Mr. Nicholson.

Mr. J. HARRISON gave notice that at the next meeting he would bring forward a motion that steps should be taken to extend the exemption from juries to registered chemists and druggists.

It was announced that the next lecture in connection with the Society would be given by Mr. Sharp on November 7th.

After the transaction of other business, and the usual compliment to the Chairman, the meeting separated.

The work of this Society is now fairly inaugurated.

A library has been established; a reading-room, to which many of the leading medical and pharmaceutical periodicals are supplied, is open nightly, a course of lectures has been arranged, and classes have been formed for the instruction of the apprentices in the various branches of knowledge required for their examinations.

Proceedings of Scientific Societies.

AMERICAN PHARMACEUTICAL ASSOCIATION.

Meeting at Baltimore.

The Eighteenth Annual Meeting of the American Pharmaceutical Association was commenced on Tuesday, September 13, in the Lecture Room of the University of Maryland, Baltimore, under the presidency of Mr. E. H. Sargent, of Chicago.

The President, after a few words of welcome to those present, referred to the concurrence in the time of meeting of two kindred associations in different and widely separated nations. He thought that as the British Pharmaceutical Conference was in session in Liverpool at that moment it would be appropriate to render something more than a formal recognition of the fact, and that some expression of interest in an Association having the same aims and speaking the same language was called for.

A list of forty-eight applications for membership from all parts of the country was read, and the applicants having complied with the requirements of the bye-laws were unanimously elected.

On the motion of Mr. A. B. Taylor, of Philadelphia, it was resolved unanimously that "the Secretary be requested to telegraph a fraternal message to the British Pharmaceutical Conference, now in session in Liverpool."

After reports had been received from various committees, the President read his Annual Address, which was well received. A committee was appointed to consider and report upon its recommendations and suggestions.

On Wednesday morning, after the minutes of the previous meeting had been read, the Secretary said that on the previous evening he had sent a telegram to Liverpool, in accordance with the resolution adopted:—

"Pharmaceutical Conference, Liverpool.

"Fraternal greetings of American Pharmaceutical Association. Maisch, Secretary."

About two hours later he received the following telegram, signed by the President of the British Pharmaceutical Conference:—

"American Pharmaceutical Association, Baltimore.

"The most successful meeting ever held sends hearty fraternal greeting."

Their English brethren had thus preceded them in time, and the messages passed each other *in transitu*.

The officers for the ensuing year were then nominated and elected, the office of President being conferred on Mr. Richard H. Stabler, of Virginia.

The Secretary then read the Annual Report, which referred specially to the regulation of pharmacy in the United States. It mentioned that the State of Rhode Island had adopted a law, compelling all persons desiring to engage in the business to pass a satisfactory examination before a committee of five pharmacists, appointed by the Governor. In New Jersey efforts were made to have a drug law passed by the Legislature, but they were not successful. It is expected this will be accomplished in the next meeting of the Legislature. The Maryland Legislature has passed a law, compelling all persons who intend to practise pharmacy in the city of Baltimore to pass a similar examination.

A list of queries was then submitted, thirty-seven in number; these had been prepared for acceptance, and the names of the persons who had agreed to prepare the replies for the next annual meeting were reported. Among the subjects referred to were—

I. The preparations of rennet, pepsine, and pancreatic juice, which have been recommended to assist assimilation of fat in the human stomach. In the course of the day Mr. S. M. M'Collin read a paper relating some of his experience in the preparation of pepsine. He prepared fluid preparation, in which glycerine was the chief preservative agent.

II. The system of apprenticeship and the amount of preliminary education to be required of apprentices. Interesting meetings were held by the delegates on the evenings of Wednesday and Thursday for the discussion of this subject, at which a series of resolutions were passed, which will be given in our next number.

III. Granulated effervescing compounds sold by druggists under popular names that do not correspond with their composition.

IV. The comparative value of carbolic acid and other disinfectants and antiseptics.

The reading of answers to queries of last year was then proceeded with, and occupied nearly the remainder of Wednesday and Thursday.

Mr. Joseph P. Remington, of Philadelphia, read a paper "On Glycerine," giving the results of some careful experiments on samples of the leading kinds in the market. The experiments showed conclusively that the lower grades of glycerine were unfit for medical use, while the best quality of several of the leading manufacturers were inodorous, colourless, free from impurities, giving with the usual reagents negative results in almost every case. The specific gravity varied from 1·245 to 1·253.

Dr. E. R. Squibb inquired if he had met with formic acid as an impurity, but Mr. Remington replied that he had not noticed it. Dr. Squibb stated that it had been asserted that that acid was the cause of the unpleasant symptoms in some cases where it had been used. To detect the unpleasant odour of glycerine, it was best to dilute it to about ten times its bulk with water, and apply heat, when the odorous principles are more readily distinguished than if it be heated alone.

The Secretary read a paper upon a case of poisoning by fluid extract of aconite, by Dr. S. P. Duffield, of Detroit, in which it appeared that there was culpable negligence of an *employé* of a large manufacturer, who had labelled a pound bottle, "Fluid Extract Actæa Racem.," instead of "Fluid Extract Aconit. Rad." The question would naturally suggest itself, how many more bottles were thus labelled, and had any others died from this criminal neglect? In the course of some remarks by Dr. Squibb and others, it was elicited that the odour and chemical reactions of *Veratrum viride* are almost identical with aconite; and that cimicifuga and aconite root have been found repeatedly mixed in the same package. It was also stated that owing to negligence on the part of the physician, who had written badly, or of the pharmacist, who had imperfectly translated the wretched hieroglyphics, fluid extract of belladonna had been substituted for taraxacum, and fluid extract of veratrum for valeriana.

Mr. William Procter, jun., contributed a paper on the assaying of opium to determine its contents of morphia. After narrating various processes conducted on several portions of the same solution of opium, Mr. Procter said that he preferred a slight modification of the present United States Pharmacopœia process, more familiarly known as Staple's process, which he thought would best meet the wants of pharmacists who desire to test this drug. The chief points to observe are to exhaust the drug thoroughly, evaporate with care to a small bulk, and, after adding alcohol to the remaining solution, to add the ammoniated alcohol, allowing it to stand 24 to 36 hours, preventing the loss of ammonia by evaporation.

Dr. Squibb said that in the case of opium, he always advised pharmacists to buy it already in powder and test it for themselves, With all other drugs he advised, on the contrary, that they should buy them whole and powder them themselves. He attributed the cause of the considerable superiority found in the morphia strength of some of the grades of opium to superior cultivation, care in preparation, and freedom from diluting substances.

Mr. B. F. Stacy, of Charlestown, Mass., read a very interesting paper on the "Honey Trade in the United States." From the statistics furnished, it appeared that the various States yield honey in the following order:—New York, North Carolina, Kentucky, Missouri, Tennessee, Ohio, Virginia, Pennsylvania, Illinois, Indiana; the yield of the other States was not given. In 1868, the total production sent to market was over 30,000,000 pounds, besides 212,000 gallons imported from the West Indies.

Mr. A. B. Taylor called attention to the resolution adopted at the National Pharmacopœia Convention, which directed the abolition of all measures of capacity, and showed some of the difficulties which would be met with in its practical application. Statements were also made by Dr. Squibb and others upon the subject.

Resolutions were passed tendering the thanks of the Association to Messrs. Gail and Ax, to Messrs. Maltby and Co., and Messrs. Thomas Kensett and Co., for the courtesy shown by them to the Association upon its visit to their respective establishments; also to the faculty of the University of Maryland for the free use of their hall for the purpose of the meeting.

Another resolution was passed thanking the pharmaceutists of Baltimore and their friends, especially the Reception Committee and the Local Secretary, for their endeavours to render the visit pleasant and social.

Before the meeting separated, however, it was decided to appoint a committee to take into consideration a suggestion to invite the International Congress of Pharmacists to meet in the United States in 1876, the committee to report upon the subject in 1871.

Messrs. Maisch (Philadelphia), Sargent (Chicago), M'Murdy (Albany), Menninger (Ralegh) and Ash (Jackson) were appointed a committee to report upon the legislative action upon pharmacy and the drug trade in the different States of the Union.

Dr. E. Hoffman (New York), Professor John Maisch (Philadelphia) and Mr. E. H. Sargent (Chicago) were appointed a committee to draw up an address of felicitation, embodying the kind sentiments of the Association on the occasion of the fiftieth anniversary jubilee of the North German Apothecary Association, and to forward the same to its permanent President Mr. William Dankworth, at Magdeburg, in the name of the American Pharmaceutical Association.

It having been resolved to reassemble at St. Louis, Mobile, on the second Tuesday in September, 1871, the Convention adjourned.

In connection with the meeting there was a very interesting and instructive exhibition of drugs, chemicals, druggists' sundries, materia medica and pharmaceutical preparations.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting at Liverpool.

Wednesday, September 14th.

(*Continued from page* 316.)

Discussion on Facilities for Pharmaceutical Education in the Provinces.

The following communication received from the Secretary of the Pharmaceutical Society was read:—

"At a Meeting of the Council of the Pharmaceutical Society, held on the 7th September, 1870, it was resolved,

"That a copy of the following resolution of the Provincial Education Committee be forwarded to the General Secretaries of the British Pharmaceutical Conference:—

"*Copy of Resolution.*

"This Committee recommend that the Council invite the British Pharmaceutical Conference to bring forward the question of Provincial Education for discussion at its Meeting in Liverpool, in September, which would give an opportunity for the interchange of opinion amongst those best acquainted with the question."

The President expressed his great regret that his friend Mr. Schacht was unavoidably prevented from being present. It was very much to Mr. Schacht's earnest interest in the question of Provincial Education that its present prominent position was due. They were, however, fortunate in having amongst them the President of the Pharmaceutical Society, Mr. G. W. Sandford, and he would invite that gentleman to favour the meeting with any remarks which he might be disposed to make. He was glad to refer the meeting to the proof-sheets of a return on Provincial Education from 1868 to 1870, obtained by the Pharmaceutical Society, a supply of which had been forwarded for the use of those present.

The President of the Pharmaceutical Society, Mr. Sandford, said that in responding to the invitation made by his friend Mr. Stoddart, he felt that his own position there, during the present discussion, ought rather to be that of a listener than a speaker. The meeting would understand that some reticence was a duty in connection with his official position, since he could not lay down any special line of policy as having been agreed upon by the Society which he had the honour to represent. At the same time, he made no secret of his personal wish to promote Pharmaceutical Education in the provinces. It was impossible to ignore the fact that under the present transitional system, there were many masters who would not—he should hardly be wrong in saying could not—teach their apprentices the essentials of their duties in connection with pharmacy. Where, then, should this want be supplied? It was not to be expected that all young men could afford the means necessary to come up to Bloomsbury Square, and avail themselves of its curriculum, but if proper means were provided in the provinces, there would be no difficulty in young men fitting themselves to pass the Minor Examination very soon after completing their apprenticeship. When the Pharmaceutical Society was first established, one of its earliest proceedings was to open a school of pharmacy, accessible to young men at a very slight cost. It was by carrying on that sort of expenditure for a few years that the Society could help Pharmaceutical Education. "Providence helps those who help themselves," and the Society should only help those who were inclined to help themselves. Some persons suggested rewards for passing good examinations; others wanted something to go on with at the beginning. The Society wanted to encourage the schools which would send up lads for examination, and should in a moderate way give grants where there were lectures established and a sufficient number of pupils to warrant the grant. Some candidates came up from employers who had taught them so well that they were able to pass their examination without going into the Society's laboratory at all.

Mr. W. D. Savage (Brighton) said he had had thirty-eight years' experience of apprentices, and his opinion was that if they were afforded opportunities for study there would soon be a better class of assistants.

Mr. H. S. Alpass (Liverpool) said the difficulty was to find apprentices with a sufficient preliminary education to begin with. They had not a proper knowledge of Latin, and their general knowledge was defective.

Mr. Sandford remarked that the difficulty would be obviated if masters would agree only to take apprentices who had passed the preliminary examination of the Pharmaceutical Society.

Mr. F. B. Benger (Manchester) urged that there should be assistance afforded in scientific education during apprenticeship; and that there should be a special technical school which would give instruction in sound elementary knowledge of chemistry, botany and materia medica.

Mr. Abraham (Liverpool), in reply to a question, said that for the last twenty years the Liverpool Chemists' Association had provided classes and lectures free to the apprentices, but the number of pupils had been and still remained extremely small. But he quite expected that the stringent changes already effected in the state of the law permitting the practice of pharmacy would compel a very much larger number to seek scientific instruction. The means provided in Liverpool had been ample,—good instruction in the classes and free lectures of the best character, yet they had been poorly attended; the apprentices and assistants to whom the opportunities had been offered either did not know their necessity, or they were unable or unwilling to take advantage of them. The lecturer on chemistry was Mr. Edward Davies, the secretary of the local committee of that Conference. He (Mr. Abraham) was anxious that the rudiments of chemistry should be taught in secondary schools for boys, so that they might have the groundwork of the science before commencing their special technical training. That such a system was practicable had been convincingly shown in a large and excellent school in Liverpool, where about eighty boys had at once passed the Government examination in chemistry.

Mr. H. Matthews, F.C.S. (London), said that as a former pupil of the City of London School, he could not refrain from naming its early and earnest labours in promoting science-teaching. A sufficient number of years had now elapsed to judge of the fruit of such a system, and they found accordingly that amongst the old pupils of the City of London School the following well-known chemists could be ranked, viz., Messrs. Perkin, Bloxam, Spiller, Heaton, Divers, etc., whilst other departments of science included amongst their active workers the former students of the same school. It was unquestionable that the future tastes and pursuits of the man depended upon the bent given to them during boyhood.

Mr. E. Bremridge, Secretary and Registrar of the Pharmaceutical Society, said that most of the failures of students to pass the Minor Examination arose from deficient elementary education. He thought that masters should require every youth to pass the Preliminary Examination before he commenced his apprenticeship.

Mr. Mackay (Edinburgh) cited his own apprenticeship to show the extreme difficulty that formerly existed for study. When he was an apprentice he used to steal from his meal times one hour for the study of pharmacy and another for materia medica. The system of apprenticeship in Scotland differed from that of England. The apprentice did not reside in the house, and his parents paid no premium; but, on the other hand, the employer paid a small salary, which might be progressive or not. About twenty years since, the chemists of Edinburgh mutually agreed that they would make it a condition of every apprentice's indenture that his friends should pay the fees for his attendance upon classes in chemistry and materia medica, the master covenanting at the same time to allow sufficient time. He and some other chemists in Edinburgh still adhered to this system. In Scotland now chemistry was being taught in most schools. It is also extended to ladies' schools. Physiology and chemistry were taught in the High School of Edinburgh, and a regular lecturer was appointed. There was, therefore, no excuse for lads going into the establishment of a chemist and druggist without passing the Preliminary Examination. The Pharmacy Act gave the pharmacists much power, and they ought not to take an apprentice without he could produce evidence that he had passed the Preliminary Examination of the Pharmaceutical Society—an examination not over-severe or over-strict.

Mr. H. C. Baildon (Edinburgh) confirmed the statements of the previous speaker, and concurred in his opinions.

Mr. A. T. Horton (Liverpool) referred to the limited attendance on the classes of the Liverpool Chemists' Association as described by Mr. Abraham, and suggested that it might partly be accounted for by the fact that there were in the town many other classes for instruction in chemistry.

Mr. H. B. Brady (Newcastle-on-Tyne) wished to make a few remarks on preliminary education. Firstly, with reference to botany. It had been his intention, till quite a recent period, to have made a communication to that meeting on the *means* of teaching botany, supplementary in some measure to Mr. Schacht's paper of last year. Mr. Matthews had spoken of the importance of the bias given to the mind at an early age. This was eminently true of botany; and whilst they knew that at Professor Henslow's village schools, where the scientific teaching absorbed but an hour or two per week, girls of from ten to thirteen years of age acquired an excellent knowledge of English botany, it was monstrous to suppose that it presented any difficulties for pharmaceutical students. But *method* of teaching was a most important point. Let botany be regarded in the first place as a subject for observation rather than one of mere book definitions. The Sunday afternoon walk would yield material for study; but if not, the student had a fair claim on his master for the medium of time necessary for the purpose, and he could not believe it would ever be refused. Professor Oliver's 'Elementary Lessons in Botany' would stand in the place of a teacher. As to the general question, and the modes of facilitating provincial education, he had last year given some account of what had been done at Newcastle, viz. the establishment of a chair of practical pharmacy in the University of Durham (the medical faculty of which has its head-quarters in Newcastle), and the institution of a distinct programme for students in pharmacy. Many present at that meeting had thrown doubt and distrust on the association of pharmaceutical with medical students, and it was gratifying to be able to report on the authority of Mr. Freire-Marreco, the reader in chemistry, that so far as could be observed the arrangement worked in every way satisfactorily. He maintained that if the experiment should go on as satisfactorily as it had begun, it would, in their case at least, be a distinct waste of teaching power to separate the two classes of students. It was interesting to find that an arrangement almost exactly identical, even to the amount of fees demanded, was already in vogue at Chicago. Whilst they were calling upon medical men to refer to them in matters touching chemistry, materia medica and the like, he (Mr. Brady) thought it absurd to fix a lower standard of education and shorter courses of lectures for pharmaceutical students than medical students themselves enjoyed.

Mr. Sutton (Norwich) lamented the want of opportunities afforded for instruction in some districts. Norwich, for instance, did not yet possess the means of scientific instruction which Liverpool had. The remedy for the difficulty mentioned by Mr. Alpass was in the hands of the pharmacists themselves. He would not take an apprentice under sixteen years of age, and unless the youth was well educated.

Mr. Ekin (Bath) said he was surprised that no mention had been made of the Government scheme of education, which, he thought, would go far to get us out of our difficulties. The second-grade schools which were shortly to be established all over the kingdom would give just the education that was required. The scheme was to give a boy a thorough knowledge of his own language, to enable him to read Latin easily, and to give him a sound elementary knowledge of chemistry, botany and physics. If only the Pharmaceutical Society would require in addition to the subjects now insisted upon at the Preliminary Examination a thorough elementary knowledge of chemistry, botany and physics,

—and by an elementary he by no means meant a superficial knowledge,—they would get just the class of pharmaceutical students they wanted. He did not believe in the science-teachers holding certificates from the Science and Art Department, who were for the most part men of deficient education, and who would entirely fail to command the respect of boys of the class from which pharmacists were taken; and he need hardly say that if boys had no respect for their teachers, they would get but little benefit from their teaching. If needs be, and until these second-grade schools, as they were called, were fairly established, technical schools, as recommended by his friend Mr. Benger, would fill up the void; but he thought they need not be under much concern about ways and means; only let the Pharmaceutical Society create the demand by their requirements at the Preliminary Examination, and the supply would quickly arrange itself.

Mr. Savage (Brighton) suggested that in publishing the names of those who passed the Minor Examination, the names of the institutions where their education had been obtained might be added.

Mr. Payne (Wallingford) wished to call the attention of the meeting to the position of pupils in small towns, where there were insufficient numbers to employ combination.

Mr. R. Sumner (Liverpool) said that it had always been an opprobrium to their local Chemists' Association, that it received so little support from Associates. He felt strongly upon the extensive and growing refusal of the larger establishments to receive apprentices,—a refusal which some of them even blazoned abroad, adopting as a motto, "No apprentices taken, and no arsenic kept on the premises." He held that this was an evil which required correction.

Mr. Dymond (Birmingham) said that they need not be too anxious about young men availing themselves of the means of instruction. The legal position would now compel them to do this. For the subjects required by the Preliminary Examination, Government Science Classes might be looked to as valuable auxiliaries, and they saw how extensively such subjects as chemistry were being introduced into middle-class schools. Doubtless, much remained to be done, for whilst there were about 8000 chemists and druggists in Great Britain, he only found 245 students recorded in the returns on provincial education as attending classes in chemistry. He thought that they should appeal to the Government to aid such science-teaching.

Mr. Martindale (London) feared that the distribution of aid from the Pharmaceutical Society would produce local jealousies, and that the smaller towns would be neglected. He agreed with Mr. Ekin that the elements of chemistry and botany should be introduced into the Preliminary Examination. The School of Pharmacy at Bloomsbury Square had now spread over the country a large number of well-trained pharmacists, to whom we might look as competent teachers of Materia Medica.

Mr. Atherton (Nottingham) gave the experience of the Local Chemists' Association to which he belonged, and said that all the assistants and apprentices of the town had joined it. In the organization of lectures, it was most desirable that they should be delivered by those who knew the exact requirements of the students of pharmacy, since a want of this knowledge on the part of medical or other lecturers had sometimes defeated the object of the course.

Mr. M. Murphy (Liverpool) continued the discussion.

The President agreed with Mr. Alpass as to the importance of primary education, and regretted that the education of the present day was getting too superficial, the simple fact being that pupils neglected to learn how to spell. In the Crimean war many dispensers were thrown out because of their inability to spell even one-syllable words. Few persons who had not given special attention to this subject would credit the extent of the evil. He had examined a class of five boys, supposed to be prepared for the Preliminary Examination, and, upon dictating a sentence of words of one syllable, none of the boys made less than three mistakes in the spelling. It had long been a rule with him to give time for instruction to his assistants and apprentices. He wished to take that opportunity of commending to the notice of all their young men the admirable little work by Professor Oliver, entitled 'Lessons in Elementary Botany.' The use of this text-book would afford a very delightful introduction to the science.

Mr. R. Reynolds (Leeds) could not allow the discussion to end without alluding to the facts disclosed by the printed return on provincial education, of which the proof-sheets were before the meeting. It appeared to him a hopeful circumstance that, in several towns, there was already provision for teaching some of the subjects required in the technical training of pharmacists. It was to the aid and extension of these existing means that they should look. He must specially allude to the experiment which had been made by the University of Durham, in connection with the College of Medicine at Newcastle-on-Tyne, where sixteen students had paid a fee of six guineas each for perpetual tickets to a full curriculum of pharmaceutical education. In the discussion of this subject last year, several members, including himself, had expressed doubts whether the affiliation of schools of pharmacy with those of medicine would be to the interest of the former. It was now placed on record by their friends in Newcastle, as the result of a year's trial, that no inconvenience had been found, and that they were pefectly satisfied with the arrangement. If this continued to be the case in the future, it would much simplify their task, since there were eight or nine other towns having schools of medicine, to which the system could be extended. He (Mr. Reynolds) hoped that they would not overlook the necessity for thoroughness in any system to which they gave their sanction. Now that a certain standard of professional training was required by law, students must be prepared to be thorough; and those providing the classes must not let their duties to be performed a *dilettante* spirit. It must be a serious part of tha work of the day, and not merely depend on spare time.

The Conference adjourned at 12.30 p.m.

Parliamentary and Law Proceedings.

Worship Street Police Court, *October 17th.*

BEFORE MR. NEWTON.

Miss Alice Maud Kemp was charged with having attempted to commit suicide by taking laudanum. A police-constable said, that on Saturday night, having been called to a house in Stoke Newington and told that a young lady had taken poison, he went upstairs and found the prisoner in a state of semi-insensibility. He was informed that she had taken something from a bottle, and a small phial was shown him which smelt of laudanum. A medical man attended, and she gradually recovered. She told witness that she had procured the laudanum from Mr. Cooper, of Amherst Road, and had bought an ounce and a half.

A solicitor here said he appeared on behalf of Mr. Cooper.

Mr. Newton said that no doubt Mr. Cooper would be called on to answer what had been stated against him, but at present he was not before the Court. He had better attend on a future day.

The prisoner was remanded for a week.—*Standard.*

Notes and Queries.

*** *In accordance with a wish expressed by numerous correspondents, a column will in future be devoted to notes and queries, with the object of facilitating the exchange of information among members of the trade and students.*

In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.

[2.]—MOUNTING MICROSCOPIC OBJECTS.—*R. J. M.* may mount sections of leaves, wood, etc., for the microscope, as follows:—Make several sections, which may be roughly viewed under the microscope, with the object of choosing the thinnest and most regular one for the purpose. Having done this, place it on the centre of one of the glass slides that are sold for the purpose by most philosophical instrument makers, and carefully drop on it one or two drops, or just sufficient to cover it, of Canada balsam. One of the very thin little squares of glass, which are also sold by the above, is now carefully dropped on to the object, and the slide has then to be heated very gently over the flame of a spirit-lamp to dispel any air-bubbles that may have formed, and this part of the process is very essential. The slide should be put away for a week or so to dry, either on the top of a bookcase or the cabinet-work of the shop. It will have been sufficiently long when the superfluous balsam that has oozed out from the sides is found to be quite hard. This should be carefully rubbed off the glass with a little turpentine, or cut and scraped off, and, the name being appended, the slide is complete. This is a simple process, which will render most opaque organic substances transparent and permanently mounted.—"GIVE AND TAKE."

If *R. J. M.* will forward his address to Mr. Alfred Laslett, Market Place, Hadleigh, Suffolk, that gentleman will be happy to give him a few hints on mounting microscopical objects.

[3.]—PATENT MEDICINE LICENCE.—*T. Marshall* is informed that chemists keeping more than one shop are required to take out only one licence for the sale of "patents," etc.—"GIVE AND TAKE."

COMPOUND SALTS.—*Major Associate*, in reply to "*Spes*," refers him to the manufacture of hydrochloric acid (HCl); the acid of pharmacy is obtained by the action of sulphuric acid on chloride of sodium, the resulting gas being dissolved in water. The following represents the decomposition which takes place:—

$$\left.\begin{matrix} 2\,NaCl \\ H_2SO_4 \end{matrix}\right\} = \left\{\begin{matrix} Na_2SO_4 \\ 2HCl \end{matrix}\right.$$

showing that hydrochloric acid is a *compound* of hydrogen and chlorine. He would also refer "Spes" to sulphuric acid (H_2SO_4), oxide of antimony (Sb_2O_3), ferrous sulphate ($FeSO_4$), and ferric sulphate ($Fe_2 3SO_4$); the decompositions occurring in the manufacture of each of these compounds are given in Attfield's 'Chemistry.'

[6.]—ESSENCE OF COFFEE.—*R. J.* (Manchester) desires to be informed what is the best method of making essence of coffee.

[7.]—CHILBLAINS.—*J. W. D. H.* (Yorkshire) would feel obliged if any of our readers would tell him of a remedy for chilblains "to be taken internally."

[8.]—PATENT MEDICINES.—"*Socius*" wishes to know whether any registration, certificate, or special licence is required for the introduction of a new patent medicine.

[9.]—GREEN FIRE.—*T. M.* (Nottingham) wishes for a good recipe for making green fire.

[10.]—WHOLESALE DRUGGISTS' ASSISTANTS' SOCIETY.—*J. Hart* (Bow) having heard that the assistants in the wholesale drug trade are about to form a society, which would afford them the means of interchanging trade opinions and tend to improve their social and intellectual position, would feel obliged by any of our readers furnishing him with further information on the subject.

[11.]—AUSTRALIA.—Can any of your correspondents inform me what chance there is of a druggist, with moderate capital, succeeding better in Australia than in this country? —W. MILLER.

Correspondence.

Communications for this Journal, and books for review, should be addressed to the EDITOR, 17, *Bloomsbury Square.*

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE POISON QUESTION.

Sir,—I hope the action taken by Messrs. Brown and Reynolds, and those who joined them at the Council meeting held on the 5th instant, will meet with the hearty approval and appreciation of the majority of the members of the Pharmaceutical Society and of druggists generally. I imagine that the recommendations made by the late Council were sufficiently well understood, and had for their object the compulsory adoption of one or other of the methods suggested for the storing and selling of poisons, and that the objectionable feature in the scheme was that it was to be made compulsory, and, of course, to be attended with the obnoxious machinery of inspector, etc., to ensure its being put in operation.

I do not think the number of cases of accidental poisoning, arising from carelessness on the part of chemists, calls for such interference with their rights and privacy as the making imperative of any such measure necessarily would.

At the general meeting Mr. Haselden, in seconding the adoption of the regulations, said, "that it was much better to saddle themselves than let anybody else do it," but is it not best not to be saddled at all?

Let the Council be united and object to any scheme, by whomsoever proposed, which has for its object the fettering of the members of our profession.

I trust that the compulsory scheme will again be successfully opposed.

JOHN R. THOMPSON.

Bishopwearmouth, Sunderland, Oct. 18th, 1870.

"EXTRA CHARGES AFTER OR BEFORE BUSINESS HOURS."

Sir,—There are very few assistants or apprentices but are rejoiced to see this subject brought forward. It is one which exerts great influence on their future mental prospects.

How many of us are there who, by reason of frequent interruptions, are prone in despair to cast aside, *pro tem.*, "Attfield," "Royle" or "Bentley," the study of which demands close application! The experience of many will doubtless coincide with mine, that often the greater part of the evening's business is done between 8 and 10 o'clock. That such a state of things should continue is what I hope few will affirm. I beg to suggest that as it does not appear (to me) to be a subject for the "Council," the local secretaries should take the matter in hand. Let them canvass the chemists in their own districts, and, having obtained the signatures of those willing to adopt the plan, advertise it with the signatures appended in the principal local papers,—say, for four weeks,—the expense of which I am sure would be cheerfully borne by the assistants and apprentices.

Of course the extra 25 per cent. would be at the disposal of the chemists themselves, but I hope it would be willingly devoted to the benefit of Associations or to the Benevolent Fund.

I look forward to the time when we shall cease, like the medical men, to be at the beck and call of the public, without extra charge.

October 18th. H. B.

NOTES AND QUERIES.

Sir,—I congratulate you on the new feature introduced in the last number of the PHARMACEUTICAL JOURNAL; I refer to the space you intend devoting to "Notes and Queries." Doubtless the advantages will be incalculable, if our members only enter into the matter with spirit and "give and take" in their ideas for the general weal of our body. In one of your contemporaries—*The English Mechanic*—the system has been found to answer so well, and the readers have been so generous in their anxiety to help their brother readers in all subjects, whether mechanical, chemical or philosophical, etc., that that part of the work alone, in itself, forms quite an encyclopædia of useful information and formulæ. I should like to see our "Notes and Queries" answering the same useful ends.

May I also suggest that the "Queries" and "Answers" be both prefixed with a number and the name of the subject in large type, and that should the "Queries" remain unanswered for two weeks, that the number be again inserted under a list called "Unanswered Queries," as many contributors would not answer some of the queries, thinking that others would be sure to reply to them. And, again, should two or three answers, differing in detail, be given to the same query, I think that they should be inserted, thus affording a choice of replies to the querists.

Wishing the new feature every success.

October 17th, 1870. J. Ross Faulkner.

Poisonous Feeding Bottles.

Dear Sir,—About nine years since my wife used a feeding-bottle, having a glass tube reaching to the bottom, armed with a tip of vulcanized india-rubber; in the night she observed an offensive smell from it, and, calling my attention, I found the disgusting odour of sulphuretted hydrogen very strong. I at once got up and washed it, but not until I had used pure chlorine could I get rid of the smell; of course we did not use the bottle again. In the morning the child's body was inflated and very tense, and we have no doubt but that a few minutes more use of the bottle would have proved fatal.

The milk, which was perfectly new, was thus prepared:—

2 oz. new milk, mixed with 2 drams sugar of milk, dissolved in 2 oz. hot water and a very little salt added.

I presume the sulphur of the vulcanized india-rubber acted on the hydrogen of the milk, but whether the process was facilitated by the presence of salt or the sugar of milk, I do not know. We ever after used the plain old bottle and calves teat, fitted with sponge, well washed with hot water every time, and the teat taken off and kept in spirit.

Plymouth, October 17th, 1870. F. P. Balkwill.

Dear Sir,—Your correspondent C. B. N. asks for a little information respecting feeding-bottles, in consequence of a statement made by Dr. W. L. Emmerson; which statement he considers singular, but the truth of which is beyond a doubt. If I understand your correspondent correctly, he wishes to know what chemical change takes place in the milk, which would cause it to become poisonous? I will endeavour simply to explain it to him. The following is the composition of milk:—

Water	858
Casein	68
Butter	38
Sugar with extractive	30
Salts	6
	1000

The casein comes under the head of the nitrogenous food-stuffs, which compounds are essentially necessary to build up the principal tissues of the body, as muscular fibre, nervous substance, etc. Now it is well known that the nitrogenous compounds are most easily decomposable; and though, as in milk, the sugar and salt are sufficient to preserve the nitrogenous principle, casein, when in the living tissues, they are not in sufficient quantity to preserve it when out of the living tissues. Casein is under the most favourable circumstances for decomposition when allowed to remain for any length of time in an india-rubber tube with warmth applied. Though the nitrogenous compounds are so very essential in building up the tissues, they are, nevertheless, when decomposed, most poisonous. If taken into blood-vessels by the absorbent in only small quantities, pyemia, or blood-poisoning, takes place, and death in the majority of instances is the result. Can these unfortunate circumstances take place through the means of feeding-bottles? I believe they can; and, moreover, I believe hundreds of children die annually of pyemia, caused through the decomposition of casein in the tubes of feeding-bottles. I do not for one moment blame the feeding-bottles, the blame rests entirely upon those who have the management of them; in short, it is for want of cleanliness. I would recommend that the tubes be no longer than six inches; that the milk which is put in the bottle should always have a little salt and sugar added to it; that every time the bottle is used, the teat and pipe should be separated, and with the aid of the tube-brush well washed out with salt and water; the strength of which solution should be a small teaspoonful of salt to one pint of water. If these precautions are taken, no one need fear blood-poisoning by means of feeding-bottles; and their safety will be equal to their use, which is great.

Thomas Pemberton.

Birmingham, Oct. 17th, 1870.

Pharmacy and Medical Practitioners.

Sir,—"Reformer," the *Lancet* correspondent, appears to me to be writing on a subject of which he knows nothing at all; and in writing thus only exposes his ignorance to those "dignitaries" whom he so contemns. If a doctor of any standing at all, he ought to know that an ordinary prescription does not easily cost from 2*s*. 6*d*. to 3*s*. Of course, if there should be mixture, pills and ointment on one prescription, it may easily cost 2*s*. 6*d*. or 3*s*.; but an ordinary prescription contains a mixture only, which would be charged 1*s*. 9*d*. or 2*s*. at the most.

"Reformer" says that "people whose family doctor does not supply his own medicines find their drug bill is equal to, or even exceeds, their doctor's bill." Granted that a chemist gets 3*s*. even for a prescription, we will suppose written by "Reformer," I think that he ("Reformer") would be something more than astonished at his patient if he offered him only 3*s*. as his fee; and if a doctor's practice is among so poor a class that he can only get 3*s*. as his fee, it is very certain that it is impossible for a chemist to get 2*s*. 6*d*. or 3*s*. for the medicine. And yet "Reformer" states as a fact that the patient's drug bill equals or exceeds the doctor's.

Mr. Mee, in commenting on "Reformer's" letter says, "It seems a most extraordinary fact that a chemist in one part of town should charge as much for preparing a prescription as a licensed apothecary or medical practitioner should charge for both visit and medicine in another." As Mr. M. is a chemist, he ought to know that such is not the case. That a chemist at the West-End charges more than one at Highbury we can all understand; for a man who pays £300 or £400 rental cannot be expected to charge the same as one whose rent is only £60, and whose general expenses are in the same ratio. But I do not think that Mr. M. knows of an instance where a surgeon's fee for visit and medicine is as little as the chemist's charge for medicine only. As Mr. Mee dispenses for a surgeon, it is very possible that he speaks feelingly when he says, "We must be friendly with them (the doctors), for they are our best friends;" but I fail to see as yet in what way they are "a most generous race."

So long as practitioners persist in prescribing medicines in such concentrated forms as now appears to be general, they must not be surprised if their patients' bills are rather heavy. I have to-day dispensed for a surgeon the following prescriptions:—

No. 1.

℞. Tr. Cinchonæ Simpl. ℥iv
Ft. Mist. Sig. ʒj bis die ex aq. sd.

No. 2.

℞. Tr. Cinchonæ Co. ℥iij
Acid. Nitr. dil. ʒiv
Tr. Aurantii ʒiv.
M. ft. Mist.

Two teaspoonfuls three times a day in a wineglassful of water.

It is a curious, though an undeniable fact, that the surgeon who dispenses his own medicine prescribes the most simple remedies, and not in a concentrated form. Another grievous sore with "Reformer" is chemists' prescribing, and he insinuates that they do harm rather than good. What would he say to a doctor who ordered tr. lyttæ for a child suffering from hooping-cough? If a chemist ventured to prescribe it he would be put down as an ignorant man, to say the least. I know, however, a M.R.C.S. who ordered it. So far as my experience goes, I think that chemists cure their patients sooner than medical men. If doctors would give up dispensing, the chemists would give up prescribing, but not till then, I think.

Bristol. An Assistant.

Sir,—In noticing the communication of Dr. Leslie, I hope that gentleman will do me the justice to remark that I have not in any degree reflected upon the position or practice of the honourable section to which he belongs, namely, the physicians, who are, indeed, our best friends, and whose function, although exercised upon a higher level, does not conflict with the interests of pharmacists; as for the "position" we occupy, and our intelligent appreciation thereof, the learned doctor may find an illustration in the correspondence which appears in your weekly columns. The chemists would not have assumed the defensive had it not been for the unscrupulous attacks of the *Lancet*, which are not only insulting to an educated body of men, but amount to a gratuitous offence against the good manners that regulate our social system.

NON-MALCONTENT.

BRIGHTON CHEMISTS' PRICES *versus* BRIGHTON CHEMISTS' ASSOCIATION.

Sir,—Having read in the Journal a letter of Mr. W. D. Savage on the Brighton Chemists' Association, I wish to offer a few remarks in connection with that subject.

Having been for the last few months in Brighton, I have become acquainted with the "cutting" system prevalent there, of which I give the following instances:—

A six-ounce saline mixture for 6*d*. A quarter of a pound of tartaric acid for 4½*d*. Epsom salts, two ounces for 1*d*. Prepared chalk, 1½ oz. for 1*d*. Camphorated chalk, 3*d*. per oz. Citrate of magnesia, 2*d*. per oz., etc.

Now, I am persuaded that where the trade is divided against itself by such a system of underselling no Chemists' Association will stand, and no brotherly feeling can possibly exist.

A PHARMACEUTICAL STUDENT.

SPECIFIC GRAVITIES AND VOLUME MEASURES.

Sir,—In your report of the discussion, which followed the reading of my papers on "Specific Gravities and Volume Measures" at the Pharmaceutical Conference, it was stated that "the contents per ounce were coincident with the specific gravity" (solid contents being referred to). On making reference to my notes and memoranda, I find that as regards the class of fluids I have been operating on this rule does not apply, or make any approximation to the truth, and, therefore, the statement ought to be corrected.

As examples I will give two or three instances:—

Vin. Ipecacuanhæ,	sp. gr. 0·993……	solid contents,	19·2	per oz.
Tinct. Hyoscyami	„ 0·937……	„ „	18·35	„
Tinct. Opii	„ 0·940……	„ „	18·79	„
Dec. Sarsæ Co.	„ 1·027……	„ „	50·00	„

As applied to solutions of sugar and salts the approximation will be closer. A solution of pure sugar containing 30 grs. to the ounce has a sp. gr. of 1·028.

F. M. RIMMINGTON.

UNG. AQ. ROSÆ AND TINCTURÆ.

Sir,—As medical gentlemen occasionally order ung. aq. rosæ in their prescriptions, is it not desirable that dispensers should have a recognized formula for it? Nearly every establishment having its own recipe and *modus operandi*, each would prepare a prescription containing the above differently from every other; a result not at all in accordance with "uniformity in physic."

The Pharmacopée Française contains a formula, and (if I were *F.* instead of A. P. S.) I would suggest the following modification for insertion in a future edition of the B. P.:—

Ceræ Albæ ℥j
Cetacei ℥ij
Olei Amygdalæ f℥x
Aquæ Rosæ f℥iij
Tinct. Benzoini ♏xx. F. s. a.

The benzoin and the small quantity of aqua render it less liable to change than would be the case were the former omitted or the latter augmented, and that is a desideratum in a pharmacopœial preparation.

While I am on the theme of the B. P., perhaps you will permit me to say it is my opinion, founded on observation and practice, that it would add much to attaining "uniformity in physic" if tinctures were required to be kept at least one month before being used, so as to allow time for that peculiar change to take place which most vegetable solutions undergo. Tinct. aurantii, for instance, when prepared, either by maceration or percolation, from recently dried peel or from fresh peel, grows much darker and developes a finer flavour after three or four weeks. Of course the remedy for this, in respect of colour, is to use stale peel in which that resinous change, alluded to in PHARM. JOURN. Vol. XI. p. 604, has taken place. But there is no remedy, except time, for others, such as squills, colchicum, etc.

Now with regard to tinct. calumbæ, why not use the root in coarse powder instead of "cut small"? the result is far more satisfactory. The colour is richer because more calumbate of berberine (?) is taken up, and there is little or no amylaceous deposit.

The mortar instead of the knife is resorted to in the case of tinct. rhei, a proceeding which, at one time, would have been thought very unpharmaceutical.

H. E. GODFREY.

"*Ignorans*" (Tamworth).—Sulphate of lime and caustic potash would be formed.

C. C. (Taunton).—(1.) Ten ounces. (2.) In London to send ten ounces.

M. P. S. (Liverpool).—The *dilute* acid is obviously intended. We should dispense the prescription with this acid.

A. P. S. (Liverpool).—SARSAPARILLA AND QUININE.—(1.) Add the *simple* fluid extract of the B. P. to a solution of the quinine in a slight excess of dilute sulphuric acid. (2.) Probably a combination of quinine with astringent matter. Filtration would not be justifiable.

"*A Cliftonian*" (Windsor).—We know of no form for this preparation. We should suppose 1 to 5 a convenient preparation.

G. H. H. (Helensburgh).—(1) GLYCERINE CREAM. Beat almonds into a thick emulsion with water, strain, dilute, and add q. s. glycerine and otto. (2) We know of no such preparation, but it might be readily made by dissolving 5 grains of the scaly preparation in each drachm of water.

T. H. C. (Southsea).—We cannot explain the difference. The appearance should be that described as belonging to the lotion dispensed by yourself.

A. E. J. (Norwich).—We confess to being not philosophical enough to answer your question.

"*Englishman*" (Leamington).—Wanklyn and Smith's *Water Analysis*, Bowman's *Medical Chemistry*.

G. K. (Surbiton) and *Caradoc Jones* (Ebbw Vale) are informed that an article giving advice to students preparing to pass the examinations of the Pharmaceutical Society has been reprinted, and may be had on application to the Registrar.

"*Inquirer*" (Pontypool).—Such sale is not illegal, prussiate of potash not being a poison.

We have received a communication from Mr. Condy, which shall receive early attention.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. T. B. Groves (Weymouth), Mr. C. Umney (London), Mr. F. P. Balkwill (Plymouth), Mr. J. R. Faulkner (London), Mr. F. Buck (Chelmsford), Manager of the Floriline Company, The Committee of the Burgoyne Testimonial, Mr. Chapman (Manchester), Messrs. Jones and Son (Worksop), Mr. Wood (Barnsley), Mr. Reynolds (Leeds), Mr. C. R. C. Tichborne (Dublin).

The following journals have been received:—The 'British Medical Journal,' Oct. 15; the 'Medical Times and Gazette,' Oct. 15; the 'Lancet,' Oct. 15; 'Nature,' Oct. 13; the 'Chemical News,' Oct. 14; 'Journal of the Society of Arts,' Oct. 13; 'Gardeners' Chronicle,' Oct. 15; the 'Grocer,' Oct. 15; the 'English Mechanic,' Oct. 15; the 'New York Druggists' Circular' for October, from Mr. Deane: the 'Baltimore Gazette,' Sept. 17; the 'Canadian Pharmaceutical Journal' for September; the 'Journal of Materia Medica' for August and September; 'Neues Jahrbuch für Pharmacie,' numbers for February, March, April, May, June, July, and August, from the Editor.

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes to be endorsed for "Pharm. Journ."*

RATIONAL THERAPEUTICS.

In the introduction to a course of lectures just commenced, Dr. Richardson treated of the method to be followed in studying the relation between remedies and their effects, illustrating the connection between variation of physiological power and variation of chemical constitution by reference to the ethyl compounds. The radicle ethyl furnishes a multitude of compounds that are analogous in possessing narcotic power; commencing with the hydride $\left.\begin{matrix}C_2H_5\\H\end{matrix}\right\}$ which is in composition least removed from the radicle itself, we find it is a gas, insoluble in blood and negative in its action on nervous material; hence it is not active either as an excitant or as a narcotic. It must be inhaled with air in the proportion of 30 or 40 per cent. in order to produce any decisive effect. Then it acts like nitrogen, producing temporary insensibility by interfering with the respiratory process, which cannot be sustained.

Again, alcohol $\left.\begin{matrix}C_2H_5\\H\end{matrix}\right\}O$ (which differs from hydride of ethyl by containing oxygen and from water $\left.\begin{matrix}H\\H\end{matrix}\right\}O$, in having ethyl in place of half its hydrogen) is a stimulant and narcotic. It acts directly on the nervous system and excites the action of the heart. Given freely it induces deep narcotism, but as it is largely absorbed by the blood, a great quantity of it is required before there is sufficient saturation to induce narcotism. Hence it is not difficult to make an animal insensible with alcohol vapour.

Replacing the whole of the hydrogen in water by ethyl, we obtain ether, $\left.\begin{matrix}C_2H_5\\C_2H_5\end{matrix}\right\}O$, a powerful narcotic, having less direct stimulating action than alcohol, but producing its effects more rapidly. Being less soluble in blood than alcohol, it may be administered by inhalation of its vapour so as to saturate the blood, and then it acts as a narcotic. Still it is too soluble, and is, therefore, wanting in potency, so that we are obliged in using it to keep up the saturation by persistent administration to the exclusion of much air. Thus symptoms of asphyxia and restlessness are often produced, which prevent the use of ether.

In the chloride of ethyl, C_2H_5Cl, we have a substance which produces great excitation of the heart and deep narcotism. Being sparingly soluble in blood the saturation necessary for this effect is soon reached. But like chloroform, which it resembles chemically, this substance produces rigid muscular contraction as it narcotizes; it also causes vomiting, and, by arresting first respiration, then the action of the heart, it kills, as chloroform does, when its administration is continued too long.

The iodide of ethyl produces with narcotism great excitement of the heart and circulation as well as free glandular secretion.

Bromide of ethyl, C_2H_5Br, possessing good physical qualities for a volatile narcotic, produces deep narcotism and but slight muscular excitement, though to some extent, like the chloride and iodide, it excites, causes vomiting and irritates the mucous surfaces.

Sulphide of ethyl, $\left.\begin{matrix}C_2H_5\\C_2H_5\end{matrix}\right\}S$, produces rapid narcotism without excitement, and though with frogs the insensibility may be sustained for many hours without death, it induces paralysis of the nervous centres supplying the heart and the muscles of respiration.

Nitrite of ethyl, $C_2H_5NO_2$, produces, besides narcotism, a general paralysis of the nerves governing the contractile function of the blood-vessels, causing suffusion of the face, and rapid action of the heart.

A similar series of relations between constitution and physiological action is found in the amyl series. Between the actions of the ethyl and amyl series there is a difference in regard to what Dr. Richardson calls persistency of effect, due, he considers, to the radicle amyl being richer in carbon and hydrogen.

Dr. Richardson ascribes the narcotism in all these cases to the ethyl of the several compounds, and the phenomena which lie outside the narcotism he considers to be referable to the various other substances with which it is combined. He considers that wherever a basic element or radicle exists it always plays a part of its own, at the same time modifying the action of the substances with which it may be united but not destroying their action or preventing them from being recognized. But in some cases the action of the associated substance may be so determinate that it becomes the prominent fact, while the action of the base is obscured. This is to some extent the case with the nitrites, and very markedly so in the case of the cyanides.

The physical properties of a substance probably modify the physiological action belonging to its constituents; thus vapour density will regulate the rate of diffusion; the boiling-point, solubility and other characters will also exercise some influence in modifying the effects of a substance as a medicine.

We must also admit the probability that some medicines undergo chemical alteration within the body. Thus, for instance, hydrate of chloral is perhaps converted into chloroform by contact with weak alkaline liquids in the organism.

Again, though animals are, as a rule, affected in like manner by various substances, there are peculiarities in some animals in consequence of which the effects of certain substances are modified in particular cases. Pigeons are insensible to the influence of morphia, goats are unaffected by nicotine.

The specific action of substances is another point to be studied. Of late years it has been customary to suppose that all agents act through the blood; but we are now learning that many substances act directly upon the peripheral nerve-surfaces, the effect being transmitted by light or sound. Dr. Richardson considers that nitrite of amyl acts thus, for in an animal recently dead the heart can be influenced by its application to the surface of the retina, or to the olfactory tract. Dr. James Jones has also shown that prussic acid acts fatally by application to the medulla oblongata.

The study of this subject leads to ground so entirely new that it cannot easily be traversed, but having got a glimpse of what is to be learnt it is, as Dr. Richardson remarked, impossible to leave such ground untraversed. "Better get over it ever so little, and even in lame and shambling gait than not to venture at all. Let us once fairly get upon this new ground and we march straight to the positive science and art of cure; then the fate of quackery *intra* or *extra* the ranks, is sealed for ever. Let us not venture on the new ground, and we remain as we are—wiser than gross uncertainties but weak because, uncertain ourselves, we are constantly obliged by our questionings and admissions to proclaim to the vulgar that even the guides cannot find their way."

THE CHEMICAL REACTIONS OF CHLORAL HYDRATE.

BY J. F. BROWN.

The few simple experiments which I have here briefly noted were suggested by the letter of "F. B." in the Journal for October 8th, asking for a list of incompatibles with the above-named substance. Their results may perhaps fulfil, to some extent, his requirements.

The sample of the hydrate used was of the ordinary kind, in cakes and fragments of cakes, and yielded 70·9 per cent. of chloroform when tested by the method proposed by Mr. Umney in the 'PHARMACEUTICAL JOURNAL,' p. 107.

Chloral hydrate, when heated, fuses and boils, giving off an acid vapour.

Treated with strong nitric acid, fumes of nitric peroxide, N_2O_4, were evolved. On the addition of water and an excess of ammonia the usual reaction followed, a globule of chloroform collecting at the bottom of the tube.

Half a drachm was readily dissolved by f ʒss of pure alcohol, and no separation resulted on the addition of water. The hydrate is freely soluble in rectified spirit, and the solution mixes well with distilled water; but I remember some time since dispensing a mixture containing chloral hydrate, tincture of orange peel, and water, when on dissolving the hydrate in the tincture and adding it to the water, a separation took place of numerous oily drops, which were with difficulty diffused through the mixture. The sample used on that occasion was obtained from a well-known firm of manufacturing chemists, but was strikingly different to any that I have seen, either before or since, being in distinct transparent, needle-like crystals, very damp, but with difficulty soluble in water.

Ether dissolves the hydrate in the same proportion as alcohol, but on adding to the solution five times its volume of distilled water a very curious separation occurred. It was evident that a stratum of heavier liquid was forming at the bottom of the tube, but the mode in which this took place was to me a novel one.

Looking attentively at the column of liquid, I could perceive an *ascending* current of tolerably large globules. These, when they reached the surface, coalesced, to form a large drop suspended from it, which presently parted from its support, much as a soap-bubble would have done, and descended slowly to the bottom.

This was repeated until the liquids were completely separated, and on examining the lower stratum I found it to consist of an ethereal solution of chloral. A little exposed in a watch-glass left a residuum of dense, oily liquid, which imparted a transient greasy stain to paper.

Glycerine is a good solvent for the hydrate of chloral, and the solution mixes with water unchanged.

A solution of one part of the hydrate in six of water was mixed with different alkaline solutions of the same strength (except that of acid carbonate of sodium, which was one in twelve) with the following results:—Carbonate of potassium induced decomposition at the temperature of the atmosphere 62° F. Carbonate of sodium at 100° F. Acid carbonate of sodium, acid carbonate of potassium, and carbonate of ammonium at 212° F., and only after the disengagement of carbonic acid gas, from which it may, I think, be inferred that the reaction is due, not to the acid salts, but to the neutral compounds to which they are reduced by boiling.

With saccharated solution of lime a white precipitate of hydrate of calcium was obtained.

With tincture of perchloride of iron a precipitate of ferric hydrate.

With solution of subacetate of lead a white precipitate of hydrated oxide of the metal; and on boiling with solution of silver nitrate, oxide of silver was thrown down.

A solution of tannic acid, at a boiling heat, caused the evolution of pungent acid vapours, probably of formic acid.

The solution of the hydrate was apparently unaffected by sulphuric, acetic or gallic acids, and neither in substance nor in solution was it affected by iodine or perchloride of mercury.

May I, in conclusion, express a hope that the attention of my fellow-students will be called to this subject, that my statements may be confirmed or invalidated by further and more complete experiments.

Dover, October 21st, 1870.

JAVA CINCHONA BARK.

Some months ago several bales of cinchona bark were imported into Holland from the Dutch plantations in Java. Samples of this bark have been sent out by the Handels-Maatschappij in sealed packets with the analysis of Professor Gunning. In a recent number of the *Neues Repertorium für Pharmacie*, Herr Jobst describes this bark as consisting of larger pieces than the first samples sent over in 1867 from the English plantations in the Himalayas, although in both instances there was a want of that fine character presented by the older bark from the Andes as regards colour.

Dr. Henkel, of Tübingen, is now engaged in a microscopic examination of this bark, the results of which will shortly be published, and Herr Jobst gives the following results of his chemical examination:—

No. I. T. P. King's Bark.

Containing, according to Professor Gunning, when dried at 100° C.—

Alkaloid soluble in ether . 3·5 p. c. (much quinidine).
" insoluble " . 2·0 "

This sample consists of single and double quills from 2 to 7 inches long, from the size of a goose-quill to ½ an inch in diameter and about 1 line in thickness. The pieces are mostly of a dull brown colour, with longitudinal cracks and faintly-marked, transverse striæ, covered with warts at some parts, and pale yellow at the interior. Herr Jobst found it contained in all 3·2 per cent. of alkaloids, much of which was conchinine and cinchonine, only a trace of quinine and no quinidine, but an amorphous basic substance that has not yet been examined.

Nos. II. and III. T. P. King's Bark.

Containing, according to Professor Gunning, when dried at 100° C.—

Alkaloid soluble in ether . 2·1 p. c. (little quinidine).
" insoluble " . 1·3 "

This sample consists of fine, uniform quills of a grey colour, covered here and there with lichens. The quills were 7 inches long, from 5 to 6 lines diameter and about 1 line in thickness. The cracks and striæ were scarcely recognizable, and the colour of the bark inside was pale or dark yellow. The total amount of alkaloids was 3·5 per cent., consisting of 1·7 quinine with some quinidine, conchinine, cinchinine and amorphous basic substance.

No. IV. M.

Containing, according to Professor Gunning, when dried at 100° C.—

Alkaloid soluble in ether . . .	1·1 per cent.
„ insoluble „ . . .	0·9 „

This consisted of grey, greyish-brown and brown quills, and flat pieces about 8 inches long, with longitudinal cracks, but no transverse striæ: reddish-yellow inside. It contained in all 1·9 per cent. alkaloids, including 0·5 quinine, besides cinchonine, some quinidine, conchinine and amorphous base.

Brown Java bark.

Total amount of alkaloids 1·2 per cent., chiefly quinidine and amorphous base with trace of quinine, but neither cinchonine nor conchinine. This bark (*Pahudiana*) is already well known to be worthless, and the Dutch Government has forbidden its production.

These results show that only two of these samples (Nos. II. and III.) contain any sensible amount of the alkaloid that is alone of use,—crystallizable quinine,—and in regard to this the samples are nearly the same as a very ordinary sample of Calisaya bark. Consequently the Java bark, as produced at the present time, is quite unfit for the manufacture of quinine.—Abstract of paper in the *Neues Jahrbuch für Pharmacie*, xxxiv. 18.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Acidum Sulphuricum.—Sulphurous acid gas is procured either by burning sulphur or by roasting iron pyrites (FeS_2); it is passed, together with the vapour of nitric acid, in a stream of air into a large chamber lined with sheet lead. At intervals, jets of steam are thrown into the chamber. These materials react on each other in this way: oxygen from the nitric acid and water (of the steam) unite with sulphurous acid gas, and form sulphuric acid, which, being scarcely volatile, collects as a liquid at the bottom of the chamber. The nitric oxide (NO) which results from the deoxidation of the nitric acid combines with oxygen, which enters in the form of atmospheric air and produces nitric peroxide (NO_2); this, in turn, gives up oxygen to a second portion of sulphurous acid and itself is again reduced to nitric oxide. These changes go on in this order incessantly. On the one hand we have sulphurous acid gas and vapour of water, on the other atmospheric oxygen and, occupying an intermediate position, the nitric oxide. As the oxygen comes in it is handed over, by the intervention of the NO, into combination with the SO_2, H_2O.

O (*from the air*).	NO (*alternately* NO and NO_2).	$\left.\begin{matrix} SO_2 \\ H_2O \end{matrix}\right\}$ or H_2SO_3 *becoming* H_2SO_4.

The above reaction is accompanied by other changes. Sometimes, when water is deficient, a crystalline body forms in the lead chambers. This compound is believed to contain the elements of sulphurous anhydride, SO_2, nitric peroxide, NO_2, *plus* oxygen; but its constitution is quite unknown.

The weak acid of the lead chambers is concentrated first by evaporation, afterwards by distillation. Sulphuric acid is an oily liquid; specific gravity 1·843. It has an intense affinity for water, absorbing water greedily when exposed to the air, evolving considerable heat when mixed with water, and the mixture undergoing diminution or contraction of volume. When diluted, it gives with chloride of barium a white precipitate of sulphate of barium, insoluble in acids and in water. Sulphuric acid chars and decomposes almost all kinds of organic substances. In consequence of its attraction for water, it removes part of their hydrogen and oxygen in that form, and a mass of highly carbonaceous composition and appearance remains. Some bodies dissolve in it without blackening; indigo does this. Others do not blacken, but are completely decomposed; for example,—

$$\underset{\text{Oxalic acid.}}{C_2H_2O_4} + \underset{\text{Strong sulphuric acid.}}{H_2SO_4}$$

$$= \underset{\text{Carbonic monoxide.}}{CO} + \underset{\text{Carbonic dioxide.}}{CO_2} + \underset{\text{Hydrate of sulphuric acid.}}{\overbrace{H_2O, H_2SO_4}}$$

Nordhausen or fuming sulphuric acid is made by distilling at a strong heat partially dried sulphate of iron. The product, notwithstanding its ready decomposability, is generally looked upon as a definite compound. Some chemists still regard it, however, as a mere solution of sulphuric anhydride, SO_3, in sulphuric acid, H_2SO_4. The old name, *oil of vitriol*, arose from its being thus prepared from sulphate of iron, or green vitriol. White vitriol is sulphate of zinc; blue vitriol, sulphate of copper.

The sulphuric acid of commerce contains traces of many impurities; bisulphate of *potash* or *soda* would be left by evaporation in a platinum dish; *nitric* or *nitrous* acid, detected by a solution of sulphate of iron, which, poured over the surface, developes a purplish colour where the two liquids unite; *arsenic* or *lead*, by diluting with a considerable quantity of water, and saturating with sulphuretted hydrogen. A white cloud of sulphate of lead is usually observed on adding water to common oil of vitriol; this is derived chiefly from the pans in which the first concentration is effected; it is slightly soluble in the strong acid, but scarcely at all so when diluted, this is the cause of the precipitation.

Impure sulphuric acid may be freed from contamination with arsenic by heating it with a little hydrochloric acid; the arsenic is expelled in the form of chloride. It may be purified from nitrous compounds by distillation with a little sulphate of ammonia.

$$(NH_4)_2SO_4 + N_2O_3 = 2N_2 + 3H_2O + H_2SO_4.$$

[§ 5·06 grams, mixed with an ounce of distilled water, require for neutralization 100 c.c. of the volumetric solution of soda.] Sulphuric acid is bibasic;

one molecule of it will therefore require two molecules of hydrate of sodium for neutralization,—

$$\overset{98}{H_2SO_4} + \overset{40\times2=80}{2NaHO} = Na_2SO_4 + 2H_2O$$

or,—

$$\tfrac{1}{2}\overset{49}{H_2SO_4} + \overset{40}{NaHO} = \tfrac{1}{2}Na_2SO_4 + H_2O.$$

1000 c.c. of vol. sol., which contain 40 grams of soda, will therefore neutralize 49 grams of sulphuric acid; 100, therefore, neutralize one-tenth of 49, or 4·9 grams. 5·06 grams of the official sulphuric acid, which require 100 c.c. of volumetric soda, therefore contain this quantity of real acid. This is 96·8 per cent., for

5·06 : 100 as 4·9 : 96·8.

Acidum Sulphuricum Dilutum.—35·9 grams of the diluted acid are neutralized by the addition of 100 c.c. of vol. sol. of soda; this indicates 13·64 per cent. of H_2SO_4.

The strength of the diluted acids of the Pharmacopœia is so arranged that six fluid drachms of any of them contain sufficient acid to neutralize one molecule *in grains* of an alkaline hydrate.

f ℥vj	Contain
Acid. Hydroch. Dil.	1 grain-mol. (= 36·5 gr.) HCl
Acid. Nitric. Dil.	1 grain-mol. (= 63 gr.) HNO_3
Acid. Sulph. Dil.	$\frac{1}{2}$ grain-mol. (= 49 gr.) H_2SO_4
Acid. Phosph. Dil.	$\frac{1}{3}$ grain-mol. (= 32·6 gr.) H_3PO_4

Either of these quantities would neutralize

1 grain-molecule (= 40 gr.) of $NaHO$
or 1 grain-molecule (= 56 gr.) of KHO
or $\frac{1}{2}$ grain-molecule (= 53 gr.) of Na_2CO_3
or $\frac{1}{2}$ grain-molecule (= 69 gr.) of K_2CO_3.

PARICINE.*

BY O. HESSE.

This alkaloid was discovered by Winckler, in 1845, in a sample of bark brought from Pará, which, according to Howard, had been derived from *Cinchona lutea*, a tree which is called 'lengua de vacca' (cow's tongue) in Huanuco, by reason of the rough feel of its leaves. Weidenbusch made an analysis of the alkaloid, which showed that its percentage composition was very similar to that of aricine, and, on this ground, Gerhardt asserted that it was merely amorphous aricine.

Subsequently Winckler, in studying cortex chinæ pallidæ in 1865, took up the subject again, and compared paricine with beberine, because the latter has also the character of being precipitated from its solutions by nitric acid. Winckler found that these alkaloids had the greatest resemblance in their chemical behaviour towards the reagents he employed, and he was, therefore, of opinion that elementary analysis would prove them to be identical.

Upon this basis Flückiger assumes not only the identity of paricine and beberine,—buxin or pelosine,—but also conjectures that paricine probably exists in all kinds of cinchona bark. In order to separate it from the mixture of bases Flückiger suggests that those bases should be converted into the sparingly soluble iodine compounds, and the paricine extracted by ether.

Hesse disclaims the intention of examining whether the method is suitable for detecting paricine or not, but rather seeks to show that the alkaloid in question does not exist in the kinds of cinchona bark used for making quinine. During the last eight years he has given attention to this matter, but has not succeeded in obaining the smallest trace of paricine from those kinds of bark. In all instances the alkaloids readily soluble in ether, after separating quinine and cinchonine by means of tartaric acid, were submitted to examination by treating the sulphuric acid solution of these bases with concentrated nitric acid; but in no single instance was there any precipitation or turbidity caused thereby. If paricine had been present, however, it should have been found in this way.

The author adds, moreover, that paricine is not even identical with pelosine, since the latter, as Flückiger has observed, turns light towards the right, while pelosine is, according to De Vry, optically inactive.

* Abstract from a paper in the *Reports of the Berlin Chemical Society*, 1870, no. 5.

EXAMINATION OF THE RESIN OF TAMPICO JALAP.*

BY PROFESSOR H. SPIRGATIS.

The author has published the results of a preliminary examination of the resin contained in this drug with the object of comparing it with the resin of true jalap.†

Tampico jalap resin was obtained by first extracting the root with water, then digesting it with alcohol, evaporating off the alcohol and washing the resin with water. A second solution in alcohol and treatment with animal charcoal completed the purification. The author gives the resin the name of *Tampicin*.

This substance presents a general resemblance to convolvulin. It is translucent, colourless or slightly yellow, brittle, without odour or taste, and readily soluble in alcohol or ether. Its solubility in ether distinguishes it from convolvulin,‡ as well as from jalapin, the resin of the *Ipomœa orizabensis*. It also differs from them in composition. The alcoholic and ethereal solutions have a slight acid reaction.

By the action of streng bases this resin is, like convolvulin, converted with addition of the elements of water into an acid soluble in water,—Tampicinic acid.

Strong acids, such as hydrochloric, nitric or sulphuric acids, when diluted dissolve the resin gradually, converting it into sugar and a fatty acid—Tampicoleic acid. Concentrated sulphuric acid colours the resin yellow at first, then dissolves it with a fine red colour, which gradually becomes brown. With acetic acid this resin behaves in the same manner as convolvulin, dissolving without being broken up.

Tampicin is much more readily affected by heat than convolvulin. Its melting-point is about 130° C.

Analysis of the resin dried *in vacuo* at 100° C. gave results corresponding with the formula $C_{34}H_{54}O_{14}$; Mayer gives $C_{30}H_{50}O_{16}$ as the formula of convolvulin.

Tampicinic acid resembles convolvulinic acid, being an amorphous, yellowish, shining, translucent mass without odour, and having a rankish, bitter taste. It is hygroscopic, readily soluble in water and alcohol; the solution has an acid reaction, and expels carbonic acid from the alkaline carbonates. It is scarcely soluble in ether.

This acid is precipitated only by acetate of lead and chloride of mercury. Dried at 90° C. *in vacuo* and analysed, it gave results indicating the formula $C_{34}H_{60}O_{17}$; Mayer gives $C_{31}H_{50}O_{16} + 1\frac{1}{2}H_2O$.

Tampicoleic acid is white and crystalline, with a sharp taste, without smell, readily soluble in alcohol, sparingly in ether, both solutions having a distinct acid reaction. When heated it melts to a yellowish, oily liquid that solidifies on cooling to a hard, white, radiated mass. The

* Read before the Royal Bavarian Academy of Sciences, 2nd July, 1870.

† Kayser, Ann. Chem. Pharm. li. 81, and W. Mayer, *ibid.* lxxxiii. 121, xcv. 129.

‡ Sometimes this drug appears to be mixed with the tubercles of other Convolvulaceæ, perhaps those of true jalap. One sample of Tampico jalap yielded a resin only in part soluble in ether.

alcoholic solution expels carbonic acid from the alkaline carbonates. Analysis indicated the formula $C_{16}H_{32}O_3$. The alkaline salts of this acid are soluble in water, the ether crystallizes in rhombic tables.

Summarizing the result of this investigation, it appears that the resin of Tampico jalap resembles convolvulin in belonging to the class of conjugated sugar compounds or glucosides, while it differs from that substance by its perfect solubility in ether and in composition.

Experiments made in the Königsberg hospital to ascertain the medicinal action of Tampicin appear to show that in this respect it resembles true jalap resin, though it is less certain. Moreover, the use of this drug in the place of true jalap does not seem advisable, for although its price is only a third of what it was, the much smaller amount of resin it contains, and the large amount of alcohol required for its extraction, renders tampicin dearer than convolvulin.—Abstract from paper in the *Neues Repertorium für Pharmacie*, xix. 452.

KASHMIR MORELS.

BY M. C. COOKE, M.A.

That Truffles and Morels are found in North-Western India and Kashmir, has for years been an article of faith with mycologists, although no opportunity has occurred for satisfactorily determining the species. It is quite true that names have been applied to them, but without just cause.

Through the kindness of Dr. J. L. Stewart we have at length received from Mr. Baden Powell, of Lahore, a string of dried Morels procured by him from Kashmir. This string contains two species, both of them small, and neither of them the *Morchella esculenta* of Europe, which the Rev. M. J. Berkeley has quoted as inhabiting Kashmir. In a paper recently communicated to the Botanical Society of Edinburgh we have described these two Kashmir Morels.

In his 'Notes on the Products of Kashmir,'* Lieutenant Lowther says, "I saw fungi of all sizes and hues daily collected and devoured by old women, which in Europe would have entailed death to the eater. Either the soil of this favoured valley, or the stomachs of these hungry beldames, must be of an uncommon order. On the green slopes, which are constantly grazed on by sheep and horned cattle, I gathered quantities of superior mushrooms, and observed numerous champillons (a French dainty) in the thickets on the hills. Morels or Truffles are produced, which are dried and sold in the chief markets." This writer mentions a Morel which sells at two annas per seer, and is called "Kungutch."

Honigberger says,† "Morels are imported from the hills into Lahore, but are very little used by the natives, and the English use them not medicinally but for culinary purposes. The Morels which are brought from the Hozara country are large." From this it would appear that another species of *Morchella*, quite different from the two alluded to, is found in this region.

Dr. Royle states in his Himalayan Botany that he only obtained specimens of common Morels, or *M. esculenta*, the "Kana Kuchoo" of the natives of India, which are every year brought down for sale from Kashmir, whence some fine specimens were procured in 1831 by the plant-collectors detached from the Saharunpore Botanic Garden. The recently-published 'Handbook of Punjab Products' states that large quantities of Morels are brought down from Kashmir to Umritsur.

In his 'Punjab Plants' Dr. Stewart refers the Kashmir Morel to *M. semilibera*, and gives as vernacular names, "Kana kach," "Kangach," "Kana bichu" and "Girch hatra," and for the plains, "Khumb." He adds, "This appears to be abundant in and near Kashmir, from which considerable quantities are, after drying, exported to the plains. I have only once noticed it growing fresh at 6000 feet, near Chumba. It is much eaten by natives, both fresh and dry, and is said to be preferred by them to the mushroom. Dried, it is a not unsatisfactory addition to a stew, even for an European taste. I have no proof that a Morel which is found abundantly in the desert about Jhung, etc., and is said to be got near Hoshiarpur, etc., is the same species. It is considered a great dainty by the natives, and relished by those Europeans who have tasted it."

* *Journal of Agri.-Hort. Society of India*, viii. p. 207.

† 'Thirty-five Years in the East,' p. 323.

Dr. Henderson has remarked that "in Shahpur and other districts where there is 'Kalr' in the soil, both Morels and mushrooms are abundant; the former in August and September, the latter in the end of the cold season, after heavy falls of rain." He adds that he has seen Morels half a pound in weight and mushrooms half a foot in diameter.

This is the sum of information that we have been able to collect respecting the Morels of Northern India; from which it appears that there is still one or more large species of Morel, different from the two here recorded.

The dried Morels are perforated through the pileus, and strung upon coarse twine at about half an inch distance apart. Each fungus is from an inch to an inch and a half in length, and from a quarter to half an inch or more in diameter. Usually the short stem is broken off and the pileus alone remains. The specimens consist of the two species intermixed, of which the following are the specific characters:—

MORCHELLA DELICIOSA, *Fries.*—Pileus subcylindrical, acute, adnate at the base; ribs longitudinal, firm, connected by transverse folds; stem even, short; asci cylindrical; sporidia elliptical, one and a half diameters in length.—Fr. Sys. Myc. ii. p. 8; Krombholz, t. 16. f. 17–19. "Kana kach," "Kan gach," "Kana kuchoo" of Lahore. (Fig. 1. Spore magnified 500 diameters.)

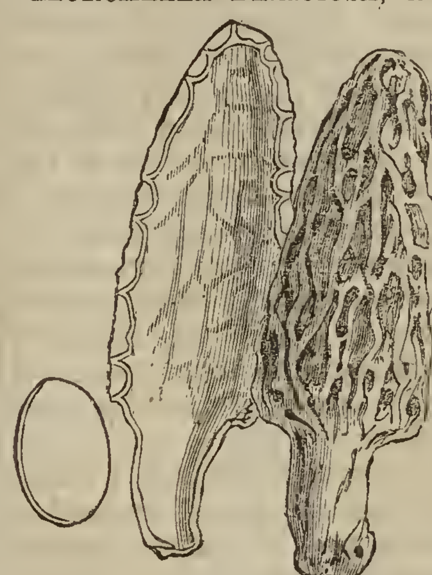

Fig. 1. *Morchella deliciosa.*

The total length of the dried specimens is an inch or an inch and a quarter, including the stem, which is about one-fourth of the entire length. It differs from *M. esculenta* in its much smaller size, different form of areolæ, longitudinal ribs and smaller sporidia, as well as other points. It is found in Java as well as Kashmir and Europe. The sporidia are ·0006 in. long by ·0004 in. broad.

MORCHELLA GIGASPORA, *Cooke.*—Pileus subcylindrical

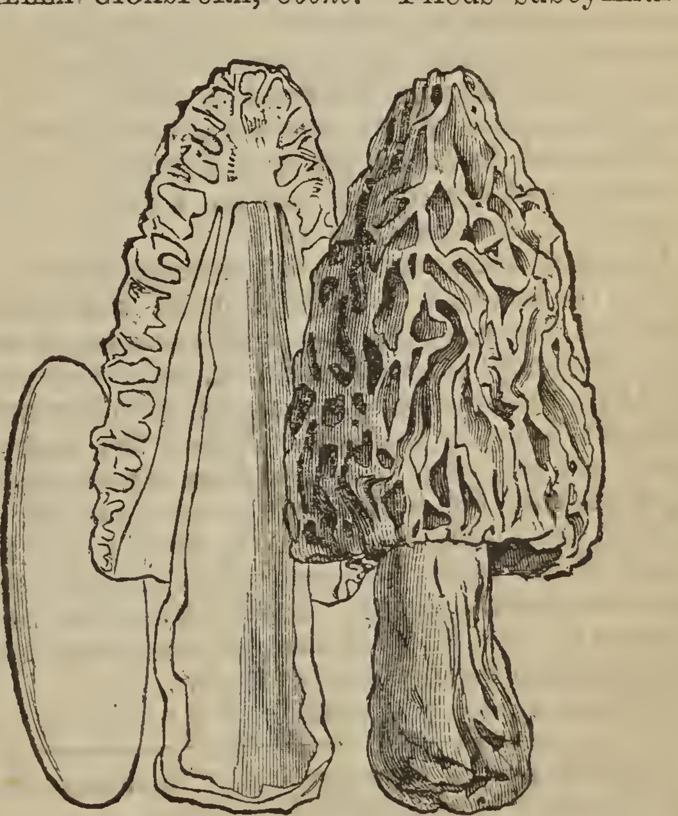

Fig. 2. *Morchella gigaspora.*

or somewhat conical, free at the base, and nearly to the top of the pileus; ribs somewhat longitudinal; connected by distant transverse folds, forming elongated, nearly linear pits; stem even, short; asci cylindrical; sporidia cylindrical, rounded at the ends, three diameters and upwards in length.—Trans. Bot. Soc. Edin. 1870. "Kana kach," "Kan gach," "Kana kuchoo" of Lahore. *M. semilibera* of Stewart's 'Punjab Plants.' (Fig. 2. Spore magnified 500 diameters.)

The total length of the dried specimens does not exceed an inch and a half. The exposed portion of the stem not more than half an inch in length, and the diameter of the pileus at the base, its broadest part, not more than three-quarters of an inch. Sporidia ·002 in. long by ·0006 in. broad.

This species is distinguished from all its congeners by the very large size of its sporidia. It is, perhaps, most closely related to *M. patula*, certainly not to *M. semilibera*. It is evidently the least common of the two Kashmerian species. What is the uncertain third or fourth species? We must wait and hope.

THE CITRATES OF THE U.S. PHARMACOPŒIA.*

BY C. LEWIS DIEHL.

The author of this paper is of opinion that almost every pharmacist who personally superintends the production of his preparations could, by noting the difficulties and phenomena which occur during the various processes, materially aid the progress of pharmacy. Many, from various causes, are prevented from doing this, and thus a great deal of valuable information is lost to the pharmaceutic world. Among the observant workers, a large class will be found who, from motives of gain, are prevented from publishing their observations; others are prevented by reason of excessive modesty, which causes them to view their experiences as a necessary result of their inexperience; and still others, who are not encumbered by this excess of modesty, are prevented by press of business or events beyond their control.

The design of the author is to draw attention to a number of preparations, most of which have come under his observation within the last twelve months. Some of them —officinals of the United States Pharmacopœia—he has found to admit of improvement, either in their general character or their methods of preparation; while for the unofficinals he has, in some cases, constructed formulæ deemed by him in accordance with the spirit of the national standard.

Citrate of Iron.—The Pharmacopœia directions for making this preparation are to take a convenient quantity of the solution of citrate of iron, evaporate it to the consistence of syrup, and spread it on glass, so that, on drying, the salt may be obtained in scales. The formula for the preparation of the solution is as follows:—

Citric acid, in coarse powder, 5 troy oz. 360 grs.
Solution of tersulphate of iron, 1 pint.
Water of ammonia,
Distilled water, each, a sufficient quantity.

Dilute the solution of tersulphate of iron with 2 pints of distilled water, add to it a slight excess of ammonia, while constantly stirring, then transfer the precipitate formed to a muslin strainer, and wash it with water till the washings are nearly tasteless. When the precipitate is drained, put half of it in a porcelain capsule on a water-bath, heated to 150°, add the citric acid, and stir the mixture until the precipitate is nearly dissolved. Then add so much of the reserved precipitate as may be necessary fully to saturate the acid. Lastly, filter the liquid and evaporate it, at a temperature not exceeding 150°, until it is reduced to the measure of a pint.

To obtain a good preparation, it is advisable to employ an excess of hydrated sesquioxide of iron. If the process is conducted in conformity with the directions of the Pharmacopœia, and the ingredients are in the condition intended, a satisfactory article may be prepared; but strict adherence to the formula is necessary to ensure uniformly a successful product. One principal difficulty exists practically in maintaining the temperature of the mixture of citric acid and hydrated sesquioxide of iron without exceeding 150° F. Constant attention to ensure this end is required, for by an elevation of the temperature above 150° F., a portion of the hydrated sesquioxide is molecularly changed and becomes insoluble, rendering it difficult to determine whether or not the solution has become completely saturated with iron. This difficulty has been overcome by precipitating about one-eighth more of hydrated sesquioxide of iron than is required by the Pharmacopœia, and adding to about three-fourths of the magma the citric acid prescribed. By occasional stirring, a clear solution is obtained, which should be gently heated by a water-bath: fractional parts of the remaining magma should then be added, until it is no longer dissolved, each portion being allowed to dissolve perfectly before adding the next.

During the evaporation of a quantity, however, it has been observed that, although the ingredients had been in proper condition and the manipulation correct, the solution became uncommonly dense before it had been reduced to the proper measure; and that on diluting it with water, a turbid mixture was produced. It was inferred that a portion of the uncombined hydrated sesquioxide of iron had been dissolved. This was apparently substantiated by the addition of a relatively small portion of citric acid, which rendered the solution quite limpid and miscible with water without the production of turbidity. The conclusion drawn is that when a warm solution of citrate of iron exercises a prolonged action upon recently precipitated hydrated sesquioxide of iron, it has the property of dissolving a portion of the hydrated base.

The preparation of scales of citrate of iron is not at all difficult, even if all the citric acid has not been saturated.

Ammonio-citrate of Iron.—In the preparation of this salt, according to the U. S. Pharmacopœia, 1 pint of the solution of citrate of iron is mixed with 6 fluid ounces of water of ammonia; the mixture is then evaporated in the same manner as the citrate of iron, care being taken that the temperature should not exceed 150°. The result should be in garnet-red translucent scales, of a slightly ferruginous taste, readily and wholly soluble in water. The solution causes no change in the colour of litmus or turmeric, and does not yield a precipitate with ferrocyanide of potassium. Solution of potassa produces with it a precipitate of sesquioxide of iron with the evolution of ammonia. To prepare it successfully, the complete saturation of the citric acid with hydrated sesquioxide is quite necessary. If this be not the case, the resulting salt is removed from the glass with difficulty, neither can it be obtained in handsome scales, being generally of a muddy colour. By reserving about one-sixteenth of the solution of citrate of iron, adding to the main bulk of the solution aqua ammoniæ until in slight excess, and then the reserved portion, a salt has been obtained which was found to be rapidly soluble in water, readily removed from the glass plates, and less prone to deliquescence than the compound completely saturated with ammonia. The direction of the Pharmacopœia to use a given measure of aqua ammoniæ is objectionable, on account of the variable strength of that article as found in the shops, or obtained from the manufacturer; for while it is a simple matter for the skilled operator to determine its strength expeditiously, it requires more time than pharmacists not skilled or prepared for these determinations are willing to devote to it.

(*To be continued.*)

* Abstract from a paper entitled "Pharmaceutic Items," in the *Chicago Pharmacist* for September.

Poisoning by Yew Berries.—A case of poisoning by yew berries (*Taxus baccata*) is reported in the *Medical Times and Gazette*. In the afternoon of the 24th of September a patient was found dead in the ward of the Sussex County Asylum. In the morning he had eaten a hearty lunch and returned to work; at dinner he complained of pain in the epigastrium, and vomited part of his food. As he was a very greedy man, eating all he could get hold of, this was not considered remarkable. At five o'clock, when the attendant went to rouse him to bathe, he was sitting in a chair quite dead. Suspicion of poison was awakened by the presence of yew berries in a motion passed into his clothes. Upon inquiry it was found that he had eaten some about ten o'clock. Upon a *post-mortem* examination berries were found in the intestines. The medical gentleman who reports the case asserts that poisoning by yew berries is a very rare occurrence, many persons being able to eat them with impunity. He suggests that it would be interesting to know to what extent these berries are really poisonous, and, if the narcotico-acrid properties reside solely in the stones, whether the active principles might not be separated and employed in medicine in the place of more expensive drugs.

The *Suffolk Chronicle* of Tuesday last reports what may prove to be another case of poisoning by yew berries, which has occurred at Sudbury. Five children, after playing in the cemetery with some berries, went home ill, complaining of headache and sickness. One of them, five years old, died the next day. Some berries were found, which proved to belong to the wild Guelder-rose. The only other berries in the cemetery were those of the yew. The children all deny having eaten any; but one of them says that the deceased was playing with a berry, which she squeezed, causing the juice to squirt into her eye and mouth, and making her cry because of the smart. No seeds were detected in the excreta. The inquest was adjourned, that a *post-mortem* examination might be made.

Death through an Overdose of Chlorodyne.—An inquest was held in Liverpool, on Tuesday last, upon the body of Mr. Glover, a cotton-broker. Evidence was given that on the previous Thursday the deceased purchased five drams of chlorodyne from Mr. Buxton, chemist, 78, Kensington. The bottle containing it was labelled, and the dose was stated on the label to be ten drops. He told the chemist he was in the habit of taking half a spoonful. He afterwards purchased half an ounce of laudanum and two ounces of castor oil from another chemist. The next morning the servant, finding that she could not rouse him, sent for medical assistance. Dr. Prichard and Dr. Parker attended, but except for a few minutes, when he said that he did not intend to take so much, the patient did not recover consciousness, and he died the same evening. The laudanum and castor oil he had purchased were not found. Only about one dram and a half of the chlorodyne remained. The jury returned an open verdict, expressing an opinion that the deceased had taken an overdose of chlorodyne.—*Liverpool Mercury.*

Poisoning by Croton Oil.—At Sydney, a child thirteen months old, has been poisoned by a liniment containing 1 drachm of croton oil to 15 of soap liniment. It is estimated that the dose was two minims and a half, which proved fatal in six hours. The child's father, who administered it, could neither read nor write.—*Medical Times and Gazette.*

Poisoning by Oil of Vitriol.—On Saturday, October 1, an inquiry was instituted relative to the death of Mr. Robert Chambers, an oilman, residing in Hunter Street, Brunswick Square. Evidence was given that the deceased was a highly nervous man, and had lately been under the delusion that he was liable to be hanged for an accident which had happened in his shop. On the previous Thursday he drew off a quantity of oil of vitriol from a carboy in the shop, and, after saying that the police should not hang him, drank about a gill of it. The jury returned a verdict of "Suicide while in an unsound state of mind."

Death from Chloroform in Japan.—Considerable sensation has been created at Yokohama in consequence of a death following the administration of chloroform. After a protracted inquiry a coroner's jury returned a verdict of "Death from the effect of chloroform administered without proper degree of care." The surgeon who administered the chloroform (Dr. Dalliston) has, in consequence, been committed for trial, but liberated on bail in the sum of 5000 dollars. Public attention in Japan and China has been called to this case by Dr. Edward Henderson, Municipal Medical Officer and Health Officer at Shanghai, who criticizes the various statements made by the witnesses in a masterly manner. —*Medical Times and Gazette.*

Statue to the late Professor Graham, F.R.S.—It has been decided by the friends and admirers of the late Professor Graham to erect a statue of him at Glasgow. Leave has been asked and obtained from the Town Council for placing it at the south-east corner of George Square. The sculptor is Mr. William Brodie, of Edinburgh. The pedestal will be of Aberdeen granite, and the figure of bronze, corresponding with the figure of Watt at the south-west corner.

New Sulphur Deposit.—A new source of supply of sulphur is announced in the *New York Times*. It is in the island of Saba, one of the Dutch West Indies, situated about 110 miles south-east from St. Thomas and 40 miles south-west from St. Martha. The island is of volcanic origin, about 11 miles in circumference, and at its highest point about 2800 feet above the sea-level. Though a Dutch possession, the language spoken by its 2000 inhabitants is chiefly English. The sulphur deposit was discovered by a person from New York, who, noticing indications of sulphur-ore, quarried, with the help of the natives, two sloop loads, which he took to New York, and submitted for analysis. The report of the chemists was to the effect that while the Sicily ores yield only about 30 per cent. of brimstone for the ore consumed, the Saba ore yields an average of over 60 per cent. Adding to this the fact that the island is only about 1500 miles from New York, it will be seen that this is an important discovery, and it will not be wondered at that steps have been taken to secure leases of the best tracts on the island.

Scarlet Fever.—Dr. Renfrew, of Glasgow, recommends that in scarlet fever a medicine consisting of a mixture of tincture of steel and chlorate of potash. This mixture, he says, contains chlorine, which destroys the poison; muriatic acid, which supplies an acid wanted in the blood; iron, to improve the impaired red disks and to assist in forming new ones; and chlorate of potash to supply oxygen, to oxidize the disintegrated matters floating in the blood.

Permanganate of Potash.—Dr. H. S. Thorne, of Chicago, reports* that he has treated oxaluria and dyspepsia successfully with grain-doses of permanganate of potash made with bread into pills, three of which were to be taken daily for ten days. On examination of the urine after a few days not a crystal of oxalate of lime could be seen. Dr. Rose, of Michigan University, had previously prescribed it in the following form:—

℞. Permanganate of Potash gr. viij
Water ℥ij.

M. sig. One teaspoonful to be given three times a day.

It should not be given except on an empty stomach, as it is decomposed in contact with organic matter, yielding its oxygen to any substance, simple or compound, that will receive it.—*Druggists' Circular.*

* *Michigan University Medical Journal.*

CONVENTION OF DELEGATES FROM COLLEGES OF PHARMACY.

In compliance with a request of the Maryland College of Pharmacy, a meeting of delegates from the various colleges was held on the evenings of September 14th and 15th, at the Hall of the Maryland College of Pharmacy.

The object was to confer upon the subject of pharmaceutical education, and a uniform standard for the graduations of students.

Joseph Roberts and Prof. J. Faris Moore, both of Baltimore, were duly elected President and Secretary. Delegates were in attendance from the Maryland, New York, Philadelphia, Massachusetts and Chicago Colleges, also from the California Pharmaceutical Association and New Jersey Pharmaceutical Association.

The following recommendatory resolutions were adopted:—

1. That, in the opinion of this meeting, more attention to the preliminary education of those who propose to enter the business of pharmaceutists is needed, and it is earnestly recommended to the colleges and societies of pharmacy to urge their members and the profession generally to give greater care to this subject in taking apprentices.
2. That a term of four years' service in a dispensing drug store be recommended to be exacted from students in pharmacy before coming up for examination.
3. Apprentices not to be taken under sixteen years of age, and shall be twenty-one years of age before being entitled to receive their diplomas.
4. The branches to be taught in colleges of pharmacy should at least include lectures on general chemistry, elementary botany, materia medica, and the general facts and principles of pharmacy; and, when practicable, opportunity should be provided for general and analytical chemistry.
5. Whatever method of examination be adopted should include questions both oral and written, and that particularly a familiarity with the physical properties of specimens should be insisted on.
6. Diplomas should not be recognized as evidence of qualification, unless based on four years' service in a dispensing shop.
7. Each college of pharmacy is requested to take action on these resolutions, and report next year.

This organization of delegates was, on vote, made permanent, and it is to meet annually, at the same time and place as the American Pharmaceutical Association.

The meeting then adjourned.

IRISH SCIENTIFIC SOCIETIES.

As the time draws nigh for the *savoir-faire* of the scientific world, it may not be uninteresting to give a list of the principal scientific bodies in Ireland, most of which are comparatively unknown in England, although of considerable importance as publishing Societies. The oldest, most important, and best known is the Royal Irish Academy, the members of which luxuriate in the letters M.R.I.A. after their names. This Society has for the last few years been rather monopolized by the archæologist. That important branch of the Academy has perhaps received an undue development, to the detriment of pure science, from the beautiful archæological museum and antiquarian library which it possesses. The appointment of the last President, Professor Jellett, whose researches in connection with polarized light are well known, has tended, however, to neutralize this propensity. The Academy has the distribution of a Government grant of £200 per annum, in aid of original research, which it distributes in the most careful and conscientious spirit. The Academy is devoted to pure science; technical papers are not received. It publishes both "Transactions" and "Proceedings." The Royal Dublin Society is taken up chiefly with applied science. It gives annually a series of popular lectures, similar in character to those given by the Royal Institution. The Society receives considerable aid from Government, and it has charge of the fine botanic gardens, natural history museum, agricultural museum, and national gallery of art. The curator of the minerals is Dr. Emerson Reynolds, a chemist of considerable standing. This Society has also a very fine library, and publishes its "Proceedings."

The "Royal Geological Society of Ireland" is also a chartered Society, and it also publishes its proceedings.

The Zoological Society possess a fine collection of animals at their gardens in the Phœnix Park.

The other Societies (non-publishing) are the Natural History Society, and the "Chemical," "Scientific," and "Microscopic" Clubs. The last-named publishes its minutes, however, in one of the journals of microscopic science. It records the work done by some of our best microscopists, viz. William Archer, Dr. Percival Wright, Eugean O'Meara, etc.

Amount of Active Substance in Conium maculatum.—In an address recently delivered by Professor von Schroff to the Society of Physicians in Vienna, he stated that his experiments have led him to the following conclusions:—

1. The unripe fruit of one-year conium plants contains the smallest amount of conia.
2. The unripe fruit of the two-year plants contains most conia, especially when the development of the fruit is advanced and it is near ripening.
3. The perfectly ripe fruit, which is produced only by the two-years plant, stands in regard to its efficacy between those mentioned above.—*Wochenblattes der K. K. Gesellschaft der Aerzte in Wien*, 1870, no. 1.

Test for Butyric Acid in Glycerine.—Perutz states that when glycerine is gently heated with alcohol and sulphuric acid, butyric ether is formed if the glycerine contains butyric acid, and it may be recognized by its characteristic odour.—*Journ. Chim. Méd.*

Syrup of Ipecacuanha.—The following formula is sent to the *Chicago Pharmacist* by Mr. L. E. Sale, of Huntsville, Alabama, who says that it will give a good syrup of ipecacuanha, which will keep without deterioration:—

R. Fluid Extract of Ipecac. (U. S. P.) f ℥xvijss
Granulated Sugar ℥xxxij
Water f xvj.

Pour the fluid extract of ipecacuanha on the sugar in a shallow evaporating vessel, and set aside in a warm place to dry; when dry add the water, dissolve the sugar with aid of gentle heat and strain.

Application for Ringworm.—Spirit of turpentine brushed over the surface has been recommended as a cure for the common ringworm.—*New York Druggists' Circular.*

Palatable Hydrate of Chloral.—Hydrate of chloral ℈ss; chloroform water ʒij; syrup of oranges or tolu ʒi–ij; tincture of ginger 6 to 12 drops; water to $1\frac{1}{2}$ oz. The chloroform water is prepared by dissolving half a fluid ounce of chloroform in a gallon of water. This seems to intensify the action of the chloral hydrate, and covers the acrid taste.—*Richmond amd Louisville Medical Journal.*

Delicate Colour-Test for the Detection of Strychnia.—Mr. T. Wenzell, of San Francisco, states that in experimenting for the discovery of the presence of minute portions of this alkaloid, he has found that a solution of 1 grain of permanganate of potash in 2000 grains of sulphuric acid, to be the best test for the purpose. In delicacy of reaction, brilliancy and duration of colours, it is greatly superior to the bichromate of potassa and sulphuric acid test.—*American Journal of Pharmacy.*

The Pharmaceutical Journal.

SATURDAY, OCTOBER 29, 1870.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes to be endorsed "Pharm. Journ."*

THE EFFECTS OF DRUGS.

For some thousands of years the question, How medicine cures disease? has rather afforded scope for the exercise of fancy than it has admitted of being considered by the aid of precise observation and direct experiment. Even at the present day we have scarcely any acquaintance with the rational connection doubtless existing between the individual nature of a medicinal agent and those physiological effects which we know it produces. Our knowledge in this respect is almost entirely empirical, and it is only of late years that some glimmer of light has been thrown upon this obscure though important subject. Dr. B. W. Richardson, one of the foremost pioneers in this field, has for some years devoted his attention to studying the physiological action of various definite substances, and he has already obtained results of great interest, which he makes known in occasional courses of lectures. On another page we give some account of an introduction to such a course. It may be asked by some acutely practical people, What has this to do with Pharmacy? Is it not rather mere scientific speculation? We do not think so, and with all regard for the practical requirements of trade, we believe that subjects such as those discussed by Dr. Richardson ought to receive the careful consideration of pharmacists.

We believe also that their exposition rightly finds a place in this Journal, inasmuch as it is the official organ of the body which is charged with the duty of raising the standard of pharmaceutical competence. For that reason it should be a leader of opinion as well as of practice, and since the art of healing is so capable of expansion, its handmaiden pharmacy should not refuse to look beyond the narrow boundaries of the present, nor confine her attention solely to the range of past experience.

A few months ago Chloral was a substance altogether outside the pale of pharmacy; the mention of it in a pharmaceutical journal might have been censured as unpractical; but since then it has become perhaps one of the most important items of the materia medica. Who can say which of the substances now known only to theoretical chemistry, may be the next to take place with opium and bark and calomel as a daily necessity for the physician, as a material to be used hourly by the pharmacist?

The question as to whether quinine exists in plants other than the *Cinchonæ* has often been raised, and it has just received another answer in the negative. The bark of the *Hymenodictyon excelsum*, a large forest tree, has long been in repute in India as a valuable native febrifuge, its properties being due, it was thought, to the presence of quinine. It was, moreover, formerly considered one of the *Cinchonæ*, and known under the name of *C. excelsa*. Mr. Broughton, the Government Quinologist at the Ootakamund Plantations, has recently examined the fresh bark of this tree, and finds that the bitter taste is owing to the presence of *æsculin*, the principle found also in the bark of the horse-chestnut-tree. The bark when dry becomes almost tasteless, owing to the *æsculin* coming in contact with decaying organic matter, and being changed into *æsculetin*. Curiously enough, both these barks, which contain *æsculin*, have been recommended for the same purpose. As, however, *æsculin* is much dearer, less plentiful, and less efficacious than quinine, it is not likely to come into use in India. We may also mention that a very interesting tree (the bark of which is also said to contain quinine) grows in Central Africa, forming large forests; it is used largely by the natives in cases of fever. Dr. Welwitsch, who discovered, and figured it in his 'Sertum Angolense,' under the name of *Corinanthe paniculata*, is endeavouring to obtain a supply of the bark for chemical analysis and trial. The tree is remarkably cinchonaceous in habit.

It appears from a recent article by Dr. Pott in the *Zeitschrift für die Gesammten Naturwissenschaften* that extracts of flesh and fish have been prepared in Java and Sumatra for several centuries. The raw material, after being boiled and comminuted, is placed in a press, the expressed juice being exposed to a moderate heat till it assumes the consistence of syrup. The extracts so prepared all possess an intensely saline taste, arising from the accumulation of organic salts caused by their great concentration. Upon analysis they were found to contain mere traces of gelatine and to give no indication of albumen. One sample contained 20·9 water, 16·4 ash. The dry extract contained 9·54 nitrogen.

CHEMISTS AND DRUGGISTS' FUND ON BEHALF OF THE SICK AND WOUNDED IN THE PRESENT WAR.

Since the publication of the last list of subscribers some further contributions have been received. We propose closing the Fund on the 30th November next, and shall then give a final list.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

October 19*th*, 1870.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Edwards, Gale, Garle, Hanbury, Haselden, Ince and Southall.

Dr. Greenhow was also present on behalf of the Privy Council.

Twenty-eight Candidates were examined,—four Major and twenty-four Minor; the following passed:—

MAJOR (registered as Pharmaceutical Chemists).

*Butterworth, Albert ....Sowerby.
Strickland, George Hodgson ..Darlington.
Barrett, Frederick John ......Fakenham.
Joule, John Samuel ....Buxton.

MINOR (registered as Chemists and Druggists).

*Ward, Edwin ....Cheltenham.
*Marshall, Eli................London.
*Newman, Arthur Joshua ....High Wycombe.
*Wright, Joseph ....Knutsford.
*Nicholson, Edward ....Manchester.
Chandler, John..............Nottingham.
Thomas, John Darby Dermott. Clifton.
Foster, Henry Pibworth......Portsmouth.
Udale, Daniel ....Congleton.
Robinson, Joseph ....Chester-le-Street.
Thomas, Thomas Rees........Llandovery.
Darby, Samuel Aldred........Reading.
Bradford, Cordley ....Spalding.
Salmon, Thomas ....Pontypool.
Little, Arthur Nicholas ......Bristol.
Eden, Thomas ....Dublin.
Marshall, Austen ....Stratford-on-Avon.
Springall, John Barcham ....Norwich.
Part, Edward James ....Dover.

The above names are arranged in order of merit.

FIRST, OR PRELIMINARY EXAMINATION.

The Certificate of Examination of the undermentioned by the University of Cambridge was accepted in lieu of the Preliminary Examination.

Folkard, Montague ....Colchester.

October 20*th*, 1870.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Gale, Garle, Hanbury, Haselden, Ince and Southall.

Dr. Greenhow was also present on behalf of the Privy Council.

Eighteen Candidates were examined; the following passed:—

MINOR (registered as Chemists and Druggists).

*Lyddon, Richard ....London.
*Sweetman, Robert ....Warwick.
*Roberts, Joseph Elliott ......Leeds.
*Hardy, Robert ....Boston.
Loveless, Edward William....Bath.
Elliott, Thomas ....Clay Cross.
Melhuish, Thomas Boucher ..London.
Francis, George Bult ....Diss.
Walker, John Sydenham ....Manchester.
Slater, Jonathan ....Keswick.
Rieveley, Charles ....Birkenhead.
Grinstead, John ....Chichester.
Goodman, Daniel Henry......Bath.

The above names are arranged in order of merit.

* Passed with honours.

FIRST, OR PRELIMINARY EXAMINATION.

The Certificate of Examination of the undermentioned by the Incorporated Law Society was accepted in lieu of the Preliminary Examination.

Riley, Charles Reynolds ......South Lambeth.

FIRST OR PRELIMINARY EXAMINATION.

October 3*rd*, 1870.

The following is a list of towns in which Examinations were held, with the number of candidates annexed:—

(Omitted last week.)

Aberdeen	18	Lymington	1
Abingdon	1	Manchester	11
Ashton-under-Lyne	3	Newcastle-on-Tyne	4
Banbury	2	Newcastle-un.-Lyme	1
Barnstaple	4	Newport (I. of W.)	1
Berwick	1	Newport (Mon.)	1
Birmingham	4	Northampton	4
Blackburn	1	Norwich	5
Boston	1	Nottingham	1
Bradford	1	Peterborough	1
Brighton	1	Preston	4
Bristol	8	Plymouth	2
Buckingham	1	Portsmouth	2
Bury St. Edmund's	1	Ripon	1
Cambridge	2	Rochdale	2
Cardigan	2	Rochester	1
Chesterfield	1	Ryde	1
Cockermouth	1	Sanquhar	1
Colchester	2	Scarborough	1
Darlington	1	Shaftesbury	1
Devizes	1	Sheffield	3
Diss	1	Shrewsbury	1
Doncaster	3	Southport	1
Dover	2	South Shields	1
Dudley	2	Stafford	2
Exeter	1	Stockport	2
Glasgow	1	Stourbridge	1
Grantham	1	Swansea	1
Guildford	1	St. Alban's	1
Halifax	3	Taunton	1
Hartlepool	1	Tenterden	2
Hastings	1	Tewkesbury	1
Hereford	3	Thirsk	2
Horncastle	2	Torquay	1
Huddersfield	2	Tunbridge Wells	2
Hull	2	Ulverstone	2
Ipswich	2	Wakefield	2
Leamington	1	Walsall	1
Leeds	10	Warrington	1
Leicester	3	Whitehaven	3
Leighton Buzzard	2	Wigan	1
Lewes	1	Winchester	2
Lincoln	2	Yarmouth, Great	2
Liverpool	7	York	3

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The following programme of classes to be held in connection with the school of pharmacy of this Association during the session 1870–71 has been issued.

Chemistry.—A course of lectures will be delivered by Edward Davies, F.C.S., Lecturer on Experimental Physics in Queen's College, on inorganic and organic chemistry, preparation of chemical products used in pharmacy, qualitative and volumetric analysis. Each lecture will be followed by questioning upon the previous lecture, and illustrated with experiments. The course will commence on Friday, November 4th, from 8 to 9.30 P.M., and will be continued weekly until the end of April at the laboratory, 17, Back Colquitt Street. Fee for the course, one guinea. Pharmaceutical students will be received at the laboratory for the study of practical chemistry at any hour between 9 and 5 o'clock. Fee, one guinea and a half for three months, two hours per week.

Materia Medica.—A course of lectures will be delivered by W. Carter, M.B., B.Sc., F.R.C.S.I., Lecturer on Botany and Zoology in Queen's College, having special reference to the requirements of the examinations under the Pharmacy Act, and will be illustrated by specimens from the museum. The course will include the recognition of drugs, properties of drugs, adulterations of drugs, plants and animals yielding medicinal substances, etc. The lectures will be delivered in the Museum, Royal Institution, on Tuesday evenings, at 8.15, from November 1 to the end of March, 1871. Fee, one guinea.

Botany.—This course, by Dr. Carter, will include (1) Structural and Physiological Botany—cells and vessels, roots, stems, leaves, flowers and fruit, functions of the organs of vegetation and reproduction; (2) Systematic Botany and Demonstrations on Plants—general classification, Linnean and natural systems, distinctive characters of the British Natural Orders. Attention will be paid to the recognition of plants by dried and fresh specimens and plates. The class will be held on Tuesday evenings, at 8.15, from April 4th until the end of July, 1871. Fee, one guinea.

Further particulars may be obtained at the School of Pharmacy, 17, Back Colquitt Street, or of Mr. Edward Davies, Hon. Sec.

THE LINCOLN CHEMISTS' ASSOCIATION.

The First Meeting of the Lincoln Chemists' Association for the session 1870–71 was held on Tuesday, October 18th. Nearly all the members were present, and the following officers were elected:—*President:* Mr. W. Harrison. *Vice-President:* Mr. C. Clayton. *Hon. Secretary:* Mr. C. F. Gadd. *Councillors:* Mr. F. Mack, Mr. J. Wingate, Mr. W. Cox.

Several new members were elected, the accounts audited, and the funds were found to be in a prosperous condition.

This Association has sent several members to Bloomsbury Square for the different examinations, and it is to be hoped that its sphere of usefulness may greatly extend.

HULL CHEMISTS' ASSOCIATION.

The Second Annual Meeting of this Association took place at the Cross Keys Hotel, on Tuesday, October 18th, to pass the accounts and elect officers for the ensuing year. Mr. Baynes was re-elected President, Mr. A. Smith Vice-President, and Mr. Bell, Secretary.

Through the able management and liberality in time and money of these gentlemen, supported by an active Committee, this Association was, during the session 1869–70, not only self-supporting, but enabled to provide interesting and instructive lectures on botany, pharmacy and materia medica to a good number of the apprentices of Hull. The lecturers give a very satisfactory report of the attention, good conduct and intelligence of their pupils.

It is hoped that, in future, all the chemists in Hull, and especially those who have apprentices, will take more interest in this movement by attending regularly the monthly meetings, and inducing the youths under their care to attend the lectures.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Wednesday, September 14th.

The Conference reassembled at 2 P.M.

The PRESIDENT said it gave him great pleasure to introduce to the meeting one of their oldest members, who had often contributed valuable papers to their Proceedings, but who resided at so great a distance that they had not had his personal presence before. He alluded to Mr. Tichborne, Chemist to the Apothecaries' Hall of Ireland, who had come from Dublin to attend the meeting.

ON SULPHITE OF ZINC.

BY CHARLES R. C. TICHBORNE, F.C.S., M.R.I.A.,
Chemist to the Apothecaries' Hall, Ireland, etc.

The interest that attaches to the sulphites from a pharmaceutical point of view is increasing every day, and the following notice of the chemical and general properties of one of them will, I have no doubt, be of use. The sulphites are gradually creeping into favour with the medical profession. No doubt this is due more or less to the development of the germ theories and kindred views, for as regards the antiseptic properties of the sulphites there are no two opinions. The antiseptic power of the anhydride is perpetuated through all its salts, more or less modified by its solubility or decomposibility.

Having had occasion to prepare the sulphite of zinc, I was impressed with an opinion that it was one of those compounds that bid fair to become practically useful, and was therefore worthy of careful investigation.

Preparation.—Zinc being bivalent, 6 ounces of sulphate of zinc and $5\frac{1}{4}$ ounces of sulphite of sodium were dissolved respectively in 6 and 10 ounces of distilled water, and poured together whilst hot. If necessary, the solutions should be filtered before mixing. The quantities are calculated after the following equation:—

$$Zn''SO_4;\ 7H_2O + Na_2SO_3;\ 7H_2O$$
$$= Zn''SO_3 + Na_2SO_4 + 14H_2O.$$

The salt is, as will be seen further on, practically insoluble, and this method of preparation is much better than dissolving carbonate of zinc in sulphurous acid. The salt does not immediately form whilst the mixed solutions are hot, but as they slowly cool it is deposited in needle-like prisms; these crystals are, when once formed, extremely insoluble in hot or cold water. As regards its purification, the mode simply consists in well stirring during the cooling, so as to get microscopic crystals. These are thrown upon a filter, and well washed with distilled water as long as the washings give any decided precipitate with chloride of barium in the presence of hydrochloric acid. The washing, however, always gives a minute precipitate, but the sulphate will not practically amount to an impurity of any importance, and it is this reaction that has evidently given the idea of a constant oxidation going on which is unlimited as regards its extent. The salt, when properly washed, is dried at 100° C. The yield is about 43.

Composition.—The following formulæ have been given by different authorities as the composition of this salt:—

Fordos and others, $ZnSO_3 2H_2O$.
Rammelsberg, $2(ZnSO_3)5H_2O$.

There was evidently some discrepancy here, and it was therefore considered necessary to determine the actual composition.

The sulphite was finely powdered and dried at 100° C. 1·237 gramme of the salt so prepared required 2090 grain-measures of the B. P. volumetric solution of iodine to colour the solution blue, mucilage of starch and a few drops of acid having been previously added. This gave

35·01 per cent. of anhydride as being present. Now, theory requires for 2 molecules of water 35·35 per cent., therefore this is rather low, which is no doubt due to a trace of sulphate of zinc.

Air-dried sulphite, however, only consumed 2985 grain-measures of the decinormal solution, the weight taken being 1·918, which corresponds with the terhydrated salt. Thus, theory $Zn''SO_3; 3H_2O$ would give 32·16 anhydride, practice gives 32·39. Sulphite which had been finely powdered, and submitted to the prolonged action of sulphuric acid under a bell-glass, gave a similar result. We therefore see that the discrepancy observed in different authorities is easily accounted for; the composition of the salt varies according to the method by which it is dried. It is as follows:—

Dried in the air, or over sulphuric acid, $Zn''SO_3; 3H_2O$.
Dried at 100° C. . . . . $Zn''SO_3; 2H_2O$.

M. Fordos' formula is correct as long as the salt is dried at 100° C., but not unless this is the case; whilst Rammelsberg had evidently been operating upon a salt one molecule of water in which had been partially dissociated by heat. The terhydrated salt may be viewed as the normal compound, as it seems perfectly stable under ordinary circumstances.

General Properties and Stability.—Sulphite of zinc is very insoluble in water at the ordinary temperature. 500 grains of a saturated solution consumed 82·5 measures of the iodine solution, which represented ·164 per cent. of the hydrated salt. It crystallizes in semitransparent prismatic crystals, which are pellucid on recrystallization from sulphurous acid. It decolorizes a solution of iodine without being acidulated. One extraordinary property of the sulphite of zinc is its ready solubility in an excess of sulphurous acid. If washed, sulphurous anhydride is passed for some considerable time through 1 part of the salt suspended in about 3½ parts of water. A solution is readily obtained containing about 20 per cent. of sulphite, and having a specific gravity sometimes as high as 1·240 to 1·245 at 15° C. 15 per cent. easily dissolves in the ordinary sulphurous acid of the Pharmacopœia.

When dry, neither the di- nor tri-hydrate suffers oxidation on exposure to the air. They are, contrary to what is stated in the books, perfectly stable salts; however, like most of the sulphites when in solution, they suffer a gradual but slow oxidation; and thus its antiseptic power. Thus a saturated solution of the sulphite when tested with the volumetric solution gave the following results,—in each experiment 500 grains were taken:—

Day of the Month.	Grain Measures of Vol. Solution.
8th	82·5
9th	66·
10th	50·
11th	25·
12th	10·

On the 15th the sulphurous acid had become converted into sulphuric. The saturated acid solution was diluted with water, and tried in a similar manner. The oxidation was not nearly so rapid, and at the expiration of fifteen days it had not lost ten per cent. of its strength. The *saturated* acid solution suffers very little change.

Uses in Pharmacy.—The composition of sulphite of zinc would naturally point to its therapeutic uses. It might be viewed as a desiccant, antiseptic, astringent and caustic (we are now speaking of its external applications). As regards the last its insolubility renders it so mild that it could be hardly considered under the head of a caustic at all, and more nearly approaches the desiccant, oxide of zinc, in this respect. Its antiseptic properties, like all the readily oxidizable sulphites, are well marked; nor is it, indeed, necessary for it to come in contact with acid secretions for its power, in this respect, to come into play. It has been tried in some of the hospitals, and well spoken of in many cases.*

The following formulæ may be suggested:—

Sulphite of Zinc Lotion.

Take of
Finely powdered sulphite of zinc 20 grains.
Distilled water ℥xx.

Digest twenty-four hours, occasionally shaking, and then decant the clear solution for use. This lotion should be made as required.

This lotion will contain about ½ grain to the fluid ounce, and might be advantageously used as a cold-water dressing for wounds.

Acid Sulphite of Zinc Lotion.

Take of
Powdered sulphite of zinc 8 grains.
Sulphurous acid B. P. ʒi fluid.
Mix, and when dissolved add
Distilled water ℥i ʒvij.

Sulphite of Zinc Ointment.

Take of
Prepared lard ʒvij.
Powdered sulphite of zinc dried at 100° C } ʒi.

Compound Sulphite of Zinc Ointment.

Take of
Lard ℥iiiss.
Oxide of zinc ʒiij.
Sulphite of zinc ʒi.

The above ointment has been found most useful as a mild desiccant and antiseptic ointment in skin diseases.

The President said the sulphites were coming into very general use, especially the lime, potash and soda sulphites; and that one large mode of consumption was for brewing purposes, for making weak beers keep from turning sour in summer weather.

Mr. Cottrill (Shepton Mallet) said that in Somersetshire the use of bisulphite of lime for cider was very extensive.

Mr. Tichborne stated that bisulphite of lime was much used in the porter breweries of Dublin, and its preservative effect was undoubted. However, it was open to the objection that some of the nitrogenous compounds of the porter united with the liberated sulphur, and when this porter was bottled a fetid gas was developed. This difficulty did not exist in the case of ale.

Professor Attfield remarked that the discussion of the paper by Mr. Tichborne had somewhat drifted into one of its bearings only, but beyond this they must recognize that the paper represented a large amount of able and laborious work, for which they were greatly indebted to the author.

The Flax Lints of Commerce under the Microscope.

BY THOMAS GREENISH, F.R.M.S.

The introduction of machine-made lint, which dates from about 1847, has to a very great extent superseded

---

* A medical friend, of considerable hospital experience, writes as follows:—"A lotion of the sulphite of zinc proved highly beneficial in a case of gonorrhœa, rapidly lessening the discharge, and causing but slight pain. From the rapidity of the change in the character of the discharge after each injection, it would appear as though it acted not only as an astringent, but also as an antiseptic, causing decomposition in the pus, with which it came in contact; and subsequently in its chronic stage an injection, formed of 1 grain of sulphite to the ℥i, held in solution by a sufficient quantity of sulphurous acid, caused a complete cure, without pain or inconvenience. It requires further experience before pronouncing definitely on its merits; but there is sufficient evidence of its usefulness to warrant extensive trial in other cases. It would, no doubt, make an excellent collyrium (without the acid) in purulent ophthalmia, and a stronger solution might be used in ulceration of the mouth and gums. The solution of 2 grains to ℥i of the acid solution was tried with excellent results to lessen the fetor in a case of extreme suppuration from a burn. In skin diseases, especially those of a parasitic origin, sulphite of zinc would probably prove invaluable."

that made by hand. The latter had many defects, and the former possesses many advantages. Machinery, by lowering the price of lint, has very much increased its consumption; but there still lingers in the minds of many persons the feeling that there is no lint like that made by hand, and also a suspicion that the so-called "flax-lints" contain a mixture of cotton, varying in the samples of different makers, but objectionable in all.

Just at the time when I was engaged on this subject a circumstance occurred which will serve to illustrate my remarks. A medical man called on me for some lint. I unrolled a packet of Taylor's Super A 1 flax lint. He objected to it, remarking that it was mixed with cotton, and also that the presence of cotton in lint detracted from the value of the lint as a dressing for sores; and this was especially the case when applied to a blistered surface. Now here was a question of fact and also one of opinion; and to determine one at least of these—the presence of cotton, or otherwise, in samples of professedly flax lint—was the object I had in view, and I have thought that the subject possessed sufficient interest to justify me in bringing the results under your notice.

A difficulty met me at the outset. I had purposely discarded all "*cotton lints,*"—they did not come within the scope of my inquiry; and to examine every sample even of those labelled "flax lints," whether from wholesale houses or retail establishments, would occupy more than the limited time at my disposal, and be of no practical value, for the absence of the maker's name left no means of identification. Here, for instance, is a sample of lint. The packet had a very pretentious label —"Superfine Lint," etc. It does not profess to be flax, nor does it say that it is cotton, neither has it the maker's name. Its composition is about half cotton and half flax, and the same remark will apply to the linted surface. I have examined a good many samples labelled flax lints, from different sources, but shall illustrate this paper by reference to those of a few well-known makers.

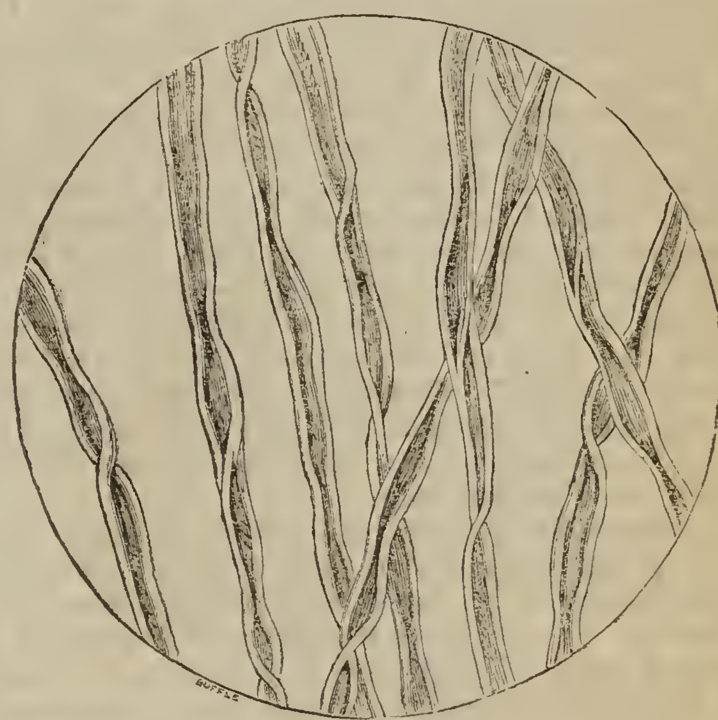
No. 1 Sample.—I will commence with the lint to which objection was made, Taylor's Super A 1 Flax Lint. I certainly was somewhat startled to find that it did contain cotton. By taking a piece of this lint and detaching from it a few threads, without reference to any particular part, the presence of cotton may be detected; but when the sample is subjected to a more methodical investigation,—when, for instance, the warp is separated from the weft which crosses it at right angles, and they and the fluff on the surface are examined,— it is found that the "warp" consists of a yarn of loose linen fibre, the "weft" of a closely-twisted thread of cotton, and that the fluff on the surface contains no cotton whatever, being composed entirely of flax. I use the words "yarn" with reference to the flax warp, and "thread" to the cotton weft, to convey a tolerably correct idea of their relative size and condition in the fabric. A stray fibre of cotton may be found on the surface, but it is not there in any appreciable quantity. The cotton would appear to have its place and value in binding together, so to speak, the flax yarns; but it forms no part of the linted "pile," consequently all the fibres coming into contact with a wound are pure flax. It is just possible that the presence of a thin thread of cotton as a weft, may make the material lighter and more porous, and assist in producing a larger linted surface to a given weight of lint. The view adopted is probably borne out by reference to the next. I think, therefore, that we are justified in considering this sample as a flax lint.

No. 2 Sample is Maw's Ellesmere Lint, composed entirely of flax in warp and weft, and consequently the fibres of which the linted surface is composed have no mixture of cotton. It is a coarse lint as compared with some others.

No. 3 Sample is Robinson's, of Chesterfield, Flax Lint. Warp flax; weft cotton. Surface for the most part flax.

No. 4 Sample is hand-made lint, composed entirely of flax. It has very little fluff on the surface.

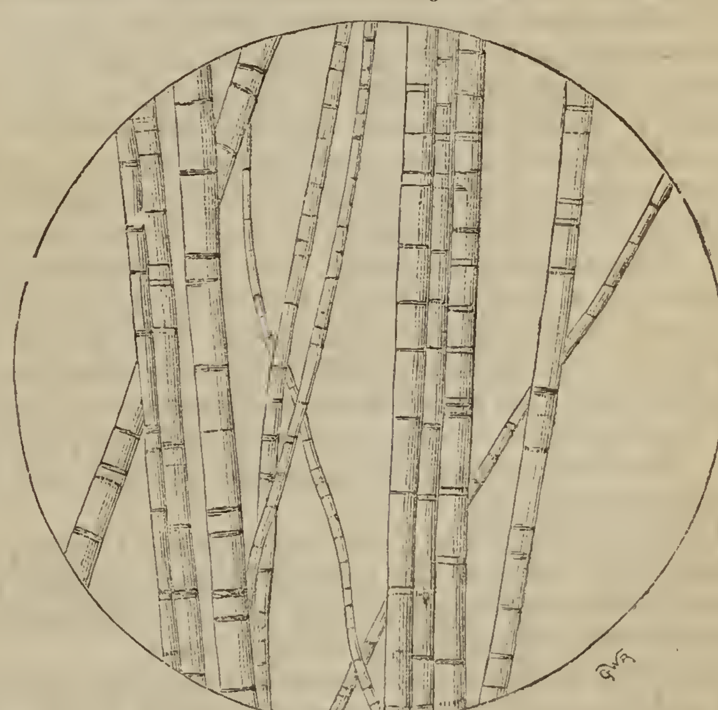
The second question may now be considered. Is the presence of cotton in any quantity really objectionable when forming part of the linted surface? It would be difficult for me by any direct experiment to determine this point. I must leave others to speak. I shall only quote one authority bearing directly on lint, and his remarks I think embody the opinions of most of those who have alluded to the subject. Erasmus Wilson, in his treatise on 'Healthy Skin,' says, in substance, "that he attributes the softness and smoothness of linen to the roundness and pliability of its fibre; the cold feeling to its being a good conductor of heat,—the porosity of its fibre rendering it very attractive of moisture, absorbing it freely, which, as water is a conductor of heat, removes it rapidly from the body. On the contrary, "cotton is a bad conductor of heat; it does not absorb moisture to conduct the heat away. It wants the freshness of linen; it is not, like linen, composed of fibres which are perfectly rounded, but, on the contrary, its fibres are flat



Cotton.*

and have sharp edges, which are apt, in delicate skins, to excite irritation. It is on this account that we carefully avoid the application of cotton to a graze or wound, and employ for such a purpose its softer and smoother rival, linen."

You will observe that his objections to cotton apply,



Flax.*

in the first place, to its being a bad conductor of heat, and, in the second, to the sharp edges of the cotton. His first objection may be valid, but the second has no

* The woodcuts represent the appearance of the fibres by transmitted light.

foundation in fact. Cotton has no sharp edges; its fibre may be compared to a tube of some thin material collapsed, and with rounded edges, ribbon-like, but more or less twisted. The fibre of flax *is* rounded. There is certainly a difference in the feeling between linen and cotton when applied to the skin, to whatever cause this may be attributed.

The superiority of linen to cotton as a dressing for wounds is generally admitted; and I think, therefore, that we may accept as a fact that cotton, in so far as it forms part of the linted surface, detracts from the value of the lint. But how is the occasional preference for hand-made lint to be explained? On carefully comparing a piece of hand-made lint with that made by machinery, both being flax surfaces, I think it can only be a question of the relative quantity of "pile" on the surface of either sample; and a reference to the next lint would seem to support my views.

No. 5 Sample is "Charpie," a kind of lint used in the German hospitals, with reference to which I will quote a paragraph from one of the newspapers:—"*A Good Hint.*—'Charpie' is a game at which all ladies should now be playing. It is played in this way. Tear pieces of linen into fragments about three inches square, and draw out every thread separately. It is capital fun, especially adapted for the delicate fingers of young ladies, who can arrange parties for it at each other's houses; and the best of all is that this charpie—a kind of lint—is invaluable to the poor wounded soldiers, whose sufferings, for the want of such a thing, are often excruciating and intolerable." These detached threads are scraped into fluff, which is applied first, and then covered with the piece that remains, from which the threads have been drawn in one direction only.

No. 6 Sample is Marine Lint, which, through the necessities of the present time, has acquired some notice. For this sample I am indebted to the kindness of Mr. Martindale. In a letter to the *Lancet* of September 2nd, the maker says, "Marine lint is made from a variety of fibres (generally vegetable), prepared by a peculiar process, and will retain its disinfectant qualities and tarry fragrance for many years." I take a piece of this, and clean it by several immersions in methylated spirit. Its tar and its mystery disappear together. It is composed of flax or hemp fibres; in fact, it seems to me to be nothing more than "tow waste" passed through a solution of tar.

One word more as to the means adopted for the detection of cotton-fibre in combination with that of flax.

The microscope is perfectly efficient for this purpose. The value of polarized light in determining form and structure is well understood by the microscopist. I have availed myself of it in these investigations. By its aid, and with a little management in manipulation, every fibre of which the thread or fluff is composed can be told with unerring accuracy. In the examination of a sample of lint, I would suggest that in the first place a low power be employed to determine from the back of it the relative size of warp and weft, their closeness or otherwise; then that fibres from each and also a portion of the linted surface be examined separately by polarized light. By this means no specimen of lint can fail thorough investigation.

If I have succeeded in throwing any light upon, and investing with interest, the subject brought before you, my time in the investigations and yours in listening to the results will not have been spent in vain.

I have here for distribution some lithographic plates of cotton and flax under the microscope, kindly supplied me by Mr. Suffolk, F.R.M.S., to whom I am indebted for much information and many kind suggestions on this subject.

The PRESIDENT said that referring the different qualities of cotton and flax lints to the microscopic structure was an exaggeration and a popular error. If any difference really existed in their relative merits, which many doubt, it probably was not because one fibre was flat and the other round, but because the cotton twisted by being wetted by the moisture from the wound, and by its movement caused the irritation complained of.

Mr. INCE remarked upon the very different practice of this country and that of France and Germany in the selection of lint. In common with many others, he had lately given up a good deal of time to making *charpie* to send to the seat of war. In France, *charpie*, made by pulling out each separate thread of a linen or cotton fabric, was sold by weight. The French and Germans will not use English lint because of the fluff, and large quantities sent out for the relief of the wounded have been returned to England to be exchanged for other articles. The new material called "marine lint" was highly appreciated.

Mr. MARTINDALE referred favourably to the experience of "marine lint" in some of the London hospitals. As an antiseptic dressing, a little loosely applied as a padding, placed above the ordinary lint dressing, it had been found efficacious, especially in cases where there was much fetid discharge, of which it was a most effectual deodorizer. The surgeons at St. George's Hospital spoke well of it, having used it for some time, and at the University College Hospital it had been used with success. Its application was found to add much to the comfort of the patient by destroying the disagreeable odour which is often so persistent from gunshot and other wounds. It had been largely used for this purpose during the American war, where it was first introduced as a surgical appliance.

Mr. BAILDON regarded the prejudice against cotton lint as being without any good foundation, and stated that in the hospitals of Edinburgh cotton lint was used. As to the new "marine lint," carbolic acid was evidently its active agent.

SOCIETY OF ARTS.

ON FERMENTATION.

BY PROFESSOR A. W. WILLIAMSON, F.R.S.

Lecture III.—continued.

I will now leave these experiments for the present, in order that I may tell you of some other discoveries, which will afford a key to them. One of the most important observations was made, at an early stage of the investigations, on the subject of ferments, by Dr. Schwann. He passed air through a red-hot tube, and he asserted, as the result of his observations, that air which had been so heated was incapable of producing the effects, which I mentioned just now as having been noticed by other observers as produced by common air; that whereas ordinary air starts fermentation, air which has been passed through a red-hot tube does not. That was what he said, and in some of his observations he was quite correct, but in some others he must have been misled. Shortly after his observations, another German philosopher thought of using cotton-wool as a strainer. He passed air through a glass tube fitted up somewhat in the same manner as the one I have here, with a tolerably compact plug of cotton-wool, which allowed the air to pass through it, but at the same time acted as a strainer, and collected a quantity of dirt at the side where the air entered it; and he found that the air which had been thus strained was no longer capable of producing the phenomena of decomposition, which air in the unstrained or unheated state does. Since then, Pasteur has done the same thing in a more accurate and more decisive manner; and he has repeated the experiment with heated air, with precautions which leave nothing to be desired. One novelty in Pasteur's process is the use of a kind of cotton which is soluble—cotton which has been in contact with strong nitric acid, which is called gun-cotton. It retains the structure and appearance of ordinary cotton, but has this peculiarity, that it dissolves easily in a mixture of alcohol and ether. He put into a tube a plug of this gun-cotton, and then, by means of an aspirator, he drew air through this strainer for a long time, until he had collected quite a quantity of dust. He then took this gun-cotton with the dust upon it, and put it into a tube, where he poured alcohol and ether upon it until the cotton was dissolved, and nothing left but the dust. In that manner he got the lightest portions of the dust and the heavier portions by themselves, as they very soon subsided in the liquid in which the gun-cotton had been dissolved. He then poured fresh alcohol upon them, so as to thoroughly cleanse them, and then put them under the microscope, in order to examine the particles of which they consisted. He found in this dust a great many particles of sand, calcic carbonate, and other mineral particles, as would naturally be expected, and also a great quantity of organic matter—little particles of cotton wool, wood, and so on, and mixed with these he found some little spherical or oblong particles of very different sizes, and of some considerable varieties of shape. Some of these little round particles he found consisted of mere starch, and many of you are, no doubt, aware that starch consists of little spheroidal masses of different sizes. These he got rid of by a solvent, and others were then left, which resembled in their appearance so closely the germs of various fungi and organisms of those kinds and eggs of animalcules that they were, to outward appearance, undistinguishable from them. He then took a liquid which had been boiled, but which was capable of decomposing—such a one as I mentioned here—by the action of any of these substances, and he put it into a flask, with precautions which I will not detain you by mentioning now, more than to say that he slid into this liquid, which had not got anything present to induce the formation of organisms, some of the gun-cotton with the dust yet in it. It was the same thing as I mentioned before, only that the substance had got some of this dust from the air added to it; and he found that he also got the formation of organisms very readily and abundantly. He found that these little particles, which were to the eye undistinguishable from germs and spores, behave towards liquids of this kind just as if they were so. In various other ways the same form of experiment has been repeated, and uniformly with the same result, viz., that when little particles collected from the air, particles of extreme tenuity, are put into a liquid susceptible of undergoing decomposition, a great variety of organisms will make their appearance, just as if their seed had been sown in the liquid. This circumstance is one which, I think, will justify us in going back to what I told you of Pasteur's previous observations. I told you that he opened a number of the little bulbs which had contained yeast-water and sugar, so as to allow the air to rush into them. He found that, in some cases, he got one kind of organism produced, and in others another; in fact he got a great variety. But if, instead of allowing the air to go into these bulbs in this way, he poured the liquid out into an open vessel, he always got the same sort of organisms; there was no variety. The appearance of the particles which resembled germs is, as I said, exceedingly various, and there are many reasons to suppose that if there are the germs of these organisms in the air, there must be an immense variety of them, a variety so great that we could not even venture to guess at its extent at present. When the liquid had free access to all of them, it is found, for reasons which would easily suggest themselves, on reflection, to anybody, that some of them, those which can thrive best upon the particular substance, develope themselves to the exclusion of the rest. I will give you one or two examples of the influence of food upon the development of ferments, instances which are well known, and are of some importance, as serving to prove the point which I have just mentioned. You are aware that the mixture which I have been speaking of, yeast-water with sugar, can be made to undergo alcoholic fermentation. I have already referred to it repeatedly in that point of view. We can make it undergo alcoholic fermentation if we put some alcoholic ferment into it, and keep it at a proper temperature; but if, instead of putting some number of cells—and even a few grains weight consist of an enormous number of cells—if, instead of that, we were merely to leave some of this liquid in contact with the air, we should have no alcoholic fermentation set up in it. That particular mixture of yeast-water and sugar does not, when exposed to all these germs, get yeast-cells developed in it, at all events not to any perceptible extent. Instead of that, it gets cells formed which are similar to those in the second bottle I showed you, which is forming lactic acid, that is to say, the lactic fermentation will set in. The fact is, that the liquid is unwholesome for these particular cells; and does not agree with the alcohol cells, or yeast-cells, so that if a great number of various germs are thrown into these particular substances, those which can thrive better, which are the lactic acid cells, develope themselves, and the alcohol cells do not. Again, if instead of taking this decoction of yeast and sugar, you were to take some grape juice, you would have alcoholic fermentation at once. That is the way it is done. If I were to leave a decoction of malt in contact with the air, in the same manner you would get the same thing set in as a rule. Again, if some of the liquid which I have in the glass dish here—some of the yeast-water with a little alcohol and acetic acid—be left in an open vessel, it gets an organism formed upon it; in fact, that is a process which Pasteur recommends for getting vinegar cells, if you want any. He says the air will, if you give it time, and supply the requisite conditions, start these cells in that mixture, but no alcohol cells, nor lactic acid cells, can be grown in it. It does not suit them; it is a substance which suits vinegar cells, and them only. Whatever may be the variety of the cells present in the air, it only developes those of that particular kind.

(*To be continued.*)

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

The First Meeting of this Association for the season was held on Saturday, October 15, at the Scottish Corporation Hall; the President, Dr. Druitt, in the chair.

Specimens of the new antiseptic chlor-alum, Whitehead's soup squares and meat preserved by Mr. Richard Jones's process were exhibited.

Mr. Rogers introduced the subject of the registration of disease, which he advocated with great earnestness.

Dr. Druitt read an address on the Sanitary Topics of the Day. Alluding to the prevalence of scarlet fever in the metropolis, he said that this was the season when it might be expected to increase after a partial diminution during the summer months. In the week ending October 8, 192 deaths from this disease were reported, being the largest number registered since last December. It was clear that we wanted a registration of disease, coupled with a provision for making its existence known to the sanitary authorities. The existence of scarlet fever in a house instead of being made known, is, from various reasons, studiously concealed. It was clear that scarlet fever is propagated by the bodies of the sick, and the clothes, apartments, etc., contaminated by them, or by such causes as fermenting heaps of impurities, receptacles of excretions, drains, and the like. He believed scarlet fever to be emphatically a product of sewer gases. In disinfecting pipes and sewers by carbolic acid a sufficient quantity should be used to drench the whole canal, as infusoria in putrid water are not killed until the acid is freely used. As a disinfectant for rooms and bedding, he preferred the fumes of burning sulphur to any other. He advocated periodic fumigations of crowded houses; the drenching of drains, closets and earth with carbolic acid; the oiling, staining and hardening of floors, so that instead of being scrubbed, they might be cleaned with something of the turpentine kind; the abolition of fixed carpets in bed-rooms, and the burning of the sweepings of sick-room floors. The other subjects discussed in the paper were, the Contagious Diseases Act, baby farming, the principles of sanitary law, the necessity of Building Acts, the dwellings of the poor and local taxation.

Dr. Rogers believed that scarlet fever arose from animal decomposition. In twelve years' experience at the Strand Union he had never had a case of scarlet fever spread in the sick-wards, while eleven or twelve days after a woman entered the receiving ward with a child that had the measles, the disease ran through the whole of the nursery, which was fifty yards off. Scarlet fever was more under control, he thought, than any other of the preventible diseases. The reason of its spreading so rapidly in some districts was that the excreta were not properly got rid of. At the Strand Union the drains were of the best, and as soon as there were any smells in the wards he punished the nurses by stopping their beer and other extras. The result was, the smells soon vanished.

Dr. Liddle thought inspectors should be appointed to decide whether houses were fit for habitation or not, and if not, Government should take steps to pull them down.

Dr. Gibbon said the result of the last speaker's action would be that the poor would have no houses at all, for he had made ample provision for pulling them down, but none for building them up again.

Dr. Aldis said that at Eastbourne an outbreak of scarlet fever had originated in the old and badly-drained portion of the town.

Dr. Tilly remarked that he had recently inspected forty or fifty houses, into which there was a constant admission of sewer gases.

Dr. Stevenson said he had found sulphurous fumigation very effective, but there were considerable difficulties in the way of burning sulphur. The bisulphide of carbon was very volatile, and should be used carefully, but it was much more effective than solid sulphur.

Dr. Iliff said scarlet fever in his parish had not originated from dirt, filth or bad drainage.

MEETINGS FOR THE ENSUING WEEK.

Wednesday, *Pharmaceutical Society of Great Britain.*—"On Some of the Infusions of the Pharmacopœia." By Mr. J. B. Barnes.—"On the Purity of some of the Alkaloids of Commerce." By W. L. Scott, F.C.S.

Parliamentary and Law Proceedings.

Thames Police Court.

BEFORE MR. PAGET.

The Shipment of Dangerous Articles.

Messrs. James M'Ewan and Co., merchants and shipbrokers, of Cannon Street, City, were summoned before Mr. Paget, at the instance of the East and West India Dock Company, for unlawfully causing to be sent to the East India Dock for shipment on board a vessel called the "Coloena," two packages of mineral extract, without distinctly stating the nature of such goods on the outside of the packages containing the same, or otherwise giving due notice thereof to the superintendent of the dock, whereby the defendants had incurred a penalty not exceeding £20. It was proved that three packages of goods were shipped on board the "Coloena" for Wellington, New Zealand, as lamps. Two of the packages contained a highly combustible and dangerous substance, petroleum spirit, and the third only contained lamps. The dangerous nature of the petroleum spirit was proved by Mr. Ogston, analytical chemist, on behalf of the dock company, and it was stated by Mr. Young that if an explosion had occurred on board the "Coloena" on the voyage nothing could have saved the ship, cargo, 110 passengers and crew from total destruction. Mr. Paget said the liquid shipped on board ship was a most dangerous article. It was described as the most dangerous part of petroleum, and very inflammable. If the stuff had been shipped, and stowed away under hatches, every living soul on board would have been on a volcano. This was a case of so much importance that he felt bound to inflict the full penalty of £20 and £3. 5*s.* costs.—*Times.*

Worship Street Police Court.

BEFORE MR. BUSHBY.

Alice Maud Kemp was charged, on remand, with having attempted suicide by taking laudanum. The facts of this case were reported last week. The prisoner stated that she had purchased an ounce and a half of laudanum at Mr. Cooper's, chemist, of Amherst Road, Hackney.

The prisoner, in answer to the magistrate, said that when she purchased the poison at Mr. Cooper's she stated that she wanted it for some silk. She could not say for what purpose laudanum might be used with regard to silk, but she said that as it was the first thing she thought of. She had only been there once before, but Mr. Cooper did not know her address or name until she told him at the time of purchasing the laudanum. She denied that she had stated she wanted the poison for a lotion for her leg.

The mother of the prisoner having expressed her willingness to become surety for her daughter's good behaviour for one month, she was set at liberty.

A solicitor wished to address the Court upon behalf of Mr. Cooper, but

Mr. Bushby said that he could not hear him, as Mr. Cooper was not before the Court. Adverting to the sale of the poison by Mr. Cooper, Mr. Bushby said that from what the prisoner had stated, it appeared that the poison was sold by the chemist to her without any introduction given by a friend known to both, as required by the Act of Parliament, and without any previous knowledge of the party to whom he had sold the poison. In the interest of the public safety he, Mr. Bushby, thought that the police should make inquiries into the case, and see if the 17th section of the Act (31 & 32 Vict.) had not been infringed, and he directed that to be done.

The solicitor begged to be allowed to call attention to the Act.

Mr. Bushby declined to allow anything so irregular. If the police found that the Act had been infringed, and Mr. Cooper was brought before the Court to answer for having incautiously sold the poison, there would be ample opportunity of arguing the question.

At the Southwark Police Court, a young woman charged with being destitute and creating a disturbance in the public streets, said that she had been to a chemist the evening before, and had he supplied her with what she wanted she would have been dead by that time and all her sorrows forgotten.

[*** This case serves to illustrate the truth of the opinion expressed last week, that druggists are careful to exercise discretion in the sale of poisons.—Ed. Ph. J.]

At the Manchester Police Court, on Tuesday, October 8th, a lamp manufacturer was summoned for having thirty gallons of petroleum stored in a cellar without a licence. The defendant, who had been refused a licence six months ago, because he had failed to comply with the instructions of the watch committee, was fined £10, and the petroleum and vessels containing it were ordered to be forfeited.

Notes and Queries.

*** *In accordance with a wish expressed by numerous correspondents, a column will in future be devoted to notes and queries, with the object of facilitating the exchange of information among members of the trade and students.*

In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[1.]—GALLIC ACID SOLUTION.—*A. P. S.* would have well rubbed the gallic acid in a mortar and made into a solution with ʒvj of the S. V. R. and aq. rosæ previously mixed, and have rinsed out the mortar with the remaining ʒiv; he would also have affixed a "shake the bottle" label above the ordinary label. He thinks it impossible, according to all writers and his own experience, to keep gallic acid "in such a concentrated state" in solution, except at about 200° F.

I beg to say that I should have dispensed the prescription as follows:—

Introduced the sp. vini rect., aqua rosæ and acid. gallic. into a test-tube, shaken them together and applied heat until a perfect solution was obtained, after which I should have poured it into the bottle I intended for it. When I found that the mixture "congealed" on cooling, I should have ascertained what directions the prescriber had given for its use. If they were such as could be applied to the mixture in the congealed state, or when "liquefied," by placing the bottle into a vessel containing "hot" water, well and good; but, if otherwise, I should have communicated with the prescriber, informing him that the mixture could not be used, if made up in the manner prescribed, and suggesting that a "perfect" solution might be obtained by subtituting "glycerine and otto of rose" for the aq. rosæ, or "acid. tannic." for the "acid. gallic.," either of which when treated in the above manner, will form a mixture that does not congeal on cooling.—J. T. C.

[2.]—MOUNTING MICROSCOPIC OBJECTS.—*R. J. M.* will find every information required as regards the mounting of objects, etc., for the microscope in Wood's 'Common Objects for the Microscope,' 1*s.*, or Lankester's 'Half Hours with the Microscope,' 3*s.*, either of which he may procure from any London publisher. The latter is an excellent little work.—J. T. C.

[7.]—CHILBLAINS.—In reply to *J. W. D. H.*, a correspondent sends the following:—Magnes. sulph. c. potass. oxymur. omni mane.

[9.]—GREEN FIRE.—

℞. Pul. Barytæ Nit. lbj
Pul. Potassæ Chlor. Ex. ℥j
Pul. Gum Shellac ℥iij
Pul. Antim. Nigri ℥ss
Misce secundum artem.—W. A. C.

℞. Barytæ Nit. ℥xij
G. Shellac ℥iss
Potassæ Chloratis ℥j
Carbonis ℥ss
Arsenici ʒij
Note.—Let the Shellac be well powdered.—Druggist.

℞. $BaNO_3 = 62\frac{1}{2}$
S $10\frac{1}{2}$
KCl $23\frac{3}{4}$
C $1\frac{3}{4}$
Sulphuret of Arsenic $1\frac{3}{4}$
Mix.—A. H. J.

Reduce to an impalpable powder separately, and mix together in a sieve,
Nitrate of Baryta 16
Picrate of Ammonia 6
Flowers of Sulphur 2.
Burns with great brilliancy; yields no smoke.—A. H. J.

Answers have also been received from "*Corsock*" and *J. F. Pollard*, giving recipes essentially the same as the above.

FIL D'ARCHAL.—While looking for something else, the communication of "*Ignoramus*" in the Journal for July 30 has just caught my eye. The articles in question belong, if I am not mistaken, to a small perfume lamp, of which I have a specimen. It is not unlike an ordinary spirit-lamp, except that the wick is confined in a glass tube fitting loosely in the neck, and retained in its place by a flange at its upper end.

To use the lamp it is partly filled with perfumed spirit, and the stalk or "handle" of the platinum ball is thrust into the wick so as to allow the latter to project a little above the ends of the strand of cotton composing it. The wick is then ignited, and when the platinum sphere is red-hot the flame is blown out with a sharp puff. If shielded from draughts of air, the metal ball will retain its temperature by continuing to decompose the vapour of the spirit rising through the wick.—J. F. Brown.

OIL OF KERMES.—*D. C. L.* writes in answer to "*Quærens*" that syrup of red poppies is sold as oil of kermes in the West of England.

[12.]—TEETH STOPPING.—"*Odontalgia*" would be glad of a good formula for metallic cement for teeth-stopping.

[13.]—EAU SÉDATIVE.—Can any one of your correspondents tell me how to make an elegant preparation of the following French recipe?

Strong Liquor of Ammonia . . . . ʒxvss
Camphorated Alcohol . . . . . . ʒijss
(made by adding 150 parts camphor to 500 alcohol)
Salts . . . . ℥vijss
Water . . . . ℥xvij.

[14.]—SACHET PERFUME.—"*Ignoramus*" wishes to know the best method of perfuming a writing-desk, or making a suitable sachet for the same object.

[15.]—MEZEREON EXTRACT.—Is the mezereon extract contained in the lin. sinapis comp. of any other use than as a colouring agent?

[16.]—ROME AND PARIS.—*A. S.* asks at what hour the pharmaciens in Rome and Paris close in the evening?

[17.]—AQ. MENTH. PIP.—*W. S. R.* wishes to be informed why aq. menth. pip., made with the foreign oil, turns pink upon exposure to the light.

[18.]—RUBINI'S CAMPHOR.—*J. Botham* wishes for a formula for Dr. Rubini's Camphor.

[19.]—SALE OF POISONS.—*E. P. W.* wishes to know if grocers can legally sell "Wheat Dressing" and "Fly Powder for Sheep," or whether these preparations are to be classed as vermin killers.

[20.]—BLEACHING LARD.—*T. B. Allkins* wishes to be informed of a cheap and easy method of bleaching lard, without impairing its qualities for domestic use.

[21.]—GLYCERINE JELLY.—*R. W. W.* (Sheffield) is in want of a good recipe for making glycerine jelly.

[22.]—COSMETIQUE.—*A. P. S.* would be glad of a good recipe for making brown cosmétique for fixing the hair and moustache.

[23.]—COLOURING FOR POMADE.—*S. W. S.* (Hull) would feel obliged by any of our readers telling him of a good colouring ingredient for pomade (yellow) which will not fade with the light.

Pharmaceutical Titles.

Sir,—In your issue of the 17th ult. a letter appears, signed "Omega," on which I should like to make a few remarks, since I consider it to refer to all who, with "Aspirant to the Major" and "T. C.," share the opinion that some distinct title ought to be given to those who have succeeded in passing the three examinations of the P. S. at great expense not only of money but of time. "Omega" accuses us of wishing "to parade our intellectual status," which is, by his bitter repining for a grand flaming diploma, evidently one of his peculiar weaknesses, but where he has seen this desire displayed amongst the Major Candidates beyond the ordinary desire all men have of reaping some advantage by their expenditure of money and labour, I am at a loss to conceive; he seems to think it very unjust that those who have worked hard for many months to pass the three examinations of the P. S., should enjoy any precedence over those who have merely passed such an examination as any apprentice who has been in the trade a year or two ought to be able to pass creditably.

I suppose our dear brother in pharmacy is one of those persons of retiring demeanour (and surely he had better have kept in the shade than have paraded his ignorance before the eyes of an intelligent profession) who wish for a higher social position, but shrink from paying the inevitable price of hard labour, energy and perseverance. If he have a very burning desire for a grand flaming diploma, I should advise him to apply the saying of the great man whom he quotes to himself, and employ his time in getting sufficient wisdom whereby to pass the Major,—and he might at the same time get a little understanding, of which he seems to be sadly in want at present,—and then he may also find that there is a higher reward in the satisfaction of having improved his mind than in having a title to his name or even than in having obtained that supreme height of human bliss,—the possession of a grand flaming diploma. But even if he does not choose to take my advice, he may still have the satisfaction of deceiving the public into the belief that he is on an equality with a Pharmaceutical Chemist by styling himself "Chemist by Examination of the Pharmaceutical Society," for the public can see no difference between the two terms.

I am also ignorant of the remarkable fact of which our correspondent kindly informs us, viz. that true doctrine leads men to humble themselves before men; I had rather thought that it led them to humble themselves before their Maker, not before their fellow-men, but probably our correspondent's humility is another of the virtues which he is anxious to parade before the eyes of the public.

Before he next exhibits himself in print for the ridicule of the profession, he had better take the trouble to consult Dr. Johnson, where he will find that doctrine and knowledge, advice and motto, are not synonymous terms as he uses them.

I must now leave our dear brother to agitate for his grand flaming diploma, and sincerely hope he may succeed in obtaining it, when, as he gazes on the coveted object of his life, he will, perhaps, be content to hold his peace and leave us to obtain our title of Fellow undisturbed.

Candidate for the Major.

Sir,—The reason why Major men would like the title of "Fellow" is, that at present the public are quite unable to distinguish between them and the Modified men. In fact, a friend of mine, who has passed the Modified Examination is considered far in advance of me by some, because he went up to London and passed it immediately, whilst I had to prepare for the Major.

To show the necessity of parading our status even before our *confrères*, I would mention that a Minor Associate opened a shop just before the passing of the Pharmacy Act, and, being elected a member of the Society, a chemist close at hand quite thought he had a Major to contend with, because he was a member. Again, Modified men call themselves "Chemists by Examination of the Pharmaceutical Society," and boast that their title sounds grander than ours; and when asked what is the difference between an Associate and a Member, reply, that "all Associates have been examined, but that all Members have not."

In conclusion, I think that if the Society could be called "The Royal College of Pharmacy," its Majors and Founders, "Fellows," and its Minors and Chemists "Members," our whole Society would be raised in the estimation of the Public.

Alpha.

Dear Sir,—No one will dispute the fact that the vast majority of the public does not appreciate the difference between the titles of Pharmaceutical Chemist and Member of the Pharmaceutical Society. I confess that I fail to see how those members who are such merely from being in business two years ago, can object to all who have passed the Minor and Modified Examinations being classed with them as members, whilst the Founders of the Society (that is to say, all who were members before the Act of 1868) could then, with all those who have passed the Major Examination, enjoy the title of Fellow. If such were the case, it would perhaps be found advantageous to admit those who pass the Preliminary Examination to the title of Associate. We should then have three distinct and well-marked gradations of rank in the Society, which could hardly fail to be understood by the public, as only the Fellows and members could conduct businesses.

I feel confident that the agitation which is now commencing on this point will rapidly attain its end, and the thanks of all concerned will be due to you for your courtesy in inserting correspondence on the subject.

Philip H. Mason.

Norwich, September 2, 1870.

Sir,—I have noticed several communications in your Journal on pharmaceutical titles. I fully agree with some of them. "Aspirant to the Major" tells us that the "Modified men" are of a class whose retiring dispositions are such that they are perfectly satisfied with their present attainments. I think it might be proved that he is under a delusion to suppose this, for some of them, I have no doubt, would be glad to compete even with "Aspirant to the Major," were it not for the expense and—a not less important thing—the sacrifice of time required for the Major. I do not hesitate to say, any young man of ordinary ability can pass either the Modified or Minor Examination by making good use of his leisure time and working systematically, without losing more than a week in London; whereas for the Major, it is almost imperative that he should have a course of study which it is next to impossible to obtain in the ordinary routine of business.

The titles themselves are very secondary, I have no doubt; but the public can in a great measure judge of their chemist's ability without requiring to see his diploma. Should it be deemed necessary to make a change, let the pharmaceutical chemist be Fellow, the chemist and druggist Member, and he who chooses to subscribe to the Society, and has passed the Modified or Minor, Associate,—each having his certificate to that effect. If "Aspirant to the Major" studies the lists of the Minor Examination, he cannot but be convinced that large numbers stop at this qualification, and consequently will be a very strong body, unless the Pharmaceutical Society step in with an additional Act, enforcing all to pass the Major Examination.

Wakefield, Oct. 17*th*, 1870. A. P. S.

Sir,—"To be, or not to be?" that is the question. Is it granted, or is it *not* granted, that the Modified Examinations of the Pharmaceutical Society are worthy the time and labour of the gentlemen conducting them? If not sufficiently stringent, why do the Privy Council sanction, the President and Council of the Society endorse, and the majority of our brethren acknowledge them? Such are the questions I submit to the omniscient philosophy of our worthy friends "Spes" and "Aspirant to the Major."

"Spes" does not see his own fault when complaining that last session he passed the Minor, and, not being able to distinguish the "Major" title from the great bulk of titles accorded to the body of English chemists, he declined "going in" for the "grand event."

In "Aspirant's" former epistle he gives us to understand that we Modified men "resort to means whereby we may mystify the public," and that they, the Majors, having passed a highly scientific examination, have not the least desire to do so. Had he been addressing his note to an independent journal there might have been some need of such a full explanation regarding the curriculum for these large minds; but, as the letter appeared in our Journal, I contend that all of us knew, in all probability, as much about the examination for Fellows as "Aspirant" did; hence I maintain the great desire of parading his *status* before our eyes, which, however, he flatly denies.

It seems to me an injustice not to grant a similar diploma to the one given to men simply on account of their being in business prior to the Act of 1868 to all who have gone in for and come out from the "very modified affair." The whole tenor of "Aspirant's" ill-wind has been directed against Modified men (he forgetting those who have not passed any examination); consequently I have taken upon myself, as much as lies in my power, their defence, in the hope that abler hands will render assistance, seeing that we are constantly being slighted.

I suppose it is perfectly understood that all men in business prior to the late Pharmacy Act (whether old or young) are entitled to become members, to sit on the Council (if elected), and to have a "grand flaming diploma;" whereas we, the "Modified men," are not entitled to any one of the former, but, whether old or young, we are allowed to pass the Minor (I believe) and Major Examinations, and then we can assume the same titles as our scientific brethren, but on no account can the law be relaxed towards us (as I think it was with regard to Assistants), so that we might be on a par, not with Pharmaceutical Chemists, but with members of the Society.

Barnsley, October 11th, 1870. OMEGA.

Sir,—I put in a plea for the "Modified gentlemen," as they are called; certainly I shall never forget the scene which I witnessed in the Society's Library on the morning of the examination day on which I was present. There were fifty men, most of whom had been dragged out of the even tenor of their way from all parts of the country; some of them considerably over thirty years of age, with business settlements and prospects, to show reason why they should call themselves "Chemists." From several I heard tales of real suffering and hardships, the inevitable results of retrospective legislation.

And now, to find youthful "aspirants" tauntingly write of "retiring dispositions," "very modified conclusion," etc., must to some be rather irritating, and warrants the remark that such expressions are neither dignified nor brotherly. For my own part, it was of little consequence to me whether one examiner told me that I could read a Latin prescription, or another, that I knew one tincture from another, when for more than ten years I have either personally or by deputy dispensed about eighty prescriptions a day. I base my claim (and so I feel persuaded do all my Modified friends) to be a Chemist and Druggist, not upon having passed the Modified Examination, but upon having honourably served a term of apprenticeship to the business. Personally I should scorn to write up "Chemist by Examination of the Pharmaceutical Society." It is untruthful, because intended to convey more than the truth.

"ALPHA" (1).

Sir,—"Aspirant to the Major" speaks patronizingly of the "very modified curriculum" through which the Modified gentlemen have to pass; leading any one to regard such an examination as a mere farce, and in reality no test at all. I would ask if this be complimentary to the Council of the Pharmaceutical Society? They have instituted this examination professedly for the purpose of testing our ability, and are we to conclude that gentlemen in the capacity of examiners will waste their time in conducting a sham? If it be no test, why does it exist? I think by referring to "Omega's" letters, "Aspirant" will find that he chiefly complains of the injustice of established Chemists and Druggists, who have not passed any examination (not even excepting the "very modified test"), being admitted Members of the Society; whereas we, who have also complied with the requirements of the Pharmacy Act (though belonging to those of retiring dispositions), are only admitted as Associates. This is the objection. Place us upon terms of equality with those who were in business prior to 1868, and we shall be satisfied.

Barnsley, October 19th, 1870. "ALPHA" (2).

FEEDING BOTTLES.

Sir,—In connection with the subject of infants' feeding-bottles allow me to draw your attention to the following important statement, which appears in the official report of the Hon. Mr. Thurlow to the Foreign Office, on the International Exhibition of Domestic Economy held at Amsterdam last year, concerning an infants' feeding-bottle exhibited there.

L. M.

"This infants' feeding-bottle meets with so much demand in Lancashire, where I am told its sale is counted by several hundreds of thousands each year, and indeed on the Continent, wherever it has been introduced, that I could not but regard it as my duty to inquire of Professor Gunning, the Government Analyst at Amsterdam, the reasons which had led to its condemnation. These reasons were kindly given to me, promptly and without reserve; and the question being one, in which it is of the first importance, to challenge criticism, and by all means to arrive at the truth, I do not hesitate to quote them in translation, leaving the further discussion of the knotty points involved to the scientific world. With these objections, which probably apply more or less to all infants' feeding-bottles made upon the same principle, I shall close this review of Class IV.:—

"'I object to the 'infants' feeding-bottles' in all instances when any part of them is composed of caoutchouc, or any like material. There is nothing so ill suited to the constitution of the human body as the material in question. Milk, which by contact is only slightly tainted with the smell thereof, although this is, perhaps, imperceptible to the keenest sense, must have lost a portion of its quality of quick and easy digestion.

"'When, in consequence of suction, the pores of the caoutchouc are enlarged, some portion of milk always remains behind in them, which cannot, or at least cannot without great difficulty, be removed. This milk quickly becomes bad, and spoils the fresh milk with which it comes in contact. The caoutchouc material in question is made up of several ingredients. White zinc or white lead is very commonly employed, which are very poisonous. My objections are not founded exclusively on *à priori* conclusion. In this country many fatal cases have happened among infants, which, on solid grounds, may be ascribed to the use of these bottles.'"

HYDRAULIC PRESSES FOR TINCTURES.

Sir,—In the very useful and interesting article on Tinctures by Mr. Umney, found in this week's Journal, he mentions the use of the hydraulic press for the recovery of the solvent. There can be no question as to the great saving that would be effected by this means as compared with the screw.

The hydraulic press is a very simple piece of mechanism. I greatly wonder that no mechanician has introduced a handy little press, suitable for tinctures in quantities of from 2 to 4 quarts. Is it not worth some one's while to think of it? By the bye, is Mr. Umney right in attributing a loss of 37·5 per cent. to the preparation of tinct. zingiberis fort.?

Manchester, Oct. 22nd, 1870. J. T. SLUGG.

HOSPITAL DISPENSING.

Sir,—Allow me a few words in reply to Mr. Fitch.

I did not intend the remark "greasy card" to apply to his case, although if he will examine the patient's card at this date I feel sure he will find it in that state.

Upon the second or third visit to the surgeon, the card is generally unfit to write upon. If Mr. Fitch understood hospital work, he would not rush to print his single complaint. The majority of cases are greatly exaggerated.

Scores of patients never intend and never do take the medicine given. All bottles ought, of course, to be properly labelled.

I have had posted in the waiting-room the following

NOTICE.

"Send for medicines as early as possible after the visit of the surgeon as the dispensary hours permit.

"Bring clean bottles, etc. Take the corks out of the bottles. Let all labels remain on the bottles. Medicines will not be given to children."

With Mr. Fitch, I hail with pleasure the "good time coming," but it will not be in his time nor mine.

EDWARD BARBER.

83, *Devonshire Street, Sheffield.*

Public Dispensaries.

Sir,—That a stricter surveillance is necessary in the management of our public dispensaries will, I think, be granted by every one at all conversant with the subject. I am convinced there are few chemists in our larger towns but could narrate instances, if not of the blundering, most certainly of the slipshod manner in which the dispensing is conducted in these dispensaries. The following instance of the latter may be given, not as one of the grossest, but as one of the most recent that has come under my own observation, having occurred no later than Saturday last.

A poor but respectable woman received a prescription, which she was instructed to present at one of our public dispensaries. The prescription was for drops (liquor of arsenic) and an ointment (nitrate of mercury). She had no phial for the drops, but one was supplied her, charged for, and then handed to her *without a cork*. Part of the contents in consequence were spilt in the basket in which she carried it, and more than probably amongst the small purchases she had been making when out, and was then carrying home. On the phial was the simple word "Poison." No label to state whether for external or internal administration. No name to indicate where it had been got. No number, as indeed there could not be, seeing the prescription was not copied. She was asked for a box, into which to put the ointment, and as she had none, a two-ounce willow box was given her, and into it was placed the two drams of ointment ordered. (The ointment, I may state, was quite black.) This box was an old one which had previously contained pills, and the pill-label was neither removed from the lid nor a new one pasted over, so that the ointment was actually sent out labelled as pills. For this box the charge of *one penny* was made, but whether this penny was a perquisite to the dispenser, or was one of the sources of income of this most excellent charity, I could not discover.

I neither expect nor advocate for our public charities all the comforts or niceties of independent means, but I do expect, and would insist that the ease or comfort or indifference of our public dispensers should not interfere with the proper discharge of their duty, or neutralize in any way the good of these useful and worthy institutions. Δ.

Pharmacy and Medical Practitioners.

Sir,—As a proof of the "monstrously excessive charges" which we shall be enabled to make if "this spirit of bickering" be further indulged in, the following prescription was handed to me this week,—"Tincture of *Actæa racemosa*, ½ ounce;" and as the patient supplied his own bottle, you can imagine the amount of profit made by the transaction. I have received several similar prescriptions written in Latin, with either verbal directions or "To be used as directed," and on being repeated, the article has been asked for in English. In all cases the parties have been in by no means "humble circumstances." In one case the patient was told to ask for "1 drachm of pill mass, for which the charge would be 3*d*."

I cannot agree with your correspondent that "it is a most extraordinary fact that chemists in one part of town should charge as much for preparing a prescription as medical men should charge for both visit and medicine in another," as he must be well aware that "locality regulates prices" to a great extent. I certainly should be surprised if I paid the same for having a mixture dispensed in Bond Street and Ratcliff Highway.

We should all be extremely obliged to "Reformer" if he would kindly inform us where retailing ceases and counter practice begins, as I was informed by a medical gentleman the other day that digestive pills, hair washes and cough linctuses were decidedly "contraband of war," and I fear until I see the "breadth of the line" more clearly, I must remain,

"A Pharmaceutical Sinner."

Sir,—When I read the letter of Mr. Mee, upon the extract from the *Lancet*, I was astounded at the one-sidedness of it. If chemists were in the same odour with the public as the surgeons, at least 50 per cent. of the former would "cave in" instantly, and the remainder within a short period. A head of a family has just informed me that those doctors' bills are the black spots flickering about his memory day and night. I try to relieve him for 6*d*. or 1*s*., whilst he has to pay three times as much for the "nobbut water and salts" of the doctor. The haphazard messes that leave dingy surgeries are not to be classed at all with the correctly-dosed and neatly-wrapped bottles of the chemist; the patient, sick and weary, will not swallow aq. menth., made by adding ess. menth. to aq., with the oil floating in greasy abundance round the bottle. I have dispensed for surgeons and supplied them with the whole of their drugs; I find 2½ per cent. an average outlay, or £25 per £1000 practice,—this does not include bottles,—the bottle is frequently the most expensive part of the parcel of medicine. Mr. Wade's letter is to the point; the day will be when the inert mixture and cheap pill must give way to the well-studied prescription; the cost being a secondary matter where human life is at stake. J. Houlton.

F. R. (Camberwell).—The object of washing ether is to separate alcohol. The use of ether in this preparation has been condemned by good authorities. It will probably be omitted from the form in the next edition of the B. P.

J. W. (Attercliffe).—(1.) The formula in the B. P. *is* correct for the definite salt. Attfield, in his *Chemistry*, p. 180, states that the process does not yield *this* salt, but a mixture of two subacetates having the formula written by our correspondent. The process can only be symbolized in the modern notation satisfactorily upon the latter supposition. (2.) First person singular, indicative mood, perfect tense, of the Greek *heurisko*, to find out or discover.

T. Grainger (Birmingham).—The labels sent would be liable to stamp duty. As explained in the Appendix to the Calendar of the Pharmaceutical Society, the Medicine Stamp and Licence Acts require that if the medicine be a secret preparation, or if it has been recommended on the label, or on a handbill, or by any public advertisement, for the cure or relief of any disorder, it shall then be stamped and the vendor must take out a licence for its sale.

Advertising by Postal Cards.—The manager of the Floriline Company writes, in reply to a letter from a "Country Chemist," in which he supposes the Company to be alluded to, that (1) the price cards were only sent to the trade, so that with the exception of the letter-carrier they would not be likely to be seen by the general public; (2) that the article advertised would not be supplied to any but the trade, except at the retail price, no matter in what quantity ordered.

G. M.—(1.) Yes. (2.) Melt equal parts of zinc and tin together, and combine these with three parts of mercury: the mass must be shaken until it is cold; the whole is then rubbed down with lard to the proper consistence.

"A Country Apprentice."—The Latin Grammar.

"Registered Student" (Alnwick).—(1.) Yes. (2.) Yes. Apply to the Registrar.

W. A. C. (Lynn).—The numbers of the specimens this year were—Mr. Webb's, 460 and duplicates? Mr. Rammell's, 542; Mr. Wood's, 330.

A. H. J.—The questions were published at p. 288–9.

"Ignorans."—The chemists and druggists eligible to be elected members of the Pharmaceutical Society are those who were in business before the 1st of August, 1868, and the Associates those who were admitted before the 1st July, 1842.

"Inquirer."—We should think a perfectly saturated solution of chloride of iron is meant, or such a preparation as the ferri perchloridi fortior liquor of the B. P.

"Botanist" (Southport).—Professor Oliver's 'Elementary Lessons in Botany' is published by Messrs. Macmillan and Co., price 4*s*. 6*d*.

"Santonica" (London).—(1.) Make the citrine ointment twice over. (2.) We have not observed this action, and do not see why it should occur. Your description indicates the reduction of a portion of the oxide to the metallic state.

J. Botham (Manchester).—Dr. Rubini's camphor is a proprietary article. We do not know of a formula for its preparation.

Communications, Letters, etc., have been received from Mr. J. F. Brown (Dover), Mr. A. P. Towle (Manchester), Mr. J. H. Gortling (Halesworth), Mr. T. B. Allkins (Tamworth), Mr. J. Houlton (Wetherby), Dr. Divers (London), Mr. Reynolds (Leeds), Mr. H. W. Maleham (Sheffield), Mr. A. H. Mason (Liverpool), Mr. W. Shaw (Hull), Mr. C. Tucker (Bridport), Mr. W. D. Williams (Salisbury), Mr. T. Perkins (Norwich), Mr. Davies (Liverpool), Mr. F. H. Cumine (Southport), Mr. Hornsby (Brighton), "Assistant," "A Pharmaceutical Sinner," D.C.L., M.P.S.

The following journals have been received:—The 'British Medical Journal,' Oct. 22; the 'Medical Times and Gazette,' Oct. 22; the 'Lancet,' Oct. 22; 'Nature,' Oct. 20; the 'Chemical News,' Oct. 21; 'Journal of the Society of Arts,' Oct. 20; 'Gardeners' Chronicle,' Oct. 22; the 'Grocer,' Oct. 22; the 'English Mechanic,' Oct. 21; the 'Journal of Materia Medica' for October.

THE OPIUM TRADE OF CHINA.

BY P. L. SIMMONDS.

Few are, perhaps, aware of the enormous trade still carried on in opium from India to China; and what is, probably, even less generally known, is that the poppy is largely cultivated in China itself, and that the native drug is beginning to replace much of the Malwa opium. Mr. R. Fortune saw the poppy extensively grown in China for the purpose of inspissating the juice, but was able to form no estimate of the quantity actually grown. We have, however, confirmatory recent evidence of the extension of the culture and production in China. More than thirty years ago it was stated in the *Chinese Repository*, on the testimony of the counsellor Choo Tsun, that in his native province, Yunnan, the poppy was cultivated all over the hills and open country, and that the quantity of opium annually produced there could not be less than several thousand chests. Indian opium now brings in an average annual gross revenue to the Indian Government of about £8,200,000.

The value of the opium shipped from India to China in the last ten years is thus given in the official statistics; from which it will be seen that the average annual import has not varied very greatly in the two quinquennial periods, although there are alternate high and low years, and the price fluctuates much:—

	£		£
1860	9,054,394	1865	9,911,804
1861	10,184,713	1866	11,122,746
1862	10,553,912	1867	10,431,703
1863	12,494,128	1868	12,309,915
1864	10,756,093	1869	10,695,654
Total	53,043,240	Total	54,471,822
Average	£10,608,648	Average	£10,894,364

In 1856 the consumption of Indian opium in China was about 82,000 chests of 140 lb. each, but this was exceptionally large.

In his report upon the trade of Tien-tsin for 1866, our Consul drew attention to the fact that the increase in the importation of opium in that and the previous year had been immediately preceded by an Imperial edict, issued on the 28th April, 1865, which prohibited the cultivation of the poppy throughout the empire. He stated that though, at first, the operation of this edict was beneficial to the trade in foreign opium, the poppy was still grown extensively, and the prohibition would prove ineffectual. That such has hitherto been the result is proved by the fact of another edict having been issued on the 31st January, 1869, redirecting all viceroys and governors to cause proclamations to be issued, forbidding altogether the cultivation of the poppy, which is stated to have been introduced from Kan-suh into Shen-si and Shan-si, and afterwards grown in the provinces of Kiang-su, Honan and Shan-tung. The ground of objection to the poppy, and even to potato culture, stated in the edicts, is that they withdraw land from the cultivation of rice and grain.

There is little doubt that the competition of native-grown opium has had much to do with the declining price of the foreign-grown since 1866, and that at the same time the increased production of the native has lessened the importation of Indian opium.

At Tien-tsin, since 1866, it is certain that a yearly diminishing importation has accompanied a yearly falling price, plainly indicating a decreasing demand for foreign opium. There is no evidence, however, according to Mr. Consul Mongan, of the decrease of opium smoking, but rather of its increase; and therefore it may fairly be inferred that the quantity of native opium has so much increased, or its quality so much improved of late, as to have shut out a considerable amount of the Indian drug. This inference, too, is much strengthened by the reference which the late edict makes to the spread of poppy culture over northern China.

In addition to the provinces enumerated in the edict, there is also ample evidence of extensive poppy cultivation in other parts of the Chinese empire. It seems to have been carried on for many years in the extreme south-west in the province of Yunnan, the largest portion of which has thrown off its allegiance, and is now a practically independent kingdom.

Sze-chuen has also been for many years a great poppy province, and the drug produced there very perceptibly affects the market at Hankow. When Lord Elgin visited that city in 1858, he stated (Blue Book, 1859, page 443) that he saw there "shops where native opium was openly advertised for sale." Mr. T. T. Cooper, in some notes on his travels towards India through Central China, speaking of Sze-chuen, says, "In spring the country was white with the flower of the opium poppy, now one of the staple productions of the province;" and Mr. A. Wylie, the well-known Sinologue, who has travelled lately in the same province, says in a letter, "One fact I can vouch for, and that is the widespread use of the drug, and consequent degradation of the people. It was pitiable to see the victims of this practice coming to us to ask for relief and desiring to be cured, and such were by no means confined to the lower classes. I believe the practice in Sze-chuen, as elsewhere, is very widespread among the literary and governing class. From all the information we could gather, it commenced in this province within twenty or thirty years past. In the 'Statistical Account of Sze-chuen,' published in 1817, which gives a detailed list of the productions of the province, the poppy is not named. I do not remember seeing any foreign, though it is sold there, but at every market the farmers bringing in their little lumps of native production were always to be met with. As far as I could learn, the price ranged from 140 to 250 cash the tael weight."

Another vast region, not mentioned in the edict of 1869, in which poppy culture has been spreading rapidly within the last few years, is Eastern Mongolia and Central and Northern Manchuria, the drug thence brought down to the coast competing with Indian opium in the Newchwang market. Thus, in the provinces of Yunnan, Sze-chuen, Shen-si, Kansuh, Shan-si, Honan, Shan-tung and Kiang-su, as well as in Manchuria and Mongolia, native opium is produced; and that its consumption by the Chinese is lessening the demand for the Indian drug, would seem to be indicated by the fact that in 1868 the total importation of the latter was less than it had been in 1867 by 4789 chests, representing a value, at the average ruling rate, of nearly two millions sterling.

These figures are given in a letter that was published in the *North China Daily News* of the 22nd February, 1869.

Native opium sells in Tien-tsin at from 125 taels to 200 taels per picul less than Indian, and though nominally prohibited, it pays a similar local duty to foreign. Opium is brought into Tien-tsin either crude or prepared. When in the former state it is generally spoken of as "tu," earth or clay, from its outward resemblance to lumps or cakes of common clay: and the native, as distinguished from the foreign, which is termed "yang-tu," or foreign earth, is called "hsi-tu," or western earth—a name that has clearly a geographical reference to the producing provinces. (Consular Reports, No. 2, 1869.)

Prepared opium, called "ya-pieu-kao," is generally composed of foreign and native drug boiled down, and often largely adulterated by an admixture of various glutinous substances, and amongst the rest by a decoction of the berries of a leguminous tree called the "huai-shú," which grows abundantly in the province.

Before concluding, I may give a few figures showing the imports and consumption of opium in the United Kingdom. Opium imported and used in this country:—

	Imports. lb.	Consumption. lb.
1830	209,076	22,668
1845	259,644	38,229
1850	126,318	42,324
1855	50,143	34,473
1860	210,867	112,795
1865	401,571	225,571

The Board of Trade returns for the last two years are, of course, not yet issued.

The largely increased imports and consumption, unless a greater home stock is held, would give ground to the opinion that opium is beginning to be used somewhat extensively for other than medicinal purposes.

In 1858 we imported but 82,085 lb., and retained for consumption 77,639 lb. In 1868 we imported (nearly all from Turkey) 322,309 lb. and re-exported 123,965 lb., thus leaving 198,344 for home consumption. The reshipments are principally to Holland, the United States, New Granada and the West Indies. In the latter countries it is evidently destined for consumption by the Chinese.

NEW REMEDIES.

The following extracts from a recent lecture by Dr. B. W. Richardson will probably be of interest to pharmacists:—

Nitrite of Amyl.—The physiological action of nitrite of amyl is directly exerted on the ganglionic nervous tract; it paralyses so that the nervous supply over the extreme vascular system is impaired; if the effect be sustained, the muscular system generally is thrown into relaxation. The observation of this effect of the nitrite has led Dr. Richardson to suggest it primarily as a remedy for excessive spasmodic action,—for tetanus specially,—and it has been applied in that direction with much success. Lately, Mr. Foster, of Huntingdon, has administered the nitrite with complete success in a case of traumatic tetanus,—holding the convulsions in check for the long period of nine days. The nitrite is best administered by inhalation, five minims on a piece of folded linen or handkerchief being the dose for an adult. It will act if given by the mouth; but as the action is very energetic, and requires to be kept under the control of the administrator, it is much safer administered by inhalation. In tetanus, the periods of recurrence of the spasmodic attacks should be carefully watched, and, when the paroxysm is threatened, the inhalation of the nitrite should commence, so as to subdue the spasmodic seizure. The agent has been administered also with success in spasmodic angina, asthma and colic.

The action of the nitrite is curative only in so far as it controls the spasm,—that is to say, it prevents death, and so leaves time for recovery. Dr. Richardson has observed that frogs under strychnine tetanus are immediately relieved of spasm by nitrite of amyl, and that, with great care in keeping the animals free of spasm, they can be sustained until the strychnine is removed from the body, when there is recovery; in this explanation he defines the true place of the nitrite as a remedy. In tetanus the administration of the nitrite is not to be considered as displacing other rational means of cure. On the contrary, it favours other means; it enables food to be freely supplied, it gives time for the action of purgatives and diuretics, or for the employment of the hot-air bath.

Caustic Ethylates.—The ethylates are crystalline substances, in which one atom of hydrogen of absolute alcohol is substituted by one of potassium or of sodium. Brought into contact with the body, the ethylates at first produce no action, but as they pick up water from the tissues they are decomposed, the potassium or sodium is oxidized, yielding caustic potassa or soda in the fresh state, while alcohol is reformed from the recombination of hydrogen derived from the water. Dr. Richardson proposes the employment of these ethylates as caustics. He believes they will be found to be the most effective and manageable of all caustics; and that in cases of cancer, when it is desirable to destroy structure without resorting to the knife, and in cases of nævus and other simple growths, they will be of essential service. The ethylates can be held in solution with alcohol in various degrees of strength; the solution can be applied with a glass brush or injected by the needle, and a slow or quick effect can be ensured, according to the wish of the operator. The ethylate of potassium is the most active agent.

Triethylic Ether.—When the ethylate of sodium is acted upon by chloroform, the chemical action which takes place is very fierce, and great care is required to secure a fair product. The chlorine of the chloroform combines with the sodium of the ethylate to form chloride of sodium, and triethylic ether remains. As chloroform contains three atoms of chlorine, each single part of chloroform decomposes three parts of ethylate of sodium. Thus:—3 (C_2H_5NaO), ethylate of sodium; $CHCl_3$, chloroform $= 3\,NaCl$, chloride of sodium, and $C_7H_{16}O_3$, triethylic ether.

The ether is a heavy, aromatic, ethereal fluid, having a vapour density of 74, a specific gravity of ·896, and a boiling-point of 145° C., 297° F. It acts much like alcohol physiologically. Dr. Richardson has lately used it as a menstruum of ethylic ether for general anæsthesia. The ethylic ether carries over with it, in evaporation, sufficient of the heavier ether to form a compound vapour which is very pleasant to breathe and equable in action. He has administered this compound twice for operations on the eye,—once while Mr. Brudenell Carter operated for strabismus, and once while Mr. Walker, of Liverpool operated for cataract. The anæsthesia in both cases was perfect. The ether also forms an excellent mixture with bichloride of methylene; and if mixtures of anæsthetic substances were satisfactory scientific applications, it might be brought into extensive use. Dr. Richardson accepts it, however, rather as an index of the way than of a resting-place. He looks for a simple ether which shall have the full and safe qualities of the mixture, together with perfect stability. There is, in truth, already another ether, called trimethylic, made by acting on methylate of sodium, CH_3NaO, with chloroform; the product being 3 (Na Cl), common salt, and $C_4H_{10}O_3$, trimethylic ether. But this ether, which has a vapour density of 53, and a high boiling-point, is not quite, though it approaches, the substance required.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

(*Concluded from page* 344.)

Acidum Sulphurosum.—Strong sulphuric acid is heated with charcoal, and the resulting mixture of gases conducted by suitable tubes, first through a small quantity of water to free it from impurity, then into the water in which the sulphurous acid gas is to be dissolved.

$$2H_2SO_4 + C = 2H_2O + 2SO_2 + CO_2.$$

From this equation, it appears that the sulphurous acid gas evolved is mixed with half its volume of carbonic acid gas. The latter escapes.

Sulphurous acid gas may be made in many other ways.

By burning sulphur,—$S + O_2 = SO_2$.

By the action of undiluted sulphuric acid on many metals, as on copper and mercury,—

$$2H_2SO_4 + Cu = CuSO_4 + 2H_2O + SO_2.$$

By boiling sulphur with sulphuric acid,—

$$2H_2SO_4 + S = 2H_2O + 2SO_2 + SO_2.$$

Compare this with the action of carbon.

Or by the action of acids on sulphites or hyposulphites.

Sulphurous acid gas, sometimes called sulphur dioxide, is not an acid, but, like other anhydrides, generates an acid when united with water.

$$\underset{\text{Sulphurous acid gas.}}{SO_2} + H_2O = \underset{\text{Sulphurous acid.}}{H_2SO_3}.$$

It is a pungent gas, condensable to the liquid state by application of cold or pressure; soluble in water;* the gas in a moist state, as well as the solution, possessing the power of bleaching organic colours. With sulphuretted hydrogen the solution gives a deposit of sulphur with formation of water and pentathionic acid.

$$SO_2 + 2H_2S = 2H_2O + S_2$$

and

$$5SO_2 + 5H_2S = 4H_2O + S_5 + H_2S_5O_6.$$

The most delicate test for sulphurous acid and sulphites has been described under *Acidum Aceticum.* The solution, by exposure to the air, absorbs oxygen, and is soon converted into sulphuric acid. If fresh it gives no precipitate, or but a very slight one, with $BaCl_2$, but a copious one if solution of chlorine be also added. In the latter case sulphuric acid is formed.

$$H_2SO_3 + OH_2 + Cl_2 = H_2SO_4 + 2HCl.$$

Sulph*ite* of barium is soluble in acids, sulph*ate* not so. Iodine does the same when the liquid is sufficiently diluted.

$$H_2SO_3 + OH_2 + I_2 = H_2SO_4 + 2HI.$$

It must not be overlooked that in more concentrated solutions the reaction goes the other way, *e. g.*,

$$2KI + 2H_2SO_4 = K_2SO_4 + I_2 + 2H_2O + SO_2.$$

The strength of sulphurous acid solutions is to be tested by the volumetric solution of iodine. The reaction has just been shown. As soon as the whole of the SO_2 has been changed into H_2SO_4, the next drop of iodine which is superadded remains in the liquid unchanged, and therefore forms with the starch previously added its characteristic blue compound. When this point is reached the dropping in of the iodine is stopped.

3·47 grams of the official sulphurous acid require for complete oxidation 100 c.c. of the vol. sol. of iodine. 1000 c.c. of the vol. sol. contain $\frac{1}{10}$ of an atom of iodine, or 12·7 grams; 100 c.c. therefore contain $\frac{1}{100}$ of an atom, which, according to the equation already given, is sufficient for $\frac{1}{200}$ molecule of SO_2, or ·32 gram. This would be the quantity in 3·47 grams of the solution; it is equivalent to 9·2 per cent.

3·47 : 100 as ·32 : 9·2.

* It is proposed to employ a 5 per cent. solution, there being a little difficulty in preparing a liquid of the official strength as a commercial article.

THE CITRATES OF THE U.S. PHARMACOPŒIA.

BY C. LEWIS DIEHL.

(*Concluded from page* 346.)

Citrate of Iron and Quinia.—The formula of the United States Pharmacopœia for this preparation is as follows:—

Solution of citrate of iron 10 fl. oz.
Sulphate of quinia 1 troy ounce.
Diluted sulphuric acid.
Water of ammonia.
Distilled water, each, a sufficient quantity.

"Triturate the sulphate of quinia with six fluid ounces of distilled water, and having added sufficient diluted sulphuric acid to dissolve it, cautiously pour into the solution water of ammonia, with constant stirring, until in slight excess. Wash the precipitated quinia on a filter, and, having added to it the solution of citrate of iron, maintained at the temperature of 120° by means of a water-bath, stir constantly until it is dissolved. Lastly, evaporate the solution to the consistence of syrup, and spread it on plates of glass, so that, on drying, the salt may be obtained in scales. In thin transparent scales, varying in colour from reddish-brown to yellowish-brown, with a tint of green, according to the thickness of the scales. Its taste is ferruginous and moderately bitter. It is slowly soluble in cold water, more readily so in hot water, but insoluble in ether and officinal alcohol. Ammonia, added to the aqueous solution, deepens its colour to reddish-brown, and causes a whitish curdy precipitate of quinia; but no sesquioxide of iron is thrown down."

The solubility of this compound is so excessively sparing, even when heat is applied to favour it, that it is a question whether its medicinal efficacy is not impaired thereby. There exists no particular difficulty in preparing a handsome article when the directions of the Pharmacopœia are followed. But these directions are liable to the same objections as specified previously with regard to solutions of citrate of iron, as a good result is dependent entirely upon the accurate attention given to the preparation during the process of heating; for if the heating reaches a certain point of temperature higher than directed when the quinia is being dissolved, it is apt to agglomerate into masses which are very unmanageable and difficult to dissolve. The difficulty may be obviated by triturating the properly precipitated and washed quinia with a portion of the solution of citrate of iron, introducing it into a flask, and then adding the remaining solution. By occasional agitation, the quinia dissolves in a short time, forming a clear solution, which may be concentrated on a water-bath without paying any special attention to temperature, and will scale with perfect facility. But by far the more popular salt is the *ammonio-citrate of iron and quinia*, which appears to have replaced the officinal compound almost entirely. This may be prepared successfully by reserving about one-sixteenth of the solution of citrate of iron and quinia, obtained as above, and adding to the remaining fifteen-sixteenths, contained in a flask, dilute aqua ammoniæ in fractional portions, until a permanent precipitate results. Upon each addition of ammonia, quinia is copiously precipitated, but it re-dissolves readily by agitation until toward the end of the process, when it will dissolve more slowly, and care must be exercised to avoid an undesirable excess of alkali. The addition of the reserved one-sixteenth of solution will, by careful manipulation, redissolve the precipitate formed; and the solution, which in this instance may be evaporated to the consistence of treacle on an ordinary water-bath, without special care as to temperature, will, when spread upon glass plates, form fine scales of a handsome garnet colour, of perfect and rapid solubility and only moderate deliquescence.

Solution of the Soluble Citrates.—An expeditious method of dissolving the soluble scaled preparations is to place the salt in a mortar, add just sufficient water to cover it, allow it to stand a minute or two, then gently triturate the mixture with a pestle, when perfect solution will result. If it is attempted to dissolve the salts by direct trituration with water, they will adhere to the pestle and sides of the mortar and greatly delay the operation.

Pills of the Soluble Citrates.—These may be conveniently and expeditiously prepared by adding from ten to fifteen per cent. of finely powdered elm-bark, and forming a mass by the aid of glycerine, which appears to exercise just sufficient solvent power to effect proper cohesion. A plastic mass is obtained, which does not harden rapidly, and is readily rolled into pills.

GLYCERINE IN BEER AND WINE.

The demonstration by Pasteur, ten years ago, and later by Nessler, Pohl and others, of the natural presence of glycerine in fermented liquors, gave rise to an advantageous process for the improvement of wines. It was also inferred that a certain admixture of glycerine with beer would improve its quality. A series of experiments were made. Several kinds of celebrated beer, from Dresden, Culmbach, Bohemia and Erlangen, were analysed. In all these beers glycerine could be detected, in none in less proportion than ·02 per cent., while in the Erlangen beer it rose to ·09 per cent. This proves that in wort, besides the conversion of the sugar (glucose) into alcohol and carbonic acid, another form of fermentation, the so-called succinic fermentation, sets in, by which a part of the glucose is converted into succinic acid and glycerine; glycerine being a constant constituent, influencing, and in fact determining to some extent the quality of the beer.

Glycerine is employed for the improvement of wines made from inferior grapes, the juice of which, being deficient in sugar, can never yield a sweet wine. It is preferable to sugar for the purpose, as although sugar is cheaper, it would produce a second fermentation, which is not wanted.

The extent to which glycerine is employed to improve wines cannot be demonstrated, as no wine merchant will admit that he uses it; but in western Germany the makers of purified glycerine send their travelling agents not only to the wine merchants, but to the wine farmers themselves, so that the former buy already improved wine, and need not therefore add any more glycerine. Experiments have proved that what thus improves wine will do no harm to beer. Beer containing but little glycerine has had 1 per cent. of glycerine added to it, effecting a great change in taste and fulness. Glycerine added directly to the wort will not interfere in any way with the manipulation or processes of brewing.

In the preparation of a full beer that will keep without being too bitter, glycerine may be used instead of sugar to counteract the bitterness with advantage, as it does not prolong the fermentation and clearing as sugar does. Glycerine is not readily volatile, but in a boiling liquid it passes over with the vapour of water. For this reason it should be added after the wort has become cool and before it goes into the fermenting-tubs. One or two pints of it may be used to every hundred quarts of beer, according to the quality of the hops used. One pound of glycerine represents two pounds of malt extract, or three and one-third pounds of malt, which accordingly may be reduced in quantity.—*New York Druggists' Circular.*

IODIDE OF CALCIUM, AND SYRUP OF IODIDE OF CALCIUM.*

BY OTTMAR EBERBACH.

Having had occasion to use the chemical specialities called iodide of lime and syrup of iodide of lime, and finding that the articles sold under these very unchemical names were not simple chemical combinations (as for example, iodide of iron or syrup of iodide of iron), but mixtures, the former a mechanical mixture of iodine and quicklime, the latter of the two distinct chemical combinations called iodide of calcium and iodate of oxide of calcium, and being desirous to obtain a preparation in strict accordance with the title,—the author investigated the matter, with the following results:—

The preparation called iodide of lime is a mechanical mixture of iodine and quicklime which, when put into hot water, undergoes a chemical reaction, forming iodide of calcium and iodate of the oxide of calcium, as illustrated by the following equation:—

$$6\,CaO + 6I = 5\,CaI + CaO\,IO_5.$$

These combinations are both contained in the so-called syrup of iodide of lime. To prepare the iodide of calcium free of the iodate of oxide of calcium, the most practical method is as follows:—prepare first a solution of the protoiodide of iron, by mixing iodine with a small excess of iron and sufficient water; let this stand until the solution assumes a pale green colour; filter, and add to the filtrate one-third as much iodine as had been used to make the solution of protoiodide of iron; heat to the boiling-point, and add sufficient milk of lime to precipitate all of the iron, which precipitates in the form of Wœhler's granular magnetic oxide of iron, according to the following equation:—

$$FeI + Fe_2I_3 + 4\,CaO = FeO.Fe_2O_3 + 4\,CaI.$$

To obtain the iodide of calcium, filter the solution and

* From the *Michigan University Medical Journal.*

evaporate the filtrate with the exclusion of air, as carbonic acid has the tendency to decompose it. It crystallizes in the form of needles; by evaporating to dryness it forms a white fusible mass. It is soluble in alcohol, very deliquescent, and decomposes when fused in contact with air, forming oxide of calcium and free iodine. To make the syrup of iodide of calcium, the following formula is proposed. Take of—

Iodine	4 oz.
Iron (in form of wire)	7½ dr.
Distilled water	q. s.
Milk of lime (fresh)	q. s.
Sugar	28 oz.
Simple syrup	q. s.

Mix 3 oz. of the iodine with the iron and 4 oz. of water, in a thin flask with long neck; shake occasionally until the reaction has ceased and the solution assumes a pale green colour; filter the solution and add the remainder of iodine; heat to the boiling-point, and add milk of lime until all of the iron is precipitated; filter and wash the precipitate with hot water until all the iodide is washed out, then bring the whole to the measure of 20 oz.; add the sugar and dissolve by a gentle heat; to the solution add enough simple syrup to make it measure 40 oz.; mix thoroughly, and fill into 2 oz. bottles, well corked.

The syrup is a transparent, colourless liquid, which does not tinge starch paper blue. Mixed with sulphuric acid it gives a white precipitate of sulphate of oxide of calcium and turns the supernatant liquid brown, which, by heating, emits violet vapours of iodine.

THE MULLEIN PLANT.

The Mullein (*Verbascum Thapsus*) is a biennial plant, with a straight, tall, stout, woolly, generally simple stem, occasionally with one or two branches above, winged by the decurrent bases of the leaves, and from three to five feet high. The leaves are alternate, oblong, acute, rough and densely tomentose on both sides. The flowers are a golden yellow colour, rotate, nearly sessile, and are arranged in a dense, spiked, club-shaped raceme; calyx five-parted and downy; corolla five-lobed, rotate.

Mullein is common in the United States, growing in recent clearings, along the sides of roads, in slovenly fields, etc., flowering from June to August. Some botanists consider it to have been introduced from Europe. The leaves and flowers are the parts used. They have a faint, rather pleasant odour, resembling that of a mild narcotic, and a somewhat bitterish, albuminous taste, and yield their virtues to boiling water. Mullein is demulcent, diuretic, anodyne and anti-spasmodic. The infusion is useful in coughs, catarrh, hæmoptysis, diarrhœa, dysentery and piles. Its diuretic properties are rather weak, yet it is very useful in allaying the acridity of urine which is present in many diseases. It may be boiled in milk sweetened and rendered more palatable by the addition of aromatics, for internal use, especially bowel complaints. A fomentation of the leaves also forms an excellent local application for inflamed piles, ulcers and tumours. The leaves and pith of the stalk form a valuable cataplasm in white swellings, and infused in hot vinegar or water, it makes an excellent poultice to be applied to the throat in cynache tonsillaris, cynache maligna, and mumps. The seeds are said to pass rapidly through the intestines, and have been successfully used in intestinal obstructions. They are narcotic, and have been used in asthma, infantile convulsions and to poison fish. The infusion may be drunk freely. The flowers, placed in a well-corked bottle and exposed to the sun, are said to yield an excellent relaxing oil.—*New York Druggists' Circular.*

DARWINISM IN CHEMISTRY.

A writer in the *Medical Times and Gazette* asks the question whether the groups of elements which resemble each other so strangely can be composed of isolated species of matter, or whether they are not rather formed of individual members of a family having a community of origin? Towards the elucidation of this subject he brings forward the following statements:—

The existence of natural families of elements has long been recognized by chemists. Chlorine, bromine and iodine form one such family; potassium, sodium and lithium (to which the metals cæsium and rubidium have been added by Bunsen's spectrum analysis) constitute another. The group barium, strontium and calcium, as also the group magnesium, zinc and cadmium, are well recognized. There is also the very extensive nitrogen family, comprising nitrogen, phosphorus, arsenic, antimony, vanadium, bismuth, boron and some others. Then there is the carbon family, comprising carbon, silicon and tin. Oxygen, sulphur and tellurium form a group. Lastly, there is the singular group comprising aluminium, chromium, manganese, iron, nickel and cobalt. The place of the metal copper is difficult to assign; silver likewise presents difficulties. Hydrogen is placed by some in the chlorine family, but is commonly taken to belong to the potassium family; in short, nearly every element has been assigned to one or other natural family. In the first-mentioned example, viz. chlorine, bromine and iodine—the family likeness is not in the obvious physical characters of the elements themselves: chlorine is a greenish-yellow gas under ordinary atmospheric pressure and temperature; bromine is a brownish-red liquid; iodine a dark crystalline solid, yielding violet vapour on being heated. Many compounds of these elements, however, require analysis to distinguish them. Hydrochloric acid, hydrobromic acid and hydriodic acid are colourless gases, very strongly fuming in moist air, and very soluble in water. They need to be subjected to some chemical test, or else to have their density determined in order to become distinguishable. Again, chloride, bromide and iodide of potassium are very much alike.

There is also a close parallelism between the possible combinations of chlorine, bromine and iodine with other elements. Thus, there are the chloride, the bromide and the iodide of potassium or of sodium, etc. Chloride of ethyl is represented by bromide and iodide of ethyl, and chloroform finds its analogues in bromoform and iodoform. But the parallelism, although close, is not absolute. Thus, there appear to be more oxides of chlorine than of iodine. The chloride of copper does not appear to have an iodine representative; and probably there are many complex organic chlorides which admit of no corresponding iodides; inversely, compounds of iodine, with iodides of the compound ammoniums, seem to be unrepresented by corresponding chlorine compounds.

In the second group—that of the metals potassium, sodium, and lithium—there is in their compounds a resemblance very often so close that chemical analysis has to be called in to distinguish whether there be potassium, sodium, or lithium in the compound. There is, again, the closest parallelism between the possible compounds of these metals. Not a single potash-salt of any one of the thousands of possible acids but has its fellow sodium-salt. The only breaches of the parallel that occur to the writer are in the oxides of the metals and in the degree of hydration of the salts—potassium- and sodium-salts taking up different numbers of atoms of water of crystallization; the individual uncombined members of the potassium group present also a physical similarity. All are solids under ordinary conditions; potassium and sodium having very nearly the same melting and boiling points.

Between the chemical equivalents of the different members of a natural family some very curious and interesting relations have been traced. Thus, the equivalents of potassium, sodium and lithium are, respectively, 39·1, 23 and 7. Now, 23 is the exact arithmetical mean between 39 and 7; and in energy and general resemblance sodium is the mean of potassium and lithium. The equivalents of the members of the chlorine group exhibit a somewhat similar relationship, only not so precisely. They are 35·5, 80·0 and 127·0, the middle one not being quite the arithmetical mean. Barium, strontium and calcium afford a similar example, viz. 68·5, 43 and 20 respectively. In the potassium group the highest equivalent and highest energy go together; in the chlorine group the least equivalent is joined to the highest energy (chlorine being more energetic than bromine, and bromine more energetic than iodine); in the barium group the order is curious, viz. highest equivalent with highest energy (barium); next, intermediate equivalent with lowest energy (strontium); and last, lowest equivalent with intermediate energy (calcium).

A suggestive relationship subsists between the *equivalents* of oxygen and sulphur, chemical fellows with strongly-marked resemblances, whose equivalents bear to one another the exact ratio of 1 to 2.

Lastly, nickel and cobalt offer a marvellous case of resemblance. Chemically, they are almost indistinguishably alike in their compounds; physically, they are like one another as isolated elements; and their equivalents are absolutely identical, so far as the most accurate determinations have been able to show.

Postal Cards and Sympathetic Ink.—The introduction of the halfpenny postal-cards, with the direction on one side and the correspondence on the other, has given interest to the subject of sympathetic ink. One of the best-known kinds of sympathetic ink consists of a weak solution of chloride or nitrate of cobalt. Writing executed with such a solution is invisible until it is warmed, when it appears green or bluish, disappearing on exposure to moist air; the explanation being, that the anhydrous chloride and nitrate of cobalt are deep green or bluish, whilst the hydrated salts are very pale pink—invisible in small quantities of salt. If, instead of chloride or nitrate, acetate of cobalt containing a little nitre be used, then the writing will come out in pale rose-coloured characters, visible whilst warm and invisible when cold. Another variety of sympathetic ink consists of weak infusion of galls. To render the writing visible, it must be dipped into solution of an iron-salt, the common sulphate or green vitriol answering the purpose very well. Yellow prussiate of potash, dissolved in water, also makes an ink which becomes visible on treatment with persalts of iron. A great number of possible solutions will at once suggest themselves to the chemist; thus the writing might be done with acetate of lead and rendered visible by means of a solution of sulphuretted hydrogen. No doubt basic acetate of lead would be superior to neutral acetate for such a purpose. Most, and possibly all, kinds of sympathetic ink give writing which becomes more or less visible when the paper written upon is very strongly heated, to the point of becoming slightly burnt. Some of the solutions which are sometimes recommended as sympathetic ink, as, for instance, solutions of silver and gold, are very unsatisfactory, becoming visible on exposure to the light. Hence, many sympathetic inks are little to be relied on, and the safest are those, such as the basic acetate of lead, which require a special solution for their development.—*British Medical Journal.*

Explosion of Naphtha.—On Wednesday evening, Oct. 26, while a party of men on board H.M.S. Hercules were lowering a cask containing Hay's Patent Anti-Fouling Composition into the carpenter's store-room, it fell from the slings, and bursting, its contents ran over the deck. Some men were sent to clean the deck, who took with them two lamps. The vapour of the naphtha used in the composition coming in contact with the lights caused an explosion, which was followed immediately by a second, the flame on each occasion rising through the hatchway to the upper deck. Upon descending into the storeroom, where the effluvium was most overpowering, it was found that six men were severely, and three slightly, burned. As a quantity of the liquid had reached the "double bottom" under the store, both compartments were, as soon as possible, flooded with water, to prevent the possibility of a fire breaking out.—*Standard.*

Poison of Acorns.—Sir George S. Jenkinson has written a letter to the *Times*, stating that in the neighbourhood of his seat at Eastwood Park, Berkeley, Gloucestershire, the cattle are dying by scores from having eaten too many acorns which had fallen during the late gale. If once a beast is taken ill nothing seems to have any effect on the inflammation which ensues, death following more or less quickly in each case. The poison affects the intestines, blackening and rotting away the mucous membrane. He says that it is only the cattle that have been out and eaten largely of the acorns that are affected.

Preserved Meat.—It is well known that meat preserved in tins by the ordinary process of heating in a chloride of calcium bath for a prolonged period and then closing the orifice, is surrounded by jelly, which, with most of its juice, has been extracted from the meat, leaving a tasteless and exhausted fibre. To obviate this objection a method has been adopted by Mr. Richard Jones, in which the steam is exhausted from each tin by a tube connected with a vacuum chamber, the meat being thus dried with its juices left in their natural place amongst the muscular substance, while the whole process can be effected at a lower temperature, and with less injury to the flavour and appearance of the meat.

Local Applications to Burns.—Dr. A. D. Binkerd, writing in the Philadelphia *Medical and Surgical Reporter* (July 9th, 1870), prefers, as an application to burns when first seen, carbolic acid and glycerine, in the proportion of from 5 to 10 drops of the former thoroughly incorporated with 2 ounces of the latter, spread on with a camel's-hair or other light brush, then a layer of raw cotton, over which a roller-bandage is neatly adjusted. For the suppuration following burns he recommends the following dressing:—Yellow wax, melted and strained, ℥i; raw linseed-oil ℥iij; tannin ʒi; subnitrate of bismuth, gr. xx. The wax must be first melted, the oil then added, and the whole stirred until incorporated; next, the tannin is added, and lastly the bismuth. The ointment should be applied on pieces of lint.

Adulteration of Catechu.—It is a well-known fact that catechu is often adulterated; the sophisticated substance injuriously affecting various operations in which it is employed, especially dyeing and calico-printing. According to Tissandier, genuine catechu, when exhausted by means of ether, loses 53 per cent. of weight, leaving, after drying, 47 per cent. of residue. A mixture of catechu and alum gives a white precipitate with nitric acid and with chloride of barium.

Solvent for the Ear Wax.—After a series of experiments made by Dr. Petrequin, of Lyons, in which he tried successively olive oil, glycerine and oil, alcohol and olive oil, olive oil and oil of turpentine, ether, alkaline solutions, soap and water, chloroform, sulphuret of carbon, etc., he has arrived at the conclusion that the old remedy of tepid water is the best for the purpose.

Antidote to Carbolic Acid.—Sweet oil or castor oil swallowed in large quantities are recommended as the most efficient antidotes to carbolic acid, when it has been taken in poisonous doses.

New Application of Chloral Hydrate.—A writer in the *Lancet* reports that he has used chloral hydrate combined with chloric ether successfully in severe cases of diarrhœa.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 5, 1870.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes to be endorsed "Pharm. Journ."*

THE ELECTION OF ANNUITANTS.

IN another column our readers will find particulars of the election of two more annuitants on the Benevolent Fund, raising this class of recipients to the number of twelve. By the passing of the Pharmacy Act of 1868, the advantages of the fund were thrown open, as many of our readers know, to the whole class of chemists and druggists, instead of being restricted, as was the case before that period, to members of the pharmaceutical body.

Though the number of applicants for temporary and permanent relief is increasing annually, we are surprised to notice that the amount of subscriptions and number of individual subscribers are decreasing. This apathy on the part of the large majority of the trade is much to be regretted, and we hope, for the sake of our cloth, will not be allowed to continue. A body of men, mustering somewhere about 10,000, should, without much special pleading, be able to provide assistance for the whole of its distressed members, and for all the widows and orphans having a claim upon it.

If every chemist and druggist were to subscribe five shillings yearly, the directors of the fund would have a revenue approaching the necessities of the charity; and we commend this suggestion, in all sincerity, to those who have not hitherto made it their practice to subscribe. It is painful to notice how frequently the most skilful and highly endowed men become unfortunate in business; and we only allude to the circumstance to quicken the sense of responsibility which, in our opinion, devolves upon every registered chemist and druggist, that of contributing annually, as a *matter of duty*, at least *some* amount towards the relief of his distressed brethren.

SOME time since, we noted the serious illness of Dr. ANDERSON, and we have now the sorrowful task of recording his death.

WE are glad to state that at the moment of going to press permission has been received from the Post-Office for the posted copies of the Journal to be cut.

Proceedings of the Pharmaceutical Society.

BENEVOLENT FUND.

ELECTION OF ANNUITANTS.

A meeting was held at the house of the Society on Friday, the 28th October, pursuant to notice, for the ELECTION OF TWO ANNUITANTS on this Fund, each to receive Thirty pounds; Mr. A. F. HASELDEN, Vice-President, in the chair.

Four applicants remained on the list of Candidates approved by the Council for Election.

Scrutineers were appointed from the voters present, who, after examining the votes, presented the following report:—

"We, the undersigned scrutineers, appointed at the sixth election of annuitants on the Benevolent Fund of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following result:—

	No. of Votes.	Brought forward.	Total.
Hannah Greaves	1982	739	2721
Charles Thomas Anderson	1715	787	2502
John Watkins	929	763	1692
Sarah Wilson	623	91	714

"Signed,

JOHN BRADLEY. H. F. GROVES.
I. BOURDAS. FREDERICK ANDREWS.
CHARLES E. TURNER. WILLIAM A. TILDEN.
CHARLES COLES. T. H. HOLLOWAY."

Votes polled for unsuccessful candidates are carried forward.

PHARMACEUTICAL MEETING.

Wednesday, November 2nd.

The Chair was taken by Mr. HASELDEN, Vice-President.

The SECRETARY having read the minutes of the previous meeting, announced the following donations to the Library and Museum:—

Calendar of the Royal College of Surgeons for 1870: from the College,—Transactions of the Clinical Society, vol. iii.: from the Society,—Specimen of Bauxite (aluminate of iron) used as a source of aluminium,—Specimen of Cryolite: from H. B. Brady, Esq.,—Specimen of falsely-packed Chiretta: from Mr. H. S. Evans.

The following papers were then read:—

REMARKS ON A SPECIMEN OF CHIRETTA, PRESENTED TO THE MUSEUM BY MR. H. SUGDEN EVANS.

BY E. A. WEBB.

I wish to draw the attention of the meeting to the packet of chiretta upon the table, which Mr. Henry Sugden Evans has kindly presented to the Museum. It is one of a number of packages that were imported into England about a year ago. It is curious from having in the centre a package of a distinct plant, which has been first carefully tied up by itself, and then surrounded by the chiretta.

When first shown to me, I saw it must be a madder of some sort by its square, rough stems, which, as well as the roots, are red, and by its coming from India I suspected it might be munjeet, *Rubia cordifolia*. I have since had my opinion confirmed in several ways.

1st. I obtained from the stems a very fair quantity of alizarine by digesting them in strong sulphuric acid and then diluting with water, whereby the alizarine was precipitated.

2nd. I submitted a sample to Mr. Daniel Hanbury, who kindly compared it with the illustrations and descriptions he had of the plant, with which it agreed as far as the specimens would allow us to judge.

And 3rd, by his advice, I sent a sample to Mr. M. C.

Cooke, Curator of the Museum at the India Office, from whom I had the following satisfactory reply:—

"Dear Sir,—I have not the slightest doubt that your specimens are *Rubia cordifolia*. Yours most obediently,
"M. C. Cooke."

The following are, I think, the chief characters by which it may be distinguished from chiretta:—

It is a trailing plant, with an underground stem about the thickness of a quill, giving off rootlets at intervals; of a dull reddish colour externally, but brighter internally. The stems are long and trailing, quadrangular, the angles being covered with small recurved prickles. The cortical portion, when old, soon breaks off from the internal woody portion, which is round, and of a red colour like the root.

The *leaves* are about an inch and a half long, supported upon peduncles about half that length, arranged in whorls of four at the nodes, which are very conspicuous. They are 5-ribbed, with an entire or dentate margin, and generally more or less cordate.

The specimen I examined had no signs of flower or fruit upon it.

The true *Ophelia Chiretta*, on the other hand, has a thick branching root, a round, smooth brown stem, sessile amplexicaul opposite leaves, and purely bitter taste.

The reason of this false packing is I think very evident, when we know that about that time chiretta was between 2*s.* and 3*s.* a pound, while munjeet was between 4*d.* and 6*d.*

Mr. Tilden asked if Mr. Webb was sure it was alizarine he had procured from the plant.

Mr. Webb said that he had tested it with potash and in other ways, and he had no doubt of the result.

Mr. Tilden said he had thought the appearance might be due to purpurine. He was working with Dr. Stenhouse when that gentleman discovered mungistine, which presented the most magnificent crystals, in the shape of beautiful golden scales, while alizarine was not contained in *Rubia cordifolia*. It might easily be proved by boiling some in water.

Mr. Webb said, that when boiled and reprecipitated, it appeared in an amorphous condition. He had sublimed some, from which he had got crystals very similar to alizarine.

Professor Bentley said he was quite sure the meeting would agree with him that it was of great importance that such specimens as that on the table should be brought before the notice of the Society immediately they found their way into the market. Very fortunately in the present case the adulteration was so palpable that it would be at once detected, but in some cases there would be more difficulty, and, therefore, it was of importance that their attention should be called to the matter, in order that they might be on their guard. He had looked over many specimens of chiretta, but had never met with such an instance of adulteration before; indeed, according to his experience, it was a substance very little subject to adulteration, but in this case the reason assigned by Mr. Webb was evidently the correct one, and the difference in price had led to an attempt to deceive the public. He might add that he had no doubt of the plant being munjeet.

Dr. Attfield said he believed the adulteration was not nearly so manifest when the specimen was first placed in Mr. Webb's hands.

Mr. Clements drew attention to an improved atmospheric gas-stove of his manufacture, a specimen of which was placed on the table; the advantages he claimed for it being the small amount of gas burnt and the perfect combustion which took place. A gallon of water could be boiled in fourteen minutes, at the ordinary day pressure, which would support a combustion of about 8 feet per hour. The burners were made of silicate of magnesia or soap-stone; he had himself had one in use for two years and a half without its getting out of order, and Dr. Odling had also used it, and reported favourably of its capabilities. The size exhibited was sold at 15*s.*, but they were made larger if required, and might be adapted for cannel-coal gas as well as ordinary gas.

Experiments on Some of the Infusions of the Pharmacopœia.

BY J. B. BARNES.

In the two last editions of the Pharmacopœia the time for the preparation of most of the infusions has been very properly lessened, but I shall be able to show that a still further reduction in the time of making infusions can be made without detriment to the resulting product. In each separate set of operations the sample of drug employed was the same; the measuring and weighing were carefully made; each infusion, excepting that of linseed, was filtered through paper before the specific gravity was taken and the evaporation set going; the latter was made in porcelain dishes over a water bath, and the resulting extract finally dried in a water oven at 212° F. until the weight became constant.

In the following tables the results obtained are exhibited:—

Infusions of the Pharmacopœia, prepared in accordance with the Time ordered.

Infusion.		Quantity of Ingredients to half a pint of Distilled Water.	Time of Infusion.	Quantity Evaporated.	Specific Gravity.	Weight of Dried Extract obtained. Grammes.	In Grains.
Bearberry		½ ounce	Two hours	Ten fluid ounces	1·215	5·33	82·25
Buchu		½ ounce	One hour	,,	1·213	3·57	55·08
Cascarilla		1 ounce	One hour	,,	1·211	2·74	42·28
Cinchona		½ ounce	Two hours	,,	1·210	1·94	29·93
Cusparia		½ ounce	Two hours	,,	1·210	3·05	46·45
Digitalis		30 grains	One hour	One pint	1·208	1·07	16·51
Dulcamara		1 ounce	One hour	Ten fluid ounces	1·215	5·13	79·16
Gentian	Gentian root	60 grains	One hour	,,	1·215	2·26	34·87
	Orange peel	60 grains					
	Lemon peel	¼ ounce					
Hop		½ ounce	Two hours	,,	1·213	2·79	43·04
Linseed	Linseed	160 grains	Four hours	,,	1·210	1·28	19·75
	Liquorice root	60 grains					
Rhatany		½ ounce	One hour	,,	1·210	2·16	33·33
Rhubarb		¼ ounce	One hour	,,	1·211	2·71	41·82
Senega		½ ounce	One hour	,,	1·213	3·69	56·93
Senna	Senna	1 ounce	One hour	,,	1·223	9·08	140·12
	Ginger	30 grains					
Serpentaria		½ ounce	Two hours	,,	1·209	·71	10·95
Valerian		120 grains	One hour	,,	1·210	1·91	29·47

Infusions of the Pharmacopœia **NOT** *prepared in accordance with the Time ordered.*

Infusion.	Quantity of Ingredients to half a pint of Distilled Water.	Time of Infusion.	Quantity evaporated.	Specific Gravity.	Weight of dried Extract obtained. Grammes.	In Grains.
Bearberry	½ ounce	One hour	Ten fluid ounces	1·215	5·35	82·56
		Half an hour		1·213	2·82	43·51

Valerian	120 grains	,,	,,	1·210	1·86	28·7

Infusion of bearberry made in two hours gave 5·33 grammes extract; that which had infused one hour yielded 5·35 grammes; the infusion which had stood for half an hour gave 2·82 grammes; the conclusion is, that the one-hour infusion is as good as that which stood two hours.

Infusion of buchu, made to infuse half an hour, gave 3·55 grammes of extract, and that which stood one hour 3·57 grammes; there is no real difference.

Cascarilla infusion, made in one hour, gave 2·74 grammes of extract, and that which had stood half an hour 2·73 grammes.

Infusion of cinchona bark, prepared in one hour, yielded within two centigrammes the same amount of extract as that which had been infused for two hours; practically they are identical.

Infusion of cusparia (although the temperature of the distilled water is ordered to be at 120° F., and the time of infusion two hours) is equally strong when macerated for one hour only.

Infusion of digitalis made in fifteen minutes gave exactly the same amount of extract as that which had stood one hour.

That of dulcamara, infused for half an hour, yielded within one centigramme the same weight of extract as that which had infused one hour.

Compound infusion of gentian, made in accordance with the time and manner ordered in the Pharmacopœia, namely, one hour, and the root sliced, gave 2·26 grammes of extract; whilst when infused for half an hour, and the gentian root was *bruised*, the amount of extract obtained was 2·85 grammes; therefore there can be no doubt that it should be directed to be bruised instead of sliced. Of course, when gentian root is fresh, it is tolerably soft and can be easily sliced as thin as you please, but it is seldom met with in that state.

Infusion of linseed, which had stood for two hours, was within one centigramme as strong as the Pharmacopœia infusion, which is directed to be infused for four hours.

Infusion of hop, made in one hour, was also within one centigramme as strong as that which had stood two hours.

Infusion of rhatany, made in half an hour, yielded 2·15 grammes, whilst that which had infused one hour gave 2·16 grammes of extract.

Senega infused for half an hour gave 3·6 grammes of extract, and that of the Pharmacopœia, which stood one hour, 3·69 grammes.

Infusion of senna, made in accordance with the time in the Pharmacopœia, yielded the large amount of 9·08 grammes, that prepared in half an hour gave 8·9 grammes of extract; therefore, this is not so good as that which had stood one hour, but by a slight increase in the quantity of senna, this infusion can be made in half an hour equally as strong as the Pharmacopœia preparation.

Infusion of serpentaria, which had stood for two hours, yielded ·71 gramme of extract, whilst that made in half an hour, gave ·7 gramme.

That of valerian, made in one hour, gave 1·91 gramme of extract, and the infusion prepared in half an hour yielded 1·86 gramme.

From these results, I draw the following conclusion:—namely, that infusions of bearberry, buchu, cascarilla, cinchona, cusparia, dulcamara, gentian, hop, linseed, rhatany, rhubarb, senega and valerian, can be prepared in half the time ordered by the Pharmacopœia; those of digitalis and serpentaria in one-fourth the time directed for infusion; and this without resorting to any special manner of making.

I trust the Pharmacopœia Committee will take up this subject, examine it for themselves, and make the necessary abridgment of the time in the directions for making these infusions, and thereby facilitate their speedy preparation.

The extracts obtained in this series of operations are of course perfectly dry, for the most part in a spongy condition, and can be easily reduced to powder. Extract of rhubarb, as all dispensers must know, is either very soft or tough, and, when in the latter condition, is difficult to manage in pill making; the exsiccated extract on the other hand is exceedingly manageable, and can be at once without trouble reduced to fine powder.

Dr. Attfield said Mr. Barnes seemed to have given his result in terms of the weight of extract, but he presumed he also judged of the character of the infusions by the nose and palate.

Mr. Barnes said he had done so.

Dr. Attfield said it would have been interesting, in the case of the extract of cinchona, to ascertain whether there was the same proportion of the alkaloids in each case, although, no doubt, they would go into solution at about the same rate as other substances.

The Chairman said the remark of Dr. Attfield suggested the desirability of carrying these experiments further; but, whatever might be the result of such researches, it was evidently of importance to pharmacists to know that, in case of necessity, they might make an infusion in half an hour as well as in one or two hours. He was sorry to say that prescribers did not order infusions as much as formerly, because, in his opinion, a good fresh infusion, if employed as a stomachic, was much better than a tincture of the same substance. He believed, however, the great difficulty with medical men had been the delay which was necessary in the preparation, which often could not be allowed; and other preparations were therefore had recourse to. He believed this matter was well worthy of the attention of the Pharmacopœia Committee whenever they sat.

Mr. Bass asked if Mr. Barnes had tried the experiment of redissolving the extract in the same amount of water required to make the infusion; and, if so, whether the difference in smell, taste, and general appearance was very perceptible, or whether he found much difficulty in redissolving the extract.

Mr. Barnes said he had not made the experiment referred to, but in washing out the dishes he found the extract very readily soluble.

Mr. Carteighe said the paper was one of great practical value, but he believed it was possible to carry the experiments further, and, by increasing the quantity of ingredients, get quite as satisfactory results in a quarter of an hour. It would certainly be a great desideratum if any infusion in the Pharmacopœia could be made in ten minutes or a quarter of an hour; and he could not help thinking that very often, if they were content to waste a little more of the drug, it would, in the long-run, be much more economical than waiting so long as they were in the habit of doing.

Mr. Umney said he did not suppose that, in the case of infusions made at a very high temperature, the extract would be redissolved very readily, on account of the albuminous matter being coagulated, but those obtained at the temperature of boiling water would probably be readily soluble.

Mr. Tilden said, no doubt the suggestion made by Mr. Carteighe was one founded on practical experience; but he fancied that increasing the proportion of the ingredients, and using a shorter time, would hardly be a fair way of altering the mode of preparing infusions. For instance, in the case of an infusion of orange or of buchu, if such a plan were adopted, the result would be very different to what it would if the infusion stood for a longer time. A cup of tea that had stood for a long time was not exactly the same as one made quickly.

Mr. Carteighe said, no doubt the thing must be done cautiously, but the experiments showed such a trifling difference in the most extreme cases that a slight increase in the ingredients would probably reduce the time materially.

Mr. Barnes did not think that the dry extract of buchu, if dissolved in water, would represent the infusion, and the same with gentian.

Professor Redwood said, all facts of this kind must be of importance to those engaged in revising the Pharmacopœia; and, no doubt, it was desirable to reduce the time required for making infusions, but still there were other points to be taken into consideration in connection with that object. This matter received attention at the time the last edition but one of the Pharmacopœia was being prepared; and the whole of the infusions were submitted to a careful examination, with the view of determining the best proportion in which to use the ingredients, the best time during which to conduct the maceration, and the best temperature for the water. He was not prepared to offer any specific opinion with reference to the points specially alluded to by Mr. Barnes; but he must say he did not consider the shortening of the time during which the infusion stood was the most important point to attend to. Indeed, he believed the product might be considerably deteriorated by aiming too much in that direction. For instance, in tea-making there was a certain specific time, which was found to be most advantageous for making a good infusion; and all tea tasters had come to the conclusion that seven minutes was the period during which tea ought to be infused. In order to bring out the best qualities of the tea, this time should be neither longer nor shorter. It was the same with several of the infusions orderd in the Pharmacopœia. For instance, in the case of chiretta it had been found that water at 120° yielded a more agreeable infusion, and one which was considered to act better as a tonic than when made with water either hotter or colder. The mere amount of the extract, therefore, was not the only point to be considered, nor did he suppose that Mr. Barnes had confined his attention solely to that. At any rate the subject was one deserving of attention, and if it were found that the time could be shortened without detriment, there was no doubt that it would be advantageous, but he believed many chemists were under the impression that there was more difficulty in keeping fresh infusions fit for use than the facts would fully warrant. It was by no means difficult to keep even those most susceptible of change, in a fit state for use, not only for days, but weeks, and in some cases he had done so for months, by properly preparing and bottling them, either with stoppers or with cotton-wool in the neck of the bottle, so that no unfiltered air could reach the contents. In such cases, therefore, the time occupied was of comparatively little importance.

Mr. Barnes said he was led to make these experiments by having to make an infusion of serpentaria one day, when, the patient being very unwell, it was wanted in a great hurry, and he found that by the method suggested the infusion was made in half the prescribed time (two hours) equally agreeable and as good in every respect. When half a pint of an infusion which had macerated half an hour, was evaporated to dryness, the resulting extract weighed and found to be the same weight, or within a centigramme or two over or under the amount obtained from the same quantity of infusion which had taken one hour to make,—he could not conceive how it was possible to suppose that the one infusion was not as good as the other.

The Chairman said Mr. Barnes had chosen a very fair way of arriving at something like a definite conclusion; and certainly, for his own part, if he were to make two infusions of the same drug, allowing them to stand different times, he should scarcely like to rely upon his own judgment in tasting and smelling the results as a means of judging whether they were precisely alike. He should almost want a committee to decide upon such a point. Dr. Redwood had referred to the system of filling up bottles with fresh infusions, which had been adopted over and over again, and no doubt they would keep good in the ordinary sense for a considerable time, that is to say, they did not turn mouldy or sour, but he did not think there was the same aroma as when freshly made. That was why he suggested at one time that infusions intended for keeping should have a small quantity of alcohol added to them, which from some experiments seemed to have the effect of retaining the odour and aroma. He had known infusions carefully made go bad in twelve hours in hot weather,—senna, for instance, —even when kept in a cool place.

Mr. Bland said the remarks of Professor Redwood showed the necessity for caution in the mode of preparing infusions, and it must be remembered that even if they could be made in ten minutes the patient could not take the medicine boiling hot. With regard to cinchona, he was quite satisfied that in most of the processes given for its preparation a large quantity of the alkaloids were wasted. He was satisfied that no infusion of cinchona made in one hour would contain all the alkaloids which might be extracted from it.

Mr. Umney said, some time since, Professor Redwood, in his *résumé* of the alterations which would in all probability be made in future editions of the Pharmacopœia, mentioned the fluid extract of ergot as one of those preparations which he thought could be equally well prepared without ether. He (Mr. Umney) had made considerable quantities in both ways, and he found no difference in the product after it had been kept four or five months. He would lay on the table two specimens which had been made about four months, one prepared in each way. It was important to recollect that the loss of ether was something considerable,—70 or 80 per cent.; and it appeared to him a farce to take up an inert body by means of an expensive solvent like ether, and then to redistil it, and then to throw away that inert body.

Mr. Barnes asked what solvent Mr. Umney employed.

Mr. Umney replied water only at 120°.

The Chairman said he supposed Mr. Umney had followed the directions in the Pharmacopœia, simply omitting the ether. He had always thought the ether process unnecessary, and it involved not only a waste of material, but a waste of time.

Mr. Martindale said he had always felt that there was a disadvantage besides that of taking the oil from the ergot by means of the ether, for they could not be certain that they did not take away some active properties which the water alone would not have done. There was therefore a great disadvantage in using ether to exhaust the oil, because it might likewise take with it other principles which might be of great service. He had made the fluid extract as Mr. Umney had suggested, and it had been used for a considerable time at University Hospital, and equally approved with that made in the ordinary way.

Professor Redwood said that if the ether was not thoroughly well washed, so as to deprive it entirely of spirit, it would remove some of the active principle of the ergot. The result of the experiments made seemed to indicate that pure ether did not take out the ordinary active matter of the ergot, but only the essential oil. In justice to one of the members of that Society, he should say his attention was first drawn to this subject from the fact of Mr. Hemingway having communicated to him that the fluid extract of ergot could be made quite as well without ether as with it, and that he had been in the habit of so preparing it for some time.

A Member said he had prepared the extract without ether for some years before it was introduced into the Pharmacopœia, and had not found that there was any difference in its strength.

The Chairman said Professor Redwood had suggested other matters in which some alteration in the mode of preparation might be made, amongst others purified oxgall and belladonna plaster. He should like to know whether any of the members had made experiments upon any of these preparations.

Mr. Umney thought that the belladonna plaster would be much better if made in the mode suggested by Mr. Balmer, with the alcoholic extract of the root.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

Annual Meeting.

Session 1869–70.

The Annual Meeting was held at the Royal Institution, October 13th, 1870. In the absence of the President, Mr. Shaw took the chair.

Messrs. F. Allison, J. Blair, A. T. Horton and E. Keighley Sharp were elected members of the Association.

The Secretary then read the Annual Report.

Annual Report.

The Report which your Council lay before you this year presents features of unusual interest, both with reference to the Association itself and also as regards events closely connected with it, and which should exert considerable influence on its progress and vitality. Having completed the twenty-first year of its existence, the Association has given evidence of its ability to contend with and overcome the difficulties incident to the youth of all voluntary societies, and may now look forward confidently to years of strength and usefulness. Still there are dangers to be avoided; the enthusiasm which greeted its early years has passed away, and from its solid advantages and practical value to its members it must now derive its support. To provide these, and to watch over the interests of the Association are the duties of your Council, and they trust that you will find that they have not neglected their responsible functions.

15 members and 2 associates have been elected during the past session; 24 have resigned, or by death and removal have ceased to belong to our ranks, leaving 127 at present on the roll.

In that important department of the work of the Association which consists in its fortnightly meetings, your Council cannot report so favourably as in some former years. The interest of these meetings can only be kept up by the united efforts of the members, and your Council trust that by an increased supply of papers, and more vigorous discussion of them, their usefulness may be augmented. The papers read have principally related to the practice or ethics of pharmacy, and your Council desire to express their acknowledgments to those gentlemen who have contributed them.

Several additions of valuable works have been made to the library, and its treasures have been freely used. The Librarian reports that 374 books have been taken out, against 290 in the previous session, and that this does not represent the whole benefit resulting from the constant access which members have to the books, as in many cases they are consulted at the library, and not taken away.

Your Council have the pleasure of announcing that ten guineas have been voted by the Pharmaceutical Conference from the Bell and Hills' Fund for the purchase of books for the library.

The Materia Medica collection in the museum is arranged, affording a complete illustration of the Pharmacopœia, and your Council have much pleasure in informing you that a valuable collection of 70 dried medicinal plants has been presented to the Association by Mr. Ransom, of Hitchin.

The School of Pharmacy has been conducted as in the previous sessions. Your Council have had the subject of providing pharmaceutical education under their careful consideration, and trust that the measures which they have adopted will be attended with increased success.

The lectures on the evenings of the general meetings by Mr. Davies, F.C.S., have also been continued during the past session, and have formed a valuable part of the proceedings of the session.

Your Council have been much gratified by the visit of the Pharmaceutical Conference. The meeting has been most successful, the numbers attending having been large, and the expressions of satisfaction general.

A very pleasant opportunity for friendly intercourse was afforded by the President at his house in January last, and a large number of members enjoyed his hospitality.

The following members of Council retire by rotation, and are eligible for re-election:—Messrs. Davies, Murphy, Sharp and Dr. Symes.

Your Treasurer will present a report of the finance of the Association which shows a balance due to him of £14. 15*s.* 3*d.*

The Treasurer read the financial report.

Examined and found correct, October 13th, 1870.

Charles Sharp,
Alfred Henry Mason } *Auditors.*

Mr. Shaw moved "That the Reports as read be adopted, and together with the Transactions of the General Meetings, the Laws and Bye-laws, the Catalogue of Books in the Library and the List of Members, be printed and circulated among the members." He explained that the deficit was caused by extra expenditure on the museum and library. Next year there would be several items of expense omitted, and he hoped that this feature would not recur.

Mr. Mason seconded the resolution, and observed that in many cases employers did not give sufficient opportunity to their apprentices and assistants for study. The resolution was carried unanimously.

The meeting then proceeded to the election of four members of the Council in place of Messrs. Davies, Murphy, Sharp and Dr. Symes, who retired by rotation. The retiring members were re-elected.

Mr. Mason moved that a special vote of thanks be given to Mr. Ransom, of Hitchin, for his donation of 70 dried medicinal plants for the museum.

The vote was seconded by Mr. Redford and carried unanimously.

Mr. Tanner moved the following resolution, That the best thanks of this meeting be given to the donors to the Library and Museum, and to the authors of papers during the past session.

The motion was seconded by Mr. T. F. Abraham and passed.

Mr. Woodcock moved, "That the best thanks of this meeting be given to the officers and council for their valuable services during the past session."

Mr. Tate seconded the motion, and alluded to the constant attendance of the President, and to the large amount of labour which had fallen upon the Secretary during the session. Carried *nem. con.*

Mr. Redford said that he was glad that no expression of regret had appeared in the Report with reference to the deficit, as he considered that the money had been well spent and fully accounted for. He called attention to the new arrangements for the School of Pharmacy, and hoped that a new epoch of success had been commenced. He proposed a vote of thanks to the Chairman.

Mr. Tate seconded the motion, which was carried by acclamation, and the meeting separated.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The First General Monthly Meeting of the Winter Session, 1870–71, was held in the Music Hall, on Wednesday evening, October 19th, when there was a good attendance of Members and Associates to hear Dr. J. C. Hall deliver the Inaugural Address. Mr. E. Wilson, the President, occupied the chair. Dr. Hall commenced his remarks by saying that he had the honour of being the first President of the Associated Society of Chemists and Druggists in that district, and he could not but remember that he then said that it was of the utmost possible importance that all chemists and druggists should be associated together in one body, and that the same good plan should be adopted with regard to them as was pursued in respect to his own profession in the passing of the Apothecaries Act of 1815. That Act had done more to advance the interests of the medical profession than any measure that ever was passed. He had the greatest possible respect for the then Pharmaceutical Society, but he could not help at the time expressing the feeling that a wise thing would be done if a general association of chemists and druggists could be formed. He congratulated the meeting that his advice had been taken and that they now were a united body. The newspapers were filled with discussions on the subject of technical education. Educational Boards were now being formed all over England; and a Bill had been passed with a view to giving that education to the young which had been found to be of so much importance, more especially in Germany. If young chemists and druggists did not desire to be pushed aside, they must be up and doing; they must be active in their determination to possess that general knowledge which would fit them for the acquisition of the technical learning absolutely necessary to enable them to succeed in the profession on which they had embarked. They might ask how could they find time to cultivate their intellectual powers when they had to rise early in the morning, and from the time they pulled down the shutters to the time they put them up again were incessantly engaged. All he could say was, that as soon as they could, they should get up an early-closing movement, which would do them good and do their masters no harm. He had always found, too, that men with an earnest purpose could find time to make time, and a lad should get up an hour before it was time to take down the shutters rather than be left behind in the race. It was really astonishing how fruitful the shortest season was found to be when rightly employed. He would exhort them to profit by every spare moment, and, amongst other things, to acquire a knowledge of the French or German language,—better if of both. He would not deny any one relaxation from toil, but he could assure them that the solid enjoyment to be realized in the pursuit of knowledge was to an indefinite degree better than that to be found at casinos and singing-rooms. He pointed to the wide field which chemistry opened to them for the exercise of their talents, and besought them not to be daunted by any difficulties in the cultivation of that science which had done, and was still destined to do, so much for mankind. The lecturer, on resuming his seat, was loudly applauded.

Mr. Radley proposed, and Mr. Wilson seconded a cordial vote of thanks to Dr. Hall for his able address, and it was unanimously carried.

The minutes of the last meeting having been read and confirmed, and other business transacted, the meeting broke up.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Annual Business Meeting.

The Annual business Meeting of this Association was held in the Mechanics' Institution, 38, Bath Street, on Thursday evening last, 27th Oct. There was a large attendance of members; Mr. John M'Millan, the retiring President, occupied the chair. The Treasurer, on being called upon, made his statement, which showed a balance of £5. 12*s.* 6½*d.*, being much larger than that of any previous year. The Secretary then read the following report:—

"It is very gratifying to notice from the records of this Association, that a gradual improvement has been going on from year to year in the character and importance of the Association; and this progress has not been less noticeable in the past year than in any of its predecessors. The number of members on the roll is ninety (twenty-three of whom are employers); and though it is not what might be expected in such a large city as this, still it shows a vast improvement from what it was five or six years ago. This increase is doubtless attributable to the interest created by the passing of the Pharmacy Act in 1868, an interest which, we trust, will never die away. The first point of interest to be noticed among last year's records is the short course of lectures on chemistry by Dr. Moffat, all of which were well attended and highly appreciated. Those papers of professional interest, read by the members at the fortnightly meetings, were most creditable to the authors; while the discussions which usually followed brought out the great amount of pharmaceutical knowledge to which many of the members have attained. The President's Prize for the best Essay on "The Iron Preparations of the British Pharmacopœia," was not the least important of last year's transactions; and though it is to be regretted so few took advantage of that respected gentleman's liberality, it is gratifying to note that the papers sent in were of such a character that the examiners had some difficulty in giving their decision. The Pharmaceutical Journal has been received regularly throughout the year by your Secretary, and its contents perused by those members who do not get it direct. The annual Soirée and Ball of the Trade was, as usual, quite successful.

"The arrangements for the forthcoming Session are in a very forward state. Dr. Moffat is expected to follow up his course of lectures on chemistry of last year this Session also; and Mr. Hennedy, Lecturer on Botany to the Mechanics' Institution, is expected also to contribute to this winter's course; while 'Volumetrical Analysis,' 'Volatile Oils,' and other important subjects, will be discussed by the members. Your Committee also trust that the discussion last year on the 'Trade Price List' and 'Early Closing' will not be forgotten; for, though some improvement has already been made, we are not to rest satisfied. It is the province of societies such as ours, as it is to the interest of every member of the profession, assistant or employer, to take up such questions. Success in this, however, as well as in other things, depends altogether upon the unity and co-operation of all. It is therefore hoped that a large number of additional members will come forward this Session, and that the committee to be appointed will work as faithfully as former committees have done in the past."

The President, in proposing the adoption of the report, delivered his valedictory address, in course of which he took occasion to notice the action taken by this and other societies throughout the kingdom in reference to the proposed "Regulations for Keeping and Storing Poisons," expressing a hope that we shall hear no more of them after the opposition which they met; and that as the education of the pharmacist was now compulsory, the manner in which his business should be conducted would be left to his own discretion.

The reports were afterwards adopted, and the following officers were appointed for the ensuing Session, viz.: —*President*, Mr. Thomas Davison; *Vice-President*, Mr. R. Brodie; *Treasurer*, Mr. T. D. Cassells; *Secretary*, Mr. J. M. Fairlie; with a large and influential Committee.

Votes of thanks to the retiring officers brought the meeting to a close.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting at Liverpool.

Wednesday, September 14th.

(*Continued from page* 354.)

Mr. Brady informed the Conference that the meeting of the General Committee of the British Association had just decided to make some important alterations in its future procedure as to towns to be visited. It had been determined to fix the place of meeting two years beforehand, which would give more time for making local arrangements. Of course, this alteration had a special interest for the Conference.

The President then called for any invitations to the Conference to hold its meeting next year.

Dr. Attfield read the following communication from Glasgow:—

"*Glasgow, Sept.* 10*th*, 1870.

"Dear Sir,—Anticipating that the members of the British Pharmaceutical Conference will honour this city with their presence next year, the Committee of the Glasgow Chemists and Druggists' Association have desired me to express their gratification at the prospect of meeting those who are so well known in name among them, but whom they have as yet not had the pleasure of seeing here; and to state that, in the event of such being agreed upon, they will be prepared to give them a hearty welcome, and be most happy to co-operate with and assist them in making the necessary arrangements.

"I am, dear Sir, yours respectfully,

"James M. Fairlie,

"*Sec. G. C. and D. Assoc.*"

"*To Dr. John Attfield,*

"*Sec. of the British Pharmaceutical Conference,*

"*Adelphi Hotel, Liverpool.*"

Mr. W. D. Savage said that at a meeting of the Chemists and Druggists' Association of Brighton, it was resolved that the Mayor (A. H. Cox, Esq.) and himself should appear at that meeting as delegates to convey to the Conference an invitation to visit Brighton. He regretted that his Worship the Mayor was unavoidably prevented being present, but he assured the Conference that, if it visited Brighton, it would have a hearty welcome. The wishes of the chemists of the town had been made public in the following announcement, which appeared in the Brighton papers of August 30th:—"At a meeting of the Chemists and Druggists' Association, held in the Mayor's Room on Friday last, S. A. Brew, Esq., in the chair, it was unanimously resolved to invite the members of the Pharmaceutical Conference to come to Brighton next year, or whenever the British Association favours us with a visit; and his Worship the Mayor (A. H. Cox, Esq.) and W. D. Savage, Esq., were delegated to convey the invitation. At the same meeting, Mr. T. J. Gwatkin sent in his resignation as honorary secretary in consequence of ill-health. A vote of thanks, and a unanimous feeling of regret to lose such valuable services, was passed, and Mr. Julius Schweitzer was elected in his stead."

Mr. Baildon (Vice-President) rose to convey, on behalf of Edinburgh, the message of invitation to the Conference with which he and his fellow-delegates were charged. He did not know if the British Association would select Edinburgh for its meeting in 1871, but he could promise the Conference that whenever it visited that city, it would receive a hearty welcome, and that everything would be done for the convenience and gratification of its members.

Mr. Mackay cordially seconded his friend Mr. Baildon's representation of the feeling of the chemists of Edinburgh.

The President expressed his sense of the honour done to the Conference by the invitations now received, and stated that, in accordance with usual custom, the decision upon the place of meeting would for this year be postponed until a final meeting, to be held on the following Tuesday.

The Fulmar (*Fulmarus glacialis*) and Fulmar Oil.

BY EDWARD C. C. STANFORD, F.C.S.

In the parish of Harris, Inverness-shire, nearly 200 miles from Inverness, and about forty-five miles west of the nearest point in North Uist, 57° 50′ N. lat. and 8° 35′ W. long., is situated perhaps the most remarkable, certainly the loneliest, little village in Great Britain.

"St. Kilda's lonely isle" is seldom reached by strangers, and I therefore record briefly some impressions derived from a recent visit. There are several islands, one of which only, the south or main island, is inhabited.

Seen from North Uist on a very clear day, the main island has exactly the appearance of an enormous whale on the horizon, and the north islands look like a huge sea-fortress with a tower on each side.

The north island, or island of Boreray, with its surroundings, is perhaps the boldest. We sighted this island in the early morning looming through a dense mist, and quite close to the vessel. As the mist suddenly cleared away, a startling scene presented itself. A perpendicular rock, some 1000 feet in height sheer out of the Atlantic, towered above our heads. Its face, covered with lichens of every variety of colour, was gorgeously illuminated by the rising sun. It was flanked by two enormous rocky pillars 800 to 900 feet in height, one of which is beyond the perpendicular. This rock is an extraordinary sight; it is perfectly white from sea-line to summit, being completely covered with the white eggs, droppings and feathers of an innumerable family of Solan geese, which are said to keep this rock entirely to themselves. We astonished the winged inhabitants by a cannon-shot, but they repaid the astonishment with interest, for we were unprepared for the extraordinary effect of the myriads of wings which immediately hovered over and around us, and turned day into night.

St. Kilda proper lies about three miles south of Boreray. It may be described as a precipitous mountain ridge, which in some parts falls sheer into the sea, with enormous precipices some 1500 feet high. It is three miles long and two miles in its extreme breadth. It lies $50\frac{1}{4}$ miles due west of Schillay Island in the Sound of Harris. The formation is marked in Nicholl's geological map as greenstone with syenite veins. On the south-east side the hill slopes down to a small open bay much exposed, and the landing is difficult. On this side of the hill the village is situated. About thirty houses, well built and better roofed than is usual in the West Highlands, are occupied by about seventy inhabitants. The population does not increase, the infant mortality is large, and said to be peculiar to the island.

It is somewhat remarkable that the inhabitants are not fishermen, but are all farmers and birdcatchers. Until quite recently none of the men knew how to fish. The staple food of the island is a bird called the fulmar, which forms the subject of this notice.

This bird is a species of petrel, the *Fulmar glacialis*, or *Procellaria glacialis* of Linnæus, the Fulmar petrel of Buffon, belonging to the family of *Procellarieæ*, order *Natatores*. At a distance the bird might be mistaken for a gull, which it resembles in size and colour; it is more nearly allied, however, to the albatross, which it resembles in its remarkable bill and its vomiting oil when attacked. The head, neck and lower parts are pure white, the wings and back bluish-ash, and the bill bright yellow. The bill is stout and thick, the upper mandible considerably hooked at the tip, where it is also dilated and sulcated; the lower mandible is straight and slightly truncated. The nostrils are united in a single tube. A sharp claw on the legs takes the place of a hind toe. The flight of the bird is very beautiful, and it has a remarkably graceful movement of the head. The fulmar inhabits Polar regions, and, so far as I can ascertain, is unknown in any other of the outer Hebrides, and is found only on St. Kilda. It breeds enormously there in the rocks, laying a single large white egg, and the young is fed by the oily matter disgorged by the parents.

The strong bill enables them to extract oily matter, by perforating the skin of dead seals or whales.

In Newfoundland they feed largely on the codfish offal, and probably they are experienced fishers everywhere.

The method of catching these birds is peculiar to St. Kilda; the men may well call themselves bird-catchers, for assuredly there are none like them. The process seems simple enough, but the awful danger must be seen to be appreciated; indeed, the climbing propensities of these men would astonish any member of the Alpine Club.

Hanging on a rope (often made of heather) the bird-catcher descends the fearful precipices, armed with a sort of fishing-rod, having a slip noose at the end. This he dexterously throws over the head of the bird, which is sitting on a ledge of the rock beneath him, and hauls him up. He then dips the bird's beak into a small leather bag suspended to his waist, and there the oil is vomited. The bird is then killed and eaten as food, the feathers and the oil forming the two articles of export. Beds made of the feathers are said never to harbour insects, but it is alleged also that they are difficult to keep dry.

The oil is a good deal mixed with a rougher sort from Solan geese, and realizes a poor price as an ordinary rough fish-oil. The sample I exhibit is genuine. It is of a clear, dark, slightly reddish sherry-colour, and has a powerful and peculiar odour,—an odour of which the whole island and all the inhabitants smell. It is certainly a fish-oil, and it possesses nearly all the properties of cod-liver oil.

Its specific gravity is midway between cod-liver and sperm.

Fulmar Oil,	sp. gr. . . .	·902
Cod-liver, light	,, ...	·924
,, brown	,, ...	·929
Sperm Oil	,, ...	·875

It is soluble in ether. Cold alcohol dissolves less than 1 per cent. and hot alcohol 3 per cent.

Treated with a drop of oil of vitriol, it produces precisely the same coloured reactions as cod-liver oil, which, if the generally-received views be correct, would show it to be a liver-oil.

It contains a very faint trace of iodine.

Heated with oil of vitriol and excess of potash it gives off a strong odour of oil of rose.

Saponified with soda, the soap retains the peculiar odour, and yields a tolerably fluid fatty acid on acidifying the solution.

I shall be glad if this short notice of fulmar oil will induce any one to experiment with it for medicinal purposes. I have no doubt a good deal might be obtained, and a good market would be a boon to that isolated people.

The specimen of fulmar exhibited, and which is offered to the Museum of the Pharmaceutical Society, was one of two that I had stuffed after keeping them alive for about a fortnight. It has suffered a little in appearance from its captivity.

The PRESIDENT expressed his interest in the singular facts laid before the meeting by their friend Mr. Stanford. The habits of birds included some phenomena which were startling by their uniformity and obedience to some hidden rule. Thus, the sea-birds frequenting the rocks near Tenby were in the habit of appearing for the season upon a certain and uniform day each year.

Mr. GROVES, remarking upon the powerful odour of guano evolved by the stuffed specimen upon the table, said that the egg of the fulmar had also a strong smell.

A MEMBER referred to the recent Sea-birds Preservation Act, mentioning that the island of St. Kilda was specially exempted from its operation.

Mr. MACKAY stated that the deplorably destitute condition of the population of St. Kilda was ample justification for this exemption. Sea-birds and their eggs might be said to be the sole food of the people, who were often on the verge of starvation. Food was occasionally sent to the island, but sometimes the sea was so rough that no communication could take place for a period of months. He had understood that the skin of the bird was made into shoes.

A FEW NOTES ON ALOES.

BY WILLIAM A. TILDEN, B.SC. LOND., F.C.S.,

Demonstrator of Practical Chemistry to the Pharmaceutical Society.

In the list of subjects for investigation issued to the members of the Conference is the following question, No. 176:—"Compound Decoction of Aloes loses bitterness after some time; to what is this due?"

Before attempting to answer this question, a few points in the chemistry of aloes require notice.

In the last edition of Pereira's 'Materia Medica' four proximate principles are enumerated as forming the most important constituents of aloes.

1. Aloetin, aloesin, amorphous aloin, bitter principle of aloes.
2. Crystallized or hydrated aloin.
3. Resin.
4. Aloesic acid; supposed by some to be gallic acid.

Experiments made by myself, in addition to those already published by Mr. Groves and other chemists, induce me to adopt an opinion respecting the constitution of aloes somewhat modified from the foregoing.

I. *Aloetin.*—The first of these bodies certainly forms a constituent very important as to quantity of all the varieties of aloes. There can be no doubt that it is the product of the alteration of crystallizable aloin, partly by the action of heat, partly by the oxidizing action of the air. I regard it as a mixture of anhydrous aloin, which is capable in the presence of water of recovering its crystalline condition, and the brown oxidized substance referred to further on.

II. Crystallizable *aloin* is the body to which especially all the varieties of aloes owe their bitterness. Its isolation is usually thought to be a matter of some difficulty, but the following simple process will furnish any desired quantity,—pounds if necessary.

Select a specimen of Barbadoes aloes, the most powerfully odorous that can be procured, bright-looking, and not the most waxy: break it up and dissolve it in a quantity of boiling distilled water, to which a few drops of sulphuric, sulphurous, or hydrochloric acid have been added. The proportions employed may be those of the Pharmacopœia for Extractum Aloes, viz. one pound to a gallon. Let the liquid stand a night to deposit resin, then pour it off and evaporate quickly till, if 1 lb. of aloes have been used, about 2 lbs. of liquid remain.

This left for twenty-four hours will deposit an abundant crop of yellow crystalline matter. The fluid portion poured off and duly concentrated yields a first-rate extract. The yellow crystals must be well drained and pressed, and will yield pure aloin by recrystallization once or twice from water mixed with a small proportion of rectified spirit. If the selection of the aloes be looked to, the product will amount to about 20 per cent. of the material employed.

Aloin has been said to be with great facility decomposed or altered by the simple application of heat to its aqueous or alcoholic solution. I have found, however, that it will bear without appreciable change comparatively rough treatment in this way, provided the solution is quite neutral or slightly acidified. A little pure aloin dissolved in distilled water may be evaporated to dryness and heated till it fuses, and then redissolved in water, and this operation repeated several times, but the aloin undergoes but slight change of colour, and will still crystallize on letting the solution stand for an hour or two, or almost immediately on stirring. The transparent yellow varnish left by evaporating solutions of it consists merely of anhydrous aloin; treatment with water restores to it its crystalline state. It is of course already known that if kept in a moist state on a water-bath for some time, the pure substance becomes gradually brown, and assumes the appearance of Socotrine aloes; but this is a comparatively slow process, and even after some time a considerable quantity of the aloin is still capable of crystallizing.

A further illustration of its stability is exhibited in the following experiment and accompanying specimen. About ten years ago, a paper by Kosmann appeared in the *Journal de Pharmacie*, the object of which was to show that aloes was a mixture of glucosidic bodies. The experiments by which grape sugar was obtained, and its presence indicated by the asserted production of alcohol and carbonic acid, were performed by Kosmann solely upon Cape aloes. I have made a number of experiments which convince me that he is quite incorrect in his statements, but as I hope to reproduce the subject at a future meeting, I will cite only one experiment made with pure aloin. Some aloin was dissolved in about an equal weight of oil of vitriol (it forms a clear orange syrup); the solution was gently heated for a few minutes, and then poured into water and kept boiling for about four hours.

Saturated by excess of pure carbonate of barium, filtered and evaporated on a water-bath, a minute quantity of barium retained in solution precipitated by dilute sulphuric acid and the liquid further concentrated, unaltered aloin was deposited in yellow crystals. A part of the solution which had been thus treated was submitted to the fermentation test. Three tubes full of mercury were inverted in a small mercurial trough. Into the first was introduced some washed yeast and distilled water. Into the second some washed yeast and a weak solution of sugar. Into the third some yeast and the boiled solution of aloin. The first and third gave no bubbles of gas larger than a pin's head; the second tube was completely filled with CO_2 in half an hour.

To ascertain if the aloin prevented fermentation, two similar tubes were set up. The first contained yeast, distilled water and sugar; the second had in addition a portion of the solution which had been boiled and tested as above. Both gave gas in about half an hour nearly equally. A portion of the same sample of yeast was used in all these cases. There is consequently no sugar produced by boiling aloin with acids, and the aloin undergoes practically no change.

The copper test is inapplicable, inasmuch as pure aloin which has undergone no manipulation reduces alkaline copper solutions rapidly and freely.*

Aloin gives no apparent change with tartar emetic nor with ferrous salts, but with ferric salts it strikes an olive coloration, which is destroyed by reducing agents.

III. The substance termed *resin*, which abounds in all kinds of aloes, is not very happily so called, for it is soluble in considerable quantity in hot water. It is said

* I have found that many other bodies besides the glucoses do this; amongst others, tannin and orcin.

to yield chrysammic acid by treatment with nitric acid, and is therefore related in some way to the soluble part of aloes; but this is a point upon which nothing is known at present.

IV. There can be no doubt that the "aloesic acid," supposed to be present in aloes, has no existence. The reaction with iron salts, ascribed to it is due to the crystallizable aloin, and the acidity to test-paper presented by an infusion of aloes is a property of the half-oxidized substance contained in the uncrystallizable "aloetin."

V. In addition to those bodies, there is in all aloes a small but notable proportion of vegetable albumen. It is left when either kind is exhausted with rectified spirit. Its presence probably promotes the change to which solutions of aloes are always subject.

Pure aloin, then, in pure solutions, is liable only to very tardy alteration. Exposed to the air, it gradually absorbs oxygen, and the solution deepens in colour; but the change which is thus slow under such circumstances, is very rapid indeed if a small quantity of any alkali is introduced. The solution then becomes in a few hours of a deep brown colour; and after the lapse of three or four days, if the air be admitted, the aloin entirely disappears, and is transformed into a substance, or mixture of substances, which no longer possesses any bitterness, but is perfectly insipid. An experiment was made by dissolving pure aloin in water with an equal weight of carbonate of potassium; the solution, left in an imperfectly closed flask for about a week, entirely lost its bitter taste. Nitrate of barium was added to remove the carbonate, and the filtered liquid mixed with acetate of lead. The result was a dirty greenish precipitate, which was removed and basic acetate of lead added. This gave a bright orange precipitate, which was collected and analysed. Its composition, compared with that of aloin, is shown by the subjoined numbers:—

Aloin (Stenhouse).		Yellow Precipitate.	
C	60·67	C	14·30
H	5·65	H	1·40
O	33·68	O	25·71
		Pb ..	58·59
	100·00		100·00

From which it appears that whilst in aloin the carbon stands to the oxygen nearly as 1 to $\frac{1}{2}$, in the oxidized substance it is, roughly speaking, in the proportion of 1 to 2.

Some extract of Socotrine aloes was boiled with carbonate of potash and water, in the proportion directed for the preparation of compound decoction of aloes, the remaining ingredients being omitted. Keeping this solution in the way described, it also became tasteless and gave the same reactions.

Mr. William Young, pharmaceutical chemist, proposed the question which stands in the Conference list, and I am indebted to him for the specimens upon the table, and also for his permission to quote from a letter with which he has favoured me.

He says, "For more than ten years I have observed that decoct. aloes co. loses its bitterness on keeping, but I cannot say that it loses its aperient property. I have frequently taken a fluid ounce of various degrees of bitterness, and have always found it produce the desired effect. But this is a matter which does not affect the pharmaceutist so much as the fact that the public cannot be persuaded that a medicine which is not uniform in taste is rightly prepared. I venture to assert that if a customer were to purchase successively at one establishment four ounces of decoct. aloes co. weekly, and each sample being a week older than the one immediately preceding, no two samples would be alike. Of course if, as I understand is the custom in some large establishments, a large quantity is prepared and kept some weeks before use, a greater uniformity would be arrived at; but that puts the small tradesman at a great disadvantage, who perhaps prepares a pint at a time, and sends it out fresh and intensely bitter. I know an instance of a chemist who nearly lost a valuable customer in the following way. He had been in the habit of dispensing a ℥xij mixture, containing ʒvj vini aloes. When he first prepared it he had a pint of the vin. aloes in stock, which probably had been made five or six years, and had not the slightest taste of aloes in it, but it pleased the patient. At length the stock was exhausted, and the mixture prepared with a fresh supply of vin. aloes recently prepared. The patient could hardly be convinced that a mistake had not been made; and it was found that ʒss of the recently-prepared vin. aloes imparted more bitterness to the ℥xij mixture than the whole ʒvj of the old. I have tasted samples of dec. aloes comp. concent. 1 to 3, almost devoid of bitterness; and a maker of that article informs me that it is a most unsatisfactory preparation."

The active constituent of aloes is still unknown. That the purgative property is not due to aloin was first shown by Robiquet, and is proved, I think, by the fact of its complete disuse after a very short trial. Mr. Young says that he has not noticed any variation of power in the specimens of different degrees of bitterness which he has tried; but, on the other hand, I have myself taken large doses of the oxidized alkaline solution of aloin, or of extract of aloes, without perceiving the slightest effect.

There is in Druitt's 'Surgeon's Vade Mecum' a prescription which, I am informed by the author, is the most active form in which any kind of aloes can be administered. Barbadoes aloes is made into a mass with strong sulphuric acid, and in that state rolled out into pills. Dispensing difficulties may have stood in the way of the more extensive employment of this form, but if it bears out the character attributed to it, it would seem that a half oxidized condition of the aloes is the most advantageous.

The questions which still remain to be solved with reference to aloes are numerous. Amongst others, two very important points seem to me to require examination. These are the nature and properties of the resinoid matter, and the cause of the differences between the several varieties of this important drug known to commerce.

The President said that the question discussed in Mr. Tilden's paper had very great interest, and he felt surprised at the extent of the change which had been found to occur.

Parliamentary and Law Proceedings.

A correspondent has forwarded to us a paragraph from the *Sherborne Journal*, in which it is stated that Joseph Grassby *alias* Gardiner, a chemist's assistant, was convicted at the late sessions of a robbery from Mr. Mason, of Weymouth, and sentenced to seven years' penal servitude. There were, besides, three other indictments hanging over him. The prisoner is well known in the trade, having held situations in many parts of the country, most of which he lost through dishonesty.

Obituary.

Another breach in the still narrowing circle of the original pharmaceutical body has occurred by the removal of Mr. Charles Wright, of Manchester. Those who were most intimately acquainted with the deceased gentleman have reason to remember his kind and liberal conduct, affording every facility for study, lectures, etc.

For several years past, increasing infirmities have prevented Mr. Wright taking an active part in business. His death was accelerated by a severe attack of bronchitis, the complaint which had troubled him much during the latter part of his life. He died last month at his country residence, Fairfields, aged 70 years, sincerely beloved and regretted by many friends. R. G. M.

Notes and Queries.

In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[2.]—MOUNTING MICROSCOPIC OBJECTS.—Allow me to recommend *R. J. M.* to peruse Davies on 'Preparing and Mounting Microscopic Objects' (2*s.* 6*d.*, Hardwicke), the most comprehensive book on the subject.—J. H.

[12.]—TEETH STOPPING.—*W. A. C.* sends the following recipe for the preparation of enamel for decayed teeth:—

℞. Hydrargyri,
Pulvis Stanni, aa ʒss.

Shake together for five minutes, then mix in the palm of the hand to a paste and fill up the cavity. No food should be eaten for three hours afterwards.

[13.]—EAU SÉDATIVE.—I suppose the "elegance" required by your correspondent in eau sédative is the removal of the particles of camphor. The only plan I know is by filtration; or would it not be better to substitute aq. camph. conc. for the sp. camph.? On the Continent the working classes, when purchasing eau sédative, generally ask for the bottle to be "well shaken up," the disciples of Raspail preferring to have some body in their lotion.—PHARMACIEN.

Your correspondent [13] has not sent the correct formula for the above preparation. The following is Raspail's recipe for the *weak* eau sédative, No. 1, which is that adopted in the Paris Codex:—

Ammoniaque liquide de 22°, equiv. to liq. ammoniæ ·923, or *about double* the strength of liq. ammoniæ, B.P. . . . . f℥ij
Alcool camphré (1 to 9), equiv. to sp. camph. B.P. . f℥iss
Sel marin (sodii chloridi) . . . . ℥ij
(*not Salts* ℥viiss.)
Eau distillée (aq. destill.) . . . . f℥xxxss
(*not* ℥xvij.)

Dissolve the salt in a small quantity of water, add the ammonia, then the sp. camph., and last the water (by small portions), diligently shaking after each addition.

Nos. 2 and 3 differ from the above only in the quantity of ammonia,—No. 2 containing ℥xx and No. 3 ℥xxv in the litre (℥xxxv). The solution is usually filtered, but some pharmaciens send it out turbid.—E. B. S.

[14.]—SACHET PERFUME.—Sachet perfume may be composed of nearly any agreeable mixture of dry scents, such, for instance, as lavender flowers, orris root, rose leaves, and benzoin, of each equal parts, with a little tonquin, vanilla and musk added according to taste. It should be ground up or roughly powdered. Or paper may be perfumed by steeping cotton wool in any favourite *esprit*, and placing it when dry in a desk with the paper.—GIVE AND TAKE.

[15.]—MEZEREON EXTRACT.—The mezereon extract in tinct. sapon. co. is doubtlessly added to increase the stimulating properties.—GIVE AND TAKE.

[16.]—ROME AND PARIS.—"*Pharmacien*" begs to inform *A. S.* that the hours in an English Continental pharmacy are generally from 7 A.M. to 10 P.M., and often much longer in the season, Sundays and week-days alike.

E. B. S. says the time of closing in Paris varies from 10 P.M. to midnight in different quarters of the city. Usually, however, regular work is suspended at nine o'clock, but the *élèves* remain ordinarily in the *pharmacie* (as their sitting-room), and are expected to spend their evenings in study.

[18.]—RUBINI'S CAMPHOR.—Alcohol and S.V.R. partes æquales. Camphor ad sat.—INQUIRER.

"*An Unexamined Member*" writes that Rubini's Tinct. Camphor is made by dissolving 5 oz. camphor in 6 oz. fluid sp. vini rect. 60 over proof, *i. e.* in its own weight of spirit. He finds, however, that in winter part of the camphor is deposited. Probably Dr. Rubini, living in Naples, never experienced this objection to so strong a solution.

"*Pondere*" says the term "Rubini's Camphor" has been applied by a homœopathic house in the north to ordinary camphor pilules, he supposes "in the exercise of homœopathic licence."

[22.]—COSMETIQUE.—Two parts wax and one part oil, melted together, and coloured to the desired shade by grinding or rubbing up in a mortar brown umber with oil. Or, two parts beef suet and one part wax, and coloured as above. —GIVE AND TAKE.

L. R. (Birmingham) recommends the following:—

℞. Adeps præp. melted with a third of its weight of wax in winter or half in summer; colour with fine brown umber; strain. Stir it constantly, and when it begins to thicken, pour it out into proper moulds.

[23.]—COLOURING FOR POMADES.—If *S. W. S.* adds a small quantity of powdered gamboge he will find it a nice colouring ingredient, and unaffected by exposure to light.—B. T. M.

J. Barker (Sudbury) says that Mr. Alfred Allchin supplies an oleum flav. which answers the purpose well for colouring oil yellow, and does not fade from exposure to the light for some months.

J. F. Brown (Dover) says that yellow wax is worth a trial as a yellow colouring if used instead of white wax in proper proportions, and care be taken to select a clean, bright sample.

T. F. Hudson (Exeter) recommends gamboge digested in olive oil for several days, with frequent shakings, and either decanted after settling for a couple of days or filtered.

PULVIS GLYCYRRHIZÆ CO. (*Pharm. Boruss.*).—In answer to *W. T.* (Edinburgh) we give the formula—

℞. Foliorum sennæ 2
Radicis glycyrrhizæ, singulorum pulveratorum partes duas 2
Fructuum fœniculi pulveratorum 1
Sulphuris depurati, singulorum partem unam 1
Sacchari albissimi pulverati partes sex . . . 6

Misceantur.

EASTON'S SYRUP OF PHOSPHATE OF IRON, QUINIA AND STRYCHNIA.—In answer to "*Dispenser*," the following is the formula, as given by Squire (p. 125):—

Sulphate of iron, 2½ oz.; phosphate of soda, 3 oz.; sulphate of quinia, 1½ oz. and 48 grains; strychnia, 24 grains; diluted phosphoric acid, 56 oz.; sugar, 56 oz.; distilled water, *q. s.* Dissolve the sulphate of iron and the phosphate of soda in separate portions of water, mix the solutions, collect the precipitate, wash it, dissolve it and the quinia and strychnia in the phosphoric acid, mix all together, add the sugar to form a syrup.

[24.]—TANNIN IN GALLS.—*F. C.* is desirous of knowing the proportion of tannin in the following galls:—English, Aleppo, Mecca, Chinese and Japanese.

[25.]—FUMIGATION.—"*Inquirer*" wishes to know the best method for fumigating rooms after fever.

[26.]—CHLORAL HYDRATE.—What is the dose of chloral hydrate and in what diseases is it generally administered?—CHEMICUS.

[27.]—BENZINE.—Can chemists sell benzine, for cleaning purposes, in 6*d.* or 1*s.* bottles without having a petroleum licence?"—CHEMICUS.

[28.]—SYMPATHETIC INK.—*J. H. B.* would feel obliged if any of our readers would furnish him with a good recipe for sympathetic ink which will become legible upon the application of steam or heat.

[29.]—QUININE MIXTURE.—*A. P. S.* wishes for a formula for a quinine, sarsaparilla and dandelion mixture, with the dose.

[30.]—HAIR-OIL SCENT.—*G. C. W.* asks for a good hair-oil scent formula. It must not contain ess. limonis or be too costly.

[31.]—TOOTH PASTE.—*L. R.* would be glad of a good recipe for making cherry or rose tooth-paste that will *not* ferment.

[32.]—DENTISTRY.—*S. S.* would be glad of information as to the qualification required to take a "surgeon-dentist's" diploma, and the best books treating of the subjects taken up in the examination.

⁂ Several queries have been received which have not been accompanied by the name and address of the senders, in compliance with the regulations printed at the head of these columns.—ED. PH. J.

Pharmaceutical Titles.

Sir,—As you have given a place in your Journal to the remarks of "An Aspirant to the Major," I would submit the following facts to your kind consideration:—

Up to my fourteenth year I received the education of a gentleman; then, being unfortunately deprived of the indulgence of further school-training by the death of my father, I was apprenticed to a chemist in the year 1860, when the watch-word was "push on" and time was occupied by work and bed. After a five years' apprenticeship and six years' assistancy under these unfavourable circumstances, I have, by dint of perseverance and unwearied attention to study, succeeded in passing the Modified Examination, only to find that my position will not permit a further outlay of time and money for the Preliminary, Minor and Major. Am I not to be excused for wearing the hardly earned plume of

Associate of the Pharmaceutical Society?

Sunbury, September 26th, 1870.

Sir,—I should like, as a "Major man," to express a hope that Pharmaceutical Chemists will make an effort to obtain a title sufficiently distinctive to recompense them in some degree for their labours. The principal facts of the case have been very clearly stated by "An Aspirant to the Major," and it is not only those who aspire to, but also those who have passed the higher examination who are interested in the subject.

Until about two years ago, membership of the Society was an honour granted only to Pharmaceutical Chemists, and the terms were generally regarded as synonymous; then, perhaps, the title was sufficient; but, for the good of the Society and to prevent opposition to the "Pharmacy Act," membership was thrown open to all chemists and druggists in business and, now the difference between the numerous titles of the Society, so nearly alike, is scarcely understood by the trade itself, while it certainly never will be by the public at large. The creation of the new titles would in no way interfere with existing interests, therefore it need cause no jealousy, as the examination would be open to all, and those who have the intellect might also have the title. "Omega," at the commencement of his letter, satirically criticizes the vanity of those who desire the title of "Fellow," and shortly after falls into the same weakness himself, complaining that a flaming diploma is not awarded to the Modified. For the admission that he would grant what we ask without a moment's reflection, I am grateful, and hope it will be borne in mind. I also quite agree with him on another point, which is, that unless some real advantage be given to those who pass the professional examination the number who enter for it will ultimately fall off. In fact, I know several who would readily attempt it, if any reasonable advantage would be gained by so doing. Your correspondent makes a statement which I believe to be incorrect, namely, that the passing of the Modified involves a yearly subscription. I always understood that the expenses cease with a nominal examination fee.

In conclusion, I would ask "Omega" whether, solely on the ground that knowledge should make men humiliate themselves, he could justly object to a distinctive title as a reward for hard study and no inconsiderable expense? In reply to his quotation, I would recall to his memory another one equally important, about "giving honour where honour is due."

I hope this subject will be fully discussed,—not in a party spirit or in one of jealousy, which would break the unity of the Society and endanger its prosperity,—but as a matter of justice to those who have passed the Major and as an incentive to those who aspire to do so. M.P.S.

Sir,—Respecting pharmaceutical titles, would it not be well for "Omega" and his critics to display rather less asperity? I owe my membership to the mere fact of being in business before July, 1868, but think it really hard that those who pass the Major Examination have not a title manifestly superior to mine. I would therefore support the movement for urging the creation of a class of Fellows, to consist of all who pass or have passed the Major Examination, and of the founders, among whom I would include all who were members before the passing of the first Pharmacy Act in 1852. The case of "Modified Men" also presents some degree of hardship, but I apprehend it is only what is almost necessarily consequent on the passing of any such law as the Pharmacy Act, introducing a new era in pharmacy. However these gentlemen may console themselves with the reasonable prospect of reaping the benefit of it in years yet to come, when the Act shall have had time to produce its natural result of diminished competition.

An Unexamined Member.

Sir,—Permit me to add my quota to the discussion now going on in the pages of the Pharmaceutical Journal relative to the advisability of establishing a Fellowship. For some time I have held the opinion that such a course would be the best that could be followed under existing circumstances. In the first place, I consider it would tend to unravel the mystery which at present shrouds all pharmaceutical qualifications and titles in the public mind; secondly, it would tend to restore the confidence of a large majority of gentlemen (who have passed the "Major" Examination) and allay their dissatisfaction, felt at several clauses in the "New Pharmacy Act;" an Act which I consider was a great injustice to pharmacists, and by which the then Council of the Society certainly forfeited all claims to our confidence. I think there is no question that the title "Royal College of Pharmacists" would have much greater weight with the public than the present title, and convey a better idea of what our Society really is. Most people seem to imagine that the Pharmaceutical Society is of a similar nature to an Oddfellows' or Foresters' Society; in fact, I have several times been asked by persons, noticing my diploma of membership from a distance, to what lodge I belonged; imagine how gratified I feel, at such times, to receive such an acknowledgment for money and time expended in obtaining the said diploma!

I will now, with your permission, offer a suggestion for the consideration of those who hold similar views to mine, as I think there has now been plenty of talking, and it is quite time some steps were taken to promote the object we have in view.

I would suggest, then, that a meeting be called by announcement in the Journal (to be held in town) to draw up a petition for presentation to the Council, praying them to frame a short measure for the ensuing session of Parliament, embodying the following views:—

1st. The title "Pharmaceutical Society" to be altered for the title "Royal College of Pharmacists."

2nd. Founders of the Society, Pharmaceutical Chemists, and all who pass the "Major," to be admitted Fellows of the College, with the title "Pharmacist."

3rd. All who pass the Minor or Modified Examinations, together with those now in business, to be admitted "*Members*," with the title "Chemist and Druggist."

If this could be carried out, it would have the effect of showing to the public that there is a difference between a Pharmaceutical Chemist and one who, having passed or complied with the forms of a Modified Examination, flamingly announces himself as a "Chemist by Examination," "Member of the Pharmaceutical Society," etc. If this course cannot be carried out, then we must use our elective powers in altering the constitution of the Council; we must make it a *sine quâ non* that all who seek re-election must first positively express themselves in favour of these views before we accord to them our support.

Tamworth, Oct. 31st, 1870. T. B. Allkins.

Sir,—It seems "Aspirant to the Major" would fain induce the Council to ignore the nationally-recognized title of Pharmaceutical Chemist, a title obtained, after immense trouble, by a special Act of Parliament.

The assertions of your correspondent must appear extremely vague to those who understand the past history of pharmacy and fully appreciate its present position. The special privileges of Pharmaceutical Chemists are—

1st. The honourable distinction acquired by those who have shown sufficient diligence and interest in their profession to obtain the requisite theoretical and practical information which enables them to pass the examinations of the Society. This can be no vague honour, as it is well known that the Pharmacy Act prevents any, excepting the "founders," from obtaining the honour without examination.

2nd. The recognition and reliance placed in this class of men by the medical profession, though there may be no personal knowledge of the dispenser on the part of the prescriber, further than that he holds the rank and title of a Pharmaceutical Chemist.

3rd. Pharmaceutical Chemists, being the only fully qualified body, are empowered to elect the largest number of their body to the Council, so that as a natural consequence they will always occupy an influential position.

4th. The preference given by Government and local governing bodies to Pharmaceutical Chemists as dispensers or analysts.

5th. Exemption from serving on juries, a matter of no small moment, as our young friend will find when he gets into business.

In conclusion, let me remind any other "Aspirants to the Major" that the examinations, like those of the legal and medical professions, are fitting to the requirements of the times, and adapted more especially to the wants of practical pharmacy, and if young men think they deserve higher distinctions for what they know let them measure their abilities against the standard of any of our learned universities, and there seek the high degrees and diplomas ambition leads them to crave after. PHARMACIST.

*** Our correspondent might also have added that *Pharmaceutical* Chemists are *alone* eligible for the responsible and eminently honourable position of Examiner, and that they *alone* receive the special original diploma with which the public and medical men have been gradually taught to associate high *professional* attainments. No other graduates in pharmacy, whether examined or not, receive a diploma.

In regard to connection with our Society—which is altogether voluntary—"Majors" are eligible, immediately after they have passed, to be elected full *Members* of it; while "Minors" and those who pass the *Modified* Examination are at no time eligible for membership. The highest position the latter can obtain, even when in business, is that of *Associate.*

It is obvious that when the aspiring youths of 1870 shall have become the successful hardworking pharmacists of the future, the anomaly of which they now complain will have, in great part if not entirely, disappeared by efflux of time, and the Society will be constituted of *Members* who will be examined *Pharmaceutical* Chemists, and Associates who will be examined Chemists and Druggists.

This correspondence, which must now *close*, seems to indicate that to avoid being mistaken for an *un*examined competitor, or for one who has passed only the *Modified* Examination, the safest way is to "go in" heart and soul for the "Major," so as to win a *living* title which cannot be assailed or simulated, that of a highly educated and accomplished *professional* man.—ED. PH. J.

LOSS OF SPIRIT IN MAKING TINCTURES.

Sir,—The kind remarks of your correspondent Mr. J. T. Slugg, of Manchester, upon my communication "The Loss of Spirit in Making Tinctures of the British Pharmacopœia" (PHARMACEUTICAL JOURNAL, October 22nd), require some further explanation from me.

The loss of 37·5 per cent. of alcohol (·838) in making tinct. zingib. fort. in accordance with the Pharmacopœia is strictly correct, as the "sufficiency" to produce the measure there ordered is represented by the volume of the final product, plus 37·5 per cent.

Now the Pharmacopœia does not mention (as in other tinctures) the application of pressure to the contents of the percolator, and for the reason that its compilers well knew that such a large quantity of ingredient was only to be exhausted by the displacement of one pint of fluid.

Perfection would seldom have been attained had the percolation been made with 75 per cent. of the alcohol (as tinct. zingib.), or even with the whole of the spirit, and then pressure applied to the ingredients, finally making up the measure.

No pharmacist would (as Mr. Slugg has properly queried) consider as worthless any marc containing such a large percentage of alcohol; he would, of course, resort to pressure or heat for its recovery. By the former method he would obtain 12 per cent., and by the latter, with suitable apparatus, at least 20 per cent. should be recovered.

The subject of hydraulic pressure, as adapted to small pharmacies, I hope shortly to comment upon.

CHARLES UMNEY.

Laboratory, 40, *Aldersgate Street, E.C.*

DRUGGISTS' CHARGES.

Sir,—The following is a copy of a prescription dispensed to-day, and which will be charged more than "half-a-crown," which appears to be the utmost value put on any prescription by some of our "medical friends." It may perhaps interest some of our "pharmaceutical brethren" to see it.

℞. Quinæ Disulph. ʒiss
Acidi Nitrici dil. ʒiij
Aquæ ℥j.

M., signa: A teaspoonful to be mixed with 6 oz. cold water and two tablespoonfuls to be taken twice or thrice a day.

Cheltenham, Oct. 25th, 1870. D. C. L.

THE MAJOR EXAMINATION.

Dear Sir,—Allow me to give, in reply to "A Candidate for the Major," the following extract from the PHARMACEUTICAL JOURNAL of March, 1869:—

"Do not be misled by those who state it to be a 'mere bagatelle.' Get up as thoroughly as you can the different branches mentioned in the synopsis, and, if practicable, spend at least a week in daily attendance at the library and museum of the Society. You will then find it comparatively easy; but if you come up the day before with an idea that it is nothing, and without that preparation, you will probably be numbered with those (of whom there is more than one West-End assistant) who, in failing, have only to blame their own carelessness."

Wakefield, Oct. 31*st*, 1870. THOMAS W. ROMANS.

PHARMACY AND MEDICAL PRACTITIONERS.

Sir,—"Reformer's" letter is so offensively worded, that it entitles us to unusual liberty of speech respecting it, and, as in the attack he leaves open his most vulnerable side, I shall not hesitate to throw a spear.

We are charged, I understand, with "prescribing," high charges, and "general insubordination" to the profession. Well, I suppose, to the first charge we must plead guilty; and, speaking for myself, I wish I were more guilty of this offence, and, for these reasons:—Firstly, I consider myself quite as competent as some medical men to deal with small matters. If the parties applying to me are satisfied with the aid they obtain, and they ought to be the sole judges of their own affairs, it is not for medical men to feel aggrieved because they will not accommodate themselves to public requirements.

Secondly, because the medical man frequently keeps what he calls an "open surgery," where he vends pennyworths of senna, salts, etc., to servant girls, and yellow ochre for the joiners' planes.

Now, as to high charges for dispensing, I believe the usual charge for an 8-oz. mixture, coming from a surgery, is 2*s.* 6*d.* exclusive of an additional charge for investigating the patient's complaint at the surgery; whereas the druggist's charge for the same mixture averages from 1*s.* 6*d.* to 2*s.* at the most; it is usually infinitely better prepared, more neatly and attentively finished, probably contains very superior ingredients, and has not been put together by his wife or by a man who also serves as groom.

A surgeon of standing, extracted a guinea from my pocket in less than five minutes, for an opinion upon a rather trifling matter, although I called at his house for it, and he knew me to be a druggist; on the other hand, a perfect stranger, passing through the town, came to me with his wife and family, and was surprised that I did not take cognizance of his being a medical man and make a large reduction upon the mixture and other things he was taking. The acquisitiveness of druggists is not to be compared to that of the medical man—M.D. shall I say?—who bargains with "Reformer's" incompetent druggist that he is to get for 9*d.* that for which he himself charges his patient 2*s.* 6*d.*, without even the trouble of sending it home.

As to the third charge, I consider myself and my fraternity quite equal to "Reformer" in education, the polite arts and morality. We take our places and perform our office in society on equal terms, and I hope we shall always possess sufficient spirit for the maintenance of our dignity, and not stoop to the dictation of any man. Law and prudence demand that a third party should stand between the Palmers, Pritchards and Monks of the profession and their patients; a man better qualified than they, to dispense prescriptions, who could correct errors, give evidence as to medicine prescribed, and, in many cases, prevent "dark deeds." Are we quite sure that death has never unwittingly lurked in a bottle emanating from a surgery, and his dread presence at the bedside of the patient been accounted for as "unfavourable symptoms set in!" "Quite what I expected from the first," etc.? I believe that the public and Government have only to be well instructed on this head, to see the propriety of taking dispensing out of the hands of the faculty as far as possible, and handing it over to persons exclusively educated for the purpose. Finally, having been in the business thirty-seven years, and educated in the first houses, I am of opinion that as a whole, and looking at the limited nature of the sale of drugs, most businesses are preferable to that of a chemist and druggist, notwithstanding the great profits we get.

I append a specimen of prescribing by the faculty, which I call "grape shot." I make no remarks upon it, except that the complaint which it is intended to cure must be of a peculiar and ramified character.

Feeding Bottles.

Sir,—Possessed of a mind somewhat addicted to the "curious," I was induced, by the perusal of Mr. Balkwill's letter, to try an experiment or two, to ascertain how far the *india-rubber* portion of a *feeding-bottle* was concerned in the production of the poisonous compound, so detrimental and sometimes fatal to the *little ones.*

To this end a portion of india-rubber tube was immersed in some fresh milk and exposed to the same treatment it would undergo in an ordinary feeding-bottle, for the space of forty-eight hours; during this interval it was examined several times, and although the character of the milk had changed, there *was not* the faintest trace of sulphuretted hydrogen. The tube was then removed, wiped with a cloth, cut open, and thoroughly examined, but no change whatever had taken place.

The milk was again examined, after the lapse of some hours more, and found to be in a state of decomposition, giving plain evidence of the formation of sulphuretted hydrogen, but without the presence of india-rubber.

It is evident, therefore, that this poisonous compound is not produced by the teat or tube, but is, *de facto*, the product of milk decomposition, which takes place entirely independent of the india-rubber.

The theory "that the sulphur of the india-rubber acted on the hydrogen of the milk," appeared unsatisfactory, and was not sufficient to account for the change.

The probable solution of that part of the question appears to be this,—the casein of the milk is decomposed, the sulphur which it contains combines with some hydrogen, set free in consequence of this decomposition, and this accounts for the sulphuretted hydrogen liberated unnoticed in the feeding-bottle.

But this will not take place if the feeding-apparatus is properly looked after, and the very simple and necessary precautions suggested by Mr. Pemberton adopted.

There is little doubt that a very small portion of already decomposed milk allowed to remain in the tube, teat or bottle, will act as a ferment, and in a very short space of time infect the entire body of fresh milk; and here lies the entire difficulty and danger.

Attention to cleanliness removes the whole; neglect of this alone produces the "poisonous compound" which may induce disease and result in death.

I have thought it would be a wise plan to discard the use of "corks" in feeding-bottles.

Corks (and especially when faulty or fissured) are absorbent, and, unless long-soaked and well-brushed, will contain quite enough decomposed matter to contaminate fresh milk, if allowed to remain long in contact.

In conclusion, I cannot but think that if children are really poisoned by this means, it must exhibit, on the part of those who use the "feeder," an amount of wanton *carelessness*, scarcely credible in an age which boasts of its progress and sanitary reforms.

Brighton, October 25th, 1870. G. G. Hornsby.

Aurora Borealis.

Sir,—The late magnificent display of the Aurora Borealis was witnessed in perfection at Richmond. Viewed from the high ground of Mount Ararat and the Park, the whole hemisphere appeared in a rich, ruddy glow, a vast sea of flickering flame, the beauty of which surpasses any attempt to describe.

The highest perfection of the display continued from about seven till half-past eight o'clock on Monday evening the 24th ult., suggesting the idea of a tremendous conflagration. The fire brigade turned out, but after scouring the country from Mortlake to Brentford, returned without having extinguished the "awful blaze."

On the following evening a repetition of the phenomenon occurred, and lasted from about half-past six until nearly eight o'clock, when the brightness gradually declined.

At early dawn on the morning following each of these displays, beautifully illuminated clouds were observed towards the eastern horizon, much resembling in appearance those tender cirro-cumuli, surrounded by a bright atmosphere, sometimes seen on a calm summer evening.

By a remarkable coincidence the 24th of October is the anniversary of "one of the most brilliant auroras ever known in this country," noticed by Mr. Glaisher, October 24, 1847, and we shall probably be favoured with records of the magnetic storm by the electricians at the Kew Observatory. See Humboldt's 'Cosmos,' vol. i. p. 188.

R. Goodwin Mumbray.

"Student X."—The salary that might be expected for services in a laboratory would depend more upon the practical competence possessed than upon the mere possession of the degree of B.Sc.

F. J. B., Major Associate, is requested to communicate with the Editor respecting his letter, as no answer has been received to a letter sent to the address he named.

W. D. Williams (Salisbury).—Prussiate of potash is not a poison, nor is it included in Part I. of the poison schedule, therefore it is not subject to the regulations as to labelling, etc.

Owen Jones (London).—In our opinion they certainly do.

"Druggist" (Birkenhead).—According to the terms of the Act, we should consider the article mentioned as being liable to duty. In reference to a similar article, the Inland Revenue Office has taken a contrary course, though it is now considered to have been wrong in doing so.

R. J. O. (London).—Elixir of garus is a preparation of the French Codex. It is also given at p. 449 of Dorvault's 'L'Officine.'

Communications, Letters, etc., have been received from Mr. W. D. Boon (Lynn), Mr. A. H. Mason (Liverpool), Mr. H. H. Pollard (Ryde), Mr. Perkins (Norwich), Mr. J. Watts, jun. (Sheffield), Mr. R. G. Mumbray (Richmond), Mr. T. Appleton (Fulham), Mr. A. W. Bennett (London), "Registered Chemist and Druggist" (London), J. C. (Wakefield), "Agitator," "The Original Modified Man," "An Associate," L., A. E. J. (Norwich), J. E. T. C. (Manchester).

The following journals have been received:—The 'British Medical Journal,' Oct. 29; the 'Medical Times and Gazette,' Oct. 29; the 'Lancet,' Oct. 29; 'Nature,' Oct. 27; the 'Chemical News,' Oct. 28; 'Journal of the Society of Arts,' Oct. 27; 'Gardeners' Chronicle,' Oct. 29; the 'Grocer,' Oct. 29; the 'English Mechanic,' Oct. 28; the 'Canadian Pharmaceutical Journal' for October; 'Journal of Applied Science' for November; the 'Educational Times' for November; the 'Practitioner' for November; the 'Food Journal' for November.

HOSPITAL PHARMACY 120 YEARS AGO.

A most interesting account of the early history and practice of St. Thomas's Hospital is given by Dr. W. H. Stone in the first volume of a new series of the Reports of that Hospital just published. The facts are obtained from several different sources, and amongst others a most quaintly written book, which emanated from the shop of one "E. Duncomb, in Duck Lane, Little Britain," in 1741, and bears the title of 'The Physical Vade Mecum, or Fifth Gift of Theophilus Philanthropos; wherein is contained the Dispensatory of St. Thomas's Hospital, with a catalogue of the Diseases, and the nature of their cure, prescribed in the said Hospital;' a book peculiarly interesting to pharmaceutists, as showing how unexpectedly great has been the progress of the science they cultivate within the space of a single century. Dr. Stone tells us that the frontispiece portrays a fourfold conversation which is being carried on between the Patient and Doctor, Death and the Deity. A coffin and a skeleton in the foreground serve as emblems of mortality, and the doctor, after seeking the Divine assistance, is represented as having produced the following prescription, which is written on a scroll in his hand:—

"From infection sprung, it is a fever strong,
Unless with present speed a vein be open,
Thou must die or bleed.
VS ad ℥ix statim,
Episp. Nuchœ quam primum.

℞ Bol. Alex. ℈j cum
Nitri. gr. xij, 6tâ quâque horâ sumend.
Jul. Card."

The author of the work says of himself, that "whether ever it will fall to my lot to be much concerned in the curative or practical part of this Art I at present know not; and can't think upon it but with some kind of Anxiety or Fear! yet since God put it into my mind, and inclined my heart towards obtaining knowledge thereof, I have not been idle, as tho' I hoped to receive it by Revelation, or might obtain the Art of Healing by Inspiration; but on the contrary, have used what industry and diligence I could in acquiring the previous knowledge needful hereto; and after some years attending the Academy of Liberal Arts and Sciences under the most Learned, Worthy, and Pious Professor Eames; various courses of Anatomy by the Incomparable Dr. Nicholls, Professor of Anatomy at Oxford, and of Chemistry by the Ingenious Dr. Pemberton, Professor of Physic at Gresham College, I entered myself Physician's pupil at St. Thomas' Hospital on the 2nd March, 1728, in order to acquire the Practical Art of Physick." This estimable gentleman attended regularly the "Apothecaries' shop, which is a very neat, pretty place, well stored with medicine; besides which, it is ornamented by the Apothecary, who is a very Judicious, Prudent, Curious, and Ingenious Gentleman, by a Museum or Cabinet of various curiosities, and a large handsome framed skeleton, without Decorations and Ornaments." The actual pharmacopœia of the hospital was, at the time our author published his book, made up of a printed work bearing date 1718, and various old manuscripts, and the remedies used were, some of them, as follows:—

Aqua Limacum, or Snail Water.

Directed to be thus made:—

℞ Garden Snails, cleansed and bruised, 6 gallons.
Earthworms, washed and bruised, 3 gallons.
Common Wormwood, Ground Ivy and Carduus, each ½ lb.
Pennyroyal, Juniper Berries, Fennel Seeds, Aniseed, each 1½ lb.
Cloves and Cubebs, bruised, each 3 oz.
Spirit of Wine and Spring Water, each 8 gallons.

Digest together for twenty-four hours and draw off in a common alembick. This compound was said to be "well-contrived for cheapness and efficacy, and for persons whose circumstances and manner of living have not habituated them to any delicacies, it is as good a snail-water as can be made." How the fashions have changed!

Salivation was the very commonest practice, the calomel bolus containing 20 grains for a dose, "the common bole for salivation." Another bolus, "the Turbith," contained 5 grains of calomel and 3 of tartar emetic. There is a significant "N.B." appended to this last prescription that "in the working of this vomit it is needful to drink plentifully of Carduus Tea, through defect of which I knew one that Died." Marvellous must have been the effect of the "Viperian Bolus," which contained ʒss of the Flesh of Vipers in powder, the dose being two boluses a day. Viper's flesh, with opium in addition, were the chief ingredients of the "Venice Treacle," or Andromachus's electuary. But this was almost surpassed in delicacy by the "Expressio Millepedum," or expression of woodlice, made of three ounces of lice in spirit and water. Several well-known names occur, Pilulæ Cociæ Majores and Minores; Matthews; Rudius' and Ruffy's, or the Common Pill. The extent to which salivation was pushed may readily be gathered from the statement that "Some spit plentifully, viz. 5, 6, or 7 pints in 24 hours; with others it passes off more by sweat and urine than by mouth; which things must be observed with regard to the Patient's Welfare."

There appears to have been a special "powder for diseased eyes, made of glass what quantity you please," well pounded. It was used to "clear the eye of specs which cloud the sight by blowing thro' a Quill some of the powder upon the Parts affected, though it is not often used." A favourite diuretic was the tinctura Veneris of Boerhaave; it used, according to all accounts, to work wonders. Our author found that by its aid he cured one case of dropsy completely; "and a prodigious Discharge of Urine being excited, that it ran as out of an open Cock, upon which the Integuments of the abdomen became so loose that they might be wrapt over one another. The Patient grew perfectly well, and enjoyed a good state of Health many years after." Dr. Stone declares the following to be the gem of the whole collection. It is described as a "good medicine," and directions were given that if the dose be too noisome, it may be lessened and repeated the oftener." Here it is: Take of fresh Horse Dung ℥vj; Penniroyal water ℥xij; Treacle water ℥iv. Infuse them warm, and to the strained Liquor add Mithridate ℥ij; White Sugar, a sufficient quantity to sweeten it: drink half a Pint twice a day. Dr. Stone exclaims, Can we wonder at reactionary movements in favour of infinitesimal doses? What has often surprised us is the fact that the sick and suffering should ever have been induced to swallow so many beastly compounds. We imagine the fact to be in great measure explained by the secrecy with which the apothecary surrounded his concoctions. Be that as it may, the reminiscences of the not very long past, enable us to institute a most satisfactory comparison as regards the doings and knowledge of our immediate ancestors and ourselves relative to the practice of pharmacy, and give us much encouragement for the future. Whether our practice at the present day will cut, to the generation to come, as sorry a figure and excite as great a laugh as does that of the last century, is a matter upon which we may freely speculate. Who will venture to say with any confidence in this age of rapid progress, when to-morrow revolutionizes the things of yesterday, that this may not be the case?

CONTRIBUTIONS TO THE HISTORY OF THE ACONITE ALKALOIDS.

BY DR. TH. HUSEMANN, OF GÖTTINGEN.

The researches made by the author, in conjunction with Professor A. Husemann, on plant-products, enable him in answering the question proposed by Flückiger to offer some additional remarks. In the first place he agrees that the name pseudaconitina ought to be retained, and he prefers it to nepaline, in which is involved a theory as to its origin. Aconitina is a body whose physiological action is better understood than its chemical relations.

The physiological actions of pseudaconitina and of aconitina, when applied externally, differ in this respect; the former acts similarly to veratria, the latter not. Taken internally, pseudaconitina is given in much smaller doses than aconitina, and then often acts fatally. They both depress the action of the heart and lungs, and act similarly, but unequally, on the bowels.

Adelheim could perceive only a difference in strength between aconitina and pseudaconitina derived from *Aconitum ferox*.

Keeping these distinctive characteristics in view, we may conclude that "so long as aconitina has been used in Great Britain, pseudaconitina has most frequently been used in the place of it."

Turnbull's aconitina was said by him to cause numbness and contraction, with a feeling of weight lasting from two to twelve hours when applied externally. But soon after its introduction differences in the quality of the alkaloids were noticed; some being much stronger than others, some dilating, some expanding the pupil. So late as 1854, Hilton and others were inquiring as to the kind of aconitina that could have produced effects on the skin similar to veratria.

Fleming found that 6 milligrams exhibited by the stomach, or 5 milligrams subcutaneously, caused death in 11 minutes. The alkaloid was made by T. and H. Smith from the leaves of *Aconitum Napellus*.

Schroff's experiments with Morson's aconitina show results very similar.

Headland, using an alkaloid prepared by himself from *Aconitum ferox*, found 6 milligrams to kill a cat in 20 minutes.

Exact experiment as to the action of pseudaconitina on men is confined to one by Pereira, who found 15 milligrams to have a violent and dangerous effect.

It is clear, then, that the English aconitina does differ from that of Geiger and Hesse. This is also proved by the want of activity as a topical application evidenced by the German alkaloid.

The author is decidedly of opinion that pseudaconitina should not be regarded as a mere impurity, but as the real, active principle, for which the Swiss aconitina has, without cause, been substituted. He thinks we ought to endeavour to introduce pseudaconitina as well as aconitina into the dispensary, and discover a method of preparing the first in a pure state, whereby we should be in a position to have a constant preparation of real efficacy in the treatment of neuralgia.

From his own experience he states that rabbits have survived from 1 to 2 grains of German aconitina dissolved in water, and introduced through the mouth; *i.e.* from twelve to twenty-four times as much as would be required of pseudaconitina. Others have quoted similar experiences.

He cannot admit that English aconitina owes its virtues to an impurity, but rather that pseudaconitina is the substance to which English aconitina owes its reputation; in which case the term impurity would, of course, be inappropriate. Since 1864 even, two kinds of aconite alkaloid were obtainable in the London market; the one, pseudaconitina, sold as pure aconitina; the other, aconitina, of presumed foreign manufacture, impure and useless. Of this fact both pharmaceutists and doctors have more or less been aware for some time.

Probably the present state of the aconitina trade is occasioned by the scarcity of bikh root in the English market, from which we believe pseudaconitina is derived. Headland has stated that with great care pseudaconitina may be extracted from *Aconitum Napellus* in very small quantity. T. and H. Smith appear to have done this. The method adopted by Morson is not known, he having declined to give information thereupon; further than that his method is a peculiar one. Perhaps after all his method depends on the selection of the roots operated on.

As regards the colour tests of these alkaloids, Husemann remarks that according to Adelheim, the colour reaction (phosphoric acid?) is as well marked with pseudaconitina as with aconitina.

Great doubt still hangs over the various other alkaloids said to have been derived from the genus Aconitum.

Buckheim and Lisenmenger seem to have established a distinction between napellin and acolyctin, and have proved that napellin and lycoctonin are inferior in activity to aconitina.—*Abstract of Paper in Neues Jahrbuch der Pharmacie.*

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

ACIDUM TANNICUM. $C_{27}H_{22}O_{17}$. Powdered galls are damped with water, and then made into a paste with ether. On submitting the mass to pressure a strong solution of tannin is obtained, which is evaporated at first spontaneously, and at last in an oven at the temperature of boiling water. The tannin is then left in the form of vesicular masses, made up of thin glistening scales. The amount of tannin obtained varies from 30 to 60 per cent. of the weight of the galls employed.

Tannin is uncrystallizable, very soluble in water and in rectified spirit, and gives a yellowish-white precipitate with solution of gelatine. [Contrast these with the characters of gallic acid.] It is almost insoluble in pure ether, but in a mixture of ether and water readily dissolves.

It is soluble in about six times its weight of glycerine; in less if warmed. It gives precipitates with almost all metallic solutions, and with most of the alkaloids. If free from adulteration, it is completely soluble in rectified spirit, and burns without leaving a residue.

The amount of tannin dissolved in a liquid, *e. g.* a vegetable infusion, is usually estimated by ascertaining the amount of a solution of gelatine of known strength, which is precipitated by a given quantity of it.

Tannin is a "glucoside," that is, when boiled with acids, or when under the influence of the peculiar ferment contained in galls, it splits up, yielding glucose among the products of its decomposition. [See gallic acid.] There are several varieties of tannin; this from oak galls (gallotannic acid) is distinguished by giving a *bluish*-black precipitate with ferric salts; another kind from catechu (mimotannic acid) gives a *greenish* compound with ferric solutions.

Acidum Tartaricum. $H_2C_4H_4O_6$. Acid tartrate of potash is first boiled with chalk until the effervescence has ceased and the liquid is neutral. There is then formed a precipitate of tartrate of calcium, and a solution of neutral potassic tartrate.

$$\underset{\text{Acid tartrate of potassium.}}{2(KHC_4H_4O_6)} + \underset{\text{Carbonate of calcium.}}{CaCO_3}$$

$$= \underset{\text{Neutral tartrate of potassium.}}{K_2C_4H_4O_6} + \underset{\text{Tartrate of calcium.}}{CaC_4H_4O_6} + \underset{\text{Carbonic acid.}}{H_2O, CO_2}.$$

To the liquid is added a solution of chloride of calcium; this causes a further precipitation of tartrate of calcium:—

$$K_2C_4H_4O_6 + CaCl_2$$
$$= CaC_4H_4O_6 + 2KCl.$$

The mixed precipitates are collected, drained, washed, and decomposed by digestion with diluted sulphuric acid:—

$$CaC_4H_4O_6 + H_2SO_4 = H_2C_4H_4O_6 + CaSO_4.$$

Most of the sulphate of calcium produced is removed by filtration; the tartaric acid crystallizes from the concentrated solution.

Tartaric acid is recognized by blackening, when heated, with an odour like that of burnt sugar. It gives a white crystalline precipitate ($KHC_4H_4O_6$) with solution of acetate of potash. Admixture of oxalic acid would be detected by the solution giving a precipitate with one of sulphate of lime; alum or any sulphate, by forming a precipitate with chloride of barium; sulphate of lime, by giving a precipitate with oxalate of ammonia, also by leaving a residue when burned with free access of air.

7·5 grams ($\frac{1}{20}$ of a gram-molecule) of tartaric acid require, for neutralization, 100 cubic centimetres of the volumetric soda. 100 c.c. vol. solution contain $\frac{1}{10}$ of a gram-molecule, or 4 grams of $NaHO$.

Tartaric acid offers an example of *isomerism*. There are three (or perhaps four) acids all represented by the same chemical formula, being of the same composition, but differing from one another in chemical and physical properties. Dextrotartaric acid, the common kind, rotates a ray of polarized light to the right; lævo-tartaric acid to the left; and racemic acid, which is formed by the union of the two former, is inactive. Bodies which thus have the same composition, but exhibit characteristics which show that they are not identical, are said to be isomeric. The differences are considered to be due to a difference of constitution, or manner of arrangement of their constituent atoms. The particular kind of isomerism exhibited by the modifications of tartaric acid is sometimes called physical isomerism or allotropy. The related bodies are convertible one into the other, and differ chiefly in mechanical, slightly in chemical properties.

Oxalic Acid.—Appendix I. The oxalic acid of commerce is made in two ways. Sometimes sugar is boiled with slightly diluted nitric acid: nitrous fumes are evolved, and on cooling, the oxalic acid crystallizes out. Saccharic acid, $C_6H_{10}O_8$, is formed at first, and is afterwards converted into oxalic acid, but the reactions cannot be shown in any simple or probable equation. A large quantity is now made by roasting sawdust (impure cellulose) with a mixture of caustic potash and soda. The resulting alkaline oxalate is boiled with lime, which gives insoluble oxalate of calcium, and this is converted into the acid by digesting with diluted sulphuric acid.

[§ Test. It is entirely dissipated by a heat below 350° F.] The commercial acid almost invariably leaves a small residue of sodic carbonate. Oxalates give a white precipitate with chloride of calcium, which is not dissolved by the addition of acetic acid: when heated they give off carbonic oxide, CO, and leave a residue of carbonate of the metal. Neutral ammonium oxalate, heated gently, gives up water and furnishes a white, nearly insoluble, slightly volatile residue of oxamide.

$$\underset{\text{Oxalate of ammonium.}}{(NH_4)_2C_2O_4 - 2H_2O} = \underset{\text{Oxamide.}}{(NH_2)_2C_2O_2}.$$

Oxalic acid is resolved by heating it gently with glycerine into formic acid and carbonic acid gas.

$$C_2H_2O_4 = CH_2O_2 + CO_2.$$

The glycerine takes no obvious part in the decomposition; but without it a much higher temperature is requisite. Oxalic acid and oxalates, heated with strong sulphuric acid (*q. v.*), evolve carbonic monoxide and dioxide gases. The latter may be separated from the former by passing the mixed gases through solution of potash. The CO_2 is absorbed, the CO left untouched.

Oxalic acid is dibasic and therefore gives two series of salts, neutral and acid.

Crystallized oxalic acid . .	$H_2C_2O_4, 2H_2O$.
Neutral potassic oxalate . .	$K_2C_2O_4, H_2O$.
Acid potassic oxalate (Binoxalate of potash) . .	HKC_2O_4, H_2O.

But it also gives another class of compounds formed by the union of the normal acid oxalates with oxalic acid.

Quadroxalate of potash (Salt of sorrel) $\left.\begin{matrix} KHC_2O_4 \\ H_2C_2O_4 \end{matrix}\right\} 2H_2O$.

The antidote to oxalic acid is chalk or whiting.

THE USE OF AMMONIA IN SNAKE BITES.

The following has been sent to the *Pall Mall Gazette* by a correspondent signing himself "An American":—

"While a temporary resident of one of the Southern states of the United States, where rattlesnakes are numerous, a man who had been bitten by one of these venomous reptiles sent for the writer to visit him. Being absent at the time, my visit was delayed some twelve hours. I found the patient was wounded over the top of his shoe, just above the instep. His leg was swollen to an enormous extent up to the body; and, having no pretensions to medical or surgical science, I sent immediately, a distance of twelve miles, for a medical man. In the meantime, as the case seemed certain to terminate fatally, and having read in some newspaper that ammonia was a sure antidote for snake poison, I determined upon an immediate experiment. Having no instruments, with the patient's razor I cut the wound entirely out, applied to the part cotton saturated with a mixture of ammonia and olive oil, and renewed the application every thirty minutes. I also gave him ammonia, diluted with whisky, in large doses, every thirty minutes, and applied a bandage to his thigh, as tightly drawn and as close to the body as possible. Under this treatment, to my utter astonishment, the patient recovered. Lest this case may be regarded as exceptional, I would add another, which soon after came under my observation, to confirm it, in which a rattlesnake so perfectly grappled his fangs through the ball of a man's little toe (as it projected through a hole in his shoe), and so firmly fastened upon it, that the head of the snake had to be cut off to disengage it. In this case also some eight hours elapsed ere I was called to it; and on approaching the patient such was his agony from the wound he begged me to 'take his rifle and shoot him.' The leg was terribly swollen to the knee, but on cutting out the wound (the entire ball of the toe) and applying the same remedies as in the first case, this patient also recovered.

ON THE COMBINATIONS OF CARBONIC ANHYDRIDE WITH AMMONIA AND WATER.

BY EDWARD DIVERS, M.D.

(*Continued from page* 128.)

III. *Acid Ammonium Carbonate.*

History.—Berthollet announced his discovery of the acid carbonate in 1806, in his 'Troisième Suite des Recherches sur les Lois de l'Affinité,'* and gave an excellent account of its properties. Dalton, Phillips, Rose, St. Claire Deville and others, have since then added materially to our knowledge of this salt.

Preparation.—It is obtained by exposing any other carbonate of ammonium to the air; by treating the half-acid or the commercial carbonate with water or with aqueous alcohol, or by treating the normal carbonate with aqueous alcohol; by cooling sufficiently-concentrated aqueous solutions of the half-acid or the commercial carbonate, when it crystallizes out; by treating a solution of any other carbonate of ammonium with carbonic anhydride; and by mixing together carbonic anhydride, ammonia and water, the first being in excess. A modification of the last method is to distil the acid carbonate at a temperature not exceeding 62° C. The operation is a very slow one, but, if the acid carbonate is more rapidly converted into vapour, the process fails. In any case, some of the product will be impure.

Sensible Qualities.—Acid carbonate has a cooling, saline taste, not at first ammoniacal, and has no smell when dry.

Form.—It occurs in the form of powder; in crystals, transparent or opalescent, obtained from water; and in crystalline semi-transparent cakes.

Crystalline Form.—A great deal has been written on this subject. The crystals belong to the right prismatic system, and exhibit the faces of the three orders of rhombic prisms, as well as the three pairs of faces of the right rectangular prism. When the crystals form in a solution of commercial carbonate, cooled a little below its point of saturation; or in a not too-concentrated solution, prepared by pouring hot water over the carbonate in a flask and then corking the flask; or in a solution of commercial carbonate, moderately strong, which has been treated with a stream of carbonic anhydride, they are hard and brilliant, and have the general contour of a flattened ovoid. The flatness of the crystals varies according to the strength of the solution in the more basic carbonates of ammonium. Generally there are to be seen among the ovoid crystals deposited from a cooled saturated solution of commercial carbonate, some long, essentially four-sided crystals with truncated summits. These do not differ in composition, or otherwise in form, from the first-described crystals, and give way to, or else are transformed into, the other variety when left for a time in their mother-liquor. When a warm saturated solution of acid carbonate is made by digesting the acid carbonate with the water in a firmly-closed bottle, the crystals which form are opaque, and first appear as simple rhombic prisms with dihedral summits. These, however, rapidly thicken, and then might be described as octahedrons on a rectangular base. They have the same faces as the previously mentioned forms. They readily cleave into long rhombic prisms. Their opacity is evidently due to their having a composite structure and retaining mother-liquor in their interstices. When a very concentrated solution of the commercial carbonate is made in warm water in a flask, and especially when some effervescence is permitted to go on, and the solution allowed to cool, crystals, very different in appearance from those already described, make their appearance. They generally form at the surface of the solution, and remain hanging vertically; and present a remarkable appearance from being closely packed together, and all extending down into the solution to an equal depth, with their lower edges parallel to the surface of the solution. In other cases these crystals form at the bottom of the vessel, and this generally happens when the crystals are prepared by taking a solution of commercial carbonate which has already yielded a good crop of crystals, and dissolving in it, by the aid of heat, as much, or nearly as much, fresh commercial carbonate as possible. When the crystals form at the bottom of the vessel, some rest on their broad sides, but most of them stand up, closely packed in groups, nearly parallelly arranged, with their angles, not their edges, projecting upwards. They have not the transparency and brilliancy of the ovoid crystals, but this is evidently due to the peculiar character of their faces, and not to the existence of any interstices in them. They have the form of thin, rectangular, and nearly equilateral plates, with or without the corners slightly cut off, with their broad faces crinkled and with bevelled edges. The faces forming the edges and truncated corners of the plates, are those of the different orders of rhombic prisms apparent in the previously-described crystals. The broad faces of the plates are not at all like true crystalline faces. They are not only crinkled or waved, but are not always in their general bearings parallel to each other and to the normal macro-pinacoids of the rectangular prism, the places of which they occupy. Rose has described crystals, also right rhombic prisms, which have different angular measurements, identical with those of the corresponding potassium-salt. These, however, he only succeeded in obtaining once. Deville at one time thought that he had seen oblique rhombic prisms of acid carbonate produced by the decomposition of the half-acid carbonate, but he has since come to the conclusion that only one form of acid carbonate exists. The cakes of acid carbonate produced by its own slow distillation, exactly resemble well-crystallized specimens of the commercial carbonate.

* *Journal de Physique*, lxiv. 168.

Chemical Composition.—Rose analysed the acid carbonate prepared in different ways, and obtained results which led him to consider that the following acid carbonates existed:—

$$CO_2OH_2NH_3$$
$$(CO_2)_4(OH_2)_5(NH_3)_4$$
$$(CO_2)_2(OH_2)_3(NH_3)_2.$$

But crystals like those to which he gave the second formula have a composition expressed by the first one, according to Berthollet, J. Davy, Deville and myself. The salt found by him to have the composition represented by the third formula was a product of distillation once only obtained by him in small quantity. For this reason, and from a consideration and repetition of some of Rose's methods of preparing carbonates by distillation, I am disposed to regard the existence of such a salt as extremely doubtful.

Behaviour on Exposure.—It is probably quite fixed in dry air. In ordinary air it is very slowly dissipated, as was pointed out by Dalton. According to John Davy, it is decomposed by the atmospheric moisture, and rendered alkaline. Certainly, the moister it is, the more ammoniacal it renders the air confined with it in a bottle. By exposure to air, the faces of the crystals lose much of their lustre. It is not quite easy to recognize the nature of the change which the salt undergoes by exposure; for example, when the salt has been left for a while in a closed bottle, how is the strong smell of ammonia which is generated to be accounted for? What has become of the carbonic anhydride that was in combination with it?

Behaviour when Heated.—Like the normal carbonate, when heated in a retort, a little of it is first decomposed, and yields a few drops of liquid distillate, at about 49° C., which gradually crystallize in needles; while the rest, getting thus enveloped in an atmosphere of the products of this decomposition, undergoes no change at this heat. At about 60° it is slowly decomposed into carbonic anhydride, water and ammonia, the salt in the retort remaining dry; but when the heat is carried much above 60° C., the salt in the retort gets wet. The effect of heat is therefore thus represented:—

$$CO_2OH_2NH_3 = CO_2 + OH_2 + NH_3.$$

Behaviour with Water.—As was first pointed out by Berthollet, the acid carbonate dissolves in about 8 parts of water, at 15° C. By exposure to the air this solution rapidly loses carbonic anhydride, but, as also pointed out by Berthollet, this loss is soon arrested. Gently heated, it effervesces. The solution placed in contact with solid acid carbonate decomposes it even at low temperatures, large bubbles of carbonic anhydride being formed, as was pointed out by Davy, which adhere to the crystals, and, if the latter are small, carry them to the surface. A saturated solution of acid carbonate crystallizes out when cooled.

Behaviour with Alcohol.—Acid carbonate is very slightly, if at all, acted on by strong aqueous spirit, cold or boiling. The crystals boiled with the spirit are slowly decomposed, as they would be by the heat alone; carbonic anhydride and ammonia escape, and the remaining spirit is left weakened, and with a little caustic ammonia dissolved in it.

Behaviour with Ammonia.—Dry crystals of the acid carbonate are not acted on by ammonia gas, either at ordinary temperatures or that of 0° C. When the powdered salt and strong solution of ammonia are brought together, a hissing sound is produced, the mixture becomes warm, and the salt cakes together and shows little evidence of being dissolved.

By digesting the acid carbonate with the strongest solution of ammonia in a closed vessel, at a temperature of 20°–25°, ammonium carbamate is slowly formed in considerable quantity. The mode of procedure is exactly similar to that already described for converting the normal carbonate into the carbamate; as are also the results, except that, as might be anticipated, the yield of the carbamate is greater. In the first stage of the reaction, by which the carbamate is formed, the acid carbonate and the ammonia probably react, to form carbamate and normal carbonate; in the second stage, the normal carbonate thus formed changes into water, and carbamate, as was explained when treating of the reactions of the normal carbonate. Representing the change by a single equation between the substances employed and those finally obtained, we have—

$$CO_2OH_2NH_3 + NH_3 = CO_2(NH_3)_2 + OH_2.$$

(To be continued.)

CYSTINE.*

This rare substance has the composition $C_3H_7NO_2S$; it crystallizes in the form of six-sided plates, and forms with hydrochloric, nitric and phosphoric acids, definite crystalline compounds.

Dr. Bence Jones has shown that nitrous acid decomposes cystine with evolution of nitrogen, the sulphur it contains being oxidized to sulphuric acid, whilst a non-crystalline substance is left which is precipitable by nitrate of silver, mercuric chloride, or acetate of lead.

The cystine used in the author's experiments was obtained by treating pounded calculi with strong liquor ammoniæ, which dissolved the greater part, then evaporating the solution at a very gentle heat. The cystine which separated was again dissolved in ammonia and recrystallized.

Hydrochlorate of Cystine,—obtained by dissolving cystine in boiling hydrochloric acid, separated on cooling as beautiful needle-shaped crystals, very soluble in water. When thoroughly dried in vacuo over quicklime, the crystals were found not to be readily soluble in water. 0·05 gram of crystalline hydrochlorate of cystine yielded 0·0452 gram of $AgCl$, corresponding to 22·2 per cent. of HCl (calcined 22·5).

When cystine is dissolved in strong solution of ammonia, and a solution of silver nitrate in ammonia added, no precipitate is formed, nor does the solution darken in the cold. When slightly acidified with nitric acid, a canary-yellow precipitate is thrown down. The filtrate blackened when heated, and on filtering off the black precipitate a clear colourless solution was obtained, which was not further blackened when boiled with ammoniacal solution of oxide of silver. On analysis the yellow substance proved to be a compound of cystine with nitrate of silver.

In a subsequent experiment an ammoniacal solution of cystine was boiled with an ammoniacal solution of nitrate of silver. A black precipitate fell which consisted of sulphide of silver. The filtrate from the precipitate of sulphide of silver was subsequently treated with solution of chloride of ammonium to separate the excess of silver. The solution was found not to be precipitated by hydrochloric acid and chloride of barium nor by sulphate of calcium. It is therefore evident that when an ammoniacal solution of cystine is heated with ammoniacal solution of oxide of silver, the sulphur is separated entirely as sulphide of silver, none being oxidized; it is also obvious that no oxalic acid is formed.

Cystine, treated with $NaHO$, and evaporated in a silver basin, gives a reddish liquid; sulphide of sodium is then produced, blackening the basin, and ammonia is copiously evolved. On treating the residue with water, neither sulphuric nor oxalic acids can be detected, but the liquid contains a large quantity of sulphide of sodium with a mere trace of sulphite.

Cystine, heated to 150° C. with solution of caustic baryta in sealed tubes, gives off ammonia, a large quan-

* Abstract from a paper by James Dewar, F.R.S.E., Lecturer on Chemistry, Veterinary College, Edinburgh; and Arthur Gamgee, M.D., F.R.S.E., Lecturer on Physiology at Surgeons' Hall, Edinburgh, published in the Proceedings of the Royal Society of Edinburgh, 1869–70.

tity of sulphide of barium, a smaller quantity of sulphite of barium, and a trace of hyposulphite being formed. No trace of sulphocyanide could be detected.

Cystine was heated for several hours in a sealed tube at 130° C. with an alcoholic solution of potash. At the conclusion of the experiment a small quantity of dark sticky matter was found adhering to the tube, which contained a yellowish liquid. The latter smelt strongly of ammonia, which was separated by distillation. The residue was acidified with dilute sulphuric acid, and shaken up with ether. Ether left a yellow non-crystalline substance, possessed of an indefinite but disagreeable odour. This substance had a strong acid reaction, and was found to contain no sulphur.

When cystine is added to a mixture of tin or zinc and dilute hydrochloric acid, large quantities of sulphurated hydrogen are given off; even after the action has gone on for several days, traces of sulphuretted hydrogen continue to be given off. When treated in the same manner taurine does not evolve H_2S.

It is to be noted that this evolution of H_2S might be used as a test for cystine, care being previously taken to separate any sulphide.

Cystine was placed in water and a stream of nitrous acid gas passed through it. No action took place until the water was heated; it then commenced and proceeded briskly, with abundant effervescence, until the whole of the substance was dissolved.

The clear solution contained a large quantity of sulphuric acid, but not a trace of oxalic acid. When boiled with an ammoniacal solution of nitrate of silver, considerable reduction took place, a beautiful mirror of silver being deposited on the glass. The fluid was again subjected to the action of nitrous acid; still no oxalic acid could be found, and the reduction of an ammoniacal solution of oxide of silver continued.

Cramer believed that cystine was intimately related to the body called Serin, $C_3H_7NO_3$, which is obtained as one of the products of the action of alkalies on silk. Serin, when treated with nitrous acid, yields glyceric acid, as alanine under the same circumstances yields lactic acid, and therefore serin may be looked upon as amido-glyceric acid.

Cramer further believed that cystine was a sulpho-amido-glyceric acid, *i. e.* serin in which hydroxyl has been replaced by HS.

This supposed relation is exhibited below—

CH_2OH	CH_2NH_2	CH_2NH_2
$CHOH$	$CHOH$	$CHSH$
CO_2H	CO_2H	CO_2H
Glyceric Acid.	Amido-glyceric Acid or Serin.	Cystine.

Considering that this relation of cystine to serin really exists, some have argued that on treatment with nitrous acid, cystine should yield glyceric acid. The authors do not admit that this would really be the case, and they refer to the case of sulpho-lactic acid, a body analogous to the supposed sulphur derivative of serin, and giving on oxidation sulpho-propionic acid; if therefore cystine were built up as Cramer supposes, it might be expected that sulpho-acid would be formed on treatment with nitrous acid. But, however carefully the action of nitrous acid was regulated, the sulphur separated as sulphuric acid, thus pointing to a decided difference in its reactions from what might have been expected from the supposed constitution of cystine. Although, not considering the experiments as definitive, the authors assert that glyceric acid is not a product of the action of nitrous acid, and they predict that, in all probability, cystine will be found related to pyruvic acid—to be an amido-sulpho-pyruvic acid. This supposition is based on the near approach of the analyses of the silver salt of the acid obtained by the action of nitrous acid on cystine to the composition of a pyruvate, and on the general character of the oily acid produced.

Supposed Poisoning by the Berries of the Guelder-Rose.—At the adjourned inquiry into the death of a child at Sudbury, referred to on p. 347 of this Journal, the medical men who made a *post-mortem* examination of the body said that they had found the stomach perfectly empty, and that, although they made a careful examination, they failed to detect any poisonous substance in the bowels, or any signs of poisoning. As they could not discover any natural cause for death, they had come to the conclusion that it had been caused by the absorption of the active principles of some narcotic poison. With respect to the berries of the wild Guelder-rose, which, it was suggested, had been eaten by the deceased, they were not aware of any medical work referring to them as poisonous. The jury returned a verdict in accordance with the medical evidence.

What is a Poison?—In reference to the recently reported cases of poisoning by acorns, the *Observer* remarks:—"Boys at school have not unfrequently to mourn the loss of that pretty but unsavoury little pet, a white mouse. The white mouse has an inordinate love for apple, and if allowed slices of apple without discretion will eat until he dies in a fit of something, which may be either colic, or indigestion, or apoplexy; and in its symptoms resembles all three combined. The same fate has often befallen chickens which have been allowed raw rice. The warmth of the crop makes the rice expand, and the chicken is choked in much the same way as a human being would be choked if he were to mix and drink the contents of a dozen white seidlitz papers first, and of a dozen blue papers afterwards, or as the boa-constrictor was choked who swallowed his blanket. And so, too, it seems that hungry cattle will gorge themselves to death with raw acorns, exactly as a starving man might eat himself to death with raw chestnuts or raw potatoes. Out of this fact has arisen an immense turmoil of words, some writers stoutly asserting that acorns are "poisonous," others as stoutly denying the assertion. The answer is easy enough. Anything is a poison which, if swallowed (or inhaled, or even injected), produces death; and in the strict acceptation of the term a man is poisoned who is killed by swallowing a penknife or a dose of ground glass. But the term "poison" is, as a rule, restricted to those things which are poisons in very small quantities. Children have often been poisoned by an over-dose of common salt given as an anthelmintic, and men have been poisoned by drinking for a wager a bottle of raw brandy, by eating for a wager ten pounds of beefsteak, and even by drinking cold well-water in hot weather. But yet we do not as a rule apply the term "poison" to salt or to brandy, or to beefsteaks or to well-water. The whole difficulty is one of ambiguity, and shows how a quarrel may arise from a mere misconception as to the exact meaning of a technical term."

Madeira.—The war, in the exercise of its remote influences, is giving at the present time a twofold prominence to the Island of Madeira. Coincidently with the neglect of the vineyards in France and Germany, an overflowing vintage has been gathered in. A large increase of produce was naturally expected from the progress of an extending vine culture; but a circumstance apparently trivial, a general paucity of seeds in the grape, was unforeseen, and has caused the yield to overflow the provisions of the most liberal calculations. There is a scarcity of casks to store the new wines, the few coopers on the island not being able to meet the demand on their labour. The absence of seeds, however, is stated by Dr. Graham, a Madeira authority, to be a constant result of a moist winter and spring. As a health resort, also, Madeira now obtains unwonted prominence by the defection of the popular winter retreats of the South of France. Notwithstanding the suggestions of circuitous routes to avoid disturbed districts, many persons prefer facing a sea voyage to the doubtful society of an excited and revolutionary population.—*Times.*

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 12, 1870.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes to be endorsed "Pharm. Journ."*

AID TO PHARMACEUTICAL EDUCATION IN THE PROVINCES.

WE have now before us the complete Report* of the Committee appointed to inquire into the facilities existing for provincial education in pharmacy, and this subject, one of the greatest importance to the future progress of our calling, is treated in a way which indicates that the future and the permanent have been steadily kept in view in their treatment of a difficulty which is transitional and only of the present.

The whole question hangs upon two points, the extent and kind of education which, for the public good, it is the duty of the Board of Examiners to demand from the students, and the remuneration which the pharmacists are enabled to reap as a consequence of their extended education. Another generation will see the present difficulties pass away under the action of the natural law of supply and demand, and the wisdom of those who hold the helm of our affairs will be seen in their endeavour to permit events to pass on as nearly as possible in their natural course, giving their attention to the assistance of those who do the best they can for themselves, and diminishing, wherever practicable, the sacrifices which individuals have to make for the general good.

With the experience before us of so many small societies which have sprung up and died of apathy in the second or third year of their existence, it would be imprudence on the part of the central body to give freely without some guarantee that the money was invested and not thrown away. It would likewise be a waste of strength to keep schools in operation which are not capable of providing their students with instruction in all the subjects required by the Board of Examiners. A student ought not to feel, on entering a school of pharmacy, that he would have to pass on to another for instruction in some subject in which the curriculum of the first school was deficient.

But in looking over the tabulated returns, p. 330, how few of the local organizations give us any assurance of either permanency or efficiency! Of the 27 enumerated, only 14 give lectures at all, and only 3—Edinburgh, Newcastle and Sheffield—give the complete curriculum. In Liverpool 26 lectures are made to include botany, materia medica and pharmacy. In Manchester practical chemistry and pharmacy are wanting. In Leeds materia medica, pharmacy and botany are wanting. In Leicester botany is treated in three lectures. To deny assistance to these latter towns, because their curriculum is not complete, would be blighting to our most hopeful prospects. Of the sixteen organizations which give the date of their establishment, ten were established in 1868 or 1869, and are only now at that period which is usually most trying to the vitality of institutions depending for their existence upon the labour of a few individuals who reap neither riches nor honour in return. A little judiciously-bestowed assistance will probably convert several of these into permanent and efficient institutions.

Many other modes of giving to the provinces have been suggested besides those recommended by the Committee; but any mode which did not involve a special inquiry into each case would save present trouble at the expense of the future. The arrangements now recommended are framed with the view to their naturally dying out; as the change in circumstances, which ten years will bring about, enables the teachers in the provinces to have sufficiently large classes and sufficiently high fees to remunerate them for their services.

As yet we can scarcely be said to have any data upon which to form an estimate, either of the number of students who will desire to avail themselves of official aid, or of the fees which may be expected from them. Allusion is made to the requirements of medical students having resulted in the establishment of medical schools in eight of the principal towns of England; but it must be remembered that the medical is more numerous than the pharmaceutical body, and that the medical student cannot take up his degrees without having attended lectures at recognized schools; whereas our students, so long as they have the required knowledge, may pick it up where and how they can. The attendance of students upon lectures when not compulsory will be determined by the fees charged and the value of the aid derived from them. The experience at Edinburgh and Newcastle shows that, even at the present time, something like remunerative fees may be obtained where the quality of the curriculum is satisfactory.

After making all due allowance for the difficulty of obtaining either large classes or large fees where the attendance is optional, we think the Committee have underrated what may be reasonably expected from provincial institutions; they say "the requirements of the Minor Examination may be met by a large section of young men who will take situations in towns offering the means of technical education." But there is no reason why provincial education in pharmacy should not shortly

* See page 389.

become as efficient as is the medical education provided in the eight towns alluded to in the report.

The value and permanence of local schools must depend mainly upon their enabling students in their neighbourhood to qualify themselves fully without the necessity of their attending lectures or laboratory practice in the Metropolis; and, while we would urge upon every student to avail himself of every means of gaining knowledge within his reach, we must admit that a mutual improvement society, with a small library and materia medica collection, should afford all the assistance required *by any earnest student* to enable him to pass the Minor. So long as there is a Minor Examination conferring the title of "Chemist and Druggist," and enabling the holder of the same to carry on business, the mutual improvement associations of small towns will do the work of providing the lower grade pharmacists for those neighbourhoods which do not afford scope and remuneration enough to tempt men of higher status.

The great preponderance of lectures on chemistry, a popular science, compared to those upon materia medica and pharmacy, subjects especially pharmaceutical, suggests that local associations have already availed themselves of science classes at mechanics' institutes, etc. In aiding such schools it will be necessary to see that contributions, either to a library or museum, for the benefit of pharmacy students, be not appropriated as the property of the mechanics' institution.

Clause 4 provides that the Council may impose conditions upon the recipients of their gifts, and clauses 9 and 10 indicate that a watchful eye will be kept upon the uses made of their contributions.

We shall look forward with interest every year to the tabulated return which they promise.

It now remains for our provincial friends to take stock of their own resources; to ask what they have done and what they can do for themselves,—what prospect they have of establishing permanent schools of pharmacy with such assistance as it would be reasonable on their part to ask, and on the part of the parent body to give; and, in the event of their expectations being of a less ambitious nature, to consider what help will meet the temporary wants of their neighbourhood, or will facilitate the working of mutual improvement classes, which, it must be remembered, was the only kind of school for pharmaceutical education which afforded assistance to many distinguished pharmacists of the present day.

We learn from a letter just received from Baron Liebig that he is scarcely yet recovered from his late severe illness, which was brought on by overexertion in working at the papers on "Fermentation," "Source of Muscular Power" and "Nutrition," of which translations were recently published in this Journal.

Our readers will notice with regret that at the last meeting Mr. H. B. Brady resigned his seat at the Council. Few besides those who have laboured with him have any conception of the energy and conscientiousness with which he performed *more* than his share of the Society's business, and of the impetus he gave to the moving power at a time when there were many Councillors and but few active *workers*. It is fitting that it should *now* be recorded in these columns that to him the Members and Associates are mainly indebted for the publication of this Journal *weekly*. Zeal for the Society and for pharmacy prompts us to hope that after the lapse of a few years, when he shall have grown proof against London fogs and English winters, Mr. Brady will allow his late constituents to again draw upon his time and comfort. We promise beforehand, on their behalf, that it shall *then* be for only a very *moderate* amount.

We understand that Messrs. Jenkins and Phillips, of Lime Street, E.C., have just received a large parcel of cinchona bark from Columbo, Ceylon. It consists of the bark of the twigs and young branches, and is in very fine condition. It is to be sold in Mincing Lane in about three weeks' time.

Our readers will regret to hear that Mr. Richard Reynolds, who has lately taken an active part in the preparation of the Report on Provincial Education, published this week, has met with an accident in a railway collision, and though we understand the result is not believed to be serious, it will require his being kept quiet for some time.

NOTICE.—In order to prevent delay in the insertion of advertisements, we find it necessary to remind advertisers that they should send to the Publishers, Messrs. Churchill and Sons, 11, New Burlington Street, and not to either the Editor of the Journal or the Secretary of the Society.

Proceedings of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

November 2nd, 1870.

MR. SANDFORD, PRESIDENT, IN THE CHAIR.
MR. HASELDEN, VICE-PRESIDENT.

Present—Messrs. Atherton, Bottle, Bourdas, Deane, Dymond, Edwards, Groves, Hanbury, Hills, Reynolds, Savage, Stoddart, Sutton and Woolley.

The minutes of the last meeting were read and confirmed.

The President read the following letter from Mr. H. B. Brady:—

"*To* G. W. Sandford, Esq., *President of the Pharmaceutical Society.*

"Dear Sir,—The time has come when it seems right for me to tender my resignation as a member of the Council of the Pharmaceutical Society, and I beg you to convey to the November meeting of the body my decision not longer to hold a seat at their board.

"I need not go into the reasons that impel me to resign now rather than retain office till the end of the year, but may just say that I have held office as long as in my opinion a member representing a country district should; that with the present preponderance of country members of the Council, I could not, during the winter months, do the amount of Committee work which it is absolutely necessary each should take, and that it would be wrong for me longer to hold a position which can readily be filled by some one with larger opportunities and greater power of benefiting the Society in these particulars.

"I need not assure the Council of my desire, whether in office or out of it, to further by every means in my power the advancement of pharmacy and the welfare of the Society.

"I remain, dear Sir, faithfully yours,
"Henry B. Brady."

Whereupon it was

Moved by Mr. Deane, seconded by Mr. Hills, and

Resolved—That the Council, in accepting the resignation of Mr. H. B. Brady, desire to record their great regret at the loss they sustain, and that circumstances necessitate the course he has found it desirable to adopt.

It was ordered to be recorded on the minutes,

That the portrait of the President, George Webb Sandford, painted by J. P. Knight, R.A., was presented to the Society at the first Evening Meeting for the session, October 5th, by Frederick Barron, Esq., in the name of the Committee of the Fund raised for that purpose.

The Report of the Finance Committee was presented, showing on the General Fund Account a balance in the Treasurer's hands of . . . . . . £1390. 5*s*. 3*d*.
Submitting for payments Accounts amounting to . . . . £582. 15*s*. 7*d*.
On the Benevolent Fund Account a balance of . . . . £547. 12*s*. 11*d*.

Resolved—That the Report be received and adopted and payments made.

The Report of the Library, Museum and Laboratory Committee having been read, it was

Resolved—That it be received and adopted.

Benevolent Fund.

Resolved—That Charles Thomas Anderson and Hannah Greaves, having at the late election obtained the largest number of votes, be declared elected annuitants, and that the Treasurer be requested to pay them their several annuities to Christmas next.

Application for temporary assistance having been made by the two unsuccessful candidates, it was

Resolved—That the sum of £10 be granted to each of them.

Resolved—That the Report of the House Committee be received and adopted.

Upon the Report of the Parliamentary Committee, it was

Resolved—That the Registrar be requested, and is hereby authorized, to erase from the Register of Chemists and Druggists the names of Thomas Holmes, of Great Grimsby, and Samuel Dicey Holmes, of Mortlake Road, Richmond, Surrey.

The following Report of the Provincial Education Committee having been read was received and adopted.

Report.

Your Committee have already presented to the Council tabulated results of their inquiries into the present facilities for Pharmaceutical Education in the provinces. These returns show the existence of a considerable amount of educational effort, which may be taken as confirmatory evidence of an educational demand.

The Committee next proceeded to the second stage of the inquiry remitted to them. They gladly embraced the opportunity of inviting Mr. Geo. F. Schacht, of Clifton, to attend their meeting, at which it was considered how to aid Provincial Education. The Report now presented shows the conclusions at which, after full discussion, the Committee arrived.

It is clear that the requirements of the Pharmacy Act of 1868 will annually compel the technical education of a number of young men, many times greater than can be received into the Society's School of Pharmacy in London. Many of these may obtain the needful amount of knowledge by diligent private study, but the case of the majority will probably be analogous to that of provincial students of medicine, whose wants have resulted in the establishment of medical schools in eight of the principal towns of England. To a large extent the students of these medical schools pursue their studies simultaneously with engagements as assistants to medical men. It is evident that the cost of an educational course is thus much reduced. Your Committee believe that whilst the greatest advantages will fall to the lot of those students who pass a session at the Society's School in London, still, the requirements of the Minor Examination (viewed as the portal to the title of Chemist and Druggist) may be met by a large section of young men who will take situations in towns offering the means of technical education.

Such a system, when established, will bring its attendant changes to both employer and employed. The former must be prepared to grant a regular amount of time to his assistants for attendance upon lectures, and the assistant will doubtless find that the money-payment for his services is somewhat reduced in consequence.

The Committee consider that there are many reasons tending to make this system of education a desirable one. The following are the more prominent, viz.:—the interests of the students, to whom a complete course of instruction would be offered, to the discouragement of spasmodic effort and cramming; the advantages of a healthy competition and the stimulus of class-teaching would be secured; the standard of the Board of Examiners would be upheld by the circumstance that the required education could be obtained by those who wished for it; finally, the above-named influences would raise the tone of the body corporate, and increase its *esprit de corps*.

It does not appear to be the function of the Society to initiate new Schools of Pharmacy, but it may materially strengthen the endeavours which are being made in this direction in various districts, and aid the further development of existing institutions. Theoretically, the Society ought to require as a condition of granting aid that there should be a complete curriculum of the subjects required for the Minor Examination, viz. Chemistry, Practical Chemistry, Materia Medica with Pharmacy, and Botany. The Committee recommend that this standard be deemed to be that recognized by the Council, but that at first its application be not enforced.

It frequently happens that courses of lectures delivered at other institutions are available for the students of provincial Chemists' Associations. Where no reason to the contrary exists, this economy of teaching-power is to be commended and encouraged.

The discussion upon Provincial Education at the recent meeting of the British Pharmaceutical Conference at Liverpool exhibited great unanimity of feeling upon the elementary education to be required from those entering the calling of pharmacy. The opinion was expressed by nearly all the speakers, that no youth should be accepted as an apprentice until he had passed the Preliminary Examination. The Committee cordially endorse this view, and they would exclude the subjects of this examination from those to be aided by the Society.

The question of *permanence* in the system of grants in aid of Provincial Education has received attention, and the Committee wish to record their views upon this important aspect of the question. They regard the present as a period of transition, since a large number of young men are now engaged in pharmacy who entered upon it prior to the passing of the Pharmacy Act of 1868, and who find that qualifications which they did not anticipate are demanded from them. These young men represent the class which will probably be the earliest to reap the full benefits of the Pharmacy Act, but it must be admitted that they do not find those educational institutions which should be complementary to the examinations they must undergo. For a period of five or six years this class will continue to exist, but in a diminishing ratio. The history of the School of Pharmacy in Bloomsbury Square affords a precedent, since private enterprise could not sustain the earlier years of an establishment so favourably situated as that was. The fact that education was a voluntary act justified the support given by the Society to the School of Pharmacy. The position of the class of young men now referred to justifies the extension of aid to educational courses in the provinces. When this transition period shall have passed, the *raison d'être* of the present scheme will have passed with it, and the experience of its working will certainly leave some valuable lessons. The Committee do not consider that it will permanently be the duty of the Society to contribute funds for educational purposes in the provinces, and they would urge upon all who undertake the management of local education to bear in mind that in a few years it should be self-supporting. Even now, thoroughness ought to be ensured in any course offered to students, and such fees should be fixed as are compatible with this.

The Committee recommend that for the present the following be laid down as conditions for making grants in aid of Provincial Schools of Pharmacy, viz.:—

1. That the application be made in writing by three or more resident members of the Pharmaceutical Society.
2. That it shall state the kind of aid required, and, where a money grant is applied for, shall indicate the sum intended to be applied to each specific purpose.
3. That where a grant is made for the purpose of providing materials for class-teaching, the applicants shall be prepared to guarantee their safe custody for a period of three years. The said materials to be the loaned property of the Pharmaceutical Society for three years, at the expiration of which they may be resumed by it, or otherwise disposed of. The Council may, in special cases, forego this guarantee where it deems it not desirable.
4. Such duplicate specimens as may from time to time be available from the Society's Museum shall be distributed amongst the Museums of Societies making application in accordance with Clause 1, and shall be regarded as absolute gifts unless the Council shall impose conditions.
5. Applications for aid to libraries must give particulars of the number of volumes already contained in such library, and specify the name of each book applied for and its price.
6. That where a grant is applied for towards guaranteeing a minimum sum to a teacher of chemistry, practical chemistry, materia medica, pharmacy, or botany, a statement shall be made of the number of lectures to be given, the lecture hours, and the fees to be paid by the students. If such grant be made, the names and attendance of the students at each lecture must be recorded, and reported to the Council at the end of the course.
7. The Council may grant sums to pay to provincial schools one-half of the salary of a student or other person as curator and lecture assistant.
8. The relative claim of any town to receive aid from the Society must be indicated by the earnestness and efficiency of local effort. A complete curriculum of chemistry, practical chemistry, materia medica, pharmacy and botany, is the standard to be aimed at.
9. All applications to the Council for aid may be referred to a standing Committee appointed annually for this purpose. The recommendations of the Committee to be laid before the Council for action thereon.
10. The Committee to present annually a tabulated return of the state of Provincial Education.

Resolved—That the Committee on Pharmaceutical Education be continued as a standing Committee.

Resolved—That a grant of not less than eight guineas be made to applicants from Norwich for the purchase of sets of Botanical Diagrams, subject to the conditions already adopted by the Council.

REPORTS OF EXAMINERS.

October, 1870.

England and Wales.

	Candidates Examined.	Passed.	Failed.
October 14, Modified	45	30	15
„ 19, Major	4	4	0
„ „ Minor	24	19	5
„ 20, „	18	13	5
„ 3, Preliminary	224	164	60
„ „ Certificates in lieu of Preliminary Examination	9	0	0
	324	230	85

Scotland.

	Examined.	Passed.	Failed.
October 11, Major	2	2	0
„ „ Minor	6	4	2
„ „ Modified	9	7	2
„ „ Preliminary	5	4	1
	22	17	5

Resolved—That diplomas stamped with the Seal of the Society be severally granted to the following Pharmaceutical Chemists:—

Barrett, Frederick John ...... Fakenham.
Butterworth, Albert .... Sowerby Bridge.
Joule, John Samuel .... Buxton.
Strickland, George Hodgson .. Yarm.

Resolved—That the following, having passed their respective Examinations, be elected

ASSOCIATES OF THE SOCIETY.

Minor.

Bradford, Cordley .... Spalding.
Eden, Thomas .... Dublin.
Elliott, Thomas .... Clay Cross.
Foster, Henry P. .... Portsmouth.
Francis, Geo. B. .... Diss.
Goodman, Daniel H. ...... Bath.
Grinstead, John .... Chichester.
Little, Arthur N. .... Bristol.
Loveless, Edward Wm. .... Bath.
Marshall, Austen .... Stratford-on-Avon.
Melhuish, Thomas B. ...... London.
Part, Edward James ...... Dover.
Robinson, Joseph .... Chester-le-Street.
Salmon, Thomas .... Pontypool.
Thomas, John D. D. ...... Clifton.
Walker, John S. .... Manchester.

Modified.

Cullen, Robert Henry ...... Paris.
Dunn, Henry .... Shipley.
Evans, John .... Worcester.
Farrer, Robert S. .... Brighton.
Fewster, William L. ...... Liverpool.
Forster, William Day ...... Godalming.

Gregory, John .... Stockton-on-Tees.
Harland, Richard T. ...... York.
Hughes, William, jun....... Presteigne.
Lloyd, John .... London.
Oakey, Joseph .... Liverpool.
Sproat, Robert .... Hull.
Wilson, Joseph G. .... Dublin.

Resolved—That the following, having passed the Modified Examination, be elected

ASSOCIATES IN BUSINESS.

Casely, Samuel .... London.
Hollway, Albert B. .... Cardiff.

Resolved—That the following, having paid their Arrears of Subscription, and the usual fines, be restored to Membership:—

Thonger, Gilbert .... Birmingham.
Potter, Charles .... Knaresborough.
Horsfield, John M. .... Rotherham.
Hallsworth, Thomas .... Ardwick.

Resolved—That Charles Potter (Associate, 1842) be and is hereby elected a Member of the Society.

Resolved—That the following Registered Chemists and Druggists be elected

MEMBERS OF THE SOCIETY.

Henry Overbury .... Alcester.
Sidney Redman .... Taunton.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The First General Meeting of the Twenty-second Session was held at the Royal Institution, Colquitt Street, on the 27th October last; the President in the chair.

The Secretary announced that the following gentlemen had been elected officers for the Session 1870–71:—*President:* Mr. John Abraham; *Vice-President:* Mr. Edward Davies, F.C.S.; *Honorary Treasurer:* Mr. John Shaw; *Honorary Secretary:* Mr. Alfred H. Mason, 56, Hanover Street; *Council:* Messrs. Barber, Delf, Jones, Murphy, Redford, Sharp, Summer, Symes.

Professor Attfield, Ph.D., F.C.S., Thomas Hyde Hills, Esq., London, W. W. Stoddart, Esq., F.C.S., F.G.S., Bristol, were unanimously elected honorary members of the Association.

Mr. J. M. Buck was elected a member, Mr. Burnet D. Cohen was elected an associate.

Several donations to the Library and Museum were announced.

Mr. Davies, F.C.S., exhibited a specimen of phosphorus, crystallized from fusion, in crystals of peculiar form, and explained its formation.

Miscellaneous communications having been discussed, the President, Mr. John Abraham, delivered the opening Address of the Session as follows:—

"It has been usual to commence the business of the Session by a few introductory remarks from the chair, and, in accordance with this custom, I proceed to make a few general observations. Two valuable addresses have lately been delivered, which many of us have heard or read. One by Mr. Stoddart, at the recent meeting in Liverpool of the Pharmaceutical Conference; the other, by Mr. Schacht, at the opening of the Session of the School of Pharmacy in Bloomsbury Square. The former was delivered in this place, and conveyed some compliments, which, I suppose, we might appropriate to ourselves, did our self-appreciation accord with the generous sentiments of the speaker. Our pursuits demand scientific knowledge, and they afford some opportunities for scientific research; but it cannot be said that many of us devote much time to experiment or to study. Some—perhaps most—are too busy, some are so little busy in those things which keep the pot boiling that they think they can spare no time for any pursuits which do not bring fuel to the fire. It is not for me to do more than remind such of the pleasures and advantages of science; and if any one says or thinks that it is not for me to teach or censure others, I am sure that he will meet with a cordial assent from myself, only that I respectfully plead the necessities and duties of my office. Teachers, and even parents, inculcate many a valuable lesson which they do not always exemplify. Allow me to quote a few words from Mr. Stoddart, which I believe to be well worthy of repetition. 'The pharmaceutist must make the most he can of the numerous animal, vegetable and mineral substances with which he has to do, and to carry on his operations with the view of producing the best results. I am convinced that the most prosperous and happy of our body are those that bear these things in mind and who look upon mental cultivation as a delight, and not as a necessary but disagreeable task.'

"Our Society is not so meritorious as some of our friends have been pleased to think; it is not so useless as perhaps some of ourselves occasionally fear. We keep a little flame of science burning. We afford opportunities for useful discussions, and I confidently affirm that during the whole period of the existence of the Association, we have afforded full opportunities at the smallest possible cost for the acquisition of a scientific knowledge of their profession by students of pharmacy. If the number who have availed themselves of these privileges has been small, it has been from no fault of the Association or of its teachers. An honourable ambition to be useful, not hope of fees, has been the stimulus to those who have given their time and talents to this work. If any of our friends think we ought to do more, and well they may think it,—I say *let them help*, and if they do not, whatever the reason may be, I venture to think they should not discourage those who may try to do a little. The other address to which I have referred is that of Mr. Schacht on the opening of the session at Bloomsbury Square. Those who had not the pleasure of hearing it will be rewarded by a reference to the Pharmaceutical Journal and *Chemist and Druggist*, and I would strongly recommend every young man to read it. Mr. Schacht has taken great interest in the cause of pharmaceutical education, and he thinks that the Pharmaceutical Society should do more than hitherto to promote education in the provinces. I wait to know how he and others propose to effect their object. I fear that more is expected from the Pharmaceutical Society than the few thousands a year at the disposal of the Council can possibly accomplish. It occurs to me that possibly the Society might be instrumental in procuring the occasional services of lecturers and experimental demonstrators in places where no competent instructor resides, but where a tolerable class would bear the whole or part of the expense. The theory has hitherto been that an apprentice was taught his business by his master, and if he were not perfect by the end of his apprenticeship that he could pick up all he wanted behind some other counter. Modern ideas of the duties of the pharmacist do not accord with these. A scientific knowledge of chemistry and of botany is insisted on and required by Act of Parliament. This can hardly be acquired behind the counter, even if every master were qualified to impart it. We know that this is not the case, and that apprentices who learn nothing except what is acquired in the ordinary routine of a shop are exceedingly deficient in these necessary things.

"Of the new drugs which have been recently introduced, chloral is the most important. So far as I can learn, we are entirely indebted to the Continent for our supply, and it is by no means of a uniform character. I cannot see why it cannot be made in Lancashire as well as anywhere else, unless it be that our excise duties on spirit interfere. Surely bonded laboratories would be conceded by the Government, and I have heard that the manufacture of tinctures in bond for exportation has been commenced. The price of opium and its preparations continues very high, but it is, perhaps, still more important to note that the quality of opium brought into the market is even more variable than formerly. Mr. Morson informs me that opium supposed to come from Persia, and very similar in odour and appearance, varies in its richness in morphia from 1 to 10 per cent. Some promising specimens from a new source—Australia—were shown at our recent exhibition. The adulteration of drugs has been curiously illustrated lately in respect to two imported articles, saffron and cochineal, in both of which the weight of the genuine article is largely increased by powders made to adhere to them. For the detection of the former we are indebted to Mr. Daniel Hanbury, who has shown that carbonate of lime is made to adhere to the saffron, with hardly any change of appearance, though chemical tests and also the microscope make it apparent. In the case of cochineal, a shining powder is made to adhere to the insects, as I can easily show you. The powder is not soluble in hydrochloric acid, and it may be micaceous or barytic.

"It will have been seen that the Council of the Pharmaceutical Society have again under their consideration the provisions for the regulation of the keeping and dispensing of poisons. This office is conferred upon the Society by Act of Parliament, and every consideration of prudence and duty compels the Society, in my opinion, to attempt its discharge. It may be that some mode of effecting the object may be devised less obnoxious than that hitherto proposed, but I think that the opposition which the formerly framed regulations met with was a mistake. I should, however, be quite willing that they should at first be tried as a voluntary system only.

"In conclusion, I beg to express my hope that we may have a prosperous session; that each one will contribute his quota to the common stock, and that amongst them will be some who have not hitherto read papers to us."

After the address the President illustrated his remarks about the adulteration of saffron and cochineal, etc., and a discussion followed.

A very cordial vote of thanks was moved by Mr. Davies, F.C.S., to the President for his hopeful and practical address, and seconded by Mr. Redford, who expressed a hope that the President would impress upon principals the necessity of allowing their apprentices and assistants time to avail themselves of the opportunities for study offered for them to enable them to meet the requirements of the times.

The President having briefly returned thanks, the meeting separated.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

The Inaugural Meeting of this Society was held in the new rooms, in Duke Street, on Friday evening, October 21st. The employers having been invited to attend, the majority of the leading members of the trade were present, including Messrs. F. Sutton (Local Secretary to the Pharmaceutical Society), A. J. Caley, O. Corder, J. Robinson, J. R. Fitch, Cubitt, W. Searby, Gardiner, Cassey, F. Smith, W. S. Bird and Wilson.

Letters were read from other gentlemen, expressing their inability to attend and their hearty co-operation with the movement.

The room was adorned with some handsome rare ferns in pots, and other botanical productions; also magnificent specimens of the crystals of the Pharmacopœia, and a beautiful collection of the many alkaloids of the chinchona barks.

The President (Mr. Alfred Hill) took the chair at 8.30, and said:—

Gentlemen,—My first duty this evening is to offer thanks, in the name of this Association, to those of our employers who have shown their willingness to help by their presence here to-night. Such a public expression of sympathy was the one thing wanting to strengthen our hands; all else has been most encouraging; those gentlemen before whom any notice of our projects has been laid up to the present, have expressed their entire concurrence with them. The limited time at our disposal has, however, prevented our consulting with many principals; I beg, therefore, to lay before you, in as few words as possible, the objects of this Association, together with the means of fulfilling the same. It will not be necessary for me to advocate the utility of this project,—no one can now open a business without first passing the Examinations of the Pharmaceutical Society,—our object is, by mutual help, to render easier the preparation for these examinations. In the first place we desire to found a library. For some time to come we shall be unable to purchase, so we have inaugurated a loan system, and, as far as we have gone, this seems to be very promising. For the first fruits I beg to refer you to these shelves; the majority of these books have been lent by the members of the Council. Those principals, to whom we have at present applied for co-operation in this work, have nobly responded, and I do not doubt that other gentlemen will do the same. These books will not be allowed to circulate. In time, I hope to see the walls of this room covered by objects of Pharmaceutical interest and folios of autograph prescriptions upon the table. In both of these aims, I solicit our employers' help, as we must principally depend upon them for the nucleus of our museum.

For the use of the Chemistry Classes, Mr. Robinson has most handsomely presented a varied collection of chemicals, etc., and I now beg to thank him in the name of the Association. I regret that I am unable just at this moment to lay before you precise arrangements respecting the classes,—the first of which, however, will be held on Monday evening next, at 8.15, subject, "Elementary Chemistry," by Mr. E. Nuthall, and we hope by that time to have a list of all for your information.

The classes proposed by the Council are, Chemistry, Qualitative Analysis, Botany, Materia Medica and Latin.

I cannot refrain from noticing the kindness with which Mr. A. J. Caley and Mr. O. Corder have offered to give lectures, respectively, on Materia Medica.

On Monday, this room will be at your disposal for reading, etc., and I would recommend all those who purpose going through a regular course of study to come up then and register themselves for their respective classes.

Besides the annual income, a large outlay is required at the start for furnishing. To this fund I hope the employers will subscribe liberally. We have been compelled to lay on gas, and are desirous of doing the same with water. The last, however, we fear we must omit for the present.

With the exception of addressing a few words to those who will shortly be students, I feel my task to be ended. To them I would say that however complete the administration of this Association, its ultimate success rests with you. Unless you work with a heart and show your appreciation of the many advantages by getting rapidly through the examinations, this Association will be a mere skeleton without life. But if, on the other hand, you attend the classes regularly, supplementing this by home work, I feel sure that this Association will prove a glorious success.

Upon the means of securing regular attendance at classes, I would earnestly invite discussion. There seems to be a strong feeling in favour of some method of making attendance at classes other than a matter of fancy, so that the tutor may be saved the annoyance of the constant repetition necessitated by occasional students.

I would recommend to your consideration the system of entrance fees for each class, reminding you that that which one has to pay for one values more than anything gratuitous and is less likely to throw away; of course, these fees would go to the funds of the Association, not to the tutors. I would suggest that a portion of the money be devoted to the purchase of a prize or prizes for competition by the students. I trust to hear a full expression of feeling on this subject from all present.

From what I have said, I hope you will not infer that I look upon the passing of the examinations of the Pharmaceutical Society as the only ultimate object of these efforts. I wish you to understand that I deprecate "cramming." The simple acquirement of facts can be of little use except for the present. But if these facts are employed to develope reasoning powers so as to enable you to trace in them the working of those laws which we call nature, they will elevate you into thinking men, and make you ornaments to the calling upon which you have entered.

Mr. F. SUTTON, F.C.S., who had, at the request of the Committee, called upon the employers to be present, wished, as Local Secretary of the Pharmaceutical Society, to be permitted at that stage of the meeting to say a few words of congratulation and encouragement to those young men. He had that day received a letter from an employer, regretting that he could not be present, and stating that a similar association was formed twenty-five years ago, but fell through, owing to the lukewarmness of the young men themselves. He could quite believe that was the case, but circumstances had strangely altered since then; and now it was not a matter of choice with a young man whether he passed an examination or not, it was a matter of necessity, and it behoved every one present to look that fact fully in the face. He would caution them not to expect too great things at first, not to attempt too much. A very great deal might be done with limited means; it was astonishing how many instructive demonstrations, in practical chemistry for instance, might be shown with the simplest apparatus. He was very glad to hear that a course of lectures on pharmacy and materia medica had been promised by Mr. A. J. Caley, and another on botany by Mr. Corder. For his own part, he regretted that he could not promise a course of lectures on chemistry, but he would give them a lecture or two, and felt sure there were some among themselves whose practical acquaintance with the science was sufficient to give all the demonstrations required. Norwich laboured under the great drawback that there was no school of medicine or science in it, nor any private teachers, and he feared it would be a long time before the city could establish such public aids as were to be found in many large manufacturing towns in the North and West. He was glad to see so many of the employers present, but was prepared to see all. This was a movement which was of quite as much importance to them as to the young men; he felt sure that the better educated and more intelligent an assistant or apprentice was, so much the more would he be of service to his employer.

Mr. A. J. CALEY assured the meeting of his support, and enforced the necessity of real work. He spoke of the pleasures to be derived from the possession of knowledge, and the immense advantages of early rising, tendering much kind advice to the young men.

Most of the other employers present took part in a discussion upon the hours most suitable for having the rooms open, Messrs. SEARBY, GARDINER and WILSON advocating the necessity of closing the rooms at an early hour, to allow the apprentices to reach their homes without interference with domestic arrangements.

Mr. SMITH remarked that an evident consequence of this Association would be the adoption of an early hour for closing their respective establishments, to allow their assistants the full advantage of the Association.

Questions from Messrs. BIRD and CUBITT elicited various particulars relating to expenditure, etc., from the Treasurer and Vice-President in the unavoidable absence of the Secretary.

All the employers present joined as honorary members, and the following donations were promised:—

	£.	s.	d.
Mr. Caley	1	1	0
„ Sutton	1	0	0
„ Smith and Sons	2	2	0
„ Cubitt	1	1	0
„ Row	1	1	0
„ R. Fitch	1	1	0
„ J. R. Fitch	1	1	0
„ J. Robinson	1	1	0
„ G. P. Watson	1	1	0
„ English	1	1	0
„ R. C. Pitts	2	2	0
„ J. Watson	1	1	0
„ William Rackham	1	1	0

Mr. O. Corder a set of botanical diagrams.

A vote of thanks to the Chairman terminated the proceedings.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The First General Meeting of the Session 1870–71 was held in the Rooms of the Society, Britannia Chambers, on Friday Evening, October 21st; the President, Mr. J. H. Atherton, F.C.S., in the chair. The following Donations to the Society were announced:—Three Guineas, from Mr. Bass; the 'Pharmaceutical Journal,' from the Pharmaceutical Society; several books, from Mr. W. H. Parker; the first volume of Gmelin's 'Chemistry,' from Mr. Rayner. The thanks of the Society were heartily accorded to the donors.

Mr. Burnie's Report of the Botany Class was read by the President, and the Prize for the greatest efficiency was awarded to Mr. Bothamley.

A number of interesting objects were upon the table, the uses of which were explained by the President; amongst others,—an interesting collection of Ashes of Plants, and other substances, illustrating the more general diffusion of some of the rarer elementary bodies (including the new metals Rubidium and Indium), which was exhibited at the Meeting of the British Pharmaceutical Conference at Liverpool, illustrative of the recent researches by Mr. Stoddart, the President, in the application of spectrum analysis to medicinal substances; Limousin's Oxygen Apparatus, for preparing and inhaling oxygen gas; a new Drop Bottle; and Maw's Nautilus Life Belt.

The PRESIDENT then delivered the Inaugural Address of the Session, in which he reviewed the past work of the Society, and spoke of its future, particular attention being given to the provincial education question; the present means of technical education in London and the provinces, and the best method of supplying the demand, caused by the educational improvement necessitated by the operations of the Pharmacy Act; and the urgent necessity that assistance should be rendered to societies showing a disposition to help themselves, which, by local peculiarities, were debarred from the assistance of any existing technical schools. Referring to the general aspect of the Poison Regulation question, the President expressed his opinion that, in face of the very few accidents attributable to the carelessness of dispensers, and the higher educational standard imposed, it was unwise to insist on any "compulsory" regulations whatever. But if the Pharmaceutical Council felt that, in their interests and the interests of the public, some extra precautions were necessary, he felt sure that the issue by the Council of suggestions, to be adopted by those not already using any suitable precautions, would be met and treated with respect and consideration. The President said he felt bound to allude to the present unsatisfactory condition of the 'Journal.' He believed, however, that it was of only a temporary nature, and that an improvement would soon be manifest. He then referred to the principle involved in the issue of such a periodical by a body like the Pharmaceutical Society, and hoped that in time the 'Journal' would be simply the record of the proceedings of the Society, and that the trade and miscellaneous matters demanded by the chemists throughout the country would be supplied by the issue of an independent weekly publication like the 'Lancet.'

After referring to other practical matters, the President concluded by urging the members and associates to unite together in endeavouring, by mutual concessions, to carry out the work of the Society, and the general advancement of pharmacy.

A cordial vote of thanks to Mr. Atherton for his interesting address was moved by Mr. Rayner, seconded by Mr. Fitzhugh, and carried unanimously.

The following programme of lectures and classes in connection with the School of Pharmacy of this Association has been arranged for the ensuing Session:—

Chemistry.—A course of thirty lectures, by Mr. George Elders, M.B., on "Inorganic Chemistry," to commence on Monday evening, November 7th, at the rooms of the Association, and be continued weekly. Time, 9 to 10 P.M. Fee for the course, 5*s*.

Pharmacy and Materia Medica.—A course of twenty-six lectures, by Mr. Mayfield, M.P.S., at the rooms of the Association, commencing on Wednesday evening, November 9th, at 9 o'clock.

These lectures have been arranged with special reference to the requirements of the Examinations of the Pharmaceutical Society. Fee for the course, 5*s*.

Botany.—Arrangements will be made for a course of lectures on "Structural and Physiological Botany," to commence in the Spring, full particulars of which will be announced in due course.

Preliminary Examinations.—Although not forming part of the ordinary technical education provided by the Society, the Council have arranged for a class, provided a sufficient number of associates make application to join. (No arrangement will be made for less than ten candidates.) Fee for a course of twelve lessons, 5*s*.

Until further notice, the Library and Reading Room will be open on Monday and Wednesday evenings, from 8.30 to 10.15 P.M.

Applications for information and tickets for the various courses of lectures should be made to the Honorary Secretary, Mr. J. T. Mayfield.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

MEETING AT LIVERPOOL.

Wednesday, September 14th.

(*Continued from page 376.*)

THE STORING OF POISONS.

BY EDWARD SMITH, F.C.S.

One of the most important and interesting questions at the present moment on the pharmaceutical *tapis* is "the storing of poisons."

From the tone of the medical and general press, it is very evident that the public consider the Pharmacy Act to have thrown the onus of suggesting and providing efficient means to prevent "as far as possible the lamentable calamities from accidental poisoning which so often shock the public mind," on the Pharmaceutical Society, *i. e.*, practically on ourselves; and therefore, whether we agree with, or differ from, the reasons which induce the public to require this at our hands, it is very clear that unless we set our house in order, and, to the best of our abilities, provide some plan of storing poisons more in accordance with the wishes, and with some regard for the tender susceptibilities, of physic-takers, we shall presently find ourselves in an exceedingly unfortunate position, by having the power to act taken from us and placed in the hands of those who will turn a very deaf ear to any appeal or entreaties on our part. We shall probably find ourselves smarting under the imposition of unpractical and very irritating regulations, and possibly compelled even to submit our pharmacies to the indignity of inquisitorial supervision by Government officials.

Without entering into the general question as to the desirability, necessity, or otherwise, of *any* poison regulations, it appears to me that at the somewhat peremptory demand of the public, either from within or without, must some action proceed; and surely there cannot be a shadow of a doubt in our minds as to who are the most competent to undertake the matter. Our business is one of such a varied character—a combination, as it were, of the elements of a profession, with trade as a basis—that we cannot contemplate the interference of an external authority without shuddering at the inevitable result.

If, then, we are best able to manage our business affairs and provide our own laws and rules, the soundest policy and the truest wisdom dictate that we should lose no time in facing and grappling with this poison question, which already ripples the sea of public opinion, and which may, if we are not wise enough to calm the rising storm, ultimately swamp all our hopes of self-government, and possibly convert the Pharmacy Act into an instrument of grievous oppression. For these reasons, I now venture to bring the subject before you, in the earnest hope that some satisfactory proposition may be evolved from the discussion which may follow, and that as the fruit of your deliberations, the Pharmaceutical Council will be enabled to frame regulations, equally satisfactory to ourselves and to the general public.

When we come to consider the matter attentively, we soon discover there are two essential conditions on which every regulation must be based, viz. simplicity and elasticity.

Any complex arrangements would speedily break down, and collapse by their own inherent weakness. The first strain put upon them would create a state of things very much more conducive to an accident than the entire absence of all regulations. Indeed it is highly improbable that they would or could be carried out by the majority of pharmacists, since it would entail an expenditure of time not often at the disposal of those engaged in business houses. Pharmacists are not, as a rule, in a position to retain the services of more assistants than they can fully employ; hence, during a press of business, either behind the dispensing counter or on a market-day, when perhaps scores of pounds of arsenic and other poisonous preparations are retailed over the counter, any but the very simplest regulation would, in point of fact, be ignored.

Whatever plan we decide upon must, of necessity, therefore be so simple that it will safely bear the many and varied exigencies of everyday practical work.

In addition to simplicity, there must also be elasticity; for not only have we to take charge of the few grains of atropia or aconitia, but also 7 lb. parcels of oxalic acid and the hundredweight cask of arsenic. The same regulation should, if possible, cover every case.

Now, on reflection, it is clear that in addition to the care habitual to those who have the handling of poisons, we can frame regulations based upon either one or both of the senses of sight and touch. The former we have embodied in the use of blue poison bottles; the latter in the various angular and peculiarly-shaped bottles that have from time to time been suggested.

Hitherto, these ideas have only been carried out with regard to bottles, and it is really difficult to see how peculiarly-shaped parcels or casks can practically be used. I conceive we are compelled to fall back upon the sense of sight, which perhaps is the most acute of all our faculties, and the best for our purpose, seeing that it is the one most intimately connected with the brain and intellect. For these and other reasons I would therefore suggest that all bottles, packages and casks containing poisons be of a dark blue colour. I fix upon blue simply because it has already to a certain extent been adopted by many pharmacists, and requires but very little extension to complete the system. From time immemorial Scheele's acid has been stored, with general satisfaction, in blue bottles, and possibly may have been the *fons et origo* of all blue poison-bottles.

There can be no difficulty in wrapping parcels of poisons in blue paper, nor in painting casks with blue paint. Shop bottles as well as stock bottles would of course follow the same rule, so that without any difficulty, and with a minimum of disturbance to existing arrangements, this simple plan might very readily be adopted. Of course every package must be distinctly labelled, and the word 'poison' attached.

I object to alternative regulations, because they create confusion, and, imperceptibly, lead to no distinct regulation whatever. Our assistants, who have mainly the handling of poisons, are not fixtures; they migrate from one place to another, and if at each pharmacy a different method of storing obtains,—the changes being rung, as it were, on alternative systems,—naturally enough the mind gradually loses its sensitiveness to the danger implied by these differing regulations, no distinct impression is retained capable of acting as a caution, and the inevitable result is confusion and insecurity, if not positive danger.

I see no great advantage in every pharmacist using the same shaped bottles; I would rather allow sufficient latitude in such minor considerations, so that a man may use his own discretion, and adapt his plan to suit the especial requirements of his pharmacy.

Neither do I agree with poison cupboards or other methods of isolation. They are, at best, but clumsy mechanical contrivances, and would, in all probability, fail to secure the smallest modicum of safety; but, on the contrary, rare and seldom-used, but inoffensive preparations would be stored there as a place of safety, and thus render supremely dangerous the very place where security is supposed to reign triumphant. There seems to me, practically, to be far greater safety in the distinctively-coloured poison bottles, dotted here and there on the shelves, than having them concentrated in some out-of-the-way and dismal corner of a cupboard or room; and not only because these individual dots appeal more distinctly to the mind through the eye, but also because we thus avoid the especial danger—a danger by no means to be disregarded—of using one poison for another. I conceive there is nearly as much danger in dispensing, say strychnine for morphia, as strychnine for James' powder; and, therefore, any plan of bringing powerful medicines together has in it an element of weakness which may easily eventuate in an accident.

It may be thought that simply to enclose all poisons in a blue or other plain-coloured receptacle is, in reality, no precaution at all; undoubtedly not, unless the adoption is general and complete. But the Pharmaceutical Society has the power to make it a general, and, therefore, efficient precaution. By the first clause of the Pharmacy Act, all pharmacists must conform to such regulations as to the keeping, etc., of poisons, as may be prescribed by the Pharmaceutical Society, with the consent of the Privy Council, and the twenty-sixth clause enacts that the name of any person who is convicted of any offence against the Act, may be erased from the register of pharmacists,—that is, deprived of the right of selling or keeping poisons; and this power, invested in the Society, is the fulcrum by which all of us may most effectually be compelled to carry out any simple regulation, such as the one proposed.

I have in this paper but very cursorily touched upon the more salient points of the question, my object being rather to provoke discussion than to dogmatize.

There is one consideration, however, which the Pharmaceutical Council must, in common justice to our profession, and out of regard to the public safety, not lose sight of. I refer to the expediency of *all* dispensers of medicine adopting the same system and conforming to the same regulation. Clearly enough it would be idle to enforce regulations upon us, if dispensing surgeons, who are said to dispense on an average more medicine, and, it has been said, poison more patients than pharmacists, should be still allowed unrestrictedly to keep and sell poisons. I do not mean that they should in any way become subject to the Pharmaceutical Council, but to their own governing body,—that is to the Council of the College of Physicians or Surgeons, who should have the power to reprimand or suspend, according to circumstances.

The probable effect of this would be that many surgeons would be induced to give up dispensing, much to their own ultimate advantage, whilst pharmacists being no longer deprived of their legitimate work, would gladly embrace the opportunity of giving up prescribing or encroaching in any way on the province of the medical man. I am sufficiently sanguine to believe that so very desirable a result will eventually be secured, having, as its ultimate effect, the creation of a feeling of perfect harmony and community of interests between the members of the medical and pharmaceutical profession.

Parliamentary and Law Proceedings.

Greenwich Police Court.

BEFORE MR. MAULE.

Mr. Hassett, grocer, appeared to answer to a summons charging him with an infringement of the Petroleum Act, by keeping petroleum oil in an iron drum or cistern and a can, without wire-gauze at the openings. The inspector said, that upon visiting Mr. Hassett's premises, he found in the yard an iron drum or cistern, containing benzoline oil. The opening or neck had had wire-gauze, but it had evidently been eaten away by the oil. Near the drum was a can containing four to six gallons of benzoline, which had no wire-gauze, as required by the Act.

For the defence, it was urged that the wire-gauze of the drum or cistern had been accidentally knocked off by a boy while emptying the benzoline from the cans, which were supplied by merchants without such wire-gauze.

Mr. Maule said that it was most important that the provisions of the Act of Parliament, in relation to the storing or keeping of petroleum oils, should be strictly adhered to, and imposed a fine of £2. 10*s*. and costs.—*Times*.

Charge of having substituted a Mercurial Powder for Dover's Powder.

This case was heard at the last Cavan Quarter Sessions, in Ireland. A sub-inspector of constabulary, at Ballyjamesduff, named Henry Weir, brought an action to recover £40 damages from a Dr. Barnes, for having carelessly administered improper medicines to the plaintiff. He stated that he had a cold and applied to Dr. Barnes for a Dover's powder. Two were sent, and he took one of them on a Saturday evening; that night he was very ill, "a dry heat through his skin, no perspiration, and his throat very sore." On Sunday Dr. Barnes called to see him and gave a gargle for his throat, and he took the remaining powder. These powders did not cause perspiration, but, on the contrary, salivated to an extraordinary degree. A Dr. Mawlimney was then called in and found his pulse very high, and, on examining his mouth, Dr. Barnes agreed with him that Mr. Weir was labouring under mercurial salivation. There was then some conflicting evidence as regards the presence of an ulcer in the plaintiff's throat, and the general condition of the said plaintiff. The Assistant-Barrister, before whom the case was tried, said that it was evident that by some mistake the plaintiff got the wrong medicine, and, under the circumstances, he would give a decree for whatever amount he had been out of pocket by the transaction, viz. £6, plaintiff's cost, and £10 Dr. Mawlimney.

One of the medical periodicals, in commenting upon the foregoing, says that there was no evidence to show that the patient's salivation was caused by mercury at all, and, that if it were so, there was no evidence to show that the powder supplied by Dr. Barnes contained any mercurial; also that the amount which it could convey was obviously insufficient to cause such a result in a healthy constitution. It then goes on to pass some strictures upon Dr. Barnes for allowing an unqualified person to dispense medicines,—it having appeared in evidence during the trial, that a young woman, a sister of Dr. Barnes, occasionally made up her brother's medicines.

Obituary.

DR. THOMAS ANDERSON, F.L.S., F.B.S.E.

Dr. Anderson was educated at Edinburgh. Wishing to follow up the study of natural history, he entered the service of the East India Company, and proceeded to India. He succeeded Dr. Thomson as Superintendent of the Calcutta Botanic Gardens, and has well sustained the reputation of an office rendered memorable by the great botanists who have held it. He was for some time Conservator of the Assam Forests, and, at his death, Superintendent of the Darjeeling cinchona plantations, where his labours had met with marked success.

About two years ago, owing to a dangerous illness, he had tol eave his family in Calcutta at a few hours' notice, arriving in England in a very low state. His health greatly improving, he set to work upon his long-deferred 'Flora of India,' which promised ere long to see the light; his favourite subject of cinchona cultivation also received a large share of his attention, especially the chemical portion of it. In the midst of his valuable work he had a relapse, and left Kew for Scotland, where it was hoped rest and quiet would restore him, but he never rallied, and died on the 26th of October last at Edinburgh. Besides his valuable reports, he published many papers on systematic botany. His enumeration of the *Acanthaceæ*, an Order previously a source of much trouble to systematic botanists, has been highly praised and admired for its lucidity and philosophical treatment. The cinchona question in him has lost an able worker, especially from a botanical point of view, for much good must have accrued from the study of them *in situ* by such an accomplished botanist.

Review.

CONCENTRIC CALCULATORS: A New and Rapid Method of Ascertaining Equivalents, without stating the Sum in Writing. By JOHN BELLOWS. Gloucester. 1870.

The very ingenious contrivance published by the author under the above title is one which, although difficult to describe in a manner that is intelligible to the reader, requires but a few minutes' study to enable any person with an arithmetical turn of mind to appreciate it as an instrument by which a great deal of time and trouble may be saved. At the same time it is so very simple in its arrangement that it might be correctly used by a child. It is adapted by the author to a series of tables, to suit all classes of persons who may require such information as is generally found in the most complete ready reckoners and interest tables. Series *A*, which is specially adapted for the use of chemists, medical students, etc., contains four tables for the conversion of (1) grammes into grains; (2) kilos and grammes into pounds and ounces avoirdupois; (3) divisions of the litre into fluid ounces, drachms and minims, and (4) hectolitres and litres into gallons and pints. No. 1 may be described briefly thus. It consists of four concentric circles revolving on a pivot, each circle containing the numbers 1 to 9 in large figures, arranged at equal distance around the inside of it. In the outside circle these figures represent decagrammes, or tens of grammes, and against each figure is placed its equivalent in grains, printed in smaller type. In the next circle inwards the large figures represent grammes, with their equivalents; in the next decigrammes, and in the inside circle centigrammes. By turning these circles on their pivot, until the large figures representing the number of grammes of which the equivalent in grains is required are in a line when read towards the centre, the sum of the smaller figures by their side will give the required answer. Thus, for example, were the equivalent in grains of 65·83 grammes required, by bringing the necessary large figures in a line as described above, the following sum will be presented:—

6	925·941
5	77·162
8	12·346
3	·463

1015·912 grains = 65·83 grammes.

The Calculators are very portable and extremely well got up. The arrangement of the type is very good, and the general appearance is all that could be desired.

Carbonic Acid.—In a paper read in Section D of the British Association, entitled "New Physiological Researches on the Direct Action of Carbonic Acid," Dr. B. W. Richardson showed that the result of subjecting a vegetable alkaline infusion to the action of carbonic acid under pressure was a thick fluid substance, resembling the fluid which exudes from some trees. When gently dried it became a semi-solid substance, which yielded elastic fibres, and somewhat resembled caoutchouc. When the serum of blood was treated with carbonic acid under pressure and gentle warmth, 96° F., the colloidal part was separated; but when the blood, with the fibrine removed from it, was treated, there was no direct separation, the blood corpuscles seeming, for a time, to engage the gas by condensation of it. But blood containing fibrine, and held fluid by tribasic phosphate of soda, was at once coagulated by the acid. The bronchial secretion is thickened by carbonic acid, and a tenacious fluid is obtained, resembling the secretion which occurs in asthma and bronchitis, while secretions on serous surfaces are thickened and rendered adhesive.

Notes and Queries.

*** *In accordance with a wish expressed by numerous correspondents, a column will in future be devoted to notes and queries, with the object of facilitating the exchange of information among members of the trade and students.*

In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[18.]—RUBINI'S CAMPHOR.—In regard to *J. Botham's* query, the following formula will be found successful:—

℞. Alcohol, 1 part by measure.
Camphor, 1 part by weight.

Let the alcohol be prepared in the following way:—

Take of S. V. R. ℥xx.
Pot. Sub. Carb. ℥j.

Digest for 24 hours, and pour off the supernatant liquor, rejecting the residue.—J. T. R., *Warrington*.

[21.]—GLYCERINE JELLY.—In answer to *R. W. W.* (Sheffield), *X. Q. Z.* sends the following recipe for the above:—

White soft soap . . .	4 oz.
Pure glycerine . . .	6 ,,
Almond oil	3 lbs. in summer. 4 ,, in winter.
Otto of thyme	2 drachms.

Mix the soap and glycerine in a mortar, add the perfume to the oil, and rub it in gradually, taking care not to add the oil faster than it can be incorporated, or the result will not have the jelly-like appearance required.

[23.]—COLOURING FOR POMADE.—A preparation called "Aureoleine," made by Mr. Baldock, South Norwood, for the last six years, will fully answer the purpose intended, as it will stand exposure in the window for at least twelve months without fading.

If *S. W. S.* (Hull) will send his card to Mr. Henry H. Pollard, 140, High Street, Ryde, I.W., that gentleman will communicate with him respecting colouring for Pomades.

[25.]—FUMIGATION.—Generate chlorine by adding dilute hydrochloric acid to chlorinated lime placed in open dishes; or, equally good, disinfect with sulphurous acid gas, by burning sulphur in the form of match or in an open pan. Doors, windows and other outlets ought to be kept closed during the process of disinfection, and all polished steel or gilt furniture removed.—L. A. S. A.

[26.]—CHLORAL HYDRATE is given, to allay pain and produce sleep, in doses from 10 to 120 grains; 30 is the ordinary dose.—F. Goodwin.

[*** 10 to 30 is the ordinary dose.—Ed. Ph. J.]

[27.]—BENZINE.—A petroleum licence must be obtained. Generally the magistrates or other local authority will grant a licence to store a quantity not exceeding two gallons, if the case is properly explained to them. Application should be made, in the first instance, to the clerk to such authority.—L. A. S. A.

[28.]—SYMPATHETIC INK.—A solution of proto-nitrate of mercury developes black either by heat or the application of an alkaline solution, as lime-water. Glazed paper should not be used for secret writing, or it will be more or less visible on the surface. Rolled demy is better than ordinary note-paper.—J. Whitfield, *Scarborough*.

J. H. B. will find that by writing with the following solution and applying heat, the writing will become perfectly black:—

℞. Cupri Chlor. . . . . ʒi
Aquæ Dest. . . . . ℥ij.
Ft. Sol.

—A. J. Lance.

[29.]—QUININE MIXTURE.—Most trade formulæ contain only a *trace* of quinine, and a more appreciable proportion of chiretta. Quinine, producing a bulky sediment with sarsaparilla, is not much used in the combination.—Simon Pure.

[32.]—DENTISTRY.—*S. S.* will find all the necessary information with reference to diploma, or rather certificate of qualification in dental surgery, under the heading "Royal College of Surgeons, England," in the London and Provincial Medical Directory, by Churchill, which he can generally borrow of any practitioner of standing. Tome's 'Dental Surgery,' by Churchill and Sons, is the best Manual.—L. A. S. A.

SYRUPUS FERRI QUINÆ ET STRYCHNIÆ PHOSPHATUM (Easton's).—Mr. Squire's formula for the above preparation, as recommended to "*Dispenser*" in last week's Journal, has two objections. First, the quinæ sulphas is ordered to be added along with the precipitated ferrous phosphate and strychnine to the diluted phosphoric acid, instead of being converted into phosphate, which can readily be done by sodium phosphate in the same way as the other. The second objection is, the absence of sodium acetate invariably used in this and similar preparations, to ensure the occurrence of acetic acid in the solution,—sulphuric acid being a solvent of ferrous phosphate, while acetic acid is not. Let any one make the ferrous phosphate with and without the sodium acetate, and the advantage in favour of the latter will be at once apparent. In other respects the formula is good.—W. Robertson, 177, *High Street, Elgin*.

[*** Our correspondent "*Dispenser*" specified the formula given by Mr. Squire, which was therefore supplied.—Ed. Ph. J.]

QUILLAI BARK.—In answer to *A. Z.*, quillai or soap bark is the produce of the *Quillaia saponaria*, a rosaceous tree growing in South America, and there used as a substitute for soap. It has been used as a hair wash in this country.

[33.]—DISPENSING.—Will some of your readers kindly give me their opinion as to the best method of dispensing the following prescription, and the appearance it should present when completed:—

℞. Tr. Quiniæ Co. . . . ℥iss
Ammon. Carbon. . . gr. 1
Syrup. Aurantii . . . ℥ss
Aquæ . . . . . . ℥i.
M. ft. Mist. H. K.

[34.]—*J. W.* will be glad of a formula for making aq. camphoræ concent., B.P., extemporaneously.

[35.]—ROSE TOOTH-POWDER.—What is the best method of making rose tooth-powder so as to give a good pink colour?—*E. H.*

[36.]—EAU DE COLOGNE.—*B. Shakerley* (Liskeard) wishes for a good recipe for making Eau de Cologne.

[37.]—EAU DE PORTUGAL.—A correspondent wishes to know the composition of Eau de Portugal.

[38.]—SOLUBILITY OF FERRI CITRAS.—No doubt others have experienced the same difficulty as myself trying to dissolve in water, and sometimes in an acid mixture, ferri citras; and although many years have elapsed since the difficulty was remedied by the addition of ammonia or carbonate of ammonia, and finally the ammonio-citrate of iron became well known and generally prescribed, yet there are medical men now who continue to order the insoluble compound. I suppose they are not aware of its insolubility; and some of my friends, when spoken to on the subject, have readily altered it to the ammonio-citrate. But sometimes a prescription is presented containing the salt, and we have no opportunity of consulting the writer, nor of knowing how it was previously dispensed. It would be better for the profession to adhere as much as possible to the Pharmacopœia, and then we should know what is meant. I have generally put the ammonio-citrate when the citrate has been ordered, but not always. What do you advise?—J. L., *Birmingham, Nov.* 7, 1870.

[*** In a case of this kind we could not undertake to advise, but we believe the general practice is to use the soluble preparation.—Ed. Ph. J.]

Unanswered Queries.

In the event of any query remaining unanswered four weeks, the number and subject will be inserted for two weeks in the list of unanswered queries.

Pharmaceutical Education.

Sir,—During the discussion (on "Pharmaceutical Education in the Provinces") at the meeting of the Pharmaceutical Conference held at Liverpool, Mr. Bremridge, in a short but pithy speech, expressed exactly the opinion that I have held for some time, viz. that no master should take a youth as an apprentice unless he has previously passed the Preliminary Examination of the Pharmaceutical Society. If all masters would insist upon this it would give themselves far greater satisfaction, as they would then be able to turn out upon the world qualified assistants (unless, of course, the apprentice was a regular thick-skull), and (to me, at any rate) it is far greater pleasure to teach the sciences of chemistry and botany than to teach Latin, etc. It would also be the best thing that could be done for the would-be apprentice, as I think he would learn his Latin, etc. much better in class at school than he would at home. Any one who takes a youth as an apprentice, honestly intending to do his duty to him and to his pharmaceutical brethren, will certainly act as Mr. Bremridge suggests.

There is one more point to which I should like to call the attention of the executive of the Pharmaceutical Society, and that is the desirability of publishing more to the public the necessity of educating youths, intended to follow the profession of pharmaceutical chemists, in the Latin language. I have had many applications from farmers and first-class tradesmen in this neighbourhood, desiring to apprentice their sons to the profession of pharmacy, and in all cases to the question "Does your son know anything of the Latin language?" the answer has been in the negative.

Tamworth, October 25th, 1870. T. B. Allkins.

Pharmacy and Medical Practitioners.

Sir,—In last week's issue of the Journal I read with interest a letter, appended to which was a prescription, called by the writer of the letter "grape shot." As regards, however, the ingredients, they all seem applicable to one complaint, namely, a severe cold and cough. Not but what I think that half the number of the things would have been quite as useful.

I send you copy of recipe I made up a short time ago for a medical man, which might almost, I think, be called a panacea, as it is calculated to cure a cough, indigestion, an attack of nervous weakness, or, indeed, almost any kind of weakness, containing, as it does, five or six tonics. Here it is:—

℞. Ac. Nitric. Dil. ♏x
Ferr. et Quin. Cit. gr. x
Tinct. Nucis Vom. ♏ij
Bismuth. Nit. gr. x
Pulv. Tragac. Co. gr. x
Vin. Ipecac. ♏x
Tr. Valer. Am. ♏xx
Tr. Aurant. ʒss
Syr. ʒj
Inf. Calumb.
Aq. Menth. Pip. part. æqual. ad ℥ss.
Ft. Ht. ter die sd.

How can we get legitimate profits out of a recipe like this?

Beta.

Sir,—Being a late student in the art of pharmacy at Bloomsbury Square, I am naturally anxious, for the honour of our College, to be able to dispense any prescription which may be presented me for that purpose. The following prescription has, however, fairly puzzled me. French, German, American and other pharmacopœias have been searched in vain. In despair I ask your readers for information. Is it a relic of bygone days, when doctors exhibited as a sign a particoloured pole, and bled and shaved their customers as well; and when chemists, instead of mixing "nasty medicine," confined their attention to the conversion of ignoble metals into gold, and other similar ambitious objects? Or is it only meant to perplex country chemists, and make their clients think them fools?

As I was only able to obtain a copy, I enclose beneath a draft of this, as nearly as I could understand the cabalistic writing:—

"Mr. Scarliffe.
℞. Pulvis Cinerii gr. ij
Extr. Laxativ. gr. ij
Extr. Drastici gr. iv.
M. ft. Pil. ij h. s. bis hebdomadæ sumendæ.
℞. Liq. Alkalinæ ʒiss
Extr. Nigr. gr. ss
Infus. Amaræ ℥viij
Tinct. Amaræ ʒvj.
M. Capiat sextam partem ter in die.
Maii 17 *die*, 1869. Watson Bradshaw."

I enclose the prescription envelope for your inspection,

F. J. B., *Major Associate.*

[*** The prescription envelope sent by our correspondent bears the name of Messrs. Wilkinson, late Bridge and Co., 270, Regent Street, London, with the endorsement "Copied A. 2176." The prescription would therefore seem to have been dispensed by that firm, and probably they could furnish F. J. B. with the information he requires.—Ed. Ph. J.]

Sir,—Having read the correspondence in the Journal with regard to the concentrated form of doctors' prescribing, and the wonderful profit that "Reformer" thinks the chemist gets therefrom, I wish to enlighten him on the state of affairs in the north of London. A customer came into the shop yesterday, and, handing me a prescription, asked what I would charge for dispensing it. The following is a copy:—

℞. Pulv. Calumbæ, Pulv. Zingib.,
Sodæ Bicarb., aa ʒij
Ferri Citrat. ℈iv
Quinæ Disulph. gr. xvj
Sacch. Alb. ℥ij. Misce, ft. pulv.
Cap. i parv. ter die ex aqua.

Knowing the cutting we have to compete with here, I said 1*s*. 3*d*. The reply was, "Why, Mr. H. makes it up for 6*d*." Perhaps some of your readers will not credit this, nevertheless it is a fact, and Mr. H. is a man who places M.P.S. at the end of his name. Can "Reformer" make the chemist's bill as heavy as the doctor's at this rate? If he can, he has been brought up at a very different school to what I have.

October 25th, 1870. Assistant.

Druggists' Charges.

Dear Sir,—The following prescription was brought to my shop to be dispensed:—

Acid. Nit. Mur. Dil. . . . . . ʒijss
Liq. Taraxaci . . . . ad ℥x
Ft. Mist. s. ℥j secund. vel tert. horis.
J. B. Mulock.

My assistant, in my absence, charged 4*s*. for it. A few days after, my customer sent a friend, stating that I must have made a mistake in the price. He had it made up frequently, and never paid more than 2*s*., and only 1*s*. 9*d*. at Yarmouth and Royston. I reduced the price to 3*s*. 6*d*.; at the same time I informed him I could not believe the prescription was faithfully compounded at the low price charged. I will make no comment upon the cutting prices charged, but leave it to the consideration of my professional brethren.

A Pharmaceutical Chemist (by Examination).

Cambridge, Nov. 1870.

Sir,—Just now, when the spirit of our profession is being roused by a few medical men whose practices afford them ample time for writing, it would be well for us to bear in mind the fact that our most serious enemies are "those of our own households," and to do our utmost to reform our own ranks.

For a person to apply to us for a certain article, stating that the oilman or grocer charges for it some few pence less than ourselves, is bad enough. In this case, however, we can remark that we are chemists, leaving it to be inferred that our goods are of superior quality; but when we are told of a chemist underselling us,—it may be a neighbour,—we feel helplessly injured in pocket and wounded in mind.

I have been asked for a shilling 1*s*. 1½*d*. patent medicines, and for a 1*s*. 6*d*. pot of Liebig's Company's extract of meat; in each instance I was told that they could be obtained of chemists at the above quotations.

Now, if we look the truth in the face, we cannot fail to notice that, in spite of improved education, there is a decided falling off in the drug business; our expenses increase and our receipts decrease. This arises from two causes, over the first of which—that persons do not take nearly so much medicine as formerly, while a great deal of that which is consumed is obtained at free institutions—we have no control; but for the second surely something may be done, with proper determination on the part of the Council.

To tell us to wait a little longer, that education will do away with these miserable cutting traders, is about the same as telling us that men of talent are invariably good men. The chemist who sells spirits of nitre at 2*d*. per oz., puts up a 6 oz. mixture for 8*d*. from a prescription, or supplies 1*s*. 1½*d*. patent medicines for a shilling, is not likely to have his principles changed by any educational influences. Whatever his professions may be, what he wants is money; and he cares nothing for the honour of the Society, or the success of its members, so long as he can obtain it.

It should be borne in mind that some of these cutting establishments are large ones, and that in them young men are taught a certain mode of doing business which they in many cases carry out in other localities on their own account; and that this they will continue to do unless they are constantly cautioned against a system of business which, whilst it is certain to injure others, can never prove a source of happiness to those who adopt it.

London, Nov. 1*st*, 1870. EAST CENTRAL.

Sir,—The following came under my notice to-day, which I think ought to be made known to the trade generally:—

Having dispensed this prescription,

℞. Tinct. Lyttæ ʒiij
„ Ferri Muriat. ℥iss.
M. Capt. gtt. xxx ter die ex aqua,

I was surprised, after stating my price, to hear that it was more by 25 per cent. than the customer had ever before paid, at the same time telling me that 9*d*. was the usual price! It bore the stamps of two suburban chemists of the Metropolis. As the bottle was brought, bearing also a label of a third London chemist, I considered my charge but a fair remuneration, and was annoyed to feel that the London members of the profession should be so far behind us provincials in their prices, when they ought to be the pioneers to a better order of things.

I hope to see more uniformity in dispensing prices, which are now so irregular. "PHARMACEUTICAL CHEMIST."

Bristol, November 3*rd*, 1870.

Sir,—Your correspondent "Breasting the Hill," in the Journal of the 14th inst., alludes to the practice of non-pharmaceutists selling ordinary medicines, etc. etc., at low prices, and particularly notices sulphate of copper at 3½*d*. per lb.

Now, I believe the chemists have more to fear from each other than from outsiders.

I send you a copy of a bill circulated by a *Pharmaceutical* Chemist in a small country town south of the Thames:—

"Season, 1870.	Usual charge.
"Down's Farmers' Friend, 7*d*. per packet.........	9*d*.
"Cooper's Wheat Dressing, 4½*d*. „	6*d*.
"Best Blue Vitriol, 3*d*. per lb.	
"The above warranted genuine."	

I have seen the articles, and can testify they are as warranted.

Oct. 10*th*, 1870. M. P. S.

PHARMACY IN IRELAND.

Sir,—It was with feelings of pleasure and gratification that I perused the leading articles in the Journal of October the 22nd, with reference to Pharmacy in Ireland.

Now that the time is approaching when that very important subject, which has for so many years been left unnoticed, is about to be reconsidered, I think it a favourable opportunity of tendering a few remarks through the columns of the PHARMACEUTICAL JOURNAL, which I feel sure will be perused and receive the appreciation of many of my brother chemists in that country. It is indeed time that something should be done for them, as for many years they have had to battle against great difficulties in practising their profession.

While an assistant in a large chemist and druggist's establishment in Ireland, I had prescriptions handed me daily to dispense; but as I was not employed by a member of the Apothecaries' Hall, it would have been a breach of the law, making me liable to a heavy fine, had I done so, no matter how simple the prescription might be. For instance:—

℞. Ol. Ricini . . . . . . ℥ss
Aquæ Cinnam. . . . ad ℥ij
Cras mane sumend.

In consequence of this law the poor chemists are compelled to hand their customers over to the apothecary, and of course thereby lose the sale of other articles. In London, in the same capacity, I had the privilege of receiving and compounding as many prescriptions as the house was favoured with. As Dublin is separated from London only by a four or six hours' journey, I must confess that it appears somewhat strange that such a difference in the law should exist.

I have had many friends who served their apprenticeships in Ireland as chemists and druggists, and who had the means of opening on their own account, but had to come to England to do so; for in Ireland, their own country, they were prevented from practising the most profitable part of their business, dispensing, not being registered members of the Hall.

I think it will be admitted that a law such as this is anomalous and unjust; and I trust the Council of the Society will do their utmost to extend the Pharmacy Act to Ireland, so that the law of Pharmacy there may be assimilated to that of England and Scotland, and all Pharmaceutical Chemists, or registered chemists, with all already established there who pass the Modified, or any of the examinations of the Pharmaceutical Society, may have the privilege of dispensing and compounding. Then our brothers in Ireland will be on a par with us in England, and the monopoly which has so long stood in their way will no longer exist. Let the Pharmaceutical Society be the one recognized body of the three countries, England, Ireland, and Scotland.

A REGISTERED CHEMIST AND DRUGGIST.

London, Nov. 4*th*, 1870.

HOSPITAL DISPENSING.

Sir,—A word about Hospital Dispensing, my experience of which is limited to a fortnight, when I was lent to a hospital in the absence of one of the dispensers. What I saw during that time certainly did not encourage much hope that many of the out-patients would derive great benefit from the treatment they received. On certain days, when a popular doctor was in attendance, about 300 persons would come to see him in the course of about five hours, *i. e.* one per minute! Surely no one could in so short a time thoroughly investigate a patient's necessities, write his prescription, and make the usual entry in the hospital books. Frequently also when so many patients came, the doctor would be unable to remain long enough to give them even one minute each, and a part of them would be left to the care of a medical student, who had passed no test of his qualifications whatever. Then when the prescription was written, though the medicines were always duly labelled, they were necessarily compounded in the roughest style, minute accuracy being out of the question; and sometimes a week's supply of an infusion would be sent out when it was already rather stale, and other things in similar style.

AN UNEXAMINED MEMBER.

LOSS OF SPIRIT IN MAKING TINCTURES.

Sir,—Since looking over Mr. Umney's communication relative to the loss of spirit in the preparation of tinctures, I have referred to my own tables, which for some time past I have kept, and I find from them that the average loss has been about 4 per cent. more, which doubtless results from the use of an ordinary screw-press, instead of the more effectual hydraulic press. This amounts to a considerable loss in a year, even in a moderate-sized business; and I am consequently led to believe, with your correspondent Mr. Slugg, of Manchester, that an effective and moderately cheap hydraulic press might be manufactured for the use of pharmacists, which would be of inestimable value in the preparation of juices, etc., as well as tinctures.

Mechanicians appear to me to be, in general, very backward in ministering to the requirements of modern pharmacy, for there are several kinds of apparatus which, if made moderately cheap, would, I am sure, command a sufficiently remunerative sale. Among such I may mention the hydraulic press, a good pharmaceutical stove, and a vacuum apparatus for evaporation, etc., besides a number of less important articles. Of course these are now manufactured for the wholesale trade and a very few retail pharmacists; but the fact of their being made singly so enhances the cost of production, that only very few avail themselves of these scientific pharmaceutical appurtenances. I would therefore suggest to the notice of the Council of the Society the advisability of offering a small prize to mechanicians for each of the above articles, making the conditions for which the competitors should strive efficiency with economy of price. J. Ross Faulkner.

Ladbroke Grove Road, Nov. 1st, 1870.

Infusions of the British Pharmacopœia.

Dear Sir,—Although I had the pleasure of hearing Mr. Barnes read his excellent paper upon infusions at the evening meeting of the Society, I did not then notice that he gave the various specific gravities of the officinal preparations as compared with those made by maceration for shorter periods.

Upon reading his paper, as it appeared in the Journal, I was astonished to find that the specific gravities published ranged from 1·210 to 1·220.

Surely this must be an error?

I should imagine that 1·005 to 1·010 would more accurately represent the specific gravity of the British Pharmacopœia infusions. Charles Umney.

Laboratory, 40, *Aldersgate Street.*

Sir,—In answer to your correspondent who has discovered that the specific gravity columns in my paper on 'Experiments on Some of the Infusions of the Pharmacopœia,' are incorrect, I find that unfortunately the weight of the bottle, 207 grains, was omitted to be deducted from the weight of the 1000-grain bottle; therefore, in order to get at the correct specific gravities, it will be necessary to deduct 207, the weight of the bottle, in each case. J. B. Barnes.

Trevor Terrace, Knightsbridge, Nov. 8, 1870.

Trade Morality.

Sir,—The press is ever ready to take up the cause of justice and equity. How is it that it has so long passed over one of the greatest evils trade has ever known—an evil that is working silently, yet surely, the downfall of the middle class in England? Perhaps it is because the evil has no name, for we naturally shrink from the harsh names of covetousness and dishonesty. Shall we call it an absence of good principle, whereby our tradesman, envying his neighbour's prosperity and livelihood, conceives the idea of underselling him in some legitimate article of his trade, in the hope thereby of catching a few more herrings at the sacrifice of his neighbour's sprats, which for that purpose he sells to the public at a non-remunerative price?

As the system is rapidly on the increase, would it not be well that the public journals should ventilate the subject? The public would then be on their guard, and surely could not, if they understood it, encourage a system which, instead of tending to the general good, must end in the ruin of the entire trading class.

Examples of this system are found in grocers selling biscuits, beer and wine; bakers selling tea; drapers selling pictures, teapots, clocks, eau de cologne and general perfumery, not at a price which in itself can be remunerative, in which case there would not be the same objection, but at a price requiring the addition of larger profits on their own legitimate trade to make it pay; the result is that everybody's trade in turn is cut up piecemeal, to the injury of all and the good of nobody. If this sort of thing continues, profit will cease to exist, and, as a matter of course, the tradesman with it, and England must revert to the old feudal times when there was no middle class at all, but lords and serfs only.

If that be all that the civilization, education and enlightenment of the nineteenth century can do for us, it becomes a question whether we ought not to pause in the excessive efforts now being made in the so-called educational department, and inquire what results have already been achieved? Possibly some one will reply, "Oh, it is because we have done so little to educate the masses that this demoralization prevails." Is there not evidence that those who do such things are educated up to it—for education in the abstract contains no moral principle,—that our trading classes are well educated, and prostitute that education, and often high abilities, to commercial fraud?

Who will deny the education of the Civil Service corps? yet that body, highly enlightened though it may be, encouraged and patronized by a larger number of the higher class, has instituted a corporation of a nature utterly subversive of all trade principles and practice as hitherto understood, which, if carried out, must pauperize the kingdom by the ruin of the middle trading class, well called the backbone of the State, paying as it does, not only the largest proportion of the taxes, but the salaries of the very men who now seek its overthrow.

Perhaps to some this subject may seem inappropriate for discussion in a scientific journal; but are the professions quite clear of the moral infection which seems to be permeating all modern institutions, whether governments, professions, or trades? It is more than doubtful if there is not enough in the daily working of our own profession to set us thinking whether there is nothing to amend. Recent communications to your Journal would seem to bear me out in this. If in these few lines I have opened a subject for consideration, I shall not have thus far intruded myself on your valuable space in vain. Walter Biggs.

Hampstead.

Caution to the Trade.

Sir,—In 1863 a man came, showed me an advertisement in a paper, said he was appointing agents for his rat poison, and if I took a quantity I should be advertised as local agent. I did so, and soon afterwards (by a caution in the Journal) I found others had been victimized also.

After closing on Monday I went out, and was surprised to find on my return that the rascal had called again, and represented to my assistant that I had ordered three dozen, to be paid for on delivery. Perhaps you will kindly caution the trade again in the Journal. Henry Long.

High Street, Notting Hill, Nov. 8, 1870.

"*Audi Alteram Partem*" thinks that the writer in the *Lancet*, who says that the rate of profit charged in chemists' prices is "much too high," has fallen into the error of comparing pharmacy with other trades, from which it differs in the limited demand for the articles supplied, and the superior education it requires. While few druggists take £25 a week, many grocers and drapers take ten times that amount, and consequently they can sell their goods at a much lower rate of profit. In no case does the proverb "cheap and nasty" prove truer than in the sale of drugs; and it is doubtful whether, as a rule, cutting druggists get a very much larger amount of custom than those who adhere to respectable prices. Our correspondent is of opinion that doctors who dispense their own medicines prescribe medicine very different from that of the non-dispensing physician, and that their shelves are often very imperfectly furnished, as would appear from a letter lately published in the *Lancet*, in which the writer says of another practitioner that he did not keep such articles as glycerine or carbolic acid in stock.

T. Appleton (Fulham).—The volume will consist of the numbers for a year, and the Index will be issued as soon as the volume is completed.

"*Inquirer.*"—No person would be entitled to call himself a Member of the Pharmaceutical Society on going into business until he had passed the Major Examination and been elected by the Council of the Society.

S. C. Furmston (Richmond).—The fourth edition of Pereira's 'Materia Medica' was published in 1854, by Messrs. Longmans. The work has been considerably altered and enlarged since 1840.

E. S. Presley (Bristol).—He would be liable.

G. H. Strickland.—Apply to the Secretary.

Pharmaceutical Titles.—We have received letters on this subject from "An Associate," L., A. E. J., "Agitator," J. C., "Theta," "Aspirant to the Major," but as the correspondence is closed, we cannot insert them, more especially since they do not throw any new light on the questions at issue. The latter-named correspondent approves of Mr. Allkins's idea of a petition, but thinks many would be unable to attend a meeting in town, and suggests that some one should take the initiative by preparing a petition and advertising for signatures to be sent to him. We should advise our correspondent to communicate with Mr. Allkins by letter.

The following journals have been received:—The 'British Medical Journal,' Nov. 5; the 'Medical Times and Gazette,' Nov. 5; the 'Lancet,' Nov. 5; 'Nature,' Nov. 3; the 'Chemical News,' Nov. 4; 'Journal of the Society of Arts,' Nov. 3; 'Gardeners' Chronicle,' Nov. 5; the 'Grocer,' Nov. 5; the 'English Mechanic,' Nov. 4; the 'Produce Markets Review,' Nov. 5.

STARCH FOR THE MICROSCOPE.

BY M. C. COOKE, M.A.

It may be presumed that the time is past when the microscope required an apologist. For the use of such an assistant in the detection of adulteration, or in the discrimination of minute bodies such as starch granules, no advocate is needed, because it has become a necessity. Even the practised microscopist, as well as the occasional experimentalist, are constantly being made aware by experience, either of small errors in observation or greater errors in the preservation of microscopic objects. Perhaps as interesting and useful a series as any that could be recommended to the majority of the readers of this Journal, would be a long and well-authenticated series of starches. Unfortunately, however, these are best observed when mounted in fluid; and when thus prepared, two serious charges of condemnation are liable of being pronounced against them. Both these failures having occurred in my own cabinet, I venture to warn others, in the hope of preserving them from similar disappointment. The first charge may be preferred against all fluid mountings, that if left alone, even when flat, for a few years, the gold size or other substance of which the ring, or shallow cell is composed, flows in and discolours the starch, or there is a tendency to leakage, minute it may be, but enough to become annoying. The second charge is a far more important one, and that to which I desire more particularly, and specially, to direct attention. All starches mounted in fluid of any kind that I have seen employed, exhibit in the course of time a great tendency to change, so much so that in many instances they become of little or no value as tests in the comparison of closely allied forms. Some have become utterly valueless in four or five years. The only safeguard that I am prepared to recommend is that which I am now adopting, of mounting with every specimen that is put up "in fluid" a duplicate mounted "dry." Both can be accommodated on the same slide, which for many reasons is preferable; still, with all drawbacks, starch mounted dry is not liable to change, and to become so utterly valueless, as when mounted in fluid. The more delicate the starch, the more fatal the change. By comparing freshly mounted specimens with old ones, this change is painfully manifest.

Besides mounting starches dry, which only require a ring of old gold-size the size of the cover, and no deeper cell, they may be put up in balsam, or in balsam and chloroform, or in gum dammar dissolved in benzine. Pale copal varnish is not at all a bad substitute for balsam in mounting, but not so good as the gum dammar dissolved in benzine. Select a nice clean piece of dammar, break it up and place in a wide-mouthed bottle, cover well with benzine, let it stand till dissolved, shaking occasionally, and if too thick, add more benzine, until when well mixed it drops freely. If too thin, by leaving the bottle open the benzine will soon evaporate sufficiently to obtain the desired density. In the course of time this medium is sure to become too thick for use, but the addition of benzine, stirring all together, and then allowing it to stand until perfectly clear, will soon remedy this defect. If this substance had but a fair trial, I think, as no heat is required in mounting, that it would almost wholly supersede balsam. In fact, I have never used a drop of balsam for anything since I became acquainted with "dammar in benzine."

This communication would hardly be complete without a reference to the methods which may be, or are, employed in mounting starches for the microscope. Besides the dry method, and mounting in resinous media, the following have been recommended:—

Camphor water is one of the common media that are employed for starches and other vegetable organisms. A lump of camphor is placed in a bottle of distilled water, so that as much of it as possible may be dissolved. One grain each of baysalt and alum are added for each ounce of water, or a drop or two of creasote is shaken up with each ounce of water, which is afterwards filtered.

Glycerine is also used, especially when diluted with two parts of the above camphor water. It is worthy of remark that when glycerine is employed as a medium, gum dammar in benzine is excellent for securing the covers, because the exudation of any small quantity of the glycerine around the edges of the cover is no obstacle to the adherent properties of the dissolved dammar. In fact, a drop of glycerine may be let fall upon the centre of a slide, starch may be dusted over it, a thin cover, round or square, laid on and pressed flat, and held by a clip; all the glycerine which is pressed out beyond the edges of the cover may then be wiped away, and gum dammar in benzine run round the edges of the cover. In twenty-four hours the dammar is dry enough to remove the clip, and in a few days the slide may either be covered with paper, or the dammar may be trimmed off a little, and a coat of black varnish painted over it. If not used for starches, this mode of mounting is good for many objects, and glycerine is much more manageable than by any other method, owing to the greater affinity between the glycerine and benzine.

Glycerine and gum, mixed in the following proportions may be used: one ounce each of gum arabic, glycerine and distilled water, with one and a half grains of arsenious acid. The latter is dissolved in the cold water, then the gum, and lastly the glycerine are added and mixed.

Castor oil is a very troublesome fluid to use, but it has been employed for starch, though with no corresponding advantage.

Alcoholic fluids are always objectionable, on account of their solvent power upon most of the substances used for securing the covers.

Of all the media employed for starches, where employed at all, none are equal in my estimation, not even balsam, to gum dammar dissolved in benzine. When the polariscope is to be used, this plan should be adopted, and certainly no one would suppose an examination of starch complete without the aid of polarized light.

In his recent lectures on "Microscopical Manipulation," Mr. W. T. Suffolk has expressed similar views on this subject. "A series of starches from various plants should be mounted and kept for comparison. Two slides of each should be prepared, one dry, the other in balsam for examination with the polariscope. When starch is mounted in balsam, care should be taken to employ as little heat as possible. Starch granules are not well preserved in fluids." The use of "dammar" instead of "balsam" obviates the employment of heat at all, and consequently is preferable. In conclusion, I would enforce the advice to mount all starches for the microscope "dry" and in "dammar," but by no means to place reliance upon slides containing starch mounted in glycerine, camphor water, or fluids of any kind which maintain a condition of fluidity.

THE PURGATIVE ACTION OF ALOES.

BY T. AND H. SMITH.

In the 19th number of the Pharmaceutical Journal, there is published the report of a paper read by Mr. William Tilden, B.Sc., before the British Pharmaceutical Conference at Liverpool, entitled "A few Notes on Aloes." In this paper Mr. Tilden gives some very valuable information concerning the chemical properties of the drug, and we have much pleasure in bearing testimony to the ability of his researches, but, at the same time, we feel called upon to notice one or two points in his paper, on which we conceive his deductions to be erroneous.

He states that the active constituent of aloes is still unknown; that Robiquet first showed that the purgative property was not due to aloin; and he asserts that this latter substance is in complete disuse.

On these points we entertain entirely diverse opinions, and as the discoverers, and as far as we know the only manufacturers of aloin, we claim to some little knowledge of its chemical and therapeutical properties.

Mr. Tilden enumerates and describes four substances said to be present in aloes of the best quality, viz. :—

(1.) Aloetin, aloesin, amorphous aloin, bitter principle of aloes.
(2.) Crystallized aloin.
(3.) Resin.
(4.) Aloesic acid.

Of these four Mr. Tilden disbelieves in the existence of one, viz. aloesic acid, and adduces a reason why (3) resin should be related to the soluble portion of aloes. Of aloetin he remarks that it is very important as to quantity, and there can be no doubt it is the product of the alteration of crystallized aloin. He regards it as a mixture of crystallized aloin, capable of recovering its crystalline condition in presence of water and brown oxidized matter. We have many and various reasons for at present coinciding to some extent with Mr. Tilden in these remarks, but we are entirely at a loss to imagine to what substance he would attribute the purgative action of aloes, since he denies that aloin has any such effect, and yet concludes that aloes absolutely consists of that substance and products of its decomposition.

It is well known that the medicinal powers of aloes are not equal in different samples; that of two samples of the same variety, one may possess twice the purgative action of the other, and that when the varieties are different, the difference in medicinal value is in many cases even more marked.

The idea of an active principle is generally tenaciously associated with something such as strychnia or aconitia, of infinite power in small doses; but there are very many active principles, it must be remembered, the powers of which are not very many times greater than those of the drugs from which they are obtained, and, in this present case, taking Mr. Tilden's results, he could not possibly expect that aloin would have more than five times the power of good aloes, inasmuch as he obtains more than 20 per cent. of the principle from the drug.

If it be admitted that aloin is the active purgative principle of aloes, one manifest advantage from using it would be that we have therein a medicine of unvarying strength, and we possess what we judge to be conclusive evidence that there is no other substance of value in aloes, and that in all cases where aloes of best quality will produce purgation, a proportionate dose of aloin will be of equal and more certain effect.

When Robiquet, in 1856, published his research on Aloetin,* he denied that that substance (which he seems to have supposed identical with aloin) had any purgative effect. At the time we contemplated publishing a denial of this, but the late Sir James Simpson happening to visit our works, we mentioned our intention to him, when he dissuaded us, observing that medical men were quite sufficiently convinced of the power of aloin, and that he frequently prescribed it and often took it himself, and with unvarying good effect. We could name very many other medical men, of undoubted eminence, who constantly prescribe it in preference to aloes, finding that it has in no case any ill effect, and that there is never any need to give an increased dose when its use is regular and long continued. Our own personal experiences bear out these statements, and our commercial transactions give most emphatic testimony that the demand is not decreasing. Since its first discovery, our manufacture has increased from a few pounds to many thousand ounces yearly, and, although we have not arrived at Mr. Tilden's gratifying result of 20 per cent., yet, by recent improvements in our manufacture, we shall be able to produce it at about two-thirds its present price, and we find the dose requisite to be aloin to aloes, as 1 is to 5. We should be happy to forward that gentleman a few doses for purpose of trial, should he wish it.

Edinburgh, November 12th, 1870.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Æther.—Sulphuric acid and rectified spirit mixed together develope considerable heat, and if the mixture is distilled, ether is one of the products which find their way into the receiver. The process thus simply conducted, however, speedily comes to an end, so far as the production of ether is concerned. The plan adopted in the Pharmacopœia is therefore that known as the continuous process.

Sulphuric acid is mixed with rectified spirit, and the mixture heated to ebullition in a distillatory apparatus furnished with a good condenser; this is continually supplied with a stream of spirit [run in by a tube leading from a reservoir] at such a rate as to supply the place of that which undergoes etherification, and therefore distils over. The explanation usually given of this reaction is somewhat as follows:—the spirit and sulphuric acid give, by their mutual decomposition, water and an acid, the ethylsulphuric, or sulphovinic.

* *Journal de Pharmacie*, tome xxix.

$$C_2H_5HO + H_2SO_4 = C_2H_5HSO_4 + H_2O.$$

[The presence of this compound can be shown by saturating the liquid with chalk, and evaporating down the filtered solution: a soluble crystallizable salt $(C_2H_5)_2Ca''(SO_4)_2$ results.]

Heated, this compound is decomposed by alcohol, giving, at a temperature of 280° to 300° F., ether and sulphuric acid.

$$C_2H_5HO + C_2H_5HSO_4 = (C_2H_5)_2O + H_2SO_4.$$

The ether and the water formed by the first reaction distil over together; the sulphuric acid thus regenerated remains behind to pass again through the same changes. A little alcohol distils over unchanged, and a small quantity of sulphurous acid accompanies it; these are removed from the distillate by agitating with slaked lime and a strong solution of chloride of calcium, the ether is then redistilled.

It is important in this process to observe the proportions in the boiling mixture, so that the temperature may neither be too low (when little but spirit would pass over), nor too high (when the ether would be contaminated with oil of wine).

Ether may be formed from alcohol by the action of many other bodies. Doubtless the explanation of its production by sulphuric acid just given is correct, but in other cases, as in the action of chloride of zinc, the alcohol seems simply to lose the elements of water,—the residues of two molecules becoming condensed into one.

$$\left.\begin{matrix} H \\ C_2H_5 \end{matrix}\right\} O \quad \left.\begin{matrix} C_2H_5 \\ H \end{matrix}\right\} O \; - H_2O = \left.\begin{matrix} C_2H_5 \\ C_2H_5 \end{matrix}\right\} O$$

Ether, though of low specific gravity as a liquid, forms a very heavy vapour. This would be inferred from its formula, $(C_2H_5)_2O\,(= 74)$ forming the same volume of vapour as $H_2\,(= 2)$. It is, therefore, 37 times heavier than hydrogen, and $37 \times \cdot 0693$ (the sp. gr. of H) $= 2\cdot 564$ times heavier than the air.

Pure ether agitated with water takes up of that liquid about $\frac{1}{35}$ of its volume; whilst it dissolves in about 9 or 10 times its volume of water. Ether is used as a solvent, chiefly of fatty matters, and in the Pharmacopœia for other purposes. As a solvent, benzol or purified bisulphide of carbon might in some cases be advantageously employed instead of ether. The valuable properties of these liquids have been somewhat overlooked in pharmacy.

Alcohol Amylicum.—This liquid is employed in the Pharmacopœia as the source of valerianic acid and valerianates. The acid is derived from it by boiling with oxidizing agents, of which a mixture of bichromate of potash and sulphuric acid is the most frequently employed. Ordinary amylic alcohol is an alcohol belonging to the same series as wood-naphtha (methylic alcohol) and common spirit of wine (ethylic alcohol), and it gives products of oxidation and other derivatives similar to those obtained from those bodies. Thus, the formation of formic, acetic and valerianic acids is shown in the following equations:—

$$\underset{\text{Methylic alcohol.}}{CH_3HO} + O_2 = \underset{\text{Formic acid.}}{CHHO_2} + H_2O.$$

$$\underset{\text{Ethylic alcohol.}}{C_2H_5HO} + O_2 = \underset{\text{Acetic acid.}}{C_2H_3HO_2} + H_2O.$$

$$\underset{\text{Amylic alcohol.}}{C_5H_{11}HO} + O_2 = \underset{\text{Valerianic acid.}}{C_5H_9HO_2} + H_2O.$$

In either of these the oxygen of the air may be employed (through the agency of platinum black) or nascent oxygen developed from some oxidizing mixture.

The Pharmacopœia is hardly correct in treating fousel oil as identical with amylic alcohol. Fousel oil differs considerably in character, according to the sources from which it has been procured, some samples containing no inconsiderable proportions of other alcohols, such as butylic, which would yield butyric acid, $C_4H_8O_2$. Probably much of the valerianate of soda prepared from fousel oil contains butyrate. The characters indicated in the B.P. as belonging to amylic alcohol should be more definitely stated.

(To be continued.)

A COMBINED SOLUTION OF PEPSINE AND PANCREATINE.*

The value of pepsine as a remedial agent in cases of indigestion is generally admitted, but experience has proved that it is only in certain forms of indigestion that it is of use.

Food is divided into two classes, nitrogenized and unnitrogenized. The former, being digested in the stomach, is acted on by pepsine; the latter, digested in the intestine, escapes its action almost altogether. The only action pepsine, as it appears in the gastric juice, seems to have on fat is to dissolve the albuminous cell-wall, so leaving the fat free to be acted upon by the pancreatic secretion. This suggests a probable cause of indigestion; for if the gastric fluid be deficient in quantity or quality, the albuminous cell-walls of the fat may not be dissolved, the fat is not acted on sufficiently by the pancreatic secretion, and not being emulsified, cannot be taken up by the lacteals. On the other hand, diseases of the pancreas or intestine, by checking the absorption of fat, may cause indigestion incurable by pepsine. This indigestion should be treated by pancreatine, the chief action of the pancreatic secretion being the emulsion of fats.

There being two classes of food to be digested, each in a different portion of the digestive tract, it is evident that the more perfectly one is digested the more easily will the other be. If the stomachic digestion be weak, the fat granules are not set free nor the fibrine dissolved as they should be; the consequence being that the pancreatic secretion cannot do its work properly. If the intestinal digestion be weak, the emulsifying of the fats as they pass from the stomach being imperfectly performed, the food is detained longer in the stomach than is right, the proportion of fat to fibrine is increased, the fat enveloping the nitrogenized food hinders the action of the gastric juice, and acidity and stomachic indigestion are produced. In treating stomachic indigestion, therefore, it is important to accelerate the digestion of fatty and saccharine portions of the food; and in intestinal to accelerate and perfect the digestion of the albuminoids. There are also cases in which the digestion of both the nitrogenized and unnitrogenized food is at fault.

Impressed with the foregoing ideas, Mr. Edward Long, of Dublin, sent to the author a sample of his solution of pepsine in glycerine, asking him to try it in practice, and give his opinion upon it. The author, however, thought that a solution of pepsine and pancreatine, combined in suitable proportions, would fulfil the conditions necessary for a perfect digestive; he therefore suggested to Mr. Long the preparation of such a solution. The result of the experiment is given in a letter from

---

* Abstract of a paper by Richard John Kinkead, B.A. and M.T.C.D., in the *Lancet*, no. xx. vol. ii. 1870.

Mr. Long to the author, from which we give the following extracts:—

"Following up the subject of our conversations some time since, I have been making experiments on pancreatine obtained directly from the fresh pancreas of the calf. The result has been quite what might have been expected from *à priori* reasoning, as you will see from the subjoined statements.

"Some difficulty was experienced in obtaining the solution of pancreatine in an eligible form for administration; but at last I succeeded in producing what as closely as possible represents the digestive fluids found in man. It is composed of pepsine and pancreatine in suitable proportions, using for the former a solution of pepsine introduced by me some time ago, and adding the solution of pancreatine as now prepared.

"In the experiments made to test its effects a very curious result was observed. Meat—beef and mutton—digested in pepsine alone was found to be entirely dissolved with the exception of the fat, which floated as a film on the surface, and this film was entirely emulsified when a proper quantity of pancreatine was added, and the usual conditions as to temperature, etc., attended to. This is exactly what we might expect, reasoning from known physiological principles.

"Pepsine in an effectual form has been a great boon; but, as I have shown above, it will not digest the oily or fatty aliments; failing thus to supply the system with the substances vitally necessary in strumous diseases. It is obvious how desirable the action of this fluid will be as an addendum to the use of cod-liver oil.

"The pancreatic emulsion has never seemed to me the nicest or most eligible mode of effecting what is desired. It is nauseous to the taste of many, and often keeps badly; the quantity of mutton suet employed, which may be supposed to be all the fatty matter the pancreatine present is capable of emulsifying, is not as much as might be desirable in many cases. In some, suet at all may not be the most suitable form of fat. The fluid I now describe is very palatable, and will keep almost any time. It may be given with any kind of food. My experiments were made with fat mutton-chops and rich beef-steaks, as typical aliments, with most satisfactory results.

"The first experiments, thrice repeated, were made with muriatic acid, water, and the combined solution, to represent the gastric juice and pancreatic secretion. The second, with solution of pepsine alone, with acid and water, followed by the addition of the plain pancreatic solution after an interval of two hours. Both were entirely satisfactory; but the latter were peculiarly interesting in a physiological point of view, as stated above, and tended to show the exact part played by each fluid in the animal economy. But as the administration of two fluids in succession would be troublesome in practice, and be scarcely attended to by patients (at all times averse to trouble), I have thought it desirable to mix the two in one fluid. This has the advantage of being quite agreeable, as liquor of pepsine always is; while the taste of the liquor of pancreatine is entirely concealed by the former. Some medical friends of mine reported most favourably of it, after trial in practice.

"The experiments in the laboratory were as follows:—

"No. 1.—Mutton (fat and lean about equal parts), one ounce; water, one ounce and a half; muriatic acid, fifteen minims; solution of pancreatine and pepsine, one drachm. Digested at 100° for four hours, this was converted into a homogeneous pulp, and, when diluted with a little water, presented quite a *chylous* appearance.

"No. 2.—Beef (fat and lean), an ounce and a half. Treated in the same way, with same result, the pulp being much deeper in colour.

"Nos. 3 and 4.—I then operated on the same quantities of each, first digesting with pepsine solution alone, as intimated above, and then adding the liquor pancreatine—keeping up the heat. In these latter experiments the result seemed more perfect, but, as I have said, the same procedure would be rather inconvenient in practice.

"The results were found to be identical in three successive experiments, at intervals of several weeks."

THE PRESENT STATUS OF POTASH PRODUCTION.*

From being the most abundant and cheapest of the alkalies, potash has rapidly passed to the position of the most expensive; and one of the chief problems in technical chemistry is comprised in the efforts to lessen its consumption by the substitution of other bases, or to cheapen and increase its production by the utilization of the abundant raw materials offered by the mineral kingdom. The first step has, in many instances, been successfully accomplished by the employment of soda, ammonia or lime, as basic factors to accomplish a given result previously and almost exclusively brought about by potash. Thus, the pure potash alum has almost disappeared from the markets, its place being assumed by a chemical equivalent in which at least one-half of the original potash is replaced by ammonia—an ammonia potash alum. So also the manufacture of the somewhat useful chlorate of potash was formerly effected by the passage of chlorine gas into potash solution,—a process resulting in the production of five equivalents of the much less valuable and less useful chloride of potassium for each equivalent of the desired salt. Now, a mixture of lime and potash is employed, and chlorate of potash and chloride of calcium are produced. These two salts are much more readily separated by crystallization than were the two products of the old method; at the same time a great saving of potash is effected, 46 parts of caustic alkali producing nearly 323 parts of chlorate, where formerly upwards of 336 were required for the same operation.

In spite of these and similar substitutions, potash becomes scarcer. We cannot get rid of its use entirely. There are many important technical operations in which it is, as yet, a *sine quâ non*, and some in which it must always remain such. In the production of a pure crystal glass soda cannot replace potash, since it imparts a greenish hue to the product. Nitrate of soda cannot be substituted for saltpetre in the manufacture of gunpowder, though it has already taken off the burden from the nitrate of potash in very many of the operations of the manufacturing chemist. In the formation of the simple and compound cyanides, potash will probably always be a requisite.

Hence, new sources of supply must be sought after and be made available. The slow process by which the vegetable kingdom extracts and assimilates the valuable potash from mineral matter must be replaced by the quicker changes of art operating on the same substances. The original forests of America—one of the great centres from which potash has been sent into commerce—are so rapidly disappearing or finding such manifold uses and demands for their woods and timbers that the old source of supply and means of production—that from the incineration of terrestrial vegetation—are fast losing their prominence by the supersedure of new raw materials and new methods of manipulation. We procure potash now by the incineration of marine and littoral plants, as well as those of the land. We derive it from inorganic nature by the decomposition of feldspar and other potash-bearing minerals, and by the treatment of certain material from the rock-salt mines of Prussia. Even the animal kingdom has been placed under contribution towards the same end. Let us examine into these several sources, and arrive at the present status of potash production the world over, omitting, however, the old source

---

* Abstract of a paper in the *Scientific American*, by Professor Charles P. Williams.

of the ashes of land vegetation, as being sufficiently familiar to require nothing further than mere mention.

In the salt-deposits which underlie the variegated sandstone of Stassfurt, Prussia, a mass of carnallite (a double chloride of potassium and magnesium) has been discovered, equal to 6,000,000 tons of chloride of potassium. Large quantities of this deposit, amounting to 150,000 tons in 1866, are worked into chloride of potassium. From 20,000 to 30,000 tons of 82 per cent. chloride are now annually produced in this locality, and find ready sale at about $40 per ton.

Feldspar, containing about 13 per cent. of potash, has been proposed as a source of one alkali. Lawrence suggests its extraction, in the form of caustic or carbonate, by mixing the finely-pulverized orthoclase with sawdust and straw, and arranging the mixture in heaps, which are to be damped from time to time with urine or some other nitrogenous liquid. After undergoing for six months this process of decomposition through fermentation, the materials are mixed with a thick cream of lime, made into bricks, and calcined at a high temperature. By leaching this residue, the potash dissolves, and silicate of lime, etc., remain behind.

Hack proposes to heat the mineral with lime, and to treat the calcined mass with water under a pressure of eight atmospheres, for the production of a strong lye, through which carbonic acid is passed for the precipitation of silica and alumina, and for the formation of carbonate of potassa. Meyer's plan is essentially the same as Hack's. Ward uses fluor-spar with lime for the decomposition of feldspar for obtaining the potash. None of these methods have as yet been utilized on a practical scale, but doubtless, in time, some of them, as well as those of Wurtz and Tilghman, for extracting the alkali as chloride or sulphate from greensand marl or feldspar, will become technically important.

From about 22 tons of wet seaweed there are, on the average, produced somewhat more than 500 pounds of chloride of potassium, in addition to bromine, iodine and various soda salts. This source of potash has, however, since the discovery of the Stassfurt deposits, become of minor importance; but the weeds still continue to be collected, mainly for the extraction of the bromine and the iodine, more especially for that of the latter.

About twenty-five years ago it was suggested by Dubrunfaut that the molasses from the manufacture of beet-root sugar could be utilized in the production of potash compounds, by first converting uncrystallizable sugar into alcohol, which is distilled off, and subsequently evaporating the liquor to dryness and incinerating the residue. According to Payen, the ash of this molasses contains 49·88 per cent. of potash soluble in water, and 1·7 per cent. insoluble. This plan was first carried into practice at the distillery of Serret and Co., but has since been adopted on a large scale at several places in both France and Germany. The establishment at Waghauselin, Baden, annually produces upwards of 300 tons of commercial potashes, containing from 88 to 94 per cent. pure carbonate of potash.

In 1862, Dr. Hoffmann, in his report on the London Exhibition, called attention to a new source of potash utilized in certain parts of France, more especially at the great seats of the woollen manufacture, as Rheims, Fourmies, and Elbœuf. Here the liquors in which more than 27,000,000 kilog. of sheep's wool are washed are bought for the "suint" they contain. This "suint" is a compound of potash with a peculiar nitrogenous animal acid, about which but little is known, which was first pointed out by Chevreul as forming no less than a third of the weight of raw merino wool, and a somewhat less proportion of ordinary, coarser wools. It forms on the average about 15 per cent. of the weight of raw fleece, and is exceedingly soluble in cold water. The washings of the amount of fleece above given would give, according to J. Lawrence Smith, about 1,167,750 kilog. of pure potash, worth, at the average rate of American potashes, from $400,000 to $450,000. The process of extraction is a simple one, and consists simply in boiling the washing-liquor down to dryness, and calcining the residue, which somewhat resembles baked molasses in appearance, in retorts with the production of gas, tar, and ammoniacal liquid, together with a coke-like substance which is leached. From the solution thus obtained, sulphate, chloride and carbonate of potassa, *free from corresponding soda compounds*, are separated by continued evaporation.

PHARMACY BILL FOR IRELAND,

PROPOSED BY

The Governor and Company of the Apothecaries' Hall, Dublin.

DRAFT BILL.

To regulate the Practice of Pharmacy in Ireland, to institute a Pharmaceutical Society, and to alter and amend the Act passed by the Parliament of Ireland, in the thirty-first year of the reign of his Majesty George the Third, intituled "An Act for the more effectually preserving the health of his Majesty's subjects, for erecting an Apothecaries' Hall in the City of Dublin, and regulating the profession of an Apothecary throughout the kingdom of Ireland."

Whereas it is expedient, to enable the governor and company of the Apothecaries' Hall of Dublin to grant licences to persons (other than duly qualified Apothecaries), to assume the name of Pharmaceutical Chemists, and to keep open shop for the retailing, dispensing, or compounding of prescriptions of duly qualified medical practitioners, and also to grant certificates enabling persons to be engaged or employed as students, apprentices, or assistants, respectively.

And whereas, it is expedient and necessary that such persons should possess a competent practical knowledge of their business, and to that end, that from and after the day herein named, all persons should, before commencing such business, be duly examined as to their qualifications and practical knowledge, and that a register should be kept, as herein provided, and that there should be instituted a Pharmaceutical Society for Ireland, and also that the Act passed in the Parliament of Ireland, in the thirty-first year of his Majesty George the Third, intituled "An Act for the more Effectually Preserving the Health of his Majesty's Subjects, for erecting an Apothecaries' Hall in the City of Dublin, and Regulating the Profession of an Apothecary throughout the Kingdom of Ireland," should be amended:—

Be it enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same as follows:—

1. From and after one thousand eight hundred and seventy-one, it shall be unlawful for any person, other than a duly qualified apothecary, to sell or to keep open shop for retailing, dispensing, or compounding medical prescriptions in Ireland, unless such person shall be a pharmaceutical chemist within the meaning of this Act, and be registered under this Act.

2. Pharmaceutical chemists within the meaning of this Act shall consist of all persons who shall be duly examined and licensed in pharmacy, and registered as pharmaceutical chemists under the provisions of this Act.

3. The examiners for the purposes of this Act shall consist of the governor or deputy-governor, with six members of the Court of the Apothecaries' Hall, who examine on the subjects specified in clause 4 of this Act, together with six other examiners selected by members of the Pharmaceutical Society of Ireland, provided that until said conjoint Board be formed, the examinations may be carried on for the time being by the aforesaid members of the Court of the Apothecaries' Hall.

4. All such persons as shall have been so appointed to conduct examinations under this Act shall be, and the

same are hereby declared to be, fit and proper persons to conduct all such examinations as are provided for or contemplated by this Act, and shall respectively have full power and authority, and are hereby authorized and required to examine all persons who shall present themselves for examination under the provisions of this Act in their knowledge of the Latin and English languages, in arithmetic, in botany, in materia medica, in pharmaceutical and general chemistry, in practical pharmacy, in the British Pharmacopœia, and such other subjects, as may from time to time be determined, by any bye-law of the General Council of the Pharmaceutical Society of Ireland. Provided always, that such examinations shall not include the theory and practice of medicine, surgery, or midwifery, or any branch of medicine or surgery; and the said examiners are hereby empowered to grant or refuse to such persons, as in their discretion may seem fit, certificates of competent knowledge and qualification and skill to exercise the business or calling of pharmaceutical chemists, or, as the case may require, to be engaged or employed as students, apprentices, or assistants, respectively; provided, nevertheless, that in case of rejection, a rejected candidate may present himself for re-examination after six months.

5. The Council of the Pharmaceutical Society of Ireland shall, within three calendar months after its formation, appoint a fit and proper person to act as Registrar under this Act, and said Council shall have power to remove the said registrar, or any future registrar to be appointed under this Act, from said office, and from time to time to appoint a new registrar in the room of any registrar who may die or retire, or be removed from office, as aforesaid, and also to appoint and remove from time to time a treasurer, and such clerk and other officers as may be requisite for carrying out the purposes of this Act, and also to pay suitable salaries to the said registrar, treasurer, clerks, and officers, provided that pending the formation of such Society, the Governor and Council of the Apothecaries' Hall shall appoint fit and proper persons as registrar, treasurer, clerks, and officers.

6. For every examination and registration, and for every certificate of same, such reasonable fees or charges shall be paid as shall from time to time be fixed and determined by any bye-law to be made by the General Council of the Apothecaries' Hall of Dublin, or by the Council of the Pharmaceutical Society, as the case may be, provided always, such fees or charges shall at no time exceed the fees laid down respectively in each case in Schedule (A) to this Act annexed, and such fee shall be paid to the treasurer, and shall by him be applied as the said Council of the Apothecaries' Hall or of the Pharmaceutical Society shall direct in furtherance of the provisions of this Act.

7. The registrar to be appointed under or by virtue of this Act shall from time to time make out and maintain a complete register of all persons certified as pharmaceutical chemists by the examiners appointed under this Act, also of all persons certified in like manner as apprentices, students, or assistants, respectively, and shall keep a proper index of the register, and all such other registers and books as may be necessary for giving effect to the bye-laws which shall from time to time be made in conformity with the provisions of this Act.

8. It shall be the duty of the registrar to make and keep a correct register, in accordance with the provisions of this Act, of all persons who shall be entitled to be registered under this Act, and to erase the names of all registered persons who shall have died, and from time to time to make the necessary alterations in the addresses of the persons registered under this Act. To enable the registrar duly to fulfil the duties imposed upon him, it shall be lawful for the registrar to write a letter to any registered person, addressed to him according to his address on the registrar, to inquire whether he has ceased to carry on business, or has changed his residence, such letter to be forwarded by post as a registered letter, according to the Post-Office regulations for the time being; and if no answer shall be returned to such letter within six months from the sending of the letter, a second of similar purport shall be sent in like manner; and if no answer be given thereto within three months from date thereof, it shall be lawful to erase the name of such person from the register, provided always, that the same may be restored by direction of the Council of the Apothecaries' Hall of Dublin, or of the Council of the Pharmaceutical Society, as the case may happen to be, should they think fit to make an order to that effect.

9. No name shall be entered in the register except of persons authorized by this Act to be registered, nor unless the registrar be satisfied by the proper evidence that the person claiming is entitled to be registered; and any appeal from the decision of the registrar may be decided by the Council of the Apothecaries' Hall of Dublin, or of the Pharmaceutical Society, as the case may be; and any entry which shall be proved to the satisfaction of such Council to have been fraudulently or incorrectly made, may be erased from, or amended in, the register, by order in writing of such Council.

10. The registrar shall, in the month of January, in every year, cause to be printed, published, and sold a correct register of the names of all pharmaceutical chemists, and a correct register of all persons registered as students, apprentices, and assistants, and in such registers respectively the names shall be in alphabetical order, according to the surnames, with the respective residences, in the form set forth in schedule (B) to this Act, and such printed registers shall be called "The Registers of Pharmaceutical Chemists, and of Pharmaceutical Students, Apprentices, and Assistants for Ireland," and a printed copy of such registers for the time being, purporting to be so printed and published as aforesaid, or any certificate under the hand of the said registrar, and countersigned by the Governor or two members of the Council of the Apothecaries' Hall of Dublin, or by the President or two members of the Pharmaceutical Society, shall be evidence in all courts, and before all justices of the peace, and others, that the persons therein specified are registered according to the provisions of this Act, and the absence of the name of any person from such printed register shall be evidence, until the contrary shall be made to appear, that such person is not registered according to the provisions of this Act.

11. Any registrar who shall wilfully make, or cause to be made, any falsification in any matter relating to the said registers, and any person who shall wilfully procure, or attempt to procure, himself to be registered under this Act, by making or producing, or causing to be made or produced, any false or fraudulent representation or declaration, either verbally or in writing, and any person aiding or assisting him therein, shall be deemed guilty of a misdemeanour, punishable by fine or imprisonment, and shall, on conviction thereof, be sentenced to be imprisoned for any term not exceeding twelve months.

12. Every registrar of deaths in Ireland, on receiving notice of the death of any pharmaceutical chemist, or pharmaceutical student, apprentice, or assistant, shall forthwith transmit by post to the registrar under this Act a certificate, under his own hand, of such death, with the particulars of the time and place of death; and on receipt of such certificate, the said registrar under this Act shall erase the name of such deceased pharmaceutical chemist, or student, apprentice, or assistant, as the case may be, from the register, and shall transmit to the said registrar of deaths the cost of such certificate and transmission, and may charge the cost thereof as an expense of his office.

13. From and after the one thousand eight hundred and seventy-one, any person who, not being a duly registered pharmaceutical chemist, or duly qualified apothecary, shall keep an open shop or

wareroom for the retailing, dispensing, or compounding medical prescriptions, or who shall take, use, or exhibit the name or title of apothecary, pharmaceutical chemist, or pharmaceutist, or pharmacist, or dispensing chemist, in Ireland, or make use of any sign or title, implying that he is a qualified apothecary, or that he is registered as a pharmaceutical chemist under this Act, or any pharmaceutical chemist or apothecary who shall take or employ any person as student, apprentice, or assistant, without such person having obtained the proper certificates hereinbefore directed, or who shall compound any medicines of the British Pharmacopœia except according to the formularies of the said Pharmacopœia, each and every person so offending shall for every such offence be liable, on summary conviction before one or more justices of the peace, to pay a penalty of five pounds, and, when recovered, such penalties shall be applied to the purposes of this Act; but nothing in this Act contained shall prevent any person from being liable to any other penalty, damage, or punishment, to which he would have been subject if this Act had not passed.

14. Upon the decease of any pharmaceutical chemist or apothecary actually in business at the time of his death, it shall be lawful for any executor, administrator, or trustee of the estate of such pharmaceutical chemist or apothecary, to continue such business for a period not exceeding six months, and provided such business shall be *bonâ fide* conducted by a duly-qualified apothecary, or by a pharmaceutical chemist registered under this Act; provided always, that registration under this Act shall not entitle any person so registered to practise medicine or surgery, or any branch of medicine or surgery.

15. It shall, nevertheless, be lawful, anything to the contrary notwithstanding, for the examiners appointed under this Act to admit to examination any chemist and druggist who shall have been in business, as such, on his own account, for a period of not less than five years before the passing of this Act, and who shall, within six months after it has passed into law, make application in writing for examination to the registrar under this Act, accompanied with a certificate according to schedule (C) to this Act; and every such chemist and druggist who shall have satisfied the examiners as to his knowledge, skill and competency to carry on and conduct the business of a pharmaceutical chemist, shall receive the certificate of pharmacy from the said examiners, and shall be entitled to be placed on the register of pharmaceutical chemists of Ireland; and the person so certified shall pay the same fees as other pharmaceutical chemists under this Act; provided always, that in case of rejection, the rejected candidate may be re-examined after six months.

16. It is hereby further enacted, that a Pharmaceutical Society shall be instituted, to be named "The Pharmaceutical Society of Ireland;" and authority is hereby given for the formation of such Society; and in order to the formation of same it shall be lawful for every person who has been duly licensed and registered as a pharmaceutical chemist by this Act, and also for every duly-qualified apothecary, upon payment of an annual subscription of one guinea each to the Treasurer appointed under this Act, to become a member of said Society, and to have a voice and vote in all general meetings of the Society; and the Governor and Council of the Apothecaries' Hall of Dublin are hereby authorized and required, within one year after the passing of this Act, to convene a meeting of all members of the Society, to be held at their Hall in Dublin, by written or printed summonses, to be issued ten days previous to the day agreed upon for holding such meeting; and it shall be lawful for the members in assembly at such meetings to appoint a President, Vice-President, Council, and Secretary, for conducting the business of the Society, and like meetings of the Society shall be holden annually.

17. At all general meetings of the Society, it shall be lawful for the Society to make all such bye-laws and rules for the advancement of pharmacy and for the good government of the Society as the members present shall in their wisdom, and by a majority of votes determine; provided always, that said bye-laws and rules shall be consonant with, and not contrary to, any of the provisions of this Act; and it shall also be lawful for the Society at every such annual meeting, for the members present to elect from among themselves, by a majority of votes, six persons to be conjoint examiners with the examiners on the Pharmacy Court of the Apothecaries' Hall, to record their votes as to the merits of the several candidates who have undergone examination.

18. The parts hereinafter mentioned of the aforesaid Act of the "Thirty-first of George the Third, chapter thirty-four," shall be, and the same are hereby repealed; that is to say, so much of the tenth clause as relates to seven years' apprenticeship, the whole of the twenty-third clause, so much of the twenty-fourth clause as relates to fees for certificates, and the whole of the twenty-fifth and twenty-sixth clauses.

19. This Act may be cited as the Pharmacy Act, Ireland, 1870.

20. This Act shall apply to Ireland only.

SCHEDULE A.

Scale of Fees for Certificates.

Apprentices and Students	2 Guineas.
Assistants	3 Guineas.
Pharmaceutical Chemists	5 Guineas.
The Fee for Registration	5 Shillings.

SCHEDULE B.

Name.	Residence.	Date of Registration.
A. B.	Grafton Street, Dublin.	Jan. 10th, 1871.
C. D.	Patrick Street, Cork.	March 4th, 1871.
E. F.	Corn Market, Belfast.	June 15th, 1871.

SCHEDULE C.

Certificate to be signed by a *duly qualified medical practitioner* or *magistrate* respecting a person who was in business as a chemist and druggist in Ireland for five years on his own account.

To the Registrar appointed under the Pharmacy Act, Ireland, 1871.

I, residing at in the county of hereby certify that I am a duly qualified medical practitioner (or magistrate), and that to my knowledge residing at in the county of has been in business as a chemist and druggist on his own account for a period of not less than five years.

(Signed)

This day of 1871.

Punitaqui Quicksilver Mine.—According to *Nature*, an attempt is again being made to work the quicksilver mine of Punitaqui, in Ovalle department, Chile. It was worked for the crown in Spanish times, but the War of Independence and Indian incursions stopped it, as the latter did again in 1830.

Obstinate Hiccough.—Dr. Juaritz states, in the *Siglo Médico*, that a medical man, just convalescent from gastric fever, being seized with a very persistent and fatiguing hiccough, obtained relief, after many antispasmodics had been tried without effect, from an infusion of mustard, which he drank in mistake, thinking it an infusion of linseed.—*Lancet.*

CONDY'S FLUIDS.

The article on this subject in No. 12 of the Pharmaceutical Journal has called forth a reply from Mr. Condy which, besides being irrelevant to the point discussed, is much too long for insertion. As the article in question was taken by us from the pages of the *Practitioner*, and as Mr. Condy's objections to it have been answered in that journal so well as to leave nothing more to be said, we can merely remark in reprinting this reply, that we fully concur in the views expressed therein.—Ed. Ph. J.

"We have received a lengthy remonstrance from Mr. H. Bollman Condy on the subject of our report on the various disinfecting and purifying fluids sold in his name, and we must say that Mr. Condy's letter shows a strange want of appreciation of the motives with which we called attention to the composition and the prices of his goods. Our statement was substantially this :—The manganates and permanganates were long ago known to the chemist as powerful oxidizers, but Mr. Condy was the first person to see that this property might be turned to the purposes of disinfection, and to commence the manufacture of these agents on the large scale. We remonstrated with him, however, for maintaining so high a price for these fluids in proportion to the intrinsic cost of the active ingredients. We showed that *pure permanganate of potash*, representing the highest oxidizing, and therefore disinfecting power, possessed by any ingredient of Mr. Condy's fluids, can be purchased retail for *two shillings an ounce*, and that with this quantity it would be possible to convert 400 ounces of distilled water into a disinfecting fluid of equal power with the No. III. "Ozonized water;" 400 ounces of which, at Mr. Condy's price, would cost *about eight guineas*. That with the same two shillings' worth of permanganate of potash one could convert 50 ounces of distilled water into a disinfectant of equal strength with the "green" or the "red" solutions, while the same quantity of the latter, at Mr. Condy's prices, would cost respectively 1*s*. 9*d*. and 3*s*. 6*d*.; but that the red and green fluids, being made mainly with the cheap manganates and permanganates of soda, the cost of which is very greatly less than that of chemically pure permanganate of potash, there is in fact an extremely large margin of profit to the manufacturer. In restating the gist of our original remarks, we have now to add, that we might have greatly strengthened them; for we have discovered that, in Germany, the purest possible permanganate of potash can be procured for *threepence* an ounce, or *eight times cheaper than the specimen which formed the basis of our comparisons*.

"Now to these criticisms Mr. Condy makes three kinds of objections, which it is necessary to separate carefully from each other. In the first place, he maintains that a trader has a right to make what profits he can; to quote his own words, "It (our table of analysis) shows indeed that the selling price of Condy's fluid is somewhat (!) higher in two of the kinds than that of the equivalent quantity of its active ingredient. But surely this is nothing unusual; on the contrary, it is the rule in such cases, as every chemist and druggist must know. Is the Liquor Potassæ Permanganatis of the Pharmacopœia dispensed per ounce at the price of the eight grains of the permanganate contained therein? Far from this being so, sixpence per ounce is very commonly charged for it. Is it not the case that all other proprietary disinfecting preparations sell at rates greatly in excess of the value of the quantity of the active ingredients contained in them?" Really, this needs no comment. We had paid Mr. Condy the compliment of presuming that his views were not altogether those of a mere trader; the claims to scientific discovery which he put forward had led us to believe in his patriotic intention to bring a valuable sanitary discovery within the reach of the poor, and of public health authorities who might require to use it on a large scale. We beg his pardon if we have been mistaken.

"The second objection which Mr. Condy makes to our remarks is to the effect that even the oxidizing power of the manganates was not applied in laboratories before Hofmann (1856), and that Hofmann learned it from Condy. That is quite erroneous; our analyst informs us that this use of these salts was common *long before* 1856, to his personal knowledge.

"The third objection to our remarks is a charge of inaccuracy in our analysis of the "Ozonized water." In answer to this we have to remark that the examination was made by one of the first analysts of this country, and we are therefore disinclined to attach any very great importance to Mr. Condy's hints about some previously quite unknown permanganate. The only object in using a permanganate for toilet purposes, one would think, must be for its oxidizing power. It is a fact that for three farthings one could impregnate eight ounces of distilled water with $\frac{1}{4}$ per cent. of pure permanganate of potash (purchased in Germany); and it is also a fact that such a solution would be practically tasteless.

"After all, however, it is comparatively unimportant what the character or price of a toilet-water may be. But we must repeat the expression of our regret that Mr. Condy does not yet see his way to reducing the above-mentioned scale of profits on his green and red fluids, which, in order to make them useful as disinfectants in precisely the places where there is the most urgent need for this class of agents, ought certainly to be sold at a considerably cheaper rate. We would even venture to predict that, in the long-run, commercial success would also be found to attend upon the lower rather than the higher rates of profit; and we should be delighted to hear that Mr. Condy had benefited himself while doing a service to the public."

DRUG MARKET NOTES.

RESIN OF SCAMMONY.

We have had an opportunity of examining a recent importation of *resin of scammony*, said to have been manufactured in Smyrna from scammony root.

It had a resinous fracture, translucent edges, fragrant odour, and was nearly wholly soluble in ether; and, as far as could be ascertained, was entirely free from other resinous substances likely to be used as adulterants; its pale brown colour would almost lead one to suppose that animal charcoal had been used for its decolorization.

Analysis of 100 *Parts.*

Resin (soluble in ether dried at 212°)	91·4
Insoluble in ether	2·8
Water	5·8
	100·0

It was certainly quite equal to any we have seen produced by the British Pharmacopœia process, and far superior to some of the so-called *resin* of scammony of pharmacy, which is little better than the hardened alcoholic extract of the root (resin with glucose).

Former parcels of this resin, sent from Smyrna, are said to have found a ready sale in France; the excessive price, however, asked for this London import prevented a sale being effected.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 19, 1870.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes to be endorsed "Pharm. Journ."*

PHARMACY AND MEDICAL PRACTICE.

The controversy which has for some time been carried on in the correspondence columns of this Journal and of the *Lancet*, as to the existing relations of pharmacy to medical practice, has assumed a different and more important aspect since the scattered grievances of the profession have been gathered up and adopted by the editorial pen of our influential contemporary. As in actual warfare, the skirmish of outposts threatens to involve the opposing parties in a general engagement; but we will not willingly permit ourselves to be drifted into an impolitic and unnatural quarrel with our proper allies, the medical profession; therefore we do not hesitate to hang out the olive branch and confess that we have observed with regret, the acrimonious tendency of the correspondence *on both sides.* At the same time, we owe a duty to our members which we shall not shrink from fulfilling; and this duty constrains us to take serious exception to the tone of the leader in the *Lancet* of October 22nd, founded, as it appears to us, upon an entire misconception of the case it professes to deal with. We think the tone of that article must be deprecated by all who desire the maintenance of good relations between the profession of medicine and its handmaiden, the art of Pharmacy, amongst whom we fondly believe that the quantity and quality of both bodies are included.

While we are solicitous to show all proper respect to the exalted profession of medicine, and to extend that consideration to the *Lancet*, as being, in some sense, its recognized organ, our first duty is to uphold the independence of Pharmacy, and we protest, in terms admitting of no misinterpretation, that Pharmacy, while willing to concede respect and deference to the higher branch of the healing art, owes neither obligation, subjection, nor allegiance to its members. It acknowledges no authority by virtue of which they may assume to interfere with its internal affairs; it repudiates any suggestion of subservience inconsistent with its own absolute independence in that respect.

Having said this, our readers will understand that we do not propose to follow the *Lancet* into a futile discussion of the alleged overcharges of chemists. So far as the *Lancet* and the medical profession are concerned, Pharmaceutists are free to make their own arrangements with the public, without reference to such extrinsic considerations as the ability of their customers to pay a further sum to some other person for medical advice. It argues little wisdom to suppose that competition will not surely bring prices to a fair average, but it implies absolute folly to suppose that where competition fails, any other influence—be it the remonstrance of the *Lancet* or the pleadings of angels—will have a chance of success. Were it necessary to do so, we are prepared to prove, not by vague assertions, but by statistical facts, that the average dispensing charges of Pharmaceutists are fair and moderate; but for the purpose in hand it is sufficient to refer to our own pages during the last two or three years, to show that, in the opinion of those upon whose action any alteration must depend, the dispensing department of Pharmacy is less remunerative than ordinary retail trade.

Having, then, disposed of the accusation of overcharges, as not admissible in a discussion upon what the *Lancet* properly terms "the relation of pharmacy to medical practice," it is surprising how little remains that is tangible, and how obscure that little is. After a most earnest study of the article under consideration, we are obliged to confess that we do not know what is the exact nature of the *Lancet's* complaint, nor what is the precise character of the restrictions which it calls upon Pharmaceutists to observe. We suspect, indeed, that the *Lancet* could not venture to put forward any proposition in express terms which would not either outrage public opinion or dissatisfy its malcontent correspondents, whose statements, we take leave to observe, do not, according to our belief, represent the feelings of an enlightened profession. We fear that whatever would satisfy those correspondents would be so impracticable, that it would be no more effectual against public opinion than a cobweb against the charge of an infuriated bull. The *Lancet* tells us that the essential things are "two;" we venture to interpolate that the two essentials of any restrictions of pharmaceutical functions are that they should be rational and practicable. This being granted, we see no difficulty in candid advocates arriving at a fair understanding; and the time appears to have come when it is desirable that this vexed question, the source of many petty jealousies in time past, should be set at rest by frank and full discussion. The following passages will put the views of the *Lancet* fully before our readers; but we profess ourselves unable to interpret their combined signification until we are informed whether the stringent restrictions of the first two quotations are intended to be moderated in the spirit of the latter. We cannot derive this information from their position or context; this may, however, be more our fault than due to want of perspicuity in the writer.

We are told—

It is essential that drugs be taken only upon medical advice.

Druggists must be prepared to limit themselves to the work of preparing drugs prescribed by others.

Pharmacists and druggists must know that they are entirely unfitted for advising persons affected with serious ailment or disease.

A great deal of prescribing by chemists confessedly goes on. It is in constant evidence in our (*Lancet*) columns that chemists prescribe even in serious cases and sometimes visit.

If a literal interpretation be attached to the first two passages, we must say frankly that they will prove intolerable to the trade and to the public, and it would be useless for Pharmaceutists to pretend to accept them. But if we may understand them to be limited by what follows, to an improper assumption of responsibility in circumstances where the chemist must admit his want of qualification, we can only express our unconditional concurrence. But, then, we wonder why the article was ever written! It asserts a truism of which every reasonable person must be aware, one which Pharmacy unreservedly acknowledges; any infringement of it being a breach of pharmaceutical discipline, to be visited upon the offender, not upon the innocent commonwealth. We are not prepared to deny the statement that "a great deal of prescribing by chemists" goes on; but we believe that the prescribing here spoken of is, for the most part, justifiable and unavoidable. We are intuitively conscious that there are, in this country, millions of persons—graphically described by the *Lancet* as "people who believe in paying for all that they receive, and refuse to pauperize themseves"—who have no accessible means of obtaining relief for their minor ailments, other than recourse to the chemist.

We venture to assert that the organization of the medical profession is totally unequal to cope with this gigantic public necessity, and this conviction helps us to understand a dark saying of the *Lancet*, that the remedy for the grievance of prescribing chemists "*rests first with the medical profession in perfecting its own efficiency*." When it has done that,—when it has brought a better medical service within reach of these classes,—it will be time to call upon chemists to vacate the functions which they now discharge conscientiously, kindly, and to the best of their ability. This is the prescribing to which we confess, on the part of Pharmaceutists chiefly in the poorer districts, from which the complaints of interference usually proceed. We hope, for the honour of the medical profession, not to be reminded of the fable of the dog in the manger, by medical men restraining others from doing that which is beyond their physical ability to do themselves. Any present interference with existing custom would indeed be to place "artificial and injurious restrictions" in the way of the supply of drugs; nor are we sanguine enough to hope that it will ever be possible to supersede the present imperfect accommodation by a better one. Nothing is more common than for a person who has not a shilling to spend, to apply to a chemist for sixpence worth of cough drops, or some other simple remedy. Can human ingenuity devise a way by which any portion of this modest coin can be diverted to the payment of a medical fee without grievously taxing the patient, and placing an artificial restriction upon the use of drugs? It is open to the *Lancet* to say that the man would probably be better without the drops, but you cannot make him think so, and you have no right to control his freedom of choice.

We cannot close this article without expressing a hope that the discussion is now finally removed from the sphere of personalities, and that, if it be continued, it may be in an earnest and temperate spirit, becoming two departments of a profession devoted to the relief of human suffering. We have carefully abstained from introducing topics of an irritating nature, which will at once present themselves to our readers as trenchant weapons of debate, for we are not actuated by desire to heap confusion upon an enemy, but are sincerely anxious to appease a friend, and deem it better to restrain the exuberance of our own members than provoke asperities from those with whom it is our policy and our desire to cultivate relations of mutual respect. Therefore we exhort Pharmaceutists, as they value that independence for which we shall ever strenuously contend, to avoid its abuse, and to show by their conduct that they know how to exercise their privileges in a spirit of good feeling and good faith.

PHARMACY IN IRELAND.

A few weeks ago we notified the probability of an attempt being made to assimilate the law as to the practice of pharmacy in Ireland with the Pharmacy Act of Great Britain. The need for such a measure is, we are sure, sufficiently well appreciated by all who have any cognizance of the case, to ensure their attentive consideration of the steps taken with the object of giving an independent existence to the art of pharmacy in the Sister Isle, and of creating there a body of competent pharmacists. We mentioned at the same time that the Apothecaries' Hall at Dublin would probably bring forward a Bill with this object, and we are now enabled to place before our readers the draft of this Bill.* It proposes to amend the Act for regulating the profession of an apothecary, and that a Pharmaceutical Society of Ireland should be instituted, since it is deemed expedient to enable

* See page 405.

the Governor and Company of the Apothecaries' Hall of Dublin to grant licences to persons—other than duly qualified apothecaries—to assume the name of pharmaceutical chemists, and to keep open shop for the "retailing, dispensing, or compounding of prescriptions of duly qualified medical practitioners, and also to grant certificates enabling persons to be engaged or employed as students, apprentices, or assistants, respectively."

A copy of this draft appears to have been sent round to the chemists and druggists in Ireland by the Governor and Company of the Apothecaries' Hall, with a request that they should give it careful consideration and communicate to that body their opinions, together with any suggestion they might wish to offer.

The chemists and druggists of Ireland seem, however, to have regarded the action of the Apothecaries' Company as being too paternal, and not calculated to promote the interests of Pharmacy, for at a meeting called shortly afterwards by the Association of Chemists and Druggists of Ireland to discuss this Draft Pharmacy Bill, which was largely attended, a decided objection was expressed to the Apothecaries' Company taking the position of a governing body in regard to Pharmacy. At the meeting held in Dublin on the 11th inst., a resolution was passed "that the Association of Chemists and Druggists of Ireland, whilst admitting the necessity of a Pharmaceutical Society for Ireland, decline to place themselves under the control of the Apothecaries' Hall of Ireland."

In this state of the matter it would probably be somewhat premature to offer any remarks, since the Draft Bill will most likely attract the attention of our Council. We would, however, suggest that the Chemists and Druggists of Ireland, who are most of all concerned in the proposed measure, should individually express their views regarding it in this Journal; and doubtless there are many members of the trade here who will also feel disposed to do the same in the general interest of Pharmacy.

The recent accession of Mr. Dakin to the position of Lord Mayor affords an opportunity for reminding our readers of his connection with the drug trade as the head of a firm of wholesale druggists in St. Catherine Cree Lane, Leadenhall Street. Mr. Dakin was born in 1808, and was educated at the Grammar School, Knutsford, and afterwards at the University College, London. He was one of the original promoters of mechanics' institutes in the Metropolis, and with Dr. Birkbeck assisted in the foundation of the London Mechanics' Institution, Chancery Lane. He has been twenty-eight years connected with the Corporation, and served the office of sheriff in 1864. He is also a magistrate for Middlesex. We may add that Mr. Dakin was for many years proprietor of a retail establishment in King William Street, City, and it is with regret we do not find his name on the Register of Pharmaceutical Chemists; but we hope during the period he occupies his exalted position we shall find him identifying himself with his professional brethren. We are glad to state that he has consented to be one of the stewards of the Chemists' Ball, to be held on the 25th January next.

The friends of Mr. Richard Reynolds will be glad to learn that we hear he is progressing favourably, and that it is hoped he will not experience any serious ill-effects from the accident he met with last week, though it may be necessary that he should, for some time, abstain from business occupations.

Proceedings of the Pharmaceutical Society.

EXAMINATION IN LONDON.

November 16th, 1870.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Edwards, Gale, Garle, Haselden, Ince, and Southall.

Thirty candidates presented themselves for examination, seven Major and twenty-three Minor; the following passed, and were duly registered:—

MAJOR (as Pharmaceutical Chemists).

*Haydon, William Frederick.... Blandford.
*Metcalfe, Edmund Henry...... Richmond.
*Mason, Philip Henry .... Norwich.
Young, Joseph .... Leicester.
Ingham, John .... Tooting.
Chase, Thomas .... London.

MINOR (as Chemists and Druggists).

*Makinson, Thomas .... Hampstead.
*Bannard, Henry .... London.
*Wright, Thomas .... Leicester.
*Collishaw, John .... Nottingham.
*Shenstone, William Ashwell .. Colchester.
*Wills, Joseph .... Carlisle.
*Noad, Joseph .... Coleford.
Fairbairn, Robert Waller...... York.
Hillier, Henry .... Newport, Mon.
Binns, John George .... Manchester.
Riches, William James........ North Walsham.
Milton, Thomas, jun. .... Henley-on-Thames
West, William .... Leeds.
Mumford, Francis Charles .... Gloucester.
Mountain, Robert .... Harrogate.
Glazier, Walter Henry........ London.
Robertson, George............ London.
Stubbs, Tyson............ Rye.
Sanderson, Thomas .... Birmingham.

The above are arranged in order of merit.

FIRST OR PRELIMINARY EXAMINATION.

Certificates presented by the under-mentioned were accepted in lieu of this Examination:—

Stefford, Charles .... Sydenham.

---

* Passed with honours.

Provincial Transactions.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting was held on November 3rd, in the Council Room of the Manchester Chemists and Druggists' Association, attended by a large number of the chemists' assistants and apprentices of this city.

It was proposed by Mr. W. Metcalfe that an Association should be formed, to be called the "Manchester Chemists' Assistants' Association," to have for its object the mutual assistance of its members in all matters relating to business, and as a help to those preparing for the examinations of the Pharmaceutical Society. After being supported by several gentlemen, the meeting was adjourned until that day week, when a code of rules was to be submitted for revision.

The second meeting was held on November 10th, and was more largely attended than the previous one.

Mr. Metcalfe having been unanimously voted to the chair, the rules were submitted, and after a very lengthy discussion were revised and passed, after which the following officers and committee were elected for the ensuing year:—*President:* Mr. W. Metcalfe. *Vice-President:* Mr. Yeats. *Honorary Secretary and Treasurer:* Mr. B. H. Cowgill. *Committee:* Mr. Cooper, Mr. Gill, Mr. Mercer, Mr. Midgley, Mr. Raworth, Mr. Spencer.

The benefits to be derived from the Association having been very earnestly discussed, the meeting was dissolved.

It is proposed to read a paper at each weekly meeting upon some subject of a practical nature, after which discussion will be invited upon the same.

This Association will work in unison with the "Manchester Chemists and Druggists' Association," one of the rules making it compulsory for each member to be also an Associate of that Society. The session will extend from the 1st October to the 31st April in each year.

SUNDERLAND CHEMISTS' ASSOCIATION.

The Monthly Meeting of the above Society was held on Monday evening, November 7th, at the Society's rooms in Fawcett Street; Mr. R. Robinson in the chair.

Mr. Sharp read a paper on Sulphur, tracing its history from the earliest record, describing the various sources from whence it is obtained, its commercial uses and chemical characters.

Owing to the unavoidable absence of Mr. Harrison, his resolution, concerning the exemption of Chemists and Druggists from juries was postponed to a future meeting.

At the close, a vote of thanks was passed to Mr. Sharp. The next meeting was announced to be held on December 5, when Mr. Cockburn will read a paper on Cinchonas.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting at Liverpool.

Wednesday, September 14th.

(*Continued from page* 395.)

A better Excipient for the Official Pill-masses, and for exhibiting Substances generally in a Pilular Form.

by W. Martindale, F.C.S.,

Dispenser and Teacher of Pharmacy to the University College Hospital.

The making of pills and pill-masses is such an everyday performance of the pharmacist, and, being one which requires a little dexterous manipulation, "the rapid and skilful preparation of them from all the numerous substances of which they are composed has been justly considered to demand his highest qualification as a practical dispenser."*

The active medicaments which prescribers wish to administer in a pilular form vary very much in their physical and chemical characters; most frequently the bulk of the ingredients are powders, or substances capable of being reduced to the state of powder. In such, and indeed in all cases, the choice of a suitable excipient is of the greatest importance, both as regards the therapeutic action of the ingredients, and likewise its being adapted for the purpose of combining with them to form a firm plastic mass, which can be readily rolled out and divided into pills capable of retaining their globular form. To quote Dr. Redwood, the excipient should therefore be such as "will not be incompatible with any of the ingredients of the pills; will modify as little as possible their action, either by causing them to become hard, or in any other way; and will not unnecessarily or inconveniently increase their size."† For the sake of uniformity in dispensing, to the last condition there should, I think, be this marginal allowance, as small doses and active principles are now so much in vogue, that unless specially required, the active ingredients and excipient together in each pill should not, in any case, weigh less than one grain, that is if, say, a quarter of a grain of hydrochlorate of morphia were ordered to be made into a pill, three-quarters of a grain of excipient should be used.

The excipients for pill-mass which are required to be kept as such—not moulded into pills at the time of making; the official pill-masses, for example—should, if possible, keep them in a plastic condition, or, at least, in such a state that they could readily be made to assume this condition again by beating up in a mortar, without any further addition of excipient being needed, as this would lessen the quantity of active ingredients contained in a given quantity of the mass.

I will briefly examine how far the excipients in general use fulfil the required conditions.

Confection of Hips.—This is directed to form sulphate of quinine into a mass in the official pilula quiniæ, and it is much used as an excipient for powdered crystallizable salts, and metallic powders generally,—but it is unstable in its chemical character,—the sugar it contains becomes partially converted into grape sugar, and this being less soluble soon crystallizes. It therefore requires on some occasions much more of this excipient necessary for the purpose of forming a plastic mass, than at others. Unless very recently prepared, it is impossible to combine one part of it with three of sulphate of quinine into a mass which can be rolled and divided into pills, as is directed in the official pilula quiniæ.

Confection of Roses.—This confection, although it varies a little in consistency, is not liable to undergo the granular crystallization to which confection of hips is so prone. It is directed to be used as an excipient in eight out of the twenty official pill-masses, and with the exception of pilula aloes cum ferro, it makes masses which retain their plastic condition tolerably well. Its fault is, the quantity needed materially increases the bulk of the mass, for example, five-twelfths of its weight of the official mass of pilula aloes cum myrrha is composed of the excipient. Its bulkiness generally precludes its use as an extemporaneous excipient.

Treacle.—This is the excipient in five of the officinal pill-masses. It does not find favour with the dispenser, because it is so peculiarly viscid that when a little is taken from the bulk, there is apt to be formed a thread-like, attenuated attachment, which is not conducive to cleanliness. It is better adapted for making pill-masses in quantity than for extemporaneous dispensing, but it does not generally keep them in a plastic condition. About one-third of its weight of the compound rhubarb pill-mass is composed of this excipient, and even that

* Cooley's 'Encyclopædia of Practical Receipts.'
† Mohr and Redwood's 'Practical Pharmacy.'

quantity does not make a mass which, when kept, can readily be made to assume its plastic condition again. *Simple syrup* is sometimes used for vegetable powders, but it likewise forms a somewhat bulky excipient.

Hard Soap.—This is one of the excipients in seven of the official pill-masses. A little powdered soap is useful in reconciling an essential oil to an obstinate pill-mass, but on account of its chemical action its use should, as much as possible, be avoided. *Mucilage* is often used for extemporaneous work, but pills made up with it are apt to become very hard and insoluble,—in fact, with some fine metallic powders it forms a good cement. *Bread crumb* and *manna* are used for such substances as calomel. Those containing bread crumb, it is well known, get very hard when kept.

But where a somewhat fluid excipient is needed, the one which either alone or with some admixture, finds most favour, is *glycerine*. If there be any extractive matter among the active ingredients, such as there is in vegetable powders generally, it forms of it a ready solvent, and of the whole a plastic mass. But there is a great danger of adding too much of this excipient, in which case it oozes out to the surface of the pills after a time, and gives them an unsightly moist appearance. To avoid this, it is generally mixed with one-third of its bulk of water, or better still, of rectified spirit. A little in this diluted state, kept in one of Chalk's drop bottles, flows more readily than the pure, and, if used in slight excess, the more volatile fluid evaporates, there is thus less likelihood of the surface of the pills becoming moist, but a mass of this kind does not keep sufficiently plastic. On account of its peculiar properties, for therapeutic reasons glycerine forms about the best general excipient for pills. In the pure state it is not liable to change in itself,—its taste is agreeable, and excepting in a few instances with metallic salts, it produces no reaction more than mere solution of them, with non-metallic salts the same, but of these it is a much more general solvent,—and its solvent and preservative action on vegetable substances generally is such, that a class of preparations of this kind has been suggested as substitutes for tinctures. When the vegetable ingredients of a pill are bulky, powdered rhubarb for example, less is required of it than of any other excipient. It has, too, the advantage of keeping them in a readily soluble condition, and by reason of its non-volatility, if a mass containing it should not remain plastic, it easily becomes so, without further addition of excipient, when "worked" in a mortar. But the disadvantage of the pills made with it becoming moist on their surface is a great drawback to its being generally used, I have, therefore, endeavoured to get some absorbent for this excess of moisture.

We used to have at the University College Hospital a general excipient for pills, which was then called *bread mass*. This was composed of a mixture of wheat flour, powdered soap, and treacle beaten together; it did duty for confection of roses, confection of hips and most other excipients; and generally did this well, as regards rapidity with which it would form substances into a suitable plastic condition for rolling into pills. But when required for such salts as calomel, corrosive sublimate, nitrate of silver, the sulphates of iron and copper, etc., these were decidedly incompatible with the soap it contained. Nevertheless, when I interdicted its use, I found we had need of something resembling it, as most frequently we get the excipient left to the option of the dispenser, and no other excipient in ordinary use was found so generally applicable as it has been. To obtain this desideratum, I first tried a mixture of *flour* and *glycerine*, but this I was surprised to find possessed little or no adhesiveness, very unlike the mixture of *flour* and *water*, of which the gluten contained in the flour forms such an adhesive paste; yet I found the flour was an excellent absorbent of the glycerine. I next tried various proportions of glycerine and flour heated together, to form a jelly resembling the glycerine of starch, but of firmer consistence. By stirring constantly and heating together until a temperature of about 240° F. is reached, five parts of glycerine, by weight, and one part of flour, a firm adhesive paste is formed, which I call *Glycerine Mass*. As an excipient for vegetable powders it answers well, and for other substances on which it can exert a partially solvent action, it is eminently useful. Among these are such salts as valerianate of zinc, 4 grains with 1 of the glycerine mass forms a good pill. Quinine, 3 parts with 1 of the mass,—B. P. strength,—works well. Compound powder of ipecacuanha, 5 grains with $\frac{3}{4}$ of a grain of the mass makes a small pill. Oxide of zinc, too, 4 grains with 1 makes a good mass. But for most mineral and insoluble powders it is too moist, and will not form with them a firm mass; some additional absorbent is necessary, and for this purpose I found nothing better than the one I have before mentioned—flour; equal parts of the glycerine mass and flour forms a tolerably firm, solid, adhesive paste, somewhat resembling dough, but it is not so elastic; this I *now* call *Bread Mass*. It possesses great capacity for the absorption of insoluble powders, such, for example, as calomel (3 grains with $1\frac{1}{2}$ grain of this mass makes a good pill), nitrate and carbonate of bismuth, arsenic, etc. Of reduced iron, three parts with two of it forms a good mass, in which the iron is not liable to oxidation. Carbolic acid, too, of which it is a good solvent, is readily made into a pill with the bread mass,—a little additional flour being necessary for this substance. Then again, substances that are given in minute doses, as the salts of morphia, resin of podophyllum and other active principles, to partially dilute their action, or where an excipient is needed to slightly increase the bulk of a pill, it is well adapted for use. And among the official pill-masses, an equal quantity of it can with great advantage be used to supplant confection of roses in all these, with the exception of pilula aloes cum ferro—for which the glycerine mass is needed, and pilula ferri carbonatis, this too, requires the glycerine mass, with which it mixes well, but after a time the pills have a tendency to become moist. Mercurial pill I have not tried with it. The same quantity of this bread-mass will replace the treacle in pilula scillæ composita. Equal parts of it and powdered soap in place of powdered soap alone (if this might be permitted), form a much better mass than the official one of pilula saponis composita. This pill-mass, made strictly according to the British Pharmacopœia, soon becomes set into a condition resembling a piece of soap, in which state much beating is necessary to make it again plastic.

Of the glycerine mass to be added to the Pharmacopœia quantities of

Pil. Cambogiæ Comp. (*vice* Syrup) 1 oz. makes a good mass.

,, Colocynth. Comp. (*vice* Water) 3 dr. makes a good mass, and does not get so hard.

,, Hydrarg. Subchlor. Comp. (*vice* Castor Oil) $1\frac{1}{2}$ oz. makes a good mass, but becomes slightly moist.

,, Ipecac. c. Scillâ (*vice* Treacle), 1 oz. makes a good mass, which does not crumble.

,, Rhei Comp. (*vice* 4 oz. Treacle) 2 oz. makes a good mass, and keeps tolerably plastic.

Among the other official pill-mass which I have not tried with these excipients are pilula colocynthidis et hyoscyami and pilula conii composita—these I find do not generally require any excipient—and pilula ferri iodidi, the starch contained in the flour with that would not form an elegant preparation.

Nitrate of silver is generally recommended in works on Materia Medica to be made into a pill, with bread crumb, but this contains common salt, with which it is incompatible. I recommend the following formula, which is a modification of the bread mass:—

℞ Nitrate of silver, 6 grains.
Distilled water, 6 minims.

Dissolve and add—

Glycerine mass, 12 grains.
Flour . . . 24 grains.

Mix to form a mass which may be divided into two-grain pills, each containing a quarter of a grain of nitrate of silver. The mass rolls out well. Keep them from exposure to the air and light.

For *perchloride of mercury* pills :—

℞

Perchloride of mercury, 6 grains.
Distilled water . . 48 minims.

Heat in a test-tube till dissolved, and add it to

Glycerine mass, 48 grains.
Flour . . . 96 grains.

Mix well and divide into ninety-six two-grain pills, each of which will contain a sixteenth of a grain of perchloride of mercury.

In recommending these excipients, *glycerine mass* and *bread mass*, for general use, I consider them therapeutically the best, but pharmaceutically they are not always so, as glycerine has some affinity for moisture, and pills containing it suffer if exposed to this in any way; a damp situation or a very humid state of the atmosphere, will sometimes spoil the appearance of a batch of them. But in the use of these masses as excipients for the extemporaneous dispensing of pills, the utmost cleanliness may be observed, as they are not viscid or clammy like treacle, syrup or pure glycerine. They likewise keep pills more plastic than the other excipients used, and they are more neutral in their chemical action than those in general use.

Substances like nitrate of silver and perchloride of mercury may form different combinations with the albuminoid principles contained in the flour, but in such state they will probably be quite as readily assimilated, and have a similar medicinal action, as physiologists affirm that most metallic substances enter into the blood as albuminates. I have had some fear lest the gluten contained in the flour might favour some decomposition similar to fermentation, but such, from nearly two years' use of them, I have never yet seen take place, the glycerine seems to check anything of the kind. The crude gluten obtained in the moist condition from flour, I find is nearly entirely soluble in glycerine, the solution does not appear to undergo any change when kept.

Taking these points into consideration, and the fact that the masses I have suggested form economical excipients, and for hospitals, where some quantity of these are needed and form an item in their expenditure, I think they may meet with some favour.

A mixture of glycerine and tragacanth is often used, and produces very similar results to those I have obtained from the glycerine mass. I have not had much experience with such a mixture, but I find it makes a more elastic paste, which is often a disadvantage, as it causes the pills to have a certain amount of springiness, and renders them difficult to form perfectly globular.

Glycerine of starch, or a mixture of glycerine of starch and flour, do not form such adhesive pastes as those I have used.

Phosphorus is sometimes ordered in a pilular form; and to exhibit it in that condition, oil of theobroma is a good excipient. One per cent. of phosphorus may be readily dissolved in this by the following process:—Having melted the oil contained in a wide-mouthed bottle placed in a water-bath, add the phosphorus, and partially closing the mouth of the bottle, heat till this too melts, and the temperature of the mixture becomes about 180° F. Then cork it tightly, and with a little brisk agitation the phosphorus will dissolve almost immediately. Allow the fluid to cool and solidify; and having in this condition divided it into suitable lots for rolling, beat each in a mortar to render it plastic before applying it to the machine, and work off quickly. A three-grain pill will contain $\frac{1}{33}$ of a grain of phosphorus. They may be coated with a solution of sandarach in absolute alcohol in the following manner:—place the pills in a covered pot, and pour upon them a few drops of the solution, agitate well, and turn them out upon a slab, separate them from each other and allow them to dry in the air. This gives them a tolerably impervious coating. The process of coating may be repeated if necessary.

For *dried sulphate of iron*, of which a large quantity is sometimes ordered in a pill, I find syrup is the best excipient. No form of glycerine seems to answer well for this substance. The water in the syrup for a time appears to have more affinity for the sugar than it has to form water of crystallization for the sulphate, and a little syrup therefore keeps the mass plastic for a sufficient length of time, that it can easily be rolled into pills. Five grains of this substance can thus be made into a small pill.

In conclusion, you are well aware the task of pill-making is not always an easy one, as frequently substances are ordered together in a pill-mass which have great repulsion for each other—the dexterous reconciling of them brings into play much of the art of pharmacy.

Note on Hydrargyrum c. Creta.

BY M. J. ELLWOOD.

A sample of hyd. c. creta sent out by a London firm came recently under my notice. Its black colour and exceedingly strong metallic taste at once attracted my attention, and aroused my curiosity as to its manufacture. I remember a paper being read at the Birmingham meeting, describing a new method for preparing blue pill, the mercury being obtained in a state of fine division by precipitation from mercuric chloride with stannous chloride. I have no doubt this grey powder was prepared by a similar process as regards the mercury. To ascertain the truth of my supposition, I prepared a small quantity of precipitated mercury and mixed it in its moist state with the proper proportion of chalk, and dried with a gentle heat. The resulting powder resembled the original in colour and general appearance, but had not quite so strong a taste, probably owing to the precipitated mercury prepared by myself having been very carefully washed from any traces of tin.

I send a sample of that prepared by myself, but regret to say that the original sample was destroyed; that sent, however, will give you a pretty accurate idea of it.

Since writing the above, I have referred to the discussion attendant on the reading of Mr. Benger's paper on "Blue Pill," and find that Mr. Brady remarked that the process alluded to *might* possibly answer for preparing grey powder. Some manufacturer evidently took the hint at the time, for the bottle from which the sample was taken was marked as received into stock in 1866, just one year after the Birmingham meeting.

Microscopic Examination of Extracts made from Officinal Tinctures.

BY M. J. ELLWOOD.

Messrs. Deane and Brady's interesting papers on "Microscopic Analysis applied to Pharmacy," induced me to repeat their experiments on opium preparations, and afterwards to extend my researches to several of the officinal tinctures. I prepared slides of ten tinctures according to the plan recommended by Messrs. Deane and Brady; after a lapse of from two to eighteen months, and in two cases more than two years, crystals have appeared in—

Tincture of Belladonna.
,, Conium.
,, Digitalis.
Purified ,, Opium (B. and D.'s form).

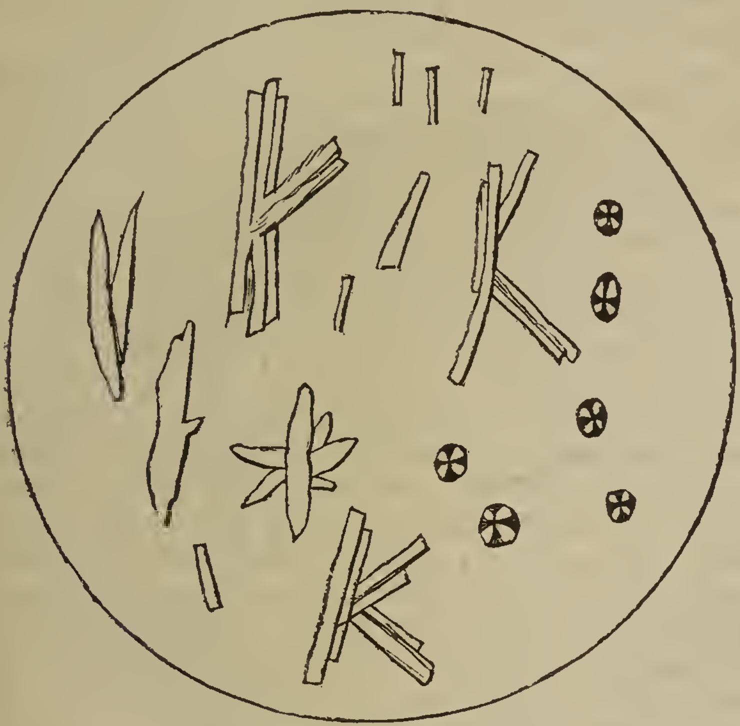
I may also state that a very gradual growth of crystals has continued up to the present time, now nearly three years since the experiments were made.

No appearance of crystals are observable however, in

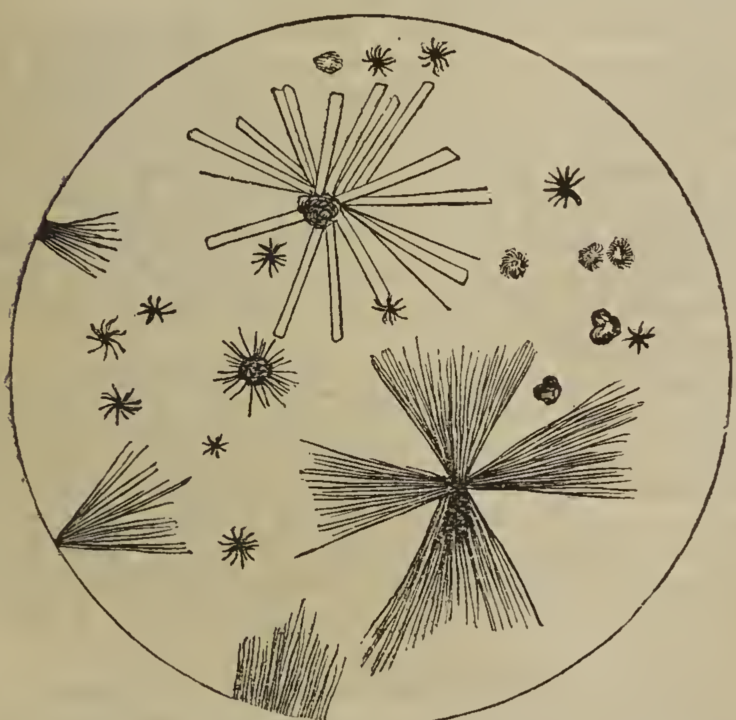
	Tincture of	Cascarilla.
	,,	Buchu.
Simple	,,	Cinchona.
	,,	Nux Vomica.
Simple	,,	Rhubarb.

except in the case of Tincture of Pellitory, which is as yet doubtful.

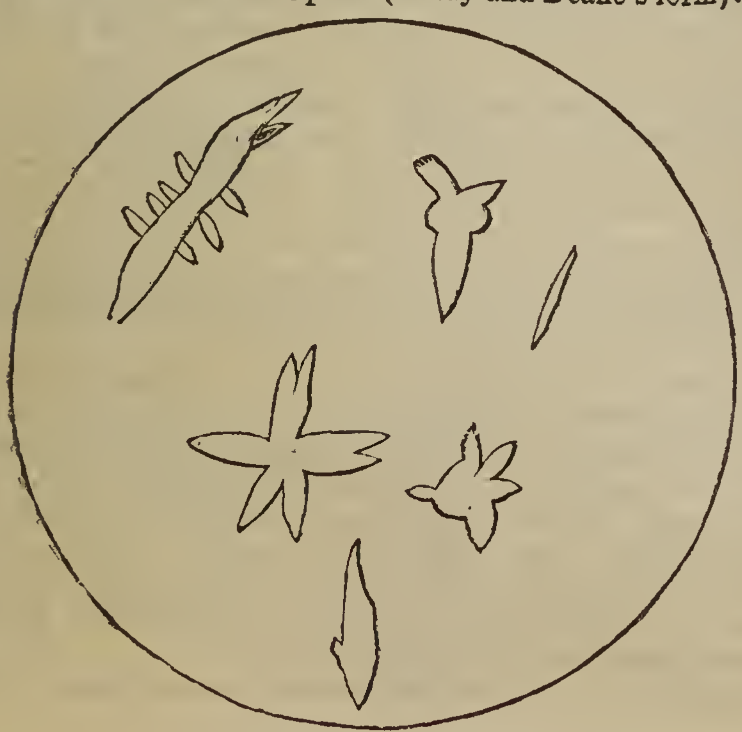
I am not prepared to say what the crystals are, but the forms of some of them incline me to suspect oxalate of lime.



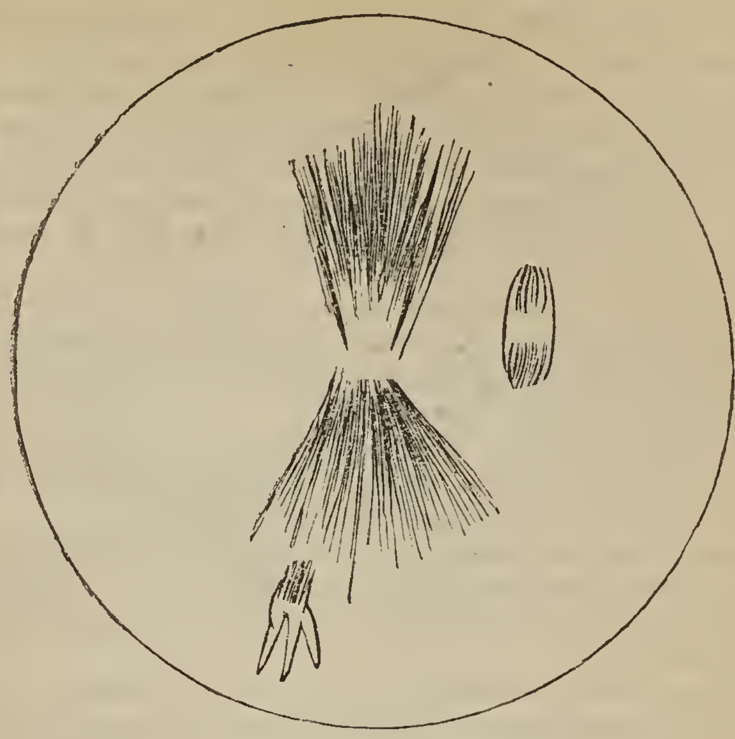
Tincture of Belladonna.



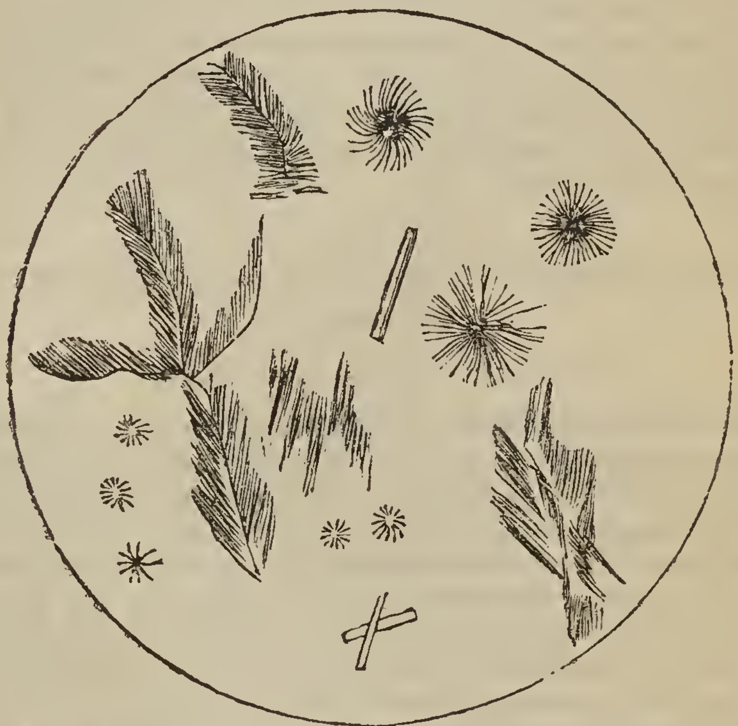
Purified Tincture of Opium (Brady and Deane's form).



Tincture of Digitalis.



Tincture of Conium.



Aqueous Solution of Opium, after maceration in Ether.

One of my experiments with opium proved extremely interesting. I washed powdered opium with ether, and then made an aqueous extract of the residual powder, which soon produced on my slide magnificent feather-like crystals, but without any appearance of the prismatic crystals of narcotine, forming an excellent polariscope object.

Laboratory Notes on Turmeric.

BY JAMES COOKE.

Although but a short time has passed since my becoming a member of the British Pharmaceutical Conference, yet the conviction that members of a Society should all be contributors to the common welfare and prosperity, inclines me to send a few lines, even should they be only suggestive, through Joseph H. Richardson.

It is possible that few of the Pharmaceutical Conference have prepared or seen Cheiranthine, a crystalline product of the wallflower petals. A small portion prepared by me some years ago will be sent with this, which may interest some not yet acquainted with it.

My principal object here is, however, not cheiranthine.

As brevity on such occasions as the present is important, a short communication must suffice.

Several vegetable products, but little examined as yet, have in years past and to the present time yielded interesting results.

Indications of new substances with basic properties in plants, British and foreign, of various Natural Orders, may readily be obtained by curious inquirers. Vegetable *acids* seem to receive less exact inquiry.

In recent experiments with turmeric, I have discovered a basic substance, which, separated by ammonia from its combinations with sulphuric and nitric acids, presents a finely granular semicrystalline precipitate, readily soluble in hydrochloric acid. This combination crystallizes in long prismatic crystals with oblique terminations. It is colourless, and much disposed to become opaque.

The nitrate crystallizes in very short prisms with a tendency to unite in pairs which, much magnified ($\frac{2}{3}$ object-glass), resembled the disposition of the two lobes of some anthers in the Gramineæ.

The sulphate also presents groups of long crystals, grouped in a stellate manner, opaque by prolonged drying in warm air. This salt is also colourless.

There were indications of another base, resembling in some points that existing in calumba root. I say *that*, but believing that there are at least two, mean the principal one.

The colouring matter is quite another product.

I have some intention of undertaking for another year, if health and leisure allow it, the examination of the salts of lithia, which I find noted in the desiderata.

Let me conclude by wishing success to the Conference, an organization which may prove very serviceable by carefully and earnestly encouraging working bees, and by putting in their way what is worth having in forthcoming Year-Books.

The Chemical Constitution of Sulphurated Potash.

BY JOHN WATTS, D.SC. LOND.

The following paper contains an account of some experiments upon which I have been engaged during the last few months, in order to ascertain more directly the exact chemical composition of sulphurated potash.

Different chemical works give different and, apparently at first sight, discrepant results respecting the reaction which ensues when a mixture of potassic carbonate and sulphur is submitted to fusion. By some, especially by those of high authority, it is asserted that the reaction takes place according to the following equation,

$$4K_2CO_3 + 5S_2 = \underbrace{K_2SO_4}_{\text{Sulphate.}} + \underbrace{3K_2S_3}_{\text{Sulphide.}} + 4CO_2,$$

potassic sulphide and potassic sulphate being produced, while carbonic anhydride is evolved. By others it is stated that potassic hyposulphite is one of the products of the reaction, and that either potassic sulphate is not produced at all, or the equation proceeds in two stages, thus,

$$3K_2CO_3 + 4S_2 = \underbrace{K_2S_2O_3}_{\text{Hyposulphite.}} + 2K_2S_3 + 3CO_2.$$

$$\underbrace{4K_2S_2O_3}_{\text{Hyposulphite.}} = \underbrace{3K_2SO_4}_{\text{Sulphate.}} + \underbrace{K_2S_5}_{\text{Sulphide.}}$$

the hyposulphite being resolved into sulphate and sulphide when the temperature at which the fusion is conducted approaches ignition.

A few qualitative analyses of some samples of "sulphurated potash," prepared with varying molecular proportions of materials, immediately decided in favour of the latter equations; the presence of potassic hyposulphite in considerable proportion was readily established, while potassic sulphate was detected only in very small quantity, and in one sample disappeared altogether. It is well, perhaps, to mention that there is much difficulty in preparing a sample entirely free from sulphate, since if the heat employed be somewhat too high or too long continued, a proportion of sulphate is immediately formed at the expense of the hyposulphite present.

Being now enabled to calculate the percentage composition, I proceeded to the quantitative analysis of several commercial samples, to see how closely their percentage might agree with that which had been deduced from theoretical considerations. The samples were procured from some of the best wholesale houses, and fairly represent the article as met with in commerce. The analysis resolves itself into the quantitative separation of a mixture of potassic sulphide, hyposulphite and sulphate, but the probable presence of potassic sulphite and potassic carbonate must not be ignored, since the former may be derived from incipient oxidation, and the latter may result from imperfect decomposition.

There are two methods of effecting the separation of sulphides from hyposulphites and the higher oxacids of sulphur:—1. By adding to a solution of the salt in question a strongly ammoniacal solution of argentic nitrate, the sulphur existing as potassic sulphide is alone precipitated as argentic sulphide, while the remaining silver salts are retained in solution by the excess of ammonia present; the argentic sulphide is collected and washed, and the sulphur estimated either by oxidation or by reduction in a current of hydrogen. To another portion of the salt, solution of argentic nitrate is again added, omitting the previous admixture with ammonia,—argentic sulphide is precipitated as before, while at the same time the hyposulphite is resolved into a mixture of argentic sulphide and argentic sulphate; when the decomposition is complete, excess of ammonia is added and the sulphide collected and estimated as before. The amount of sulphur corresponding to one-half of the hyposulphite present is then calculated, by deducting, from the total amount of sulphur found, the weight of sulphur as obtained in the first operation.

2. By *Werther's* method. Recently precipitated cadmic carbonate is added in excess to the solution to be analysed; double decomposition ensues, potassic carbonate formed, and cadmic sulphide precipitated; this latter is washed, oxidized with fuming nitric acid, and the sulphuric acid estimated as baric sulphate. The hyposulphite present is unaffected by cadmic carbonate, and consequently will be found undiminished in the filtrate, where it can be readily estimated by the usual decinormal iodine solution.

Werther's method is preferable to the first process for several reasons. The cadmic sulphide washes with great rapidity, since, like argentic chloride, it has a tendency to coagulate into small clots; moreover, it has no inclination to oxidize by exposure to the air. The substitution of a volumetric estimation in the case of the hyposulphite is likewise more expeditious, and in accuracy perhaps excels the gravimetric method. I give the actual analyses more in detail.

Estimation of the Sulphide.—About 1·5 gramme were dissolved in water, and excess of cadmic carbonate added. The reaction takes place almost instantaneously, without heat, and if the carbonate has been used in sufficient quantity, the cadmic sulphide separates perfectly. The sulphide was then collected on a filter, washed with hot distilled water and partially dried; then transferred to a small flask and oxidized with fuming nitric acid, the boiling was continued until the unoxidized sulphur had acquired a pure yellow colour, when the whole being allowed to cool, the sulphur was separated and weighed. The sulphuric acid formed was then estimated with baric chloride in the usual way.

Estimation of the Hyposulphite.—A volume of carbonic acid water was added to the filtrate from the cadmic sulphide precipitate, to convert the carbonates present into acid carbonates; decinormal iodine solution was then run in, till the blue colour appeared as indicated by starch paste. The value of the iodine solution being known as corresponding to crystallized sodic hyposulphite, the equivalent quantity of anhydrous potassic hyposulphite was readily calculated.

Estimation of the Sulphite.—But the estimation of the hyposulphite requires a correction, lest any of the iodine employed should have been consumed by sulphurous acid. The direct estimation of the SO_2 is based upon the fact that while iodine oxidizes hyposulphurous acid into tetrathionic acid, it converts sulphurous acid directly into sulphuric acid; therefore, by estimating the sulphuric acid so formed, we are enabled to calculate with facility the amount of sulphurous acid from which it was derived. Further, the amount of sulphurous acid being known, the iodine required for its complete oxidation is known also; the weight of this latter being deducted from the total weight of iodine employed, the remainder represents correctly the proportion of iodine consumed by the hyposulphite.

In no single instance was any potassic sulphite detected in solution of sulphurated potash; the numbers obtained in the analyses after oxidation with iodine, always exactly corresponded with those yielded by the estimation of the sulphuric acid originally present.

Estimation of the Sulphate.—About seven grammes were dissolved in a small quantity of water, and the solution completely decomposed by addition of dilute hydrochloric acid. A gentle heat was applied to volatilize sulphuretted hydrogen and sulphurous gases. After filtering off and washing the precipitated sulphur, the sulphuric acid in the filtrate was estimated with baric chloride.

Estimation of the Carbonate.—6·5 grammes were dissolved in water, and directly precipitated with excess of baric chloride. The precipitate consisted of baric carbonate, sulphate and a small quantity of the sparingly-soluble hyposulphite; this was washed with distilled water, transferred to the usual carbonic anhydride apparatus, a little potassic chromate added to effect the oxidation of any hyposulphite which might chance to be present, and the carbonic anhydride determined by loss in the usual way.

Estimation of the Total Potassium.—Two grammes of the salt having been weighed in a porcelain crucible, the latter was very slowly and carefully brought to a red heat so as to decompose the hyposulphite, and at the same time convert nearly the whole of the sulphide present into sulphate. After allowing the crucible to cool slightly, a few drops of nitric acid were added, and the whole evaporated to dryness. The subsequent addition of a drop of strong sulphuric acid ensured the conversion of the whole of the salt into sulphate, and the excess of sulphuric acid being expelled by a red heat with the assistance of ammonic carbonate, the potassium was weighed in the form of sulphate.

I give the theoretical percentage composition of sulphurated potash, supposing it to be formed according to the equation—

$$3\,K_2CO_3 + 4\,S_2 = K_2S_2O_3 + 2\,K_2S_3 + 3\,CO_2,$$

but the Pharmacopœia orders a slight excess of potassic carbonate:—

Sulphur	35·68	} in combination.
Potassium . . .	29·00	
Pot. Hyposulph. .	35·32	
	100·00	

The following are the results of the analysis of four distinct samples, A, B, C, D:—

A.	Sulphur	36·13	} potassic sulphide.
	Potassium . . .	25·28	
	Pot. Hyposulphite	38·32	
	,, Sulphate . .	0·87	
		100·60	
	Excess . . .	·60	
		100·00	

B.	Sulphur	25·45	}
	Potassium . . .	17·21	
	Pot. Hyposulphite	21·56	
	,, Sulphate . .	3·38	
	,, Carbonate . .	32·72	
		100·32	
	Excess . . .	·32	
		100·00	

C.	Sulphur	28·17	}
	Potassium . . .	22·65	
	Pot. Hyposulphite .	38·00	
	,, Sulphate . .	2·34	
	,, Carbonate . .	7·50	
	Ferrous Sulphide .	·92	
		99·58	
	Loss	·42	
		100·00	

D.	Sulphur	28·32	}
	Potassium . . .	20·20	
	Pot. Hyposulphite .	31·82	
	,, Sulphate . .	4·32	
	,, Carbonate . .	14·09	
	Ferrous Sulphide .	1·00	
		99·75	
	Loss	·25	
		100·00	

Sample "A" has been very carefully prepared; it contains no carbonate, only a trace of sulphate, and the full percentage of sulphide. All the other samples contain carbonate, especially "B," which latter is a very indifferent preparation, containing not less than 32 per cent. of undecomposed carbonate, with a proportional decrease in the amount of sulphide.

The ratio of potassium to sulphur in potassic trisulphide is 78 of potassium to 96 of sulphur. In the foregoing analyses the ratio, as might be expected, is not quite so uniform, at the same time it is sufficiently so to show that the potassium exists in the salt principally as trisulphide admixed with a certain varying proportion of tetra- or pentasulphide.

Ratio in A	78 to 111
,, B	78 to 115
,, C	78 to 97
,, D	78 to 109

In sample "B," owing to the deficiency of potassium in combination with the sulphur, due to imperfect preparation, the ratio more nearly approaches tetrasulphide than trisulphide of potassium.

I append the analysis of one sample in which complete decomposition has taken place, owing to its having been kept for a period of about nine months in a bottle with an imperfectly-fitting stopper. As will be seen, the potassic sulphide has entirely disappeared, having been oxidized principally to hyposulphite and sulphate with separation of sulphur.

E.	Potassic sulphate	18·06
	,, hyposulphite . .	51·60
	Free sulphur	15·42
	Ferrous sulphide	1·73
	Potassic carbonate . . .	3·10
	Moisture	8·89
		98·81
	Loss	1·19
		100·00

Ferrous sulphide must be noticed as an impurity in several samples. In every case the ferrous sulphide formed a superficial coating upon one side only of the fragments; it is obvious that the salt when in fusion has been poured out upon an iron plate instead of upon a stone slab, and hence has contracted this objectionable contamination. When sulphurated potash is of yellow colour, or breaks with a yellow or orange fracture instead of a deep brown, it is almost certain that it contains a considerable amount of undecomposd carbonate. Specimen "B" shows this orange colour exceedingly well, and I have noticed it in several samples which I purposely prepared at a very low temperature. In carefully-prepared samples the colour varies very slightly indeed, being always of a rich mahogany-brown tint, commonly described as liver-coloured. The colour may be seen in specimens A 1, B 1, which have been preserved from oxidation by enclosing them as soon as cold in bottles previously filled with coal-gas.

There is no difficulty in preparing sulphurated potash upon the small scale; indeed, since more care can be taken in its preparation, it is likely to prove a superior article. A quarter to half a pound of a mixture of 20 parts of *dry* potassic carbonate and $12\frac{1}{2}$ parts of sulphur are placed in a Florence flask, and carefully heated by a Bunsen burner. The mouth of the flask is to be stopped with a plug of cotton-wool; as soon as the contents commence to liquefy the flask must be gently agitated once or twice, and when effervescence has ceased, and the mixture perfectly fluid, the gas is withdrawn, and the whole allowed to cool for two hours. The flask is then broken, and the contents immediately transferred to a well-stoppered bottle. If the salt has not been permitted to become quite cold, it is not sufficiently brittle to be broken into pieces; and further, it then adheres so firmly to the glass that it is very difficult subsequently to remove it.

I have said that the reaction which occurs in preparing sulphurated potash is such that potassic sulphide and hyposulphite are produced, but that if the heat be increased the hyposulphite splits into pentasulphide and sulphate. It might be supposed at first sight that the percentage of sulphide would be increased by employing an elevated temperature, and possibly, if closed vessels were always used in its preparation, this might to some extent be the case; but it is impossible so to prepare it on the large scale; and when atmospheric oxygen obtains access to the mixture the decomposition of the hyposulphite proceeds differently, oxygen being absorbed, while sulphurous anhydride is given off.

$$2K_2S_2O_3 + 2O_3 = 2K_2SO_4 + 2SO_2.$$

Potassic sulphide also undergoes combustion when unduly heated, producing the same compounds as result from hyposulphite, consequently sulphurated potash containing a large amount of sulphate can only be regarded as a faulty preparation. It appears, however, that the error more generally lies in the opposite direction.

With respect to the test given in the Pharmacopœia, that three-fourths of its weight should be soluble in alcohol of 84 per cent., it appears that few samples will come up to this standard; nevertheless, if the salt contain only half its weight of potassic sulphide, it may fairly be considered as a good preparation.

The Fluid of Pitcher-Plants.—Mr. G. B. Buckton records in *Nature*, No. 54, for November 10th, some experiments on this subject. Difference of opinion has been expressed as to the nature and use of the liquid found in the so-called pitchers of various plants, such as *Nepenthes*, *Sarracenia*, and certain orchidaceæ. It is generally supposed to be pure rain-water stored up for the use of the plant. In the artificial circumstances under which tropical plants are grown in this country, it is difficult to distinguish this fluid from the water used in watering. Mr. Buckton has, however, collected the liquid from two flowers of *Coryanthes*, a species of Orchidaceæ, which had just opened, to the extent of about two centimetres. He found it clear and somewhat glutinous in consistence, possessing a high refractive power, and a specific gravity of 1·062. Its odour was pleasant but faint, becoming more marked by a gentle heat; although the taste was not acrid, the mawkish flavour would render it quite unpotable. It was neutral to test-papers, became milky by concentration in the water-bath, and finally yielded a transparent gum insoluble in alcohol. Oxalates produced no precipitate of lime, but basic lead acetate gave a curdy reaction. Hot concentrated sulphuric acid blackened it. 100 parts of the liquid contained—

98·51 water and volatile oils.
1·49 non-volatile residue.

No further analysis is given.

Parliamentary and Law Proceedings.

Southwark Police Court, *November 4th.*

Before Mr. Partridge.

Elizabeth Morvin, described as a needlewoman, was charged on remand with attempting to commit suicide by swallowing a quantity of aquafortis, which had been supplied to her child by a chemist in the Waterloo Road. A police constable said that he was called in to a house in Duke Street, where he found the prisoner suffering great agony. Being told she had swallowed aquafortis, he took her to a surgeon, and thence to the hospital, where the stomach pump was used, and she eventually recovered. On inquiry he found that she had sent her daughter to purchase two-pennyworth of aquafortis. The child told him that she went to several chemists, and at last one of them supplied her with the poison, which she gave to her mother, who drank it off. The prisoner said that having had a dispute with the father of her child, she had been drinking to excess, and did not know what she was about. Mr. Partridge told her that she had had a narrow escape, which he hoped would act as a caution to her for the future, and after suitably admonishing her, ordered her to be given up to her landlady.

BOOKS RECEIVED.

A Manual of Botany: including the Structure, Functions, Classification, Properties and Uses of Plants. By Robert Bentley, F.L.S., M.R.C.S.E. Second Edition. London: John Churchill and Sons, New Burlington Street. 1870. From the Publishers.

Dublin Quarterly Journal of Medical Science. November, 1870. Dublin: Fannin and Co., Grafton Street. From the Publishers.

On the Fulgurator: a New Apparatus for producing Electric Sparks of very great length. 1870. From the Author.

Elementary Chemistry. By the Rev. H. Martyn Hart, M.A. London: Cassell, Petter and Galpin. 1870. From the Publishers.

The Natural History of Commerce, with a Copious List of Commercial Terms and their Synonyms in Various Languages. By John Yeats, LL.D. London: Cassell, Petter and Galpin. 1870. From the Publishers.

(Piesse's 'Art of Perfumery.')—F. A. H.

SYRUPUS FERRI QUINIÆ ET STRYCHNIÆ PHOSPHATUM.—In the last two numbers of the PHARMACEUTICAL JOURNAL, under "Notes and Queries," I have seen communications respecting "Syrupus Ferri Quiniæ et Strychniæ Phosphatum (Easton's)," and in one number a formula is given as stated by Squire.

On reading this I notice that it differs from one I have, both in proportions of ingredients and manipulation, although, as regards the ingredients, the difference is not a great one.

The formula I have I copied from a portion of a work lent by Dr. Aitken (and I believe written by him) to a former employer of mine, in which he mentions the syrup as having been recommended by Mr. Easton to him for trial in his practice. As the formula may be useful to chemists, I give it as there stated.

℞. Ferri Sulph. ℨv
*Sodæ Phosph. ℨvj (vel ℥j)
Quiniæ Sulph. gr. excij
Acid. Sulph. Dil. q. s.
Aq. Ammoniæ Fort. q. s.
Strychniæ gr. vj
Acid. Phosphor. Dil. ℥xiv
Sacchar. Alb. ℥xiv.

* ℨvj is the quantity generally used.

Dissolve ferri sul. in 1 oz. of boiling water and sodæ phosph. in 2 oz. boiling water; mix and wash the precipitate till the washings are tasteless. With q. s. of diluted sulphuric acid dissolve the quinine in 2 oz. of water, precipitate the quinine with liq. ammon. fort. and wash carefully. Dissolve the phosphate of iron and quinine thus obtained, and also the strychnine in the diluted phosphoric acid, add the sugar and dissolve without heat; product should measure 24 oz.—HENRY NEWMAN, *London.*

[39.]—LIQUOR COCCI.—"*Percontator*" would be glad of a good practical formula for cochineal colouring, which will keep, remain bright and not deposit.

[40.]—CHLORAL HYDRATE.—"*Hypnotic*" would like a form for syr. chloral hyd. gr. x to dr. in which the taste of chloral is *masked* on dilution.

[41.]—BATH POWDER.—*A. B. C.* (Norwich) wishes to be informed what the powder or preparation is which is used in baths after a patient has been suffering from scarlet fever.

[42.]—CHILBLAINS.—"*Lugoney*" and *C. Bennett* wish for a formula for a good chilblain liniment.

[43.]—VEGETABLE ALKALOIDS.—"*A Bookworm*" asks for a reference to practical works on the preparation of vegetable alkaloids (non-officinal).

[44.]—PERFUMES.—"*Chemicus*" would feel obliged if any gentleman would favour him with a recipe for a cheap lasting perfume.

[45.]—WATER TEST.—*J. G. M.* will be glad if any one could inform him of a simple way of testing water for organic impurity, especially such as is derived from sewage.

[46.]—WEATHER GLASS.—Can any correspondent give the recipe for making a liquid for indicating changes of the weather by the rise or fall of a sediment in the same?—C. E. M., *Bury.*

[47.]—SMALLPOCK MARKS.—*A. H. C.* (Cirencester) wishes to know if there is any application for temporarily effacing smallpock marks, and if so, what it is or where it can be obtained.

[48.]—CRYSTALLINE POMADE.—*A. H. C.* is in want of a good recipe for making crystalline pomade.

[49.]—EAU DE MILLEFLEURS.—*G. S.* will be greatly obliged if "*Utile*" (Boston), who supplied a recipe for jockey club bouquet in the Number for February, 1870, would now be kind enough to give one for eau de millefleurs.

[50.]—SYRUPUS CHLORAL (HYDRAT.).—*G. M. T* (Penzance) wishes to know of a good formula for syrupus chloral (hydrat.).

[51.]—BRILLIANTINE.—*G. M. T.* wishes for a recipe for making brilliantine.

[52.]—COFFIN'S COMPOSITION POWDER.—Can any of your correspondents furnish me with a formula for Dr. Coffin's composition powder?—A. B.

[53.]—DISPENSING.—Will any of your correspondents inform me how to dispense the following mixture, so as to make it CLEAR and of a sherry colour?—

℞. Beberiæ Sulphatis ℈i
Ferri Citratis ℈i
Syrupi Aurantii,
Tincturæ Calumbæ, ana ℨi
Infus. Calumbæ ad ℥iv.
Fiat mistura. C. F., *Winchester.*

[54.].—PLATES OF MEDICINAL PLANTS.—*B. M. S.* (Boston) wishes to be informed where he can obtain plates of the medicinal plants, especially of the indigenous, and the probable cost.

Pharmaceutical Education.

Sir,—To a certain extent I agree with Mr. Bremridge and Mr. Allkins on the subject of Pharmaceutical Education, but my idea is that, in the main, practical experience is far better than theoretical knowledge; the former is carried out in daily pursuits, the latter is, in many instances, laid on the shelf when once the "necessary examination" is over. At any rate, I think Mr. Allkins would not advocate the placing of a youth under the tuition of an M. P. S. such as "Assistant"* speaks of, more particularly if he is like some of our brother chemists, who, for the consideration of fifty or sixty pounds premium, undertake (as per indenture) to board, lodge, teach, and instruct, by the best means possible, the art of a Chemist and Druggist (dispense a 6-oz. mixture for 8*d*., retail sp. æther. nitr. 2*d*. oz., make their proof spirit for tinctures, half and half, mix alum with cream of tartar, prepare tr. opii with ext. papaveris, etc.).

It is very right to assist apprentices in some theoretical parts of the business, but pharmacists ought to adopt no other methods than the authorized formulæ, and they should scorn the idea of any kind of sophistication. If such were the case, depend upon it the cutting system would gradually wear out.

Brighton, Nov. 15*th*, 1870. "Proof Spirit, P.B."

Preliminary Examination.—Prize Scheme.

Sir,—In the hope of giving some encouragement to candidates for the Preliminary Examinations of the Pharmaceutical Society, allow me to propose the following scheme:—

That candidates for these examinations shall pay, in addition to the ordinary fee of two guineas, one or two shillings extra (at discretion); that this sum shall be appropriated at the end of the year to the purchasing of medals, books, etc., and that these shall be given as rewards of merit to the three or four best competitors at each examination during the year. This scheme may be either optional or compulsory. If, however, the latter plan could be adopted the affair would be made much easier, for by the former plan the prizes would be available only to those who subscribed the extra fee. This might cause confusion. Suppose, then, that a shilling was fixed as the extra fee, and that this was compulsory. I think that so trifling an amount would not cause many objections, but, on the contrary, the plan would meet with much approbation.

An Encourager.

Dispensing Charges.

Sir,—Several correspondents having addressed you in last week's Journal upon the above subject, allow me to give an instance which came under my own observation, showing how inexpedient it is to be so influenced by mere statements, as not to make a fair and proper remunerative charge for dispensing. About a week since I dispensed the following prescription:—

℞. Quinæ Sulph. ℈i
Acid. Sulph. Dil. ʒi
Tinct. Cardam. Co. ℥ss
Tinct. Hyoscyami ʒiij
Mist. Camphoræ ad ℥viij.
M. Take two tablespoonfuls three times a day.

An empty bottle without label was brought by the servant, and from some little observation made I thought a very moderate charge was requisite. Accordingly 1*s*. 9*d*. was charged. To my surprise, in the evening of the same day the mixture was returned, with a statement that Mr. G. could not think of keeping the medicine at such a preposterous price. The gentleman subsequently called himself, and asked why I should charge 1*s*. 9*d*. for dispensing a prescription which had been prepared several times by Corbyn in the Poultry for 1*s*. 3*d*., and once in my own neighbourhood for the same amount (in the latter case it afterwards transpired that the charge was made on account of it *being stated* Corbyn's had charged that sum). I said I could not think of altering my price, which was exceedingly moderate, and that I did not think it possible Corbyn's should make such a charge for it. Wishing fully to investigate the matter, and see how far such a statement was correct, the following morning I took a copy of the prescription to Messrs. Corbyn and Co. (Poultry), giving them an account of what had taken place. Their reply at once was, if the prescription has been dispensed by them their charge for it was 1*s*. 10*d*. Comment, therefore, is needless. Upon my return I wrote, informing the gentleman of the result of my visit to Messrs. Corbyn's. I need scarcely say I have heard nothing since.

E. Applegate.

Upper Holloway Road, November 14*th*, 1870.

Pharmaceutical Apparatus.

Sir,—The very excellent suggestion made by Mr. Faulkner in your last issue will, I trust, meet with the approval of the Council of the Society. I crave permission to add that I consider it would be most politic at the present juncture, while so much is being written about "Pharmaceutical Education in the Provinces," if the Council were to invite competition for the best complete set of laboratory fittings suited to the requirements of an ordinary retail business. I think a prize of sufficient value to excite an active competition, together, perhaps, with the privilege of the successful competitor being permitted to erect a model at the house of the Society, where it might be seen by any person connected with pharmacy, would yield us what has been long a desideratum; while at the same time, by means of this small encouragement, some of the difficulties which beset a successful prosecution of pharmacy in the provinces would be obviated.

If you consider the above remarks of sufficient interest, I should feel obliged by their insertion in the next number.

Cliff Town, Southend, Nov. 14*th*. Jas. Wheeler.

Obscure Prescriptions.

Dear Sir,—Some of your readers may feel interested in reading another specimen of Mr. Watson Bradshaw's *peculiar* style of prescribing, commented upon by *F. J. B.* last week, and I therefore enclose a formula, which was brought to me some time since to dispense:—

℞. Pulv. Cinerei gr. ss
Ext. Sedativ. gr. iv
M. ft. pil. h. s.
℞. Liq. Alkalin. ʒiss
Extr. Nigr. gr. ss
Ess. M. Pip. ♏xx
Infusi Subamaræ ad ℥viij
Tinct. Subamaræ, ʒvj
M. capiat partem sextam ter in dies.

Aprilis 19*mo die*, 1869. Watson Bradshaw.
43, Welbeck Street, Cavendish Square, W.

INFUSIONS.

BY A. ALLCHIN.

The infusions used in pharmacy have perhaps given rise to more discussion than any other class of preparations contained in the British Pharmacopœia. But though much has been said and written on the subject, nothing very satisfactory has as yet resulted, and the position of this matter, as it now stands, is hardly creditable to pharmacists as a professional body.

The questions respecting the use of concentrated preparations are still undecided, and, what is worse, there is no uniformity of practice. We have on the one hand pharmacists of acknowledged ability refusing to recognize these preparations, which we know to be in daily use in many establishments; while on the other hand, they are recommended as well as used by men of great experience, whose opinion is entitled to respect, inasmuch as they conscientiously believe that in using concentrated preparations, they are faithfully fulfilling the intentions of the prescriber as well as their duty towards patients.

Anything that would tend to do away with these differences, both in practice and opinion, that have so long perplexed pharmacists, should be gladly welcomed by them, and for this reason alone the paper recently brought before the Pharmaceutical Society by Mr. Barnes merits the careful consideration of all concerned with dispensing. The author may fairly be considered to merit the thanks of the trade, not only for having directed attention to the subject, but also for having taken a step in the right direction, and, in a great measure, disposed of the difficulties by which it has been surrounded.

Before proceeding to speak more particularly of this paper, it appears desirable to give a brief *résumé* of what had previously been published on the subject of infusions.

In the first volume of the Pharmaceutical Journal the preparation of infusions and decoctions was brought forward by Mr. Bell, and he drew attention to the fact that a paper had been written on the subject by Mr. Alsop, of Chelsea, in the year 1836, but owing to the want at that period of any channel for the publication of such papers in this country, it had been sent to Philadelphia and published in the *American Journal of Pharmacy*. An abstract of this paper was published in the Pharmaceutical Journal,* and the hope was expressed that such communications might in future be furnished to the Society instead of travelling from London to England by way of Philadelphia. Among the points discussed in this paper, the best form of pot or jar for infusions was first referred to, and the one recommended was that in which the ingredients are allowed to rest on a perforated plate, placed nearly at the top of the vessel, rather more boiling water being added than would be sufficient to cover the ingredients, so as to allow for absorption. This plan was adopted, in order that, during the maceration, the liquid in contact with the infused material might become charged with soluble matter, and then sink through the perforations while the unsaturated portion of water took its place, the action continuing until the whole of the soluble matter became extracted.

The most convenient mode of preserving infusions was then considered; the one recommended—the most valuable that has ever been devised—was at once adopted. It is still used by many of the most enlightened of our brethren, and has been at all times strongly recommended by the Professor of Chemistry and Pharmacy to our Society as well as many other distinguished men.

The operation is briefly as follows:—When the maceration has continued the prescribed time, the infusion should be strained and transferred to stoppered bottles of convenient size, the bottles being filled to the top of the necks, and if the liquid be sufficiently hot, the stopper is to be inserted and made to displace its own bulk of liquid. In cases where the infusion becomes cold before the expiration of the time which it is directed to stand, it is necessary to place the filled bottles in a water-bath and again heat them before the stoppers are inserted. Ordinary bottles with corks can, with a little judicious management, be made to answer the purpose either by perforating the cork and closing the aperture as the liquid cools with sealing-wax, or by using the cork entire. In the latter case, the cork having been previously fitted to the neck, has only to be placed on the top of the filled bottle, and gradually pressed down on the receding fluid as it cools.

When the discussion of this subject was first commenced, in August, 1841, the names of two gentlemen were mentioned who were at that time making concentrated preparations said to possess the requisite properties of the drugs in a convenient form, but the plan adopted for making them not being generally known, their use was limited and it was considered difficult to form any decided opinion as to the real value of these preparations. In 1845, Mr. Thomas Greenish communicated a paper on infusions,* confining his observations principally to the temperature at which infusion of calumba ought to be prepared. He admitted that when made with cold water, it possessed the requisite strength and aroma, and had also the advantage of being bright, but he showed that owing to the presence of albumen, it was more liable to decomposition than an infusion made at a temperature of 212°. On this occasion Dr. Redwood referred to the plan of Mr. Alsop for the preservation of infusions, and stated that he had found infusions preserved in that way were perfectly good at the end of twelve months when put into six- or eight-ounce bottles and the mouths closed with tinfoil while quite hot.

In 1847, the sixth edition of the Prussian Pharmacopœia appeared, and in order to guard against the too rapid cooling of infusions when made in small quantities, the vessels in which they were made were ordered to be exposed to the influence of steam for five minutes.

In 1853, at a meeting of the Edinburgh Chemists' Association, on March 16th, Mr. James Gardner read a paper on the watery infusions of the Pharmacopœia, and on concentrated infusions,† in which he stated that his attention had for many years been directed to concentrated infusions, and gave a detailed account of a method for their preparation. According to this, we were directed to take of the materials ordered by the College as much as would make any number of pints or gallons of an ordinary infusion, then to exhaust them with hot or cold water, and having strained carefully, to evaporate the liquid to a ninth part of the measure ordered by the College; lastly, to add an eighth part of rectified spirit,

* New Series, Vol. II. p. 89.

* Pharm. Journ. 1st ser. v. 307. † *Ibid.* xii. 485.

and when the concentrated liquor had become clear, it was to be decanted off or filtered. One ounce of such a concentrated infusion, added to seven of distilled water, was said to form a mixture equal in strength, and possessing all the medicinal properties of an ordinary infusion. This mixture was also said to be superior to an ordinary infusion in appearance. Mr. Gardner concluded his remarks by stating that several similar preparations were in use, but that so far as he had an opportunity of judging, they did not adequately represent the strength required by the College. This appears to have been the first formula published for making concentrated infusions, and it is obviously open to objection, inasmuch as it would be impossible to evaporate such infusions as those of "orange," "chamomile," "cascarilla," etc. etc. without impairing their qualities. This communication was supplemented by another in 1855, in which a proposition was made to overcome these objections by first digesting these bodies in the spirit that was ultimately to be used for their preservation.

In 1854, Mr. Frederick Curtis presented to the Pharmaceutical Society several specimens of concentrated preparations,* which were placed on the table at a meeting on December 6th, and gave rise to one of the most animated discussions that ever took place on this subject. Mr. Curtis, when pressed, made known the mode by which he made his preparations.

At two subsequent meetings the discussion was continued.

In 1855, Dr. Edwards read a paper on concentrated infusions and decoctions at the Liverpool Chemists' Association,† in which he stated that concentrated infusions were at that time much in use, especially among medical men who dispensed their own medicines, and he believed their experience would go far to justify their use.

About the same time, Messrs. Barton made known a formula for preparing Inf. Calumbæ Concent.‡

Mr. Jacob Bell furnished several formulæ for concentrated preparations. On these occasions much valuable information was elicited, but no advance appears to have been made in regard to the real question at issue, viz. whether, if "fresh" infusions be ordered, it is justifiable to substitute "concentrated" preparations.

Mr. Southall communicated a short note at a meeting of the Society,§ in which he pointed out that one difficulty in the way of adopting the use of concentrated infusions was that some of them would not keep well without the addition of at least 25 per cent. of rectified spirit, and he also suggested that this spirit should be utilized in obtaining the active principles of some of the ingredients which were little soluble in water.

A paper was also read by Mr. Bastick,|| in which he expressed his opinion that in order to render the concentrated infusions efficient substitutes for those of the Pharmacopœia, it was necessary to study the constituents and characters of every drug employed in their preparation, and that, in consequence of the varied properties of these drugs, no uniform method would be found applicable for the manufacture of such concentrated infusions.

Another paper was read by Mr. Schacht,** in which he advocated the use of concentrated preparations in certain instances, as they had been already acknowledged by the Pharmacopœia authorities; and he suggested that an extension of the principle would be attended with considerable advantage. He also gave a series of formulæ for their preparation.

* Pharm. Journ. 1st ser. xiv. 304.
† *Ibid.* xiv. 348.
‡ *Ibid.* xiv. 368.
§ *Ibid.* xiv. 437.
|| *Ibid.* xiv. 439.
** *Ibid.* xiv. 486.

Mr. Whipple read a paper, in which he said of the infusions* that he believed they were invaluable remedies when prepared according to the Pharmacopœia, whilst his conviction concerning the so-called concentrated infusions was that they were inadmissible in preparing prescriptions, as they were not sanctioned by the College of Physicians.

While making some remarks upon this subject, Mr. Henry Deane stated that he had made a calculation what the cost would be in a small establishment to make infusions "fresh" every morning, and he found it to be about £8.

In Mr. J. Gardner's second paper on the subject† he said that if the College of Physicians were right in ordering boiling water as the best solvent of the substances ordered to be prepared by hot infusion, he did not see what there could be to prevent the practical pharmacist from producing concentrated infusions which would keep well, and would, when diluted, be equal, if not superior, to those made in the ordinary way.

(To be continued.)

NITRITE OF AMYL.

BY C. UMNEY, F.C.S.

Although the experiments made by therapeutists with nitrite of amyl, have been upon somewhat a limited scale as compared with the research bestowed upon other novel remedial agents, still even now, without the charm of novelty, there may be many practitioners who are desirous of further experimenting with such a potent body.

In order to give the physician an opportunity of fairly estimating the value of this medicine, it is necessary that the pharmacist should supply it in a state of almost absolute purity.

It is much to be regretted that at the present time most of the nitrite of amyl, as found in the leading pharmacies in town, is far from being uniform; indeed, it is in a most unsatisfactory state, as the following experiments show.

It will, however, be well to preface the publication of the details by saying that *true nitrite of amyl* should be made by passing nitrous acid into amylic alcohol, which has been previously subjected to fractional distillation until the portion retained for use has a boiling-point of 132° Cent. A nitrite so prepared, when deprived of any excess of acid it may contain by rectification over fused potassic carbonate, will have a boiling-point of 98°–99° C.

A glance at these tables will clearly show the great difference in the various specimens examined. The deviation from the correct boiling-point evidently indicates that in specimen γ more especially, crude or merely rectified fousel oil was used for its preparation, without any previous subjection to fractional distillation.

Specimen β was certainly some little better, but far from perfection; upon α care had evidently been bestowed, but this doubtless might be considerably improved.

Surely with such a valueless basis as fousel oil, greater pains might be taken for the production of pure amylic alcohol as a starting-point, in order to produce a nitrite that would be reliable, instead of one likely to become a source of annoyance to the profession, and a disgrace to our art.

Laboratory, 40, *Aldersgate Street, E.C.*

ALOES.

BY WILLIAM A. TILDEN, B.SC., F.C.S.

The appearance of a note by the Messrs. Smith on the "Purgative Action of Aloes" affords me an opportunity for explaining one or two points in my paper on an allied subject which are not quite so clearly stated as I could wish.

Under the head 'Aloetin' in my paper, the view is expressed that it is a mixture of anhydrous aloin with a brown oxidized substance "referred to, further on." By an absurd oversight, which can only be explained by the hurried manner in which the account of these experiments was collated from my notebook, definite allusion to this oxidized substance is altogether omitted in the subsequent part of the paper. An apology for this omission is therefore due to the Conference, and acknowledgment to the Messrs. Smith for taking the trouble to draw attention to it. The following passage, however, does occur in the original paper:—"It is, of course, already known that if kept in a moist state in the water-bath for some time, the pure substance becomes gradually brown, and assumes the appearance of Socotrine aloes." And again, in paragraph IV. "The acidity to test-paper presented by an infusion of aloes is a property of the half-oxidized substance contained in the uncrystallizable *aloetin*." This was the brown substance to which I intended to refer. In the absence, as I fancied, of any evidence pointing to aloin as the active part of aloes, in presence of the experiments adduced by Robiquet (*The Chemist*, 1856), and of the fact that I have myself repeatedly taken in the course of these experiments doses of ½ grain and 1 grain of pure crystallized aloin without discovering the cathartic action with which it is credited, I attributed to this substance in my own mind the qualities for which aloes as a drug is valued. I am, however, perfectly open to receive information on this point, and to modify my opinion accordingly. My desire was to express that opinion with due caution and reserve. With reference to the employment of aloin in medical practice I must, however, say that in my own experience, and in that of pharmacists of whom I have made inquiries, aloin is but rarely prescribed here in the south, and indeed there are few druggists who keep it in stock.

The action of the air upon alkaline solutions of aloin or of aloes is to produce a body, or mixture of bodies, whose distinguishing characteristic is absolute freedom from bitterness. It was certainly not this substance which I desired to indicate as that to which preparations of aloes owe their activity, nor do I believe it to be a constituent of aloes in its ordinary condition, at least to more than a trifling extent. The main point in my paper was to furnish an answer to the question, why does decoction of aloes lose its bitterness? I reply that it is in consequence of the absorption of oxygen by the aloin; this extreme stage of oxidation being scarcely obtainable except in the presence of free alkali.

IMPROVED MOULD FOR SUPPOSITORIES AND PESSARIES.

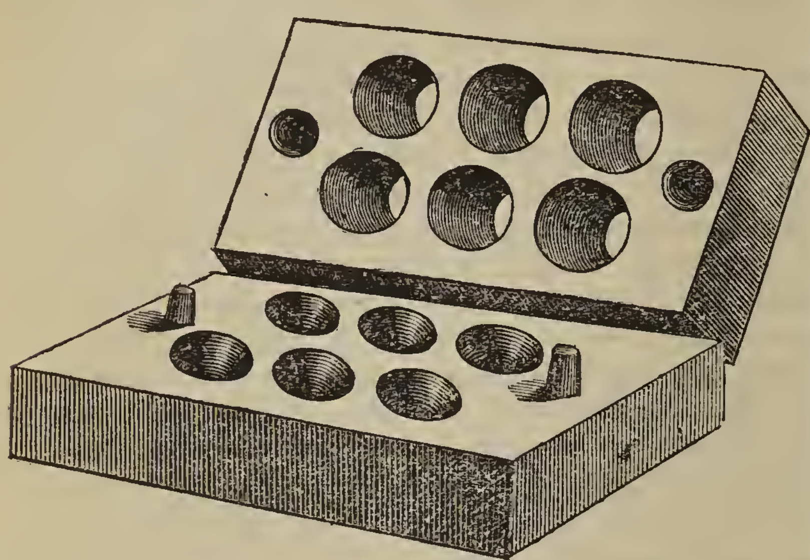
BY A. W. GERRARD,

Dispenser, Guy's Hospital.

Between three and four years ago the subject of medicated suppositories and pessaries, and the best kind of mould for casting them, engaged the attention of pharmacists, and a paper was read before the Pharmaceutical Society by Mr. H. B. Brady, in which he discussed the various means employed for moulding them, and rightly came to the conclusion that metal moulds would be found the most convenient, giving the best results. At the same time he introduced a mould, made at his suggestion, by Messrs. Maw and Son, which, I believe, has come into general use.

On examining Mr. Brady's pattern (an illustration of which may be seen in the number for May, 1866), it will be observed that it is a piece of metal divided into three by a longitudinal section passing through each row of holes, these three pieces open upon two hinges for the purpose of removing the cones; there is also a fastening at each end which holds it firmly together. Whilst using one of these, it seemed to my mind unnecessarily complicated, and that one could be made simpler and cheaper, giving equally good results.

The mould which forms the subject of the accompanying illustration is the result of my experiment. It is composed of two pieces of metal, one lying upon the other, kept in position by a pin at each end; the holes are drilled through the top into the bottom piece, the two pieces thus forming a transverse section through the apertures. The two flat surfaces which meet together form a perfect joint, the weight of the top piece of metal being sufficient to keep it in



position, so that none of the melted material can run between. The working of this mould is comparatively easy. Having poured in the substance and allowed it to cool sufficiently, it is only necessary to lift the top piece from the bottom, which brings the suppositories with it, then a gentle pressure with the thumb easily removes them. From my practice and that of others, I find this mould answers extremely well, and its simplicity over that of the other will enable it to be sold much cheaper.

I will add a few practical remarks on the successful working of the moulds, and the making of suppositories. Let the moulds be perfectly clean, and as cold as possible before using. Whilst pouring in the material, stir continually, otherwise the amount of active principle will vary in each cone. In dealing with tannin, do not use too great a heat, or it will run together, forming a resin-like mass, which is unmanageable and useless. Various agents have been proposed to assist the removal of the cones, but in my experience I have found nothing answer so well as the condensation of moisture obtained by breathing into the holes immediately previous to pouring in the fluids. If these precautions are neglected, whether this mould be used or any other, failure may be the result; it will not, however, be the fault of the machine, but of the machinist. In this as in many other branches of our profession, it is the skill, dexterity and common sense of the manipulator that ensures perfect success.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

ALUMEN.—The most interesting process by which alum is made, and by which large quantities are produced, is that in which 'alum schist' is the material employed. This mineral is a rough silicate of alumina, containing iron pyrites, $Fe\,S_2$. By roasting it, and afterwards exposing it to the air, oxygen is absorbed, and the mineral effloresces and crumbles down to a crystalline mass. This, treated with water, gives a solution which contains sulphate of aluminum and ferrous sulphate; concentrated and mixed with sulphate or chloride of ammonium it gives alum, which crystallizes out, and a salt of iron, which is drawn off in the mother-liquors.

The salt is purified by recrystallization. The alum of the Pharmacopœia is not the only salt known under this title. *Alum* is, in fact, a generic name for a class of double sulphates, containing one of the univalent metals, and one of those which, like aluminum, forms a sesquioxide. They all crystallize in octahedra, and contain the same amount of crystallization-water.

Ammonia Alum, B.P.	$(NH_4)_2SO_4$,	$Al_2 3SO_4$	$24H_2O$
Potash Alum	K_2SO_4,	$Al_2 3SO_4$	$24H_2O$
Chrome Alum	K_2SO_4,	$Cr_2 3SO_4$	$24H_2O$
Iron Alum	K_2SO_4,	$Fe_2 3SO_4$	$24H_2O$
Or	$(NH_4)_2SO_4$,	$Fe_2 3SO_4$	$24H_2O$

Common alum is soluble in about eighteen times its weight of cold water, and the solution reddens litmus strongly. [§ Its aqueous solution gives, with caustic potash or soda, a white precipitate (aluminic hydrate, $Al_2 6HO$) soluble in excess of the reagent, and the mixture evolves ammonia, especially when heated. The aqueous solution gives an immediate precipitate with chloride of barium (this shows it to be a sulphate); it does not acquire a blue colour from the addition of yellow or red prussiate of potash.] This last test is intended to indicate that it is free from iron; but no ordinary alum is ever met with so free from impurity as this would indicate. Traces of iron do not interfere with the application of alum to ordinary purposes, and probably its complete removal by any practical method would be impossible.

Dried alum is nearly insoluble in water, but recovers its solubility by long boiling.

Roche alum was originally a native salt (roche, French=rock), but is now always a factitious substance, made by stirring up some oxide of iron with alum solution whilst crystallizing.

AMMONIÆ CARBONAS.—[§ Produced by submitting a mixture of sulphate of ammonia or chloride of ammonium and carbonate of lime to sublimation.]

Ammonia gas is lost in the operation, and the salt which condenses in the solid state is of very uncertain composition. The formula given in the Pharmacopœia, $N_4H_{16}C_3O_8$, is intended rather to indicate the average composition of the commercial salt than to set it up as a compound of definite character. It appears in crystalline cakes, which are often partly made up of a white opaque portion. This is less pungent than the translucent parts, and is probably chiefly acid carbonate. When treated with a small quantity of water, it leaves a residue of acid carbonate, and also when exposed to the air it loses something to which it owes its pungency, and gives the white pulverulent odourless acid carbonate as a residue. It is usually from these characters considered to be a mixture of two salts, one of which is almost certainly the acid carbonate NH_4HCO_3; the other more volatile and soluble portion is by some believed to be the normal carbonate $(NH_4)_2CO_3$, by others the ammonic carbamate $(NH_4)\,NH_2CO_2$, or $(NH_3)_2CO_2$. The latter hypothesis is in accordance with the formula of the Pharmacopœia. The following equation would represent the changes by which it would be formed:—

$$6\,NH_4Cl + 3\,Ca\,CO_3 = 3\,Ca\,Cl_2 + 3\,(NH_4)_2CO_3.$$

Two molecules of the resulting carbonate of ammonia lose ammonia, and the remainder parts with water, so that the actual reaction is somewhat as follows:—

$$6\,NH_4Cl + 3\,CaCO_3$$
$$= 3\,CaCl_2 + \begin{cases} 2\,NH_4HCO_3 \\ 2\,NH_3 \end{cases} + \begin{cases} NH_4NH_2CO_2 \\ H_2O \end{cases}$$

Perhaps the safest and simplest course is to regard it as a compound of carbonic anhydride, ammonia and water $(NH_3)_4\,(CO_2)_3\,(H_2O)_2$.

Ammonii Bromidum.—Usually made by first digesting together iron wire, bromine and water, so as to obtain a solution of ferric bromide, and then decomposing this by a sufficient quantity of solution of carbonate of ammonia. On filtering off the ferric hydrate and evaporating down the solution, a crystalline mass is obtained. Or it may be obtained by decomposing calcic bromide by carbonate of ammonia. The iodide of ammonium is prepared in a similar manner.

[§ A solution of the bromide in water, mixed with mucilage of starch and a drop of an aqueous solution of bromine or of chlorine, does not exhibit any blue colour.] This test shows the absence of iodide; should any part of that salt be present iodine would be liberated, $2\,NH_4I + Br_2$ or $Cl_2 = 2\,NH_4Br$ or $2NH_4Cl + I_2$, and this would form with starch the characteristic blue compound.

Ammonii Chloridum is formed by neutralizing the ammoniacal liquors obtained in gas-making with hydrochloric acid and evaporating till the solution crystallizes. The salt is purified by sublimation. The ammonia which exists in these liquors in the form of carbonate, sulphide, cyanide, etc., is the result of the decomposition at a high temperature of the nitrogenous constituents of the coal. Chloride of ammonium generally contains a little iron and traces of tarry matters; frequently, too, the chlorides of volatile alkaloids (compound ammonias) are present in minute quantity.

CITRATE OF IRON AND QUININE.

In the Practitioner for October the following table is given, showing the results of analyses of six specimens of citrate of iron and quinine purchased in London. According to the British Pharmacopœia, this preparation should contain 20 per cent. of ferric oxide and 16 per cent. of quinine.

No. I.—A. Cooper, Abingdon Terrace, Kensington.—Olive-green scales.

No. II.—W. Lambert Kiddle, 34, Tavistock Place.—Dark olive-green scales.

No. III.—W. J. Jones, 3, Newland Terrace, Kensington.—Very small olive-green scales.

No. IV.—Burgoyne, Burbidges and Co.—Pale yellowish-green scales.

No. V.—Glover and Co., 19, Goodge Street, W.—Golden-brown scales.

No. VI.—Knowles, 33, Seymour Street, Euston Square. Golden-brown scales.

CUCUMBER OINTMENT.

Mr. Luther E. Sale, of Huntsville, Alabama, publishes in the *Chicago Pharmacist* the following as a simple formula for making cucumber ointment:—

Take of Oil of Sweet Almonds, seven fluid ounces.
Spermaceti, eighteen drachms.
White Wax, five drachms.
Glycerine, one fluid ounce.
Green Cucumbers, 4 lb.

Cut the cucumbers in small pieces, mash them in a Wedgewood mortar, let them macerate in their own liquor for twelve hours, express and strain; melt the almond oil, spermaceti and wax together by means of a water-bath; add the strained liquor, stirring constantly, so as to incorporate the whole together. Set aside in a cool place (an ice chest preferred) till it becomes hard, then beat with a wooden spoon to separate the watery portion of the cucumbers from the ointment; pour off the liquor thus obtained, and mix the glycerine with the ointment without the aid of heat by working it with the hands until it becomes thoroughly incorporated. Put up in four-ounce jars, cover with a layer of rose-water, and set aside in a cool place. The ointment prepared in this way will keep sweet and nice for twelve months.

DETECTION OF ADULTERATIONS IN COPAIVA BALSAM.

BY DR. H. HAGER.

The author has met with copaiva balsam adulterated with oil of sassafras. The adulteration is detected in the following manner: 1 c.c. balsam and 2 c.c. concentrated sulphuric acid are mixed; after the mixture has cooled, 20 c.c. alcohol are added, the mixture is heated to boiling, and then set aside. If the balsam be pure, after the addition of the alcohol, a milky grey yellowish or pale reddish yellow liquid is obtained, which on boiling becomes yellow, clear and transparent, a resinous compound settling to the bottom. If adulterated with oil of sassafras, the addition of alcohol produces a dark brown-red colour, becoming after boiling much darker, with a tint of violet, similar to the juice of black cherries.

Oil of turpentine, which is probably rarely used as an adulterant, is readily detected by heating slightly two to four drops of the balsam, dropped upon bibulous paper, in such a manner that no visible vapours are evolved. Oil of turpentine evaporates first and is recognized by its odour.

This test is unreliable if Venice turpentine is used for adulteration. The author invites experiments with the following test, which has given him reliable results: 5 or 6 drops of water and 5 to 7 c.c. balsam are mixed in an evaporating-dish with sufficient levigated litharge to form a thick semi-liquid mass. At a temperature of 20° to 25° C. (68° to 70° F.), a well-marked turpentine odour is given off, if the balsam contains but 10 per cent. Venice turpentine, and even 5 per cent. may be still recognized.

An approximate quantitative estimation of the adulterant may be made as follows: 5 grams balsam, 8 to 10 drops water, and 15 grams litharge are heated for a quarter of an hour in a sand-bath, then for several hours in a water-bath. After cooling, the hard mass is rubbed to powder and boiled with benzin, the liquid evaporated and the residue macerated with 90 per cent. alcohol for several hours. The alcoholic filtrate evaporated to dryness, leaves about 0·2 to 0·3 resin, which when boiled with solution of potash, yields a filtrate which is not or scarcely tinged by sulphide of ammonium. In the presence of turpentine, however, this last residue contains about three-fourths of the resin of the adulteration, and yields with potash a liquid in which sulphide of ammonium produces a bulky brown-black precipitate. The lead compound of the resin of turpentine is soluble in benzin and alcohol, but not the corresponding compound with the resin of copaiva.—*Ph. Cent. Halle*, 1870, 296, 297.

AMOUNT OF ARSENIC IN PHOSPHORUS OF COMMERCE.

BY C. J. RADEMAKER, M.D.

In preparing dilute phosphoric acid according to the process of the U. S. P., the author passes a current of sulphydric acid through the solution, in order to free it from all substances precipitable by that agent in acid solutions, invariably obtaining a yellowish precipitate, which upon examination proves to be sulphide of arsenic.

In order to find the amount of arsenic present in a given quantity of phosphorus, he has resorted to the following process:—

100 grammes of phosphorus were oxidized with nitric acid, the solution diluted and the arsenic precipitated as a sulphide (AsS_5) by means of sulphydric acid, the solution allowed to rest for six days. The precipitated sulphide of arsenic was collected on a filter and washed, transferred to a small evaporating dish and oxidized with nitric acid, and reduced by means of sulphurous acid to arsenious acid, and precipitated in the form of AsS_3, by means of sulphydric acid; the precipitate digested with ammonia, in order to free it from the small amount of sulphur present, the solution filtered from the undissolved matter, and evaporated, dried and weighed, and found to weigh 15 grains, or nearly one gramme.—*American Journal of Pharmacy.*

AN ELEGANT COUGH MIXTURE.

Hydrochlorate of Morphia . . gr. ss
Glycerine . . . . 2 fluid ounces.
Mix. A teaspoonful when the cough is troublesome.

Poisoning by an Escape of Gas.—An inquest has been held at Leeds concerning the death of five persons supposed to have been suffocated by coal-gas during the night of the 12th and 13th November. It appeared that the deceased, who lived in two adjoining houses, were known to have been in good health on the previous day. The families not making their appearance as usual on the 13th, the police and others, late in the day, broke open the doors and windows, when two bodies in one house and two children in the other were found dead. The father and mother of the children were insensible, and the father has since died.

Mr. J. E. Jenkins, surgeon, said that he had made a *post mortem* examination of the body of one of the deceased children, and he was of opinion that death had resulted from narcotism produced by coal-gas. On the bedroom being filled with gas there would be first stupor, then vomiting, and soon total insensibility, which would end in death by the exclusion of atmospheric air.

Evidence was given that upon search being made, it was found that the main-pipe between the two houses was broken across. This seemed to have been caused by the subsidence of earth resulting from the making of a drain underneath.

The jury found a verdict of "Accidental death," with a recommendation to the authorities to require gas-mains to be put on solid ground by the parties to drainage operations.

A New Source of Lead Poisoning.—Dr. Johnson reports in the *British Medical Journal*, a curious case of lead poisoning that has come under his notice at King's College Hospital. There were well-marked symptoms of lead poisoning in the patient, but there was no evidence as to the source of the lead. Upon being questioned as to the materials used in his trade, the patient, who is a portmanteau maker, said that he worked much with a black glazed cloth, which he called "overland cloth," used for making portmanteaus and covers. A portion of this cloth was obtained and examined for lead. Three or four square inches of the glazed cloth were incinerated in a porcelain crucible; a considerable quantity of a greyish-white ash was thus obtained. This was treated with nitric acid, which dissolved it pretty completely with a brisk effervescence. Lead was found in the filtered solution by the following tests:—(1) a white sulphate on the addition of dilute sulphuric acid; (2) a yellow precipitate of chromate on the addition of potassic chromate; (3) a yellow iodide in silky scales on the addition of potassic iodide. The reaction in each case was well marked. The ash contained also a good deal of chalk. Dr. Johnson supposes that the man, who works at his own home, and confesses that he often takes his meals without washing his hands, in cutting the cloth would get his hands covered with the lead-contaminated dust, and that some of this would be swallowed with his food. The man says, too, that he is in the habit of using the cuttings and remnants of the cloth as fuel, and it is possible that some volatilized lead might enter the system through the lungs.

The Colour of Butterflies' Wings.—A writer in *Nature* says that wishing to test the effect of acid on the colours of the wings of a butterfly or moth, he applied muriatic acid to a dried and set specimen of the six-spotted burnet (*Zygæna filipendulæ*). The only change that followed in this and subsequent experiments was that the red became yellow; where there was no red there was no change. Upon applying the acid to the red parts of the red admiral butterfly (*Vanessa atalanta*), no change took place. Comparative examination under the microscope failed to explain the phenomenon, which appears to point out a clear difference in the nature of the wing of a moth and that of a butterfly. A remarkable fact, perhaps connected with this, is that a yellow variety is known of almost every moth containing red in the wings.

Nitro-Glycerine Explosion.—At Frankfort, near Painesville, Ohio, on November 1, two magazines, containing 150,000 lbs. of nitro-glycerine, exploded. Four persons were killed. The buildings in the neighbourhood were greatly damaged, the shock from the explosion being felt for miles. Where the magazines stood are now two ponds of water, 50 feet across and 75 feet deep. The loss to the Glycerine Company is estimated at not less than 25,000 dollars. This is the second explosion of the kind within two months.—*Times.*

Oil of Peppermint as a Local Anæsthetic.—Dr. Alfred Wright, writing to the *Lancet*, says, that a few years ago, when in China, he became acquainted with the fact that the natives, when suffering from facial neuralgia, applied oil of peppermint to the seat of pain with a camel-hair pencil. Since then, in his own practice, he has frequently employed oil of peppermint as a local anæsthetic, not only in neuralgia but also in gout, with remarkably good results. He has found the relief from pain to be almost instantaneous.

Water-Glass as a Bandage.—Professor Darby, of the University of South Carolina, speaks very favourably of the employment of liquid glass in the formation of immovable bandages. He considers it preferable to either gypsum, dextrine, glue, or starch. The mode of application is to envelope the limb in wadding, to protect prominences of bone from undue pressure, and round the wadding to wrap three or more bandages of unglazed muslin, each bandage being freely painted with silicate of potash. Between the second and third bandages strips of muslin saturated in the solution may be applied, to give extra support to the broken parts. The limb should be kept at perfect rest until the bandages are dry, the time required varying from three to twelve hours, according to the amount of material used.—*Medical Times and Gazette.*

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 26, 1870.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes endorsed "Pharm. Journ."*

HENRY DEANE.

We cannot too cordially thank our contemporary, the *Chemist and Druggist*, for the admirable memoir given in its last number of Mr. DEANE. The editor exercised a wise discretion in publishing the paper intact as an autobiography, although, as we gather from the apology offered for doing so, it was sent rather as memoranda from which he might cull such material as suited him for the pages of his journal. No curtailment could have made the record more modest, no addition more interesting and valuable. We would that this memoir could be perused by every registered apprentice and student of our Society, nay, by every youth entering on the business of life, to whom it is all-important to feel that "there is nothing beneath the dignity of a man which is not dishonourable!"

To those who know HENRY DEANE the perusal must be a source of immense pleasure. We laid aside the paper, refreshed by the contemplation of his continuous effort to pursue the right path, to build up knowledge brick by brick, and, while following science for pure love of her, yet so to utilize her benefits at every step as to make himself a benefactor to his fellow-men as well as an ornament to his profession. Long may HENRY DEANE be with us to continue his career of usefulness, and enjoy the respect he has so justly earned!

A FEW copies have lately arrived in England of the 'Supplement to the Pharmacopœia of India,' which consists of a catalogue of Indian synonyms of the medicinal plants, products, and inorganic and organic substances included in the Indian Pharmacopœia, in fourteen languages, with explanatory and descriptive remarks. It has been prepared by Mooden Sheriff, G.M.M.C., and printed and published by order of the Government at the request of the Committee of the Pharmacopœia of India. We hope shortly to be furnished with a copy, so that we may be enabled to give a much fuller notice of the work in our pages.

WE are sorry to hear that the delay in the arrival of the October number of the *Chicago Pharmacist*, has been caused by the occurrence of a fire at the establishment in which it was printed. The whole of the stock of the *Pharmacist*, which was unfortunately not insured, has been entirely destroyed.

THE persistency with which the word "Ozokerit" was kept before the public in advertisements for a considerable time caused an amount of curious speculation, which was remarkably illustrative of the general ignorance prevailing even among the educated classes in regard to natural productions and phenomena. At a time when petroleum and paraffin are things of every-day familiarity, it seems strange, indeed, that no one should have recognized in the name which caused so many silly surmises, an ordinary mineralogical designation of earth-wax, or the natural paraffin, occurring abundantly in Galicia, the Danubian provinces adjoining the Carpathians, and even in this country to some extent. Specimens of it exist in most mineralogical collections, and a report of a chemical examination of the substance was published in the first series of this Journal.*

As will be seen by an advertisement in another part of the Journal, dispensers are required for two of her Majesty's foreign hospitals. The candidates must have passed the Major examination of the Pharmaceutical Society, and be not less than twenty or more than twenty-five years of age.

THE fact that the highest of Civic dignities in this country is now held by a member of the drug trade will be sufficient reason for our pointing out that in several provincial towns the office of mayor is held by members of the trade. Thus at Reading the mayor is PETER SPOKES, Pharmaceutical Chemist; at Launceston, JOHN CHING, Chemist and Druggist; at Richmond, Yorkshire, THOMAS THOMSON, Pharmaceutical Chemist; and at Newbury, R. A. RYOTT Chemist and Druggist.

VISITORS at the Liverpool meeting of the Pharmaceutical Conference will be glad to learn that at a late meeting of the Liverpool Chemists' Association the valuable services of Mr. A. H. MASON, in connection with the exhibition of pharmaceutical objects, met with special recognition, and that the President presented him with three handsomely bound volumes, Longfellow's 'Hyperion,' and Meteyard's 'Life of Wedgewood,' containing the following inscription:—

BRITISH PHARMACEUTICAL CONFERENCE.
Liverpool Meeting, 1870.

This volume, with two others, was presented to Mr. ALFRED H. MASON by the Local Committee, as an expression of their high appreciation of his services, especially in connection with the arrangements for the exhibition.

(Signed) *Chairman*, JOHN ABRAHAM.
Hon. Secretary, EDWARD DAVIES, F.C.S.

It must be as gratifying to Mr. Mason, as it is well deserved to receive such a mark of appreciation.

EDINBURGH MEETING.

The First Meeting of the Session took place in St. George's Hall, 119A, George Street, on Tuesday evening, 21st November, at 8.30 P.M.; Mr. AITKEN, President, in the chair. There was a good attendance. The Secretary announced—

1. The following additions to the Library:—Pereira's Materia Medica. Squire's Companion to the B. P., 7th edition, 1869. Balfour's Manual of Botany (new edition). Animal Chemistry (Odling). Attfield's Chemistry (1869). Bentley's Manual of Botany, 2nd edition. Roscoe's Elementary Chemistry. Selecta e Præscriptis, 2 copies.
2. The following presentations to the Library:—Edinburgh Medical Pharmacopœia of 1722, presented by J. Wilson, Perth. Milne's Materia Medica, 1869, presented by the publisher. Several Numbers of the 'Pharmacist.' Proceedings of American Pharmaceutical Association.
3. Presentations to the Museum:—Two very handsome specimens of Sugar of Milk, from J. C. Pottage, Edinburgh. Various Articles used in the preparation and dispensing of Medicines, from Messrs. Poths and Haas, London. A Series of Sixty-six dried Medicinal Plants, carefully laid down on papers from Mr. Ransom, of Hitchin. These were very much admired.

The PRESIDENT then made the following remarks:—

Gentlemen,—You will have seen from the billet calling this meeting that I am expected to give a few opening remarks.

I am glad that on the present occasion I am neither to be burdened nor to burden you with a long speech, the more so, as I doubt not you are looking forward with some degree of impatience to the interesting paper we are to be favoured with from our esteemed and talented friend Dr. Stevenson Macadam.

Our museum and library are at present in good working order. The curator of the museum will be glad to arrange to meet young men who are desirous of becoming acquainted with the specimens there, for an hour in the evenings, and for this purpose, the Secretary will receive the names of those who may wish to attend, in order that due arrangements may be made, and the time fixed. The admittance will be free to all connected with the Pharmaceutical Society.

The catalogue of the library contains a fair number of works on scientific subjects well worthy of your earnest attention. The Council, therefore, would be well pleased to see those more fully appreciated, and they invite all

"To read who have not read before,
And those who always read to read the more."

A complaint very frequently made, by those particularly who would be well pleased to get over their examinations with the smallest amount of labour or study, is that they have not been taught this or that branch in early life. It may be so, but we are inclined to think, and do consider such excuses as a sort of refuge for inert minds, for generally we find the things a man knows best are those he teaches himself when his mind is matured. Much, no doubt, may be done to improve what is termed a neglected education, but we would have you bear in mind, education to be efficient can never limit itself to the mere giving of information; that the development of the mental powers, the guidance of the mental tendencies, and the formation of taste, are at least of equal importance. It behoves us then to depend as much on our own resources as on the tuition of others. At the same time we ought to lose no opportunity for improvement, in whatever shape it may be placed before us. You cannot, and therefore need not expect all to be prizemen; you may not achieve the greatness or excellence attained by others, but do not imagine you are inferior to them because of the condition in which you may be placed.

"Honour and shame from no condition rise;
Act well your part, there all the honour lies."

As the most casual observer cannot fail to perceive the gigantic strides education has made within the last few years among all classes, he will not fail to discover at the same time the increasing attention being paid to its extension. It is also one of the most encouraging features of our times that much of our former literature, which could find its way to the libraries of the wealthy only, has now been brought within the reach of almost every one.

We would, therefore, have you to read and master what you read, cultivate habits of thinking, and by these means you may place your foot upon the ladder of elevation, which but a few years since could only be surmounted by some genius. Let it be your earnest desire to raise yourselves in the social scale as intellectual and moral beings, keep always in mind, that as

"The twig bends, the tree inclines."

Gentlemen, before closing these few and imperfect remarks, allow me to thank you for the honour conferred in placing me for the third time in the Presidential chair. I beg to say the duties will be performed to the utmost of my ability, and, I trust, to your satisfaction.

Dr. STEVENSON MACADAM read an interesting paper on "Fermentation." He referred to the old theory as to the effect of a nitrogenous substance upon one that was not so, and then introduced the more recent experiments of Dr. Tyndall, M. Pasteur and Dr. Angus Smith. He also referred to the striking effect produced by a certain amount of heat in destroying the spores or germs present in the atmosphere, and which were now believed by many to be the means, acting upon sugar and other materials, of causing the peculiar change which yeast effects in inducing and carrying on fermentation. Dr. Macadam illustrated his subject by several diagrams and tables.

At the close of the paper, a cordial vote of thanks to Dr. Macadam for his interesting and instructive communication, proposed by Mr. BAILDON and seconded by Mr. YOUNG, was unanimously carried.

The SECRETARY then intimated that he would be glad to receive the names of any young men who wished to meet with the Curator of the Museum, who had kindly agreed to devote an hour in the evenings to go over the various specimens contained in the Museum. These meetings would be free, and open to all connected with the Pharmaceutical Society.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The Annual Meeting of this Society was held in the Library of the Association, on Wednesday evening, October 12th, 1870.

The minutes of the previous meeting were adopted, when the following gentlemen were unanimously elected Members and Associates:—

MEMBERS.

Charles Daniel Hart........Burley Road.
John William Hardman ....Woodhouse Lane.
Edward Fenton Atkinson ...Kirkstall Road.

ASSOCIATES.

George Fell Bowman, residing with Mr. Bowman.
John Bradley, " Mr. Stead.
John Exley, " Mr. Exley.
John William Dewhirst, " Mr. Beedle.

The HONORARY SECRETARY then read the

REPORT.

In presenting their Report, your Committee have to state that there is an increase in the number of Members of two as compared with that of last year; but in the number of Associates there is a decrease of eleven. The numbers now in the Association are as follows:—

Members 37
Associates.............. 39

The decrease in the number of Associates is anything but satisfactory, and seems to indicate a feeling of apathy in the junior members of our trade; and your Committee strongly exhort those rising up amongst us to avail themselves of the privileges so liberally offered for a small fee.

The privileges of an Associate are—

1st. Access to a valuable and gradually-increasing library and materia-medica cabinet.

2nd. Admission to the lectures and discussions of the Society at the monthly meetings during the session.

3rd. If an Associate wishes information upon any particular point, a written query dropped into the question box elicits the desired intelligence.

4th. Attendance at certain chemical and botanical lectures at the lowest fees.

5th. Power to compete for certain prizes occasionally offered. Probably, if more would come forward to contest, more prizes would be forthcoming.

All these advantages are open to our Associates at the nominal charge of 2*s.* 6*d.* per annum, or a fraction over one halfpenny per week. Your Committee, therefore, earnestly urge upon all assistants and apprentices in this district that, if for no other reason, they ought from a feeling of self-interest to join the Leeds Chemists' Association.

At the last annual meeting, after the transaction of the usual yearly business, the newly-elected President, Mr. Wm. Smeeton, read an address in which he earnestly advised our associates to cultivate habits of observation and of mental application. At the second meeting, Mr. E. Thompson gave an interesting account of the construction and uses of a few meteorological instruments lent for the occasion by Messrs. Harvey, Reynolds and Co. Mr. James Abbott occupied the third meeting; subject, "Palms and their Products." The paper read was interesting and full of facts. At the fourth meeting, a Member failing to be ready with the expected paper, Mr. R. Reynolds considerately filled up the gap, and reviewed some portions of the proceedings of the American Pharmaceutical Society. Mr. Samuel Taylor read, at the fifth meeting of the session, an essay "Upon some Articles of Every-day Request." The President favoured the concluding meeting with the results of his experience in the preparation of linimentum potassii iodidi cum sapone, and of chloral hydrate; and, after a short discussion, Mr. E. Thompson introduced the proposition of the Council of the Pharmaceutical Society with respect to certain proposed regulations for keeping, selling, and dispensing poisons. The proposed regulations, being considered unnecessary and prejudicial to the interests of the trade, a committee was appointed to draw up a memorial against the same, which, with a statement of objections attached thereto, was presented to the Council of the Pharmaceutical Society. The effort made was successful, and it is not likely that the objectionable regulations will ever become law.

Your Committee thankfully acknowledge the receipt of some valuable gifts to the library and museum:—'The Pharmaceutical Journal,' from the Pharmaceutical Society; 'A Medico-Botanical Map of the World,' and two books of labels, from Mr. Barker, of Liverpool; 'A Post-Office Directory of the Manufacturing and Retail Chemists of England,' from Mr. Edwin Yewdall; Portraits of Dr. Pereira, Mr. Wm. Allen and of the late Jacob Bell, Esq., from Thomas Hyde Hills, Esq.; 'The Chemists and Druggists' Almanack,' from Mr. R. Reynolds; nine specimens of roots, fruits, etc., from Mr. James Collins, Curator of the Pharmaceutical Society; 'A Collection of Prescriptions,' from Joseph Ince, Esq.; three specimens of fruits, etc., from Mr. R. Reynolds.

In order to secure the successful working of the library, it has been judged expedient to alter certain bye-laws.

Four Associates competed for the prize of one guinea offered by Thomas Harvey, Esq., for the best herbarium. Two of the herbaria were not very unequal, and yet much superior to the others; and Mr. R. Reynolds therefore kindly offered a prize to be given to the collector of the second in order of merit. The first prize was obtained by Mr. Frederick Casson, and the second was awarded to Mr. Francis Mather.

Twenty-two Associates have attended Mr. Ward's lectures on chemistry, and, according to that gentleman's statement, have made creditable progress. Seven of these have passed the Science and Art examination.

Messrs. R. M. Atkinson and R. Reynolds attended the British Pharmaceutical Conference, lately held in Liverpool, as delegates from our Society.

Your Committee deeply regret the resignation of their Secretary, Mr. Edwin Yewdall, on account of ill-health and by medical advice. Whilst tendering him their hearty sympathy on this occasion, they offer him warm thanks for the unremitting zeal he has manifested in furthering the interests of the Association, and trust at the next annual meeting he will feel able to resume those duties which he has heretofore so satisfactorily discharged.

When the accounts were audited, it was ascertained that there was a balance due to the Secretary of nine shillings and sixpence.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The First Ordinary Monthly Meeting of the session was held in the Memorial Hall, Albert Square, on Friday evening, November 4; Mr. W. S. BROWN, President, in the chair. Tea was served at 7 P.M.

The formal business of the meeting included the election of about twenty new associates.

A resolution was then passed expressive of the deep regret felt by the officers and members of the Association on hearing of the death of Mr. Charles Wright, so long and honourably connected with the business in Manchester.

Letters were read from Professor Attfield and Mr. T. H. Hills expressing their satisfaction in having been elected honorary members of the Association.

The PRESIDENT then called on Mr. Benger to introduce the subject chosen for discussion, "Pharmaceutical Education and Apprenticeship," by reading a paper he had contributed to the British Pharmaceutical Conference.

Mr. BENGER having read this paper, added, it was scarcely an appropriate introduction of the subject to a local association. He hoped nothing he had said would be construed into disrespect for any of the older members of the trade. Nothing could be further from his intentions than to depreciate the value of apprenticeships served to some non-scientific chemists and druggists; there are hundreds of thoroughly practical men whose success amply testifies to the wisdom and skill with which they have conducted their businesses. The privilege of serving an apprenticeship to such men is great, and will be appreciated by all sensible young men. Business habits cannot be acquired in the lecture-room, but by the careful, observant study of the business transactions of honourable men. An important point seems to be, how much and what kind of personal scientific instruction the apprentice can reasonably expect to receive at the hands of his master. He must depend mainly on his own efforts; he pays a premium to be introduced into a special field of observation, the amount of premium generally depending on the extent of that field, while the advantages he derives depend on his own powers of observation and the use he makes of them. It is essential to his success that he shall have acquired previously, or that he acquire at an early stage of his apprenticeship, some knowledge of the sciences bearing upon pharmacy. Should his master be competent and willing to undertake the direction of his studies in these subjects, so much the more money value should be attached to the indenture, but this should be clearly understood by the contracting parties. It must not be assumed that a body of men accustomed to conduct businesses in which scientific knowledge has been often wellnigh superfluous shall, upon the passing of a Pharmacy Act, be able suddenly to transform themselves into professors of chemistry and botany. Should the medical profession confine itself more strictly to the practice of its legitimate duties, the rising generation of pharmacists may, and doubtless will, have more general need of scientific knowledge; and, having availed themselves of the facilities now afforded for its acquirement, will, in their turn, be competent to instruct their apprentices in these higher branches of pharmaceutical education, but he thought that in ordinary apprenticeships the masters' responsibility does not extend so far. On the other hand, accurate scientific knowledge of no trifling nature is absolutely demanded by the Pharmacy Act, and the apprentice has a perfect right to inquire what opportunities will be afforded him for meeting these requirements. In London and large provincial centres, where courses of lectures are provided with a library and museum open for study, much difficulty need not be apprehended; but there still remains a large number of apprentice-taking businesses scattered throughout the smaller towns of the country where such opportunities do not exist; and in such situations a young man who had previously become possessed of a sound elementary education in science would have many advantages over his fellows located in large cities,—more leisure and more opportunities for following up some of his studies. It is probable that the improved school system about to be introduced by Government will afford such an education, otherwise it might be given in some such special technical school as he had suggested; failing these, it will always be desirable that the apprentice, on completing his term, shall obtain employment where the efforts of local association have provided the necessary means of scientific education. There is, he feared, in the present day much danger of regarding the passing of examinations as the main object of study, and an inclination to do just so much and no more than would ensure that end. It is this spirit which encourages the pernicious system of cramming. The chief aim of elementary scientific education must be to create a taste for and a love of the subject. In conclusion, he quoted some remarks bearing on this by the late Dr. Channing:—"The mark of a good teacher is not only that he produces great efforts in his pupils, but that he dismisses them from his care, conscious of having only laid the foundation of knowledge, and anxious and resolved to improve themselves. One of the sure signs of the low state of instruction among us, is, that the young on leaving school feel as if the work of intellectual culture were done, and give up steady vigorous effort for higher truth and wider knowledge. The universe is charged with the office of education; it is not confined to a few books anxiously selected by parental care. Innumerable voices come from all they see, meet, feel. Nature, society, experience are volumes opened everywhere, and perpetually before their eyes. They take lessons from every object within the sphere of their senses; from the sun and stars; from the flowers of spring and from the fruits of autumn; from every associate from the pursuits, trades, professions, in which they move; all these, and more than these, are appointed to teach, awaken, and develope the mind.

Mr. Waterhouse (Ashton) agreed in the main with what had been said, but he thought if apprentices had received a good English education, there would be no great difficulty about technical matters, with the help of Associations like their own.

Mr. Siebold remarked on the much larger proportion of successful candidates in the examinations than formerly, and attributed this partly to the help of local associations.

Mr. Wilkinson said that all the 11 apprentices who had presented themselves at the last "Preliminary" in Manchester had passed, still there was a very large proportion of those who had examinations to pass who could not or did not avail themselves of the lectures and classes now going on.

Mr. Woolley, alluding to the proposed assistance from the Pharmaceutical Society, thought such help should be at first directed to those who had entered the business previous to the passing of the Pharmacy Act.

The Chairman, Mr. Siebold, Mr. Bostock, and others, spoke with approval of the class for mutual improvement which had just been formed amongst the associates, the Chairman promising that the Council would give it all possible assistance and encouragement.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The Second General Monthly Meeting of the present Session was held in the rooms of the Association, on Wednesday, November 9th; the President, Mr. Wilson, in the chair. A lecture was delivered by Mr. F. T. Griffiths, Esq., M.D., upon "The Nightshades,"—it was of a most interesting and instructive character, comprising an enumeration of the natures, properties, and histories of the varied classes belonging thereto. The following is a brief abstract.

The *Solanaceæ*, or Nightshade family, constitute one of the richest and most interesting group of plants, and their history is also very complex. If amongst them are some worthy of honourable mention, there are many, on the contrary, which come short of glory. Nightshades and felonworts do not all possess lenitive properties; there are in the group many other plants, and, perhaps, the best known are those which represent nothing less than a collection of violent poisons. The general physiognomy of these unwholesome plants fully justifies the unflattering names given to them from the time of Linnæus, who termed them all livid, even to that of modern botanists, who stigmatized them as suspicious, venomous or hideous. Poisonous principles are entirely absent in some species, or, if present, are so in such small proportions as to exercise but feeble influence over the animal economy; whenever they are secreted in an appreciable quantity, we may affirm that they are similar, and that they belong to that class of poisons which are specially noxious and stupefying. The special details of this family of plants afford sufficient materials for the purpose of classification, and botanists have been able to establish the characteristics rigorously based upon the nature of the fruit, sometimes bacciform, *id est*, more or less succulent, as that of the tomato or the potato, and sometimes capsular, that is dry, like those of tobacco and of the stramoniums. Thus they have been grouped into two grand general sections, subdivided into six varieties, and from these we select and glance rapidly at the history of the most important species.

Belladonna, *Atropa Belladonna*, whose generic name was taken by Linnæus from that of Parque, *Atropus*, owes its specific name of "beautiful lady" to the reputation which lotions compounded from the plant had in Italy for preserving beauty; this solanum is tolerably common everywhere in woods and uncultivated spots around our dwellings; it hides in the angles of old walls and ruins, and it is thus too often found by children and ignorant persons, who, seduced by its aspect and sweet taste, become victims to their curiosity. The stems and the root are not less dangerous than the leaves and berries; amongst the symptoms of intoxication by belladonna is that which is termed *carphologie*, which means a seeking for little objects; the affected person imagines he sees insects everywhere around him, small birds continually flying before him, and he madly excites himself in their useless pursuit; amongst the numerous symptoms of poisoning by this plant are violent delirium, extreme agitation, frightful visions, dilatation of the pupils of the eye, etc.

Thorn-apple, *Datura Stramonium*, known also under various names as stramonium, devil's herb, or sorcerer's herb; the Arabs call it datora, the Persians tatula,—the word is manifestly derived from the radical "tat," which means to prick or puncture, in allusion to the spinous envelope by which the fruit is protected. It is of all poisonous solanals the most energetic and the most remarkable; it is the one which has caused the most serious accidents. A decoction of three capsules, made with milk, was taken in mistake by a man, and it occasioned in him a furious delirium, followed by general paralysis, which continued for several weeks.

The hyoscyamus, nicotiana, mandragora, *Solanum Dulcamara*, etc., were also fully treated of, and their poisonous natures and peculiarities illustrated by numerous interesting anecdotes by the lecturer, who proceeded at some length to describe the alkaloids—atropine, hyoscyamine, daturine, solanine and nicotine, their therapeutic properties, physiological action, etc., and concluded by a short *résumé*, in which he spoke of the general symptoms produced by the toxic action of the solanals, manifesting themselves with a constancy which supplies valuable indications for the treatment of the poisoned victims, and for the detection, and perhaps punishment, of the poisoner. The eminently irritating action of the solanals concentrates itself in the brain, where it is rendered manifest by the contraction of the temples, the redness of the face, the intense headache, delirium and convulsions. Irritation is then the first effect produced. Later on, a second effect is stupor; but it must be borne in mind that this stupor is only due to the irritation exalted to its highest pitch; it is only when the cerebral inflammation has, by congestion, distended the vessels and tissues of the brain so as to cause their compression against the bones of the skull, that dull and profound narcotism begins. This narcotism differs also from that produced by certain other somniferous plants, such as opium, for example. In the latter case, it is rather a languishing of the nervous system, or the retardation of the circulation of the blood which induces sleep; in the former, on the contrary, it is because the blood is over-driven at first, and subsequently reduced to impotence by the excess, that the vital activity falls into torpidity.

At its conclusion a cordial vote of thanks was awarded by the members present to the lecturer.

Messrs. Branson, Collinson, Davy, Horsfield and A. and C. Laycock, of Rotherham, were elected members, and Messrs. Blacker, Booth, Hollinrake, Johnson, Learoyd, Robson and Thomson, associates.

The PRESIDENT announced the following donations to the library and museum:—Thirty-seven bound volumes of the *Lancet* and seven volumes of Bell's 'Surgery,' from Mr. Nathaniel Booth, of Rotherham, and a cabinet collection of minerals and metals from Messrs. Cutley and Preston, High Street.

Mr. G. B. COCKING proposed and Mr. HUDDLESTONE seconded a vote of thanks to Mr. Booth, and Mr. WILSON proposed and Mr. WATTS seconded a vote of thanks to Messrs. Cutley and Preston for their handsome donations, both of which were unanimously carried. This concluded the business of the meeting.

DUNDEE CHEMISTS AND DRUGGISTS' ASSOCIATION.

The First General Meeting of Session 1870-71 was held in Lamb's Hotel on the 9th of November; Mr. LAIRD in the chair.

The following were elected office-bearers for the session:—*President:* Mr. Wm. Laird, Ph.C. *Vice-President:* Mr. David Russell. *Treasurer:* Mr. G. Jack. *Secretary:* Mr. Jas. Russell. *Council:* Mr. A. B. Anderson, Mr. Wm. Doig, Mr. D. H. Ferries, Mr. C. Kerr, Ph.C.

The report from the Committee having been read, it was resolved to rent a room, in order to facilitate the formation of classes for instruction of apprentices in chemistry, materia medica and pharmacy. A Committee was appointed.

A vote of thanks to the Chairman terminated the proceedings.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Second General Meeting of this Association was held at the Royal Institution, on the 10th November; the President, Mr. JOHN ABRAHAM, in the chair. There was a large attendance.

The minutes of the previous meeting were read and confirmed.

Letters were read from Messrs. Attfield, Stoddart, and Hills, acknowledging their election as honorary members.

Mr. Joseph Hallawell, Mr. Charles C. Bell, and Mr. Thomas Williams were elected members.

Mr. William Hallawell, Mr. Edward Olivant, and G. Harriman were elected associates.

The PRESIDENT exhibited a bottle, labelled "Palatable Cod-Liver Oil," which contained a mixture consisting of nine parts of cod-liver oil and seven parts of syrup, flavoured with lemon and oil of aniseed or dill. Particular care was taken to cover the whole of the bottle with the labels, and prominent instructions were given that "the bottle should be well shaken." He observed that a circular accompanied each bottle, with testimonials from medical men and some who held the title of F.C.S., and he could not understand how such men could lend their names to a practice by which the public were led to believe that they were purchasing genuine cod-liver oil, whereas what they received was only about half oil. He strongly condemned such a practice, and was unanimously supported by the members in an animated discussion which followed.

The SECRETARY exhibited a sample of chiretta, falsely packed with munjeet (*Rubia cordifolia*), presented to the museum by Messrs. Evans, Sons and Co., a description of which appears in the PHARMACEUTICAL JOURNAL, 3rd Series, No. 10, page 367.

Mr. RICHARD EVANS (Cleveland Square) called attention to the correspondence which appeared lately in the PHARMACEUTICAL JOURNAL respecting poisonous feeding-bottles, and stated that six years ago, one of his children died, and upon application to the medical man who attended the child for a certificate of death, it was refused, the child exhibiting strong symptoms of having been poisoned, which symptoms he considered were produced from the use of an ordinary feeding-bottle, the white tubing, not being india-rubber, but a composition (consisting of india-rubber dissolved in 10 per cent. of bisulphide of carbon, and thickened up with white lead, resin, and sometimes oxysulphuret of antimony, to give it a pink colour), from which, when coming in contact with the milk, sulphuretted hydrogen was evolved, and lactate of lead formed in the stomach. He exhibited a feeding-bottle (which he had originally made for use in his family for some years, but at the request of many friends and medical men, he now had it for sale), the advantage of which was that the tubing and teat being formed of native rubber, vulcanized by means of magnesia, none of the evils mentioned in the other case could possibly occur. He stated that Dr. Nevins, the lecturer at the Royal Infirmary School of Medicine, had been so convinced of the value of this arrangement, that he recommended the students when they met with cases of vomiting, griping, and diarrhœa in infants, to ascertain how they were fed, and if the white tubing was used to treat the patient for lead poisoning.

Mr. A. Norman Tate, analytical chemist, stated that at the request of a medical gentleman, he had analysed some samples of tubing, and found lead in each.

Mr. Davies had tested several samples with the same result, and testified the value of Mr. Evans's suggestion from practical experience.

Mr. Edward Davies, F.C.S., read a paper upon "Ozone," of which the following is an abstract:—

When the electrical machine was invented, it was soon noticed that a peculiar odour was produced during the working of the machine. Von Marum, about a century ago, found that on passing sparks through oxygen it assumed the same smell and attacked mercury.

In this state our knowledge of ozone remained until Schönbein published his first paper on ozone in 1840, showing its production in the electrolysis of water, and afterwards in the slow oxidation of phosphorus.

Ozone can be prepared in many ways. 1st. Clean phosphorus is put into a bottle with a little water for an hour or two, then removed, and the enclosed air well washed to remove phosphoric acid. 2nd. A hot glass rod is held in a vessel containing ether vapour and air. When the rod is sufficiently heated, in the dark a pale blue lambent flame, resembling that emitted by phosphorus, is seen. If oxygen be employed instead of air, and a heated glass tube used, an explosion ensues. 3rd. By the electrolysis of water strongly acidulated; according to M. G. Plante, more ozone is obtained by using lead electrodes. 4th. By electrical discharges in air or oxygen. This method yields the largest quantity of ozone. By passing dry oxygen through Siemen's ozone generator (which is essentially a Leyden jar, the two coatings of which are connected with the terminals of an induction coil), a stream of strongly ozonized oxygen may be obtained. 5th. By the action of strong sulphuric acid on permanganate of potassium. It is also said to be produced during chemical combinations, as that of sulphuric acid with potash, in fermentation and putrefaction, and by plants when in flower.

The tests used to indicate its presence are:—1st. Paper brushed over with starch-paste containing iodide of potassium; the ozone oxidizes the potassium, and the free iodine unites with the starch. 2nd. Red litmus moistened with solution of iodide of potassium. The potash set free turns the paper blue. 3rd. Paper moistened with solution of sulphate of manganese. The paper turns brown from formation of di-oxide of manganese. 4th. Paper moistened with oxide of thallium, which turns brown owing to formation of peroxide of thallium.

Ozone tarnishes silver foil and mercury; corrodes cork and india-rubber; oxidizes indigo into isatin, ferrocyanide of potassium into ferricyanide, and destroys bad smells. Peroxide of manganese and peroxide of lead convert it into ordinary oxygen without undergoing change themselves; peroxides of hydrogen and barium also convert it into ordinary oxygen, and are decomposed into oxygen and protoxides.

Ozone possesses a powerful odour, from which it derives its name—οζειν signifying, to have a smell. It is almost insoluble in water.

Oxygen in the free state is combined with itself to form a molecule, which may be represented as $\oplus\ominus$. The view of ozone generally received is that it is $\ominus\oplus\ominus$ condensed into two volumes. This view is supported by the fact that when put in contact with iodide of potassium it does not contract. If this be so, when ozone is produced by electrical action, either both atoms of ordinary oxygen must become negative and unite with ordinary oxygen, or the molecule must split into positive and negative oxygen, and a molecule of antozone $\oplus\ominus\oplus$ be also formed. Antozone has, however, not been satisfactorily isolated, unless the fumes produced in contact with water when ozonized oxygen is passed through iodide of potassium solution consist of antozone mechanically mixed with aqueous vapour (Meissner). Williamson and Baumert considered ozone to be H_2O_3; but this view seems disproved by the experiments of Andrews.

Ozone is found generally in the air, Dr. Richardson says that the amount may be $\frac{1}{10000}$. It is absent generally in large towns, especially in close courts. It is doubtful if it produces disease, though catarrh may be a result of excess, as it produces the symptoms of that disease when inhaled. Equally uncertain is the action which it exerts in preventing disease. According to some observers the occurrence of cholera is coincident with absence or diminution of ozone, and its departure with a return of ozone. Against this view must be set the observations of Father Denza, that in Turin during cholera the amount of ozone remained an average quantity, and of M. Fournet, that at Lyons, where no ozone can ever be detected, cholera is not more frequent or severe than elsewhere.

Many of the discrepancies observed may be due to the method used for measuring the amount of ozone. This, consisting in the use of iodide of potassium and starch papers, is liable to many sources of error. Many other substances will set iodine free besides ozone, and the tendency of free potash to convert free iodine into iodide and iodate of potassium, must have some influence on the delicacy of the test. Until some more certain means is discovered, present observations must be received with great caution, or the knowledge which we possess will be worse than ignorance, as being calculated to mislead.

The methods for preparing ozone, and the various tests for it mentioned by Mr. Davies, were fully and ably illustrated by many very successful experiments.

The President said that at the *soirée* of the Pharmaceutical Society an apparatus was exhibited for producing ozone in large quantities.

A discussion followed, in which Messrs. Tate, Wright, Blair and Samuel took part.

Mr. A. Norman Tate said he was very glad to hear Mr. Davies close his valuable paper as he did. He had always avoided ozone, as he considered the knowledge that chemists had of it was worse than ignorance, as ozone was often said to be present when other things might exist. He complimented Mr. Davies on his concentration of the subject, and moved a vote of thanks.

Mr. Blair, in seconding the vote, said that when ozone was absent cloth goods would not dye, and instanced the remarkable effect of a thunderstorm, during which the power of the mordant was increased, and the stuff was dyed. In the island of Skye ozone was very abundant, and the people never suffer from catarrh. He considered also that if ozone could be produced in quantity at a reasonable rate, it would be of great service to decolorize sugar.

The vote having been carried by acclamation, Mr. Davies returned thanks, and the meeting separated.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

MEETING AT LIVERPOOL.

Wednesday, September 14th.

(*Continued from page* 418.)

NEPAUL ACONITE.

BY T. B. GROVES.

It had been my intention to furnish the Conference with a general view of the recent researches of Professors Flückiger and Klebs on the aconite bases, but for several reasons I now abstain from doing so. In the first place, Professor Flückiger has himself communicated to the PHARMACEUTICAL JOURNAL a *résumé* of his long and able paper, and secondly, poor Professor Klebs, to whom had been entrusted the physiological portion of the inquiry, having been prevented by illness from elaborating his notes on the termination of the experiments, has now been ordered to the front as a military surgeon, leaving his manuscripts unaccessible, and nothing further published respecting his labours than is to be found in Professor Flückiger's paper already alluded to. I much regret this delay, as I should attach the first importance to such method of testing in the case of substances so ill-defined chemically, so susceptible of modification in the process of extraction, and withal so immensely powerful in their action on the living body, as are the group of aconite alkaloids.

Flückiger's motive in undertaking his investigation was a desire to determine whether or no there were at the present time two different aconitinas supplied to the medical profession, and if so, in the second place to determine exactly their respective characteristics, and lastly, to ascertain the source from which each alkaloid was derived.

In the first and second parts of the subject, he was highly successful, and pharmaceutists are greatly indebted to him for establishing indubitably the fact that there are both aconitina and pseudaconitina. As regards the source of the latter, he regrets his inability to settle the moot question, whether it owes its origin to the Indian aconite roots known under the name of Bikh, or not. Von Schroff early declared that such was the case, and that he had extracted from Bikh roots an alkaloid he regarded as the acrid principle of aconite, as distinguished from the narcotic principle represented by German aconitina. But he unfortunately identified this acrid principle with Morson's aconitina, which substance Flückiger was able to prove identical with the German article, and moreover, that it for many years had not perceptibly altered its character. Flückiger's examination of Bikh, limited to the physiological testing of an extract of that root, pointed to the conclusion that it contained aconitina, not pseudaconitina. It will be well here to read a summary of Flückiger's conclusions.

1. Aconitina is found in the roots of the European blue-flowered aconites, especially *A. Napellus.*

2. It is also found in the Himalayan species that go by the name of Bikh, amongst which occurs *A. Napellus,* sp.

3. According to Hübschmann aconitina is wanting in *A. Lycoctonum,* the yellow-flowered aconite.

4. Aconitina is characterized by the following properties. It softens in boiling water, and imparts to phosphoric acid that has been concentrated by heating over a water bath at from 80° to 100°, a violet tint that in the cold lasts for whole days. Its watery solution tastes bitter, not acrid. It is not precipitable by chloride of platinum. Soluble in 5 pts. sp. v. r. (75 p. c.), also soluble in ether and chloroform. It fuses completely at about 120°. Its nitrate crystallizes well, the free base not so distinctly.

5. The above description (par. 4) applies generally to English aconitina, except that occasionally an acrid taste accompanies the bitter.

6. Hence the term "English aconitina" is not distinctive.

7. There is found among the varieties of aconitina an entirely different basic body, of unknown origin. A conjecture may be hazarded that it is derived from the Indian Bikh roots.

8. It is here referred to under the name pseudaconitina. Its discoverer, Von Schroff, however, called it English aconitina. Other chemists have termed it napellin, nepalin, acraconitina.

9. Pseudaconitina does not soften in boiling water, does not give the violet colour with phosphoric acid, tastes acrid not bitter, does not dissolve in water, is little soluble in ether, chloroform and sp. v. r. in the cold, crystallizes readily in large prisms from boiling saturated solutions in the above.

10. Napellin proper is an alkaloid distinct from the above alkaloids.

11. Lycoctonin is likewise a distinct alkaloid, and is exceedingly well characterized by the behaviour of its watery solution with bromine water and iodohydrargyrate of potassium.

Equally striking is the quickness with which cautiously melted lycoctonin, after completely cooling, becomes reconverted by moistening with water into crystals.

I am happy to be in a position to throw considerable light on the source of the long-sought pseudaconitina.

When last in London (in August last) I ascertained from our esteemed ex-president, Mr. D. Hanbury, that there had been a large importation of Indian aconite roots, and that they were obtainable at an exceedingly low price. They were represented as coming from Nepaul, but whether they were the produce of *Aconitum ferox*, or of some other aconite, was not ascertainable. I at once determined on testing the nature of the alkaloid or alkaloids they might contain, and procured from Messrs. Barron, Harveys and Co. a supply of the roots, for which I paid the absurd price of 8*d.* per lb. I say absurd, for I have it on record in my price-book that when, some years since, I asked for a quotation of price of *Aconitum ferox*, I obtained the answer 22*s.* per lb.!

Six pounds of these roots I treated after the method explained in my paper on aconite, read before this Conference at Nottingham in 1866. I need not, therefore, repeat its details. Of the roots themselves I exhibit some characteristic specimens. In texture they differ much from English aconite roots. They are often tough and leathery, so that they are difficult to powder, even after considerable exposure in the drying closet. These refractory roots are, when completely dry, hard and flinty. It appears that, in these cases, starch has become converted into dextrine. In fact, on tearing a root, the broken edge appears inclined to transparency, exhibiting a sort of waxiness. That this was not due to an unusual proportion of resin was evidenced by the result of my analysis, which showed that the Bikh roots were less resinous than the English roots I had previously operated upon.

Omitting mention of the earlier processes, I will commence detail at the point when the alkaloids had been concentrated into a crude acid solution, measuring about 6 ounces.

This solution, first partially decolorized with animal charcoal, was transferred to a separating funnel and alkalized with ammonia. It became nearly solid; and I was at once aware of the extraordinary richness of the material I was treating. Washed repeatedly with ether, the magma disappeared. After each ethereal washing, the ether was shaken with acidulated water, and used over again. The acid solution thus obtained was again treated with ammonia and ether. Care was taken to contract the bulk as far as possible; and the ether, loaded with alkaloids but yet scarcely coloured, was put aside for spontaneous evaporation. After about half an hour, white, shining crystals began to make their appearance. These increased from day to day, until the mother-liquor had become syrupy. They were then removed, washed

with ether, and dried on blotting-paper. Examined chemically, they correspond in every respect with Flückiger's description of pseudaconitina. They weighed 43 grains.

The syrupy mother-liquor, evaporated to dryness in a tared capsule, weighed 130 grains, without reckoning what was temporarily lost in the washings. It had the appearance of resin, became soft over the water-bath; when cold, was brittle and structureless. It was dissolved in alcohol, and the solution poured *guttatim* into boiling water kept slightly acidulated with nitric acid. It dissolved without residue. The solution was concentrated to a thin syrup, and set aside to see whether it would crystallize. It showed no tendency that way, in this respect differing from the alkaloid of *Aconitum Napellus*, so it was diluted with water, and treated with a slight excess of ammonia. The white magma was thrown on to a filter, washed a little with water, then drained on blotting-paper and dried. It weighed in that condition 87 grains.*

The loss occasioned by precipitation thus amounted to 43 grains. This was caused mainly by the solubility of aconitina in water. It is stated to dissolve in 150 parts of that fluid, but that proportion is much too little for the recently precipitated alkaloid and an ammoniacal liquor. To avoid loss, therefore, the wash waters and absorbent papers must be looked sharply after.

It is, therefore, probable that the pseudaconitina that from time to time has made its appearance in the European markets, under the name of aconitina, has been derived from the Indian aconites, of which it seems to be characteristic, as lycoctonin is peculiar to the yellow-flowered aconite. The very large proportion of true aconitina yielded by Bikh, and the facility of purifying it from its crystalline and sparingly soluble concomitant, point unmistakably to the future source of the alkaloid, and to a large reduction of its present enormous price.

Note on Calamine.

BY R. REYNOLDS, F.C.S.

It has been supposed that those who desired the genuine calamine of pharmacy (prepared carbonate of zinc) could obtain such from a manufacturer in Derbyshire. Although this used to be the case, it is so no longer, as the calamine issued from the above source is now a silicate of zinc (the electric calamine of mineralogists) and not a carbonate. The maker appears to be satisfied, because the mineral contains about 70 per cent. of oxide of zinc, and the substitution seems to be the result of difficulty in getting the right substance, and not from any fraudulent intention. However, the fact is not a satisfactory one, and some other means of supply is desirable. The silicate is easily distinguished from true carbonate, inasmuch as it partially dissolves, without effervescence, in hydrochloric acid, and then gelatinizes, from the separation of silica.

The President confirmed the statement of the difficulty in obtaining genuine calamine. He was able, however, to announce that a recent discovery of this ore had been made in the Mendip Hills, which he hoped would soon be made available for the purposes of pharmacy.

Mr. Williams (London) also spoke of the absence of genuine English calamine from the market, but said that a satisfactory article was imported from Belgium.

Mr. Wentworth Lascelles Scott, F.C.S., furnished a paper on "The Purification of Ammoniacal Salts from Gas Liquor so as to utilize them for Pharmaceutical

---

* Since writing the above, I have had an opportunity of ascertaining the opinion of Dr. Th. Husemann respecting pseudaconitina and aconitina, expressed in a paper published subsequently to that of Dr. Flückiger in the *Neues Jahrbuch der Pharmacie.* He writes, "The physiological actions of pseudaconitina and of aconitina, when applied externally, differ in this respect—the former acts similarly to veratria, the latter not so. Taken internally, pseudaconitina is given in much smaller doses than aconitina and often acts fatally. They both depress the action of the heart and lungs, and act similarly but unequally on the bowels."

Adelheim, however, could perceive only a difference of degree, not of kind, between aconitina and pseudaconitina derived from *Aconitum ferox.*

Very soon after Turnbull's discovery of aconitina, and its introduction into medical practice, differences in the action of alkaloids of various sources were noticed. Some would not produce the sensation of numbness, contraction and weight, lasting from two to twelve hours, as described by Turnbull; some were stronger than others; some dilated, others expanded the pupil. From 5 to 6 milligrams of the stronger kind seem to have been the poisonous dose for a cat, whereas the weaker kinds were toned down step by step to almost positive inertness.

Husemann is decidedly of opinion that pseudaconitina ought not to be regarded as a mere impurity of aconitina, but rather as the true active principle of aconite, and thinks that both alkaloids deserve a place in the dispensary as soon as a method shall have been devised for preparing them in a state of purity.

He regards the Indian aconite roots as the most likely source of pesudaconitina, although he thinks it probable that *Aconitum Napellus* may possibly contain it in small quantity.

Morson's preparation, it is well known, cannot always be relied upon. Its topical action is at times much more powerful than at other times. The method of extraction adopted by him is not known. It is said to be a peculiar one; but there is reason for supposing that its success depends more on careful selection of the roots than on any refinement of chemical treatment.

Purposes," which was a continuation of his paper of last year on the same subject.

The next paper was by the same gentleman, and was entitled a "Report on the Purity of Commercial Salts of Lithium." The author had examined twenty-seven samples, obtained from different sources. Of these sixteen were found to be pure, six showed signs of extraneous matter, and five were adulterated to a greater or less extent, a result which the author thought on the whole to be satisfactory.

Mr. Williams remarked that some carbonate of lithium had been met with that contained 60 per cent. of carbonate of sodium.

Mr. Atherton (Nottingham) moved the following resolution:—

"That the best thanks of the Conference be given to the authors of papers read before it."

Mr. H. S. Evans seconded the resolution, which was heartily carried.

Mr. Carteighe said he had been permitted the privilege of moving the following resolution:—

"That the cordial thanks of the assembled members be presented to their brethren of Liverpool and the neighbourhood, especially to Messrs. Abraham, Sumner, Shaw, Davies, and the other members of the Local Committee, for their great and successful efforts in organizing the Exhibition, making arrangements for the meetings, and promoting the general objects of the Conference, as well as for the hospitable reception they have accorded to their visitors."

He begged to assure the Chairman and all the gentlemen on the Local Committee that this resolution expressed, though feebly, the *real* feelings of all the visitors, and that they were not only thoroughly conscious of the large expenditure of time and money required in organizing their Exhibition of singular excellence, but also deeply sensible of the personal kindness and hospitality displayed with so much continuity by their Liverpool friends. He was convinced the resolution would be received with all the acclamation that it deserved.

Mr. Savage (Brighton) seconded the motion.

Dr. Attfield said that he could not allow the resolution to pass without adding his testimony to the excellence of all the arrangements which had been made by the Local Committee. The Chairman, Mr. Abraham, and the Local Secretary, Mr. Davies, had shown every anxiety to ascertain what steps would be most conducive to the success of the meeting, and these were in all cases carried out promptly and efficiently. The wishes of the officers of the Conference had been completely anticipated by the Local Committee.

The resolution was carried amid hearty cheering.

Mr. Abraham acknowledged the vote of thanks, and expressed his satisfaction that their arrangements had met with the approval of their friends. A knowledge of this and the kind way in which it had been now expressed was an ample reward for any exertions which they had made.

Mr. Shaw replied, and said that they had, during twelve months, looked forward with pleasure to the meeting which had now been held. His post as Treasurer of the Local Committee had brought him into contact with the members of the trade generally, and all were anxious that a suitable reception should be given to the Conference.

Mr. Davies also replied, and received from the meeting a very cordial and well-deserved recognition of the admirable way in which he had performed the onerous duties of Local Secretary.

Mr. Savage moved, and Mr. Mackay seconded a vote of thanks to the Treasurer and General Secretaries.

Mr. Williams moved, and Mr. Shaw seconded a vote of thanks to the President, which was put to the meeting by Mr. Abraham, and warmly received. The President acknowledged the vote.

Closing Business.

Tuesday, September 20.

The Conference met at 10 A.M.; Mr. Abraham, Vice-President in the chair. He said that the first business to be considered by the meeting would be some proposed alterations in the rules.

It was then proposed by Mr. Carteighe, and seconded by Mr. H. Matthews,—

"That Rule 1 be altered as follows:—Any person desiring to become a member of the Conference shall forward his name to the General Secretaries, and be balloted for at a general meeting of the members, two-thirds of the votes given being needful for his election. If the application be made during the recess, the Executive Committee may elect the candidate by a unanimous vote."

Mr. Redford expressed an opinion, in which Mr. Davies concurred, that there should be no restrictions upon the admission of members to the Association, but that it should be thrown open to all.

Mr. Savage thought that the right of demanding a ballot should be retained.

Mr. Atherton thought the Executive Committee should have the power to reject a candidate.

Mr. Horton asked whether there was any rule about expulsion? He would also like to know how often the Executive Committee met?

Mr. Reynolds said that any member whose subscription was more than two years in arrear, after written application, was liable to be removed from the list by the Executive Committee. Members might be expelled for improper conduct by a majority of three-fourths of those voting at a general meeting, providing that fourteen days' notice of such intention of expulsion were sent by the Secretaries to each member of the Conference. The Committee met whenever there was any business to transact.

Mr. Redford suggested that a list of candidates for membership should be posted to the members every three months.

Mr. Sumner suggested that each candidate should be nominated by a member residing in the same locality.

Mr. Robbins thought that persons on the Register of Chemists and Druggists should be entitled to membership without election; all others should be elected.

An amendment was then proposed by Mr. Savage, and seconded by Mr. Robbins,

"That all members registered as chemists and druggists, on payment of the annual subscription, be freely elected; but all others not so registered shall either obtain the signature of the local treasurer, or be subject to the veto of the Executive Committee."

This, upon being put to the vote, was lost.

Another amendment was moved by Mr. Davies and seconded by Mr. Dutton,—

"That any person desiring to become a member of the Conference shall forward his name and address to the Treasurer, with subscription for the current year."

Mr. Sumner asked what scrutiny the Executive Committee could exercise in the case of candidates living at a distance.

The amendment was then put to the vote and rejected.

The original resolution was carried unanimously.

The following alteration in Rule V. was proposed by Mr. Groves, seconded by Mr. Savage, and carried unanimously,—

"The officers of the Conference shall be a President, four elected Vice-Presidents, all past Presidents, who shall be Vice-Presidents, a Treasurer, two General Secretaries, one Local Secretary and nine other Members, who shall collectively constitute the Executive Committee. Three members of this Executive Committee to retire annually by ballot of the annual meeting, the remainder being eligible for re-election

The Executive Committee shall be elected at each annual meeting by ballot of those present."

Upon the proposition of Mr. EVANS, seconded by Mr. ATHERTON, it was resolved unanimously,—

"That the invitation to hold the next meeting of the Conference in Edinburgh, in August, 1871, be accepted."

Upon a ballot being taken, the following were declared to be the retiring members of the Executive Committee:—Mr. S. C. Betty, Mr. Cooper, and Mr. J. T. Robinson.

It was proposed by Mr. ATHERTON, seconded by Mr. WILLIAMS, and carried unanimously,—

"That in consequence of the large increase in the number of members, the Executive Committee be recommended to appoint a paid agent as Assistant-Secretary and Sub-Treasurer."

The ballot for officers for 1870–71 was then taken; the Chairman declared the result to be as follows:—

President.

W. W. STODDART, F.G.S., F.C.S.

Vice-Presidents who have filled the office of President.

H. DEANE, F.L.S.
Professor BENTLEY, F.L.S., M.R.C.S.
D. HANBURY, F.R.S., F.L.S., F.C.S.

Vice-Presidents.

J. ABRAHAM, Liverpool. | J. INCE, F.L.S., F.C.S.
H. C. BAILDON, Edinburgh. | J. WILLIAMS, London.

Treasurer—G. F. SCHACHT.

General Secretaries.

Professor ATTFIELD, PH.D., F.C.S.
R. REYNOLDS, F.C.S., Leeds.

Local Secretary.—J. MACKAY.

Committee.

F. B. BENGER, Manchester.
H. MATTHEWS, F.C.S., London.
M. CARTEIGHE, F.C.S., London.
G. BLANSHARD, Edinburgh.
T. B. GROVES, F.C.S., Weymouth.
W. MARTINDALE, London.
E. DAVIES, F.C.S., Liverpool.
H. B. BRADY, F.L.S., F.C.S., Newcastle-on-Tyne.
F. SUTTON, F.C.S., Norwich.

It was proposed by Mr. SUMNER, seconded by Mr. BOURDAS, and carried unanimously,—

"That Mr. H. S. Evans and Mr. J. F. Robinson be elected Auditors for the present year."

It was proposed by Mr. ROBBINS, seconded by Mr. EVANS, and carried unanimously,—

"That a grant of books, of the value of ten guineas, be made from the Bell and Hills Fund to the Library of the Liverpool Chemists' Association."

The President of the Liverpool Chemists' Association thanked the Conference, on behalf of the Association, for the gift, and said that their Library now amounted to about six hundred volumes.

It was proposed by Mr. MATTHEWS, seconded by Mr. BOURDAS, and carried unanimously,—

"That the best thanks of the Conference be presented to the Committee of the Liverpool Royal Institution for the use of its rooms for the meetings of the Conference."

It was proposed by Mr. MARTINDALE, seconded by Mr. WILLIAMS, and carried unanimously,—

"That the best thanks of the Conference be tendered to the Trustees and Managers of the Liverpool Savings Bank for the use of its rooms for the Exhibition of Objects relating to Pharmacy."

A vote of thanks having been accorded to the Chairman, the proceedings terminated.

MEETING FOR THE ENSUING WEEK.

THURSDAY, *London Chemists' Association*, at 9.30 P.M.—"On Hypophosphites." By Mr. R. JEWELL.

Parliamentary and Law Proceedings.

DOUBLE SUICIDE BY CYANIDE OF POTASSIUM.

An inquest was held on Wednesday, Nov. 16, at Redhill, upon the bodies of Robert Walker and Helen Mason, who had been found dead. A document, signed by both the deceased, in which they expressed their intention to commit suicide, was produced.

W. Mills, in the employ of Mr. Padrick, chemist, Warwick-town, said the deceased man came to his employer's shop on Friday night, and asked for two pennyworth of prussic acid to clean gold lace, which he refused to give, as by the new Act of Parliament a witness was required. The man called again in about a quarter of an hour, accompanied by James Crouch, a person known to witness, and he was then served with half an ounce in its crude state.

James Crouch, gardener, said that while he was looking into Mr. Padrick's window the man asked him to go in as a witness. He said he did not mind if there was no harm. He then went in and signed the book as a witness. He never saw the man before.

Dr. Hallowes said he had no doubt cyanide of potassium, which contains prussic acid, was the cause of death. Three grains would be sufficient to destroy life. He thought it was most likely taken in a crude state, and that death ensued in four or five minutes after taking it.

Evidence was given, showing that both the deceased were very peculiar in their manner. The jury returned a verdict "That the deceased destroyed themselves while in an unsound state of mind." They also censured the man Crouch for signing his name when he did not know what it was for, and the coroner refused him his expenses.—*Times.*

Obituary.

WILLIAM M'CONNELL, a prominent member of the Canadian Pharmaceutical Society, died on the 28th of September from the effects of a railroad accident, after lingering for ten hours. He resided at Coburg, and has left a widow and four children.

Poisoning of a Family by Sheep-Dipping Composition.—A case of poisoning of a family consisting of a farmer, his wife and their son, showing a large amount of carelessness in dealing with poisonous washes, is reported in the *Leeds Mercury* as having occurred near Driffield. Three ounces and a half of mercury had been purchased by the son for the purpose of making a sheep-wash, which he prepared over the kitchen fire in the evening. When the mercury was sufficiently dissolved, it was removed from the fire, poured into a tin vessel and placed under the kitchen table, where it remained during the night. Next morning the servant went to fill the kettle for breakfast, and did so from the tin vessel containing the mercurial preparation, mistaking it for one she had been in the habit of using. From this mixture coffee was prepared, all three partaking of it. Strong symptoms of poisoning were immediately manifested, and medical assistance was obtained, but in spite of every effort the father died on the following day, after suffering great agony.

The following journals have been received:—The 'British Medical Journal,' Nov. 19; the 'Medical Times and Gazette,' Nov. 19; the 'Lancet,' Nov. 19; 'Nature,' Nov. 17; the 'Chemical News,' Nov. 18; 'Journal of the Society of Arts,' Nov. 17; 'Gardeners' Chronicle,' Nov. 19; the 'Grocer,' Nov. 19; the 'English Mechanic,' Nov. 18; the 'Produce Markets Review,' Nov. 19; the 'Chemist and Druggist' for November; the 'Chemists and Druggists' Advocate' for November; the 'Chicago Pharmacist' for October; the 'American Journal of Pharmacy' for November.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[26.]—DOSE OF CHLORAL HYDRATE.—The dose of chloral hydrate varies very much as to quantity. In a patient this week, to whom I prescribed it, 50 grains had no effect; but by pushing it to 75 grains, excellent and most invigorating sleep was procured.—CHARLES KIDD, M.D.

[29.]—QUININE MIXTURE.—If *A. P. S.* will try ext. cinchonæ liq. B. P. with sarsaparilla, he will probably be more successful than with quinine alone; the following produces an elegant mixture:—

Decoct. Sarsæ Co. Conc. 5 parts
Ext. Cinchon. Liq. B.P. 2 „
Sp. Vini Rect. . . . 3 „
Tinct. Quinæ Co. . . 2 „
Syr. Aurantii . . . . 4 „
Mix. Dose ʒi to ʒij, in water.

If dandelion be desired, some of the succus tarax. B. P. may be added, but then the mixture is not quite clear.—J. H. BALDOCK, *S. Norwood.*

[33.]—DISPENSING.

℞. Tinct. Quiniæ Co. ℥iss
Ammon. Carb. gr. l
Syrup. Aurantii ʒss
Aquæ ℥j.
M. ft. mist.

Mix the tinct. quinæ co. and syr. aurantii. Dissolve the ammon. ses. carb. in the aqua, and add this last *to* the tincture; an opalescent mixture is obtained, but no appreciable precipitate, which is *not* the case if the conditions be reversed. In either case, however, a thick mixture, with deposition of quinine, is the ultimate result.—J. H. BALDOCK, *S. Norwood.*

[35.]—ROSE TOOTH POWDER.—Add ℈i of carmine to each pound of precipitated chalk, *well rubbing* it with a little of the chalk first. The more it is rubbed, the more the colour is developed.—J. H. BALDOCK, *S. Norwood.*

[36.]—EAU DE COLOGNE.—*B. Shakerley* (Liskeard) will find the following a good recipe for making Eau de Cologne:—

℞. Oil Bergamot ℥iij
„ Lemon ℥ij
„ Lavender ʒiiiss
„ Neroli ʒiiss
„ Thyme ʒij
„ Rosemary ʒj
Ess. Vanilla ʒij
Otto of Rose gtt. xxxiv
Ess. Patchouli ʒj
Musk gr. x
Orange Flower Water Oj
Rectified Spirit of Wine Oxiij

Macerate for fourteen days and filter.—J. F., *Aberdeen.*

[38.]—SOLUBILITY OF CITRATE OF IRON.—In answer to *J. L.* (Birmingham) *T. H.* (Bideford) writes,—"I frequently have to make up prescriptions, written by an eminent physician of a neighbouring town, in which citrate of iron is ordered; but as I never allow any in my shop to substitute one medicine for another, and knowing how little soluble citrate of iron is in cold water, I always have it put into a test-tube with distilled water and dissolved over the gas, which only takes a short time, and then forms an elegant mixture."

[42.]—CHILBLAINS.—In answer to "*Lugoney*" and *C. Bennett*, "*Utile*" (Boston) says that the following makes an excellent chilblain lotion:—

℞. Glycerine ℥iij
Arnica Root ℥j
Spirit of Camphor ℥ss
Rose Water ʒj. M.

Directions—To be well rubbed in night and morning.

Dr. Dewar's lotion—

℞. Sulphurous Acid,
Glycerine, each ℥j
Distilled Water ℥ij. M.

—*Chemists and Druggists' Almanack*, 1869.

A solution of chloride of ammonium, variously disguised, is also used.—H. H. P.

[44.]—PERFUMES.—In answer to "*Chemicus*," who requires a good, cheap, lasting perfume, "*Utile*" sends the following:—

℞. Ylangylang,
Ess. Bouquet, each ℥iv
„ Millefleurs ℥ij
„ Patchouli ʒij. M.

[46.]—WEATHER-GLASS.

℞. Nitrate of Potash,
Sal Ammoniac, each ʒss
Camphor ʒij
Rectified Spirit of Wine ℥ij. M.

This composition to be put into a bottle 8 or 10 inches in length and about ¾-inch in diameter, and the mouth covered with perforated bladder.

The following are the changes which may be observed:—

If the weather promise to be fine, the insoluble matter will settle at the bottom of the tube, while the liquid remains pellucid; but previous to a change for rain, the compound will gradually rise, the fluid remaining transparent.

Twenty-four hours before a storm or very high wind, the substance will be partly on the surface of the liquid, apparently in the form of a leaf, the fluid in such case will be very turbid and in a state resembling fermentation.—W. J. WATKINSON, *Preston.*

[51.]—BRILLIANTINE.

Honey ℥j
Glycerine ʒss
Eau de Cologne ʒss
Rectified Spirit of Wine ℥ij.

—*Chemists and Druggists' Almanack*, 1869.

The following is another formula:—

Castor Oil, 2 parts
Absolute Alcohol, 6 parts.
Scent with otto of rose.

[55.]—OIL AND COTTON CAKE.—*D. Jenkins* (Bridgend) wishes to know the best form of giving oil and cotton cake.

[56.]—HAIR WASH.—"*Alumen*" (Bayswater) asks for a formula for a good inexpensive hair wash, one that will have a clean appearance.

[57.]—FLORIDA WATER.—"*Nemo*" (Sudbury) will be glad if any of our readers can give him a recipe for Florida water, or tell him where to procure it.

[58.]—WALNUTS.—What is the best method for keeping walnuts in good condition?—IODI.

[59.]—DISPENSING,—What is the best way of preparing the enclosed prescription? I have prepared it several times, but with a very peculiar result, a copious black precipitate being thrown down.—MAGNESIA.

℞. Quinæ Sulph. gr. xij
Ferri Sulph. gr. xij
Magnes. Sulph. ℥iss
Tinct. Zingiber. ʒiss
Aquæ ad ℥vj
M. ft. mist.

A tablespoonful in water twice a day after food.

[60.]—CHEMICAL CABINETS.—How does the Pharmacy Act affect the sale of chemical cabinets? They mostly contain one or two chemicals, such as sulpho-cyanide of potassium, corrosive sublimate, or prussiate of potash, which come within Part I. of the Schedule A. of the Poisons Act, and require registration before sale, and yet this, I think, is never done. I am anxious to know if I can bring out a new chemical cabinet which should contain the above.—E. J. B.

[*** It would not be legal to sell poisons in chemical cabinets, except in accordance with the provisions of the Act. Sulphocyanide of potassium and prussiate of potash are not poisons.—ED. PH. J.]

Obscure Prescriptions.

Sir,—I forward a copy of another peculiar prescription also bearing the signature "Watson Bradshaw." I was informed it had been dispensed without difficulty at the pharmacy of Mr. Wilkinson, Regent Circus, Oxford Street.

I should be obliged if he or some other correspondent would state in your columns what recognized preparations are indicated by the names written in this prescription.

A Puzzled Druggist.

London, 15th Nov. 1870.

43, *Welbeck Street, Cavendish Square, W.*
Nov. 15, 1870.

Sir,—A respectable chemist in my vicinity has just handed to me for my amusement, I presume, a copy of your serial of Nov. 12th. I find therein a letter from a correspondent who styles himself as "Major Associate." I am not finding fault with your remarks, which I consider very appropriate, and I shall not condescend to offer any observations on the "animus lividus et mordax" which must have animated the writer; but I certainly must be permitted to think that in the columns of a justly influential Journal like yours, it is unwise, nay, unfair, to associate the name of a Physician with such a vile specimen of Latinity as that I find inserted in connection with myself.

Your correspondent ought to know that if he aspire to any "honour," which a Society of your reputation is calculated to confer, that he is shedding no lustre on himself or his fraternity by making such gross blunders as he has sought to fasten upon me.

I simply write this, lest any respectable reader might espouse the belief that I really was the 'Ipse Auctor' of the vile Latinity in question. The errors are so flagrant that I think the writer ought to blush for his own ignorance and temerity.

For *Cinerii* read *Cinerei.*
For *Hebdomadæ* lege *Hebdomadâ.*
For *Alkalinæ* read *Alkalini.*
For *Amaræ* read *Amari.*

I beg utterly to deny ever having indited such barbarous Latin as that imputed to me, and remain,

Yours faithfully,
Watson Bradshaw,
Formerly Surgeon H.M. Royal Navy.

43, *Welbeck Street, Cavendish Square, W.*
Nov. 20, 1870.

Sir,—You have not only omitted to insert my letter, wherein I repudiated the Authorship of a Prescription full of false Latinities; but you have absolutely, in defiance of my carefully-couched protest, suffered your columns to be made the ready vehicle of a repetition of such injustice.

Understand, Sir, I consider it infinitely 'infrà dig.' to enter the arena with such correspondents as yours appear to be, and condescend to dissert upon the squabblings of silly druggists; but when I find my name is so unblushingly paraded in your Journal, in such a mode as to serve merely to excite the cachinnations of a few ignorant readers, by identifying me with Incorrect Latinity, it is time that I should take up arms, and emphatically remind you that you are immeasurably transgressing the license of all tolerable Journalism. What right do you conceive yourself to possess to make use of my name in a private matter between my patients and myself?

My patients are invariably reminded that they can only have their medicines compounded by the especial druggists, to whom I hand them over.

I have a perfect personal right, and shall continue to exercise it whenever I think proper, of inditing my prescriptions in any mode I may deem expedient, without the risk, I should think, of subjecting myself to the Censorship of a posse of angry druggists.

You are widely over-rating your legitimate sphere of action if you consider that you have a right to dictate to the Medical Profession how they should conduct their own private affairs.

You have no right whatever to interfere with Medical Men, much less to allow your correspondents to take their names in vain.

You have been guilty of an actionable offence (Constructive Libel) in having twice allowed my name to appear in your columns under a false and invidious guise. I will not retread the ground (see last letter), but, having counsel's opinion on the subject, I have to inform you that unless you do me all just reparation for the unwarrantable manner in which my name has introduced into your columns, I shall direct my solicitor to institute immediate legal proceedings.

I beg to observe, finally, that you have no moral or legal right to make use of my name under any pretext whatever.

Your obed^t^ ser^t^
Watson Bradshaw,
Formerly Surgeon H.M. Royal Navy.

*** We are sorry Mr. Watson Bradshaw considers our publication of the prescriptions an injustice to him. They were printed exactly according to the copies sent by our correspondents, but we were informed that the writing of the originals was difficult to decipher.

The letter of our correspondent *F. J. B.* affords internal evidence of his freedom from personal animus in asking for an explanation of a prescription he could not understand. Probably he did not know of the existence of Mr. Watson Bradshaw, and was as little concerned as ourselves whether his Latinity be classical or "vile."

That was not the point to which attention was directed, and Mr. Watson Bradshaw is entirely mistaken in supposing any question raised as to his Latinity.

The difficulty experienced by *F. J. B.* was of a totally different nature, and, as we think, one much more serious. How was he to dispense an unintelligible prescription? How to convince his customer that his inability to dispense it was not a result of incompetence, but was, as it now appears from Mr. Watson Bradshaw's letter, due to a proceeding by which that prescriber limits the compounding of his patients' medicine to certain druggists?

Had the name of any particular druggist been indicated on the prescriptions, perhaps no difficulty would have arisen; but this does not appear to have been part of the system by which Mr. Watson Bradshaw hands his patients over to especial druggists, for notwithstanding his reminding patients of this fact, we find that his prescriptions are taken to other druggists, in distant parts of the country to be dispensed.

Though we have not offered any comment on the practice of writing prescriptions in such a manner as not to be generally intelligible to pharmacists, we believe we should be justified in expressing an opinion on a matter so closely connected with pharmacy, and that, in doing so, we should not be considered "to dictate to the medical profession."

However, we are enabled to show, as a matter of fact, that such a practice is dangerous, by a case that has come under our notice, in which a prescription, similar to those published and written in unusual terms, was actually dispensed in a country town, remote from the prescriber's residence, much in the same manner as a hieroglyphic inscription might be translated; the medicines thus administered on speculation being, among others, the extracts of henbane and belladonna and a preparation of mercury. A proceeding so fraught with danger to the patient was unquestionably improper on the part of the dispenser, but the fact must not be overlooked that a large share of censure is due to the writer of the prescription, in so far as he furnished the druggist with a provocation to go beyond his legitimate sphere of action, in order to meet the wants of a customer under circumstances which rendered a reference to the prescriber impossible.

Mr. Watson Bradshaw's remarks do not touch this point, and it is solely in the wish to afford him full publicity that we give space to his letters, by which it appears that from having regarded this Journal as a source of amusement, he now makes it an object for scolding. At the same time, to avoid any ground for suspicion that we desire to misrepresent his Latinity, we publish a *fac simile* of one of his prescriptions which may also account for the difficulty experienced by *F. J. B.* in deciphering the one he sent us a copy of.—Ed. Ph. J.

Pharmacy in Ireland.

Sir,—Taking advantage of the invitation you kindly offer Irish chemists and druggists, to express in the columns of your Journal their opinions on the proposed Pharmacy Bill for Ireland, I would submit a few reasons why we, the Chemists and Druggists of Ireland, who are likely to come under its immediate influence, decidedly object to it.

Primarily we object to it because it is not in accordance with the tenor of the Pharmacy Act of 1868—an Act which we deem every well-wisher of Pharmacy would like to see made general over the three kingdoms, or, if this is not found possible, that at least the Irish Bill should be in as close harmony with the other as circumstances will admit.

Now, the proposed Bill does not make any advance towards attaining this object, but, instead, makes a retrograde movement and endows with supreme power a body of men whose influence on pharmaceutical matters the Bill of 1868 curtailed and endeavoured to eradicate,—I mean the medical profession.

We do not seek to deny that they ought to have an important voice in the matter, but to give apothecaries supreme control over Irish pharmacy is a principle running right in the teeth of pharmaceutical advance, and will prove an insuperable obstacle towards assimilating English and Irish legislation on the subject. We have now a British Pharmacopœia, why not endeavour to obtain a British Pharmacy Act?

Again, is there any satisfactory reason why an individual who in England is a pharmaceutical chemist under the Act of 1868 should, when he removes over to Ireland, be denied the privileges of compounding and dispensing medicines, simply because he does not bring with him the diploma of the Governor and Managers of the Apothecaries' Society of Dublin? We think not, and in the interest of a large and increasingly influential body of men who have already had to submit too long to the tyrannical rule of the apothecaries, we protest firmly and unmistakably against the proposed Bill, trusting that our brethren across the Channel will at once see the cloven hoof protruding itself, and act accordingly.

That pharmacy in Ireland should be confined exclusively to the members of a profession who, in their own domain, are so jealous of their dignity that we find them continually harping on the time-worn complaint that chemists and druggists do not separate completely prescribing from dispensing, seems to be, to say the least, inconsistent with justice, while it certainly leaves out in the cold those who till now considered that the practice of pharmacy was their profession.

The chemists and druggists of Ireland will be blind to their best interests if they allow such a Bill as the one proposed to be passed into law, and we trust that they will agitate on the subject and be able to show that might is not always right.

Cork, November 22nd, 1870. J. S.

Threats of Law Proceedings against Druggists.

Sir,—A female asked over the counter for sixpennyworth of "steel pills;" about a dozen and a half were given to her (pilulæ ferri carb. P.B.), labelled "steel pills" on the box, and without any comment upon their dose, etc. A gentleman called the next day, saying that the lady had taken some of them, and in consequence was seriously ill, and that proceedings in law would be taken.

What I would ask is, whether the person so purchasing a medicine can bring an action against the vendor? for threats such as these are by no means uncommon in this neighbourhood (generally from people of the Jewish persuasion), and are a source of anxiety, especially as more than one, not far off, have been ruined or nearly so by similar means. I would ask also whether there is a society for the mutual protection of the chemists' trade.

Whitechapel, November 1st, 1870. C. G.

[*⁎* Any one can, if he please, bring an action against any one else, either with reason or without. It is the privilege of those who are unreasonably proceeded against to prove that this is the case, and in some instances to incur much trouble and expense in doing so. We are not aware that any such Society as that referred to is in existence.—Ed. Ph. J.]

Poisonous Feeding-Bottles.

Sir,—I should feel obliged by your inserting these few lines on the above subject, to say that from what has been written and the erroneous impression created in consequence, I made an experiment (on the bottle used by my own baby) with a view of finding out the true cause of the undoubtedly disgusting odour evolved. That the sulphur used in the process of vulcanizing the india-rubber is the cause, I take it there can be no doubt, since after having had the tube and teat of pure black india-rubber in use for some time, they are as sweet and free from smell as when first adapted to the bottle.

South Norwood. J. H. Baldock.

[*⁎* Our own experience enables us to confirm the statements of our correspondent as to the sulphur of vulcanized rubber being the source of the sulphuretted hydrogen. Probably this defect might be remedied by digesting the tube and teats for some time in a moderately strong solution of caustic alkali.—Ed. Ph. J.]

Druggists' Charges.

Sir,—In reference to the letter of your correspondent, "Pharmaceutical Chemist, Cambridge," it seems probable that the mixture was prepared with decoct. taraxaci, in which case 1*s*. 9*d*. or 2*s*. might be a fair charge. That the decoction was intended seems probable from the dose, ℥j. The dose stated in the B.P. for succus taraxaci is ʒj to ʒij. Doctors appear often to write prescriptions without any definite idea of the preparations they are ordering.

As to query No. 33 (Dispensing), what would *H. K.* think of the following?—

℞. Quinæ Disulph. ℈ss
Liq. Ammon. Acet. ℥iss. M.

A teaspoonful every four hours in water.

On taking the above to the prescriber and explaining the sort of mess it would make, he at once said he knew of course it was insoluble, but had thought it would merely require shaking up; however, he rewrote it, adding aqua ad ℥vj, and directing a tablespoonful for a dose. Even this must be prepared "secundum artem," or it will make a mess too.—W. M.

Pepsine and Pancreatine.

Sir,—Having seen in your issue of the 19th inst., Mr. R. J. Kinkead's article, headed "A New Digestive," and relating to the combined use of pepsine and pancreatine in cases of dyspepsia, would you do me the favour of giving publicity to the fact that in a preparation to which I have applied the term "Gastrodyne," I have, for more than twelve months past, used pepsine and pancreatine in combination with the best results? A. Farr.

Waterloo Road, November 19th, 1870.

The Lord Mayor of London.

Sir,—Perhaps it would not be uninteresting to some of your readers to know (from information contained in the *Prescot Observer*) that Mr. Dakin served his apprenticeship with Mr. Threlfall, a Liverpool chemist, who retired from business some time ago, but still lives in the suburbs of that town, and is well known to the writer. Mr. Dakin afterwards removed to a wholesale London house, and on marrying a daughter of his employer, was received into partnership.

Vincit Amor Patriæ.

Liverpool, November 21st, 1870.

"*Spero*" (Yarmouth) is referred to the rule as to anonymous correspondence.

"*A Minor Associate in Business*" (Liverpool).—Apply at Apothecaries' Hall.

R. T. (Edinburgh).—There are no such persons.

Erratum.—The signature of the writer of the letter entitled "Obscure Prescriptions" in last week's Journal was accidentally omitted. It should have been "J. F. Brown, *Dover*."

Communications, Letters, etc., have been received from Mr. A. H. Mason (Liverpool), Dr. Kidd, Mr. J. H. Askew (Liverpool), Mr. G. Wellborn (Grantham), Mr. Jenner (Bury St. Edmund's), Mr. T. F. Best (Camberwell), Mr. E. Barber (Sheffield), Mr. G. W. Jones (Worksop), Mr R. H. Rowell (Houghton-le-Spring), Mr. F. C. Wyatt (Henley), Mr. J. Bordass (Driffield), Mr. J. Staley (Rochdale), Mr. B. P., "Two Inquirers," "Alpha" (Sudbury), "Iodi" (Sudbury), "Vulcanite," "Odor," J. S. A.

CINCHONA CULTIVATION IN JAVA.

BY JOHN ELIOT HOWARD.

Many readers of this Journal feel a deep interest in the introduction of the cinchona-trees into the regions of the East. These will naturally inquire what are the results, as practically ascertained, from the many years of labour and the great expense incurred since the month of April, 1852, when the first plant of genuine cinchona arrived safely at Java; and still more expressly since the 13th December, 1854, when M. Hasskarl (sent out by the Dutch Government to collect seeds) arrived with his precious cargo at Batavia.

The first date was that of the introduction of the *Cinchona Calisaya* from seeds collected by Dr. Weddell* (from some one of its *varieties* apparently); the latter was the period from which we reckon the acclimatization of quite another species, which seems to have found a more congenial habitat than the first on the mountains of Java. In fact, the propagation of this latter was so easy and rapid that it became soon an object of attention to botanists, and of somewhat anxious consideration. The plants ere long numbered hundreds of thousands, and the possible eventual value of the species, as a source to be relied upon for the production of quinine, was doubtful. At the end of 1863 these plants were reported 1,139,148 against only 12,093 of *Calisaya*, and a few hundreds of other species.

Being unfamiliar to botanists, it was mistaken for the *C. lucumæfolia*, an illusion which I assisted to dispel; and in the year 1860, being engaged in the publication of my 'Nueva Quinologia,' I received from my friends in Java very ample materials for the description of the species. At the suggestion of those most interested, and as a compliment well deserved by his exertions in the cause of cinchona cultivation, I named it *C. Pahudiana*, after the Governor, M. Pahud, whose term of office was just about expiring. I then pronounced it an inferior species, and expressed my belief that it would prove a source of disappointment to the Dutch Government. From this opinion I have never departed, although I have been willing to follow, with a greater or less degree of expectation, the researches of my friend Dr. De Vrij, whose analysis of the root-bark shows better results than I have been able to obtain from that of the rest of the tree.

It will be understood that I refer to the quinine-producing powers of the species, which seem to me unpromising. In other respects, I have been induced to modify my judgment in a more favourable sense. It is well known that from a therapeutic and pharmaceutical point of view, the value of a specimen of bark does not coincide with the amount of quinine it may contain. Other ingredients, and among them the alkaloid commonly known as *uncrystallizable quinine* (of which this bark possesses a large share), no doubt contribute largely to the medicinal qualities of the bark, and I believe that Dr. De Vrij considers his experiments show that this is superseded by real quinine in the roots. I have found that the bark transmitted by Mr. M'Ivor as that of *C. Pahudiana*, and skilfully prepared by him, attracted the attention of a London broker familiar with the article in preference to those of other, and, in my opinion, superior kinds sent at the same time. I have, consequently, taken up a kind of neutral position in the contest which has been waged with fierceness over this plant even in the Chambers of the Dutch Government. In so doing I have, as is usual, incurred an amount of obloquy disproportionate to the offence, and which is avowedly increased by my having been favoured with so much assistance from my friends in Java, in the way of specimens and of botanical descriptions, as I have fully acknowledged in my 'Quinologia.' Professor Miquel, in particular, has attacked me personally on the subject, though I have never either seen or had correspondence with him. In my 'Quinology of the East Indian Plantations' I expressed myself thus:—"It is extremely unpleasant to come in contact with such a state of things, and I find that I am censured for not being sufficiently one-sided in the dispute. The writer in 'Gids' says, 'Mr. Howard, who described the unfortunate sort as a new species in his noble work on cinchona, although he at first, with reason, brought its usefulness into question, afterwards took a position of weakness and uncertainty as the conflict began to wax warm,'" etc.

To this I have only to reply that I have published such information as came to my hands as correctly as I could, and intend still to do so. I see no occasion to alter my account of the species given in the 'Nueva Quinologia,' and still believe that it is without value *if looked at simply as a source for the extraction of quinine;* but as regards the *root-bark*, I have personally no information to oppose to the favourable estimate elsewhere entertained, and must therefore maintain a position of "uncertainty" till this is removed by those who can decide the question. If the *C. Pahudiana* be looked upon in another point of view, viz. as a *possible source of bark for pharmaceutical purposes*, I have shown in my reports given to the Government of British India, on specimens from Ootacamund, that the quill bark is not only *not* worthless, but that such quills as those sent by M'Ivor were actually preferred to other kinds sent with them by dealers most competent to judge in London, and this is not without reason, from their taste, appearance and chemical composition. I cannot, therefore, agree with those who *recommended** the superfluous labour of cutting down the trees; neither can I rank this plant "among the best sorts of all," as, it seems, some have attempted to do. The trees having now many years' growth, *might perhaps furnish quill bark fit for the home market;* and I shall be surprised if it is not at least equally valued there with the bark of the so-called *C. Calisaya*, which, I am afraid, will prove "unfortunate" also, at least if it produces but 1·3 per cent. as described by Van Gorkom.

It will be seen that the above estimate of mine has been fully borne out by experience, but in the meantime I must revert to the learned professor, who, as I am informed by my friends (for he has not sent me a copy of his work†), says,—

"*Veritati contrarium est*, quod nuper adhuc excla-

* Soubeiran et Delondre, de l'Introduction et de l'Acclimatation des Cinchonas dans les Indes Néerlandaises. 1868. Page 27.

* I have added the *italics* in this and other places to direct the reader's attention. Compare this with the version, "A *magistratu* nostro Indico *jussum* fuisse," etc.

† "De Cinchonæ speciebus quibusdam adjectis iis quæ in Java coluntur, scripsit F. A. Guil. Miquel, in *Annal. Musei Botanici Lugduno-Batavi*," tom. iv. fasc. ix. p. 263; 1869.

mavit Howard, a magistratu nostro Indico jussum fuisse arbores ipsas innumerabiles diruere et exstirpare" (p. 270).

An extract from the *Official* Report of the Transactions in the Dutch Parliament of 27 May, 1862 (sent me in the original and in a translation), is as follows:—

Mr. Uhlenbeck, Minister of the Colonies, speaks,—

"And to show the great difference, I communicate that in all the time that the cinchona culture has been performed on a large scale, there have only been planted 7804 cinchona-trees which really contain quinine, whilst in the meantime there have been planted 1,029,291 trees (Pahudianas), which are only fit for FIREWOOD (*brand hout*)."

Ditto of the session of the Parliament on 2nd June, 1863. Mr. Van Eck (M.P.) speaks:—

"The former Minister of the Colonies stated only the trees are *firewood*, we must DESTROY them" (*uitroeijen*, to *root out, extirpate, destroy, exterminate*).

Professor Miquel also says in the same work:—

"Tædiosam historiam haud repetam, nec habeo quæ ultro opponam Howardio qui me dissentientem indigne tractavit in plagula quadam diurnorum nostrorum mendacem me exclamans."

As I never wrote (nor could write) an article in a Dutch newspaper, M. Miquel can only refer to the following extract from a letter of Dr. de Vriese, who died in 1862, and consequently cannot defend himself.

A letter from myself to Dr. de Vrij, published with my permission, contains the following in reference to the determination of the *C. Pahudiana* (Prof. Miquel, contrary to De Vriese, Dr. Weddell, Markham, etc., identifying the plant with *C. Carabayensis*):—

"I sent over to Dr. de Vriese a fine specimen of the plant in question with the fruit well developed, given me by Dr. Weddell himself. And in a letter written subsequently, under date 4th November, 1860, Dr. de Vriese says,—The examination and comparison of *C. Carabayensis* and *C. Pahudiana* has shown me indubitably that the two species are different. To maintain a contrary opinion would be a lie."

I proceed to say, "I hesitate to copy the above strong expressions, but they throw light on the subject, as showing there must have existed some excitement of the feelings, connected, no doubt, with the great material interests at stake, which may have interfered with calm scientific inquiry, and led, in Dr. de Vriese's opinion, to erroneous statements."

So far my letter, and I must add that it is a very unimportant matter, in comparison, whether these species are identical or (as in my judgment) separate. I had shown in my 'Quinologia' their points of resemblance as well as of separation; but it *is* important that a personal attack, against which I have no opportunity to defend myself, should appear in a work published at the expense and under the auspices of the Dutch Government.

Since the departure of M. Pahud, and the death of Dr. Junghuhn, the cultivation of the plantations has passed under different management, as I have mentioned in the Appendix to my work previously mentioned.

The proportion of plants of different species is now very different. In the second quarter of 1870, according to a paper sent me by Dr. Hasskarl, the plants were as follows:—

C. Calisaya and *C. Hasskarliana*	1,100,983
C. succirubra and *C. caloptera** .	152,782
C. officinalis	222,904
C. lancifolia	43,227
C. micrantha	620
Total . .	1,520,516

The progress of the cultivation is spoken of in warm and eulogistic terms, and the number of *C. Pahudiana* trees (now grown to a good height) is left out of the account.

It is unfortunate, however, that all has to be tested by practical results, and the favourable analyses at present published, have their true value brought to light by the price per pound paid for the barks set forth for public sale in Amsterdam.

In the past season there was a pretty large importation of these barks; and samples under the name of *Konings Kina* and *Bruine Kina* were forwarded to this country, where they were examined, but did not meet with much acceptance. A sale has since taken place in Holland, and the results are not a little curious, and certainly worthy of record. The so-called *Calisaya*, or *Konings Kina*, was bought (as I am informed) by a druggist, at about 2*s*. English, with the intention of its being sold for pharmaceutical purposes, and *not for the manufacture of quinine*. The remainder appears to be *Pahudiana* (but it may perhaps be called *Hasskarliana*), and brought *a higher price*, averaging about 2*s*. 1½*d*. English money. I do not think, however, that any manufacturer of quinine would invest his money in this. As far as my information goes, there has been as yet NO PRODUCTION OF BARK FITTED FOR THE MANUFACTURE OF QUININE, with the exception, perhaps, of one sample which resembled both in appearance and in quality one of the *Calisaya légers* of the French (the product, I believe, of the *C. micrantha Calisayoides*, of Dr. Weddell's new classification). It was consequently a poor and very second-rate bark, although the best from Java. The *C. Hasskarliana* of Miquel is, according to Dr. de Vrij, the result of the interference of the pollen of *C. Pahudiana* with the *C. Calisaya*. Professor Miquel makes it a new species. On this I give no opinion, but I am pleased to see that the *C. Pahudiana*, with its congeners, is proving itself worthy of the character I gave it, as likely to be found useful as a medicine. Of this I have an additional confirmation in the examination of a good-looking sample of bark called *C. Pahudiana*, just brought into the English market from the plantation of a gentleman in Ceylon. This contains a fair portion both of quinine and cinchonidine, and is likely to prove a good bark for pharmaceutical purposes.

M. Van Gorkom concludes his official report for 1864 with the following words:—"Until now the different reports concerning the cultivation of Chinchona have thrown more darkness than light on the subject, and consequently the credit of this great undertaking has suffered."

It would be greatly to the satisfaction of the manufacturers of quinine, if this gentleman would throw light upon the question, what prospect six years of additional experience enable him now to hold out as to any possible supply of their wants from this quarter in the future?

* Probably *C. pubescens*, subspecies *C. Pelletierina*, if the deep green colour attributed to the leaves is correctly represented.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Antimonii Oxidum.—Solution of chloride of antimony is poured into water, and the white precipitate of oxichloride of antimony allowed to settle and partially washed by decantation. It is then digested with solution of carbonate of sodium till completely decomposed, and finally the deposited oxide is washed to free it from chloride of sodium. The reaction consists in the formation of an insoluble compound of oxide and chloride of antimony:—

$$x\,SbCl_3 + 3H_2O = Sb_2O_3.(x-2)\,SbCl_3 + 6HCl.$$

The proportion of oxide in the precipitate increases with the proportion of water used for washing. The carbonate of sodium removes the last traces of chloride—

$$2SbCl_3 + 3Na_2CO_3 = Sb_2O_3 + 6NaCl + 3CO_2.$$

Prepared in this way the oxide generally has a buff tint, from the presence of a minute quantity of oxide of iron. It can be procured perfectly white by redissolving the washed oxichloride in hydrochloric acid and reprecipitating with water: the second washings should be performed with water to which a few drops of acid have been added. If heated too strongly or exposed to the air too much during drying, it is apt to become partially converted into the double oxide Sb_2O_4, formerly called antimonious acid. When in this condition it will not dissolve completely in acid tartrate of potash, as stated in the Pharmacopœia. Antimonic anhydride is left—

$$2Sb_2O_4 + 2KHC_4H_4O_6$$
$$= 2SbO\ K\ C_4H_4O_6 + Sb_2O_5 + H_2O.$$

Antimonium Sulphuratum.—Black sulphide of antimony is powdered and boiled for two hours with solution of soda. The strained solution is then mixed with a slight excess of dilute sulphuric acid and the precipitate collected, washed and dried on a water bath. The sodic hydrate may be represented as acting two parts. One half undergoes decomposition with the sulphide of antimony, yielding sulphide of sodium and oxide of antimony; the other half dissolves up the oxide of antimony, as it is formed:—

$$Sb_2S_3 + 6NaHO = Sb_2O_3 + 3Na_2S + 3H_2O.$$

The sulphide of sodium that is produced takes up at the same time sulphide of antimony. Thus two soluble compounds result, the second being the counterpart of the first, but containing sulphur in place of oxygen, atom for atom:—

$$3Na_2O, Sb_2O_3 = 2Na_3SbO_3.$$
$$3Na_2S, Sb_2S_3 = Na_3SbS_3.$$

On the addition of sulphuric acid to the solution of these two, sulphide of antimony is alone deposited, for the sulphuretted hydrogen produced by the decomposition of the second compound suffices to convert the oxide of the first into sulphide:—

$$Na_3SbO_3 + Na_3SbS_3 + 3H_2SO_4$$
$$= Sb_2S_3 + 3H_2O + 3Na_2SO_4.$$

This must, however, be accepted as an explanation only of the principal features of the decomposition; other minor and more complex reactions go on simultaneously. They arise chiefly from the action of the oxygen of the air during the boiling.

If the alkaline solution be allowed to cool before the acid is added, a brown precipitate, a compound of oxide and sulphide of antimony, is deposited. This is what was formerly known and employed as mineral kermes.

[§ Sixty grains of this preparation dissolved in hydrochloric acid and dropped into water give a white precipitate, which, when washed and dried, weighs about 53 grains.] This cannot be regarded as by any means a satisfactory test. If, for example, rather too much hydrochloric acid were employed for dissolving it, a considerable proportion of the compound would be lost in the form of chloride, which would be retained in the mother liquor. A better plan would be somewhat as follows:—50 grains moistened with nitric acid, then dried and heated to redness, would give a white residue weighing about 45 grains. And the weight of this is not sensibly altered by washing with boiling water.

Antimonum Tartaratum.—Oxide of antimony is mixed with cream of tartar and water into a paste, allowed to stand twenty-four hours, and then water added and the whole boiled up, filtered and set by to crystallize. A little antimonic anhydride, Sb_2O_5, is generally left insoluble in the form of a white powder.

The formula of this compound, as given in the Pharmacopœia, seems to be anomalous. It is better to represent it as a tartrate containing an atom of potassium and an atom of a compound radicle, to which it is not necessary to give a name, but which replaces the atom of basylous hydrogen belonging to the cream of tartar from which the salt is made. Antimony is usually trivalent, Sb''', the union of one atom with an atom of oxygen which is bivalent O'', gives, therefore, a compound which is univalent $(Sb'''O'')'$. The formula of tartar emetic, written on this principle, is then $(SbO)'KC_4H_4O_6$. Crystals of the salt are easily recognized by their triangular facets, which are marked by parallel lines. A solution of the salt in a mixture of hydrochloric and tartaric acids gives with sulphuretted hydrogen an orange precipitate of sulphide of antimony. This compound, after being dried in a water bath, contains only a very small quantity of water (about $1\frac{1}{2}$ per cent.); if heated more strongly it suddenly loses its amorphous state, becoming black and crystalline. It is then identical in composition with the native sulphide.

Argenti Nitras.—Pure silver is dissolved in diluted nitric acid, and the solution evaporated till it yields crystals:—

$$3Ag_2 + 8HNO_3 = 6AgNO_3 + N_2O_2$$
$$+ 4H_2O.$$

Traces of gold, or of sulphide of silver, which may be present, will remain insoluble as a nearly black powder. Solutions of nitrate of silver are best decanted from any sediment, not filtered, since contact with the organic matter of the filter renders the nitrate of silver liable to decomposition on exposure to light. Nitrate of silver is often made by dissolving silver coins, or other form of common silver. Brazilian and Portuguese coins are used for this purpose. When this plan is adopted, the solution is evaporated to dryness and the residue heated strongly for some time. The nitrate of copper present is in this way decomposed, giving insoluble black oxide of copper:—

$$2(Cu2NO_3) = 2CuO + 2N_2O_2 + 3O_2,$$

whilst the nitrate of silver remains unchanged. On treating with distilled water the latter alone dissolves.

[§ 10 grains dissolved in distilled water give with hydrochloric acid a precipitate, which, when washed and dried, weighs 8·44 grains. The filtrate when evaporated by a water bath leaves no residue.] Adulteration of the fused stick with nitrate of potash would in this way be detected.

(To be continued.)

ON THE COMBINATIONS OF CARBONIC ANHYDRIDE WITH AMMONIA AND WATER.

BY EDWARD DIVERS, M.D.*

(Continued from page 385.)

Ammonium Carbamate.

History.—Who discovered that ammonia and carbonic anhydride unite to form a solid I do not know. Gay-Lussac first determined the proportion in which these gases combine.

Preparation.—(*a.*) By the direct union of dry ammonia and carbonic anhydride gases, when it is deposited partly as an incrustation on the walls of the vessel in which it is formed, and partly as flocculi. This is the earliest method known.

(*b.*) (Rose's method.)—By distilling together ammonium sulphamate and anhydrous sodium carbonate, when it is also obtained as an incrustation on the walls of the condensing vessel.†

(*c.*) (Kolbe and Basaroff's method.)—By passing carbonic anhydride and ammonia gases, both perfectly dry, into cold absolute alcohol, separating the copious crystalline precipitate by filtration from the greater part of the liquid, and heating it with absolute alcohol in a hermetically-sealed tube to 100° or above, when the liquid on cooling deposits the carbamate in large crystalline laminæ.‡ I have not repeated any of these processes. I am able to add to them several others made out by myself.

(*d*). By passing carbonic anhydride and ammonia gases into concentrated aqueous solution of ammonia, when the carbamate separates in crystals, which, when dried as well as possible by pressure between folds of bibulous paper, contain only a little carbonate.

(*e.*) By digesting in a closed vessel an aqueous solution of ammonia, saturated with the gas at a low temperature, with either the commercial carbonate, or any other carbonate of ammonium, at a temperature of 20°–25° for thirty-six or forty hours, when the carbamate either crystallizes out at once on cooling, or will do so after cooling the solution, passing more ammonia gas into it, adding more carbonate, repeating the digestion as before, and then again cooling. This process has been already described in the account of the reactions of the normal and acid carbonates. The best carbonate to employ is the commercial carbonate, because it yields more of the carbamate, as might be anticipated from its composition.

(*f.*) By heating the commercial carbonate of ammonia mixed with a sufficient quantity of anhydrous potassium carbonate in a retort, immersed in a water-bath at a temperature carried slowly from about 50° to about 80°, and connecting the neck of the retort with a wide tube dipping under mercury, when the neck of the retort becomes incrusted with the carbamate in a translucent crystalline condition. The water-bath is to be maintained at a temperature not much exceeding 60° C. until ammonia gas, which is at first generated in large quantities, has nearly ceased to escape through the mercury. The temperature of the bath is then to be raised, but not so rapidly as to cause any material escape of gas through the mercury.

(*g.*) By distilling, as in the last process, a mixture of the commercial carbonate of ammonia and anhydrous calcium chloride, when an incrustation forms, similar in every respect to that obtained in the last case, which is the carbamate. At a temperature of the water-bath of about 48° a considerable quantity of carbonic anhydride escapes through the mercury, and at about 52° the incrustation begins to form, and continues to do so with very little further escape of gas, while the temperature is allowed to rise very slowly to 65°, a temperature which is sufficient to carry the process to its completion.

(*h.*) By distilling the commercial carbonate extremely slowly, when the more remote part of the earlier formed incrustation will be found to be impure carbamate. I have obtained samples from an incrustation thus prepared, in which six-sevenths and five-sixths respectively of the contained ammonia were in the state of carbamate. There are no sensible qualities by which the composition of the product can be inferred, so that it is quite possible, indeed, more probable than not, that parts of the incrustation were more nearly pure carbamate than the samples selected for analysis proved to be. This process is, of course, only of interest from a theoretical point of view. The product obtained by Rose by a similar process is not the same as that obtained by me, a fact which admits of a ready explanation, as will be presently seen.

(*i.*) By distilling the normal carbonate at a heat not exceeding 60°, when a solid condenses containing even less water than the product of method (*h*).

(*j.*) By repeatedly dissolving commercial carbonate at a gentle heat in the same quantity of water, cooling after each addition, and separating the crystals, as already described, until crystals of normal ammonium carbonate are deposited; then once more warming the solution, dissolving a fresh quantity of commercial salt in it, allowing it to cool and crystallize for a day, separating the crystals, passing ammonia gas, straining off or not (as may be necessary) the precipitate of normal carbonate produced, renewing or continuing the stream of ammonia till the solution (kept cool) is about saturated, and straining off the precipitate of normal carbonate, when the solution will prove by its reactions to be apparently a solution of carbamate with a little carbonate dissolved in it. I think it not unlikely that by carrying this process further, with some modification, crystals of carbamate might be obtained; but I have made no experiments in this direction.

(*k.*) By distilling the commercial carbonate with strong spirit, or, probably better still, with absolute alcohol. The carbamate is wet—mixed with water and spirit—but contains very little carbonate.

Sensible Qualities.—Ammonium carbamate has a strong smell of ammonia, but not at all equal to that of the normal, or even half-acid, carbonate. As regards its taste also, it is strongly ammoniacal, but without the causticity of the normal carbonate.

Form.—It occurs in the form of flocculi; of an incrustation more or less crystalline; of prisms found sometimes projecting from this incrustation; of crystalline laminæ (Kolbe and Basaroff); and of crystals neither tabular nor decidedly elongated or columnar.

Of the system of the last-named crystals, I am unable to speak with any degree of assurance, but they seem to belong to either the right or the oblique rhombic prismatic system. They frequently occur massed together, like crystals of alum, one crystal capping the other, as it were. When solitary they are not only of no great size, but also are rapidly deprived of their angles and edges by the changes they undergo. When their growth is not interfered with by contact with each other and with

* Abstracted by the author from his paper in the *Journal of the Chemical Society.*

‡ Direct conversion of ammonia carbamate into urea. *Journal of the Chemical Society* (2), vol. vi. p. 194.

crystalline particles of the normal carbonate, they are perfectly transparent. The incrustation consists of prisms arranged perpendicularly to the surface of formation. The translucency of the mass attains a high degree of perfection in those parts formed nearest to the source of heat. Fragments from this part of the incrustation appear almost perfectly transparent when thrown into water. In appearance this form of the carbamate differs little, if at all, from a similarly formed deposit of acid-carbonate—with one exception. This is in the parts formed near the source of heat, which acquire an increased translucency by the continued action of the heat employed in carrying on the process, and also undergo marked contraction, so as to exhibit gaping fissures, and become partly separated from the walls of the retort on which they rest. This phenomenon is always observed in the carbamate, whether formed by the action of potassium carbonate or calcium chloride, and never with hydrated incrustations, according to my experience. The prisms which sometimes project from the free surface of the incrustation are thick and generally very short, but sometimes they pass right across to the opposite wall of the retort-neck or condensing-tube.

Chemical Composition.—It is unnecessary for me to adduce evidence to prove that ammonium carbamate is composed, according to the formula—

$$CO_2(NH_3)_2,$$

of

Carbonic anhydride . .	56·41
Ammonia	43·59
	100·00

Behaviour on Exposure.—It evolves an odour of ammonia which, when a solid lump of it, or a crystal, is exposed freely to the air, rapidly diminishes in intensity; at the same time the carbamate gradually deliquesces; by continuing the exposure it is nearly dissipated. The residue left is acid carbonate, generally in the form of a porous cast or superficial skeleton of the original fragment.

The deliquescence of the carbamate is an interesting fact, not only as affording further evidence that the carbamate has only a slowly-manifested chemical affinity for water, but also as distinguishing between the mere physical attraction of a body for water, and its chemical transformation with water into a new substance.

Behaviour when Heated.—Ammonium carbamate, unlike the true carbonates, does not fuse when heated. According to John Davy it is converted into gas at 60° C. My own experiments very nearly confirm this statement. I was not able to fix the point very closely, but found it to be about 59°.

It has been for many years familiar to chemists that the carbamate obtained from two volumes of ammonia and one volume of carbonic anhydride yields three volumes of vapour. A fact like this is now held by most chemists to be proof that a substance thus behaving is decomposed at the moment when it assumes the gaseous state. Bineau took the density of the vapour of the carbamate at ordinary temperatures,* and found it also to accord with the sum of the volumes of the ammonia and carbonic anhydride which form it. Another proof that it is decomposed when dissipated at ordinary temperatures, is to be found in the powerful odour of ammonia which is then perceived; for it is inconsistent with what we know for certain of the change in properties produced by chemical combination, to suppose that a compound of ammonia should smell like ammonia itself.

Bineau has also furnished us with special evidence that the vapour, obtained by distilling carbamate, is nothing but a mixture of the two above-named gases. He observed* that the gaseous product obtained by exposing the salt to heat retains its gaseous state at a temperature which is lower than that at which it is formed. I am myself able to confirm this statement.

Behaviour with Water.—One part of ammonium carbamate dissolves in about one and a half parts of water, sensible cold being produced by the solution. It dissolves unchanged, as is shown by the reactions of the solution immediately after it is prepared. But the carbamate in solution soon combines with water and becomes carbonate, according to this equation,—

$$CO_2(NH_3)_2 + 2OH_2 = CO_4(NH_4)_2H_2.$$

Behaviour with Alcohol.—Ammonium carbamate is soluble in spirit of sp. gr. ·829, according to John Davy. In absolute alcohol, when heated with it in a sealed tube, it dissolves, and crystallizes out when the solution is allowed to cool (Kolbe and Basaroff). I have made no experiments on this subject myself.

Behaviour with Ammonia-water.—It dissolves freely in the strong ammonia-water of commerce, with production of cold. At 15° one part dissolves in a little more than two parts of the ammonia-water. The solution, left to itself for some time, yields crystals of the normal carbonate. But when cooled down to about 0° soon after it is made, it yields the carbamate again in relatively large crystals. Ammonia, therefore, has the power, well marked, of impeding the hydration of the carbamate. To this fact is probably due the success in obtaining the carbamate from the carbonate by heating its solution in presence of ammonia.

Reactions which serve to distinguish the Carbamate from the Carbonates generally.—Rose has pointed out the following:—The carbamate is not perceptibly affected by dry hydrochloric acid in the cold, and warmed in the acid is decomposed without liberation of water. In dry chlorine gas it is not at first affected, but is slowly decomposed without formation of water. It assumes in the cold a pale yellowish colour when placed in sulphurous anhydride. Heated in sulphuretted hydrogen gas, no water is produced. It yields carbonic anhydride *without effervescence* when the vapours of sulphuric anhydride are passed over it.

Besides these, it has a special reaction in solution with calcium chloride; when mixed with anhydrous calcium chloride it can be expelled by a gentle heat, leaving the chloride unchanged; it does not melt or become moist when heated, and it dissolves freely in strong ammonia-water. Its becoming moist on exposure is not characteristic, as both the half-acid and the normal carbonates become moist also, though from a different cause.

Chemical Constitution of the Carbamate.—Analogy has caused this salt to be regarded by Gerhardt, and most chemists after him, to be like the salts formed by the union of other anhydrides with ammonia; conclusive evidence on this point is still wanting. There are no metallic carbamates known. With calcium chloride and with barium chloride it does not, however, behave like ammonium carbonate; and this is probably due to the formation of a not very insoluble calcium carbamate. In connection with this point I may state that by adding to the solution obtained from the commercial carbonate by water—method (*i*)—a concentrated solution of calcium chloride, I have obtained a crystalline precipitate not only somewhat soluble in its mother-liquor, but which, after being filtered off and pressed between bibulous paper, has sometimes proved almost perfectly soluble in water, though in a few minutes its solution deposited calcium carbonate; it did not smell of ammonia. I am not sure that this precipitate, however, was really calcium carbamate; but I made analyses of it in its impure and damp state, not venturing to wash it, and

* "Recherches sur les Densities de Vapeur." *Ann. de Chimie*, vol. lxviii. p. 416.

* "Sur quelques Combinaisons ammoniacales et sur le rôle que joue l'Ammoniaque dans les réactions chimiques." *Ann. de Chimie*, vol. lxvii. p. 240.

the results of these agree remarkably well with a compound having either of the following formulæ,

$CO_3(NH_4)_2, CO_3Ca.$ — Ammonio-calcium carbonate. $(CO_2NH_2)_2Ca.$ — Calcium carbamate.

mixed with hydrated calcium chloride. A similar precipitate is obtained with barium chloride. The probability, I think, is, that the precipitates are carbamates; and if so the constitution of the ammonium carbamate is that expressed by its name, and by the formula—

$$CO_2(NH_2)(NH_4).$$

(*To be continued.*)

A NEW MATERIAL FOR SUPPOSITORIES.

Mr. T. Carre, of Meaford, has communicated to the *Canadian Pharmaceutical Journal* a formula for a new material for the administration of opium or other medicine, by suppository. He says that in trials made upon patients suffering from hemorrhoids he has found it, from its elastic texture, to possess advantages over other excipients used for a like purpose. Gelatin being one of the ingredients, it could not be used for making suppositories containing tannin, as an insoluble and inert substance would be formed. The following is the formula:—

Best Glue	4 oz.
Glycerine	8 oz.
Golden Syrup	2 oz.
Water	8 oz.

Soak the glue in the water until quite soft, then dissolve over steam or water bath. Mix the syrup and glycerine well together, add them to the glue solution and boil until they lose about 2 oz. in weight; then pour out on an oiled tray, or into any suitable mould, previously removing any scum formed. The result is an elastic substance, which will keep for a long time, but dissolving more readily when fresh. When required for use the composition should be dissolved in a little water with gentle heat, the opium or other drug mixed with it, and then run into a mould.

CHALK MIXTURE.

The following formula is published in the *American Journal of Pharmacy*, by Mr. W. H. Robinson, of Pottsville, who says he has used it for two years and found it satisfactory:—

℞ Cretæ Præp.	1 troy ounce.
Sacchari,	
Pulv. G. Acaciæ,	each ½ troy oz.
Ol. Cinnamomi	15 drops.

Mix in the usual manner with a pint of water.

SYRUP OF CITRIC ACID.

Mr. Benjamin Lillard, of Nashville, Tennessee, sends the following original formula for the preparation of syrup of citric acid to the *American Journal of Pharmacy*:—

Take of Citric Acid, in fine powder	60 grains.
Water	a sufficient quantity.
Syrup	16 fluid ounces.
Oil of Lemon	30 minims.

Dissolve the citric acid in the water, add the syrup and spirit of lemon, shaking well until they are thoroughly mixed.

When convenient, hot or warm water may be used. He says, "I have used the syrup made by this formula for over eighteen months, including two summers in this climate, and have found it to retain its brilliancy and flavour better than when prepared by the old formula."

A Confidential Circular from New York.—A firm in New York have forwarded printed circulars to many persons in England offering to supply them with aluminium sovereigns. They say that the base coins are "minted with the express design of circulating in Great Britain, being of such perfect execution, and so admirably calculated, both as regards weight, colour, sound, and resistance to acid tests, to deceive the most accomplished experts, that their detection is almost beyond the bounds of possibility." "The aluminium of which they are composed" is stated to have been "discovered in a valley among the Rocky Mountains, and was at first mistaken, not only by the miners but by dealers in the precious metal, for pure gold. It was more than a month before its true character was discovered, for it was so much like pure gold that the difference could be detected only by its lighter weight." The price of these imitation sovereigns is annexed in the "strictly confidential circular"—namely, £2 for 20, 53 for £5, £10 for 108, £20 for 218, and £50 for 550. "No more than 550 sovereigns will be sent at one time to any one person, for fear they might lose their prudence and pass them off too rapidly, thereby causing suspicion, for they are so easily passed that some persons might get too greedy and overdo the business." The circular also contains directions how to send an "order for sovereigns" to a firm of tobacconists in the Broadway, New York, who in the list of prices, also printed, which accompanies the "strictly confidential circular," boast of having "paid over 3,100,000 dollars taxes to Government in four years." It is recommended to "word your letter in sending an order for sovereigns so as to make it read as if you were ordering so many pounds of smoking tobacco." The price list and "strictly confidential circular" are enclosed in envelopes of a yellow colour, with two three-cents postage stamps on each. —*Times.*

Tannin versus Alum.—Dr. Max Jaffé, of Hamburg, says that alum, so frequently used for gargles, is hurtful to the teeth; he thinks that tannin, dissolved in water or red wine, is far preferable.—*Lancet.*

DRUG MARKET NOTES.

Under this head we purpose giving occasionally *some* particulars as to the drugs, etc., imported into this country, and shall be glad to receive information on the subject from correspondents.

Among parcels of drugs which have lately been offered for sale were the following:—

Nux Vomica, 424 bags and 240 pockets.
Gambier, 181 bales.
Bees' Wax,—Madagascar, 9 cases; Cape, 2 cases; Angola, 46 cakes; Gambia, 58 cakes.
Japan Wax, 66 cases.
Sandal-wood, 4 tons.
Sandal-wood Oil, 2 cases.
Roll Annatto, 241 baskets.
Opium,—Turkey, 77 cases; Persian, 25; Indian, 5; Egyptian, 3.
Scammony, 23 cases.
Camphor,—China, 240 cases; Japan, 20 tubs.
Cocculus Indicus, 213 bags.
China Soy, 65 casks.
Honey,—Australian, 5 barrels; Jamaica, 2 barrels.
Castor Oil, 610 cases.
Crown Bark, 53 bales.
Cubebs, 210 bags.
Ipecacuanha, 11 serons.
Cascarilla Bark, 57 serons.
Olibanum, 61 cases.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 3, 1870.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes endorsed "Pharm. Journ."*

CHEMISTS AND DRUGGISTS' FUND FOR THE SICK AND WOUNDED.

In accordance with the notice given some weeks since, we now close the Subscriptions to this Fund. The contributions received since the last publication, October 15, 1870, are as follow:—

	£.	s.	d.	£.	s.	d.
John S. Hodgkinson, Matlock Bridge				0	5	0
Per W. F. Blake, Loc. Sec. at Stroud:—						
W. F. Blake, Stroud	0	10	6			
Mrs. Gay ,,	1	1	0			
James B. Carr ,,	0	10	6			
J. Alfred Pearce, Cainscross	0	10	6			
John Simpkins, Minchinhampton	0	10	6			
				3	3	0
W. M. B., London				0	5	0
Rev. D. Anderton				0	5	0

J. F. Thursfield, Kettering,
15 bottles Condy's fluid,
And a bundle of old linen.

Altogether the money contributions amount to the sum of £139. 17*s.* 2*d.* This has been handed over to the National Association without any deduction. In addition to this sum a large quantity of medicine and materials of various kinds has been sent up to the Society's house, by various members of the trade, and this also has been handed over to the Association. Had the subscriptions to the Fund been more general a very large sum would have been collected; but it must be borne in mind that many who have not contributed to it were compelled to give their aid in conjunction with their immediate neighbours to the local funds raised with the same object, and that this was the only reason why many names are absent from the list of subscribers to the Chemists and Druggists' Fund.

We are informed by correspondents that at two other places besides those mentioned by us last week, members of the drug trade have been chosen as mayors, viz. Beverley, Yorkshire, where James M. Robinson, Pharmaceutical Chemist, has been elected for the sixth time, and Abingdon, Berks, where William Ballard, Pharmaceutical Chemist, fills the office of mayor.

We beg to remind our readers that the meeting to be held on the 7th inst., promises to be of sufficient interest to induce a large attendance. Mr. Howden's communication on the state of Pharmacy in America will offer many opportunities for profitable discussion of our own condition, and for the comparison of various modes of dealing with details. The production of opium in our Australian colonies is also a subject that is of special importance. Mr. Allchin, we understand, will also bring before the meeting a description of an easy and effectual mode of bottling infusions, fruits, etc., for preservation. Mr. C. H. Wood is also to bring forward some pharmaceutical notes.

The *British Medical Journal* announces that the Poor Law Commissioners for Ireland have ordered an apothecary to be appointed who shall purchase drugs, compound them, and distribute them to the various unions. It is thought that, besides securing pure medicines, the expenditure, now amounting to £32,000 annually, may be considerably diminished. The salary is to be £500, and the election is vested in the hundred and sixty-three Poor Law Boards which exist in Ireland.

In the closing number of the forty-second volume of the *American Journal of Pharmacy*, which we have just received, there is an announcement that it is in contemplation to begin the next volume with a monthly issue instead of a bi-monthly one. Mr. William Procter, jun., who has for twenty-five years acted as editor of the journal, expresses his sympathy with the change, but at the same time intimates his intention of taking the opportunity to resign.

The Council of the Apothecaries' Hall of Ireland have selected "The British Pharmacopœia" as the subject for the annual prize to be competed for by apprentices to apothecaries in May next.

The Anniversary Session of the St. Andrew's Medical Graduates' Association will be held at the Freemasons' Tavern, on Saturday, December 3, at 5 p.m., when an address, entitled "For the Future of Physic," will be delivered by Dr. Richardson, F.R.S., President of the Association.

NOTICE.—The reports of proceedings at the meetings of provincial societies frequently do not reach us until some time after the meetings. The secretaries of the societies are requested to furnish these reports as early as possible for insertion in the Journal. They should reach the Editor's office not later than Wednesday morning, if intended for publication in the current week, or if a proof be required, not later than Monday.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The first meeting of this Society for the Session 1870–71 was held at the Philosophical Institution, on Friday, Nov. 11. The Hon. Secretary (Mr. Schacht), having read the minutes of the last meeting, announced the arrangements the Council had made for the ensuing session. These were—

"Organic Chemistry," a course of thirty lectures by Mr. Coomber, F.C.S.

"Inorganic Chemistry," a course of thirty lectures by Mr. Coomber, F.C.S.

"Vegetable Physiology and Economic Botany," a course of thirty lectures by Mr. Leipner.

"Systematic Botany," a course of thirty lectures by Mr. Leipner.

In addition to these regular courses of scientific instruction, there would be monthly meetings in that theatre, open to members and associates, at which subjects of professional interest would be presented. The following was the list as at present arranged:—

Friday, Nov. 11, a lecture by Mr. W. W. Stoddart, F.G.S., on "The Chemistry of the Sugars."

Friday, Dec. 16, a lecture by Mr. Thomas Coomber, F.C.S.

Friday, Jan. 13, a lecture by Mr. Adolph Leipner.

Friday, Feb. 10, Pharmaceutical Papers and Discussions.

Friday, March 10, a lecture by Mr. W. Lant Carpenter, B.Sc.

Friday, April 14, a lecture by Mr. W. A. Tilden, B.Sc.

Friday, May 12, Pharmaceutical Papers and Discussions.

Mr. Stoddart, the President of the Association, instead of the usual inaugural address, then delivered a lecture on "The Chemistry of the Sugars," explaining their natural history, manufacture, and analytical reactions. The latter were more particularly explained when Pharmaceutical preparations were alluded to, as will be seen from the following head-notes:—

The Saccharine Group.—Cane sugar; grape sugar; fruit sugar; office in plant life; office in food; Liebig's theory doubted; distinction between sugar, starch, and gum.

Cane Sugar.—(Sucrose $C_{12}H_{22}O_{11}$), in what found, manufacture, statistics, preparation on the small scale; sucrates (Liq. Calc. Sacch.), crystalline form (sugar candy), properties, decomposition, by heat (barley sugar), (Sacch. Ust.), by chemical agents, by alkalies, by acids (Syr. Limon.), (fruit tarts).

Grape Sugar.—(Dextro-glucose $C_6H_{12}O_6$), where found, manufacture, statistics, American method (bread), glucosides, from cellulose (*Cetraria islandica*), false honey, false manna, properties, fermentation (beer, alcohol), decomposition, by heat (glucose caramel), by chemical agents (Bottger's test, Trommer's test, Mel Æruginis), by acids (cod-liver oil), by alkalies (Mulder's test).

Fruit Sugar.—(Lævo-glucose $C_6H_{12}O_6$). Where found, properties (treacle).

Analysis.—Centigrade testing (Lowe's test), fermentation process, specific gravity (Syr. Simplex), polarizing saccharimeter, impurities.

The whole was illustrated by copious experiments and apparatus. Two polarizing saccharimeters were shown and explained. One of the well-known Soleil model, and the other of more recent construction by Hoffmann, of Paris. Among the specimens of cane-sugar was a splendid crystal, nearly two inches long, with the faces and angles perfectly formed,—in fact a saccharine Koh-i-noor. Among the statistics given was one that sounded somewhat startling, namely, that each Englishman consumed more than a quarter of a hundredweight of sugar per annum. The experiment showing the fermentation process was especially interesting. The sugar was seen fermenting, and the carbonic acid was collected. The carbon was then separated from the gas as a black powder.

Just as we are going to press, we have received reports of meetings of the Glasgow Chemists and Druggists' Association (Nov. 14) and the Liverpool Chemists' Association (Nov. 24).

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting at Liverpool.

Wednesday, September 14th.

(*Continued from page* 436.)

Pharmaceutical Exhibition, held at Liverpool, September, 1870, in connection with the Meeting of the British Pharmaceutical Conference.

Agnew, J., *Liverpool.*
Cod-liver oil jelly.

Attfield, Professor.
Weights and measures. Comments on the metric decimal system. Model illustrating the cubic contents of a litre.
Photographs of prominent Members of the Pharmaceutical Conference.

Austin and Co., *Liverpool.*
Cardboard, wood and ornamental paper boxes for chemists' use. Glass feeding-bottles.

Baildon, H. C., *Edinburgh.*
India-rubber poison capsules. Saccharo-chirettine—active principle preserved by sugar, by D. S. Kemp and Co., Bombay and Poona.

Balmer, J., *London.*
Specimens of the sulpho-carbolates of the metals, alkalies and alkaline earths.
The new belladonna plaster. *See* Pharm. Journ., May, 1870.

Barber, George, *Liverpool.*
Pharmaceutical labels for bottles, drawers, museums or cabinets of materia medica. Each label contains an abridgment of the information found in the Pharmacopœia. In this way the labour of reference is avoided.
The medico-botanical map of the world and pocket companion to the Pharmacopœia.

Beatson and Co., *Rotherham Glass Works.*
Poison bottles.

Blandy, H. Blandy's patent wash-bottle for nitrous oxide gas.

Bostock, W., *Ashton-under-Lyne.*
Genuine medicated lozenges.

British Seaweed Company, Limited, The, A fine collection of products from seaweeds, obtained by Stanford's process, numbering about fifty specimens; the series includes three varieties of *Laminaria* and three varieties of *Fucus*, which are generally used for this purpose. The charcoals from these are all shown, and the residues after lixiviation. The crude potash and soda-salts thus obtained, with crude iodine and bromine, follow in a series. Resublimed iodine, in fine crystals, and a collection of pure potash salts, manufactured by this Company, are also exhibited. The pure chloride forms the basis of these; sulphate, carbonate and bicarbonate, iodide and bromide are specially well-represented salts of which the Company are large makers. This admirable collection has been presented to the Museum of the Pharmaceutical Society, by Edward C. C. Stanford, Esq., who has promised further to add to it, and to exhibit results of his latest researches on seaweed.
A stuffed specimen of the *Fulmarus glacialis*, or *Fulmar Petrel* of St. Kilda, and a specimen of the oil vomited

by it. This remarkable bird is described in a paper read before the Conference by Edward C. C. Stanford, Esq., and the specimen is presented by him to the Pharmaceutical Society.

Products from excreta obtained by Stanford's process. These are sulphate of ammonia and solution of ammonia, exhibited to show the purity of ammonia salts from this source. Acetate of lime and excreta charcoal which has been burnt twenty times. The process is a dry process, in which charcoal is substituted for earth; the quantity required is one-fourth that of earth, and the supply is derived from the excreta itself; the charcoal from this source being a most powerful deodorizer.

Particulars of Stanford's patent process may be seen in the *Chemical News*, vol. xx. p. 196, also *Report of British Association*, 1869, and *Proceedings of Glasgow Philosophical Society*, 1869.

BUSHBY, THOMAS.
Pill-making machine.

CALVERT AND CO., *Manchester*.
Carbolic acid, crude and refined.
Sulpho-carbolates.
Carbolic soaps, in bar and cakes.
Picric acid.
Disinfecting powder.

'CHEMIST AND DRUGGIST,' PROPRIETORS OF THE *London*.

The whole of the designs (twenty-eight in number) for a dispensing counter, for the prize offered by the proprietors of the *Chemist and Druggist*. The competitor who obtained the prize was Filmer Kidston, Duke Street, Union Street, Bishopsgate, London, with the following report:—"This design has several points of excellence; besides being the best arranged and most convenient as a dispensing counter, it is handsome in appearance without being showy."

Five other competitors were awarded honourable mention, viz. Messrs. Beynon, Fletcher, Watson, Willis, and Young. The gentlemen appointed to judge the merits of the designs were Messrs. T. H. Hills, Joseph Ince and Charles Savory. The various designs seemed to afford great interest to pharmaceutists, and were freely criticized during the whole time the Exhibition was open.

A model of the arrangement for the storage of poisons, by Mr. J. C. Young, of Warrington. A full description, with engraving, appears in the *Chemist and Druggist*, September 15th, 1870.

DINNEFORD AND CO., *London*.
Improved horsehair flesh gloves, belts, Clarendon flesh rubbers, Cambridge and excelsior pads, horse glove brushes, etc., manufactured by them with improved machinery.

ELLIS AND CO., *Ruthin*.
Mineral medicated waters.

EVANS, SON AND CO., *Liverpool;* AND EVANS, LESCHER AND EVANS, *London*.

One of the most interesting series of objects exhibited was a large collection of living plants in pots,—mainly contributed, we understand, by the kindness of Mr. Tyerman, Liverpool Botanic Gardens, and representing the source of many articles of materia medica not produced in Great Britain. The list is as follows:—

Jalap; camphor; Barbadoes aloes; green tea; tapioca; lime; arrowroot; scammony; gamboge; annatto; lemon grass; nutmeg; cinnamon false, ditto true; clove; locust; castor oil; coffee; vanilla; cinchona pale, ditto yellow; nux vomica; mango; jatropha curcas, or physic nut; caper; ginger; long pepper; tamarind; black pepper; balsam of Peru; pomegranate; Montserrat lime fruit juice, and mature fruit; and tree with immature fruit imported from the Olveston plantation in the island of Montserrat.

MESSRS. EVANS, SON AND CO. also exhibited a large collection of drugs and pharmaceutical preparations, concentrated waters, etc.
Bengal opium.
Patna ,,
Turkey ,,
And various other raw drugs.
Sapo durus for liniments, with specimens of lin. potass. iodid., etc.
Crystallized oil of thyme, or thymol.
Cabinets of materia medica and chemicals; Lescher's 'Elements of Pharmacy,' and other books; pharmacy microscopes of various powers, prices, etc., suitable for students.

EVANS, R., *Liverpool*.
Improved feeding-bottle.

FOULKES, W. J., *Birkenhead*.
Transparent fluid cement.
Specimens of breakages in glass and pottery admirably joined therewith.

GILBERTSON AND SONS, *London*.
Poison bottles, Merrikin's patent pentagon acid bottles with indestructible labels.

GILLON AND CO., *Leith*.
Extractum carnis and essence of beef, concentrated meat essences, sweet milk, preserved fresh salmon, lime-juice cordial and other preparations.

GOODALL, H., *Derby*.
Levigating machine, and specimens of drugs ground thereby.

GOOSEY AND ROGERS, *Stepney, London*.
Marginal plasters.

HARGREAVE AND CO., *Manchester*.
Poison bottles.

HARVEY, REYNOLDS AND CO., *Leeds*.
Large photograph of business premises.
Fine specimens of extract from English beef.

HAYWOOD, J. S., *Nottingham*.
Model displaying elastic surgical stockings and the applications of elastic fabric.
Truss, chest warmer.

HERRINGS AND CO., 40, *Aldersgate Street, London*.
Expressed juices, officinal and non-officinal, of conium, digitalis, wild lettuce, henbane, belladonna, broom, colchicum, goose grass, taraxacum, buckthorn, buckbean, etc.

Resin of scammony, entirely free from saccharine matter most commonly found in the resin scammony of pharmacy, which in the majority of specimens is merely hardened alcoholic extractive of scammony root; scammony roots.

Ol. myristicæ express.—This oil is obtained by hydraulic pressure from crushed nutmegs; in odour it is far superior to common oil of mace.

Expressed oil of stavesacre obtained by hydraulic pressure (50 cwt. to the square inch) from the crushed seeds of *Delphinium Staphysagria*. This oil is now used in preference to the ointment in some of the London hospitals.

Resin podophyllin is now almost wholly imported from the United States, where it is obtained by a process somewhat different to that of the British Pharmacopœia. The specimen manufactured according to the B. P. process is equal, if not superior, to the imported resinoid.

Sulphate of quinine. Citrate of iron and quinine (containing an equivalent of 25 per cent. sulphate), also citrate of iron and quinine of corresponding strength, made with amorphous quina.

As the manufacture of quinine is only carried on in two or three establishments in the kingdom, we have seldom opportunities of seeing the results of the competition of English manufacture. The specimen exhibited is, we think, as good as any we have previously seen.

Specimens also of granular effervescent citro-tartrate of soda, and of powders as ground in their drug mills.

Messrs. Herrings' laboratories and drug mills are under the superintendence of Mr. C. Umney, whose name is well known to pharmaceutical chemists.

HODGINSON, KING AND Co.

Quinovate of lime, a new preparation of Peruvian bark.

Bichloride of methylene, a new anæsthetic.

HOOD AND Co., *Melbourne*. EXHIBITED BY MORSON AND SON, *London*.

No. 1 opium, from Sunbury, near Melbourne.
No. 2 „ from Gisborne, near Melbourne; rich alluvial soil, well manured.
No. 3 „ from Gippsland; rich soil, cold climate.
No. 4 „ from near Gisborne; volcanic soil.
No. 5 „ from South Yarra.
No. 6 „ from Dromana, on the shores of Port Phillip; very sandy soil.

A paper upon these specimens of opium was communicated to the Conference by Mr. Morson.

HOPKIN AND WILLIAMS, Messrs., *London*, LIST OF SPECIMENS EXHIBITED BY.

1. Mercury biniodide. 2. Bismuth citrate ver. 3. Zinc sulphocarbolate. 4. Soda sulphocarbolate. 5. Iron sulphocarbolate per. 6. Uranium nitrate. 7. Anthraquinone. 8. Iodoform. 9. Iron iodate. 10. Delphine. 11. Papaverine. 12. Ammonia tartrate (neutral). 13. Acid cinnamic. 14. Lithia citrate cryst. 15. Chloral, pure anhydrous. 16. Ditto (insoluble modification). 17. Chloral, hydrate (mass). 18. Ditto, recryst. pure. 19. Ditto, recryst. from Benzole. 20. Chloral, methylate. 21. Chloral, alcoholate. 22. Chloral, butylate. 23. Chloral, amylate. 24. Chloralide. 25. Bromal hydrate. 26. Ethylidene chloride. 27. Methyl acetate. 28. Ethyl bromide. 29. Amyl nitrate. 30. Amyl nitrite. 31. Amyl chloride. 32. Amylene bromide. 33. Amylene bibromide. 34. Benzoyl chloride. 35. Propylamine. 36. Acid chloracetic. 37. Hæmatoxyline cryst. 38. Cantharidine. 39. Curari poison. 40. Ethal. 41. Cholesterine. 42. Apomorphia hydrochlorate. 43. Tyrosine. 44. Leucine.

Notes on the above Specimens.

2. Bismuthi citr. ver. Suitable for liq. bismuthi ammon. citr. B. P. 5 grains to 1 dram nearly represents the Pharmacopœia strength: it is readily soluble in ammonia; is also quite free from copper, arsenic and other impurities.
7. Anthraquinone. Interesting as being the intermediate product between anthracine and artificial alizarine; also as one of the series of "kinones."
8. Iodoform. Now largely used as a local anodyne.
9. Iodate of iron. Lately used in medicine.
15. Pure anhydrous chloral. In liquid form.
16. „ In its insoluble form.
17. Chloral hydrate. Fused.
18. „ Recrystallized from bisulphide of carbon.
19. „ Recrystallized from benzol.
20. Chloral methylate. Combination of chloral and methyl alcohol, deliquescent.
21. Chloral alcoholate. Sometimes sold as chloral hydrate, but far less effective.
22. Chloral butylate. Possesses a very pleasant smell; insoluble in water.
23. Chloral amylate. Insoluble in water, crystallizing with great beauty; the combination of chloral with various alcohols is attended with great rise of temperature; in the case of the methyl compound, the mixture actually boils. All these compounds can be readily distilled, and thus be obtained of constant boiling-points, and quite pure.

Chloral hydrate, when distilled, gives a very white and beautiful product.

24. Chloralide. Product of the long-continued action of boiling sulphuric acid on chloral. This body differs essentially from all the other known chloral compounds, inasmuch as when treated with alkalies it yields no chloroform.
25. Bromal hydrate. Now being tried medicinally, but its action not yet fully understood. Its vapour produces a copious flow of tears.
26. Ethylidene chloride. A new anæsthetic, introduced to medicine by Dr. O. Liebreich, of Berlin.
30. Amyl nitrite. This body when pure has a remarkable effect upon the action of the heart, and has been largely used to relieve the spasm in angina pectoris; it is often improperly confounded with nitrate of amyl, a substance quite destitute of the peculiar properties of the nitrite.
35. Propylamine. One of the compound ammonias having a strong odour of herring-brine; used as a remedy for rheumatism.
36. Chloracetic acid. In crystals; a substitution representative of glacial acetic acid.
39. The Curari or Woorari poison; the arrow-poison of the South American Indians. When applied to a wound, it produces death, but may be administered internally without any ill effects,—is said to act as an antiperiodic.

HOWE, E. W. AND Co., *London*. Pure chloral; bromal hydrate; carbonate of lithia; white shellac.

HUSTWICK, T. H., *Liverpool*.

Specimens of sulpho-carbolates of ammonium, magnesium, sodium, calcium, copper, iron and zinc, also carbolic acid mouth-wash.

HUTCHINSON, JOHN AND Co., *Widnes*.

Specimens of alkali in various stages of manufacture, and samples of sulphur recovered by Mond's process.

INCE, J., *London*.

Collection of old books, illustrative of the pharmacy of the sixteenth and seventeenth centuries.

JONES, ORLANDO AND Co., *London*.

Chapman's entire Wheat-flour.

LIMOUSIN'S OXYGEN GAS INHALING APPARATUS.

Limousin's drop measures give drops of equal size and of the weight of 5 centigrammes of distilled water. A table, showing the number of drops of several fluids making one gramme, accompanies each measure.

LIVERPOOL CHEMISTS' ASSOCIATION.

Collection of 70 medicinal plants, presented to the Association by Ransom, of Hitchin.

LOWE, CHARLES AND Co., *Manchester*.

Carbolic acid crystals, a solid block weighing $1\frac{1}{2}$ cwt
Picric acid crystals.
„ paste.
Anthraquinone.
Sulphophenate of soda.
„ of zinc.
Anthracene, crude.
„ pure.
Rosolic acid, crude.
„ pure.
Naphthaline.
Disinfecting powder.

MACFARLAN, J. F., AND Co., *Edinburgh*.

Samples of opium.
Morphia and salts.
Apomorphia muriate, got by the action of hydrochloric acid on morphia.
Oxymorphine (morphine + O), new base (Matthiessen).
Codeine and salts.
„ reproduced from chlorocodide.
Apocodeine chloride, got by the action of chloride of lime on codeine (Matthiessen).
New base, got by the action of H_2SO_4 on codeine (Matthiessen).
Narceine.
Meconine, from E. opii.
„ „ opianic acid.

Meconine, from narcotine, by water.

These three specimens of meconine have precisely the same chemical composition and physical properties; hence it may be assumed that meconine is not a normal constituent of opium, but a product of the decomposition of narcotine.

Papaverine.

Thebaine.

Meconic acid.

Narcotine and products of decomposition.

New base, obtained by the action of H_2SO_4 on narcotine (Matthiessen and Armstrong).

Hydrochlorate of cotarnamic acid, a new poison (Matthiessen).

Greenheart bark and nuts.

Bebeerine sulphate (com.).

„ pure.

Marks, H., *London, Sponge Merchant.*

Fine sponge, on rock, very rare.

Finger sponge; Turkey cup and honeycomb.

Martin, F. R., *Redland, Bristol.*

Numerous specimens of alkaloids and pharmaceutical preparations, also microscopic slides of rare salts, also microscope and spectroscope.

Martindale, William, F.C.S., *London.*

Plaster-spreading apparatus, as described in the Pharmaceutical Journal, p. 33, July, 1869, with additional improvements, so that the front plate can be entirely removed and the whole cleansed with much greater ease than in the original apparatus, by the different arrangement of the screw-adjustment for regulating the thickness of the plaster.

Mason, A. H., *Liverpool.*

Specimens of artificial borax crystallized on rods.

Maw, Son and Thompson, *London.*

Collection of sundries common to the pharmaceutical counter. A great variety of syringes, magneto-electric machines, and an exceedingly fine specimen of enamelled glass, representing the Pharmaceutical arms—unfortunately broken in unpacking.

Pessary and suppository moulds, made according to the pattern designed by Mr. H. B. Brady, of Newcastle-on-Tyne.

We notice a stove designed by Mr. Groves, of Weymouth, and manufactured by Messrs. Maw and Son. It is made up of a series of Bunsen burners in three rings, mounted on a stand, which can be adjusted to any convenient height. Each ring of burners is under the control of a separate tap, there being also a tap which regulates the whole. This arrangement gives a great range of heating power, one good feature being that the gas can be lowered to the lowest conceivable point without going out, as in the case with ordinary large Bunsen burners. Up to this time a stove of the kind, adapted alike to the requirements of both large and small pharmacies, has been a great desideratum.

Mottershead and Co., *Manchester.*

A series of cheap German thermometers for laboratory use; the scale is permanently marked on a slip of milk-glass or paper, which, presenting a flat surface to the eye, is easily read off. This slip is enclosed with the tube containing the mercury in an outer strong glass tube. These thermometers are made with scales ranging from 212° to 600° F., at prices from 2*s*. upwards.

Various sets of hydrometers, conveniently arranged with trial jar, thermometer, etc., in cases.

Various forms of Bunsen's gas burners, illustrating methods of regulating the supply of air to that of gas.

Series of reagent bottles, with indestructible enamelled labels.

Funnel jackets for the filtration of fats, etc., at high temperatures.

Small apparatus for producing and keeping a constant supply of sulphuretted hydrogen for the use of chemists.

Fine wire-gauze masks for protecting the face in chemical experiments.

Improved Dobereiner's hydrogen lamps.

Benger's automatic apparatus for maintaining constant temperatures in some chemical and pharmaceutical operations. *See* Pharm. Journ. p. 252.

Forms exhibited, a drying closet and an evaporating basin.

Proctor, B., *Newcastle-upon-Tyne.*

Pill scoop.

Redford, A., *Liverpool.*

Improved pessary mould.

Richardson, R., *Cork.*

Goulding's flower and plant food.

Newnham's pure condensed milk.

Pessary mould.

Rimmel, E., *London and Paris.*

Perfume vaporizer and fountain.

Sarg and Co., *Vienna.*

Glycerine. Scented glycerine.

Solid and liquid glycerine soap.

Silicated Carbon Company.

Filters for domestic and manufacturing purposes.

Southall, Son, and Dymond, *Birmingham.*

The objects exhibited by this firm were in four parts:—

I. A collection of the officinal drugs of the Pharmacopœia of India, which are not contained in the British Pharmacopœia, 1867. These drugs were exhibited in glass jars, to which were affixed printed labels, conveying the

Botanical names,
Habitat of plant,
Officinal part employed,
Properties of ditto,
Therapeutic uses,
Recognized preparations,
And doses.

The following is a list of the whole of these drugs which this firm exhibited:—

Rusot (or Rasot). *Hind.* Watery extract from the wood and bark of species of Berberis (*non-officinal*).

Azadirachta Indica. *Nim or Margosa* Bark and Oil.

Luffa amara. *Bindaal.* Stalks of plant.

Coptis Teeta. *Coptis or Mishnu.* The dried root.

Datura alba. *Dhatura.* The leaves and seeds.

Aconitum heterophyllum. *Atís.* The dried root.

Aconitum ferox. *Bikh or Bish.* The dried root.

Diospyros embryoptera. *Gab.* The fruit.

Narcotine. Alkaloid.

Pharbitis Nil. *Kaladina.* The seeds.

Andropogon (Cymbopogon) Nardus. *Citronelle.* The oil.

Andropogon (Cymbopogon) citratum. *Lemon Grass.* The oil.

Mylabris Cichorii. *Telini fly.* The dried insect.

Carum (Ptychotis) Ajowan. *Ajwain or Omum.* The fruit.

Plantago Ispaghula. *Ispaghúl.* The seeds.

Tinospora cordifolia. *Gulancha.* The root and stems.

Butea frondosa. The seeds.

Gynocardia odorata. *Chaulmugra.* The seeds and oil.

Hydrocotyle Asiatica. *Indian Pennywort.* The leaves.

Cæsalpina (Guilandina) Bonducella. *Bonduc.* Seeds.

Citrus Bergamia. *Lime.* The fruit.

Dipterocarpus lævis. *Gurjun.* Wood oil.

Boswellia floribunda. *Olibanum.* The gum resin.

Sinapis juncea. *Rai or Indian Mustard.* The seeds.

Garcina pictoria. *Indian Gamboge.* The gum resin.

Soymida febrifuga. *Rohun Tree.* The bark.

Acacia Catechu. *Catechu.* The extract of heart-wood.

Alstonia scholaris. *Alstonia.* The bark.

Anamirta Cocculus. *Cocculus.* The dried fruit.

Punica Granatum. *Pomegranate.* The root bark.
" " " The dried pericarp of fruit.
Andrographis paniculata. *Kariyát.* The dried stalks and root.
Mucuna pruriens. *Cowhage.* The hairs of the pod.
Oryza sativa. *Rice.* The husked seeds.
Berberis. *Indian Barberry.* The root bark.
Gracilaria lichenoides and G. confervoides. *Ceylon Moss.* The dried plant.
Calotropis gigantea. *Mudar.* The root bark.

II. A case containing large specimens of eight scale preparations, and six salts of bromine and iodine manufactured by this firm, viz.:—
Ferri et Ammoniæ citras, P.B. 1867.
" " " made with iron wire.
Ferri et Quiniæ citras, P.B. 1867.
Ferri et Strychniæ citras.
Ferri citras; ferri pyrophosphas; ferrum tartaratum; bismuthi et ammoniæ citras; cadmii bromidum; cadmii iodidum; ammonii bromidum; ammonii iodidum; potassii bromidum; potassii iodidum.

III. Four tall glass jars, containing specimens of Analysed Drugs answering to the tests of the British Pharmacopœia, 1867, viz.:—
Opium, containing *at least* 6 to 8 per cent. of precipitated morphia.
Scammonium, yielding from 80 to 90 per cent. of resin.
Yellow cinchona bark, containing at least 2 per cent. of nearly pure quinia.
Pale cinchona bark, yielding not less than ½ per cent. of alkaloids.
(The importance of affixing to these (and other) drugs a guarantee of strength, so as to ensure uniformity in the administration of doses, cannot be over-estimated.)
Four other tall glass jars, containing specimens of
Oleum Morrhuæ,
Succus Taraxaci,
Oxymel Scillæ, and
Solution of Iodide of Iron.
(One fluid drachm of this solution is equivalent to one drachm of solid iodide of iron. It is readily employed in dispensing and in making the syrup of iodide of iron, which, if made with grape sugar, will keep well without decomposition.

IV. Several cases of the sixth edition of the collections of specimens of the organic materia medica of the British Pharmacopœia, 1867, for the use of medical and pharmaceutical students.

Silverlock, H., *London.*
Working model of poison cabinet, containing 40 labels of various sizes on revolving stand, only 1 label on either disc being exposed to view at once.
Labels on red ground, and distinctive collection of dispensing and trade labels.

Spence, Berger and Co., *Manchester.*
Samples of Mudie's disinfectant.
Jordan's Norway cod-liver oil.

Spence, Peter, *Manchester.*
Very fine crystals of alum, manufactured under exhibitor's patent.

Sumner, R., jun., *Liverpool.*
Nicely crystallized specimens of sulphocarbolates of zinc and soda.

Thonger and Co., *Liverpool.*
Poison labels.

Tomlinson, M., *Manchester.*
Mahogany dispensing counter with carved glass cases and mirror screen, and fitted with expedio label rack
Species jar, pedestal stand and sundries.

Watts, Dr. J., *London.*
Variety of tanning materials, with estimation of amount of tannin.
Extract of *Abies Canadensis.*

Webb, A., *Clapham.*
Herbarium—an excellently arranged collection of dry plants, for which the prize medal of the Pharmaceutical Society was awarded, October 5, 1870.

Whitthread, Mr., *Liverpool.*
Specimen of *Pistachia Lentiscus* plant, and of *Pistachia Terebinthus*, from Scio; also fine white gutta percha and pure silica.

York Glass Company.
Swan-necked show bottle, percolators, poison bottles, etc.

MEDICAL SOCIETY OF LONDON.

In a paper read lately before a crowded meeting of Fellows of the Medical Society of London, Dr. Richardson discussed the medical aspects of the germ theory. He pointed out that however medical men might differ on the question, yet there were some points in which they all agreed. They agreed that certain diseases owe their origin to what might be designated poisons, that these poisons are organic in their construction; that they can produce specific phenomena of disease; that they are communicable under certain well-understood conditions. They also agreed pretty well as to the diseases which are due to these organic poisons.

But from this common ground some turned to what may be called the vital road, others to the chemical, or to the physical, in which the vital and chemical are either correlated or considered identical.

Dealing first with the vital or germ theory, Dr. Richardson said that it arose from the analogy of the process of growth and development of plants and animals. The theory was that diseases called communicable have their origin in germs possessing the inherent property of reproduction. Within the body these germs reproduce themselves, and thereby excite disease. Outside the body they float in the air, mingled with dust, or adhere to solid substances, or are suspended in water in which they are not soluble. Owing to their vitality, it is urged they are indestructible under ordinary conditions of cold and heat, moisture and dryness. We ask from whence disease comes, and are told from a germ. We ask, what is a germ? We are told that it is a living organism, capable of reproduction; a ferment plant possessing the power of exciting fermentative changes in the human body, the disease being the sign of the fermentation; or it is a micrococcus, the spore of a fungus, which, put into a soil rich in nitrogen, multiplies by division, and becomes the cause of diseases bearing the signs of putrefaction. But there was a natural fermentation existing in the body previous to the fever. Is this, then, a new fermentation? If so, of what kind? Or, if it produces putrefaction, where is the putrefaction? The germs have been compared in their action to pepsine, but pepsine is an animal secretion, and a dependent substance. Germs are said to withstand influences which destroy the vitality of higher forms of life. If they are reproduced with such rapidity under favourable conditions, and possess such persistency of life, there would be so great an increase of them that in time the world would be depopulated. But where are the germs of such diseases as the black death, plague, sweating sickness, dancing mania, and the ague of London in the time of Sydenham and his contemporaries? Can improved sanitary conditions have any effect in destroying living reproductive germs which resist the ordinary causes of death and dissolution? Again the theory fails to account for the fact that some epidemics are most pronounced in the last quarter, and least in the second quarter of each year; that sometimes they are attended with low and sometimes with high mortality; that scarlet fever occurs most frequently between the fifth and tenth years, and with rapidly lessening frequency after the tenth year;

and the immunity from recurrence of such diseases as scarlet fever and small-pox.

The physical theory differs from the vital in that it places the reproductive force of the virus in the animal itself. It does not dispute that the poisons assume the solid form, and are carried about by water and air, but it declares their perfect destructibility. The result of experiments by Fordyce, confirmed by Chauveau,—showing that the virus of small-pox, diluted by water up to a certain point, is active, but beyond that point inert,—was explained by the germ-theorists as being caused by the mechanical distribution of the germs by the water, which lessened the certainty of inoculation. The physical theorists, besides this, assume the molecular disintegration of the particles by water. The author had found that, after diluting snake poison largely with water, not only was its power to infect destroyed, but evaporation of the water and reconcentration failed to bring it back. Dr. Richardson looks upon the poisons as organic products, particles derived from the secretions of the animal body. Thus, a person suffering from a communicable disease is poisonous precisely as a cobra di capello is poisonous,—that is to say, he produces by secretion an organic poison which, coming in contact in the right way with a healthy person, produces disease. In some cases, a change in the natural secretion is induced by direct contact with the poisonous matter, causing it, as it is poured out, to be changed into a substance the same as that which excited the action; this may either be carried away and replaced by a new and healthy secretion, in which case there is recovery, or be absorbed into the blood, exciting change there also, and so lead to disorganization of the blood and death. In other cases, the secretions themselves undergo decomposition, arising from atmospheric influences, or the constitutional tendencies of the person affected, the effects following being precisely the same as those following its introduction into the body. The author also maintained that the physical theory explains the specific character of each poison. Whatever the mode of entrance of the poison, it acted according to its nature, by making election of one particular secretion. It also explains the limitation of the poisons, for, if it be the particles of an animal secretion that become poisonous, their production and dissemination must cease with the life of the animal. This is the fact; the dead are not contagious like the living, and epidemics cease as their poisons are resolved into elementary forms of matter. He claimed also that it accords with the facts relating to the seasons, it being natural that changes in secreted fluids should be most active when there is excess of moisture in the air and coldness.

Dr. Richardson said that if the evidence of such change was insufficient, it was better than any produced for the germ theory. In the study of change of colloidal bodies by contact, the action of the different oxygens on animal fluids, the action of known organic chemical compounds such as nitrite of amyl, there was ample suggestion for experimental research on the organic poisons derived from animal bodies. In conclusion, his object had been to show that the germ theory of the origin of communicable disease was not to be accepted in one eager grasp as the absolute truth; that, beautiful as it was from analogy, and grand as it was as a generalization if it were true, it might after all be a delusion.

SOCIETY OF ARTS.

On Fermentation.

BY PROFESSOR A. W. WILLIAMSON, F.R.S.

Lecture III.—continued.

I stated that exposure to a red heat was found by Pasteur to act effectually in destroying the vitality of these little particles, and in every case in which he used air which had been subjected to that heat, he found that the air was incapable of sowing any of these organisms in liquids even the most favourable to them. There was, however, still one remarkable exception, which was presented by the experiment of Gay-Lussac, to which I alluded some time ago. He found that when he used a mercury trough, which he selected as giving him the best condition for the purpose, he got these little cells produced from the air which had been calcined. Now, Pasteur found that mercury exposed to the air, as it is in these operations, has adhering to it a number of these little germs, and that when no more than the ordinary precautions are taken for cleansing the mercury, it has with it a considerable variety of such little organisms, which, if placed in a suitable material, develop themselves and grow quite well. He proved this in various ways. For instance, some of the little bulbs which had been sealed up whilst full of fermentable liquor and steam, and which had been kept for some time in a warm chamber, so as to be certainly free from vital organisms, were opened under mercury, so as to allow the ends of the tubes to be filled with mercury. He then lifted it up, so that nothing came into contact with the liquid but mercury, and passed into them sometimes air which had been passed through a red-hot platinum tube, and sometimes oxygen gas given off from molten chlorate, where certainly there would be nothing of organic life present, and in almost all these cases he found that organisms developed themselves. He attributed this entirely to the mercury, because when that was absent the result was the opposite. In order to prove this point more decisively, he took a liquid which was capable of decomposing, kept it for some time in a quiescent state, and then allowed a drop of mercury, in the state in which he had been using it before, to flow into it, and put the mixture into his warm chamber. He soon found that the mercury had carried in the germs of these organisms, and that they developed themselves quite well in it. Certainly any one unaccustomed to such accurate precautions could hardly have anticipated such a result as that, and a result which is, I think, most instructive, as showing what extraordinary precautions are needed, in order to prevent the entrance of these excessively small particles into the materials which we are working with. Side by side with this, I must mention another result of Pasteur's, for it was, perhaps, hardly less startling, and that was, that when, instead of taking the liquid which I mentioned to you just now, yeast-water and sugar, he took common cow's milk, or, at all events, the mixture which is sold by that name, and boiled it, with a view of destroying any organisms that might be in it, and then he sealed up the bulb while still full of steam, so that no air could get into it, and when he kept such sealed-up bulbs for some time in a warm chamber, he found clear evidences of decomposition; he found a turbidity in the substance, a curdling of the nitrogenized materials of the milk: and on taking out some of it, he found it was swarming with little animalcula; and yet he had boiled the milk for a considerable time, and had closed the vessel whilst the ebullition was still going on, so that no air could have carried the germs into it before it was closed. Still, there were the little organisms unmistakably present. He then modified his experiment in this manner. He boiled his milk at a higher temperature. I need hardly tell you how that can be done. You are, of course, aware that the temperatures at which water, or milk, or any liquid boils are different, according to the pressure which the air exerts upon it; that is to say, if you were to boil water here, and then if you were to carry it to the top of St. Paul's, and notice the temperature in each case, you would find that at the greater height it would boil at a lower temperature. If, in like manner, you carried it down to the bottom of a deep mine, and boiled it there, you would find the temperature would be higher; the greater the pressure of the superincumbent air, the higher the temperature at which any liquid boils. Pasteur wanted to make his milk boil at a higher temperature, and for that purpose he resorted to a very simple device. He had a long tube attached to the vessel in which his milk was boiling, bent over at the top, and brought down into a glass jar containing mercury to the depth of fifteen inches, or more. Of course, under these circumstances, the steam, which was being formed in the vessel, has to force its way up against the pressure of this mercury; the pressure of these fifteen inches of mercury was added to the pressure of air, and a total pressure was obtained, about half as much again as the pressure of the atmosphere amounted to. Of course, the milk had to boil at a higher temperature, corresponding to this higher pressure; and what did he find then? He proceeded, as before, with the experiment, closing the vessel while it was boiling, and not letting any air into it. He then kept it, and he found that no organisms appeared, even on keeping it a very long time; and he was, therefore, led to conclude that the milk must have contained in it some germs which could withstand the temperature at which the milk was boiling at first, but the vitality of which was destroyed by exposure to the higher temperature to which he exposed it in the subsequent experiment. He had reason for that, for other experiments had been made by himself, and by various other philosophers, which proved that many species of organisms can withstand a very high temperature without losing their vitality. In that respect, there are great differences amongst these little organisms which are remarkable and interesting, and will, no doubt, be of value to future investigations. To give you an idea of the great variety presented by them in their power of withstanding heat, I may mention, that if I were to heat the contents of this carboy, in which the alcoholic fermentation is going on, to 60° Centigrade (100° being boiling-point Centigrade), which is rather more than half, the fermentation would be completely arrested, and the yeast-cells would be killed. On the other hand, the particles in milk are capable of withstanding 100°. Pasteur connected that fact with the circumstance that milk is alkaline, whilst this liquid is acid, and, as a rule, acid liquids destroy the vitality of these organisms at a lower temperature than alkaline liquids. That is not all. There are in the particles themselves great differences in their power of withstanding heat. Amongst the experiments which are particularly remarkable in that point of view, I ought to mention some with regard to the little spores of mould, and such-like things; for instance, the *Penicillium glaucum*, and some others. M. Pasteur collected some of these; and after taking a little piece of asbestos, or mineral flax, as it is sometimes called, and heating it in a flame, so as to destroy anything adhering to it, he put it carefully into a vessel in which some of this mould was growing, and moved it about, so that a number of particles of the seed of the mould might adhere to it. He then heated the asbestos thus coated with dust to 120° C., a higher temperature than that to which the milk had been exposed; but after putting it into a liquid capable of feeding mould, he found that the mould made its appearance in considerable quantity, so that the germs of that particular organism were not destroyed by 120° of temperature. He even went higher, as far as 125°, and found that that was not enough, but a little over 125° killed them; 130° they cannot stand, so that, according to these observations, the limit appears to be between 125° and 130°.

In all the cases of which I have been speaking, the ferments (because all these organisms are in their nature and functions analogous to the common ferments) were removed from the substances which were employed before the air and such-like materials carrying the germs, were brought in contact with them.

With regard to processes for arresting fermentations and decomposition in liquids in which they are taking place, a number of observations have been made which are of considerable practical as well as theoretical importance, in relation to the results which I have been stating. Of course, mere heating, carried to a sufficient intensity, will arrest any process of fermentation or putrefaction which may be going on in a substance, and the applications of that process are, of course, exceedingly numerous and important. The only thing is, that we do not know, and it would be most hazardous to suppose that, in any particular case, we can name beforehand the temperature requisite to destroy a particular organism. If any observer were to say that he has exposed a mixture to 100°, and, therefore, the organism must be destroyed, experience would refute him; if he said he had exposed it to 110°, or even 120°, experience again would refute him; but if he had exposed it to 150°, and asserted that he must have destroyed them, it is quite possible that experience might show that there are organisms which will resist even that temperature. It would have been almost impossible, some time ago, to admit, and we could not have admitted, that these organisms would have withstood the temperature which they have been found to withstand; and, therefore, what temperature is sufficient to destroy the organism in any case must be found by experiment, and that alone. Amongst other conditions for arresting the process of decomposition or putrefaction, which are in their nature like those of fermentation, I ought to mention the process of drying. All the processes of fermentation which I have been speaking of, and all others, which I could tell you of, are accompanied by moisture. Moisture is present, and is essential to them; in fact, these little organisms are exceedingly soft, wet things; moisture constitutes a great part of their substance, and in a dry medium they cannot live, or if the substance were dried, they would be destroyed by it. Applications, therefore, of a mere drying process are amongst the most important and interesting of this class of agencies. Many of them are well known. For instance, the ordinary process of preserving fruit by means of drying it. Germs of putrefaction or decomposition may be present in the fruit; but if you merely take away the greater part of the moisture, you render the substance incapable of decomposing. Among the agents which serve for that purpose, there are some which abstract the water, not in a state of vapour, but in the liquid state; for instance, common salt. If you put a piece of fresh meat in contact with salt, or rub it over with the salt, the salt gradually absorbs the water, and draws the water out of the meat. The action is truly a drying action upon the meat, and it is effectual by a perfectly similar process to that which would go on if you exposed the meat in a dry chamber to a current of warm air. In like manner, of course, it is known to many persons that sugar is used just as salt is, to remove water from substances containing it in any quantity. If you were to rub any fruit or animal substance with a sufficient quantity of dry sugar, you would get the sugar dissolved by the water which would be removed from the materials; and amongst the observations which are made in common life, there are some which bear, in an interesting and instructive way, upon what I have been saying to you. For instance, I have heard it said that ordinary jam—fruit and sugar, which have been boiled together for some time—keeps better if the pots into which it is poured are tied up whilst hot. The observation has been so frequently made that one was inclined to think that there must be some truth in it; and I think if we admit that the paper can act as a strainer in the same way as the cotton wool, you will see at once that it must be as people suppose. Take two cases. Suppose one pot of jam, allowed to cool before it is tied down, little germs will fall upon it from the air, and they will retain their vitality because they fall upon a cool substance; they will be shut in by the paper and will soon fall to work decomposing the fruit. If you take another pot, perfectly similar, filled with a boiling hot mixture, immediately cover it over, though, of course some of the outside air must be shut in, any germs which are floating in it will be scalded, and in all probability destroyed, so that no decomposition can take place.

Amongst other materials which serve to arrest fermentation, there are several chemical agents of considerable energy, which are frequently employed for that purpose. Amongst the foremost, I ought to mention creasote, the active material of smoke; and I have no doubt that the antiseptic action which smoke is said to exert upon ourselves—because it is said that smoke is very wholesome, although I do not lean to that view myself—is due to the presence of this creasote or carbolic acid. Every one is aware that one process for preserving meat, which has long been in use, is to suspend it in a chimney in which the smoke of wood is present. The smoke of wood, like that of coal, contains this substance, or one nearly allied to it, and amongst antiseptic agents it is one of the most energetic. A small quantity of this carbolic acid thrown into that fermenting liquid would completely kill the organisms. In the same way, if I were to introduce a little sulphurous acid into any of these mixtures, I should immediately kill the organisms and arrest the fermentation. Sulphurous acid is now largely used for this purpose, being employed, in combination with lime and water, to saturate the casks in which beer is to be stored, so that the wood being impregnated with it, any germs which might find their way from the atmosphere, and set up a process of decomposition, are arrested and destroyed. Another very powerful antiseptic agent is prussic acid, one of the most powerful of poisons to all animal organisms, and it is particularly powerful in stopping the action of these ferments. Another substance, which I think is worthy of consideration, in the same point of view, is a mixture which is, to a great extent, of unknown composition. I refer to the poisonous matter which is given off in tobacco smoke. It must, I think, when present in the air, exert a very powerful antiseptic action upon these organisms. It has been shown, by the experiments of Professor Tyndall, that in the lower vessel of the lungs there are considerable deposits of the dust which floats about in the air; and we are, of course, exposed in that manner to the action of a number of the seeds of these ferments, and, for aught we know, of diseases, because many malignant diseases are attributed to processes of decomposition analogous to those which we have been considering: and they may be—and, as some persons think, are—carried by germs in the air, in the same way as those I have been mentioning. Now, any powerful substance which would kill these germs must, of course, exert a beneficial action, and when persons are exposed to the smoke of tobacco, there is no doubt that some of it enters the lung with the air which is vitiated, and that some of the smoke must be deposited in the lower passages of the lungs with these little mischievous germs, and must certainly somewhat astonish them.

I have here several little apparatus, all alike in their general arrangement; each consists of two little tables, connected together in such a way that air may be made to pass through both of them in one direction, but not in the other. A tube goes from the top of one into the liquid in the second, and the tube from this second passes on into the air; and these bottles can, by means of an aspirator, be supplied with air which has been strained through cotton wool, and no other air can pass into them. The bottles contain the same mixture which I have been talking about so much, yeast-water and sugar, a liquid which decomposes in almost any way you like, for almost all these germs live in it more or less vigorously. After the liquid was put in, it was kept boiling for a considerable time, so that there is, I trust, in the bottles no living organism whatever; in fact, I have reason to believe that any organisms which may have been there have been destroyed by the high temperature to which they were exposed. I might draw hundreds of cubic feet of air through that apparatus, and it would remain entirely unchanged. Next Monday we will resume this again. We will also examine this particular apparatus, which is exactly the same, with this exception, that after the whole had been filled in the manner I have stated, a little mould was introduced by a separate tube into the first bottle. The apparatus will be taken back to University College, where it will be put into the warm chamber, where the organisms will be developed; and I have no doubt the liquid in the first bottle will be in a state of active decomposition before the day is over. Then next week, we will draw purified air, which, by itself, has no action on the liquid, and see whether it will carry any germs into the second bottle. I have no doubt that, by Monday next, there will be enough mould upon it to enable us to perform the experiment; and I shall then also have the pleasure of telling you of some applications which M. Pasteur has made of his theoretical results to practical purposes, such as the preservation of wines and such-like matters.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY, Dr. B. W. Richardson's Lectures on Experimental and Practical Medicine, at 5 P.M.—"A Physiological View of Dialysis and of the Colloidal and Crystalloidal Construction of Animal Bodies."

WEDNESDAY, *Pharmaceutical Society of Great Britain*, at 8.30 P.M.—"Pharmacy in the United States." By Mr. R. HOWDEN. "Notes on Australian Opium." By Mr. J. S. WARD. See page 447.

THURSDAY, *London Chemists' Association*, at 9.30 P.M.—"Regulations for the Storing and Dispensing of Poisons." By Mr. H. A. TAUBMAN.

Parliamentary and Law Proceedings.

ILLEGAL STORAGE OF PETROLEUM.

Mr. Moses Beck, grocer, of Tunbridge Wells, was summoned by the Inspector of Petroleum for keeping on his premises, without a licence, petroleum which flashed when exposed to a temperature of 100°. The inspector stated that upon visiting the defendant's premises he found a quantity of petroleum in an iron tank two or three yards from the back of the house, a sample of which, when tested, flashed at 94° F. In accordance with the Act of Parliament he tested a second sample, which flashed at 92° F. Upon cross-examination he said that he put the thermometer at the bottom of the vessel.

Mr. Langham, for the defence, urged that the instrument produced, which was used by the inspector for testing, was incomplete, and that the thermometer, instead of being immersed one inch and a half in the oil, as prescribed by the Act of Parliament, had been allowed to rest on the bottom of the vessel. Consequently, since the temperature of the metal would be ten degrees higher than that of the oil, the test had not been carried out in accordance with the Act of Parliament. He also contended that the flame used, a lamp filled with spirits of wine, was not that meant by the Act, which said a "very small flame."

Mr. Redwood, Secretary and Consulting Chemist to the Petroleum Association, said that the certificate produced, stating that the oil would not flash when exposed to a temperature of 104°, was signed by him. He tested the usual percentage of the oil. He used How's apparatus. He had frequently made tests with Dr. Letheby, who used an apparatus exactly similar. The witness pointed out several details in which he considered the apparatus used by the inspector was incomplete.

The magistrates decided that the inspector had complied with all the requirements of the Act of Parliament, and that the defendant must pay a fine of 10*s.* and costs. A case for the Court of Queen's Bench was applied for and granted.—*Grocer.*

[*** Petroleum cases generally furnish amusing illustrations of the perplexity into which not only judges or magistrates, but also witnesses and lawyers may fall, when dealing with matters they do not understand. But in this respect the argument of Mr. Langham on behalf of the defendant in the above case is probably unique, for if it were admitted that the temperature of the oil was 10 degrees less than that of the metal vessel containing it, and that the higher temperature were indicated by the thermometer,—then the flashing-point of the oil—104° F.—would have appeared to be ten degrees higher than if it were tested in accordance with the Act. But the idea of such a difference of temperature existing between the oil and the metal vessel is as absurd as the argument in which it is assumed to be the case. This is another indication of the miserable confusion that reigns in all matters connected with petroleum legislation.—Ed. Ph. J.]

Sale of Patent Medicine without a Licence.

Mr. John Kennedy, a surgeon and chemist, of Bromley, Middlesex, was on Wednesday charged before Mr. Lushington, at the Thames Police Court, with selling a patent medicine without a licence. The prosecution was instituted by the Board of Inland Revenue. The defendant for many years had been duly licensed to sell patent medicines, but he had failed to renew his licence for the past year. An officer engaged for the purpose purchased of the defendant a box of Holloway's pills for 1*s.* 1½*d.* The Government stamp was affixed to the box. It was stated that the defendant had taken out a licence since the sale of the box of pills. Mr. Lushington thought the justice of the case would be fully answered by fining the defendant the minimum fine of £5, as it did not appear that any fraud was intended.

Edward Jeake, who described himself as a chemist, though his name is not on the register, was brought before Mr. Knox at Marlborough Street, on a charge of obtaining a charitable contribution under false pretences. After evidence had been given proving the offence, the prisoner entered into a long history of his life, stating that he had been in business as a chemist, and had failed through getting involved in a lawsuit about aniline and magenta. He said that when the cholera was raging in London he had been employed as medical officer at Whitechapel, that he was master of four languages, and understood the classics and mathematics. He was sorry for what he had done, and hoped the magistrate would deal leniently with him. Mr. Knox sentenced him to three months' imprisonment with hard labour.

Suicide by Nitric Acid.

An inquest was held on Friday, Nov. 25, at Camden Town, respecting the death of Mrs. Boroughs. It appeared that she had just returned from marketing and had sat down to supper with her husband, when suddenly she started from her chair, and giving a hysterical laugh rushed out of the room. Her husband followed her immediately, and found her in the bedroom drinking from a small phial labelled "Poison," which he said had been given him some time previously for an eruption on the hands. Dr. Dyer said that when he was called to see the deceased she was insensible. From the colour of the lips and mouth, he could see that she had drunk a quantity of nitric acid; there were also stains of the acid on her hands and over the carpet. She died on the second day from the effects of the poison. A verdict was returned of "Suicide while of unsound mind."—*Times.*

BOOKS RECEIVED.

The Chemists and Druggists' Almanack and Diary, 1870. London: 'Chemist and Druggist' Office, Cannon Street. From the Publishers.

A Treatise on the Nature, Cause, Cure, and Prevention of Disease, with Practical Illustrations of the Medicinal and other Uses of Hibbert's Patent Antiseptic Solutions, etc. By W. Hibbert. Manchester: John Heywood, Deansgate. 1870.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[30.]—HAIR-OIL SCENT.—*W. M. Betts* (Grantham) recommends the following:—

Artificial Essential Oil of Almonds ℥j
Oil of Lavender ℥vij
Oil of Cassia ʒij. Mix.

[36.]—EAU DE COLOGNE.—In reply to "*B. Shakerley,*" *H. H.* sends the following formula:—

℞. Ess. Limon. Opt. ʒiv
„ Berg. Opt. ʒv
Ol. Neroli Opt. ʒij
Ol. Rosmarini ʒiss
Ol. Cassiæ ♏xx
S. V. Rect. Oiv.

Macerate for fourteen days, and filter.

[39.]—LIQUOR COCCI.

Cochineal,
Salts of Tartar,
Cream of Tartar, of each 1 oz.
Alum 1 oz.
Distilled Water 8 oz.
Sugar 4 oz.

Boil the cochineal and salts of tartar in the water, then add the cream of tartar and alum and strain through muslin, afterwards filter and make up to 8 oz. Add the sugar, and dissolve by means of a gentle heat.—Arthur W. Postans.

Similar answers have been received from *H. B. N.*, *C. Robinson*, "*Vincit Amor Patriæ,*" and *W. Biggs.*

T. F. Best (Camberwell) sends the following formula, which he says will also answer for crimson ink:—

Carmine ℈j
Solution of Potash ♏xxv
Distilled Water to ℥j.

[40.]—SYR. CHLORAL HYDRATE.—Make a syrup with concentrated orange-flower water, dissolve the hydrate, and add ♏v spiritus chloroformi to each drachm.—Arthur W. Postans.

[*** Syrup of tolu, syrup of orange or orange-flower are also used, as well as glycerine or peppermint water. Perhaps the best plan is to use equal parts of a syrup and of chloroform-water. See Pharm. Journ. No. 18, p. 348. The strength of the preparation should be uniformly 10 grains to the fluid dram.—Ed. Ph. J.]

[42.]—CHILBLAINS.—Make a liniment of equal parts of—

Tincture of Cantharides
Solution of Ammonia
Soap Liniment.—Beta.

Tincture of Aconite ʒiss
Glycerine ʒij
Compound Camphor Liniment ʒivss.

Mix. To be used every night, but not if the skin is broken.—L. S.

℞. Terebinthinæ ʒss
Sp. Camphoræ,
Liq. Plumbi Subacet., ana ʒij.

Make a liniment. To be applied night and morning with a camel-hair pencil.—F. B., *Macclesfield.*

Chilblains Unbroken.

℞. Liq. Potassæ ʒiss
Potass. Cyanidi gr. viij
Aq. Camph. ad ℥viij.
Fiat lotio sæpe utend.

℞. Ol. Terebinth. ʒij
Liq. Ammoniæ ʒiss
Lin. Saponis ℥iij
Sp. Rosmarini ℥j
Aceti Dest. ℥viij
Ft. linim. sæpe utend.—C. Wanron.

In the answer given by "*Utile*" last week, "tincture of arnica mont." was misprinted "arnica root."

[45.]—WATER TEST.—The ordinary practical test is to add liq. potassæ permanganatis gtt. x to a pint of the water. Let it stand twelve hours. If the water be pure, it retains its pink colour; otherwise, it turns greenish or muddy.—H. H. P.

Mr. C. Robinson (Streatham) and *R. H. R.* (Houghton-le-Spring) recommend a similar plan.

[*** This test is extremely crude, and one that cannot be depended upon in a matter of such importance as the quality of water for domestic use.

Probably the readiest and most convenient mode of detecting the presence of organic impurity in water is that introduced by Wanklyn, and fully described in the work reviewed last August (see No. 6).

Another very good method is that suggested by Mr. Heisch in the *Journal of the Chemical Society* for October, 1870, p. 32, adding to the water a very small quantity of pure sugar, and leaving it for some time in a stoppered bottle. If the water be contaminated with any such impurity as would result from sewage contamination, there will be an influence exercised on the sugar as in fermentation, and it will be converted into butyric acid, which can be recognized by its smell. In any case, however, the testing of water is an operation requiring so much nicety of manipulation and familiarity with analytical work, that it should never be attempted by any one but a practised analyst.—ED. PH. J.]

[46.]—WEATHER-GLASS.—Take a thin glass tube, 12 inches long and ¾-inch in diameter, and fill three-fourths of it with the following solution:—

Camphor ʒij
Nitre ʒiss
Sal Ammoniac ʒj
Proof Spirit ℥ij¼.

Solve. The tube may be tied over with bladder if required.

As a sign of *fine* weather, the sediment of white flakes will settle near to the bottom of the tube, while the liquid will be quite transparent above. As a sign of *rain*, the matter will rise to the surface of the solution. At the approach of a *storm*, the matter will float on the surface of the solution in the form of white flakes, and the fluid will appear in a state of fermentation. During *frost*, the solution will present a starry appearance, and during *summer* or *hot weather* the matter will fall to the bottom as a solid substance. Several other predictions might be given, but these glasses as a rule are not to be depended upon.—VINCIT AMOR PATRIÆ.

Similar answers have been received from *T. F. Best* (Camberwell), *E. T. G.* (Bath).

In the recipe published last week from Mr. Watkinson, "proof spirit" should have been printed and not "rectified spirit," as the presence of water is required to cause a portion of the camphor to be deposited.

[49.]—EAU DE MILLEFLEURS.—In answer to *G. S.*, "*Utile*" (Boston) sends the following recipe for eau de millefleurs:—

℞. Essence of Violets lb.j
„ Jasmine ℥j
„ Bergamot gtt. xx
Otto of Rose gtt. x. M.

[52.]—COFFIN'S COMPOSITION POWDER. — *G. Wrigglesworth* (Hull) sends the following copy of Dr. Coffin's own published formula:—

℞. Pulv. Bacc. Lauri ℥iv
„ Zingib. Opt. ℥ij
„ Pini Canadensis ℥j
„ Caryophyllarum } ana ʒij
„ Pip. Cayenne }

Mix. Dose: a teaspoonful in a cup of hot water, sweetened.

Answers similar to the above have also been received from *J. Staley* (Rochdale) and *L. S.* (Stourbridge); also one from *J. Bordass* (Driffield), who gives a larger proportion of ginger and says that a large quantity is sold in his district.

[53.]—DISPENSING.—*C. F.*, Winchester. No. 21, p. 419.

A. P. S. does not think it possible to make a clear, sherry-coloured solution with the ingredients given, even with the aid of heat.

[56.]—HAIR WASH.—"*Alumen*" will find the following a good and cheap hair wash, presenting at the same time a clean appearance:—

℞. Sp. Ammon. Arom.,
Tinct. Canthar.,
Glycerinæ, ana ʒss
Aq. Rosæ ad ℥vj.

—A. B. FLETCHER, *Totton.*

℞. Pulv. Sodæ Bibor. ʒj
Potass. Carb. ʒj
Tr. Lyttæ ʒiij
Sp. Rosmarini ʒj
Aq. Camph. ℥vj
Aq. Rosæ ad ℥xx. M.

Scent with essence of bitter almonds and filter.—
G. W. P., *Manchester.*

[59.]—DISPENSING ("MAGNESIA"). No. 22, p. 437.
If the following *modus operandi* be adopted by "*Magnesia*" he will find no difficulty in obtaining a satisfactory result:—

Dissolve the quinine with a sufficiency of dilute sulphuric acid in a small quantity of the water, and the sulphate of iron in a second portion, mix the solutions, and add the sulphate of magnesia dissolved in the remainder of the water, and finally the tincture of ginger. Thus prepared, a perfect, although opalescent solution is obtained. The black precipitate referred to I have been unable to obtain, and should suspect it to be tannate of iron, from the admixture of tannin with some of the ingredients employed.— GEO. MASSON.

Charles Schmidt suggests to dissolve the gr. xij quin. sulph. in a little aq. destill., acidulated with ♏x acid. sulphur. dil., add solut. magnes. sulph. ℥iij, and having previously mixed the ʒiss tinct. zingiber. with the same quantity of aq. destill., shake together, finally dissolve the gr. xij ferr. sulph. in the mixture.

By adding a little acid. sulph. dil. (enough to effect a ready solution of quiniæ sulphas), dissolving magnesiæ sulphas, and adding the solutions together, no deposit takes place. The ingredients rubbed in a porcelain mortar, and dissolved together, give a blackish deposit. In this state the addition of a drop or two of acid. sulph. dil. produces a fine clear mixture, of course rendered opaque by the addition of tinct. zingiberis. —JOHN H. DODDS, *Walsall.*

I have prepared the prescription which "*Magnesia*" gives, but do not get a copious black precipitate. What precipitate there is is caused by the insolubility of the quinæ sulph., and what discoloration there is results from the action of the iron on the tinct. zingib. A few drops of acid. sulph. dil. will effect a solution and at the same time prevent any darkening.—A. B. FLETCHER, *Totton.*

[*** We do not see that our correspondents would be justified in adding the acid as suggested.—ED. PH. J.]

[61.]—TASTELESS PILLS.—Any information as to the method of giving a tasteless covering (non-saccharine and unaffected by exposure to air) to pills will oblige—TWO INQUIRERS.

[*** A solution of balsam of tolu and chloroform forms the best coating for pills.—ED. PH. J.]

[62.]—ARTIFICIAL TINCTURE OF MUSK. — *W. Wilson* (Devonport) wishes for a formula for making artificial tincture of musk from the oil of amber.

*** [Put into a cup fʒj of oil of amber, and add to it, drop by drop, fʒiiiss of strong nitric acid; let it stand for thirty-six hours, then separate and wash the resinous matter.—ED. PH. J.]

[63.]—GREEN FLUID FOR SHOW BOTTLES.—*W. W.* wishes for a recipe for making a good green fluid for show bottles.

[64.]—COLD CREAM.—"*Alpha*" (Sudbury) desires a good formula for making cold cream.

[65.]—CEMENT.—"*Iodi*" (Sudbury) wishes for a recipe for making diamond cement, or a transparent cement for glass, china, etc.

[66.]—CEMENT FOR INDIA-RUBBER. — "*Vulcanite*" asks for a formula for a good cement that would fasten the ends of pieces of vulcanized india-rubber together.

[67.—TINCT. PRUNI VIRGINIANÆ.—*R. H. D.* wishes for a formula for the preparation of this tincture.

Correspondence.

Obscure Prescriptions.

Sir,—Many—I think I may say the majority of your readers—will be pleased to see that in your Journal attention has been drawn to the slovenly method in which prescriptions are frequently written. Medical journals have for some time past been making editorial attacks upon dispensing chemists for high charges and for prescribing; but I think their attention might well be turned to a matter nearer home, viz. the present loose style of prescribing. I will put the question to any average dispenser, whether he is not continually troubled by it. The prescription is frequently carelessly written, often the terms are indefinite, and sometimes two or three pharmacopœias are mixed up together, while the dispenser is all the time subject to the Pharmacy Act. He can, therefore, only dispense comfortably when he has neither conscience nor property; the absence of the first allowing him to keep what he considers self-respect, the want of the latter enabling him to defy attempts to recover penalties.

I once lived in a surgery, and by excellent fortune was on very good terms with my master. After sending out "inf. calumb." for "mist. camph." several times, and by the law of average, *vice versâ*, I was obliged to propose that after he had "written in" I should always read the entries over to him before dispensing. After that arrangement we got on pretty well together. It was no compliment to propose such conditions to him, but what was I to do?

Unfortunately dispensers in retail cannot do this, they must either hand back the prescription or make it up by guess. Of course, if they can afford to take the first course they will return the prescription; but suppose a man is "running up hill," can he avoid the second? Why, he would at least be "thought a fool," and if he had an unscrupulous brother-chemist, the honest man would be cut out. Honesty may be its own reward, but how about paying your bills?

Now how can all this petty distress be avoided? I think by all chemists, when they have doubts about prescriptions, referring, if possible, to the prescriber, and when this is impossible, declining to dispense by mere guess. If this rule was invariably carried out it would soon remedy bad writing so far as prescriptions go; the wealthy and needy would be on the same "platform." Many will say to this proposal, "What about the patient perishing for lack of physic?" My reply is, does it differ much whether a man perishes for lack of physic, or is destroyed by having the wrong? All responsibility on this point rests with the prescriber, who is amply paid for (in these cases) unfulfilled duties.

M.P.S. by election.

Brighton, November 26th, 1870.

Sir,—I beg to thank you for the remarks made in support of my letter published in your Journal of the 12th instant. You were correct in supposing that the classical acquirements of the author of the prescriptions in question were a matter of but little interest to me. May I be permitted to advise that gentleman, if he wishes his prescriptions handed down to admiring posterity, in all their purity of true classical expression, to write them in such a manner that the real terminations may be seen without the aid of a powerful microscope!

As the author appears to consider few of the readers of our Journal "respectable" enough for him to "condescend" to answer them with civility, perhaps he will think it less "infra dig." to give an explanation of his remarkable prescriptions in the columns of the *Lancet* or some other "respectable" medical journal.

He also speculates in rather a sarcastic manner upon the amount of "lustre" I am likely to "shed" upon my "fraternity." May I be permitted to ask him—with all due respect, and with a deep sense of my own ignorance and inferiority—if his prescriptions (classical though they may be) will bring him any very great amount of "honour" from the Members of the College to which he belongs?

F. J. B., Major Associate.

Sir,—The thanks of chemists generally are due to you for your publication of Mr. W. Bradshaw's prescription. It is a *chef d'œuvre* of hieroglyphic art, and reflects the greatest honour on the profession of which its author is a member.

There can be little doubt that when a being of such talent and renown (for who amongst us has not heard of Mr. Watson Bradshaw?) descends from the lofty eminence of naval surgeon to pity and relieve the bodily sufferings of poor mortals on earth, we should be careful how we offend his dignity by daring to question any word or deed of his, no matter how obtuse it may seem to our benighted senses. Nor should we take the liberty of mentioning his great name in the same breath with a posse of silly or angry druggists. Such is the tenour of his second letter, which, indicating an almost angelic serenity of temper, effectually exposes by contrast the silly squabbles that promoted its production. What business on earth has a druggist to speak? He has no professional wrongs; he is made expressly to execute the wishes of the doctor; in case of an accident to take all culpability from him and, if need be, to bear it himself. In this case it would seem that it is Mr. W. Bradshaw who suffers wrong and injustice, as he mildly hints, because some silly and ignorant druggists—incapable of reading and dispensing prescriptions of his, couched in such concise and every-day terms, and written in such a legible and masterly style of caligraphy as the specimen published last week—have asked for an explanation of the terms used. Who can blame the ex-naval surgeon for preferring druggists to whom he has imparted the key to his Euclid, the "open sesame" of his mysteries? No doubt he does it from purely disinterested motives. But if it cannot be a matter of surprise that such a man should be contaminated by entering the arena of pharmaceutical correspondence, surely legal proceedings would be "infra dig." indeed! I trust that the publication of the prescription may have the beneficial effect of inducing some surgeons to be somewhat more explicit in prescribing. If they are plain and readable, no druggist will ever complain of their Latinity.

Norwich. T. P.

43, *Welbeck Street, Cavendish Square, W.*
Nov. 27, 1870.

Sir,—I not only complained in my letter of the incorrect Latinities imputed to my authorship, but disputed your right, *in toto*, of using my name at all, still less in the way you have permitted it to be paraded in your columns.

If your intention had been simply to assist a puzzled druggist out of the quagmire, or to discuss, on the broad basis, the advisability of "obscure prescription-writing," this might have been fully effected without my name, and thus I should have been spared the necessity of troubling you on a subject upon which I could say so much, and *par parenthèse*, whatever theories you could have advanced I am certain would not have changed my opinions; and, perhaps, to set the matter finally at rest, for I admit that it is an important subject for discussion, I contend, as an invariable rule, it is better that patients (*omnium generum*) should not know what medicines they may be taking; and if this be deemed a special feature in the management of certain cases, which I could abundantly illustrate, I consider it quite supererogatory on the part of any puzzled druggist to question the motives of any prescriber; and I am well certain of this, that any pharmacist presuming to dispense any prescription "obscurely" written, which the presenter thereof had been "distinctly" told could only be made up by an "especial" druggist designated, would be held legally liable for all consequences flowing therefrom by a British judge and jury.

I have always been consistently opposed to the writing of prescriptions in English, and, in short, I think that they cannot be made too unintelligible for the patient's benefit. A general practitioner does not edify his patient by informing him what his 6-ounce mixture contains. There are many other cogent reasons which could be urged in favour of the system which I adopt, but to which I need not now advert, but I am quite prepared to vindicate anything which I may do or advocate.

The prejudices of certain patients are so well known by medical men, that there can be no dissentient opinion in such cases as to the expediency of concealing the means that may be thought by the medical adviser indispensable for their recovery. Conceive, for example, a nervous patient, requiring a full dose of morphia, indulging his morbid fear of having that drug administered to him by refusing to take a draught containing it!

I was in the habit formerly of prescribing in the usual style, but so many cases were brought to my notice, which induced me to adopt, under certain circumstances, my present system of cognomens. One patient, a lady, had been taking 4 grains of blue pill twice a week for two years. Another, whenever he had the smallest ailment, would rush to an old prescription, for which, some time or other, he had invested a guinea, and commence to take 80 minims of liq. potassæ daily. Such practices I consider fraught with much danger to the physic-taking community, and I consider also that any check which can be imposed upon prescription-holders from getting their favourite recipes dispensed at random, ought to be rather hailed as a happy omen than otherwise.

This observation applies to all the "obscure" prescriptions which have been so eagerly thrust upon your notice; that is to say, the ingredients therein contained were only intended to be taken under my guidance, and not to be had recourse to on every promiscuous occasion. Why do not such patients go and consult another medical man when they are at a distance remote from the prescriber, and not endeavour to do a little quiet flirtation with a village chemist? It is true some disappointment must be felt, when a man, whose express function it is, cannot decipher an "obscure" prescription; but he can only, at most, suffer the loss of a stray shilling or two, whereas he might quietly allow the patient to swallow 4 grains of pil. hyd. twice a week for two years, or to take 80 minims of liq. potassæ daily, when he might require very different treatment. The practice of medicine is a grave and responsible vocation, and it is quite as desirable to counteract the random use of nocuous medicines, as it is incumbent on the man of medicine to study and know aright the uses of his various therapeutic agents; and patients themselves cannot be too forcibly reminded of this fact, that when they try to "do" the doctor, they only "undo" themselves.

WATSON BRADSHAW,
Formerly Surgeon Royal Navy.

J. W. A. (Newcastle) writing on this subject, expresses his opinion that the silly druggists with whom Mr. Watson Bradshaw professes to think it *infra dig.* to "enter the arena," would probably go through an examination on the British Pharmacopœia better than he could, and that they apparently pay more respect than he does to that important work. *J. W. A.* also thinks Mr. Bradshaw's admission that his "patients are invariably reminded they can only have their medicines compounded by the especial druggists to whom he hands them over," is one that does not do much credit to him, and is decidedly a breach of medical etiquette.

Sir,—The following prescription was this morning brought to me by one of my customers to dispense:—

. Lin. Tereb. Bellad. n.m.
Mist. Menstruments No. j. (*Sic.*)

It had been written by one who signs himself M.A. and M.D., one who professes to give "advice gratis to the poor." May I ask is it honest on the part of a physician to compel these patients to go to a particular chemist, he (the doctor) receiving a percentage upon the transaction?

Is it such a great crime for a respectable chemist to do a little prescribing when such an example is set us by our "betters"? I think not; yet, Sir, this M.A. and M.D. is one of those who would prevent us. I call such a one a hypocrite and a sham philanthropist.

Sheffield. EDWARD BARBER.

[*** We insert some of the foregoing letters more for the satisfaction of correspondents than for the sake of any light they throw upon the question originally put forward by F. J. B., and we must decline to publish any further letters which do not bear directly upon that. Perhaps Mr. Bradshaw or his especial druggists will supply this desideratum.]

As to the other subjects more or less obscurely touched upon in the above letters, it would seem that the present excitement of the political world in regard to secret treaties is contagious, and a similar state of mind is being developed among pharmacists as to the nature of the relations which *sometimes* exist between prescriber and dispenser. This is a question of great importance, and so well worthy of further ventilation that we shall recur to it at an early date.—ED. PH. J.]

BEWARE OF SWINDLERS.

Sir,—Allow me to corroborate the communication of Mr. Long in your last week's issue, respecting a man going about the country to appoint agents to sell an "Infallible Vermin Killer" for the firm he represented.

It is about six weeks since a very gentlemanly-looking sort of a fellow, elegantly plumed in the fashion of the day, drove up to my shop door with a horse and gig, of first-class appearance, of such a style and in such a good condition as would not be degrading for the use of any nobleman. This gentlemanly rascal intimated that I should seldom see travellers from any respectable firm with such a grand equipage.

He professed to represent a firm of the name of Messrs. Newman, Howard and Co., Bath Row, Birmingham, stating that he was nephew of one of the partners, and that the Mr. Howard in the firm was a near relative of the well-known Messrs. Howard and Sons, the celebrated quinine manufacturers. He showed me several advertisements in newspapers respecting the vermin killer, with agents' names appended, and said it was also advertised in the PHARMACEUTICAL JOURNAL. He also displayed some very handsome posters, with blank spaces at bottom for the insertion of agents' name. An agent's district was to comprise a circuit of five miles, in which posters and handbills were to be circulated free of expense to agent.

Other special advantages, too numerous to mention, were also offered. I purchased only half of what he seemed anxious for me to take, and after he had gone I proceeded to examine all the numbers of the PHARMACEUTICAL JOURNAL I had, but, to my surprise, failed to meet with a single word concerning the matter.

I have written twice to this celebrated Birmingham firm (?), who it appears from invoice are "Manufacturers of Chemical Preparations," but have not received any reply.

I trust my brother-chemists will be on the alert, and be able to detect these profound rogues and impostors before they are duped by them, should any present themselves in their shops.

Rawtenstall, November 14th, 1870. H. HALSTEAD.

Sir,—A letter on this subject appeared in the *Lancet* and has since been copied into several of the daily papers. It appears that one chemist charged 4*s.* for a mixture for which another charged but 1*s.* 6*d.*, and, for this act of a single man, the whole fraternity are charged with extortion. In reply, I am quite ready to admit that the charge was exorbitant, provided the mixture contained only simple ingredients; it may, however, have contained expensive articles, or have been prescribed in a concentrated form; but, probably, it was not obtained from a dispensing chemist at all, but from a surgeon or apothecary keeping an open shop; and this class of practitioners get a "very fair" profit, as the following instance may show:—

A surgeon keeping an open shop told me that he frequently got 2*s.* 6*d.* for a blue pill and black draught, the usual price charged by chemists being only 9*d.* There have been cases, too, brought before the public in which doctors' bills have been disputed solely because the patients considered they had been overcharged; but who has ever heard of a chemist's bill being disputed on this score?

Chemists are not infallible, nor are they free from extortioners and unjust men, any more than lawyers and medical men are; but, as a class, they are a hardworking, honest, thoughtful body of men,—not overpaid for their responsibility, as the scarcity of retired chemists shows,—whose services are daily becoming appreciated more freely by the public. Add to this that all now wishing to become chemists are compelled to pass examinations, and it will at once be seen that the business of a dispensing chemist in England is rapidly on its way to become a profession ranking as high as on the Continent. A DISPENSING CHEMIST.

DRUGGISTS' CHARGES.

Sir,—The *Lancet* complains of the excessive charge made by chemists for dispensing, while many of us complain of some of our brother-chemists for cutting down the prices. Mr. Applegate's letter gives a fresh illustration of the fact that we ought not to take for granted all our customers say about the prices charged by other chemists, but follow his example and firmly refuse to reduce the price because the customer says that Mr. So-and-so has charged so much less.

Reliable testimony may, however, sometimes be got concerning the prices charged by other druggists. Several weeks ago I dispensed the following prescription for a stranger:—

℞. Vin. Ipecac. ʒj
Oxymel. Scillæ,
Syr. Papav. Alb., ana ℥vij
Tinct. Ferri Perchlor. ʒj.
M. A teaspoonful every four hours in water.

The customer brought a bottle and called for the mixture an hour or so after. He asked the price of the medicine and I charged 1*s.*; he told me that Mr. —— of —— only charged 8*d.* I said that Mr. —— might do so if he liked, but I certainly could not think of dispensing the prescription at such a price; consequently he would not take the mixture. Wishing to test some of my neighbours whom I suspected of doing a cutting trade, I sent a boy *incognito* to them with a copy of the prescription to inquire how much they would charge to dispense it. One replied 1*s.*, another 9*d.*, and a third, recently elected a member of the Pharmaceutical Society, said, "If you bring your own bottle, I will make it up for 6*d.*"

An apprentice of mine saw recently in the windows of a shop less than a mile from St. Paul's Churchyard, whose owner is the proprietor of a well-known patent for gout and rheumatic pills, a printed bill stating that seidlitz powders were sold there at 4*d.* per dozen. He went in as an ordinary customer and found that their seidlitz powders were 8*d.* a box, and that by seidlitz powders at 4*d.* per dozen, 4*d.* for a dozen powders was meant, six white papers (acid) and six blue papers (salts) making six seidlitz draughts. Surely such a grossly dishonourable trick would almost call for the removal of the chemist's name from the Register.

I hope that all those who declaim so loudly against the cutting prices of others, practise what they preach, but I fear that it is not so.

S. S. Holloway.

[*⁎* Several other correspondents write in reference to the statement contained in the letter of a "Prescriber" which appeared in the *Lancet* of the 19th ult.; they suggest that it would be desirable to ascertain the ingredients of the medicine referred to, and that since the correspondent of the *Lancet* writes from personal knowledge of the case, he can, perhaps, give a copy of the prescription as well as the name and address of the dispenser. We have written to the editor of the *Lancet*, requesting his assistance in this matter.—Ed. Ph. J.]

Sir,—I think it is a pity the Pharmaceutical Journal does not print occasionally half a column of rates of prices for 10 or 8 or 6 oz. mixtures, etc. Of course every medical man knows what would be a fair price for such "mixtures," but coming with the authority of your Council, it would be something for a physician or surgeon to fall back on when he is asked questions as to prices. I remember in my quiet apprenticeship days, when I saw served out thousands of ordinary 8 oz. mixtures, 3*s.* 6*d.* average price. I remember in another place, always this 8 oz. mixture, 2*s.* 2*d.* (circumstances quite equal); but now mark the difference during the last two years. I write a prescription at Kilburn or St. John's Wood, and the chemist very properly, as I think, charges 1*s.* 8*d.* or 2*s.*; but on the miserable system of "doing a trade" at any risks, I every week find that by taking the prescription to one of the "cheap and nasty" shops off Oxford Street, near Grosvenor Square, the same 8 oz. mixture, bottle, cork, label and some quack wrapper are all given for 7*d.* or 6*d.* I know, of course, all about competition as a healthy (?) phase of trade; but I must confess I tell my patients that cheap and adulterated drugs are so common that I would prefer their getting the mixture at 1*s.* 8*d.* or 2*s.* But then we have no standard rate of prices to assure our patients that a conscientious and honourable chemist cannot give an 8 oz. mixture for 6*d.*

November 15. Charles Kidd, M.D.

Citrate of Iron and Quinine.—Mr. J. Stathers.—We have received your letter and the sample of citrate of iron and quinine; but we cannot undertake to furnish professional analyses gratuitously.

H. Rayner (Owston Ferry).—The letter and stamps have been handed to the Secretary.

W. C. H. (Brighton), who asks a question concerning chloric ether, has omitted to send his name.

"*Botanist*" (Rochester).—In the last edition of the 'Calendar' there is no such reference made.

Microscopic Examination of Starch.

Dear Sir,—Mr. Cooke's remarks on the mounting of starches for microscopic purposes, induces me to add my experiences. I have given up using old slides of starches on standards for references, having, like Mr. Cooke, found that the granules in course of time become materially altered in shape and appearance, no matter in what fluid they have been mounted. Being so satisfied of their untrustworthiness, I now prefer the trouble of preparing fresh slides as occasion requires, and mount the starches temporarily in glycerine. I have for some time used a solution of dammar in benzole as a mounting medium, its use having been suggested to me by Mr. Swan, of Newcastle-on-Tyne; but I also use and prefer for most purposes the resin of Canada balsam dissolved in benzole, prepared by evaporating the balsam over a water bath until solid, and dissolving in the benzole. This last makes a brighter and cleaner-looking solution than the dammar, and dries quite as rapidly. I have also tried with partial success a solution of pure pale yellow rosin in benzole.

Leominster, November 22nd, 1870. M. J. Ellwood.

W. H. Cotterell (Dover).—Pharm. Journ. 2nd series, Vol. X. p. 180.

"*Guaco*."—We think not.

R. Hayton Davis (Harrogate).—The only officinal preparations are the fluid extract, infusion and syrup. (See Notes and Queries.)

Messrs. M'Master, Hodgson and Co. are informed that, owing to the official character of this Journal, we are constrained not to give editorial notices of new inventions, etc., which might appear to partake of the nature of advertisements; meanwhile we shall always be glad to afford space to any communications respecting novelties which may possess general interest for the drug trade.

"*A Constant Reader*" is thanked for his communication. We were already aware of the facts to which he refers, but cannot make use of his letter, since it is anonymous.

H. H. Pollard (Ryde).—The several recipes will be indexed. We are obliged for your suggestion.

Chapters for Students.—B. C. J., Manchester, writes to say, in reference to the method of making alum described by Mr. Tilden, at page 424, that nine-tenths of the alum used is now made by the following method:—The shale of the coal-measures is calcined in long ridges, it is then put into iron vessels lined with lead, sulphuric acid from the chamber is then poured over it, and the mass allowed to digest at about 230° F. to 240° F. The temperature is kept up by steam and ammonia vapour, which are blown in, and also by a small fire underneath the pans. When the solution is strong enough to crystallize, it is drawn off into large coolers and there agitated to prevent the formation of large crystals; the alum-flour so obtained is washed and redissolved by steam, and the solution run off into crystallizing-tubes, where it remains for ten days or a fortnight; the mother-liquor is then run off, and the alum is broken up, and is ready for the market. This is a brief outline of the manufacture of alum as carried on at Mr. Spence's works at Manchester and Goole, one of the largest manufactories of this salt in the world, where 250 tons are turned out weekly.

Communications, Letters, etc., have been received from Mr. W. N. Twelvetrees (Manchester), Mr. R. W. Giles (Clifton), Mr. J. E. Howard, Mr. F. C. Maggs (Yeovil), Mr. W. Aylesbury (Weymouth), Mr. A. E. Cole (Lee), Mr. H. Pollard (Ryde), Mr. A. C. Wootton, Mr. H. B. Brady (Newcastle), Messrs. Churchill, Mr. R. C. Tichborne (Dublin), Mr. A. H. Mason (Liverpool), Dr. B. W. Richardson, Mr. J. C. Pooley (Bath), "Polio," "Medicus" (Garston), "Cortex" (Manchester), "Iota" (Southampton), "Constant Reader," "A Physician" (Oldham), "Utile" (Boston), "Exhibatur," M. P. S. (Tunbridge Wells), J. F. (Aberdeen), J. F. B. (Derby), H. (Salisbury), J. F. (Halifax), J. T. R. (Warrington), E. M., T. M. (Worksop), F. C. Wyatt (Henley).

The following journals have been received:—The 'British Medical Journal,' Nov. 26; the 'Medical Times and Gazette,' Nov. 26; the 'Lancet,' Nov. 26; 'Nature,' Nov. 24; the 'Chemical News,' Nov. 25; 'Journal of the Society of Arts,' Nov. 24; 'Gardeners' Chronicle,' Nov. 26; the 'Grocer,' Nov. 26; the 'English Mechanic,' Nov. 25; the 'Produce Markets Review,' Nov. 26; the 'Journal of Applied Science' for December. The 'Medical Press and Circular' has not come to hand for two weeks.

PHARMACY IN THE UNITED STATES.

The following is a *résumé* of the information communicated by Mr. Robert Howden, at the Evening Meeting of the Society on the 7th inst.:—

This information was obtained during a tour in which he visited New York, Boston, Albany, Buffalo, Chicago, Milwaukie, Iowa, Cincinnati, Washington, Richmond, Baltimore and Philadelphia. He proposed, first, to give a description of a chemist's shop, or drug store; then to refer to the pharmacist, his clerks or assistants, and their educational resources; and, thirdly, to give some information relating to trade customs.

The Drug Store is generally situated at the corner of a street, or as it is termed in America, the corner of a block. It has externally a handsome and commanding appearance, with large plate-glass windows. On looking at the outside from the street, it will be noticed that it is well supplied with blinds,—roller-blinds within and shop-blinds without stretching over the pavement,—and that on these blinds are inscribed in large black letters, iced soda-water, cool cream soda, polar soda, Saratoga spring water, congress water, or Ottawa beer. Large boards standing on the pavement under the stall-board plate repeat these announcements. On approaching the window an English chemist searches curiously for large specie jars emblazoned with heraldic designs, or huge show-bottles filled with many gallons of coloured waters. He will look in vain for these, as well as for framed glass tablets relating to pharmaceutical membership and to carefully-dispensed prescriptions. But he will see on the floor of the window, without any inclosure, a few toilet bottles, not always in pairs; large bottles of popular proprietary medicines in faded showy wrappers, with framed show-cards printed in coloured type explaining their merits; some French essences; two or three stray smelling-bottles, supported by many empty eau de Cologne boxes: the whole covered with yellow gauze to keep off the flies. Here it may be observed that the American shopkeeper, or merchant as he prefers to call himself, knows little of the art of displaying goods attractively in his shop window; it is a method of gaining custom altogether unpractised. The display is *within*. It is there the public are desired to see and examine, and this custom is promoted by leaving the shop window bare of goods, and exposing the interior of the store as much as possible to the throng of passengers.

On entering our typical drug store, one is struck at once by its size and its whiteness. It is much larger than chemists' shops at home, often twelve feet high and more than fifty feet deep. The floor is of white marble, the counters of the same material or painted in imitation of it, and the ceilings not whitewashed but delicately coloured in panels. Against the walls behind the counters are the fixtures and shelves that give the character to the store. These begin with drawers like our own, but from them rise at intervals of about four feet from each other handsomely-carved pilasters, their tops united by a continued massive cornice. The walls are thus divided into recesses:—The first and all alternate recesses contain shelves and bottles, those intervening are hung with plate-glass doors making glass cases, wherein are shown proprietary medicines in pint and quart bottles. It is not generally considered of importance that the shop bottles should be very near each other, or that they should be quite filled. In well-conducted pharmacies, boldly-labelled three-pint bottles may often be seen with but half a pint or a pint of tincture in them,—a surprising custom with spirits of wine costing only seven shillings a gallon! In the upper part of these shelved alcoves are occasionally to be seen imposing busts of scientific or classical demi-gods larger than life, who look down with dignified and calm approval on the useful labours below.

The first object that attracts attention upon entering a store is an imposing soda-water apparatus, built of coloured marbles and bristling with silver taps. The counters beyond, except at the farthest end where a space is reserved for dispensing, are completely covered with deep glass cases, often eighteen inches high. These glass cases contain a profusion of miscellaneous goods, hair-brushes, sponges, Paris perfumery, English toilet soaps, leather purses, union smelling-bottles with gilt caps, cigar cases, wickered bottles, foreign proprietary medicines and specialities of the house.

The arrangements for dispensing are, with a few allowances, similar to our own; as are the graduated measures, pestles and mortars and palette knives. The dispensing scales are of the finest workmanship, very superior to ours, being costly and delicate balances, sometimes with plated silver beams, inclosed in square glass cases having a lifting sash, and forming a conspicuous object at the dispensing counter.

The American pharmacist is at present a self-educated man; he is very intelligent, and extremely well-informed in all matters relating to his profession. His assistants, who are called clerks, have their ranks recruited not by apprentices, a term never used in most of the States, but from the hired boys. A lad of the age of sixteen will enter the service of a pharmacist. He takes with him no premium, but immediately receives wages, and in return sweeps the shop, dusts the bottles, cleans measures, mortars and windows, takes out medicines, cuts labels and serves soda water. After the second year of "rudiments," he is encouraged to read the United States Dispensatory, corresponding to our Pharmacopœia, and other standard works, is placed behind the retail counter where he learns the art of "serving," and by degrees, from the chief clerk, the higher art of "dispensing." If the store is within reach of any school of pharmacy, the lad attends the instruction and lectures there delivered at *the cost of his employer*.

This, it is contended, is a preferable method of making pharmacists to the English one of apprenticeships. Over and over again was it said, "I would never have any one in my employ I could not discharge." Incompetent persons are summarily dismissed, the trade relieved from their dead weight, and the capable and intelligent candidates only suffered to remain. These candidates, it must never be forgotten, have previously had the inestimable advantage of a good education provided for them by the State free of all charge to their parents. This system is thoroughly republican; a boy or a man, of never so humble an origin, may advance if he will. The road upward is broad, open and direct; made easy to travel, and maintained by all statute law, by all social law, and by the enthusiastic approbation of every citizen.

No adequate educational instruction is at present available for the young American student in pharmacy. He must teach himself. There are, however, noble exceptions at Philadelphia (of a high order), at New York, Baltimore, Boston, Chicago, St. Louis and San Francisco, where lectures are delivered during the winter evenings on materia medica, chemistry and practical pharmacy, examinations held and diplomas conferred. In every instance, except the city of Baltimore, the attendance is entirely voluntary. There are no classes for teaching Latin, a knowledge of that language being considered unnecessary, as physicians now write their "directions" in English.

Of trade customs, the most important is that the whole of the medicines prescribed by the medical profession are supplied entirely by the pharmacists. No physician, the generic term for the whole body of medical practitioners, sends out his own medicines. He invariably writes prescriptions. On the other hand, no pharmacist prescribes. He carefully and scrupulously abstains from doing so. And this is the universal and national custom in all the States, with few and rare exceptions on the part of depraved members in either profession. The effect on the welfare of pharmacy is manifest; a very large number of stores, even in country towns, dispense thirty prescriptions in a day; and in the cities some thirty, others fifty, a hundred, and even a hundred and fifty. The physician is very jealous of his prerogative, and will occasionally endeavour to prevent a pharmacist repeating a prescription unless a second fee has been received by him. That a copy should be given for the use of the patient's friends, he regards as an outrage. No prescriptions are returned to the patient, but are preserved pasted in a book, by the chemist who first dispenses them. The physician's fee is generally twenty shillings for a first consultation and eight shillings for every subsequent one; lower fees are taken from the less affluent classes. The pharmacist generally charges about sixpence an ounce for medicines, that is, three shillings for a six-ounce mixture.

The next important custom is that pharmacy is a free trade all over the United States for any one who chooses to enter its ranks. Any person may open a drug store anywhere, and boldly write over it pharmacist or apothecary. Although this state of things is greatly deplored by every respectable pharmacist, at present it is the law, with the exception of the city of Baltimore, and in a modified degree of one or two States; the only condition required by the Government being one it never suffers to be neglected, —that of taking out a licence. This is done at an annual charge of two pounds. If tobacco is sold, another licence is required, at the cost of one pound; and if spirits of wine and intoxicating beverages are dealt in, a further licence is necessary, at the cost of five pounds. All pharmacists take out an apothecary's and a spirit licence, and many a tobacco licence, thus paying to the State annually eight pounds.

Throughout the United States everything is of a high money value,—according to the common phrase, "doubled since the war." The rents paid by pharmacists form no exception to this law. In a rising country town £100 a year is a moderate rental, in the inferior and third-rate streets in the cities about the same. In the second-best streets £200 and £300 are paid in very numerous instances. In the leading thoroughfares of the chief cities, as New York, Boston and Chicago, the rents are commonly £500, and in the very best situations £750, £1000 *and even more* per annum. For these enormous rentals the landlord only lets the shops with the basement, and is most unwilling to grant a lease. The rents paid by public companies, firms and particularly by drapers, are greatly in advance of these sums.

When "everything is dear" it follows that wages and salaries must be high. A boy on first entering a drug store receives about eight shillings a week, advancing as he improves to twelve and sixteen. On becoming a clerk he receives at first £60, then £80, then £100 a year. When chief clerk £140 to £200, and in rare cases £250. In every case he has to provide his own board and lodging; for no pharmacist lives at his place of business, or supplies meals to those in his service.

The hours of business are very long all over the Union, generally from 7 A.M. to 11 P.M. There are some cities where they are from 6 A.M. to midnight, every pharmacist in these cities, without exception, observing them. An inscription over one drug store announced, "This Pharmacy open night and day." All chemists' shops are open all day on Sunday everywhere. Very few shutters are used; the inside roller blind is drawn down to shut a store, and drawn up to open it. Gas is subjected to a tax by Government, and is therefore exceptionally dear, costing in different cities from nine shillings to fourteen shillings per thousand feet.

With heavy charges to defray, the returns of a pharmacist's business are necessarily large. During the summer months heavy sums are taken for iced soda-water and other gaseous beverages. In the West, in one moderately-sized city, several pharmacists will take each £8 a day for draughts of soda-water and fruit beverages, of which £5 will be taken in the evening. In the cities this sum is exceeded. There is one apparatus in the very best situation in Boston that is well-known to return £40 a day during hot weather.

The general results of pharmaceutical trading are very high; £2000 a year is a moderate annual return. Many stores return £6000 per annum, and in every large city there is at least one, if not two, pharmacists whose returns are £12,000 a year.

The art of skilfully preparing medicines, whereby they become less nauseous in taste, more easily digestible, or more permanent and convenient in form, is largely practised under the name of "elegant pharmacy." Combinations attaining any of these results are in much request, and are welcomed eagerly by the physicians, who continually order them in their prescriptions. A large increase of business accrues to the ingenious pharmacist, not only from his own city and State, but from the whole Union. Orders for these preparations are entered one after another in an order book, from places as remote from the pharmacist's city as St. Petersburg and Madrid, Vienna and Paris, Rome and Christiania are remote from London.

In conclusion, Mr. Howden expressed his admiration of and gratitude for the cordial and generous welcome extended to him in every city by every pharmacist to whom he applied. There was invariably an earnest desire to supply abundantly every kind of information that might be thought interesting to the Society in London. He found among the large body of pharmacists in the United States many individuals eminent for varied experience, practical skill and ripened intelligence, whose matured powers, at present confined to the routine of their own stores, might, under kindly and more public circumstances, nobly contribute to the service and progress of the profession of pharmacy.

SP. ÆTHERIS NITROSI, B.P.*

BY ALFRED E. TANNER.

The process in the B. P. is the one usually known as Redwood's; it consists in distilling a mixture of rectified spirit, nitric and sulphuric acids, together with copper wire, at a certain temperature, in a glass retort, furnished with a thermometer; and in operating on the Pharmacopœial quantity, 15 fluid ounces are ordered to be drawn over, and this distillate is to be mixed with 40 fluid ounces of rectified spirit, or a sufficiency, so that the mixture may correspond to the tests for sp. gr. and percentage of $C_2H_5NO_2$, this latter being determined by means of a saturated solution of Ca Cl.

Now I have followed this process for the preparation of spiritus ætheris nitrosi ever since the Pharmacopœia was published, but have never succeeded in collecting the amount of distillate there ordered; on no occasion have I been able to produce more than about 11 fluid ounces, excepting by the addition of more nitric acid than the Pharmacopœia allows, and then the product has been too rich in nitrous ether.

I have usually found this 11 fluid ounces of distillate to contain 50 per cent. of $C_2H_5NO_2$; that is, it will show a separation of 42 per cent. when agitated in a graduated tube with double its volume of saturated solution of Ca Cl; this, then, appears to contain the whole amount of $C_2H_5NO_2$ required, viz. about 5½ fluid ounces, or 36·6 per cent. of the quantity ordered by the Pharmacopœia to be drawn over, and on mixing this with four times its volume of rectified spirit, the mixture corresponds exactly with the spiritus ætheris nitrosi of the Pharmacopœia, showing 10 per cent. of $C_2H_5NO_2$ by the Ca Cl test, and having a sp. gr. ·846.

I should mention that this 11 fluid ounces of distillate was produced within the limit of temperature ordered, viz. 180°, but by increasing the heat to 200° there was no difficulty in distilling about 4½ fluid ounces more, but that appeared to consist principally of spirit; it was not acid when first distilled, but became so in a few days. On the last occasion of preparing sp. æther. nitros., I made a few notes which may, perhaps, be interesting to some.

The quantities operated upon were those mentioned in the B. P., viz. sp. vini rect. Oj, acid nitric 3 fluid ounces, acid sulphuric 2 fluid ounces, and copper wire. These ingredients (with the exception of ½ fluid ounce of the nitric acid which was set aside to be added subsequently), were put into a glass retort, and the mixture distilled at a temperature commencing at 160° and rising to 175°. The nitrous ether began to form at 160°, which is 10 degrees lower than the point indicated in the Pharmacopœia: when the temperature had risen to 175° and about 8 fluid ounces had passed over, the boiling ceased, and no more could be distilled without exceeding the limit of temperature, viz. 180°; so the contents of the retort were allowed to cool somewhat, and the remaining ½ fluid ounce of nitric acid was added; the distillation was then continued as before and 3 fluid ounces more passed over, making together 11 fluid ounces; a fresh receiver was adapted to the apparatus and the contents of the retort heated to 200°; the distillate thus produced measured 4½ fluid ounces, and consisted chiefly of spirit; it was nearly neutral to test paper, and had very little flavour of nitrous ether, its sp. gr. was ·867. I further distilled the contents of the retort until a temperature of 220° was shown; this produced about 2 fluid ounces more of a liquid, chiefly spirit and water, having a sp. gr. ·897, this was also neutral, but had a disagreeable odour. The 11 fluid ounces of distillate above referred to was then examined and found to have a sp. gr. ·881, and showed by the Ca Cl test a separation of 42·5 per cent., thus corresponding to 50·5 per cent. $C_2H_5NO_2$. This agrees tolerably well with the calculated sp. gr. of a mixture of equal parts of rectified spirit (·838) and nitrous ether (·900), which gives ·870 as a mean; the difference between these numbers may, I think, be accounted for by the condensation which takes place on mixing.

These considerations, I think, show that there is more spirit used in the first part of the process than is necessary, or what amounts to the same thing, too little nitric acid. I think a proportionate increase of nitric acid should be used, and the distillate tested as to the amount of $C_2H_5NO_2$ it contains, and if, as in the case just mentioned, it is found to contain 50 per cent., then 1 volume mixed with 4 volumes of rectified spirit would furnish spiritus ætheris nitrosi of the Pharmacopœia strength.

On the question of keeping this compound I regret having no suggestion to offer. It seems inherent in the nature of nitrous ether, even when pure, to change rapidly, becoming strongly acid after being kept a few days. Doubtless the keeping properties of sp. nitr. are in direct proportion to its strength in ether. A 5 per cent. solution is, I think, more desirable than the present strength, and it would approach nearer to that usually sent out by the wholesale houses. I have reason to believe it is never sent out of the strength ordered in the B. P.

The only possible remedy to prevent this decomposition that I can conceive may be the introduction of some other substance which will exert a preservative influence over it. I have not made any experiments in this direction, but they are well worthy our attention. Some organic substance, such as $CHCl_3$, might possibly be of use. I see acetic ether recommended in one of the American journals of pharmacy, but can say nothing of it from experience.

Before concluding, I should like to say a word or two of a practice which I consider highly reprehensible. Most of the wholesale houses, I believe, send out what they term solutio ætheris nitrosi 1 to 7 for the purpose of making sp. æther. nit., and doubtless the confiding pharmacist considers he has got hold of a most convenient article for making this otherwise uncertain preparation. I have even heard of its being used in the proportion of ʒj for every ℥j of spiritus ætheris nitrosi ordered, and trusting to the other tinctures ordered in the mixture to make the requisite amount of spirit. I had occasion the other day to examine a sample of this preparation

* Read at a Meeting of the Liverpool Chemists' Association, Nov. 27, 1870.

procured from a respectable wholesale house. It was received in a stoppered bottle covered with yellow paper, on the label of which were the words "Solut. ætheris nitros. 1 part added to 7 parts of sp. vini rect. (56 per cent.) forms the sp. ætheris nitrosi of the British Pharmacopœia." Thus, its pretensions were very explicit indeed, informing you of the strength your spirit ought to be, and also exactly defining what the mixture would be when made. Now, as the label contained no special precaution for keeping and storing this solution, I was rather doubtful of its assertions, for a solution of this strength ought to contain 80 per cent. of $C_2H_5NO_2$; and as $C_2H_5NO_2$ boils at about 65° F., this solution must be very dangerous to store, especially in summer, and unless some special precautions were adopted; but I soon found there were no fears to be entertained on this account. The sp. gr. was found to be ·857, and the separation by the Ca Cl test about 3 per cent., thus corresponding to 11 per cent. of $C_2H_5NO_2$ instead of 80, or 1 per cent. above the strength of spirit æth. nit. of the B. P. Now, as this article is usually charged from 5*s.* to 6*s.* per lb., you will see how large a price we sometimes pay for our credulity. We ought not to allow ourselves to be imposed upon in this manner. The process of the Pharmacopœia is neither expensive nor difficult, and I strongly advocate making this and other preparations for ourselves, or, when this is not practicable, to subject them to strict examination before taking into stock. I have great suspicions of many of these concentrated preparations, and doubt not that could they all be examined with the same facility as this one, many would be found very deficient.

PATENT MEDICINE LICENCES.

The amount of duty received on these in 1861 was £5384 and in 1869 £6842. The Act now in force concerning them is the 52 George III. c. 150, which, after giving a schedule of medicines liable to the duty, proceeds to enact generally that it shall apply to "all other pills, powders, lozenges, tinctures, etc. to be used or applied externally or internally as medicaments for the prevention, cure or relief of any disorder or complaint incident to, or in anywise affecting the human body, wherein the person making, preparing, uttering, vending or exposing the same to sale hath, or claims to have, any exclusive right or title to the making or preparing the same, or which now are, or shall be prepared, uttered, vended or exposed to sale under the authority of any letters patent under the great seal, or which now are or shall be by any public notice or advertisement, or by any written or printed papers or handbills, or by any label or words written or printed, affixed to or delivered with any packet, box, bottle, phial or other enclosure containing the same, held out or recommended to the public by the makers, vendors or proprietors thereof as nostrums or proprietary medicines, or as specifics, or as beneficial to the prevention or cure or relief of any distemper, malady, ailment, disorder, or complaint incident to or in anywise affecting the human body."

Artificial mineral waters were named among the articles included in the schedule, but they were exempted by the 3 & 4 Will. IV. c. 97.

The duty on the licence is in London and Edinburgh £2, in other cities, boroughs and corporate towns 10*s.*, and elsewhere 5*s.* The stamp duty on the packet, box, etc. in which the medicines are sold is *ad valorem*, and ranges from 1½*d.* to £1. The labels bearing the stamp are prepared at the Excise Office, by an ingenious machine invented by Congreve, the proprietors of the medicines paying for that portion of the die which contains their names and addresses. These labels are issued by the Registrar of Licences at his office.

It has been lately found that imitations of the labels are made in large quantities on the Continent to cover spurious preparations in foreign markets, and some few specimens have appeared in this country. The number of persons who took out medicine licences in 1869 was 11,422 in England and 849 in Scotland. The increase in five years in the number of medicine licences granted has been 1349. The amount of duty received on patent medicines in 1869 was £66,860, being almost an increase of cent. per cent. in the last fifteen years.

THE REACTION OF POTASSIC IODIDE WITH THE OFFICINAL TRISNITRATE OF BISMUTH.

BY W. BATHURST WOODMAN, M.D., AND C. MEYMOTT TIDY, M.B.

An out-patient attending at the London Hospital was taking the bismuth mixture of its Pharmacopœia, when it was thought advisable to add iodide of potassium to the previous prescription. When she came the following time, she appeared much alarmed at a red precipitate in the mixture, which she supposed to be "red lead" purposely put in by some neighbour, the sediment having been almost colourless when she reached home. As no mention is made in the ordinary text-books of materia medica of the decomposition which takes place, although it is doubtless well known to metallurgists, it occurred to the authors to examine the reaction a little more closely. The change takes place slowly, and appears to consist in the formation of an iodide of bismuth, potassic nitrate remaining in solution. This iodide of bismuth is a dark-red substance of cubic form, and seems to be a simple iodide, which is almost insoluble both in water and in excess of potassic iodide. Some of its properties are curious. It is a very insoluble substance; for, in addition to what is mentioned above, we may add that saturated solutions of chloride of ammonium, chloride of sodium, ferrocyanide of potassium, and corrosive sublimate, do not dissolve it in any appreciable proportions. Acetic acid dissolves it slightly, without effervescence. On boiling with liquor potassæ or ammonia, the hydrated oxide of bismuth ($HBiO_4$) is produced, which is insoluble in excess of either reagent. On treating this iodide with strong nitric acid, there was active effervescence; fumes of iodine being given off, a blackish, metallic-looking substance being left, entirely soluble in spirit, which proved to be pure iodine. Acid nitrate of bismuth remained in solution, which was not precipitated by a small quantity of water, or until neutralized. With hydrochloric or sulphuric acid there was no effervescence, but iodine was again precipitated; with the latter some iodic acid was formed. Oxalic acid also decomposed the salt, setting free the iodine; the action being somewhat slower than it was in the case of the mineral acids.

A few trials of it in doses of 5 to 20 grains appear to indicate that it is not an energetic therapeutic agent, which is probably to be ascribed to its comparative insolubility.—*British Medical Journal.*

POISONING BY SNUFF CONTAMINATED BY LEAD.

The following curious case of lead poisoning, which has come under the notice of Dr. Garrod, was mentioned by him in a lecture at King's College Hospital, and is reported in the *Lancet* :—

A gentleman, a resident in India, began to suffer some time since from nervous exhaustion, anæmia, and debility of both upper extremities; he was a great snuff-taker, taking, on an average, as much as an ounce in the course of a day. He consulted several medical men in India, and they attributed his symptoms to inordinate snuff-taking. He, however, continued to take snuff and to get worse, and at last came to England to seek further advice. When Dr. Garrod saw him he discovered a blue line on the gums. His suspicions were directed to the snuff, which he found to contain a considerable quantity of lead. To ascertain whether or not the presence of lead in this specimen was an accidental circumstance, six packets were ordered from the house in Calcutta with which the gentleman had been in the habit of dealing. The snuff was contained in sheet-lead packages, which were all found to contain lead to about the same extent as the first specimen. Dr. Garrod exhibited a solution which he had tested in the following way: Ten grains of snuff were burned in a platinum capsule, and the ash was treated with nitric acid; the crystallized result was dissolved in distilled water, with the addition of a small quantity of acetic acid, and then tested with iodide of potassium, which threw down an abundant precipitate of yellow iodide of lead. The leaden packages were labelled "best brown rappee," and bore the name of a well-known English firm, from which they had been exported to India. The snuff itself was rather moist. Where it adhered to the sides of the case, it was dotted with white spots, probably consisting of carbonate of lead, formed, Dr. Garrod suggests, by the fermentation of the damp snuff. Since Dr. Garrod's attention has been directed to this subject, he has spoken to a medical man recently returned from Calcutta, who told him that he had quite lately met with three cases of lead-poisoning, which on investigation were found to be due to the use of snuff.

Sulphurous Acid.—The value of sulphurous acid gas as a disinfectant has been established by many and crucial experiments, and is generally admitted. This agent is specially recommended by medical officers of health. There is a want of convenient methods of applying it, and especially of applying it in a limited space and to a definite and measured degree. Mr. John Gamgee has called attention to the convenience of employing it as disengaged from an alcoholic solution. Cold alcohol will, he states, take up three hundred times its bulk of sulphurous acid gas. Where, for example, it is desired to saturate a box of clothing with this gas, it is sufficient to drop a certain quantity of its saturated solution of alcohol into the floor of the box, and a large definite quantity is set free by the evaporation. The suggestion is one of importance, and seems to us worthy of attention. The solution of sulphurous acid in alcohol could easily, and probably with advantage, become a general article of pharmaceutical commerce for medical and sanitary use.—*British Medical Journal.*

Baths for University College Hospital.—A complete set of ordinary and medicinal baths, the first in connection with any London hospital, is about to be erected at University College Hospital. The expense will be about £1300, of which sum £1100 has been collected through the energy of Dr. Tilbury Fox, the Physician to the Skin Department. The general bath-hall will be 30 feet by 23 feet, and have attached to it a dressing-platform 15 feet by 10 feet, and a Turkish bath 10 feet by 7 feet, into which both hot air and steam will be admissible. The hall itself will be fitted with four or five ordinary baths—hip, sit, and others—and also a large needle-bath and apparatus for douche and shower applications. In this part will also be the alkaline and acid baths. Entirely separated by a lobby and anteroom, and having a distinct entrance, will be the chamber, 15 feet by 11 feet, in which patients affected with contagious skin complaints and syphilitic eruptions are to be fumigated or otherwise treated,—the fumes from the iodine, sulphur, and mercurial medications here given, being carried away by a special pipe to the top of the hospital building. Patients suffering from contagious complaints will be kept entirely away from the place in which the simpler baths are given. Adjoining this part of the baths will be a large chamber, 7 feet by 5 feet, for disinfecting by a strong heat the clothes of such patients as are suffering from phtheiriasis.

Artificial Ice.—We learn from the *New York Times* that an ice machine, constructed on Tellier's principle, is now being exhibited in the United States. The material used is gaseous ammonia, which is liquefied by pressure. It is said that the machine will make one hundred tons a day, at a cost of four or five shillings per ton; and that the ice made by it is transparent and durable. The cooling effect of the vaporization of liquefied ammonia may be applied to chambers containing articles of food to be preserved, or refrigerators might be constructed on any scale. The holds of ships could thus be converted into refrigerating chambers with the greatest ease, offering a ready means for the conveyance of meat from one port to another in a wholesome state.

Epsom Salts.—In reply to a query propounded by the American Pharmaceutical Association, as to the best method for disguising the taste of Epsom Salt, Mr. J. W. Smith, of Nashville, suggests the following :—

℞ Liquorice Root (deprived of the outer bark), 4 oz.
Boiling water, 2 pints, or a sufficiency.

Mix and allow to strain, with occasional stirring until cold; express through muslin, adding more water, if necessary, until the residue in the strainer is tasteless; then filter and to the filtrate add 4 oz. of sulphate of magnesia. Finally evaporate to dryness over a water bath. Each ounce of the compound represents about one ounce of the crystallized salt.—*Review of Pharmacy.*

A Pleasant Remedy for Sea-Sickness.—There have been many suggestions made as to the prevention of sea-sickness, none of which have, to say the least, been found completely successful in practice. The introduction into practice of hydrate of chloral, which produces with certainty sleep for a definite number of hours, has suggested a means of escaping the horrors of a short sea-passage at least, and possibly of mitigating the most prolonged horrors of sea-sickness. To go asleep at Dover, and wake to find oneself at Calais, is a plan which, failing other expedients, has in it much promise. An ordinary dose of hydrate of chloral produces sleep usually in a quarter of an hour, and with almost unfailing certainty. Some cases just published by Dr. Doring, of Vienna, seem to show that the value of hydrate of chloral to obviate sea-sickness is very great. It produces quiet and prolonged sleep. In all the instances recorded, it seems to have been of great value even during prolonged sea-voyages, giving a good night's rest, arresting violent sickness when it had set in, and stopping the tendency to its recurrence.—*British Medical Journal.*

Explosion of an Ammonia Still.—An explosion of an ammonia still took place last week at Mr. J. Barrow's chemical works, West Gorton, Manchester, doing serious injury to three workmen. The still, which was made of iron, boiler form, and about seven inches diameter, was blown over a cottage three storeys high into a pool of water, about eighty yards distant. The three injured men were taken to the Manchester Infirmary, one of them having had his skull fractured.—*Standard.*

Carious Teeth.—M. Magilot recommends the following preparation for carious teeth :—

Chloroform	5	parts.
Laudanum	2	,,
Tincture of Benzoin	10	,,

Cotton wool saturated with this to be inserted in the cavity, and renewed until insensibility of the part is produced.—*Revue Médicale.*

[*⁎* Where the nerve of the tooth is exposed, a most efficient remedy will be found in the careful application of a very small portion of carbolic acid to the inside of the tooth.—Ed. Ph. J.]

A Phase of Pharmacy in America.—The following advertisement appears in the *Canadian Pharmaceutical Journal* :—"The United Society of Shakers, New Lebanon, New York, prepare every description of vegetable medicines of superior quality, including roots, barks, herbs, etc., packed; alcoholic extracts, solid; alcoholic extracts, fluid; aqueous extracts, solid; powdered drugs; powdered sweet herbs. In ordering goods from wholesale houses order Shaker Herbs, to secure satisfaction."

Cinchona Cultivation in Java.—In 'Flora,' for October 10th, is a communication from Professor Hasskarl on the cultivation of the cinchona in Java. He reports that the weather has been on the whole favourable, and the growth of the plants leaves nothing to be desired. The total numbers of plants grown from seeds and layers is 1,520,516; of which 1,100,983 are *C. Calisaya*, next in number come *C. officinalis* and *succirubra*, etc., very few *C. lancifolia* and *micrantha*. In addition to these, there are 870,599 transplanted plants, giving in the gross total an increase of 197,699 plants since the commencement of the year. 460 kilograms of the bark were sent to Holland in December, 1869, and were sold at from 2 to 3 florins per kilogram; 900 kilograms have since been exported, and more than 1000 are now ready. The total produce for 1870 will probably be 4000 kilograms of dry bark for exportation, besides some hundreds for use in the island. The stripping, cutting, drying, sorting, and packing are already becoming a considerable industry in the island.

[*⁎* The importation here referred to is the same as that mentioned in Mr. Howard's paper last week. There is nothing here to contravene the result arrived at by Mr. Howard, that the cultivation in Java fails to produce bark suited for *manufacturing* purposes. The why and wherefore of this remains to be discovered.—Ed. Ph. J.]

DRUG MARKET NOTES.

Although no very complete details are kept of the commerce in drugs, yet the Board of Trade returns furnish us with the approximate particulars of all the most important, and under the subordinate head of "other articles," some of the minor trade products (in the quantity point of view) are given. The "annual statement of the trade and navigation of the United Kingdom with foreign countries and British possessions for 1869" just issued, enables us to make a cursory examination of the quantities imported of the principal articles; but to make any useful comparisons, the re-exports, stocks, and current wholesale prices, would have to be given. The following statistical notes may, however, prove useful. Glancing at the principal articles for the last five years, we find that of—

Arrowroot.—The exports have averaged about 22,000 cwt.; in 1836 they reached 32,000 cwt.

Cinchona Bark.—The average imports are from 9000 to 15,500 cwt.; in 1869 they were 11,232 cwt.

Camphor.—The imports fluctuate greatly; in 1865 they were 10,755 cwt.; in the next three years they ranged from 7400 to 3700 cwt., whilst in 1869 they reached 17,480.

Galls.—The imports of nut galls have been steadily increasing from 15,964 cwt. to 25,842 in 1868, and 21,040 in 1869.

Gum Arabic.—In this gum there has been a steady increase from 46,032 cwt. in 1865 to 67,989 cwt. in 1869.

Isinglass.—The average imports have been about 3000 cwt., the figures in 1869 being 3287 cwt.

Liquorice Juice and Paste.—There has been lately a gradual increase from 27,286 cwt. in 1865 to 37,208 in 1869.

Opium.—The imports have fluctuated greatly; in 1865 they were 401,571 lbs., in 1866, 198,223 lbs., in 1867, 273,522 lbs., in 1868, 322,309 lbs, and in 1869, 219,495 lbs.

Rhubarb.—Of late the imports have been rising. In 1865 they were 129,967 lbs., then they touched 383,821 lbs. in 1866, and have since varied from 227,663 lbs. in 1867 to 358,613 lbs. in 1868, and 270,627 lbs. in 1869.

Oils.—The quantity of Castor oil has more than doubled in the five years, having risen from 20,163 cwt. in 1865 to 50,426 cwt. in 1869. Essential and perfumed oils nearly average 500,000 lbs. per annum; one-fourth of these come from Sicily, about half from India, China, and Ceylon. Of Cod-liver oil we imported last year more than 1000 tuns, but only a portion of this was for medicinal use.

Of Balsams, the imports last year of Copaiva were 171,084 lbs., of Peru, 39,153 lbs., and of unenumerated balsams 13,085.

Cantharides.—Imported in 1869, 14,785 lbs.
Cardamoms.—85,512 lbs.
Cassia Fistula.—35,882 lbs.
Castoreum.—5063 lbs.
Cocculus Indicus.—825 cwt.
Collodion.—90 gallons.
Cubebs.—23,649 lbs.
Ether.—2295 gallons.
Gamboge.—481 cwt.
Gentian.—100 tons.
Guinea grains, or grains of Paradise.—2051 cwt.
Gum Euphorbium.—138 cwt.
Jalap.—73,346 lbs.
Lemon and Lime Juice.—289,916 gallons.
Leeches, to the value of £7067.
Liquorice powder, 29 cwt., and of root, 909 cwt.
Manna.—23,911 lbs.
Mineral water.—145,326 gallons.
Musk.—23,477 ounces.
Myrrh.—535 cwt.
Nux Vomica.—3899 cwt.
Olibanum.—11,753 cwt.
Pink root.—126 lbs.
Pomatum.—31,848 lbs.
Quassia.—4442 cwt.
Quinine, sulphate of.—62,086 oz.
Sarsaparilla.—306,777 lbs.
Sassafras.—132 cwt.
Croton seed.—222 quarters.
Seneka root.—9395 lbs.
Senna.—756,956 lbs.
Sulphuric acid.—19,997 lbs.
Tartaric acid.—388,523 lbs.
Tragacanth.—1525 cwt.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 10, 1870.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes endorsed "Pharm. Journ."*

DRUGGISTS' CHARGES.

WE acknowledge with much pleasure the assurance given in the following note, appended to the letter addressed to the Editor of the *Lancet* last week, in reference to a letter published in that Journal:—

"We would courteously request the Editor of the PHARMACEUTICAL JOURNAL again to refer to the *Lancet* of the 19th November, where he will find that our correspondent makes no attack whatever upon druggists as a class, but merely relates a fact regarding the conduct of an individual.—ED. L."

We hope that the daily papers which also put forward this statement regarding the conduct of an individual as a sensational illustration of the extortionate character of "Druggists and their Charges," will in like manner have the fairness to administer an antidote to the poison they have supplied—no doubt unconsciously—to the public mind, and we trust to receive from our medical contemporary a statement of the name and address of the individual dispenser referred to, as well as a copy of the prescription on which the alleged overcharge was made.

A propos of this subject, it so happens that in the medical journals of last week, charges for medicine are discussed at some length—not druggists' charges, however, but those of medical men. A correspondent of the *Medical Times and Gazette* submits a system of charges specially adapted, as he thinks, for the general practitioner in the country, and he gives the following rate of charge for medicine supplied:—

		s.	*d.*
"Mixtures for adults,	℥vj (6 doses)	1	0
" "	℥viij (8 doses)	1	6
" "	℥xij (12 doses)	2	0
" "	℥xvj (16 doses)	2	6
" " children	up to ℥vj	1	0
Gargles and lotions of similar size would be similarly priced.			
Pills	from 1 to 6	0	6
"	12	1	0
Powders	from 1 to 3	0	6
"	6	1	0
Draughts	each	0	6
Blisters and plasters, 6*s.* to 1*s.*, or more, according to size.			
Ointments to ℥j, 6*d.*; ℥ij, 1*s.*"			

He then adds:—

"Although it may sound paradoxical, in a certain sense this is the basis of the system; for the prices of medicines should be the same for all classes of private patients. They should be much what the patient would pay at an ordinary druggist's; for the doctor, be it remembered, is his own druggist."

Again, in the *Journal of the British Medical Association* we find a document emanating from the Shropshire Ethical Branch, recommending a tariff of medical fees, and among other things provided for are medicines, the charges being regulated for three different classes of patients, as follows:—

"Mixtures, ℥xij.—I. 3*s.* 6*d.* to 4*s.* 6*d.*; II. 4*s.* to 4*s.* 6*d.*; III. 4*s.* to 5*s.*
" ℥viij.—I. 2*s.* 6*d.* to 3*s.* 6*d.*; II. 3*s.* to 3*s.* 6*d.*; III. 3*s.* 6*d.*
" ℥iv.—I. 1*s.* 6*d.* to 2*s.*; II. 2*s.* to 2*s.* 6*d.*; III. 2*s.* 6*d.*
Draught, ℥iss.—I. 1*s.* to 1*s.* 6*d.*; II. 1*s.* 6*d.*; III. 1*s.* 6*d.* to 2*s.* 6*d.*
When two or more are sent, a moderate decrease in the charge should be made.
Drops, ℥iss to ℥ij.—I. 1*s.* 6*d.*; II. 1*s.* 6*d.* to 2*s.*; III. 2*s.* to 2*s.* 6*d.*
Pills, xij.—I. 1*s.* 6*d.*; II. 1*s.* 6*d.* to 2*s.*; III. 2*s.* to 2*s.* 6*d.*
" vj.—I. 1*s.*; II. 1*s.* to 1*s.* 6*d.*; III. 1*s.* 6*d.* to 2*s.*
" ij.—I. 6*d.* to 1*s.*; II. 1*s.*; III. 1*s.*
Powders, vj.—I. 1*s.* 6*d.*; II. 1*s.* 6*d.* to 2*s.*; III. 2*s.* to 2*s.* 6*d.*
" iv.—I. 1*s.* to 1*s.* 6*d.*; II. 1*s.* 6*d.* to 2*s.*; III. 2*s.*
" i.—I. 6*d.* to 1*s.*; II. 1*s.*; III. 1*s.*
Blisters.—I. 1*s.* to 1*s.* 6*d.*; II. 1*s.* 6*d.* to 2*s.*; III. 2*s.* to 2*s.* 6*d.*
Gargles and Lotions.—May be charged somewhat lower than medicines proper."

We abstain at present from any comment on these propositions, and simply submit the scales of charge for the consideration of our readers.

The fact that a tariff is proposed for medicines as well as for visits, etc., would seem to indicate that medical men do not see their way to giving up the preparation of medicines. It is to be regretted that this should be the case, for there is every reason to believe it would be advantageous both to the pharmacist and to the medical man if the compounding of medicines were left solely to the former. But, in this respect, we are far less fortunate than our cousins across the Atlantic, where, as Mr. HOWDEN has shown in his account of American Pharmacy, the functions of the physician and the pharmacist are invariably kept separate. The results of that system, as described by Mr. HOWDEN, are such as to make it well worth consideration whether it would not be wise to follow the example here.

THE USE OF CHLOROFORM AS AN ANÆSTHETIC.

AT the Royal Society of Edinburgh on Monday evening Professor CHRISTISON, in proposing a vote of thanks to Mr. MILNE-HOME for his address, alluded to the notice that had been given of Sir JAMES SIMPSON. As to the discovery of chloroform, he said the history of that had never yet been fully given. When fully given, it would constitute one of the most curious instances he knew of the gradual progress of discovery. There was one link which he thought, in justice to Sir William Lawrence, he should supply, as he could do it authoritatively. Sir William Lawrence, in the summer of 1847—the same year in the November of which Sir James Simpson made his great discovery—did repeatedly employ a solution of chloroform in rectified spirit as an anæsthetic in his surgical practice, and ascertained that it was a superior agent to sulphuric ether. Had Sir William possessed that knowledge of chemistry which Sir James Simpson very properly held that every medical man should possess, he thought there was a strong probability that he would have anticipated Sir James in his great discovery. But the article had come to him recommended by the very absurd name of chloric ether. He (Dr. Christison) rather believed there was no such thing as chloric ether known; nevertheless there was an article which had been so called. It was recommended to Sir W. Lawrence under that name; it was tried under that name; and he was informed that both Sir William and his assistant saw that something more concentrated was wanted, and that they were busy considering how they might concentrate it when suddenly the discovery of Sir James Simpson came forth and put an end to their inquiries. Had they been aware that the substance in their hands was nothing else than a solution of chloroform in rectified spirit, the solution of their problem would have been very simple indeed.

SUPPLY OF DRUGS TO UNIONS.

The announcement by the Irish Poor Law Board of their intention to appoint an officer to be called a Poor Law Unions' Apothecary, who is to have the entire management of the purchase, preparation and supply of drugs to all the Irish dispensaries, seems to have given general satisfaction. The system of obtaining supplies of drugs by contract, in the absence of a skilled officer whose special duty it should be to test their quality, and to see that the contracts are fulfilled, is one so pernicious from its tendency to promote a false economy in the acceptance of low tenders, and by the encouragement it must offer to adulteration as well as all kinds of jobbery, that it hardly causes surprise when we are told that for years past complaints have been made by medical officers in respect to the quality of the drugs supplied under contract; that adulteration has frequently prevented successful treatment of patients, whilst guardians have been often imposed upon with regard to cost. The salary of £500 a year, together with a residence at the depot in Dublin, will doubtless secure a goodly number of candidates to select from, and already it is stated that an ex-Lord Mayor of Dublin is in the field.

But surely if such an appointment is likely to be beneficial in Ireland, a similar one would not be without advantage in England. We can hardly assume that in this country drugs are less liable to sophistication, or that contractors are more honourable and guardians more intelligent than in Ireland. Therefore, since the serious evils flowing from the contract system have been thought sufficient by the Irish authorities to justify their present step, we heartily agree with our contemporary, the *Lancet*, in asking Mr. Goschen to turn his attention to the matter.

If, it is argued, the cost of drugs in Ireland be £32,000, then it would amount to something like three times as much in England; and from this point of view alone it is worth while to make sure that the money is well laid out.

OBSCURE PRESCRIPTIONS.

In referring to Mr. Watson Bradshaw's statement that his patients are invariably reminded they can only have their medicines compounded by the especial druggists to whom he hands them over, and that he considers he has the right to indite his prescriptions in any mode he may deem expedient, the *British Medical Journal* remarks:—

"The mode in which a medical man frames his prescriptions is not precisely 'his own private affair'; and the particular mode of secret formulæ which Mr. Bradshaw avows himself to employ has been emphatically condemned by the whole profession."

The *Medical Times and Gazette* is of opinion that—

"If a medical practitioner chooses to write prescriptions that cannot be understood and properly dispensed by a qualified druggist, he is to a certain extent answerable for any results that may arise therefrom. When a medical practitioner under such circumstances objects to any comments that a respectable journal, in the interests of the public, may think it right to make upon his conduct, he shows his ignorance of the law. The press is for the protection and safety of the public, and would fail in its duty if it did not fairly comment upon transactions which, to say the least of them, are 'irregular.'"

We are glad to find these opinions expressed by the representatives of the medical profession, and that the practice of writing prescriptions in secret terms is condemned from a medical point of view as much as we feel it is to be condemned from the pharmacist's point of view. In this respect we are sure that the objects with which that practice is adopted cannot promote the real interests of pharmacy; indeed it is hard to say whether the pharmacist who lends himself to such a practice, and in fact makes it possible, is not even more to blame than the medical practitioner who suggests it.

The Secretaries of the Chemical Society have (by direction of the President and Council) issued a circular stating that their attention has been directed to the absence of any provision on the part of the

Society for making known to its Fellows the progress of chemistry in foreign countries, and asking for subscriptions to enable them to defray the expense of a report to be published in the monthly Journal of the Society, of all papers whatever of scientific interest, and of all the more important papers relating to applied chemistry. A sum of £272 has already been promised. Not more than one-fifth of any contribution is to be called for in one year.

Members of the trade throughout the country will doubtless be looking forward with interest to the steps taken in reference to the storing of poisons. We may state that at the meeting of Council on the 7th inst. this question was discussed, and that it took up the greater part of a long sitting. We hope soon to place before the readers of this Journal a report of the proceedings.

Among the objects of interest at the late meeting of the Pharmaceutical Society there was a specimen of the "Herbarium Pharmaceuticum," which has been prepared for the use of pharmaceutical schools and associations by Mr. Siebold, of Manchester. The want of such a collection of plants must be frequently felt by students in the provinces.

We have much pleasure in stating that Mr. Williams has been unanimously elected a member of the Council, and we do not doubt that all who know him will be equally unanimous in thinking that the place left vacant by the retirement of Mr. Brady could not have been better or more worthily filled up.

The Rev. Dr. Henry Cheetham, D.D., of Christ's College, Cambridge, Rector of Quarndon, Derbyshire, who has been appointed to the Bishopric of Sierra Leone, was consecrated in St. Paul's Cathedral on November 30th. Dr. Cheetham's original profession was pharmacy, and he resided for some years in the establishment of Mr. Harvey (now Harvey and Reynolds) at Leeds.

By the courtesy of a correspondent we are enabled to add to the list of members of the drug trade who have been elected to the office of mayor this year, the name of Mr. Robert Walker, Pharmaceutical Chemist, Maidenhead.

We learn from Messrs. Longman's Notes on Books, that it is intended to issue early in 1871, a Supplement to Watts's 'Dictionary of Chemistry,' bringing the record of chemical discovery down to the end of the year 1869. It will form a volume of about 900 pages, and many of the former contributors have consented to furnish additions to their articles. We should be glad to see this supplementary volume made annual, so as to give a permanent value to the original work.

The *Gardeners' Chronicle* announces that by the resignation of Mr. J. J. Bennett, F.R.S., a vacancy is caused in the office of Keeper of the Botanical Department of the British Museum. If the usual course be followed, Mr. Carruthers, the Senior Assistant-keeper, will succeed to the post.

Professor Bloxam has been elected to the chair of Chemistry in King's College, vacant by the death of Dr. Miller.

Dr. John Murray has been appointed assistant-physician to the Middlesex Hospital, to fill the vacancy caused by the resignation of Dr. J. Burdon-Sanderson, F.R.S.

The election of a Professor of Chemistry at St. Bartholomew's Hospital in the place of the late Dr. Mathiessen will take place on the 13th inst.

Proceedings of the Pharmaceutical Society.

EXAMINATION IN LONDON.

December 2nd, 1870.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Edwards, Gale, Garle, Haselden, and Ince.

Dr. Greenhow was present on behalf of the Privy Council.

MODIFIED EXAMINATION.

Forty-five candidates presented themselves for examination; the following passed and were registered as

CHEMISTS AND DRUGGISTS.

Ault, Reuben	Chesterfield.
Biggleston, Edwin Radford	Exeter.
Bond, Edward	Reading.
Bond, John	Okehampton.
Borman, John Henric	Upper Norwood.
Carne, Robert Harkness	Bayswater.
Chapman, Josiah Thomas	Hulme.
Dix, Thomas Henry	Croydon.
Hall, Thomas Henry	Sheffield.
Harvey, Henry	Wakefield.
Hern, William Henry, jun.	St. Austell.
Keall, Douglas	Kington.
Martin, Amelius Hare	Paris.
Moseley, Sackville Gwynne	Cardiff.
Owen, Robert Henry	Rhyl.
Pratt, Edward Jonathan	Newbury.
Pratt, Thomas Henry	Newbury.
Richardson, Alexander	London.
Sellors, Blanchard F.	Birmingham.
Smith, Allen	West Derby.
Smith, Robert John	Horselydown.
Snell, Charles Henry	Plymouth.
Steed, Robert Owen	Southwark.
Sugden, Joseph William	High Harrogate.
Targett, Charles George	Faringdon.
Taylor, Walter	Nottingham.
Wilson, Clement Fisher	Bury.

EXAMINATION IN EDINBURGH.

November 22nd, 1870.

Eleven candidates were examined—two for the Minor Examination, two for the Modified, and seven for the First, or Preliminary; the following passed and were registered:—

MINOR (as a Chemist and Druggist).

Lee, Thomas .... Salford.

MODIFIED (as Chemists and Druggists).

Parker, William George ...... Newcastle-on-Tyne.
Pool, George .... Manchester.

FIRST, or **PRELIMINARY** (as Apprentices or Students).

Bremner, Allan Hugh .... Edinburgh.
Brown, George .... Edinburgh.
Cowper, David Burgess ...... Edinburgh.
Fenton, Thomas .... Edinburgh.
McNiven, Thomas .... Edinburgh.
McParlan, James .... Glasgow.
Young, John .... Edinburgh.

PHARMACEUTICAL MEETING.

Wednesday, December 7th.

MR. HASELDEN, VICE-PRESIDENT, IN THE CHAIR.

The Secretary having read the minutes of the previous meeting, announced the following donations to the Library and Museum:—

Medico-Chirurgical Transactions, vol. 53: from the Royal Medical and Chirurgical Society,—Manual of Botany: from Professor Bentley,—Herbarium Pharmaceuticum; a collection of the Dried Plants of the British Pharmacopœia, with Index: from Louis Siebold, Esq., Lecturer on Pharmacy at Owens College, Manchester.

Professor Attfield drew attention to a slight modification in Mr. Benger's apparatus, which has already been noticed in the Pharmaceutical Journal,* for securing equability of temperature in analytical and other operations, in which gas is used as the heating agent, and in which inconvenience has often been felt by variations in the supply of gas. Mr. Benger's apparatus, it would be remembered, consisted of a tube in the shape of the letter U, introduced between the gas-burner and the source of supply. Into one limb of the U tube was inserted the gas-pipe, at the bottom of which was a narrow slit through which the gas passed, and thence by a second pipe out of the same limb of the U tube, on its way to the burner. The bottom of the slit and the bend of the U tube was closed by mercury. The other end of the U tube is connected with any chamber that is being heated; a rise of temperature expands the air in the chamber, which immediately presses on the mercury in one side of the U tube, raises it at the other end, partially closes the slit, and thus diminishes the supply of gas to the burner. Conversely, when the chamber begins to cool, the air contracts, the mercury rises in the free limb of the U tube, falls in the other, and allows a greater supply of gas to go through tho slit. It was found, however, that when this apparatus was connected with an oven such as was exhibited (about 1 foot square), having a jacket within, it was rather cumbrous and expensive; and Mr. Benger therefore proposed, as a modification, that an air-chamber of any size desired should be lowered into an unjacketed oven, or whatever apparatus was being heated. In the connecting-pipe was a small stopcock, which, being left open until the requisite temperature was attained, would then be closed, and the apparatus at once became self-acting. Another modification was to use a glass flask, or even a test-tube, which might be connected in the same way with the U tube, and lowered into any solution which it might be necessary to evaporate at a lower temperature than boiling-point, or any other fixed temperature.

* Pharm. Journ. 3rd Series, No. 13, p. 253.

The Chairman said the apparatus appeared very useful, and the thanks of the members were certainly due to Mr. Benger for bringing it forward.

Mr. Abraham said the same principle might evidently be applied, with slight modifications, to a steam apparatus.

Mr. Grove said the only objection he had seen to the apparatus when first proposed, that the air-jacket must be made very tight, seemed to be now removed, and the present modification would not only come much cheaper, but would be more easily used.

The Chairman drew attention to the collections of prescriptions which had been laid on the table by Mr. Ince, amongst the contents of which would, he believed, be found some prescriptions illustrating the paper which Mr. Howden was about to read to them on American pharmacy.

Mr. Ince said the collections which he and his friends were forming were intended to illustrate every subject connected with pharmacy; and each of the fourteen volumes on the table contained about twenty American prescriptions, taken from the different States, and illustrating the exact style of prescription which were in use in the United States. Some were written in ink, and others, as was quite as common, in pencil. These latter had been carefully preserved, to avoid the risk of their fading; so that he hoped they would, to some extent, illustrate the general subject of American pharmacy.

Mr. Abraham asked if the volumes on the table contained any of Mr. Watson Bradshaw's prescriptions.

The Chairman said he thought the specimens which had appeared in the Journal were quite sufficient.

Mr. Ince said there were four specimens of Mr. Bradshaw's prescriptions on the table.

The Chairman said a very nice collection of dried plants, labelled "Herbarium Pharmaceuticum," had been placed on the table, but he did not know the history of it.

Mr. Brown (of Manchester) said the collection in question had been forwarded to Professor Bentley, who he had hoped would have been present to explain it. In his absence, however, he might state that this collection had been prepared by Mr. Siebold, of Manchester, who had arranged about 150 of such collections, which he intended to offer for sale, principally to Pharmaceutical Schools and Associations, at £4. 4*s*. each. Such a collection had been much wanted, and since the passing of the Pharmacy Act, many inquiries had been made for such a thing, but so far as he was aware, nothing of the kind had hitherto been supplied. About two years ago, Mr. Siebold had arranged with some friends on the Continent to supply him with such plants as could not be obtained in England; and in the interval he and his friends, with no small amount of labour, had succeeded in obtaining about 150 of such sets as the specimen on the table, which consisted of about 100 plants. He did not wish in any way to advertise this matter, and much regretted that Professor Bentley was not present to give his opinion of the collection, but certainly as far as he could judge, the plants were well selected and carefully prepared.

The Chairman said the specimens seemed extremely well set up, and he would recommend the members present to examine the collection for themselves.

The CHAIRMAN then called upon Mr. Howden to address the meeting and give the results of his observations on the condition of Pharmacy in the United States.* At the conclusion of the address,

The CHAIRMAN said Mr. Howden's paper had been most valuable and interesting, and contained so much matter that he feared it would be impossible to do it justice in the way of discussion in the short time that remained. He should therefore suggest that the meeting be adjourned to the 4th of January.

Mr. HOWDEN remarked that he wished to call attention to the bottles on the table, which were specimens of American pharmacy. He did not know that they all possessed extraordinary merit, but large quantities of them were sold. He was passing one day through a laboratory when he noticed a large tub holding about 100 gallons. The proprietor said to him, "How do you filter your syrups in London?" His reply was that they did not filter them at all. His friend said, "Not filter your syrups! why I have this to filter. I make this quantity every three weeks." The process Mr. Howden thought an ingenious one. He took a cone of felt or flannel about four feet long and filled it with water containing several sheets of white filtering-paper beaten into a pulp. As the water passed away it left a deposit of paper felt on the inner surface of the filter, admirably adapted for filtering syrups. He was rather proud of it, and justly, adding that it had this further advantage, after it had been used, he set a boy to wash the paper again, when it was as good as ever. The inventor of this filter was Mr. Frank Wyeth, of Philadelphia. There were also on the table some specimens of "elegant pharmacy." There was also on the table one ingenious device, which he believed was quite new, and for which a patent had been taken out. It consisted in first mixing certain active drugs with glycerine and then with gelatine, running the mixture out into flat cakes, with little ridges separating it into squares like a chess-board, so that each square contained a definite amount of the drug, say $\frac{1}{2}$ grain of calomel, a grain of quinine, or, as in a specimen in his hand, 1 grain of ipecacuanha. In this way a medical man in the country might possess himself of portable medicines; he only had to put a few of these gelatine sheets into his pocket, and when he wanted to make a mixture, he could snip off squares with a pair of scissors, put them in a bottle, fill up with water, and his medicine was prepared. There were also pills coated with gelatine which were well deserving of notice. Also, powdered blue pill. There was also a bottle of the celebrated sweet quinine, which had been so largely advertised, and which had led to some very painful circumstances to those interested in the manufacture. He had brought over a bottle, thinking it would be interesting for the students in the laboratory to analyse it, and see of what it really was composed. Then there were some packets of what were known as "Shaker herbs," a remedy which had a great reputation in the States, and some other preparations of a similar character. He might also draw attention to an engraving of the premises of Messrs. Powers and Weightman, of Philadelphia, who were leading manufacturing chemists.

The CHAIRMAN also drew attention to a number of American photographs which Mr. Howden had collected in his travels, and which he had kindly placed on the table for inspection.

Professor ATTFIELD thought Mr. Howden had treated his subject so exhaustively, that he doubted whether there was much left for discussion. The clear and graphic way in which he had given his experience afforded much matter for congratulation that the Pharmaceutical Society had been so well represented in America during the last few months. Mr. Howden's paper had been so interesting, that it had set the speaker longing to know something of the state of pharmacy on the Pacific coast of the American Continent. By good fortune there sat by him (Professor Attfield) a gentleman who occupied, sixteen years ago, the same relative position in the very room in which they were assembled, when they were both students in what was then the laboratory. Mr. Hugh Lloyd Jones had since resided in Vancouver's Island, at Victoria, and had visited San Francisco and other places on that coast, and he had expressed his willingness to give the Society on a future occasion the results of his experience of the pharmacy of those localities.

The CHAIRMAN said he did not intend to convey that there was any room for discussion on the merits of Mr. Howden's paper, but there were many points on which he thought it would be interesting to have a few more remarks,—for instance, on the practices of their American cousins, such as expecting the public to walk inside their stores and view their goods, instead of displaying them in the window, keeping their bottles nearly empty, which would be considered a very bad sign in England and so on. Again, Mr. Howden had spoken of American scales, and he had no doubt what he said was correct, but he should like to know whether, when powders were prescribed, they were accustomed to take the precaution usual in England of weighing each separate dose, because it appeared to him that the arrangement described would not be so convenient for that purpose as the small horizontal scales in use here. There were also other matters on which he thought useful information might be elicited by discussion.

Mr. WOOLLEY (Manchester) said he had much pleasure in proposing a vote of thanks to Mr. Howden, for he had rarely listened to a paper with so much interest; and he was very glad to have the opportunity of learning so much of pharmacy on the other side of the water. He thought it most desirable to adjourn the discussion.

Mr. BROWN (Manchester) seconded the motion. He very frequently came in contact with American citizens, and had heard somewhat of the conditions under which pharmacy was carried on in America, and the difficulties which attended the business there, but he had never received anything like the information which had been so pleasantly conveyed by Mr. Howden. He had listened with very great pleasure to the details which had been given by Mr. Howden, and thought many of them would form interesting subjects for discussion on another occasion.

The resolution having been carried unanimously,

Mr. HOWDEN, in acknowledging the compliment, said he had not gone so much into detail as he could have wished, as it was very difficult to condense the experience of six weeks into an hour, but he should be happy to attend the adjourned meeting, and if he could give any additional information it would afford him much pleasure to do so.

The meeting was then adjourned to Wednesday, January 4th.

Provincial Transactions.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The Weekly Meeting of this Association was held on Thursday evening, November 17th; the President in the chair. A very interesting and instructive discussion took place upon the prescribing of "Medical Practitioners." A paper on Water was also read by Mr. Atkinson.

---

* A *résumé* of Mr. Howden's address will be found at p. 461.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The First General Meeting of this Association was held on Thursday evening, November 17, in the Lecture Hall of the Mechanics' Institution, Bath Street; the newly elected President, Mr. Thomas Davison, M.P.S., in the chair. There was a good attendance; several new members were elected. The Treasurer announced that the following donations had been received towards the funds of the Association:—From Dr. A. M. Robertson, 10*s.*; the Glasgow Apothecaries' Company, £3. 3*s.*; James Taylor, Esq., £1. 1*s.*

The President briefly introduced Roger Hennedy, Esq., Professor of Botany, Andersonian University, who delivered a highly interesting and instructive lecture, entitled "The Histology of Plants." The lecture, which treated principally of cell-growth in the structure of plants and elicited frequent applause, was illustrated by drawings, etc., of the plants in their various stages of growth. At the conclusion, a hearty vote of thanks was awarded Mr. Hennedy for his lecture, who in reply stated he purposed following up the same subject in his next lecture.

A special General Meeting of the Association was held on the 23rd November, in the Garrick Hotel, to hear the report of the Committee appointed at a previous meeting to look out for a more suitable and permanent place of meeting. On the report being presented, it was unanimously resolved, on the motion of Mr. Kermath, to accept the offer made by the managers of the Andersonian University.

Mr. Kermath then gave notice that at next general meeting he would bring forward a motion to the effect that a price list be compiled for prescriptions, that it be issued by the Association, and that every effort be made to get the members of the profession in the city and neighbourhood to abide by it.

The Secretary then stated that as the rules, etc., of the Association were now considered to be a little out of date, and as he considered the removal of the Society to George Street, where it would be under the wings, as it were, of Anderson's University, a fitting opportunity for remodelling its constitution, he would at the next General Meeting bring forward a new code of rules, etc., for the approval of the members.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Third General Meeting of the Session was held, November 24th, 1870; the President, Mr. John Abraham, in the chair. The minutes of the previous meeting were read and confirmed.

Mr. James Agnew and Mr. W. T. Warhurst were elected members.

Mr. E. Davies, F.C.S., exhibited a bulb filled with a mixture of chlorine and hydrogen; on being exposed to the action of magnesium light the two gases combined to form hydrochloric acid gas with a loud report.

Mr. A. E. Tanner read a paper upon "Spiritus Æther. Nitrosi, B.P."*

In the discussion which followed—

Mr. Hilditch said that by mixing the 11 ounces which first distilled over (containing, as Mr. Tanner had said, 50 per cent. of nitrous ether) with 44 ounces of rectified spirit, a solution was obtained containing 10 per cent. of nitrous ether, and much sweeter than when the 15 ounces was distilled over and mixed with 40 ounces of spirit, he having always found that the latter part of the distillate had a very disagreeable smell.

Mr. Rawland stated that in manufacturing sp. æther. nit. B.P. in large quantities, he generally produced from 65 per cent. to 75 per cent. of the given distillate at the given temperature, but by an increase of temperature at this point he drew over the required quantity; he could not understand why a concentrated solution could not be made.

The President said that he had always succeeded in producing the required quantity of the first distillate, and he thought the Pharmacopœia process a very satisfactory one; the only modification he could suggest would be that the acid should be added in even more than two portions. He stated that it was the opinion of Mr. Hanbury that sp. æther. nit. B.P. was an acid preparation from the very first; he (the President) thought that the instructions given in the Pharmacopœia were so simple that every chemist should manufacture his own,—he did not see any necessity for a concentrated solution.

A discussion followed in which several members took part.

The President thanked Mr. Tanner for so ably bringing the subject before the meeting, and called upon Mr. Charles Sharp for his communication on "Some Recent Analysis of Cosmetics."

Mr. Sharp brought before the notice of the meeting a report recently made by Dr. Chandler, Chemist to the Board of Health of New York, on the presence of lead in a large number of hair restoratives, enamels, skin powders, etc.

The report referred to an inquiry which arose out of some cases of lead palsy occurring in the practice of a medical man in New York, which were traced to the use of a cosmetic known as "Laird's Bloom of Youth."

Dr. Chandler found that the preparations he examined contained acetate and carbonate of lead, corrosive sublimate and bismuth, in variable quantities. In all the hair restoratives lead was present, the skin powders were comparatively harmless, the enamels, however, were of a very deleterious character.

The following gives the result of analysis, showing the quantity of salts of lead in each fluid ounce:—

1.	Clark's Restorative	0·11
2.	Chevalier's Life for the Hair .	1·02
3.	Circassian Rejuvenator . . .	2·71
4.	Hair Vigour	2·89
5.	Wood's Hair Restorative . . .	3·08
6.	Hair Restorer of America . .	3·28
7.	Gray's Hair Restorative . . .	3·39
8.	Phalon's Vitalia	4·69
9.	Vegetable Ambrosia	5·00
10.	Mrs. Allen's Hair Restorer . .	5·57
11.	Indian Hair Tonique	6·29
12.	Sicilian Hair Renewer	7·13
13.	Physiological Hair Regenerator .	7·44
14.	Martha Washington's Restorer .	9·80
15.	Singer's Hair Restorative . . .	16·39

Mr. Blair said that a mixture of hydrochlorides of aniline and copper formed a very successful hair-dye; it was largely used by workmen employed in manufactories of anilines, and it was found impossible to prevent their using it; in fact, when aldehyde green was discovered, they were so infatuated with it, that they dyed their hair green. He thought that a solution of Hofmann's violet (which is perfectly neutral and soluble in glycerine) would form a good mixture for dyeing the hair black.

In reply to the President, Mr. Blair said this mixture would stain the ki n.

A discussion followed, in which the President, Messrs. Tanner, Sharp, Blair and T. F. Abraham took part.

The Secretary asked the members to inform him of any miscellaneous communications they wished to make, so that they could be announced upon the circulars calling the meeting, and then those who felt disposed could come with the subject considered beforehand; he moved a vote of thanks to the contributors of the communications, which was carried unanimously.

The President announced that it was proposed to hold a Conversazione in January, 1871, and that Professor

* See page 463.

Roscoe had signified his willingness to attend to give a lecture.

The announcement was received with acclamation by the members present and the meeting adjourned.

ABERDEEN ASSOCIATION OF ASSISTANT CHEMISTS AND DRUGGISTS.

At the Half-yearly Meeting of the Aberdeen Association of Assistant Chemists and Druggists, held in the St. Nicholas Lane Hall, on Thursday, 24th ult., the following were elected office-bearers for the next six months:—*President*, Mr. Donald; *Vice-President*, Mr. Tocher; *Treasurer*, Mr. Barron; *Secretary*, Mr. Gordon; *Committee*, Messrs. Cassil, Maitland, Hosil, Lunnan and Joss. This Association still continues to flourish with all its former interest and vigour; its roll is still as full, and the state of its financial matters is very healthy.

During the last six months several valuable and interesting papers have been delivered by various of its members, some upon objects connected with the drug trade, and others upon more general subjects, about which it no less behoves the young chemist to understand something, even in this age, in which pharmaceutical education is so much talked of.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

MEETINGS OF EXECUTIVE COMMITTEE.

October 5th, 1870.

In connection with the recent Annual Meeting at Liverpool a letter was read from the Local Committee, begging that the offer of a grant of money, which had been made by the Conference, as usual, to defray the expenses of the Meeting and Exhibition, might be recalled, a considerable surplus being already in hand. The Executive Committee, after some discussion in which the liability of the Conference for such costs was fully confirmed, acceded to the request, and the General Secretaries were instructed to convey to the Local Committee at Liverpool the formal thanks of the Executive Committee for the highly successful, liberal and judicious manner in which the objects of the Conference had been fulfilled and advanced by the Chairman, Secretary and every other member of the Liverpool Committee.

Mr. James Collins was elected Assistant-Secretary and Sub-Treasurer for 1870-71.

The following gentlemen were reappointed a Committee of Publication for the proposed Year-Book of Pharmacy:—Messrs. Carteighe, Groves, Hanbury, Ince and Stoddart, with Professor Attfield as Secretary.

Messrs. Cruse, Hayland, Garle, Henderson, Hopkin, Bell, Hall, Flood, Tryer and Kent, were elected members of the Conference.

December 7th, 1870.

The Year-Book Committee reported that two hundred pages of the volume were already in type, and that the other three hundred would be printed in about a fortnight. The work had been delayed in August and September, owing to the serious illness of the editor, Mr. Brough. Hoping against hope, arrangements were postponed until help became essential. The manuscript had been completed and the book conducted through the press by Mr. Joseph Ince.

The Transactions of the Conference, edited, as hitherto, by the General Secretaries, would be bound up with the Year-Book.

Messrs. Davies, Knowles, Curtis, Cocking, Clarke, Hartt, Howman, Gregory, Thomas and Breton were elected members.

⁎ Members joining during the current year, June 30th, 1870, to June 30th, 1871, and paying the annual subscription, five shillings, will be entitled to one copy of the Year-Book. Gentlemen desiring membership are invited to send in their names and addresses, legibly written, to the Secretaries, Professor Attfield, 17, Bloomsbury Square, London, W.C., or Mr. R. Reynolds, Briggate, Leeds.

ROYAL SOCIETY.

The series of experiments undertaken by Dr. Parkes and Count Wollowicz, with the object of ascertaining the effects of pure alcohol and brandy on the human body, a report of which was laid before the Royal Society last May,* has been followed by another series in which the experimenters have investigated the effects of claret of good quality. On the whole the results arrived at are very nearly identical with those of the former experiments. There was a marked increase in the action of the heart and an acceleration of the pulse, coinciding nearly with the effect produced by pure alcohol; there was no unequivocal alteration of temperature in the axilla or rectum, no alteration in the elimination of nitrogen, no alteration in the phosphoric acid of the urine, some augmentation of the free acidity of the urine: no alteration of the alvine discharges. They think that claret wine, in doses of ten to twenty ounces daily, cannot be distinguished in its effect from pure alcohol. They do not go so far as to say that the dietetic effects of red Bordeaux wine and of dilute alcohol are identical; but the difference between them must be sought in their effects on primary digestion and assimilation. The influence of the sugar, of the salts, and of the acidity, must also be ascertained by other methods than those adopted by them. As to the quantity which might be thought moderate, ten ounces of wine, containing about one fluid ounce of pure alcohol, did not cause the least unpleasant feeling of heat or flushing to a robust and healthy man to whom it was given, but twenty ounces caused him to feel uncomfortable, the face was somewhat congested, and he was a little drowsy. With regard to this man taking any alcohol at all, they were decidedly of opinion that he would be better without it, as his heart naturally acts quickly and strongly enough. He had gone through the Abyssinian campaign, and stated that when the force was without rum, owing to a deficiency of transport, he had not felt the want of the stimulant, although some of his comrades did.

LINNEAN SOCIETY.

At the Meeting of this Society on Dec. 1st a paper by Dr. Hance was read, "On the Source of Radix Galangæ minoris of Pharmacologists." The source of the Greater Galangal has long been known to be *Alpinia Galanga*, Linn., that of the Lesser Galangal has been more obscure. Galangal is not used in English medical practice, and on the Continent has become almost obsolete; its export from China is, however, considerable, and is rapidly increasing, as the following table will show:—

	lb.	Value.
1867	112,000	£478 0 7
1868	177,641	1206 13 5
1869	370,800	3046 16 9

During an expedition to the island of Hainan, a quantity of the root which furnishes the Lesser Galangal was observed exposed to the sun in baskets. On a subsequent occasion the plant itself was discovered at a spot six miles inland, at an elevation of 100 feet above the sea, growing in a dry red soil, the result of volcanic action. Here it is evidently planted, but was subsequently detected growing wild in jungles in the same island; 20 or 30 stalks spring from each root, but rarely more than one or two bear flowers. The fruit appears to be the bitter

* Pharm. Journ. 3rd Series, Vol. I. p. 136.

kind of cardamom figured by Mr. Hanbury. The plant is closely allied to *Alpinia calcarata*, which flowers readily in the Calcutta Botanic Gardens; but was determined by Dr. Hance to be a perfectly distinct and well-defined species, to which he gave the name *Alpinia officinarum*. A diagnosis of the species was given by Dr. Hance.

ANDERSONIAN UNIVERSITY MEDICAL SCHOOL.

At the opening of the Winter Session of the Medical School at the Andersonian University, Glasgow, on November 26, Dr. Thorpe, late of Owens College, Manchester, the recently-appointed Professor of Chemistry, delivered the introductory lecture. There was a large attendance. In the absence of the President, the chair was taken by Mr. Harvey.

The Chairman said the institution had been fortunate in the possession of men of great talent. To go back, they had, in the first instance, Dr. Ure, then Dr. Gregory, Dr. Graham, and lastly, one not the least among them, Dr. Penny. He trusted that the selection of Dr. Thorpe, whom he had now the pleasure to introduce to the audience, would be equally fortunate. Dr. Thorpe had done much for the science, young as he was, and he (the Chairman) trusted he would live still further to extend that knowledge which he had already brought before the world, and which was worthy of older men, and that he would be able to produce something of value to his students.

Dr. Thorpe took the opportunity of expressing the deep sense of his obligation to the trustees of the institution, who had elected him as successor to men whose names gave an imperishable lustre to science and the history of that place. He continued—No one could be more profoundly sensible than I am of the high honour which has thus been conferred upon me, and no one more keenly alive to the great responsibility which is thus attached to my office. And although I feel how utterly it is beyond my power even to attempt to extend the boundaries of chemical science as did Graham, or the range of chemical literature like Gregory, or to emulate the power of clear and lucid exposition possessed by my predecessor, Dr. Penny, I trust that I may not be found wanting in the desire to show forth the labours of these and other men, conscious that by so doing to the best of my ability, I shall reap the approbation of your trustees, and obtain the cordial co-operation of my colleagues. Thanks to the untiring exertions and zeal of the late Professor Penny, the chemical reputation of this place has become a thing to be highly prized; and I assure you, gentlemen, that it will be my constant effort, so far as I am able, to cherish and maintain it. But, to turn now to my more immediate subject, I feel that it would be in the highest degree presumptuous in me to attempt to give you anything like the usual address on occasions of this nature. Fully impressed with the truth and wisdom of the old maxim, "Ne sutor ultra crepidam," and acting under the advice of some of my colleagues, I wish rather to confine myself to the subject with which I am connected, and attempt to indicate to you the province of the science which I have the honour to teach.

Dr. Thorpe then proceeded to give an address upon modern chemistry, which we purpose printing as soon as we have space.

THE ST. ANDREW'S MEDICAL GRADUATES' ASSOCIATION.

On Friday and Saturday, the 2nd and 3rd inst., the members of this Association met at the Freemasons' Tavern; Dr. Richardson, the President, took the chair on the first day. Several honorary members were elected.

The Treasurer's and Council reports having been read, Dr. H. Day, of Stafford, was elected President, while Dr. Richardson, the retiring President, was elected to the new office of President of the Council.

Dr. Whitmore read a paper on "Sanitary Defects and Sanitary Needs of the Day," giving statistics to prove that in the last thirty years there has been no decrease, but rather an increase in the rate of mortality, especially during the last ten years, in which sanitary reforms have been most actively carried out. This he attributed to the fact that sanitary enactments were frequently a dead letter, whilst density of population and other causes of disease have much increased.

Dr. Richardson delivered an eloquent address on "The Future of Physic," in which he said that he had been led to think that it would be a pleasing and useful task to construct a history of the science of medicine in the Victorian era. In carrying out this idea, a vista of the future of medicine had often presented itself, of the course that medical science will take under the influence of change of thought respecting the physical forces of the universe, giving rise to the question, What can we who now exist do for the future? At present we live in uncertainty; we appear to dabble with questions of legislation without teaching or influencing the legislator, trusting to Government protection for the right to apply our skill instead of throwing away the oppressive shield it loans to us. He advocated the complete isolation of medicine from the trammels of such legislation as leads to useless and endless attempts to put down quacks by the power of the law. The influence of a William Harvey does more to reform medicine than all the medical reformers that ever lived. One of the first things required is the simplification of the language used by medical men. The bringing into use of a simple and reasonable scientific language would be an important service rendered to physic. It is essential also that some alteration be made in training our sons for the medical profession. The necessity of revising and extending our methods of observation was then alluded to, and the enlarged field of research opened up by recent discoveries. In the future of physic, too, it would be only according as the good of the community was sought rather than that of the individual, that the prosperity of the profession would be secured.

A report of the Second Annual Meeting of the Ashton and Dukinfield Chemists' Association has been received, too late for insertion, in consequence of having been wrongly sent to the publishers instead of the editor.

MEETINGS FOR THE ENSUING WEEK.

Monday, *Medical Society*, at 8 p.m.
London Institution, at 4 p.m.—"On Chemical Action" (Educational Course). By Professor Odling.
Tuesday, *Royal Medical and Chirurgical*, at 8.30 p.m.
Photographic Society, at 8.30 p.m.
Wednesday, *Society of Arts*, at 8 p.m.
Microscopical Society, at 8 p.m.
Thursday, *Royal Society*, at 8.30 p.m.
Linnean Society, at 8 p.m.
Chemical Society, at 8 p.m.
London Institution, at 7.30 p.m.—"On Count Rumford and his Philosophical Work." By W. M. Williams.
London Chemists' Asssociation, at 9.30 p.m.—"The Waste Products of the Pharmacopœia Processes." By G. Brownen.

Obituary.

We regret to have to record the death of Mr. Charles Coles, Pharmaceutical Chemist, of Hampstead, which happened on December 1, after a few days' illness, from inflammation of the lungs. The deceased gentleman, who was always ready to render any service to the Pharmaceutical Society, attended at Bloomsbury Square for the last time upon the occasion of the late election of the annuitants on the Benevolent Fund, when he signed the report as one of the scrutineers.

Reviews.

A Manual of Botany: including the Structure, Functions, Classification, Properties, and Uses of Plants. By Robert Bentley, F.L.S., etc. Second Edition. J. Churchill and Sons. 1870.

An Elementary Course of Botany, Structural, Physiological, and Systematic. By Professor Arthur Henfrey, F.R.S., etc. Second Edition, revised and in part re-written by Maxwell T. Masters, M.D., F.R.S., etc. Van Voorst. 1870.

One chief use of botanical text-books must always be as a companion and aid to a course of lectures; and we trust that the publication within the same year of new editions of such important works as Balfour's Class-book, Bentley's Manual, and Henfrey's Elementary Course, is a sign of an increasing demand for instruction in botany. Not that a good text-book will necessarily handle a subject in precisely the same manner as it will be discussed in a good course of lectures. We hold that the right mode of treatment varies under the two circumstances. A text-book must always start from the very commencement of the subject, taking for granted that the learner is entirely ignorant of it, and proceeding to unfold it step by step in logical sequence. The lecturer has the great advantage that he can soon form an estimate of the intelligence of his class, and moreover can often demonstrate by a single reference to the specimens with which his pupils are supplied, what will take pages to explain. He will hence frequently be able to make allusions to points of structure and to phenomena, the detailed explanation of which is deferred to a later period of the course.

In Professor Henfrey's 'Elementary Course of Botany' the subject is handled in much the order that it should be in a course of lectures: first comes the morphology of each separate organ in succession, the root, stem, leaves, etc.; then the principles and systems of classification; then the physiology and minute structure; and finally, geographical and geological botany. But, admirable as this programme is in the lecture-room, it fails to a certain extent in the text-book; and we doubt whether it would be possible for a learner unaided to gain an adequate knowledge of botany from this work. To take an instance, very early in the book we are told that "adventitious roots take their origin from the cambium-region, lying beneath the epidermis, rind, or bark of the stem, and break their way out through this." Now this sentence would be quite unintelligible to the learner, inasmuch as it is not till several hundred pages further on that he will find any explanation of what is meant by the term "cambium-region." The lecturer would, on the other hand, be able in a few words to give such explanation as would be sufficient for his present purpose. The able editor of this edition, Dr. Masters, has evidently frequently been hampered by the divergence of his own views from those of Professor Henfrey, and the work consequently loses something in unity. Some parts also have not been sufficiently brought down to the present time. It might have been better to have omitted all reference to vegetable palæontology than to have retained such a bald and incomplete outline as we find in the seven pages devoted to the subject.

The relative value of scientific text-books lies so much in the general mode of treatment rather than in the descriptive details, which are now almost uniformly accurate and reliable, that we can do little more than contrast the two works before us in the former respect. Professor Bentley commences on the more logical plan of tracing the vegetable structure from its simplest form; describing first the cell as an individual, tracing it through its various forms and degrees of complexity, to the different kinds of tissue and the contents of cells, and hence proceeding to the various organs of plants, their structure and functions. This plan has the advantage that it leads the student step by step from the known to the unknown; and the book can be used in the study as well as the lecture-room. The work being intended especially "as a practical guide to the properties and uses of plants," we find, following the description of each Natural Order, an account of its medicinal or economic properties, with a history of any species of special importance. This department contains a large amount of information indispensable to the pharmaceutist, which he will not find in so convenient a form elsewhere.

The best plan to give an idea of the completeness of the 'Manual' as a Handbook of Botany, will be simply to recapitulate the headings of the chapters. The first book, Organography, or Structural and Morphological Botany, embraces general morphology of the plant (simply introductory); elementary structure of plants, or vegetable histology, including the cell as an individual, and the kinds of cells and their connection with each other; organs of nutrition or vegetation, the stem, root, and leaf; organs of reproduction, the inflorescence, floral envelopes, stamens, pistil, fruit, ovule and seed; general morphology or theoretical structure of the flower; and reproductive organs of Cryptogams. The second book, Systematic Botany, or the Classification of Plants, includes systems of classification; and the arrangement, character, distribution, properties, and uses of the Natural Orders. The third book, Physiology, embraces special physiology, including the physiology of the elementary structures, physiology of the organs of nutrition, and physiology of the organs of reproduction; and general physiology, or the life of the whole plant, including food of plants and its sources, life of the whole plant or the plant in action; and special phenomena of plant life.

The very large amount of information useful to students or practisers of pharmacy will be illustrated by the following quotation of the properties and uses of the Order Marantaceæ:—

"The rhizomes of some species contain starch, which, when extracted, is extensively employed for food. One species has been described as possessing aromatic and stimulant properties; this, if true, is a marked departure from the general properties of the Order, for one of its distinctive characters from *Zingiberaceæ* is usually considered to be the absence of such qualities.

"*Canna.*—One or more species of this genus yield *tous-les-mois*, a very pure and useful starch, now largely consumed in this country and elsewhere. The exact species of *Canna* from which this starch is obtained, is not positively known; it is said to be *C. edulis*, but it is just as probable to be derived also from *C. glauca* and *C. Achiras*. A rhizome called 'African Turmeric,' from its resemblance in appearance and properties to ordinary commercial turmeric, has been described by Dr. Daniell in the Pharmaceutical Journal. The plant producing it is said to be the *Canna speciosa* of Roscoe. It requires further investigation. The seeds of *C. indica* are commonly known under the name of Indian Shot, from their black colour and hardness, etc. The seeds of this and other species are made use of as beads. The rhizomes or tubers of some species are eaten as a vegetable.

"*Maranta. M. arundinacea.*—The rhizomes or tubers of this plant contain a large quantity of starch, which, when extracted, constitutes West Indian arrowroot, one of the purest and best known of the amylaceous substances used as food. As this arrowroot is now obtained from *M. arundinacea* in other parts of the world besides the West Indies, it is best distinguished as Maranta starch. It forms a very firm jelly, and is, perhaps, the most palatable and digestible starch known. The name arrowroot was originally applied to this plant from the fact of its bruised rhizome being employed by the native Indians as an application to the poisonous wounds inflicted by their arrows. The name arrowroot has since been given to various other starches used as food in this country and elsewhere. *M. ramosissima* is also used in the East Indies for obtaining arrowroot."

It will be seen from this epitome and extract that we have here a complete *vade mecum* on all subjects connected with the physiology and pharmaceutical properties of the vegetable kingdom. The size of the volume is so convenient that it ought to be in the hands of every student and every practitioner.

The Manual is now so well known that we need dilate no further on its merits, more than to welcome this second edition. If we may venture a hint to all writers of similar works, we would ask why it is necessary to muddle the brains of a student by describing at length half-a-dozen old worn-out systems of classification, which have now fallen entirely into disuse, and might well be consigned to oblivion.

THE NATURAL HISTORY OF COMMERCE, with a Copious List of Commercial Terms and their Synonyms in Several Languages. By JOHN YEATS, LL.D., F.R.G.S., F.G.S., etc., assisted by several Scientific Gentlemen, pp. xvi. 436. Illustrated with Meyen's Botanical-Geographical Map. London, Cassell, Petter and Galpin. 1870.

The subject of technical education is one of great importance, and though a book like the one before us is not calculated to aid those intending to practise pharmacy in the acquisition of technical knowledge of a high standard as is now with them a legal necessity, yet the dissemination of such information as it contains amongst the less specially educated classes is a matter of interest to all, and the well-being of the country at large is affected for better or for worse as its rate of diffusion is greater or less.

On the Continent trade education is well looked to by the respective governments, and books are published with the specific object of enlightening the future merchant or artisan on the characters and properties of the substances which he will have to trade in or manipulate. The author in his Introduction, speaking of the technical schools of Leipzig, Antwerp, Berlin and Amsterdam, says:—

"In them the future Dutch or German merchant is taught to look beyond the limits of the Zollverein, and to regard the world at large as a vast storehouse, with the contents of which he must make himself familiar. At school he studies the sources of supply for the goods he must hereafter deal in. A counting-house, he is told, is a place in which he will be expected to *use* his knowledge, and *not to seek it*. He is first made acquainted with the laws and conditions of soil and climate, and then brought into contact with specimens of produce from the different kingdoms of nature; these he is required to examine and describe methodically."

The book is divided into four parts, viz.:—I. Geography of the Home Country, the adjacent Continent, our Colonial Dependencies and Foreign Trade Connections (pp. 1–125); II. Commercial Products of the Vegetable Kingdom (pp. 128–255); III. Commercial Products of the Animal Kingdom (pp. 257–348); and IV. Raw Mineral Produce (pp. 349–385). These, again, are subdivided into other divisions.

In Part I. there is much useful information on the geographical aspect of the question, which will, doubtless, prove of great use. We should have been sorry indeed if all reference to the geography of the subject had been omitted. The dearth of such knowledge is great; even amongst those who have received a fair education, it is often exceedingly vague. After giving some account of the home products, the foreign produce is treated of, and the flora and fauna of the zonal divisions indicated. From the fact that this part received the revision of Professor Hughes, its accuracy may be relied on.

In Part II., to which we shall more especially address ourselves, we have the subject subdivided into two parts; FOOD PLANTS and INDUSTRIAL AND MEDICINAL PLANTS; the former distributed under seven classes, and the latter under ten.

Amongst the cereals we fail to find any good account of rice, though it is imported in vast quantities into this country for home and foreign consumption. There is a poor account of Bengal rice, none of its many varieties being mentioned. No mention is made of Madras, of Rangoon, of Necransie (called Arracan after being cleaned), of Bassein, or of Siam rices.

In the account of *Ceratonia siliqua* we read "supposed to be the locust bean on which St. John the Baptist fed." This should have received greater qualification by the word "erroneously" being inserted before the word "supposed," as, without doubt, the animal locust is meant; it being to this day a delicacy with native tribes where it is found.

Canna coccinea is stated, with a query, to be the source of *Tous-les-mois;* as it is a *fibrous* and not a *tuberous* rooted plant, this cannot be the case: it is most likely *C. edulis.*

Hebradendron cambogioides of Graham is given instead of *Garcinia morella* as the source of gamboge.

Under the "Gums and Gum-resins" there is no mention of myrrh, galbanum or ammoniacum. Olibanum, in spite of the researches of Carter, Birdwood and others, is still said to come from *Boswellia serrata.* Under "Medicinal Barks" the Countess of Chinchon is quoted as the "Countess of Cinchona," though if it were true, the case of *Cin* v. *Chin* would be unknown. The source of red bark is stated to be "not yet ascertained." A reference to any work on materia medica will, however, show that *C. succirubra*, Pavon, ms., is the plant yielding it. *Picræna excelsa* is not mentioned; *Quassia amara* escapes with the statement "is a valuable febrifuge;" but the seeds of *Simaba Cedron*, truly an interesting object, though seen only in our museums, has nearly twelve lines devoted to it. Again, *Chondrus crispus* is mentioned, but why is *Cetraria islandica* left out?

Gambier and Cutch are both put down to the account of *Acacia Catechu*, but Gambier is obtained from a rubiaceous plant, *Uncaria Gambir*. In several places only one plant is mentioned as producing a certain substance, whereas there are several. *Ilex Paraguayensis* is the only source of maté given; Mr. Miers has mentioned eight, Gutta percha is mentioned as from one plant *Isonandra gutta;* but the researches of De Vriese, Reinwardt, Motley and others, now that *least* a dozen afford it.

Some of the substances are badly arranged; mustard and the oil of illicium (though their Natural Orders are indicated) are grouped under "Umbelliferous Plants with Aromatic Fruits." Under essential oils, oil of illicium is not mentioned.

We have thus freely criticized this part, because there are many good points in the book, and there is no reason why a certain standard of excellence having been attained in a portion of it, the whole should not be all one could desire. It requires careful revisal, and the recent literature of the subject to be well attended to. A nice power of discrimination is required to judge between necessary and unnecessary matter, for however interesting a substance may be, if it does not actually occur in commerce, it should be unhesitatingly excluded. More attention should have been paid to state the commercial varieties, and short terse descriptions of each article given, so as to enable the student to compare it with the substance itself, and thus strengthen him in the habit of "describing methodically."

Our space will not allow us to go into detail with Part III. We must say, however, that it is capitally arranged, and contains a large amount of interesting information, given in a very readable style.

We cannot close our notice without directing attention to the very valuable Appendix. It consists of nearly 400 names of substances and their synonyms, in 24 languages. It will doubtless prove a great boon, and we should like to see it enlarged and published in a separate form.

The book deserves success. It is well got up, and the type and paper are good.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[5.]—LABELS FOR HERBARIA.—Should "*Botanist*" be obliged to have his own labels printed, the following form may be of use to him:—The plants to be mounted on cartridge paper, placing above them the suborder or genera, and below, the species, common name, locus and tempus (or place where and time when gathered), and divide into fasciculi (or bundles).—VINCIT AMOR PATRIÆ.

Labels for herbaria can be had from G. Witt, King's Lynn, at 5*s*. per 1000. I enclose one.—E. M.

Mr. H. Deane recommends Newman's Botanical Drying-paper as the best for herbaria purposes. It may be obtained at 9, Devonshire Street, Bishopsgate, price 15*s*. to 18*s*. per ream. He also says that a book of botanical labels was published by the Botanical Society of London, which might be obtained from Mr. Van Voorst, Paternoster Row; but he thinks it is better to have a blank form of label printed, as the duplicate labels in the book are limited.

[30.]—HAIR-OIL SCENT.—*H. P. Hearder* sends the following:—

Ol. Lavand. ℥xvj
Ol. Rosmar. ℥xvj
Ol. Cassai ℥ij
Ol. Caryoph. ℥iv.

It costs about 3*s*. per lb.

[37.]—EAU DE PORTUGAL.—*J. F.* (Aberdeen) in answer to a correspondent, sends the following recipe:—

℞. Ol. Limonis ʒvj
Ol. Verbenæ gtt. xv
Ol. Bergamot ʒj
Otto Rosæ gtt. xv
Sp. V. Rect. ℥xx. M.

[39.]—LIQUOR COCCI.—A reply has been received from *J. T. R.* similar to one given last week.

[48.]—CRYSTALLINE POMADE.—"*Utile*" (Boston) begs to inform *A. H. C.* that the following makes a good crystalline pomade:—

℞. Oil of Almonds ℥xxiv
Castor Oil ℥viij
Spermaceti ℥iv
Palm Oil ʒvj
Oil of Verbena,
,, Cassia,
Otto of Rose, each ♏xl
Essence of Bergamot ʒj
Mix.

[57.]—FLORIDA WATER.—*Geo. Vennall*, Chemist, Cranleigh, Surrey, can supply "*Nemo*" (Sudbury).

[59.]—DISPENSING.—Although four replies have been made to this query, all of them have failed to notice the only point worthy of attention, viz. that the quantity of salts ordered is not soluble in a mixture containing one-fourth of its volume of rectified spirit, the heat generated by mixing 1½ oz. of a rectified tincture with 4½ oz. of water being sufficient to keep the salts in solution for a time, but before two doses had been taken the remainder would have set into a magma of small crystals. I fail to get the copious black precipitate noticed by your querist, the slight deposit there is being due to resin, etc., from the ginger slightly darkened by the iron.—J. H. BALDOCK, *S. Norwood*.

The peculiar black precipitate which M. Masson did not discover (was his tinct. zingib. B.P.?), but which "*Magnesia*" and others found, is clearly accounted for by the action of the ferri sulph. on the resin, etc. of the tinct. zingiberis. The undissolved quinæ sulph. carries mechanically the result—a dark, resinous tannate (?) of iron—to the bottom of the liquid, leaving an almost discoloured solution of magnes. sulph. above. I cordially endorse your opinion as to the impropriety of introducing acid. sulph. dil. in such a case.—ALPHA.

[61.]—TASTELESS PILLS.—With regard to the inquiries of two of your correspondents, I have been accustomed to coat my pills with a mixture of pulv. gum tragacanth and p. sacch. alb. in equal proportions. After having well shaken them with a small quantity of white of egg, and dusted them liberally with the powder I have named, they attain a slowly soluble coating, pleasant to the taste, and of smooth surface. —J. T. R.

[63.]—GREEN FLUID FOR SHOW BOTTLES.—*J. Barker* (Sudbury) writes:—"In answer to *W. W.*, sulphate of copper and nitric acid, diluted with water, form a very pretty green. I have some now in my window, made in 1851, and it is perfectly bright and clear, and entirely free from any deposit whatever."

C. Fields (Stamford) and "*Pestle and Mortar*" (Dorking) recommend copper coins or wire treated with nitric acid.

Chloride of nickel, diluted to the desired tint, is the *best;* chloride of copper also gives a good colour.—J. H. BALDOCK, *S. Norwood.*

The following will give a good bright colour:—

Solution of Cupri Acet.
Diluted Acetic Acid.

Mix and add—

Solution bichrom. of potass. q. s. to get the colour required. —H. BLAND, *Scarborough.*

A very beautiful and permanent emerald green can be obtained by dissolving nickel in dilute sulphuric acid with heat.—PESTLE AND MORTAR.

℞. Cupri Sulph. partem unam
Sodii Chloridi partes duas.

Dissolve in water and dilute to desired shade.—H. STOREY.

The following does not contain more than 5 grains of solid matter to the gallon, and can be altered in shade to any degree by the addition of the bichromate:—

Liq. Fer. Perch. Fort. P.B. ♏v
Sol. Potass. Pruss. ♏v
Acid. Hydrochlor. Pur. ♏x
Sol. Potass. Bichromat. ♏v vel q. s.
Aquæ cong. ij.

The solutions should be saturated, and the acid the strong P.B.

[64.]—COLD CREAM.—

℞. Cer. Alb.,
Cetacei, ana ℥j ʒiij
Ol. Amygdal. ℥viij
Aquæ Rosæ ℥iv
Otto de Rose gtt. ij.

Dissolve the wax and spermaceti; add the oil; then *gradually* mix with the rose water, previously made warm.

[65.]—DIAMOND CEMENT.

℞. Ichthyoc. Opt. ʒvj
Gum Mastic ℥ij
,, Olibani ℥ij
Aquæ Puræ ℥ix
Sp. Vini Rect. ℥xij

Dissolve the isinglass in the water (in a water bath), then stir in the mastic previously dissolved in the sp. vini, and lastly stir in the olibanum in the state of an impalpable powder. —J. W. SELWOB.

Isinglass in strong acetic acid to the consistence of a paste gives a good, *clear* cement.—J. H. BALDOCK, *S. Norwood.*

[67.]—TINCT. PRUNI VIRGINIANÆ.—

℞. Wild Cherry Bark, bruised, 2 ounces.
Proof Spirit, 20 ounces.

Digest for fourteen days; express, and filter. Or the tincture may be better prepared by the process of displacement or percolation.—ALFRED UTLEY.

See paper by Professor Bentley on *Prunus (Cerasus) Virginianæ* in PHARM. JOURNAL, Vol. V. Second Series; form for tincture, page 105.

A similar answer has been received from *J. H. Baldock* (S. Norwood); and others from *C. Fields* (Stamford) and *S. M. S.* (Weymouth), giving seven days for digesting.

[68.]—POT POURRI.—"*Iodi*" (Sudbury) would be glad of a recipe for making "pot pourri."

[69.]—FRENCH ESSENCES.—"*Odor*" would feel extremely obliged to any brother chemist who would kindly supply him with some *practical* information relative to the strength and process of preparing essences from floral pomades as practised by manufacturing perfumers.

[70.]—DISPENSING.—Will any of your readers kindly give me their opinion as to the best method of dispensing the following liniment?—

℞. Ol. Camph. ℥ij
Ext. Belladonnæ ʒss.
M., ft. linimentum. J. S. A.

[71.]—CORN PLASTER.—"*Utile*" would feel greatly obliged by any of our correspondents giving him a good formula for a corn plaister that would do to spread on sheeting.

[72.]—COUGH BALSAM.—"*A Correspondent*" wishes for a recipe for a celebrated cough balsam.

[73.]—CHLORODYNE.—*M. P. S.* desires to be furnished with a recipe for chlorodyne soluble in water.

[74.]—TOILET VINEGAR.—"*Reciprocate*" would be obliged by any correspondent giving a formula for toilet vinegar.

[75.]—DECAYED TEETH.—*G. W. P.* (Manchester) would like to know what is the best and safest thing to use for destroying the nerve of a decayed tooth. Something in the form of a paste is preferred.

[76.]—GLYCERINE JELLY.—*T. M.* (Worksop) would like a recipe for making transparent glycerine jelly either with tragacanth or isinglass.

[77.]—DISPENSING.—Can any of your readers inform me how I can dispense the following mixture so as the result shall be, without filtering, perfectly clear? It has been dispensed in London, and every time a clear mixture was sent out. I have dispensed it some twenty or thirty times, and it has always been milky?

℞. Acid. Phosph. Dil. B.P. ʒiij
Ferri Cit. c. Quin. ʒj
Tinct. Nucis Vomicæ ʒj
Sp. Chloroformi ʒij
Aq. Destill. ad ℥vj.

Ft. mist. One tablespoonful to be taken in half a wineglass of water, at eleven and five.—"EXHIBATUR."

[78.]—PASTE FOR CLEANING METALS.—"*Polio*" will be glad if any correspondent will inform him of a good recipe for making a paste to clean and polish brass, tin, etc.

[79.]—PASTIL PAPER.—Can any of your readers give me a form for making a good aromatic pastil paper?—G. H. B.

[80.]—DISPENSING.—Will some of your readers kindly tell me the best method to pursue in dispensing the following prescription?

℞. Syr. Tolutan. ʒvj
Bals. Peruv. ʒvj
Tinct. Nucis Vom. ʒij
Aquæ Camph. ad ℥vj.
M. S.—A dessertspoonful frequently. "CORTEX."

[81.]—SYRUP OF TAMARINDS.—"*Medicus*" wishes for a recipe for a syrup of tamarinds, as a basis for cough mixtures.

[82.]—COLOURS FOR CARBOYS.—*M.* is desirous to know the best way of preparing green, crimson and blue colours for carboys.

[83.]—ORANGE BITTERS.—*M. P. S.* and "*Iota*" wish for a recipe for orange bitters.

[84.]—PEPPERMINT CORDIAL.—*M. P. S.* wishes for a recipe for making peppermint cordial.

[85.]—GINGER BRANDY.—*M. P. S.* wishes for a recipe for making ginger brandy.

[86.]—PICK-ME-UP.—"*Iota*" asks for a recipe for making "Pick-me-up."

[87.]—GUM COWRIE.—*X. Q. Z.* wishes to be informed what is gum cowrie.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

"THE STORING OF POISONS."

Sir,—Your report of Mr. Smith's paper "On the Storing of Poisons," read by him at the Liverpool Conference has much interested me, and I regret that press of business prevented its being discussed.

When our Council introduced their code of restrictions, it was generally supposed to be a spontaneous act on their part; and, with others, I signed a protest against *any compulsory* regulations; but having since learned that they only yielded to Governmental pressure, I now feel that it is no longer a question whether we shall have any or no legal restrictions laid upon us, but *what they shall be*, and therefore it becomes each and all of us to assist our Council to conclusions that will satisfy the Government and the public without unduly fettering ourselves.

For this reason, I venture to express my unqualified approval of Mr. Smith's suggestions. They commend themselves to my judgment as simple, efficient and practical; and in support of these views I would say that I have kept and sold oxalic acid wrapped in purple paper for some years past, and believe it has been a useful safeguard. Also, that I have kept dangerous poisons for dispensing purposes in purple glass bottles; and I believe that, if the plan were fully carried out, it would be as effectual a preventive of accidents as could be adopted, without hindering business or inducing a dangerous trust in mechanical contrivances. It is not needful for those who have poison cupboards to do away with them; but the well-known fact that many rarely-used but innocent preparations are often kept in such cupboards, makes the necessity for some distinction in the bottles self-evident.

I sympathize with Mr. Smith's objection to alternative regulations. Unless the system adopted is one, and so simple that it could be made universal without difficulty, it would be worse than valueless.

The chief difficulty, to my mind, is the fact that, in the present Schedule, comparatively innocent preparations are classed with the most virulent as "poisons." Such an arrangement would mar the usefulness of any plan, if applied to all. We cannot associate an idea of danger with such articles as syrup of poppies or paregoric.

I also object to the indefinite wording of the present schedule, such as "Opium, and all preparations of opium, or of poppies." Every legal "poison" should be distinctly named, and only such preparations be included in the schedule as may, from their intensity or peculiarity, be considered truly *dangerous*.

It appears to me, therefore, that the first thing to be done is to get the schedule revised. When this is accomplished, there will not be much difficulty in applying the principles advocated by Mr. Smith to the "Storing of Poisons."

JOHN C. POOLEY.

Sir,—I beg to submit the following plan to your notice for the storing of poisons. As its adoption would ensure a ready system whereby order could be maintained in the position of the bottles, I sincerely hope that some of your correspondents may be pleased with the idea.

Let the shelves be covered with thin strata of wood, or other rigid material, in which holes have been cut corresponding with the size and number of the bottles; a convenient space should be left between the shelves and covering,—each bottle being thus fitted closely in separate divisions, and, presuming that they are of ordinary variety, it would be extremely difficult, without gross carelessness, to misplace them.

The closet might also be fitted with grooves in which the shelves could slide, by which the additional advantage would be obtained of permitting a closer inspection when required.

I may add that, during a ten years' experience in some of our leading dispensing establishments, I have not seen or heard of any arrangement so simple, or more practical, than the one just described. J. T. R.

FOX'S "PALATABLE" COD-LIVER OIL AND CASTOR OIL.

Sir,—Our attention has been directed to the report in your Journal of the transactions of the Liverpool Chemists' Association, November 10th, at which meeting the President directed attention to "palatable" cod-liver oil, stating that "he observed that a circular accompanied each bottle, with testimonials from medical men, and some who held the title of F.C.S., and he could not understand how such men could lend their names to a practice by which the public were led to believe that they were purchasing genuine cod-liver oil, whereas what they received was only about half oil."

The President appears to wish the Association to infer that we are deceiving the public by thus introducing the "palatable oils." Now, our object has been the very reverse of this. We have distinctly and repeatedly stated that they are a preparation, and contain a proportion of oil; and if the public will but take the trouble to look, they can see this for themselves. Had we not thus have placed the "palatable" oils before the public, but led them to believe, as stated, that they were oils only, the sale would not have reached the extent it has. Again, our preparations are specially intended for those who cannot take the simple oil, and who therefore would not have the remotest wish to purchase what would disagree with them.

It has been our great aim to put fully before the medical faculty, both by circular and weekly advertisements in the medical papers (to which we would direct attention) the fact of the oil being a combination. If we have, as stated by the President, led the public to believe they were purchasing cod-liver oil only, we have defeated our own purpose, and conveyed an impression the very opposite to our intention, inasmuch as we have most distinctly wished it to be understood that the preparations *are not* all cod-liver oil.

We fully invite the opinions of the medical profession as to the therapeutical value of these preparations in contrast to the ordinary simple oils.

Enclosed, we hand you opinions of some of the physicians of the leading hospitals and others, which will show the value of our preparations in cases where the ordinary simple oils have failed to accomplish the purposes intended, and wherein it is clearly stated "that it (cod-liver oil) is quite as efficacious as the ordinary oil, and much more readily digested by the weak stomachs of phthisical patients."

Manchester, Feb. 6th, 1870. GEORGE W. FOX & Co.

Sir,—Having seen certain strictures in your last issue, in a spirit of fairness I contradict the statement that the palatable oils have been brought before the public with a view to deceive them. I, together with my medical brethren, have received a circular on two occasions stating distinctly that the preparations of Messrs. Fox and Co. only contain 50 per cent of oil; and Mr. Abraham, the President of the Liverpool Chemists' Association, needs not to be informed that very few persons take cod-liver oil for the love of that nauseous medicine, but at the recommendation of the profession.

Messrs. Fox and Co. have not only sent circulars, but advertise weekly in the medical papers the proportion of oil in their preparations.

I, for one, have long felt the want of a more agreeable form of administering cod-liver and castor oils, and have recommended the preparations alluded to with marked satisfaction and benefit.

Mr. Abraham, perhaps, considers the chemists and druggists immaculate; but I have a preparation called "cod-liver cream," prepared by a chemist, which is stated on the label to contain 90 per cent. of oil, and, on analysis, contains about 25 per cent.

Now Messrs. Fox and Co.'s preparations contain more oil, according to Mr. A.'s statement, than they advertise.

I think it premature for the Liverpool Chemists' Association to have acted as they have, but I am afraid there is a vein of selfish interest at the foundation of their criticisms.

Oldham, November 30th, 1870. A PHYSICIAN.

Sir,—I noticed in your number of Saturday last the report of a meeting of the "Liverpool Chemists' Association," where it states, "The President exhibited a bottle labelled 'Palatable Cod-liver Oil,'" etc.

As Messrs. Fox and Co., of Manchester, have secured the right to use the term "palatable" cod-liver oil, I presume the remarks referred to their preparations: and as one of their earliest agents, and one who has pushed the sale of their oils, I feel that the remarks made by Mr. Abraham apply to me, and indeed to every chemist who has sold the preparations referred to, quite as much as to Messrs. Fox and Co.

I should be sorry to think I had assisted in deceiving the public to the extent I must have done if Mr. Abraham's idea be a correct one. I am of opinion, however, that he is wrong, and that the Liverpool Chemists' Association has acted very unfairly, by pronouncing judgment upon a matter it is evidently in ignorance about.

Messrs. Fox and Co. have depended almost entirely upon the support of the medical profession, and on the first introduction of their oils sent circulars to all members in towns where the oils were introduced, stating that they contained 50 per cent. (even less than Mr. Abraham gives as the proportion), and also sent a sample.

True, that the labels do completely cover the bottles,—for advertisement,—and that "prominent instructions are given to shake the bottle;" the very fact of that instruction being given would tell the most dull mind that it was a compound, and required well mixing before being taken.

There has been no attempt to keep the proportion of oil a secret, and now it has been made known to *every* member of the medical profession in the United Kingdom. It has not been stated on the bottles certainly, and I don't see the necessity for doing so in a preparation mostly recommended by professional men, who are quite aware of its composition.

I consider the oils to have been brought out in a perfectly honest manner; and, if medical gentlemen have found them to be all that they are represented, and to supply a great want, I think they are perfectly justified in giving their testimony, if they think fit, and feel sure most of your readers will agree with me that the Liverpool Chemists' Association has overstepped its bounds by presuming to complain of medical gentlemen having done something the particulars of which the Association had evidently not taken the trouble to inquire.

A spirit of fair play is my reason for writing these lines, and asking the favour of your inserting them in your next issue. JAS. WINTERBOTTOM.

Oldham, Nov. 30.

DRUGGISTS' CHARGES.

Sir,—Yesterday, a person brought me the following to dispense:—

℞. Ext. Col. Co. ʒj
Pil. Rhei Co. ʒss

Mix, and divide into 36 pills. Two to be taken every other night, or as occasion may require.

I charged 1*s*. 3*d*. for this, and was in return insulted by him, and told that he would never come into my shop again. On inquiring his reasons, I was told that my charge was outrageous, and that he had had the same prescription frequently dispensed at a first-class establishment in Wolverhampton for 8*d*. Is not this rather too bad, that a chemist should by thus "cutting" not only injure himself (which would not much matter), but should also injure respectable chemists, who use genuine drugs and try to make a living out of their trade, which at the Wolverhampton dispensing prices would be rather difficult?

I hope some day to see a list of prices for dispensing issued by the Society, from which no one can depart, not even the proprietor of the first-class establishment at Wolverhampton.

J. F. POLLARD.

Wavertree, near Liverpool, December 2nd, 1870.

Sir,—Your correspondent Charles Kidd, M.D., in last week's issue of the Journal, having indicated the neighbourhood in which I live as the place where cheap and nasty physic can be procured at the rate of 6*d*. or 7*d*. for 8 oz., with a bottle, etc., and as he must allude to one of two or three of us, I notice some of his remarks without apology. In reply to the worthy doctor's strictures, then, I have to say that I charge as much as he seems to think a fair price; and that in the case of physicians' prescriptions dispensed, it is the rule, and always has been with me, to send neither quack wrapper nor medicine list.

If the doctor will give me the favour of a visit, I shall be happy to show him my list of charges, which has been in use for the last ten years.

I use the infusions made fresh, and never send out stale,—

the best scammony, etc. etc.; and profess to charge a respectable price. I think therefore my brethren will see I do not come under the doctor's designation in keeping the "cheap and nasty" shop off Oxford Street, near Grosvenor Square.

THO. RAMSDEN.

29, *North Audley Street, Grosvenor Square, W., December 6th.*

NEW MATERIAL FOR SUPPOSITORIES AND PESSARIES.

Sir,—In your last number you give a formula for suppositories from the *Canadian Pharmaceutical Journal*, containing glue and golden syrup. These new materials may, I think, be advantageously represented in British pharmacies by pure gelatine and glycerine. Some time since I was handed the following prescription:—

℞. Pessar. Atropinæ gr. $\frac{1}{18}$ in sing.
c. Gelatin. mitte viij.

One to be used every night. W. O. P.

This is an "obscure" prescription. It might have been intended for an "especial" druggist, but as W. O. P. was not "formerly surgeon, royal navy," and the "Latinity" was easily to be comprehended, I ventured to dispense it. I took of Nelson's gelatine 1 drachm; glycerine, 1 drachm; water, 1 oz.; dissolved by heat; added the atropine, and poured into moulds. The evaporation will leave each pessary weighing about 1 drachm, an elegant and faithful representative of the prescriber's idea, stiff enough to be handled, and readily melting at a slight increase of temperature.

The moulds I use have some points of superiority, especially when gelatine forms the body of the pessary. They are made in this wise: cut and file a cork to the required size of the cone; round this, twist a piece of waxed paper; cut off the unequal edges, and stand the cup thus formed with its twisted point downwards in a slightly-compressed heap of linseed meal or chalk When filling these moulds, which cost little and are worth much, you can see what you are about, can use all your material, can make the pessaries all of one size, they come out clean, and, when cocoa butter is used, can be dropped into water to hasten the cooling.

WM. MATTHEWS.

Wigmore Street, December 6th, 1870.

P.S.—I hope you won't send the original of the *facsimile* prescription to Mr. Ince, to be a puzzle to future candidates. If you do, ask him to put it in, as Mr. Watson Bradshaw would say, *par parenthèse* (*vide* page 458, in a lucid paragraph, twenty-one lines long with only one full-stop), to show what a prescription ought *not* to be.

PHYSICIANS' PRESCRIPTIONS.

Sir,—Having observed more than one of your correspondents' remarks on physicians' prescriptions, I forward the appended, hoping you may find it convenient to give it a place in your next. I dispensed it some years ago, and had I not actually seen the "author" of it, I would not have taken it in hand, it seems so very "*general*." I still possess the "original."

℞. Podophyllin. gr. $\frac{1}{8}$
Ext. Coloc. Co. gr. ij
Ext. Taraxac. gr. j
Ext. Anthem. gr. j
Ext. Hyoscy. gr. j
M. fiat pil. tal. xviij. Capiat j omni nocte.

Strychnin. gr. $\frac{1}{8}$
Iodid. Potass. ʒj
Ferri Tart. ʒij
Sol. Mur. Morph. ʒij
Acet. Potass. ʒiv
Tinct. Calumbæ ʒvj
Vin. Ipecac. ʒiij
Glycerinæ ʒiv
Inf. Calumbæ ad ℥vj.
M. fiat mist., cujus capiat coch. magn. j bis vel ter in die.

℞. Hydrarg. Biniodid. ʒss
Ung. Cetacei ad ℥ij.
M. fiat ung. utend. ut dictum nocte et mane.

A burgh town on the west coast of Scotland can *even now* boast of the services of the practitioner who *wrote* this (I can't say *prescribed* it).

ALEX. FRASER, *Chemist and Druggist.*

Largs, N.B. Dec. 3rd, 1870.

WHOLESALE DRUGGISTS' ASSISTANTS' SOCIETY.

Sir,—Having seen in page 388 of your Journal a request made by J. Hart for some information regarding a Wholesale Druggists' Assistants' Society supposed to be at present in course of formation, I have carefully watched for a reply from some of your readers. I should be most happy to join in such a Society did one exist, but I fear from the fact of no one tendering the required information that your correspondent, J. Hart, must have been misinformed, or that the movement, like one made some years since for a similar purpose by Mr. O. D. Owen, has fallen to the ground for want of sufficient energy on the part of its promoters. If such a Society is actually being formed, why is so little known regarding it?

Bishopsgate Street, City, P. S. COSGROVE.
26th November, 1870.

A POINT OF ETHICS.

Sir,—In reference to the prescription dispensed by "Magnesia," you remark that a chemist would not be justified in adding "ac. sulph. dil." to dissolve the quinine, so as to make "a mixture." Now, I beg respectfully to differ from you on this point. I think any qualified chemist has a perfect right to use his discretion in properly compounding any medical man's prescription; and, in the case in point, the doctor had evidently forgotten to write "ac. sulph. dil.," or he did not understand chemistry. I have frequently compounded a similar prescription from doctors in this town, and they always invariably write "ac. sulph. dil." Medical men require looking after as well as "chemists."

CHEMICUS OF TWENTY YEARS' STANDING.

A WARNING.

Sir,—I have been taken in! I write in order to warn my brethren in London and suburbs against the same paltry imposition. A man came into my shop, and, presenting a bill of "De Conder's Pills," inquired if I kept them in stock, and being told that I did not, but could procure them, requested me to do so, and stated that he would call for them the next evening. I obtained the pills, but need hardly add that the man has not made his appearance again. I should not have troubled you in this small matter, but I found that three druggists in this neighbourhood had received similar visits from the same man, and I have no doubt many others as well. Publishing this may deter the gentleman from imposing on others in the same way, and may lead them to request him to pay before they obtain them. I would advise that he should be charged at least 1*s.* 2*d.*, as they cost that.

Bow, E., December 7th, 1870. S. D.

The Phaeton Pen.—We have received from Messrs. Macniven and Cameron a box of the above pens.

H. Rayner and *W. Wright* (Boston).—The letters and stamps have been handed to the Secretary.

"*A Student*" and *W. H.* (Canterbury) are referred to the rule requiring the name and address of correspondents.

Colchicum.—They may be obtained in London of Jackson and Townson, Griffin, or Howe; at Norwich, of Sutton; at Newcastle, of Brady, or Mawson and Swan; at Manchester, of Mottershead.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. F. Adams (Stoke-on-Trent), Mr. W. M. Macnaughten (Dublin), Mr. M. C. Cooke, Mr. T. W. Langridge (Midhurst), Mr. H. P. Hearder (Plymouth), Mr. S. Newbury (Dorking), Mr. A. F. Girdler (Shirley), Mr. Twemlow (Edgware Road), Mr. J. Stathers, Mr. W. T. Oldham (Wisbech), Mr. J. E. Howard, Mr. E. C. C. Stanford (Glasgow), Mr. W. Rew (Exeter), Mr. W. W. Stoddart, Mr. J. Beedzler, F. R. B. (Middlesburgh) F. J. B., G. H. B., "Soda-Water," T. T. (Islington), Mr. Hustwick (Liverpool).

The following journals have been received:—The 'British Medical Journal,' Dec. 3; the 'Medical Times and Gazette,' Dec. 3; the 'Lancet,' Dec. 3; the 'Medical Press and Circular,' Dec. 7; 'Nature,' Dec. 1; the 'Chemical News,' Dec. 2; 'Journal of the Society of Arts,' Dec. 1; 'Gardeners' Chronicle,' Dec. 3; the 'Grocer,' Dec. 3; the 'English Mechanic,' Dec. 2; the 'Produce Markets Review,' Dec. 3; the 'Canadian Journal of Pharmacy' for November; the 'Journal of Materia Medica' for November; Hardwicke's 'Science Gossip' for December; the 'Food Journal' for December; 'Transactions of the Odontological Society' for November; the 'Educational Times' for December.

INFUSIONS.

BY ALFRED ALLCHIN.

(*Concluded from page* 422.)

In my last paper, when stating that Mr. Deane had calculated the cost to make "fresh" infusions to be about £8, I omitted to state that that sum represented the annual cost.

In April, 1856, at a meeting in Edinburgh, Mr. Stephenson, at the request of his partner, Mr. Robertson, read a paper in which he strongly advocated the Alsop method of preserving. A sample of infusion of senna was placed on the table, which had been bottled 2½ years. When opened, it was found to possess the aroma and other properties of the freshly prepared infusion. Infusions of "Orange," "Chiretta," "Senega," and "Calumba," which had been bottled many months, were found to be equally good.

Mr. Stephenson stated that it was the practice in their establishment to prepare enough of each infusion to last two or three months, but some practical difficulties had been met with in the mode previously suggested. He expressed his opinion that the bottles used should be filled to overflowing with hot infusion, and then tied over with moistened bladder gut skin.*

On June 1st, 1859, twelve days before his death, Mr. Jacob Bell again introduced the subject, and doubtless he must have felt very keenly the desirability of coming to some common understanding on this matter. It was in all probability almost the last effort of his life, in connection with our Society. His mind was evidently free from prejudice, for both sides of the question were fairly stated.

He commenced by descanting upon the damaging effect likely to be produced on the minds of patients when they saw their mixtures compounded with fresh infusion at one establishment, and a few drams of a concentrated preparation made up with water at another; besides the probability of their finding a difference in taste, appearance, and medical properties.

The inconvenience of waiting an hour, or even several hours, while the fresh infusions were being made, was next alluded to. The comparative merits of concentrated and fresh preparations were also discussed, and the difficulty of surmounting the question at issue as long as there was no sanctioned authority either for the use or preparation of concentrated infusions pointed out. The same mistrust and doubt formerly existed respecting the decoctions of sarsaparilla, till the attention of the College of Physicians was directed to the subject, who then introduced a concentrated preparation under the name of fluid extract. Mr. Bell then dwelt upon the propriety of admitting into our Pharmacopœia formulæ for Liq. Cinchon. Taraxac. and similar liquors, and concluded by expressing a hope that the question would be settled, and the inconvenience and perplexity which had existed for so many years might be put an end to.

Mr. Haselden followed Mr. Bell, and first alluded to the high estimation in which the fresh infusions were held by medical men and others. He expressed an opinion that it was highly desirable that prescriptions should be dispensed with integrity, observing that the deposit continually occurring in all concentrated preparations, created a suspicion that when diluted they did not always represent those freshly prepared. He protested strongly against the concentrated system being promulgated by pharmacists, predicting that if we were constantly inundating medical men and others with these preparations, we should eventually have all medicines prescribed in a concentrated form, and a teaspoonful dose administered instead of two tablespoonfuls. This anticipation is rapidly being realized, for we not unfrequently hear complaints made by the pharmacist, who feels that he has been deprived of his legitimate profits by this mode of prescribing. Mr. Haselden concluded by stating that infusions would keep perfectly good, if from two scruples to a dram of tincture were added to each ounce of the freshly prepared liquid. He was quite aware that the propriety of introducing spirit in any form was questionable, but still as infusions were generally ordered in combination with tinctures, he thought the matter worth consideration.

Mr. Waugh said there was no excuse for using concentrated preparations, for he had for many years adopted the plan of bottling, as recommended by Alsop, and found it to answer perfectly.

Mr. T. H. Hills said it had occurred to him that a probable way of overcoming the difficulty would be, if possible, to shorten the time for making these preparations. With the view of arriving at some satisfactory conclusions he had tried some experiments with a French *cafetière* of simple construction, and the result proved most satisfactory. He thought that if further experiments were made in this direction it would probably be found that all infusions might be made by a uniform process that would not occupy more than ten minutes. The attention of the reader is particularly called to these last observations, for they were made by one whose experience is, perhaps, not surpassed by any other pharmacist, and whose soundness of judgment has never been questioned. I have no hesitation in saying, that had they been supported by evidence such as that now furnished by Mr. Barnes, they would have received at the time the consideration they merited, and, in all probability, some speedier steps would have been made towards the settlement of the question.

At the October Evening Meeting the opinion of Mr. Hills was supported by Mr. Geldard, of Plymouth, who said, that if full advantage were taken of the process of displacement, the period of maceration might be reduced to a mere fraction. In practice he had proved it to be so, when made according to a plan, which he described.* The dispenser, if he adopted this mode, would be able to say when a prescription containing an infusion was brought to him, that it would be ready in twenty minutes, and have the satisfaction of knowing that he was giving the patient an aromatic medicine instead of a vapid, mawkish liquid, made from a bottle which may have been on the shelf, depositing its activity, for months.

In 1866, Mr. Haselden† advocated the principle adopted in the preparation of the now called Mist. Gent. Co. He had applied the same process to cascarilla, calumba and orange, and obtained equally good results. He thought an extension of the process would meet the difficulties with regard to fresh infusions, because, when thus made, they would keep

* Pharm. Journ. Vol. XVIII. p. 564.

* See Pharm. Journ. 2nd Series, Vol. I., p. 263.

† Pharm. Journ. 2nd Series, Vol. VII., p. 572.

perfectly good any length of time, and it would always be known that a sound preparation was being dispensed.

No general remarks of any importance were made after this until Mr. Barnes again introduced the subject at the November Evening Meeting of this year.* His paper is valuable, inasmuch as he gives, I think, very good reasons for assuming that the time now occupied in making infusions might very safely be lessened. Like all honest men having the direction of a dispensing establishment, he is most anxious that all medicines compounded under his care should possess their proper medicinal value. He, however, doubtless sometimes finds much inconvenience arising from the length of time now occupied in preparing fresh infusions, and suggests the propriety of shortening the time for standing. His reasons are at once apparent, for he finds most of them when so made contain the same amount of extractive matter, and appear, in every respect, equal to those made according to the instructions of the Pharmacopœia. In many cases the time was reduced to one-half, and in some to a quarter of that officially ordered. The results, I am aware, are not sufficiently conclusive to satisfy all minds upon the subject, but has not sufficient been done to stimulate further inquiry? It is a matter in which we can all lend a helping hand, and I trust, as opportunities occur, we shall do so. Let all roots, barks and leaves be reduced to a state of comminution that will allow them to pass through a sieve having eight meshes to the linear inch; be careful always to have the infusion-jug hot, and make the infusions in quantities of not less than a pint; then examine the results, and it would not surprise me if it should be found that the time for standing can, in some cases, be reduced to a few minutes, and that not more than one or two need exceed half an hour.

Dr. Redwood naturally defends the Pharmacopœia instructions; but the fact chosen as an illustration of their soundness appears to me an unfortunate one, and might fairly be claimed by Mr. Barnes in support of his views. Surely if men of such vast experience as tea-tasters find that all the essential elements can be obtained from tea by a seven minutes' maceration, it is time for us to consider the propriety of altering our notions respecting our medicinal infusions.

* PHARM. JOURNAL, 3rd Series, Vol. I. p. 368.

BRISTOL PHARMACOLOGY.

BY W. W. STODDART, F.C.S., F.G.S.

'Twas on one of those glorious days of the month of August, when sunshine and fine weather were doing their utmost to tempt the sedentary, that the author succumbed to their influence, and wished for a dose of fresh air, with the exhilarating pleasure of a long walk in the beautiful environs of the good old city of Bristol. People were from home, some enjoying the sea-breezes of Weston or Clevedon, others the rocky cliffs of Ilfracombe or Tenby. Physic and its accessories were at a discount, and little remained to strengthen the resolve, and carry out the wish, for a day's holiday and relief from the cærulean thoughts that are said sometimes to haunt the too zealous attendant at the shrine of business.

But where should he go? Should it be the constitutional mile or two, that horridly mechanical remedy for *ennui* and excuse for exercise? That thought was no sooner born than killed. What then was to be done? The idea was suggested that a most interesting line of study might be afforded by an examination of the locality for what portion of the materia medica could be found in a natural state. So interesting and profitable did this investigation become, that the author was induced to narrate what he observed and collected, so that others might experience the same pleasure in various parts of our highly favoured country.

Bristol, be it remembered, is a veritable epitome of all that is good in opportunities for the study of natural history, geology, mineralogy, or archæology. Few, if any, spots in the world can be found to excel it. Fine downs, magnificent cliffs, contrasting with low marsh-lands; fine woods, abounding in ferns and masses, lichens and algæ; ditches of fresh or brackish water teeming with *Diatomaceæ*, *Desmideæ* and other endless work for the microscopist,—all these offer their treasures with liberal hand.

The mineralogist would be enchanted with choice specimens of rocks and ores, some of great rarity. The brilliant pyrites or galena, the sober calamine, the chaste alabaster, the sparkling Göthite and the delicate celestine, all combine to form a striking collection for the cabinet.

In short it is the neighbourhood in which such names as Bentley, Berkeley, Phillips, Buckman, Broome, Stephens and Thwaites have revelled and laboriously acted out the idea of an old poet, though in a better sense:—

> "Nec tantum segetes alimentaque debita dives
> Pascebantur humus: sic itum est in viscera terræ:
> Quasque recondiderat, Stygiisque admoverat umbris,
> Effodiuntur opes."

For the antiquarian, also, there cannot be a more interesting spot. Here may be seen the enormously thick walls of an ancient fortified city with the gateway still extant, although built in the reign of William Rufus. Camps of the old Romans and extensive monasteries are everywhere indicated. Even the remains of old Bristol castle are still visible, recalling to the memory the actual building in which Stephen was kept a prisoner, and Henry II. received part of his education.

The richness of the locality in plants and minerals is due to the variety of the geological formations, seven of which can be examined and easily studied within the radius of a very few miles.

It is well known that plants occur relatively to the strata on which they grow. Thus *Arabis stricta*, *Hutchinsia petræa* and others of the *Cruciferæ* and *Crassulaceæ* choose the carboniferous limestone; *Epilobium lanceolatum*, *Campanula latifolia* and *C. patula* prefer the Pennant; *Digitalis purpurea* and *Helleborus fœtidus* select the sandstone; the marsh-land favours the *Caltha palustris*, *Thalictrum minus* and *Nasturtium palustre*.

Some of the land is actually below the mean sea level, while the high table-lands and hills rise to an altitude of 700 feet. With such extreme contrasts in physical configuration, there is a corresponding variety of scenery.

Westward the delighted observer meets with the magnificent gorge of Clifton, rich in geological treasures, or the Nightingale valley with its sylvan recesses. To the east the Cotteswold Hills, with the coast-line of an ancient sea plainly defined, speak most forcibly of prehistoric times. On the south the top of Dundry Hill unfolds an extensive view of the Bristol Channel, backed by the mountainous scenery of Monmouthshire and the Principality.

All around spring—

> "The living herbs, profusely wild
> O'er all the deep green earth, beyond the power
> Of botanist to number up their tribes."

Such is a very brief and inadequate introduction to a neighbourhood teeming with interest and beauty, which few other places in our native country can equal, and to which the author can honestly recommend a lengthened visit.

In lieu of this the following description of the pharmacological treasures found in this locality may prove to some of our pharmaceutical brethren a source of pleasure, if not of instruction.

(*To be continued.*)

THE CHOLERA FUNGUS.

BY M. C. COOKE, M.A.

The revival of this subject, after some months of silence, is to be attributed to the publication, in Calcutta, of the first report on the microscopic objects found in cholera evacuations by Mr. Timothy Richards Lewis, M.B. It will be remembered by our readers that certain theories have been promulgated regarding the cause of cholera, and mainly that of its fungoid origin, as advocated by Professor Hallier, of Jena. In order to test the value of this theory, it was resolved that certain Government officers should make the necessary observations and experiments in India, and report results. The first instalment of such report is now before us.

It is hardly necessary to epitomize Dr. Hallier's theory except to state that, from his examination of cholera evacuations, he came to the conclusion that cholera was produced by a species of fungus belonging to the group of smuts called *Ustilagines*, to which the common smut of corn and grass, and the more imposing smut of maize, belongs. At first, Dr. Hallier referred this fungus to the genus *Urocystis*, and considered it to be closely allied to that species which attacks the rye in Europe, and which he believed was parasitic on rice in India. As soon as the Professor's treatise arrived in this country we made bold to challenge his facts, either that *Urocystis* spores would cause any choleraic disturbance in the human subject, or that any species of *Urocystis* had ever been found as a parasite on the rice-plant in India. Subsequently the Jena Professor shifted his ground, and, though still adhering to his fungus theory, renounced *Urocystis*, and maintained the "cysts" as fungus spores. The basis for the theory, at least so far as we comprehend it, is, that bodies can be found in the growing tissue of rice-plants which the author regards as identical with the cysts found in cholera evacuations; hence that cholera is generated by the consumption of rice in a diseased or smutted condition.

Common sense naturally inquires, Are the "cholera cysts" the cause of cholera? are they found under any other circumstances? what are they? are they found in choleraic discharges in India? are they found in the growing rice-plant? and what connection is there between rice-eating and cholera? To answer some of these queries Mr. Lewis has applied himself with great zeal, ability, and, in our opinion, success.

It is impossible, even were it necessary, to follow the experiments in detail, and to give all the reasons on which the conclusions are based. It will be enough to indicate what are the fair deductions to be made from the experiments already made. The caution contained in the following paragraph cannot be too strongly insisted on, and will serve as introduction to the "results:"—"In spite of more than ordinary care, very different forms of life will make their appearance in substances which are derived from the same source under conditions which *seem* to be identical, and that too in very simple mixtures. Consequently, the greatest caution must be exercised in estimating the importance, or otherwise, of any peculiar manifestations of vitality which may be observed in substances associated with disease." Had this caution been kept in view by some of those who have experimented on the cultivation of mucedinous fungi, for instance, it is probable that we should have been spared some few assumptions which have obtained currency as facts.

The "results," as indicated in this first report, are, "That no 'cysts' exist in choleraic discharges which are not found under other conditions." That is to say, the cholera cysts figured by Professor Hallier are not always obtainable from cholera discharges, are not confined to cholera, nor even to diseased conditions of the intestines, but may be cultivated from the stool of perfectly healthy persons.

"That cysts or sporangia of fungi are but very rarely found under any circumstances in alvine discharges."

"That no special fungus has been developed in cholera stools, the fungus described by Hallier being certainly not confined to such stools."

The experiments instituted to test the observation as to the inoculability of rice-plants have as yet not been satisfactory, consequently no conclusions have been arrived at on the matter.

"That the still and active conditions of the observed animalcula are not peculiar to this disease, but may be developed in nitrogenous material even outside the body."

"That the flakes and corpuscles in rice-water stools do not consist of epithelium nor of its *débris*, but that their formation appears to depend upon the effusion of blood plasma, and that the 'peculiar bodies' of Parkes, found therewith, correspond very closely in their microscopic and chemical characters, as well as in their manifestations of vitality, to the corpuscles which are known to form in such fluid. These are generally, to a greater or less degree, associated with blood-cells, even when the presence of such is not suspected, especially as the disease tends towards a fatal termination, when the latter have been frequently seen to replace the former altogether."

"That no sufficient evidence exists for considering that vibriones, and such-like organisms, prevail to a greater extent in the discharges from persons affected with cholera than in the discharges of other persons, diseased or healthy; but that the vibriones, bacteria and monads (micrococcus) may not be peculiar in their nature, for these *do* vary, may not be the product of a peculiar combination of circumstances, and able to give origin to peculiar phenomena in a predisposed person—is 'not proven.'"

Hence it seems pretty clear that the fundamental facts (?) of the Hallier theory are considerably shaken by this report, and we shall wait patiently in the full anticipation that future observations will confirm and strengthen the results obtained by Mr. Lewis, and destroy the whole theory of the fungoid origin of cholera. It is scarcely possible that such a series of observations could have been carefully and zealously performed without affording interesting facts in the conduct and development of "low life." Many such will be found recorded in these pages, and of these we may mention the observations on *Penicillium*, illustrated by Plate XXI. A preparation set aside for cultivation exhibited "on the fourth day tufts of *Penicillium* of two varieties, *P. glaucum* and *P. viride*. This continued until the ninth day, when a few of the filaments springing up in the midst of the *Penicillium* were tipped with a dewdrop-like dilatation excessively delicate,—a mere distended pellicle. In some cases they seemed to be derived from the same filament as others bearing the ordinary branching spores of *Penicillium*, but of this I could not be positive. This kind of fructification increased rapidly, and on the fourteenth day spores had undoubtedly developed within the pellicle." This example of the production of a species of *Mucor* from *Penicillium* corroborates a similar observation of our own, in the development of a new and delicate species of *Mucor* from *Penicillium roseum*, as detailed elsewhere. The microscopical student will find in the excellent figures with which this report is copiously illustrated, and in the details of observations, much that is exceedingly valuable. It is a misfortune and a mistake not to publish it in London as well as in Calcutta.

ON THE COMBINATIONS OF CARBONIC ANHYDRIDE WITH AMMONIA AND WATER.

BY EDWARD DIVERS, M.D.

(*Continued from page 446.*)

"Carbonate of Ammonia" of Commerce.

It will be more convenient to defer for the present the consideration of the manufacture of the commercial carbonate.

Form.—All I wish to point out under this heading is that the variations in the appearance of the substance, whether between one sample and another, or between different layers of the same sample, are not proofs of any material difference in composition. It may be very compact with a more or less conchoidal fracture, or in softer cakes of prisms arranged uniformly perpendicular to the surface of deposition, or in white nearly opaque layers, and yet differ no more in composition than two samples of similar appearance. On the other hand, similarity in appearance is no proof of identity in composition. Some of the evidence I have on this point is given in the succeeding paragraphs.

Chemical Composition.—No one has attributed to the commercial carbonate anything like an unvarying composition, but it seems to be universally accepted that this does usually approximate pretty closely to that expressed by the formula—

$$(CO_2)_3(OH_2)_2(NH_3)_4,$$

which has in 100 parts—

Carbonic anhydride	55·93
Ammonia	28·81
Water	15·26

And it cannot be denied that in the main the published analyses of it indicate that such is its approximate composition.

The following table contains all the published results of analyses that I have come across:—

	Date.	Carb. anhy.	Amm.
Bergman*	1774	45·	43·
Dalton*	1813	59·	24·5
Ure†	1817	54·5	30·5
Phillips‡	1819	54·2	29·3
Thomson§	1820	55·70	26·17
John Davy* . . .	1834	54·58	27·39
Rose*	1840	—	28·66
,, ...	—	—	30·70
,, ...	—	50·55	—
,, ...	—	53·40	—
,, ...	—	56·23	—
Ure‖	1853	55·89	28·86

Dalton deduced from his numbers the atomic composition since universally adopted; and if these numbers are compared with those he used to express the composition of the acid carbonate, they are found to agree closely enough with the calculated numbers.

I have analysed several samples of the carbonate at present in commerce, and have found that it is very uniform in composition with one special exception, and that this composition is no longer that represented by the formula

$$(CO_2)_3(OH_2)_2(NH_3)_4,$$

but by that expressed by the simpler formula,

$$(CO_2)_2OH_2(NH_3)_3.$$

This formula, represented by the symbols of the old atomic weights, becomes more complex than the other formula similarly represented; thus,

1st formula, old notation . . $(CO_2)_3(OH)_2(NH_3)_2$.
2nd formula, old notation . $(CO_2)_4(OH)_2(NH_3)_3$.

This, I think, had some influence on the selection of the formula. For Ure's analysis, which both here and abroad seems to have been the first which enabled chemists to adopt a formula for the commercial carbonate, agrees much more closely with the second formula than with the first. But then the first could be represented by the formula of an ammonium salt, thus,

$$2NH_4O, 3CO_2,$$

while the second could not. However, the results of other analyses corresponded more nearly with the formula adopted, and so strengthened the grounds of its selection.

The samples I have analysed were purchased at intervals over a period of two years or more, of different firms (though not of the manufacturers direct), at different prices and of different qualities. Small fragments, quite free from decomposed portions, were broken from the inside of lumps just before they were used for analysis. The following are the details and results of my analyses:—

The contents of one of the 7 lb. jars usually made up for the use of dispensing chemists was found to consist of fragments of a cake exhibiting different layers: (*a*), the outer layer, constituting the greater thickness of the cake, compact, translucent, imperfectly crystalline and of conchoidal fracture; (*b*), a much thinner layer, friable, semi-opaque; (*c*), a layer, apparently the innermost of the cake, hardly 2 millimetres thick, very translucent, prismatically crystalline:—

I. 1·085 grms. of (*a*) yielded, with hydrochloric acid, ·5952 grm. of carbonic anhydride to soda-lime;

II. 1·1600 grams of (*a*) neutralized a volume of standard sulphuric acid, equivalent to ·3783 gram of ammonia;

§ 'A System of Chemistry,' vol. ii. p. 413, sixth edition.
‖ 'A Dictionary of Arts, Manufactures and Mines,' fourth edition. Art. "Carbonate of Ammonia."

III. 1·0904 grams of (*a*) neutralized a volume of standard sulphuric acid, equivalent to ·3570 gram of ammonia;

IV. 1·1437 grams of (*a*) yielded with hydrochloric acid 1·1680 grams of ammonium chloride = ·3715 gram of ammonia;

V. ·9063 gram of (*b*) yielded, with hydrochloric acid, ·5006 gram of carbonic anhydride to soda-lime;

VI. 1·0538 grams of (*b*) neutralized a volume of standard sulphuric acid, equivalent to ·3468 gram of ammonia;

VII. 1·4405 grams of (*b*) gave, with hydrochloric acid, 1·4957 grams of ammonium chloride = ·4757 gram of ammonia;

VIII. ·9870 gram of (*c*) gave, with hydrochloric acid, ·5427 gram of carbonic anhydride to soda-lime;

IX. ·2490 gram of (*c*) neutralized a volume of standard sulphuric acid, equivalent to ·3137 gram of ammonia:

A sample labelled "commercial," indistinctly crystalline, of the rose-tint, often seen in carbonate made from gas-liquor:—

X. 1·4635 grams neutralized a volume of standard sulphuric acid, equivalent to ·4663 gram of ammonia;

XI. 1·0574 grams yielded, with hydrochloric acid, ·5775 gram of carbonic anhydride to soda-lime:

A sample purchased from the same firm as the last, but labelled "pure," identical in appearance with the last:—

XII. 1·5314 grams neutralized a volume of standard sulphuric acid, equivalent to ·4888 gram of ammonia:

A sample in sealed bottle, labelled "from volcanic ammonia," beautifully crystalline and translucent, devoid of colour, in thinner cakes than usual:—

XIII. ·9855 gram neutralized a volume of standard sulphuric acid, equivalent to ·3230 gram of ammonia;

XIV. ·9790 gram neutralized a volume of standard sulphuric acid, equivalent to ·3205 gram of ammonia:

A sample, labelled "optim," from a wholesale druggist's, not very crystalline, devoid of colour:—

XV. 1·0704 grams neutralized a volume of standard sulphuric acid, equivalent to ·3392 gram of ammonia:

A sample, purchased from the same firm as the last, labelled with a well-known maker's name, in two closely-adherent layers, of which one (*a*) was about twice as thick as the other, indistinctly crystalline, with conchoidal fracture, and the other and thinner layer (*b*) highly crystalline:—

XVI. 1·0261 grams of (*a*) neutralized a volume of standard sulphuric acid, equivalent to ·3230 gram of ammonia;

XVII. ·9667 gram neutralized a solution of standard sulphuric acid, equivalent to ·2188 gram of ammonia;

XVIII. 1·0443 grams gave, with hydrochloric acid, ·5785 gram of carbonic anhydride to soda-lime, and ·7250 gram of ammonium chloride, = ·2306 gram of ammonia.

These results, calculated for parts per cent., give the following numbers:—

		Carb. anhyd.	Amm.
a	I	54·86	..
	II	....	32·61
	III	....	32·74
	IV	....	32·48
b	V	55·24	..
	VI	....	32·91
	VII	....	33·02
c	VIII	54·98	..
	IX	....	33·05
	X	....	31·65
	XI	54·62	..
	XII	....	31·92
	XIII	....	32·78
	XIV	....	32·73
	XV	....	31·68
	XVI	....	31·48

(The calculated numbers for the results of the analyses XVII and XVIII, are entirely different from the others, and will be given and discussed presently.)

These numbers agree in the closest manner with the theoretical numbers, except that the presence of 1 or 2 per cent. more water is indicated than is required by the formula. Here are the calculated numbers for a compound of the formula,

$$(CO_2)_2OH_2(NH_3)_3,$$

—(1) when pure, and (2) when containing 2·5 per cent. additional water ($= \frac{1}{4}OH_2$):—

	(1.)	(2.)
Carbonic anhydride ..	56·05	54·65
Ammonia	32·48	31·67
Water	11·47	11·18
Additional water	....	2·50
	100·00	100·00

It will be seen, by comparing the numbers deduced from my analyses with these numbers, that all the samples examined had a composition lying between that of the pure compound, and one with 2·5 per cent. additional water. Another slight variation is, however, observable, namely, that the ammonia very slightly exceeds the calculated quantity—in the extreme cases to the extent of 1 per cent. But it will be seen that these variations from the calculated composition are immaterial so far as the determination of the atomic composition is concerned. When treating of the products of the distillations yielding carbonates of ammonia, and of the formation of the commercial carbonate, I shall have again to refer to these variations. I shall then, too, have to point out that a compound of the composition I find the carbonate of commerce to possess, is the commonest among these products of distillation. Rose also obtained and described carbonates having more nearly this composition than any other. For one of these he deduced the atomic composition expressed by the formula—

$$(CO_2)_5(OH_2)_4(NH_3)_8.$$

The sample to which he gave this formula yielded him numbers which correspond more closely with those calculated for a compound of the formula

$$(CO_2)_2OH_2(NH_3)_3$$

with 5 per cent. of additional water than with those for his formula.

By distilling the half-acid carbonate which crystallizes from solution, he obtained a product which agrees much more closely with my formula for the carbonate at present in commerce, with 8·5 per cent. additional water than with his formula—

$$(CO_2)_5(OH_2)_5(NH_3)_8.$$

Lastly, he obtained another compound from a residue from the distillation of one of the carbonates, and gave it the formula—

$$(CO_2)_5(OH_2)_{12}(NH_3)_8,$$

and this compound also yielded numbers corresponding much more closely to those indicating the commercial carbonate of the present time, associated with about 30 per cent. of water, than with those of the formula given to it by him.

The analysis of the commercial carbonate made by Ure in 1817 corresponds much better with the composition I find the carbonate at present to have, together with 4 per cent. additional water, than with that attributed to it.

It is of some interest to adduce proofs, other than analytical, that the carbonate now in commerce differs from that most generally in commerce formerly. Firstly, Rose found on distilling the ordinary commercial carbonate at a very gentle heat that the contents of the retort gradually liquefied. I have repeated his experiment, with the utmost care to proceed as slowly as possible, taking, for instance, about ninety hours' continuous and nearly uniform heating to distil about 250 grams, and obtained hardly any liquid at all; yet the products of distillation were less hydrated than those he obtained.

Secondly, as I have already pointed out, by distilling the carbonate at present in commerce with anhydrous calcium chloride, ammonium carbamate condenses. Now this allows of no explanation, unless the carbonate is admitted to have a different composition from what it used to have. The reactions in the two cases are expressed by the following equations:—

$$2(CO_2)_2OH_2(NH_3)_3 + 2CaCl_2$$
$$= 4NH_4Cl + 2CO_3Ca + CO_2 + \overbrace{CO_2 + 2NH_3}^{\text{To form carbamate.}};$$
$$(CO_2)_3(OH_2)_2(NH_3)_4 + 2CaCl_2$$
$$= 4NH_4Cl + 2CO_3Ca + CO_2.$$

Thirdly, the commercial carbonate loses by exposure a proportion of its weight corresponding closely with that calculated, as due to carbamate, from the formula deduced from my analyses.

Fourthly, its solubility is about twice as great as that of acid carbonate, and of this it contains about half its weight, according to the formula I have deduced for it.

Fifthly, its saturated solution does not seem as if it were charged with carbonic anhydride, as does that of the half-acid ammonium carbonate.

Commercial Acid Carbonate.—I have stated that I have found one special exception to the uniformity in composition of the commercial carbonate. This occurred in a crystalline layer intimately united to a barely crystalline layer of the ordinary composition. I have already given the results of my analyses of this layer of exceptional composition. Calculated into parts per cent. they give numbers nearly identical with those of the acid carbonate. This layer differed from the other, and the ordinary carbonate, in having scarcely any smell or any ammoniacal taste; in dissolving only slowly in the mouth; and in not losing its translucency by exposure to the air. The occurrence of the acid carbonate in commerce must be very rare, because its difference from the ordinary carbonate is so striking and such as to render it valueless for most of the purposes of pharmacy and medicine for which it is required. So far as I am aware, this occurrence has only once before been pointed out, and this was done nearly fifty years ago by Phillips,* who published his analysis of a sample which Henry and he had examined. Like the sample I have examined, this was more crystalline than usual. It must not, therefore, be concluded, however, that the acid carbonate in this form is essentially more crystalline than the ordinary carbonate of commerce; for this is often sent out by the manufacturer much more crystalline than the layer of the acid carbonate I have described. It was adherent to about twice its weight of the ordinary commercial carbonate, so that the cake as a whole had, therefore, the mean composition indicated for it by the 'British Pharmacopœia.' Thus:—

	Atomic wts.		Parts.
Commer. carb..... $(CO_2)_2OH_2(NH_3)_3$	157	or	2
Acid carbonate	79	or	1
	——		—
Ammoniæ carbonas, B.P. $(CO_2)_3(OH_2)_2(NH_3)_4$ ..	236	or	3

Whether this circumstance was accidental or intentional on the part of the maker I do not pretend to say.

The details of the analysis of this layer of acid carbonate have already been given. I have reserved till now giving the calculated numbers per cent. With them I place those of Phillips:—

	Calc.	XVII.	XVIII.	Phillips.
Carbonic anhydride ..	55·70	—	55·40	55·5
Ammonia............	21·52	22·63	22·08	21·16
Water	22·78	—	—	
	100·00			

The acid carbonate, it will be remembered can easily be obtained in the above form by distilling the ordinary form of it very slowly. In the remarks which follow on the commercial carbonate, it is to be understood that the usual variety only is referred to.

PLANTS AS MANUFACTURERS.*

We have been accustomed to admire plants for their beauty, to love them for their sweetness, and to prize them for the value of their products. But few have any clear notions concerning the arduousness of their labours, or the importance of the work which they perform. The life of plants seems to us a life of ease, a season of quiet repose, a waiting for all things to be done for them. Such views are wholly mistaken. No life is more fully occupied than that of a plant.

They are manufacturers, it is true, but we never hear the clink, crash, whirr, or deafening din of their machinery in motion. They darken the heavens with no reeking clouds of foul smoke, no hissing volumes of spent steam. They both spin and weave, but no rush of spindles or sound of shuttles is heard. They pack up millions of tons of goods for transportation to the furthest ends of the earth, without the aid of hydraulic pressure or huge packing-boxes. They lift thousands of tons of water and produce from the earth into the air without the help of cranes or lifting tackle of any kind. This noiselessness is the more marvellous when we remember that there is no division of labour in those plant factories. Each does all its own work for itself. Finishing-houses are unknown in these factories; and what perfection of finish we have in leaf and flower, and root and branch, timber and bark! What artist could meddle with but to mar the finish of fine fruit and glorious flowers. In design, in texture, in skill, and in finish plants are far in advance of all human manufactures. No skill of man can create a living daisy; but observe that humble plant, spreading its few simple leaves on the ground; it takes a few atoms of earthy matter, and compounds them with some raindrops and a sheathful of sunbeams, and forthwith the

"Wee, modest, crimson-tipped flower"

opens its eyes to gaze upon the sun.

The basis of all manufacture is raw material. Without this nothing can be made. Whence comes the raw material of plants? They are rooted to one spot, and have neither carriers, railways, nor fleets of merchant vessels at command. How, then, do they get the raw material to keep their factories going? In the olden times rocks were rent, avalanches rolled, water dashed and leaped with wild and hurried steps, strata were denuded and upheaved, volcanos shot out flames of fire and showered forth red-hot ashes, and myriads upon myriads of living things lived and died, and found graves in this great globe—the earth—before the raw material for the basement floor of this great plant manufactory was provided. And now plants draw their raw material from the earth, from the waters above, upon and under the earth, and from the invisible air.

The wind is freighted with fresh supplies of raw material for plants, the clouds are their water carriers, the lightning their swift-winged messenger to announce their wants in cloudland or across the earth or ocean, and bring back tidings of coming cargoes. The four so-called elements of the ancients—earth, air, fire and

* Abstracted from a paper by Mr. D. T. Fish, published in the *Gardeners' Chronicle.*

water—are laid under contribution by plants. They absorb and utilize matter in all states and conditions,—solid, liquid, gaseous, visible and invisible, clean or foul, come equally welcome to plants. We hear of great things being done by the use of waste. Old and apparently useless matters are torn up and fined down, and new products spring forth as if by magic. Fortunes have been built up out of shoddy. Plants are likewise distinguished in this line. Theirs is the largest shoddy factory in the world. They are Nature's universal scavengers, always sweeping up, utilizing, transforming, glorifying, dirt, shoddy, waste, and converting it into products of the highest value. Nothing escapes the keen, eager search of plants. They question the winds in their hurried courses, and ease them of their loads. They invite the dew to adorn them with its necklace of pearls, that they may drink in its nourishing sweetness. They tenderly, firmly hug all kinds of earth, that they may take all they need for themselves out of it. They run up into, and wave themselves about in the air, that they may feed upon its carbon and ammonia. In one word, their field for the supply of raw material is the world; and having done their best to empty it, they turn their pleading flowers and inviting leaves towards the sun, and proceed to do their utmost to absorb all its heat, to use up its light, to exhaust its chemical forces, and empty it of its energia, or life-giving powers. Such is the baldest possible outline of some of the chief sources from which plants draw their supplies of raw material.

No sooner are their factories furnished with these than forthwith they hasten to convert them into finished products. But to this end motive power is needed. Rest is the grave of production, motion its life. Plants form no exception to the general laws. They can manufacture nothing without moving force, and that force is never absent unless it is bound in the iron fetters of frost, or arrested by the colder grasp of death. True we cannot hear the rush of the sap; the heat that quickens falls softly on leaf and flower. Chemical compositions or decompositions which are incessantly proceeding in plant factories give forth no sound. The lightning plays among leaves and flowers without scorching spot or hissing noise. The energia of the sun stimulates the life of the plant to the utmost, though the summons to awake is unheard by mortal ear. But is there, therefore, no motion? Nay, are not all the greatest movements in Nature silent? We hear not the stars in their hurried courses. The daily revolution of the globe gives forth no crashing intonation.

The motive powers used in plant factories are various, —heat, light, chemical affinity, and life are probably the chief. It is impossible to dwell upon either of them. Life and heat are perhaps the most important, and between them they do an amount of work that is perfectly astounding. We know little of either; possibly they are closely related, almost synonymous. The sun in a secondary sense may be said to be the source of both, but they work everywhere to produce motion. Between them they set and keep all the fluids of plants in perpetual movement, and these fluids are the carriers of nearly all that is needed to build up structure and manufacture produce. Independently of the force expended on production, plants perform other and highly important work. They pump a great proportion of the water of the world, and thus enrich and fructify by watering the earth. The sun is the greatest, strongest raiser of water. But the sun and the atmosphere draw their supplies chiefly from the surface of the earth, rivers and oceans. The roots of trees go deeper down for their water, and the leaves distribute this water at a high elevation. What the force of steam is to your factories, these and other forces are to plant manufactories. They pervade, move, quicken, drive the entire machinery of production. Every part of the plant is set to work in extending, spinning, weaving, transforming, finishing something. The designs are most perfect, the products more varied than can be enumerated or imagined. Do you ask what plants make? Rather inquire what they do not make. They make fruit, flowers, corn, wine, oil, gum, resin, pitch, timber, cotton, flax, fibre, tea, coffee, starch, rice, spices, acids, perfumes, and medicines. They have mainly formed the tilth of our fields,—they constitute our coal measures. And all these things are made out of the most unlikely elementary materials.

Consider the lilies, the roses, the violets in their sweetness; the orchids in their gorgeous colouring and marvellous beauty of structure, perfect mimics of some of the most exquisitely and elaborately formed insects. Look at the oak-tree in its strength, and the tiniest moss in its shrinking weakness; then remember that a few morsels of solid matter, a few drops of water, some fleeting sunbeams with invisible food searched out of the air, have formed them all. These are brought in to those marvellous manufactories, plants, and forthwith duly delivered is all this beauty, sweetness and glory. The transforming powers of plants are beyond comprehension. For what skill of man could compound such a varied bouquet of sweet odours from such crude elementary matters as these?

Do you ask if over-production is ever known in these plant factories? Well, sometimes, though it is not the evil that it is among us. For their very act of production is almost as serviceable to us as the products manufactured. Incidentally, as it were, the mere working of plants fills our rivers and purifies our air. Then there is no waste in Nature: "Gather up the fragments that remain, that nothing be lost," is her constant practice. What is not needed to-day will be wanted to-morrow. There is a case in point. Ages ago the world seemed in danger of being engulfed beneath the *débris* of plants. The strongest forms of plant life, stimulated by a hot steaming atmosphere, rushed up as if by magic. They decayed almost as rapidly. Decomposition added fuel to the energy of growth. The living fed upon the dead. A great contest raged throughout many ages between life and death. Production and destruction, growth and decay, ran a neck-and-neck race for the mastery of the world, and production won the race. The earth groaned beneath its huge load of carboniferous *débris*. At last its back bent and broke with the sheer weight, possibly; then there came a subsidence or overflow—a hotpress of fresh strata rolled over—and the coal measures were formed. And now, at the present moment, we are warmed by the heat, lighted by the light, and derive most of our working force from the energy of primeval suns. Had we seen all this, we should have cried out what a shameful loss! but a greater than man said "Gather up the fragments" for the homes, the factories, the railways, the steamships of my great family in the nineteenth century, and all succeeding ages. And thus it came to pass that we filled our coal cellars with the carbon of the old world.

(*To be continued.*)

Colonial Tobacco.—The success which has attended the introduction of tobacco cultivation into some of our colonies will give fresh encouragement to those who are working in this department of economic botany. We learn from *Nature* that samples of Latakia tobacco grown in Jamaica have been submitted for approval in London and reported upon favourably, while in India the seeds of the best varieties are being distributed in the districts most suited to the cultivation of the plants. From Natal a sample has just been received, which, in the opinion of an eminent firm of tobacco-brokers in the City, is a very near approach to what colonial tobacco should be. It is of good substance and of a fair light brown colour. If carefully packed, it would probably fetch the price of 5*d.* to 5½*d.* per lb. in bond, and meet a ready sale in the London market.

The Cost of Dimples.—Those who pay fair prices for good wines should be alive to a kind of imposition which makes them pay nearly twice the nominal price for what they drink. Six bottles of brandy or wine are popularly supposed to make a gallon, and six reputed quarts do fairly make up the gallon. Mr. A. H. Church has been at the pains to measure the contents of some reputed quart bottles in which different wines and brandy were sent out by a respectable house. They contained in nearly every instance less than two-thirds of the full measure. Port at 66*s.* a dozen was really sold at 82*s.* full measure. Cognac at 60*s.* was sold at the rate of 86*s.* full measure. Santo was sold at 48*s.* a dozen; the bottle consisted of only twenty-two ounces, instead of forty, and the cost was, therefore, at the rate of 87*s.* Even the 20*s.* Roussillon bought by the bottle counts up to 30*s.* a dozen. The kick or dimple in each bottle often holds as much as a small tumbler. Evidently dimples are a considerable and probably a not sufficiently considered item in our family expenditure.—*British Medical Journal.*

Monkey Nuts.—The pods of the ground nut (*Arachis hypogæa*), commonly known by the name of "monkey nuts," chiefly used for the expression from the seeds of a light-coloured bland oil, said to be extensively used for mixing with olive oil, are now reported to be used in America for making so-called chocolate. For this purpose they are beaten up in a mortar and the mass compressed into cakes; and it is said to form a most agreeable chocolate, without a particle of true cocoa. The Americans also prepare the seeds as a dessert sweetmeat by parching them and beating them up with sugar.—*Nature.*

The Manufacture of Grape Sugar from Corn.—The *Boston Journal of Chemistry* says that large factories have been established in New Orleans, Buffalo, and Brooklyn, for making grape sugar from corn. The latter is steeped in weak soda lye, for the purpose of softening the husk and gluten, and is then ground wet and run through revolving sieves to separate impurities. It is afterwards made to flow through ways or troughs, in which the starch gradually settles as a white powder. The wash water is run into a large cistern, and allowed to ferment and produce a weak vinegar. The starch from the troughs is put wet into the mash-tub, and treated with water containing one per cent. of sulphuric acid, for eight hours. The acid is neutralized with chalk or carbonate of lime, and the liquid evaporated to get rid of the gypsum; it is afterwards further evaporated in vacuum pans and run into barrels ready for crystallization.—*Nature.*

Sulphurous Acid.—Dr. Wilks reports that he has used sulphurous acid with great success in cases of typhoid fever. He says that it "arrests the development of the fever poison, and by continuing this arrest long enough the fever is exterminated. Briefly, it is an antidote."—*British Medical Journal.*

Chilblains.—In a letter to the *Lancet*, Dr. Fergus says "that sulphurous acid is a remedy that has a surprising effect upon chilblains, especially in their irritating tormenting stage. The acid should be applied with a camel-hair brush, or what is better, by means of a spray-producer. One application by the latter method usually effects a cure." A good wash for hands or feet affected is sulphurous acid, three parts; glycerine, one part; water, one part.

Pill Knives.—Mr. Carre, of Meaford, writing to the *Canadian Pharmaceutical Journal*, recommends the use of a tool something like a carpenter's chisel for reducing stiff extracts and masses. It may be made from a stout pill-knife, by cutting the round part of the end to a square shape, and grinding both sides to an edge. This will thoroughly clean the slab as well as blend the mass most effectually. He says the pestle and mortar are nowhere beside it.

The Use of Ammonia in Snake Bites.—Mr. F. G. Adye-Curran, M.B., Assistant-Surgeon to the 83rd regiment, reports in the *Lancet* a case in which the ammonia remedy was tried without success. A native butler noticing a cobra di capello to emerge from a rat-hole, immediately informed his master, who came and fired at the cobra, wounding it in the neck, but not killing it. The butler, who was partially intoxicated at the time, seeing the cobra trying to make its escape, caught hold of the reptile by the tail, when it turned sharply round and bit him in the index finger. He was immediately removed to the hospital, where a tourniquet was placed on the arm and wrist, the finger freely lanced and ammonia and ipecacuanha applied, while ammonia and brandy were given internally. The wound was sucked and the patient kept awake; but in spite of every effort he died four or five hours after being bitten. A curious circumstance in connection with this case is that the patient expressed himself as feeling no pain, and the usual symptoms of snake poisoning were absent.

HULL CHEMISTS' ASSOCIATION.—ANNUAL SUPPER.

The Annual Supper of the Hull Chemists' Association was held on Wednesday evening, December 7th; about thirty-five members attended. The chair was occupied by Mr. J. Baynes, and the vice-chair by Mr. Anthony Smith.

After the usual loyal and local toasts had been drunk, Mr. Preston proposed "Success to the Chemists and Druggists' Association," observing that the members of the Association numbered more this year than last year.

The Chairman, in replying, stated that the Society had made material progress during the past fifteen months, and he had hopes that it would be an enduring and lasting Association.

DRUG MARKET NOTES.

The old and esteemed preparation Compound Extract of Colocynth may shortly have to find a substitute, for at the present time the officinal cardamom is almost entirely absent from commerce, and it is seldom that a parcel of true Socotrine aloes is now offered for sale.

The following were among the parcels of drugs offered for sale last week:—

Aloes,—Cape, 54 cases.
Galls,—Turkey, 37 bales.
Castor Oil, 354 cases.
Gum Kowrie, 19 bags.
Opium,—Turkey, 98 cases; Persian, 25.
Otto of Roses, 17 vases; and 850 ounces.
Ylang-ylang, 2 tins.
Senna, 124 bales; Alexandria, 64 cases; Bombay, 10 bales; Tinnevelly, 177 bales.
Chiretta, 126 bales.
Sarsaparilla, 19 bales.
Bark, 75 packages, 52 bales; Peruvian, 33 serons; Guayaquil, 5 serons; Crown, 105 packages; Calisaya, 27 serons.
Ipecacuanha, 5 serons; Carthagena, 9 packages.
Cutch, 11 cases.
Aconite, 2 cases.
Sandal Wood, 3 tons.
Matico, 7 bales.
Rhubarb, 168 chests.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 17, 1870.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes endorsed "Pharm. Journ."*

POISON REGULATIONS.

WE this week give a report of the proceedings at the Council Meeting of the 7th inst. It will be seen that the Committee appointed to report on the subject, recommended that poisons should be kept with some distinctive mark in addition to the names of the articles; also, that they should be kept in a closet, etc., specially set apart for them, or in vessels distinguishable by the touch, or in vessels closed in a manner different from the way in which non-poisonous articles are kept. On the motion that these recommendations should be proposed to the Annual Meeting, an amendment was moved to the effect that poison regulations were not necessary under existing circumstances. This amendment was lost, as well as another declaring the need for an expression of opinion by the country trade before the adoption of any regulations. The original motion was then put and carried by a majority of six out of fourteen members present.

As the matter now stands, therefore, the regulations recommended by the Committee will be presented by the Council to the Society at its General meeting, for adoption as regulations that every one in the trade will be compelled to observe, so that the poisons in his stock are kept in such a manner as to come within the terms of the regulations.

In connection with this important subject, we must also call attention to a letter from Mr. HAMPSON, the terms of which seem to suggest the possibility of open war and determined resistance to the action taken by the Council. From the neutral ground necessarily held by the Editor of this Journal, it would be obviously improper to comment on a position of such gravity any further than to express the hope that, whatever contest may be deemed indispensable, the real interests of Pharmacy, as a craft, will not be lost sight of or damaged in the endeavour to support any view less catholic in character.

THE LANCET AND PHARMACEUTISTS' CHARGES.

OUR contemporary, the *Lancet*, must, we think, by this time have become aware that the sentiments to which it has given expression in reference to the charges made by pharmaceutists for medicines supplied to the public, do not find acceptance either with the leading members of the profession or with the bulk of the general medical practitioners of the country. Indeed, though our contemporary has returned once and again to the charge, it has had to disclaim the idea that druggists' charges are generally, or even frequently extortionate; and it has only succeeded in making the unpleasant impression upon pharmaceutists that its strictures were dictated by a self-interested clique, seeking to gain a personal advantage at the expense of the dispenser, and thinking that if less be paid for physic, there will then be more room for visits, whilst it has elicited from the medical profession itself but very few instances of exceptionally high charges,—even then the statements have been unauthenticated by the names of the writers, and pharmaceutists themselves have condemned in still stronger terms the charges alleged to have been made in those instances, as altogether unusual and unjustifiable.

But in the face of the document published in last week's Journal, setting forth for general adoption by the medical profession a tariff of fees which should be charged by the profession for medicines, the strictures of our contemporary must appear very impolitic indeed, and the more unjust, since the charges in that tariff are altogether higher than those of any leading pharmaceutists. This document describes the scale of fees to be such that the humblest member of the profession need not hesitate to make it the basis of his charges,—a rate suggested, indeed, rather in accordance with past usage than from any consideration of what is essential to maintain the proper status of the profession,—due regard being had to the diminished value of money and the increase of wealth among the several classes of the community, considerations, we would say, that should be as fairly applied to the pharmaceutical as to the medical profession.

And what is the tariff which is so moderate? It is based upon house rental of patients, and recognizes three classes, those who pay from £10 to £25, those who pay from £25 to £50, and those who pay from £50 to £100 a year. Now, although it is held that medical men should be paid for their advice, "drugs" being thrown in when supplied by medical practitioners; yet we have a special scale given for medicines alone, and a very wide difference is observed in the charges suggested where medicines are supplied in the one case and not in the other. For instance, for an ordinary visit within the postal district, including medicines, it is suggested that the fees should be respectively for the three classes, 2*s*. 6*d*. to 5*s*.; 3*s*. 6*d*. to 7*s*.; and 5*s*. to 10*s*. 6*d*.; for visits, exclusive of medicines, for the same classes respectively, 1*s*. to 2*s*. 6*d*.; 1*s*. 6*d*. to 3*s*. 6*d*.; 2*s*. 6*d*. to 5*s*., that is to say, the difference where medicines are supplied in each case respectively, from 1*s*. 6*d*. to 2*s*. 6*d*.; 2*s*. to 3*s*. 6*d*.; 2*s*. 6*d*.

to 5*s.* 6*d.* In fact the medicine is charged as much as the visit and more than chemists now charge, as will be seen by reference to the table we published last week.

This tariff speaks for itself, and it is unnecessary to point out that the charges are altogether above those made by pharmaceutists furnishing the purest drugs, and specially trained to the most accurate and careful dispensing. We do say, in conclusion, that the mouth of the *Lancet* is effectually closed upon this question, by the fact of these charges being sanctioned by a body of medical men after careful deliberation, and more especially by the commendation of the report in which they are recommended by the organ of the largest medical association in the United Kingdom. At least, those who live in glass houses must not throw stones.

We deprecate the discussion of this subject in the spirit that has been manifested by some writers, and especially regret to find the charge of extortion again launched against druggists indiscriminately and anonymously in the pages of the *Lancet*, as is done in the following letter which appeared there last week; and in the paragraph referred to, which has gone the round of the papers :—

"Sir,—The accompanying quotation (the substance of which is stated to have originally appeared in the *Lancet*) tends strongly to confirm the opinion that druggists' charges are frequently so exorbitant that one of two courses must be adopted in order to afford those medical practitioners, whose patients are chiefly of the working classes, a better chance of getting recompense for their services by preserving to their comparatively poor patients much of the money now extorted from them in the shape of enormous charges by druggists for the medicines prescribed.

"That the case of overcharge referred to in the *Lancet* is far from being a solitary one is quite certain. I can adduce others, and I doubt not that most medical practitioners, who know the original price of drugs, can do so also. The charges, or rather over-charges, may not be, as a rule, so great as in the example recorded by your correspondent; but I know that they are very frequently excessive, and, in justice to medical practitioners and their patients, such extortion ought to be brought to an end.

"To remedy the evil, one of two courses, as I have already said, seems necessary—either let the medical practitioners in towns unite and have a laboratory, from which their patients may obtain their medicines at a price merely sufficient to cover all expenses connected with the laboratory, or let every practitioner supply his own patients with the medicines he may prescribe for them. Superfluous professional pride must be cast aside.

"I am, Sir, yours truly,

"JUSTICE.

"*Edinburgh, Nov. 26th,* 1870."

The following is the paragraph referred to in the above letter:—

"DRUGGISTS AND THEIR CHARGES.—A medical correspondent of the *Lancet* relates that not long ago he was informed by a young lady for whom he was prescribing, and who had been some little time under his care, that she could no longer afford to take the medicine ordered, as she was charged 4*s.* for every six ounces of it. Thinking there must be some mistake, the doctor sent for the druggist who supplied his patient with the compound, and inquired the reason of the exorbitant charge. The druggist assured him it was the usual charge made by other people as well as by himself. This, however, did not satisfy the doctor, who put on his hat, went straight to the nearest druggist's shop, and returned triumphantly with a bottleful of the same physic, for which he had paid only 1*s.* 6*d.* for the six ounces, or at the rate of 9*s.* for thirty-six ounces instead of £1. 4*s.* Unless the first druggist had the excuse that he thought the medicine prescribed would do the young lady more harm than good, and therefore put difficulties in the path, his conduct is unjustifiable; but the case shows how necessary it is for invalids to study their druggist's bills instead of, as at present, jumping to the conclusion that the more disagreeable the taste the higher should be the charge for the medicine. Probably by taking a little trouble in selecting an honest druggist, the same physic may be obtained cheap and nasty, and quite as effectual. —*Pall Mall Gazette.*"

Nothing could well be more vague and unsatisfactory than these quotations, considering the nature of the imputation they convey. As a contrast to them, we refer to the letters published this week in our correspondence columns, and, at the same time, as a remarkable illustration how little ground there is for the strictures we complain of, we may point out that complaints have reached us from several quarters of the unreasonably low prices charged by some druggists for medicine. Complaints of this nature have actually been made by medical men.

YEAR-BOOK OF PHARMACY.

THE members of the British Pharmaceutical Conference will learn with pleasure that the Year-Book is completed, and that as soon as the transactions of the Association are in type, the whole volume will be ready for distribution. We are enabled to state that besides ordinary intelligence relating to English and Continental Pharmacy, several papers have been contributed by Mr. JOHN CARGILL BROUGH, on Chemical Nomenclature and Notation, and on the Anæsthetics. An attempt has been made to represent the present state of American Pharmacy; an elaborate *précis* on the Cinchonas, and the organic bases described in the Montpellier prize thesis of Lacote, together with additional translations from the French and German, have been added by Mr. JOSEPH INCE. The autobiography of Mr. DEANE, properly belonging to next year's record, has been republished by general request.

WE understand that the Chair of Chemistry at St. Bartholomew's Hospital has been filled by the election of Mr. W. H. RUSSELL, who has been for some time Lecturer on Chemistry at St. Mary's Hospital Medical School.

WE notice with pleasure that active measures are being taken to establish a local Science College at Liverpool, and that a considerable sum has already been raised for carrying out the project.

Proceedings of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

December 7th, 1870.

MR. SANDFORD, PRESIDENT, IN THE CHAIR.

MR. HASELDEN, VICE-PRESIDENT.

Present—Messrs. Abraham, Bottle, Bourdas, Brown, Deane, Dymond, Edwards, Evans, Groves, Hills, Savage, Stoddart, Sutton and Woolley.

The minutes of the last meeting were read and confirmed.

Resolved unanimously—That Mr. John Williams, of 5, New Cavendish Street, be elected a member of the Council in place of Mr. Brady, resigned.

The President read the following letter:—

"*Plough Court, Lombard Street, E.C.*
"*2nd November*, 1870.

"My dear Sir,—I find myself unable at present to give the time and attention necessary for the right discharge of the duties of a member of the Council of the Pharmaceutical Society, and therefore I beg leave to tender, through you, my resignation of the position to which I have had the honour of being elected.

"It is with great reluctance and sincere regret that I feel compelled to take this step.

"Had I fully foreseen what membership of the Council involves, and how incompatible it would be with additional claims on my time and attention, which have recently devolved upon me, I would certainly not have allowed myself to be nominated, and I feel that an apology is due from me in having thus erred in consenting to serve.

"If I can be of use until the vacancy is filled, I shall be glad, and at any time if I can be of service to the Society, in the prosperity of which I feel a deep interest, it will afford me great satisfaction.

"I am, my dear Sir, yours very truly,
"CORNELIUS HANBURY.

"GEORGE WEBB SANDFORD, Esq., *President*,
"Pharmaceutical Society."

Whereupon it was

Moved by Mr. Deane, seconded by Mr. Hills, and

Resolved—That this Council accept with great regret the resignation of Mr. Cornelius Hanbury, and trust that at some future time he may again occupy a seat at the Board.

The Report of the Finance Committee was presented, showing on the General Fund account a balance in the Treasurer's hands of . . . . £853. 16*s*. 11*d*.
Submitting for payment accounts amounting to . . . . £680. 6*s*. 10*d*.
On the Benevolent Fund account, after purchase of £461. 12*s*. 0*d*. Consols, a balance of . . . . £64. 18*s*. 11*d*.

Resolved—That the Report be received and adopted and payments made.

On the Report of the Special Committee appointed to examine the apparatus offered by Dr. Redwood, and report to the Council as to its condition and value to the Society, it was—

Resolved—That the collection of apparatus belonging to Dr. Redwood and offered to this Society be purchased for the sum of £300.

Resolved—That the recommendation of the Special Committee on Dr. Redwood's apparatus that certain apparatus be from time to time lent to Provincial Associations be referred to the Library, Museum, and Laboratory and Provincial Education Committees, acting conjointly, for consideration, and that in the event of the Committee being of opinion that such loans could be made, that they cause a list to be prepared and presented with their Report to the Council of apparatus they recommend for the purpose, with suggestions as to rules and regulations to be observed.

Resolved—That the Report of the Library, Museum and Laboratory Committee be received and adopted.

Resolved—That this Council authorizes the President and Vice-President to arrange for the delivery of a lecture on the first Wednesday evening in February, 1871, in the Theatre of the Society.

Resolved—That the Report and recommendations of the House Committee be received and adopted.

The Report of the Sale and Keeping of Poisons Committee, recommending the following Regulations to be submitted to the Annual Meeting, was presented:—

PROPOSED REGULATIONS AS TO THE KEEPING OF POISONS.

1. In the keeping of poisons, each poison shall be kept in a box, bottle, vessel, or package, and labelled, in addition to the name of the article, with some distinctive mark indicating that it is poison.

2. In the keeping of poisons, ALL, OR ANY, OR ONE of the following systems shall also be used:—

I. The boxes, bottles, vessels, or packages, containing poison shall be kept in an apartment, cupboard, compartment, or drawer, set apart for dangerous articles.

Or if not so kept apart.

II. The bottles or vessels, used in any shop or dispensary to contain poison shall be distinguishable to the touch, and shall be unlike the bottles of vessels used to contain articles which are *not* poisonous or dangerous, in the same shop or dispensary.

Or otherwise.

III. The bottles or vessels used in any shop or dispensary to contain poison shall be tied over, capped, locked, or secured in a manner distinguishable from the way in which ordinary articles are kept.

Moved by Mr. Dymond, seconded by Mr. Abraham,

"That the Report and recommendations of the Sale and Keeping of Poisons Committee as to the Regulations to be proposed to the Annual Meeting be received and adopted."

Amendment—Moved by Mr. Brown, seconded by Mr. Woolley—

"That as the law already provides for the punishment of carelessness and prescribes due labelling, it is undesirable to issue regulations for the keeping and dispensing of poisons, as no evidence has been adduced showing that regulations are necessary, the large majority of chemists already observing all needful precautions, and considering the provisions for improved education and increased responsibility, they ought not to be subjected to any further restrictions, unless it may be considered desirable in the interests of the public to apply the same to all dispensers of medicine, including surgeons, etc., naval, military and hospital dispensers and others."

For the Amendment—

Messrs. Brown, Bottle, Savage and Woolley.

Against—

Messrs. Abraham, Bourdas, Deane, Dymond, Edwards, Groves, Haselden, Hills, Sandford and Stoddart.

The Amendment being lost, a further Amendment was moved by Mr. Woolley, seconded by Mr. Brown—

"That before adopting any regulations for the keeping of poisons it is desirable to have an expression of opinion from Chemists throughout the country, irrespective of the decision of the annual meeting, and that circulars be issued asking if such regulations are desirable or not; one month to be allowed for reply, and the result considered at the February meeting of Council."

For the Amendment—
Messrs. Brown and Woolley.

Against—
Messrs. Abraham, Bourdas, Deane, Dymond, Edwards, Groves, Haselden, Hills, Sandford and Stoddart.
Messrs. Bottle and Savage did not vote.

The Amendment again being lost, the original Motion was put as a substantive Motion, and the following division took place:—

For the Motion—
Messrs. Abraham, Bourdas, Deane, Dymond, Edwards, Groves, Haselden, Hills, Sandford and Stoddart.

Against—
Messrs. Bottle, Brown, Savage and Woolley.

The Motion was therefore carried.

Resolved—That the Report and recommendations of the Parliamentary Committee be received and adopted.

Resolved—That the Registrar be instructed, and is hereby authorized to remove from the Register of Chemists and Druggists, the name of Ambrose Lloyd, of 16, St. Andrew's Road, Southampton.

BENEVOLENT FUND.

A grant of £15 was made to an applicant (Registered Chemist and Druggist) at Brighton, for assistance from the Benevolent Fund.

REPORTS OF EXAMINERS.

ENGLAND AND WALES.

1870.		Candidates examined.	Candidates passed.	Candidates failed.
November 16,	Major	7	6	1
,,	Minor	23	19	4
,,	Preliminary Certificates approved } 2 for 1 person			
December 2,	Modified	45	27	18

		11	10	1

The Secretary presented the name of a member who had paid his subscription for the present year since the 30th April last.

Resolved—That he be restored to membership upon payment of a fine of one shilling.

Resolved—That the following, having passed the Minor examination, be elected Associates of the Society:—

Ball, George	Ormskirk.
Glazier, Walter Henry	London.
Milton, Thomas, jun.	Henley-on-Thames.
Mountain, Robert	Harrogate.
Nead, Joseph	Trowbridge.
Riches, William James	North Walsham.
Springall, John B.	Norwich.
Stubbs, Tyson	Rye.
West, William	Leeds.
Wright, Thomas	Leicester.

Applications for grants having been received from the Leicester Chemists' Assistants and Apprentices' Association, and from the Sheffield Pharmaceutical and Chemical Association, it was

Resolved—That the applications for aid from the above Societies be referred to the Standing Committee on Provincial Education.

Resolved—That the Journal and Transactions of the Society be forwarded to the Norwich Chemists' Assistants' Association regularly as published.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

An Ordinary Monthly Meeting was held on Friday, December 2nd; Mr. W. S. BROWN, President, in the chair. Messrs. Tysoe, Lane, Booth, Mercer, Dickenson, Clark and Carruthers were elected Associates.

Mr. J. T. SLUGG, F.R.A.S., then delivered a lecture on "Heat." The lecturer pointed out the effects of heat upon matter of every kind, and how necessary it was to the existence of both animal and vegetable life, also its power in inducing chemical action. He next explained the theory that heat is a motion of the molecules of matter, and that a warm body is one the molecules of which are in a state of vibration, communicating the motion to the surrounding ether, and producing the sensation of heat when the proper nerve is struck; also the striking analogies in the actions of light and heat. Reference was then made to the effect of various degrees of heat on different substances: the difference in their boiling-points; the absorption of heat accompanying liquefaction; the law of the expansion of bodies by heat and contraction by cold, some curious illustrations being given; and the exception of water and bismuth to the general rule. Heat was next considered as the great motive power in all kinds of work, the source of all force, energy, power, put forth in an infinite variety of ways and for an infinite variety of purposes. The question is, Whence is all this force derived? Is it from one common origin, or is it from many sources? The answer is, that all these forces, whether muscular or mechanical, have one common origin in the Sun. Several calculations were given that had been made as to the amount of light and heat emitted by the sun. The lecturer then explained the dynamical theory of heat, that force and heat are convertible in definite proportions, and gave several illustrations. Lastly, he alluded to the supposition that the sun's heat was maintained by the impact of innumerable small bodies with which it comes into collision.

A cordial vote of thanks was passed to Mr. Slugg for his interesting lecture.

HULL CHEMISTS' ASSOCIATION.

At a Meeting of the Members of the above Association, on Wednesday evening, December 7, the Chairman, Mr. J. Baynes, in the name of the subscribers, presented the Secretary and Treasurer, Mr. C. B. Bell, with a testimonial. In doing so, he said that that gentleman had spared neither time nor expense, but had used untiring efforts and energies on behalf of the Society. He had acted as Secretary and as Treasurer, and had carefully husbanded their funds. It had been felt that such valuable services ought to be acknowledged in some tangible shape, and on behalf of a large number of subscribers, he had to beg Mr. Bell's acceptance of a silver cup and salver. The salver bore the following inscription:—"Presented to Mr. C. B. Bell by the members of the Hull Chemists' Association, as a mark of their esteem, and in recognition of his valuable services as their Honorary Secretary."

The Vice-Chairman said the presentation was made by almost the whole Association to a gentleman who had done his best to raise the *status* of the trade without any consideration on his part of time and labour.

Mr. C. B. Bell, in accepting the presentation, said that whatever he had done was with the sole desire of furthering the interests of the trade, and he hoped the chemists and druggists would prosper still more.

SUNDERLAND CHEMISTS' ASSOCIATION.

The Monthly Meeting of the above Society was held on Monday evening, in the rooms at 60, Fawcett Street; Mr. J. J. Nicholson in the chair.

Mr. Cockburn read a paper on Cinchonas, their history and uses, describing the sources of the plants, their method of cultivation, the various alkaloids obtained from them, and their relative value and medicinal uses.

In a discussion concerning the storing of poisons, a plan was proposed by Mr. Nicholson, and seconded by Mr. Sharp, by which a distinctive colour—as red—was to be used as a danger signal, and placed on every bottle, parcel, or cask containing poisonous substances.

Mr. J. Harrison moved an amendment, which was seconded by Mr. Sidgwick, "That this meeting views with apprehension any further restriction upon the storing and sale of poisons, placing more reliance upon the care and responsibility of individual members than on mechanical safeguards." This amendment was carried by a majority of thirteen to ten.

Mr. J. Harrison then moved "That in the opinion of this Society it is desirable that the exemption from service on juries enjoyed by Pharmaceutical Chemists, should be extended to all registered chemists and druggists." He asserted that the Juries Act, viewed in conjunction with the Pharmacy Act of 1868, was a gross and glaring injustice to the whole body of chemists and druggists, and that it was a violation of every principle of justice and right. He contended that, as chemists and druggists discharged the same duties, and incurred the same responsibilities, they ought also to enjoy the same privileges as Pharmaceutical Chemists.

The motion was seconded by Mr. Clarke.

Mr. Nicholson then moved an amendment that the law ought to remain as it is, contending that the exemption was granted to Pharmaceutical Chemists as a reward for their educational attainments.

The amendment, which was seconded by Mr. Sharp, was lost by a considerable majority, and the original motion was then put and carried.

It was announced that the next meeting of the Society would be held on January 16, when a lecture will be delivered by Mr. Aslin, on the metals connected with the industries of the district.

ASHTON AND DUKINFIELD CHEMISTS' ASSOCIATION.

The Second Annual Meeting of this Society was held in the Board Room of the Mechanics' Institute, on October 20; Mr. W. H. Waterhouse, President, in the chair.

A report was read in which it was stated that the last session had been a creditable and successful one. The average attendance at the monthly meetings had been fair, though not quite so good as might be wished. It was thought that with a little effort every member of the trade might attend at the convenient hour at which they were fixed. Members were urged to use their influence to secure the attendance of those who had not hitherto been present. Already a better and more united feeling had resulted from these monthly social gatherings. Now that the Association had attained the age of two years, it might be considered to have passed through some of the dangers incident to a state of infancy.

A special meeting was held last session for the purpose of considering the propositions of the Pharmaceutical Council as to the sale and storing of poisons. After lengthened discussion, in which careful consideration was given to the subject, some vigorous resolutions were passed, and sent to the Pharmaceutical Council and to the editors of the Pharmaceutical Journal and *Chemist and Druggist*, and the Society might be congratulated upon having taken some part in securing the postponement of those regulations for at least twelve months.

Twice during the past session the apprentices and assistants of the district had met the members there in social intercourse, a proceeding which in the interest of employers and employed, it was hoped would be repeated during the next session.

Three able and profitable papers had been contributed by members and read at the monthly meetings, (1) "Pharmaceutical Pioneers," by Mr. Bostock, Vice-President; (2) "Longfellow's Poems," by the President; (3) "Progress," by Mr. Avison.

Perhaps the most popular work in which this Association had been engaged, and which it was hoped to see repeated year by year, was the course of three able public lectures, one by Mr. Slugg, of Manchester, on "Spectrum Analysis;" another on the "Elements of Chemistry," by Mr. J. Waterhouse; and the final one by Mr. Siebold, of Manchester, on "Poisons."

The two former of these lectures were profitable to the Institution, the last one resulted in a small loss to the funds. It is hoped that at any future lectures this Association may organize, every member will do his utmost to render them successful.

The retiring officers were then re-elected, viz.:—Mr. W. H. Waterhouse, as *President*, Mr. Bostock, as *Vice-President*, Mr. Neal, as *Treasurer*, and Mr. E. Fisher, as *Hon. Secretary*.

Proceedings of Scientific Societies.

BRITISH ASSOCIATION.

The Executive Committee of the British Association met in the Council Chambers, Edinburgh, on Saturday; Professor Christison, one of the Vice-Presidents of the Association, in the chair. A remit was made to a Sub-Committee to co-operate with the Local Secretary and Treasurer in the preparation of a leet of gentlemen to form a Local Committee for making the requisite arrangements to receive the British Association in August next. The same Committee were authorized to communicate with the several public bodies in Edinburgh, Leith and Portobello, and to invite subscriptions from them to the fund which it will be necessary to raise for defraying the necessary expenses. Professor Christison stated that the Council of the Royal Society had agreed to recommend the Society to subscribe £100 towards the fund, and a hope was expressed that the several public bodies, as well as banks and insurance offices, would respond liberally to the appeal to be made to them. It is understood that a sum of not less than £1500 will be required to enable the Local Committee to carry out the requisite arrangements in a manner creditable to Edinburgh.

MEETINGS FOR THE ENSUING WEEK.

Monday, *Medical Society*, at 8 p.m.
London Institution, at 4 p.m.—"On Chemical Action" (Educational Course). By Professor Odling.

Tuesday, *Pathological Society*, at 8 p.m.

Wednesday, *Society of Arts*, at 8 p.m.—"On a Method of Lighting Towns, Factories, or Private Houses by means of Vegetable or Mineral Oils." By A. Silber.

Thursday, *Royal Society*, at 8.30 p.m.
London Chemists' Asssociation, at 9.30 p.m.—"On Sulphocarbolates." By Mr. J. Sands.

Friday, *Quekett Club*, at 8 p.m.

Parliamentary and Law Proceedings.

Action against a Druggist.

Cooper *v.* Mercer.

An action was brought in the Stoke County Court on Thursday, Dec. 1, by Josiah Cooper, a plasterer, residing at Longton, against George Mercer, a chemist and druggist, of the same place, to recover £25 damages, for injury sustained by him through the defendant giving him a packet of red precipitate powder whilst supplying him with seidlitz powders.

The case for the plaintiff was that on Saturday evening, the 29th May, he was served by the defendant with two seidlitz powders in four small packets, two wrapped in white paper and two in blue. The same evening his wife mixed him a draught of water and the powder contained in one of each of the blue and white papers, that in the white paper being of a pink colour. He drank about three-fourths of the mixture, leaving the rest, chiefly sediment, in the cup, and in a few minutes afterwards became very ill, and remained so all night, vomiting much, and being in great pain. Medical assistance was called in, and it was found that the sediment in the cup was of a poisonous nature. Plaintiff said that defendant wrapped the four packets up in paper before giving them to him, and he took them home so wrapped up. He was ill and unable to work for ten days, and had never been quite well since. He had never taken seidlitz powders before. He had had some drink a day or two before, and they were recommended to him by defendant. He called about ten days afterwards to ask for some compensation, which defendant refused to make. Plaintiff's wife spoke to mixing the draught taken by plaintiff, which, she said, did not effervesce. She sent for defendant to come up on the Sunday, and he came to the plaintiff's mother's house next door, where she saw him but did not speak to him. Plaintiff's mother stated that when defendant came to her house, he told her there had been a mistake; either he had given plaintiff a wrong powder, or plaintiff had picked a wrong one up. Mr. Dawes, surgeon, said he saw plaintiff about noon on Sunday, when he found him suffering from symptoms which were not compatible with natural disease. The sediment in the cup was shown him, and he perceived it consisted of red oxide of mercury, which was poisonous in large quantities, and would produce the symptoms exhibited by plaintiff, from which it would take some time to recover. Several witnesses were called to prove that plaintiff was sober on the evening he got the powder.

In defence, it was contended that plaintiff had caused his own injury, or contributed to it by his own negligence. The defendant was called and said he had before sold seidlitz powders to the plaintiff, who knew their nature. He did not wrap up the seidlitz powders in question, but gave them, at his request, loose to plaintiff, who wrapped them up himself. There was a pile of small packets of red precipitate powders on the counter wrapped up in white paper, and amongst them he afterwards found a small packet of acid in white paper; he believed that plaintiff, who told him he had been drinking, had put it there, and taken up a precipitate powder by mistake. A fortnight afterwards, plaintiff called on him, and proposed to make the matter up for £1, or even 12*s.*, but he declined. Mr. Brough, chemist, Longton, spoke to plaintiff having frequently bought seidlitz powders from him.

Upon the judge expressing an opinion adverse to the plaintiff on the ground of negligence, he elected to be nonsuited.—*Staffordshire Sentinel, Dec. 3rd*, 1870.

Excise Prosecution.

On Saturday the Brentford magistrates were engaged some time in hearing a summons issued at the instance of the Board of Inland Revenue against William Austin, a bedridden shoemaker, residing at Isleworth, for selling certain pills without being duly licensed. The evidence showed that a supervisor of Inland Revenue, on September 29th, bought of defendant's wife a box of Dr. Mantle's gout pills for 1*s.* She said she had been selling them for years, and refused to say where Dr. Mantle lived. There was a Government label round the box, but there had been a loss of duty. Defendant's wife admitted having sold the pills for years, and said she did not know that she required a licence. The defendant was fined £5.

Reviews.

Supplement to the Pharmacopœia of India; or a Catalogue of Indian Synonyms of the Medicinal Plants, Products, Inorganic and Organic Substances included in that work, with Explanatory and Descriptive Remarks, etc., in Fourteen Languages. By Moodeen Sheriff, G.M.M.C. Printed and published by order of Government at the request of the Committee of the Pharmacopœia of India. 8vo. 676 pp. Madras. 1869.

Although bearing date 1869, this volume has only very recently reached this country. It was at first intended to have included the Indian synonyms in the new Indian Pharmacopœia; but, as such a course would have occasioned considerable delay, the work was published without them, the catalogue was somewhat expanded, and finally issued as a supplement. The table, originally prepared by Mr. Moodeen Sheriff, was composed of twelve languages, besides the Latin and English, viz. Arabic, Persian, Hindustani, Dukhni, Tamil, Telugu, Malyalim, Canarese, Bengali, Mahratti, Guzratti and Burmese, and the synonyms in all these languages were expressed in their native characters as well as in English. This Table was, in 1866, referred back to India for rearrangement in paragraphs, instead of the tabular form, and for the addition of the Cingalese and Sanskrit synonyms. It was then arranged that the work in its modified form should be printed at Madras, under the author's own supervision. Encouraged by the reception which his labours acquired at the hands of the Committee of the Pharmacopœia of India, Mr. Moodeen Sheriff set to work to revise his Catalogue, to accomplish which he states, "I have repeated the examination of medicines as before, and on this occasion obtained several supplies of them, with their names, from the bazaars of Calcutta, Hyderabad and Bombay, and a few other places beyond Southern India. This and the previous examinations have materially assisted me in removing many doubts and a great deal of confusion, and in finding out the correct names, as well as the true nature of many drugs and plants. In some instances the drugs were involved in such a confusion, that I was not able to clear it until I had actually raised the plants suspected to produce them from seeds; and in a few more, the only way I found to reveal the true nature of them, particularly with regard to their medicinal and other properties, was to take them internally myself."

From these remarks it will be seen that Mr. Moodeen Sheriff encountered his work in a right spirit, and the result has been the production of an exceedingly useful supplement to the Pharmacopœia, valuable, not only in India, but also in this country.

The first portion of the volume is occupied by the catalogue proper, arranged alphabetically, with the Latin names; as, for instance, *Abelmoschus esculentus*, W. and A. Then follow the Oriental synonyms, written first in English characters, expressed according to Sir Wm. Jones's method, and then in native characters. Afterwards, where remarks are required, these are given in a smaller type. There are 708 articles enumerated, to which a list of synonyms is furnished.

The next portion of the work is taken up with a table of the method of transliteration adopted for expressing the vernacular synonyms in English character.

Finally, the Appendix to the Supplement and the Indices occupy the latter half of the volume. The information contained in the thirty pages of the Appendix respecting obscure substances, or those but little known, is of much interest and value. The Indices are sixteen in number; one for each of the fourteen languages, one for the Latin names, and one for the English names. In some of the Indices the native characters, as in the body of the work, follow the names written in English characters. This brief summary of what the book contains will give some notion of the immense labour which it has entailed upon the writer, for which he deserves well of the medical profession, not only in India, but in this country, and also of all who are interested in Materia Medica. The promotion, by which the Government recognized his services, was no more than he deserved.

In concluding this notice we give our author's remarks on *sufed-musli*, which stands under the heading of ASPARAGUS ASCENDENS, *Roxb.*, at page 59.

"The *sufed-musli* of Southern India is the dried and splitted root of *Asparagus sarmentosus*. It occurs in thin and long pieces like strings, curled upon itself once or twice, varies in length from three or four inches to a span or more, of pale grey or dirty white colour, and devoid of any particular taste or smell. When the fresh root is splitted or torn longitudinally in three or four pieces and dried, it acquires the above condition. Although the dried root is often used by native practitioners, it is almost useless as a medicine; but when fresh, it is a nutrient and demulcent. In this state it is very fleshy and succulent, about a foot or a foot and a half in length, generally of the thickness of a finger, smooth and round, tapering to a very narrow and long point at both ends, of dull white or pale grey colour, no smell, and taste slightly demulcent. When a plant is dug out with these roots, it has a very singular appearance, as though a great number of large round worms were attached to it, and their number is often very great, amounting sometimes to about a hundred. The fresh root is distinguished in many parts of India, including Southern India, as *shaqaqul*, and its preserve, which is generally imported from China, is named *murabbahe-shaqaqul* or *shaqaqul-kamurabbah.* The above name is applied in Arabia, Egypt and Persia to some similar root, which is considered there to be the wild carrot or turnip. From its description in some books, I believe it to be a species of *Asparagus.* The *sufed-musli* of all other parts of India is the real drug to which that name is properly applicable, and it is the root of *Asparagus ascendens.* It is also procurable in Southern India, but under a different name, which is *shaqarule-hindi* or *Indian Shaqaqul.* It is a useful medicine, and a very good substitute for salep. It bears the following characters:—When new or not very old, this root looks like a thin, cylindrical piece of gum, partially translucent; very hard; whitish or yellowish grey; from one to two or three inches long, generally crooked, sometimes bent upon itself, and occasionally knotty; and of bland and mucilaginous taste. If some pieces be carefully examined, one of their ends will be found thinner and more pointed than the other, indicating their original tapering form. A few pieces are also flat or compressed, forming a kind of small irregular plates. When the root is very old, it is opaque and of light brown colour. With regard to the *kali-musli*, it is correctly the root of *Curculigo orchidioides*, as is mentioned and described in several books.

"The roots or rootlets of *Bombax malabaricus* bear no resemblance whatever to any of the varieties of the *musli.* When dried, they are as nearly useless as the dried root of *Asparagus sarmentosus.*"

This volume is very well "got up;" indeed it would hardly be suspected that it was printed in Madras, no small praise when many of the works printed in India are remembered.

THE CHEMISTS AND DRUGGISTS' ALMANAC AND DIARY, 1871. 8vo. 114 pp. *Chemist and Druggist* Office.

This book is a great improvement on all former editions, and is more than ever an indispensable counter companion to the pharmacist. The diary arrangement gives a page to a week, and just comfortable room for each day's memoranda. We do not think, however, that this part of the work will be fully developed till it attains folio magnitude; only then will it take its proper place on the desk.

The literature of the 'Almanac' comprises an exhaustive account of work done in Pharmaceutical Chemistry during the year 1870, by Professor Attfield; directions for performing the Gravimetric Tests of the British Pharmacopœia, by Mr. Tilden; and a paper on Chemical Tests for Medicinal Articles, by Mr. Sidney W. Rich; besides much information on legal and commercial matters, and innumerable hints of great value to every business man (most of them of especial value to the pharmacist) pushed into every spare corner. Dr. Attfield's paper omits nothing; from hydrate of chloral to Bouillon's method for forming pencils of any brittle caustic substance by incorporation with melted gutta-percha or paraffin,—everything finds appropriate mention. The notice of the artificial production of alizarine is very interesting. If the value of Mr. Tilden's contribution be measured by its length, a very unfair estimate will be the result. In very little space a remarkable amount of information is conveyed on apparatus, manipulation, etc., and of such character, that if the given directions be followed, the gravimetric tests of the Pharmacopœia may be performed by any pharmacist for himself. The manufacturer is at his mercy. In twenty-nine pages Mr. Rich makes us acquainted with every needful test for ascertaining the presence or absence of adulteration in chemicals and other articles of materia medica. The tests given are not simply those of the B.P.; a choice is offered. Cinchona, as its importance demands, has a good share of attention; and Carles' process for estimating the quinine value of barks is here side by side with the official one. Together, Messrs. Tilden and Rich furnish a complete system of the qualitative and quantitative analysis of the British Pharmacopœia.

On the very last page, side by side with the weights and measures, is a scale comparing the linear measures of the English and the metrical system. It shows clearly —and this mode of illustration cannot be too strongly recommended—that six inches are just equal to fifteen centimetres and two-fifths. We are sorry that it is the only notice of the metrical system to be found in the book.

There is one feature of this Almanac which we cannot commend, viz. that part which professes to be a "Trade Directory." Possibly we may not understand the principle upon which this has been constructed, but it seems very curious that such a directory should contain only four names under the head of "Drysalters," one name under that of "Comb-maker, etc." The lists of manufacturing chemists and wholesale druggists are also very meagre and imperfect. It is a pity that a good and useful work should be disfigured by anything so defective as this.

The Almanac deserves success, and will probably find its way into every pharmacy.

The following journals have been received:—The 'British Medical Journal,' Dec. 10; the 'Medical Times and Gazette,' Dec. 10; the 'Lancet,' Dec. 10; the 'Medical Press and Circular,' Dec. 14; 'Nature,' Dec. 8; the 'Chemical News,' Dec. 9; 'Journal of the Society of Arts,' Dec. 8; 'Gardeners' Chronicle,' Dec. 10; the 'Grocer,' Dec. 10; the 'English Mechanic,' Dec. 9; the 'Produce Markets Review,' Dec. 10; the 'Philadelphia Medical and Surgical Reporter,' Nos. 712 and 715; the 'Rock,' Dec. 9; the 'Eastern Morning News,' Dec. 8; the 'Maidstone and Kentish Journal,' Dec. 5.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department, 17, Bloomsbury Square, W.C., and not to the Publishers.*

[41.]—BATH POWDER and [47] SMALLPOCK-MARKS.—As no one appears to have sent the required information in reply to the above, I venture to say that the oxide of zinc, plain or scented, very finely sifted, is used as a toilet powder during the later stages of eruptive diseases. I have been told that in India its value is greater than in this country, the marks being larger in the warmer climates.—T. B. LANGRIDGE, *Midhurst.*

[42.]—CHILBLAINS.—*Lugoney* and *C. Bennett* will find this receipt of some use:—

℞. Lin. Belladonnæ ʒij
„ Aconiti ʒi
Acid. Carbolic. ♏x
Collodion Flexile ad ℥i.

Mix and apply with a camel's-hair brush. The above is for unbroken chilblains; if they are broken, the lin. aconiti is to be omitted.—A. T. GIRDLER.

[48.]—CRYSTALLINE POMADE.—*T. Stokoe* (Clare) says, "The formula given in Journal for December 10, 1870, is correct, but to obtain the crystalline appearance it is necessary to warm the bottles (I usually do so by immersing them in warm water) immediately before filling, otherwise a thin, opaque film is at once deposited."

E. M. sends the following:—

Castor Oil ℥iv
Olive Oil ℥iv
Spermaceti ʒvj.

Mix the spermaceti in the oils with a gentle heat.

A good scent for the same is—

Oil of Cassia gtt. xj
„ Thyme gtt. iv
„ Cloves gtt. xv
„ Lavender gtt. xxx
„ Lemon gtt. ij.

A similar recipe has also been received from "*Beta*" (York) and *M. H. Legg* (Edgware Road).

[64.]—COLD CREAM.—*E. M. S.* sends the following formula:—

℞. Cetacei ʒx
Ceræ Alb. ʒx
Ol. Amygd. Dulc. ℥viij
Aquæ Bullient. ℥iv
Sodæ Boracis ʒj
Otto de Rose ♏xl vel q. s.

Misce bene secundum artem.

Add ℥ij ol. amygdal. to the form given in last week's PH. J., and leave out the aqua rosæ, and you will get a cream that *will* keep well.—F. G. HOLMES, *Brill.*

A formula for the preparation of cold cream was given, *ante*, p. 340.

In the formula given last week, p. 477, *for* Otto de Rose gtt. ij, *read* gtt. xij.

[66.]—CEMENT FOR INDIA-RUBBER.—"*Vulcanite*" will find the following form all that he can desire:—

℞. Bisulphide of Carbon ℥iv
Best India-rubber ℥j
Isinglass ʒij
Gutta Percha ℥iss.

Dissolve. F. R. B.

[68.]—POT POURRI.—"*Iodi*" will find the following a good receipt:—

P. Cinnamon,
„ Cloves,
„ Mace, ana ʒiv
„ Orris ℥iv
Ess. Lemon,
„ Verbena,
„ Bergamot,
Ol. Lavand. ana ♏xl. SIGMA.

℞. Baccæ Pimento, coarsely powdered, ℥vj
P. Cinnamom. ʒij
Ol. Lavand.,
Ess. Ambergris,
„ Mosch., ana gtt. xij.

M. TOLU.

℞. Rad. Iridis Pulv. ℔j
Rad. Calam. Arom.,
G. Benzoes,
Bay Salt,
G. Storax, ana ʒiv
Caryophylli ʒj
Mace ʒss
Mosch. Gran. gr. viij
Ras. Santal Flav. ʒij
Florum Lavand. ℔ij.

M. S. A. TOLU.

[69.]—FRENCH ESSENCES.—The pomades made by *enfleurage* are generally used for the manufacture of essence in the proportion of 4 parts to 10 parts of alcohol 56 O.P. (·838), the pomades being rubbed through a sieve into the alcohol.

[70.]—DISPENSING. (*J. S. A.*)—It will be impossible to prepare the prescription as it stands,—soften the ext. belladonnæ in a mortar, with about ʒj of boiling water, and gradually mix the lin. camph.; it *will* separate under any circumstances. I do not consider this is to be regarded an unjustifiable addition, as the adding acid. sulph. dil. to a mixture containing quiniæ sulph., where none is ordered, most certainly is.—A. E. T.

H. H. Read (Peterborough) says,—Rub the ext. belladonnæ in a mortar with a few drops of water to a syrupy consistence, then gradually add the camph. oil, constantly stirring all the time.

If *L. S. A.* will weigh the camphor wanted for the ol. camph. and beat it up in a mortar with the half drm. ext. belladon. (use the alcoholic extract), then rub both up with two ounces olive oil, he will have a liniment similar to the one he inquires about.—WM. EVANS, *Liverpool.*

[72.]—COUGH BALSAM.—

Chlorodyn. ℥j
Syr. Tolu,
Scillæ, ana ℥iv
Antim. Tart. gr. x
Aq. ad ℥xx

Dose ʒj vel ʒij.

The chlorodyne is made according to Squire; the antim. tart. to be dissolved in hot water. The above is celebrated as the universal.—F. G.

[73.]—CHLORODYNE.—In answer to *M. P. S.*, wishing for a form for a soluble chlorodyne, I beg to offer him the following:—

℞. Morph. Acet. gr. lxiv
Acid. Acet. Dil. ℥ss
Acid. Hydrocyan. Sch. ℥iss
Ol. Menth. Pip. ʒij
Chloroform,
Æther. Rect.,
Tinct. Capsici, ana ℥ij
Theriacæ ad ℥xvj

Dissolve the ol. menth. pip. in the chloroform and ether, and put them in a bottle (wide mouth) capable of holding 2 lb., and which you have first graduated with a label to 1 lb. exact. Add the rest, all but the treacle, the morphia dissolved in the acid. acet. Make the treacle hot by standing it in a jug immersed in boiling water for about half an hour. This causes it to run easily, and any sediment will subside and be left in the bottom of the containing vessel. This hot treacle must be added to the other ingredients to make the whole measure 1 lb. It must be added carefully, an ounce or two at a time, and shaken gently, but as soon as it begins to cool, cork it up and shake well every few minutes until cold. —WM. G. TAPLIN.

[74.]—TOILET VINEGAR.—The following form is given by Piesse:—

Dried Rose-leaves ℥iv
Spirit of Roses triple ℥x (Otto ♏ix ad ℥j S. V. R.)
Dilute Acetic Acid ℥xl.

Macerate in a closed vessel for fourteen days.

I prefer this one.

Ess. Bergamot ♏xx
„ Ambergris ʒiv
„ Vanilla ♏xxx
Ol. Neroli ♏xxx
Acetic Acid ♏clx
S. V. R. ℥vj.

Mix. SIGMA.

W. B. S. (Bridgnorth) sends the following:—

℞. Ess. Bergamotte ʒij
„ Ambragris ʒiij
Ol. Neroli ʒiij
Acid. Acet. Fort. ℥ij
Ess. Vanillæ ʒiiss
„ Zingib. (℥j to ℥iij of Proof Spirit) ℥iij
S. V. R. ℥xxxvj.

[76.]—GLYCERINE JELLY.—*T. M.* (Worksop) is informed that neither isinglass nor tragacanth will make so bright a jelly as the gelatine such as is used for culinary purposes; this, in sufficient quantity to just gelatinize a mixture of 1 pint glycerine and 2 pints aq. rosæ, will furnish an article in every way satisfactory; a drop or two of otto of rose improves it, and it may be coloured (if desired) with liq. cocci or any of the beautiful colours now produced from aniline.—A. E. T.

[77.]—DISPENSING (“*Exhibatur*”).—With 2 ounces of distilled water mix the acid. phosph. dil., and in a separate vessel with the same quantity of water, mix the spt. chloroformi; let stand a few minutes, then mix the liquids: dissolve the ferri et quiniæ citras in the remaining water, pour the mixed liquid on the solution; lastly add tinct. nucis vom. and the mixture will remain bright.—S. HARWOOD, *Stoke Newington.*

[78.]—COMPOSITION FOR CLEANING BRASS.—

℞. Rottenstone ℥viij
Acid. Sulph. ℥ij
Ol. Olivæ Sec.,
Aquæ, ana ℥iss.

M. S. A. TOLU.

[79.]—PASTILE PAPER.—If *G. H. B.* will try the following, he will find it answer:—

Olibanum ʒxij
Styrax ʒviij
Benzoin ʒvj
Peruvian Balsam ʒiv
Tolu Balsam ʒiij
S. V. R. ℥x.

Macerate for twenty-eight days with occasional agitation, and add—

Saturated Solution Potassium Nitrate ℥j.

Soak the paper in it and dry.—SIGMA.

[82.]—BLUE COLOUR.—

Cupri Sulph. ℥j
Liq. Ammon. F. ℥iv
Aquæ Cong.

—F. G. HOLMES, *Brill.*

Similar answer has been received from “*Pestle and Mortar*” (Dorking), *T. W. C.* (Holbeach).

[84.]—PEPPERMINT CORDIAL.—

℞. Ol. Menth. Pip. Ang. ʒiss
Spt. V. R. Oiv (o. m.)
Sacchar. Alb. Hv
Aquæ Hvj
Magnes. Carb. ʒij

M. S. A. TOLU.

[86.]—PICK ME UP.—

Cardamoms 5 parts
Carraways 2 parts
Cochineal 2 parts
Cinnamon 10 parts
Raisins 80 parts
Orange Peel 56 parts
Ginger 14 parts
Gentian Root 3 parts
Wormwood 2 parts
Quassia 1 part
Alcohol (·838) 750 parts
Water 750 parts.

Macerate for fourteen days. Filter. Add Syrup 200 parts.

[87.]—GUM COWRIE is one of those commercial misnomers so common in City circles among brokers and importers. It is not a gum at all, but a fossil resin, used for varnish-making, obtained from New Zealand, being the produce of *Dammara australis.* In New Zealand it is usually written kauri. Full details and statistics respecting this product will be found in a paper I read on the gums and resins of commerce before the Society of Arts some years ago. (See this Journal, and in a paper on the gums and resins of New Zealand in my ‘Technologist,’ vol. vi. p. 475, 1866.)—P. L. SIMMONDS.

[88.]—EFFECT OF AMMONIA UPON BREAD.—Can any of your readers inform me why bread should turn yellow when exposed to the fumes of ammonia? Some time ago I was having my tea in a room in which the boy was breaking up a cwt. cask of ammonia, and, to my great astonishment, I found it turn the bread quite yellow.—A. T. GIRDLER.

[89.]—SYRUP OF PHOSPHATE OF IRON.—*W. M. B.* wishes to know the difference between Parrish's syr. ferri phosph. and the syr. ferri phosph. B.P.

[*** Parrish's is doubtless intended for the syr. ferri phosph. co., or chemical food.—ED. PH. J.]

[90.]—ARTIFICIAL MANURES.—*W. T. Oldham* (Wisbeach) wishes to be told of a good work on the manufacture and analysis of artificial manures.

[91.]—MEDICINE BASKETS.—*D. O. J.* wishes to know where he can obtain an improvement on the two-lidded square basket generally used for carrying out medicine, which will be light, durable and waterproof.

[92.]—VARNISH.—“*Sigma*” would be glad of a receipt for a flexible varnish to cover india-rubber tubing to prevent the escape of gas.

[93.]—OVER-PROOF SPIRIT.—Will your readers oblige a student with a clear definition of what is meant by spirit at a given strength over proof?—say 56 or 60 degrees over proof.—JUVENIS.

[94.]—OIL OF YLANG-YLANG.—I have frequently seen the oil of ylang-ylang quoted upon the price-currents of London houses. Can any of your readers engaged in the manufacture of perfume inform me if such is a genuine product, as stated, of one of the *Orchidaceæ*, or is it merely a mixture of other essential oils?—A COUNTRY DRUGGIST.

[95.]—COVERING FOR PILLS.—*F. R. B.* asks for the best mode of applying the solution of tolu for covering pills.

[*** Pour a small quantity of strong solution of balsam of tolu into a plate, and roll the pills in it.—ED. PH. J.]

[96.]—AERATED POTASS WATER.—In making aerated potass water according to the B.P., I find that when the bottles are laid by for a couple of weeks, a black deposit is formed on the cork. Can any one explain or give me a remedy for this?—SODA-WATER.

[97.]—OZONIZED ETHER.—*X. Q. Z.* wishes to be informed what is the nature of this preparation.

[98.]—DISPENSING.—*J. B.* (Stamford) asks for the best method of preparing the following prescription:—

℞. Quin. Disulph. gr. xij
Magnes. Sulph. ʒij
Alum. Sulph. ℈ij
Acid. Sulph. Arom. ʒij
Tr. Ergotæ ʒj
Inf. Caryoph. ad ℥viij

M. Capt. ℥j ter die.

It has always presented a dirty appearance.

Correspondence.

The Storage of Poisons Question.

Sir,—The importance of the subject will, I trust, be a sufficient excuse for troubling your readers with a few observations upon it. I have not yet heard the result of the discussion which took place at the meeting of the Council on the 7th instant, I am therefore unacquainted with the latest expression of its opinion. I am hopeful that the Council will be inclined merely to recommend with all the influence of its authority some well-considered plan for the voluntary adoption of the trade. The enforcement of regulations for the storing of poisons by the hand of the law, will not, I am sure, be tolerated; and the necessity for any legal interference, I and the majority have yet to discover. It is said that Government, through the Privy Council, has been or is putting the pressure upon the Pharmaceutical Council, and that the proposed legal interference, if the trade permit it, will be introduced, not because it is imperative to ensure the safety of the public, but mainly as a result of the bidding of the powers that be. If such pressure really exists, I hope the Council will wisely and manfully stand against it, rather than fetter the trade with vexatious restrictions. If the Council be the willing servants of the State, and are disposed to yield, I have little doubt but that the trade will put itself into a firm attitude of defence, to prevent the bartering of our trade liberty. The educational test now required, along with the caution and care resulting from an ever-present prudent self-interest, to say nothing of the penalties of judicial action under Lord Campbell's Act, are enough to ensure the safety of the public. If Government, however, is so very anxious to experiment in the direction proposed, let it bring in a measure to institute certain regulations in the surgeries of medical men, where the greater part of the dispensing of medicines is done, and where the usual safeguards are not always present. I do not say that this is at all necessary, but I do say that to attempt to saddle the chemist with restrictions, and let the medical man go free, would be a most insulting, foolish and unfair procedure. If the chemists of Great Britain permit themselves to be placed under obnoxious State surveillance and restraint in the mode of carrying on their business —for to institute regulations for the storing of poisons and not have them carried into effect, would be an absurdity—in the course of time some other new and spurious safeguard would be considered necessary. As for instance the inspection of chemical balances and scales used in dispensing, for the danger of using a wrong balance is almost as great as using the contents of a wrong bottle. Let us take warning and prevent the first wrong step, and the second will not be taken.

Robert Hampson.

Manchester, Dec. 13th, 1870.

Obscure Prescriptions.

Sir,—The correspondence in the Journal respecting "Obscure Prescriptions," brings to my mind what took place in my locality about thirty years ago.

A physician, at that time living near Blackfriars Bridge, used to give advice gratis, but compelled, as much as possible, all his patients to go to a certain chemist to have his prescriptions dispensed.

Particular marks were put upon the prescriptions by the privileged chemist every time he dispensed them, so that the physician might know whether they had been dispensed each time he saw them. He also took care that no one else could dispense them, by resorting to hieroglyphics.

This chemist after a time sold his business to another for a considerable sum, with the understanding that the physician's favours would be continued, but from some cause the physician shortly afterwards transferred them to a surgeon-retailer.

This provoked the chemist. He had circulars printed, which he sent very freely about the neighbourhood, stating that he was induced to purchase the business by the hope of having the physician's favours, that he had had to give the physician two pounds or guineas per week for the patronage, and that the physician called regularly every Saturday and never left without the money.

London, December 12th, 1870. Thos. Kent.

Druggists' Charges.

Doctor Kidd regrets that he gave a moment's annoyance to Mr. Ramsden, but he did not make any the remotest allusion to Mr. Ramsden. Grosvenor Square was given chiefly as showing that the "cutting down" system is unhappily common to this as well as other parts of London, though in such rich districts there could not be much excuse for it.

Sir,—Mr. Pollard, of Wavertree, has published a letter in this day's Journal, stating that a customer of his has had three dozen pills dispensed, at a first-class chemist's at Wolverhampton, for 8*d*. Will you allow me to tell him that he must have been the victim of a falsehood.

I do not know Mr. Pollard, but should fancy he has had little experience in such cases, or he would be very well aware that it is a very common practice with some people to have a prescription dispensed, and then, in order to get a reduction in the price, will say that they can get it for so much less at some distant town. I never believe them, for, some years ago, I took the trouble to ascertain the truth of some of these statements, when I always found I had been misinformed.

There is no doubt that some chemists are cutting the dispensing trade very much; still, it does not do to believe every exaggerated case that a strange customer will tell you. Mr. Pollard should have asked his customer the chemist's name, and should then have written to ascertain the truth of it before he published his letter in the Journal.

W. Y. Brevitt, *Local Secretary.*

Wolverhampton, December 10th, 1870.

Sir,—I have read with great interest the various letters which have lately appeared relative to the very low prices charged by some chemists, and I have often thought what a great desideratum would be conferred upon our profession, could all in a town agree to have one tariff. The other day I had a prescription brought to my shop to be compounded,—it was for an eight-ounce mixture, contained eight ingredients, including one ounce of tinct. aurantii, and an extraordinary large quantity of bismuth. trisnit. I thought no respectable chemist would charge less than 1*s*. 6*d*., which amount I asked for its being faithfully dispensed; but this morning, Sir, I had the gratification of being informed that it had since been made up in this town by a *Pharmaceutical* Chemist and a twenty years' member of our Society, and his charge was 1*s*. 2*d*., and also that the said Pharmaceutical Chemist unblushingly sells 1*s*. 1½*d*. patents for 11*d*., and charges 5*s*. for Mrs. Allen's Hair Restorer. Now, Sir, can we consistently complain of the "cutting" prices charged by those chemists who have never been educated to the profession, who have either been doctors' boys or dispensers at hospitals, when such things as these are done by an old member of our Society? I deeply regret to see it, being a reflection on that Society whose object and aim is the advance of pharmacy.

"Consistency."

Sir,—The following advertisement appeared in one of the leading Bristol daily papers:—

DRUGGISTS AND THEIR CHARGES.—Look at the Extract from the *Lancet*, copied into the Local Papers —one man charges 4*s*. for a 6-ounce Bottle of Medicine, another 1*s*. 6*d*. for the same. I charge, on an average, only 9*d*. Can it be possible that the Public will still submit to such an enormous imposition?—H. Hodder, 11, *Broad St., Bristol.*

It surely behoves us to urge on the Society at Bloomsbury Square to lay down a list of prices, whereby we may all keep as near the standard as possible without laying ourselves open to be insulted by such "black sheep" as the above.

Bristol. "Live and Let Live."

Sir,—As the profits on medicine have been so freely discussed in the pages of our Journal, owing to some remarks made in the *Lancet* respecting our charges, perhaps the following may not be out of place, to show that our profits are not so enormous as are generally considered by those who only speak from hearsay, and not from experience.

I have known the drug business just thirty years, yet I cannot give you an instance of a man retiring on a competency realized out of a retail drug trade, although he may have stuck behind the counter from 8 A.M. to 10 P.M., and scarcely taken a day's pleasure from year's end to year's end. In a town in which I resided a great many years, I could see from my door three druggists whose returns varied from £800 to £2000 per annum; being on friendly terms, we knew each other's business to a certain extent. One had married well, which rendered him to some extent independent of his business; another was a bachelor, and had a good income independent of his business; the third died suddenly, leaving a wife and family; he had the best business of the four, keeping two assistants and one apprentice; yet when the estate was wound up and all debts paid, there was a very small balance left. Now these men were many years my senior, and had been in business for upwards of twenty years, during which time neither could save £500. Though my returns were about £800 per annum from a general drug trade in a large country town, my profits did not average more than £200 per annum; what could I save out of that after paying the expenses for carrying on the business, rent, taxes, housekeeping and bringing up a family? Had it not been for an additional income, live as economically as I could, I should only have been barely able to pay my way.

Thirty years since, when provisions were much cheaper than they are now, we charged for Oss and ℥vj mixtures, 2*s.* 6*d.*; draughts, 9*s.* per dozen (we never get a prescription now for a dozen draughts; Seidlitz powders, 2*s.* 6*d.* per box; single ones, 3*d.* Compare this with the present prices, especially a Seidlitz powder retailed for 1*d.*, at a shop not a mile from St. Paul's. I wonder if Mr. — pays his rent with the profits accruing from the enormous quantity he must sell? I think these facts prove that the present profits attached to the retail drug business are not a sufficient remuneration for the time, labour and capital employed, to say nothing about the responsibility we take on ourselves, viz. the dispensing of illegible prescriptions, without having a licence to kill.

December 8th, 1870. "A RETAILER."

SIR,—There have been several inquiries in your columns for a list of "dispensing charges," and as the one adopted by the Manchester Chemists' Association is pretty generally followed in a tolerably extensive district, I beg to forward you a copy for publication, as one that may be considered fairly remunerative without being excessive, and may give an idea of what is practicable in a neighbourhood where chemists have some little confidence in each other. The use of the "price mark" is strongly recommended in all cases, as in the event of a prescription being taken to another shop, the second dispenser at once sees the price already charged, and consequently is able to obtain the same without being afraid, on the one hand, of charging more than his neighbour, or, on the other, of underselling him.

If the price mark "Mel Boracis," which has long been used in Edinburgh, and more recently in several other places, were universally adopted throughout the country as the mark for dispensing charges, it would be a great advantage, for then a prescription dispensed in various parts of the country could always be charged at the same rate, and a nearer approach to uniformity might thus be obtained.

W. WILKINSON.

Cheetham Hill, December 13th, 1870.

List of Dispensing Charges, adopted by the Manchester Chemists' and Druggists' Association, and recommended to the Trade generally.

* Scale of Prices for Pills.—The higher charge to be made when one, two, or more pills are ordered alone; if with mixture, etc., in the same prescription, the lower charge to be made.

† Mixtures, etc.—Quinine or other costly ingredients, or an extra large quantity of tincture, to be subject to a higher charge.

‡ "Drops," including concentrated medicines or tinctures. Ordinary bottles and pots are included in the above prices. The uniform adoption of the price mark will prove advantageous, as showing to subsequent dispensers the charge already made; when charged below the above rates, a mark × in the upper left-hand corner will denote exceptional.

Chloral in Sea Sickness.

Sir,—I have taken chloral five times while crossing the Irish Channel, with very good results.

My first experiment was made last March, when 50 grains took me from Kingstown to Holyhead as sound as a top. On returning a few days later, I tried 60 grains; and though it was very stormy I was as unconscious of winds and waves as an unborn babe, not waking till shaken by the steward at the Kingstown pier. My travelling companions, who had had five hours of misery, said they would have given ten shillings each for such a magic draught.

On crossing from Cork to Liverpool to attend the Pharmaceutical Conference, I took two 50 gr. doses, and slept the whole way, about twenty hours.

I would propose the following directions, a departure from which may lead to bad results:—

If a smooth passage is expected take nothing, but enjoy yourself.

If sea-sickness is feared, take a good dose about half an hour before its occurrence is expected; keep warm, go to bed, and you will sleep.

If the dose is delayed until nausea is felt, the stomach will instantly reject the chloral, and the remedy will be unsuccessful.

At this eleventh hour I would suggest the following, though I have never tried it. Take a few inhalations of chloroform, and when partially insensible, take the chloral, which would then, I think, be retained until sleep ensued.

J. Hancock Richardson.

3, Arundel Terrace, Cork.

Sir,—Allow me to endorse the correctness of your opinion, as stated in the Pharmaceutical Journal of the 3rd inst. in reference to the addition of acid. sulph. dil. in dispensing the formula as given by "Magnesia," No. 22, p. 437, and also as a consequence to protest against the contrary view put forward by "Chemicus" in to-day's issue. "Chemicus" does not seem to be aware that medical men do frequently prescribe intentionally quiniæ sulph., without the customary addition of acid. sulph. dil. An eminent provincial surgeon once informed me that he did so because his patients experienced considerably less nausea when so given. I should trust no pharmaceutist would, on reflection, consent to such an infringement of a medical man's prescription as that suggested by "Chemicus."

A Major Associate.

Tunbridge Wells, Dec. 10th, 1870.

A Point of Ethics.

Sir,—In your last week's issue, a letter appeared, signed by "Chemicus of Twenty Years' Standing," stating that when quinine is ordered in a mixture, and no "acid" prescribed with it, a chemist would be justified in adding acid. sulph. dil. in order to dissolve it. On this point I must differ from him.

Many medical men omit the "acid" because their patients dislike the intense bitterness of the quinine; and "Chemicus" ought to be aware of the fact, that quinine is *not* so bitter when undissolved as it is when in a dissolved state. Surely the members of the medical profession are not so forgetful as "Chemicus" would like to make out.

On the other hand, if there be no "acid" prescribed in a quinine mixture, but the words "solve" or "misce secundum artem" added, then a chemist would understand that it was the prescriber's intention that the quinine should be dissolved.

Bath, December 13th, 1870. D. T. W.

Irish Pharmacy Bill.

Sir,—I send you a few suggestions regarding the proposed Pharmacy Bill for Ireland.

Instead of the present Bill, let a Bill be framed by the Pharmaceutical Society, extending the English and Scotch Pharmacy Act to Ireland, but so modified as to leave out all its objectionable features, and so help to assimilate, as far as practicable, the laws of the three kingdoms, instead of having them administered by two separate bodies.

In introducing a Bill for the extension of the Act to Ireland, I would suggest the following modifications of that for England and Scotland.

1st. That no one be permitted to take apprentices until they have passed the Preliminary Examination.

2nd. That no person be permitted to be employed as an assistant who has not passed the Minor Examination.

3rd. That no person be permitted to keep open shop for the dispensing of physicians' prescriptions until they have passed the Major Examination.

Let it be further arranged that apothecaries be permitted to keep open shop in England and Scotland for the dispensing of physicians' prescriptions, and that Pharmaceutical Chemists be permitted to keep open shop in Ireland for the same purpose, but those by examination only. In this way the flock of Registered Assistants who have passed the Modified only, those who have passed the Minor only, and Registered Chemists and Druggists will be excluded.

I would suggest that the Chemists and Druggists in Ireland be excluded also, as they are a comparatively uneducated body (*i.e.* with regard to special education), and have never possessed any privileges for the dispensing of prescriptions.

William M. M'Naughton.

Dublin, 7th December, 1870.

"*Veritas*" (Ealing) and *C. B.* (Sheffield) are referred to the rule respecting anonymous communications.

C. B. L. (Towcester).—The 'Food Journal' is published by Messrs. Johnson and Sons, Castle Street, Holborn, price 6*d*.

M. P. S. (Birmingham) should apply to the Secretaries of the Chemical Society, Vernon Harcourt, Esq., and W. H. Perkins, Esq. See Answers to Correspondents, "*G. A.*" *ante*, p. 180.

J. B. (Frodsham).—It is used principally in the manufacture of gas burners.

W. A. Twelvetrees.—Nitro-Benzol is produced on a large scale by the addition to benzol of nitric acid or a mixture of nitric and sulphuric acids in a small stream, so regulated as to prevent too great an increase in the temperature. For a detailed account of the process, see Perkins's 'Cantor Lectures on Aniline,' Reimann's 'Aniline and its Derivatives' (Longmans), or any standard work on dyes.

H. (Salisbury).—The 'Homeopathic Pharmacopœia' is published by the British Homœopathic Society, and may be obtained of Messrs. Turner, Fleet Street, or any wholesale homœopathic agent, price 10*s*. 6*d*.

"*Justice.*"—In consequence of the writer not furnishing his name and address, we are unable to publish the letter with the above signature, containing a card said to have been left at the door of a medical man in Islington.

W. G. (Swansea).—The opinion of pharmacists is undoubtedly in favour of Fownes' Manual.

J. T. Freeman (Great Hadham).—The letter has been forwarded to the publishers.

J. Hands (Campden) and *J. Parry* (Chester).—The memorandum and stamps have been handed to the Secretary.

Ferri Quinæ Citr., B.P.—A manufacturer informs us that although he can obtain eight grains of quinia from fifty grains by precipitation with ammonia (the precipitate being dried at 212° F.), from small, hard scales, such as druggists would *not* use, he cannot obtain more than 7·6 grains from the large scales so esteemed for dispensing. He therefore thinks the Pharmacopœia should give 15 per cent. of quinia as the minimum quantity recognized.

J. Otley (Sheffield).—The certificate of having passed the preliminary examination of the Royal College of Surgeons would be accepted.

G. J. Rawland (Liverpool).—A letter has been received too late for insertion, in consequence of its having been wrongly sent to the publishers.

Erratum.—In the article on Sp. Ætheris Nitrosi, p. 464, line 5 from top, *for* 56 per cent. *read* 56 o. p.

PRACTICAL NOTES
ON THE
PREPARATIONS OF THE BRITISH PHARMACOPŒIA.

BY CHARLES R. C. TICHBORNE, F.C.S., M.R.I.A.
Chemist to the Apothecaries' Hall of Ireland, etc.

Acetum Cantharidis and the Vesicating Preparations of Cantharides.

The vinegar of cantharides calls for very few remarks. If made strictly according to the Pharmacopœia the result is a very pungent liquid, having a brown colour. The specific gravity at 15° C. will range from 1·060 to 1·062. It should be miscible with water in all proportions. The heat employed in the maceration is, as will be seen, conducive to the solution of cantharidine (*vide* remarks upon the solubility of cantharidine).

Taking the formula of the Pharmacopœia, 12 fluid ounces are got by percolation, and 3¼ ounces by pressure, so that 2 ounces of glacial and 22¾ ounces of acetic acid are consumed. It directs that powdered cantharides should be used, but it will be found more convenient that the flies should be simply bruised, particularly when making large quantities. The substance of the flies is easily permeated by the acid, whilst the structure generally gets into such a pulpy state from its action, that it is difficult to manipulate with large quantities of powder.

In the Pharmacopœia no characteristics or tests are given for what used to be called the "preparations" in the edition published in 1864. These preparations are in the majority of cases more easily sophisticated than the materia medica, and are frequently the vent for inferior drugs. The point is worth consideration, and any specific or general character which can be applied to them must be of importance. It is for this reason that I have given the specific gravity.

The relative strength of the present preparation to those formerly in use is given:—

	Total Crystallizable Acid.	Glacial Acid, etc. (sp. gr. 1·065).	Acetic Acid. (sp. gr. 1·044).	Cantharides.
	Per cent.	Per cent.	Per cent.	Per cent.
B.P.	39·7	10	90	10
L.P.	37·0		100	10
Ed. P.	43·75	25	75	17·5
			(Sp. gr. 1·034.)	(Euphorbium 2·5 per cent.)
Dub. P.	46·4	20	80	20

The Pharmacopœia has the following note in connection with the strength of these preparations:—"This preparation is rather stronger than the acetum cantharidis of the London Pharmacopœia; it is less active than the preparations ordered under the same name in the Edinburgh and Dublin Pharmacopœias;" in fact, as will be seen in the first and fourth columns, these two preparations are almost identical. The percentage of flies could be increased with great advantage.

Liquor Epispasticus.—It is, perhaps, as well to consider the remainder of the vesicating preparations of cantharides in this place. The first of these is the liquor epispasticus; this term having been substituted for the "linimentum cantharidis" of 1864. In the present formula for liquor epispasticus, there is evidently a mistake. Based upon a valuable idea, it is obvious that the wrong acid has been specified. The following is the formula:—

Take of
Cantharides, in powder, 8 ounces
Acetic Acid, 4 fluid ounces
Ether, a sufficiency.

"Mix the cantharides and acetic acid, pack them in a percolator, and, at the expiration of twenty-four hours, pour ether over the contents of the percolator, and allow it to pass slowly through till twenty fluid ounces are obtained."

The acid directed in the above formula is the ordinary acetic acid, having a specific gravity of 1·044. Now, independently of the want of solubility of cantharidine in cold acid of that gravity (*vide* remarks on solubility of cantharidine, p. 502), two parts of acetic acid are not miscible with fourteen parts of ether of the gravity required by the Pharmacopœia. (These are the proportions that would be used.) If we mix them in the above proportions we get a product presenting two layers; the lower one consists almost entirely of water, and is about one-half the bulk of the original acid employed; whilst the upper is ether, holding in solution about $\frac{1}{15}$ of a stronger acid than that originally used; however, these fluids act rather differently when employed for the exhaustion of the cantharides. Obeying strictly the Pharmacopœia, we find that on passing the ether through the powdered flies, the ether extracts the green oil and other ingredients of the cantharides, the latter retaining the greater part of the water present in the acetic acid. The result is an ethereal tincture saturated with water, and having a specific gravity of about ·770 at 15° C. About 14 ounces of ether are consumed to produce the half-pint of liniment. If the residue is squeezed a considerable quantity of water is the result, and on drying in the air until the whole of the ether has evaporated, the flies will be found to weigh nearly one quarter more from the water absorbed, instead of being lighter from the loss of extractive. A process of separation seems instituted by which the aqueous portion is retained by virtue of the attraction of the animal matter.

It is evident that glacial acetic acid should be used; if this is done, a rapidly vesicating and homogeneous fluid is obtained. The following is the alteration that we venture to suggest:—

Take of
Cantharides in powder 8 ounces.
Glacial Acetic Acid . 2 fluid ounces.
Ether . . . . 28 ounces, or a sufficiency.

Rub the cantharides in a mortar with the glacial acetic acid, and proceed as directed in the Pharmacopœia. The consumption of ether will be found to be about the same as in the previously mentioned formula, namely 28 ounces, the specific gravity at 15° C. being ·779; in this instance the cantharides will be found to have lost considerably in weight, for on exposure to the air for a short time until the ether had evaporated, they were found to weigh only 7 ounces.

A formula for vesicating collodion might at the same time be introduced, that preparation being more extensively used than the vinegar or liniment. The collodion is a great favourite with the ophthalmic surgeons; it is easily made in the following manner:—

Take of—
Blistering Liquid, 10 fluid ounces.
(not made with ordinary acetic acid.)
Gun Cotton, ¼ of an ounce or a sufficiency.

Mix, and shake them occasionally until dissolved, and add more gun cotton if not thick enough. This, in fact, resolves itself into the formula published by the author in 1862.*

Before considering the vesicating preparation further, it may not be uninteresting to give the solubility of cantharidine in different solvents, bearing in mind the fact that such results were obtained with the crystallized active principle, and that in the fly it may be, and probably is, considerably modified by the other ingredients.

Action of Solvents upon Cantharidine.

Water.—Insoluble.

Alcohol, Ethylic and Methylic.†—Fairly soluble in hot fluids, very insoluble in the cold.

Acetic Ether.†—Soluble.

Ether.†—Soluble in 34 parts.

Chloroform.—Very soluble in the cold. (As stated by Proctor, seems the best solvent.)

Bisulphide of Carbon.—Nearly insoluble.

Volatile oils.—Mostly solvents.

Castor and fixed oils.—Very soluble.

Fatty matter of the Fly.—Very soluble.

Sulphuric Acid.†—Soluble. Reprecipitated by water.

Glacial Acetic Acid.—Slowly dissolved in the cold, very soluble in warm acid. A saturated solution in glacial acid is reprecipitated by water.

Acetic Acid 1·044.—Scarcely soluble. Dissolves by prolonged boiling and crystallizes out on cooling.

Weak Soda, or Potash Solutions.—Nearly insoluble.

Strong Potash, or Soda.—Dissolves easily on warming and is not precipitated on diluting, but is precipitated on the addition of acids.

Ammonia.—It is stated in Watts's 'Dictionary,' vol. i. p. 736, that "ammonia has no action upon cantharidine." This statement is incorrect. Weak ammonia has no action upon it, but very strong liquor ammoniæ dissolves it easily after some time, particularly if it is warmed, without a loss of the ammonia.

The two last paragraphs might be made available for the concoction of good formulæ, whilst the reactions observed with the acetic acids bear upon the preparations we have been discussing.

* *Vide* PHARMACEUTICAL JOURNAL, 2nd ser., Vol. III. p. 506.

† The reactions are taken from these published observations of others, and not from the author's experience.

KALI-KUTKI.

(*Picrorhiza kurroa*).

BY M. C. COOKE, M.A.

For a very long time the Kali-kutki of Northern India was believed to be the black Hellebore, and under that name it has been quoted, over and over again, by one author after another, until it came to be accepted as fact. It is some years since we first became acquainted with this drug, and from that period have always maintained that it could not be the root of black Hellebore. It is probable that the error was originated by Ainslie, since he makes the statement in his 'Materia Medica;' but upon what evidence the assertion was first made it is scarcely possible now to determine. Enough for us that Kali-kutki is *not* the root of black Hellebore.

The authors of the Indian Pharmacopœia seem to have been of opinion that there were two distinct drugs known in India, the Kootki of Northern India, and the Kali-kutki of the bazaars of the South. In the Supplement to the Pharmacopœia of India, Mr. Moodeen Sheriff has disposed of this opinion in a few words, for he states that "the root sold in the bazaars of Calcutta, Hyderabad and Bombay, under the name of Kutki is identical with the Kali-kutki and Katuku-rogani, or "Kada-groganie" of Southern India. If the quantity is large, it varies much in size and appearance in each specimen, but the essential characters are invariably the same."

The Kootki of the Indian Pharmacopœia was there referred to *Picrorhiza kurroa* of Royle;* and this is confirmed in the Supplement by Mr. M. Sheriff, who affirms his belief that it is correctly assigned. There is no doubt that this determination may be relied upon as accurate.

The description which is given of the *Picrorhiza kurroa* is as follows:—(Nat. Ord. *Scrophulariaceæ.*) Root thick. Stem very short. Leaves sub-radical oblong, serrato-crenate, narrowed at the base into the short petiole, slightly rugose, smooth, or with a few scattered hairs. Peduncles scapiform, many-flowered, aphyllous, or with a few small bracts. Flowers sessile, in a dense spike, bracts lanceolate. Calyces with a glandular pubescence 2–2½ lines long, segments lanceolate, acute, subequal. Corolla shorter than the calyx, four-cleft to the middle. Stamens three times the length of the corolla. Capsules six lines long, acuminate, acute. Testa of the seed twice as long as the seed itself.

To this description we may add that portions of dried plants from time to time, picked out from samples of the Kutki, corresponded in the following particulars, although neither flower nor fruit has yet been found under those circumstances:—"Stem from 2 to 4 inches long; about the thickness of a large goose-quill; curved or bent; rough from many thin circular or semicircular scales; reddish-brown externally and black internally; very bitter in taste, occasionally divided into two stems; generally terminates in 2 or 3 small branches, which are seldom longer than an inch; soft and swollen when soaked, which indicates its fleshy condition when fresh; leaves when moistened and opened, are obovate with a very long, narrow and tapering base, which looks in the dry state like a petiole, sessile, serrate, anguli-nerved and glabrous."† There can be no doubt of the identity, though this evidence is rather circumstantial and incomplete.

The native names which are given for this drug are as follows:—Kharbage hindi, Arabic and Persian; Kutki, Hindustani and Bengali; Kali-kutki, Dukhni; Katuku-rogana, Tamil; Katuka-rogani and Katuku-roni, Telugu; Katu-rohani, Sanskrit; and Kalu-rana, Cinghalese. Of course, the Kadagaroganie of the Pharmacopœia is only another mode of writing the Katuku-rogana of the Tamils.

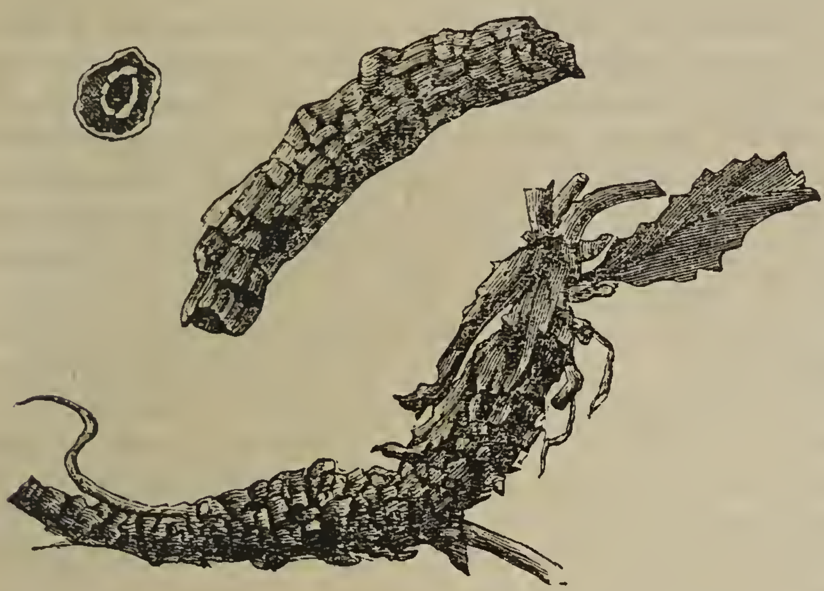
This drug, as we have usually seen it, was very much broken up, so that it consisted of fragments from an inch to two or three inches in length. Its

* Royle's 'Illustrations of the Botany of the Himalayas,' p. 291, plate lxxi.

† 'Supplement to the Pharmacopœia of India' (1869), p. 279.

more complete character can best be given in Mr. Moodeen Sheriff's own words:—

"Although this drug is commonly known as a root, it consists partly of the root and partly of the stem; therefore, if it is entire, the upper portion



(stem) differs from the lower (root) in external characters. The upper portion is about two or three inches long; very rough, from thin scales; brown or reddish-brown in colour if the scales are not worn out, but paler if they are so; in the latter condition it bears circular or semicircular marks of the scales, which occasionally make it look slightly annulated; varies in thickness from one to three goose-quills; beset with the remains of leaves; and often curved and sometimes bent upon itself. The lower portion is much thinner, varying in thickness from a quill of a fowl to that of a goose; paler in colour, being generally brownish-grey or brownish-white; nearly of the same length as the upper portion; more or less compressed; wrinkled longitudinally; and beset with elevated marks of rootlets. There is no difference between the colour and taste of the internal substance of both portions, which are black and extremely bitter, respectively. The root is generally cylindrical, but, from having the upper portion much thicker than the lower, it looks tapering sometimes. It is very light and brittle, and easily powdered." The deep black colour and short waxy fracture of the inner portion of the root are very characteristic features.

This is strictly an Indian drug. The localities given for the plant are Gossain Than, Kumaon and Kedarkonta. It has been said to occur also in some mountains near Chittoor, in Central Carnatic, but the Himalayan region is evidently the source of the bazaar drug, which goes down to Calcutta, and thence to Madras and probably to Bombay. Dr. Stewart says that it is common in the Punjab Himalaya, at from 5,500 to 14,000 feet. Honigberger declares that it is more frequently used in veterinary than in human medicine, but in the latter its root is one of the regular febrifuges. It must be used in considerable quantity, as the author of 'Punjab Plants' states that thirty-six maunds were exposed for sale from Kúllu at the Rampúr fair in Bissahir, in 1867. Davies' Trade Report gives twenty maunds of Kutki as annually exported from Peshawar to Kabul.*

The reputed purgative properties of this substance have no foundation in fact; its great use lies in its being a very valuable tonic, in which respect Assistant-Surgeon Moodeen Sheriff considers it equal to gentian and colomba, and superior to chiretta. As a dose, 10 to 20 grains as a tonic; or 20 to 40 as an antiperiodic, are recommended. If this is really a just appreciation of the value of this drug, it no longer deserves to be placed amongst the "non-officinal," but to rank with the officinal substances of the Indian Pharmacopœia. Further than this, if it has proved superior to chiretta in India, why should it not receive a fair trial, in competition with gentian, colomba and chiretta, in this country? Both this and the Atees root (*Aconitum heterophyllum*) deserve a full and fair trial, which neither of them have yet obtained.

* See Dr. J. L. Stewart's 'Punjab Plants,' p. 163. Lahore, 1869.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

ARGENTI OXIDUM.—Solution of nitrate of silver is poured into lime-water, the latter being in very slight excess. The precipitated oxide is allowed to settle and washed with distilled water:—

$$CaO + 2AgNO_3 = Ca2NO_3 + Ag_2O.$$

Lime-water is preferred, in this case, to solution of potash or of soda. When these are used the oxide is apt to be mixed with small quantities of carbonate and chloride, and also retains traces of the alkali, which it is very difficult to remove by washing.

Oxide of silver is a very powerful agent of oxidation, yielding its oxygen so readily to many organic substances, particularly essential oils, as to give rise to active combustion. It is also decomposed by common salt and all chlorides, and by many other salts. In dispensing it, therefore, these facts ought to be borne in mind.

ARGENTUM PURIFICATUM.—Metallic silver, free from copper and from all but mere traces of other metals, is obtained by dissolving crude silver in nitric acid and precipitating the whole in the form of chloride by the addition of common salt. The precipitate separated from the solution is placed in a dish, wetted with dilute sulphuric acid, and a sheet of zinc laid upon it. In about twenty-four hours the decomposition is complete, the zinc is removed, and the residual sponge of metallic silver digested with dilute sulphuric acid and finally washed. If desired, it may then be melted into a mass.

[§ If ammonia be added in excess to a solution of the metal in nitric acid, the resulting fluid exhibits neither colour nor turbidity.] This test indicates freedom from copper and lead.

BISMUTHI CARBONAS.—Dissolve purified bismuth in slightly diluted nitric acid, and add this, in small quantities at a time, to a solution of carbonate of ammonia. Collect, wash, and dry the precipitate by a gentle heat.

On dissolving the bismuth in the nitric acid, the following reaction occurs:—

$$Bi_2 + 8HNO_3 = 2(Bi3NO_3) + N_2O_2 + 4H_2O.$$

And when the solution of this nitrate of bismuth is added to the carbonate of ammonia, brisk effervescence ensues from the escape of carbonic anhydride.

$$\underset{\text{Nitrate of Bismuth.}}{4\,[Bi\,3\,NO_3]} + \underset{\text{Ammon. Sesquicarb., B.P.}}{3\,[(NH_4)_4O_2(CO_2)_3]}$$
$$= \underset{\text{Nitrate of Ammonium.}}{12\,NH_4NO_3} + \underset{\text{Gas.}}{7\,CO_2} + \underset{\text{Carbonate of Bism., B.P.}}{2\,(BiO)_2CO_3}.$$

The formula of the carbonate of bismuth is best written as shown in the equation. The radicle BiO is univalent, for the same reasons as the analogous compound SbO. [See Antimon. Tart.] It forms a series of salts, by combining with acidulous radicles. They are more stable than the normal salts of bismuth.

	Salts of Bismuth.	Salts of Oxybismuthyl.	
Chloride .	$BiCl_3$	$(BiO)'Cl$	
Nitrate . .	$Bi\,3\,NO_3$	$(BiO)'NO_3$	B. P.
Carbonate .	$Bi_2\,3\,CO_3$	$(BiO)'_2CO_3$	B. P.
Oxide . .	Bi_2O_3 or	$(BiO)_2O$.	

Some of them, however, may be viewed as containing (HO) in union with the bismuth instead of O. The official nitrate would thus be a compound intermediate between the hydrate and the nitrate.

$$\underset{\text{Hydrate.}}{Bi\begin{cases}HO\\HO\\HO\end{cases}} \quad \underset{\text{B. P.}}{Bi\begin{cases}HO\\HO\\NO_3\end{cases}} \quad Bi\begin{cases}HO\\NO_3\\NO_3\end{cases} \quad \underset{\text{Nitrate.}}{Bi\begin{cases}NO_3\\NO_3\\NO_3\end{cases}}$$

(Intermediate Compounds: the second and third.)

Carbonate of bismuth is a white powder insoluble in water, but soluble with effervescence in nitric acid. The nitric acid solution, if it contain not too much free acid, will give a white precipitate of subnitrate (hydrate-nitrate) on being poured into water. This precipitation of the acid solution by water is almost characteristic of bismuth. Chloride of antimony, which acts in a similar manner, is distinguished by forming by sulphuretted hydrogen an orange-coloured precipitate; bismuth gives a black sulphide.

[§ The nitric acid solution of carbonate of bismuth gives no precipitate with diluted sulphuric acid nor with solution of nitrate of silver.] The former of these tests indicates the absence of carbonate of lead, the latter the absence of oxychloride of bismuth.

[§ Carbonate of bismuth added to sulphuric acid coloured with sulphate of indigo, the colour of the latter is not discharged.] Freedom from any appreciable quantity of nitrate is thus ensured.

Bismuthi Subnitras.—Purified bismuth is dissolved in nitric acid, the solution reduced by evaporation, and then poured into water. The precipitate which forms is washed once, drained, and dried by a very gentle heat. The nitrate formed by dissolving the bismuth in nitric acid is converted into hydrate-nitrate (see Bism. Carb.) by the action of the water; thus—

$$Bi\,3\,NO_3 + 2\,H_2O = Bi\,NO_3(HO)_2 + 2\,HNO_3.$$

A little nitrate of bismuth is retained in solution, and, if the washings are not preserved, is lost.

Subnitrate of bismuth is recognized as a bismuth salt by the reactions described in connection with the carbonate. It is also liable to the same impurities. In addition it has been found to be extensively adulterated with phosphate of lime. To detect this substance, dissolve a portion of the sample in dilute nitric acid; precipitate out the whole of the bismuth by a stream of sulphuretted hydrogen; filter the liquid, and heat it to expel excess of H_2S. Test a small portion for phosphoric acid, by adding a slight excess of molybdate of ammonium; a yellow precipitate will be formed. Test another portion for calcium, by neutralizing by ammonia, then adding acetic acid in excess, and lastly a soluble oxalate. A white precipitate of oxalate of calcium will be formed.

Bismuthum purificatum.—The process of purification recommended in the Pharmacopœia consists in fusing commercial bismuth with the addition of a small quantity of nitre. Besides being very wasteful of the bismuth, this method is inadequate to the removal of the whole of the impurities usually present. Arsenic and lead are oxidized and carried off in the scoria; but the greater part of the copper which exists in most samples, and the silver, when that metal is present, are left in the fused metal. Probably the only method by which pure bismuth can be obtained consists in dissolving the crude metal in nitric acid, precipitating by the addition of water, and washing the precipitate. This by ignition would be converted into the oxide, and the oxide into the metal, by heating it with charcoal.

Bismuth, considering it as a metal and not as a metalloid, is a very fusible substance. Its melting-point is a little over 500° F.; specific gravity 9·8.

PLANTS AS MANUFACTURERS.

(*Concluded from page* 487.)

Many of our manufacturers excel in the art of packing, but never were goods so well or so closely packed as the coal measures. Living plants are likewise most skilful in this line. All their products are done up in handy bundles for transportation or conveyance to the end of the earth. Fancy the trouble it would have been to us had wheat grains been the size of quartern loaves, peas like dumplings, or apples big as pumpkins!

The packages of plants are not only of the best size, but the wrappers are mostly air- or waterproof. We all know the importance of this with perishable articles. Hams, tongues, meats, and sweets can only be preserved in airproof packages. There is another singular peculiarity about the packing done by the plants. The entire plant is often stowed away within a single portion of it. Annuals are packed up within their tiny seeds, and bulbous plants within their bulbs. This is of immense importance for close stowage and safe distribution. This arrangement brings, as it were, the genial climes and bright suns of other countries to cheer and enliven this. What would many of our winter drawing-rooms and conservatories be without the sweetness and the beauty of good Dutch bulbs? These let loose before our admiring eyes all the grandeur and the fragrance born of John Dutchman's summer. In the same way Cape bulbs and orchids bring to us, ready for immediate use, the glories of the tropical sunlight and the warm tints painted by the heat of such climes.

Finally, plants are cleanly manufacturers. They make little or no dirt. They touch decomposition at all points, but it is to recompose it. They absorb foul odours, but they are no longer foul, they convert them into sweetness. No law is needed to make plants consume their own smoke. They make none. No stringent enactments need to be enforced about their chemical processes; they are inoffensive. No scavengers are required to gather up their rubbish,—they are their own scavengers. True, many of their working hands (the leaves) only live one year, and then seek a grave upon or within the earth. But these speedily disappear, and are, in fact, again taken into the factory to strengthen and enlarge it.

The penalty exacted from most great centres of manufacturing industry and commercial activity is an excess of filth in the air we breathe, the water we drink, and the earth we live on. It was recently stated that Liverpool invites any disease that may be in the air, and that its foundations are tainted with disease. The town is about the most dangerous to live in of any in England, the rate of mortality being alarmingly high. Doubtless the shipping, the tramps, the emigrants are all dangerous at times to health, and there seem to be other and special centres of contamination and pollution in the chemical works, and the immense numbers of bricks burnt in clamps round the suburbs. I think I never smelt so many or such curious odours as around Liverpool. It seems as if King Sulphur had been shaking himself up, and his fumes almost stifle the breath of strangers. Add to all these the inevitable pollutions arising from work, traffic, life combustion, respiration, decomposition, all fouling great towns to the utmost of their capacity. We ourselves die daily, and, were our eyes set to a finer vision, we should see portions of every one of us in the apparently pure air of a room.

Is it asked what all this has to do with the manufacturing power of plants? It has everything to do with it. Plants are the cleanliest of all manufacturers, but we have seen that they are also shoddy merchants. More, they are chiefly this, they deal in pollution, and it is only through plants that the great problem of the day—"What shall we do with our dirt?"—can be solved. There is no other mode of extinguishing dead matter but by its conversion into living substance, and plant manufacturers are alone equal to this stupendous undertaking. All other possible means have been tried and failed. We have sent our waste up into the air, and it has returned to us in fevers and pestilences. We have turned our streams of reeking sewage into rivers and seas until our great drinking cisterns have been poisoned at their sources. Then the more sensible cry arose, "To the land with your foul waste!" But the earth is tolerably full of graves already, and if we turn it into a great dry-earth closet or huge sewage-sponge, there is great danger that by-and-by it may revolve round the sun a fever-stricken world of pestilence and death. The antidote to pollution is living plants; these absorb, transform, utilize, and annihilate it. They weave these elements of disease and death up into the very staff of life. It may be said that such manufacturers do not thrive in towns. The few there are refuse to grow. The remedy for this is, more of them. Send 100 brave soldiers against 10,000, and no courage or skill can save them from destruction. It is just so in their case; pollutions abound in all directions, and you send out against them a few ragged hosts of weakly trees. The chief remedy for the alarming death-rate is more trees around the suburbs, all the open spaces in the centre of the city filled with sweet flowers. Fight fever with the sweet incense of lovely flowers, annihilate it with the absorbing force of fever-consuming leaves.

The balance of parties, or rather forces, in the atmosphere is in great danger of being upset. A tremendous run is made in these centres of life and hives of industry for oxygen. We neither live nor work without it. On the other hand, whole volumes of dead carbon and other pollutions are thrown into the atmosphere. An actual scarcity of the former, and an excess of the latter, means suffering or death to us all. How shall we rally to the defence of the atmospheric constitution? We have no choice of instruments, we have but one, but that is all-sufficient. Plants alone can drain the air of its excess of carbon, and return to it a pure stream of oxygen. Every leaf, stem, and flower is employed night and day in restoring the atmospheric balance to an equilibrium; and, upon the whole, they have done their work perfectly. Here and there, and over large towns, there are certain changes,—an excess of foreign matter, dust, etc. in the air; but, as a whole, its constituent parts are the same. To rectify these partial changes which are so fatal to health, we must plant more extensively. Girdle each city round with a wide band of grand trees and green parks. Sentinel the streets with officers (sanitary trees) at regular distances, in green or golden uniform, that will rest not from their labours day or night, nor leave for an instant their posts of danger and of duty; enwreathe the houses, homes, workshops, warehouses, mills and factories with garlands of leaves and flowers; crowd the house-tops, window-sills, yards and areas with objects of beauty and fragrance; let flowers wave down to us a joy from every giddy garret, and send up a symbol of trustful hope from every deep dank cellar, until they cover and gladden the earth as the "waters cover the channels of the sea."

Plants are the true patron saints of these hardworking utilitarian times. Their perfume is the best of all antidotes to all foul odours. Their life is a warfare with elements that would be death to us. They gladden, purify, and ennoble the highways and byways of life, providing for rich and poor, manufacturer and mill hand, prince and peasant alike, those grandest preservatives of health, a clean earth, pure air, and clear water. The ministrations of plants to man are constant. They never leave nor forsake us. They meet us on the threshold of life, they abide with us to the last. None are too poor to enjoy flowers, none so rich as to be able to dispense with them. Through plants we live, move, and have our being. They distil for us the breath of our life. They raise our water, they make our food. They provide our clothing, our medicine in sickness, our strength in manhood, our sweet interpreters in love, our solace in suffering, our transfigurators at death. Through the agency of plants the worlds of matter and of life are linked together, and the three kingdoms—the vegetable, the animal, and the mineral—are united in bonds closer than those of holy matrimony. They clothe the invisible air, and the wondrous light, heat, chemical force, and energia of the sun with bodies of marvellous symmetry, beauty, sweetness, and glory. The Poet Laureate has said or sung that "Nature slopes through darkness up to God." As we try reverently to look through the mist that hides the life and the work of plants from our eyes the veil of darkness is partially rent asunder, and we exclaim, as we catch a glimpse of the wisdom that plans, the goodness that guides, and the power that governs all, that Nature is, in deed and in truth, the outer fringe of the glorious garment of God.

ON THE COMBINATIONS OF CARBONIC ANHYDRIDE WITH AMMONIA AND WATER.

BY EDWARD DIVERS, M.D.

(*Continued from page* 486.)

Behaviour on Exposure.—Two clean lumps of the compact carbonate, the analysis of a sample of which is numbered XII. in the list given *ante*, p. 485, weighing together 25 grams, were exposed for some weeks at a mean temperature of about 10° C., and then weighed. They were found to have lost nearly 11 grams in weight; they were opaque, but they still preserved their shape and size. They could be lightly handled without soiling the fingers, and squeezed pretty firmly without being crushed. They were found to be fully changed to their centre. Their loss corresponded to 43 or 44 per cent. This nearly agrees with the calculated loss, which is about 42 per cent., if the amount of acid carbonate in the sample be approximately estimated by the quantity of water in it, according to the tables, *ante*, p. 485. The calculated loss by exposure of the carbonate formerly in commerce of the formula $(CO_3)_3(OH_2)_2(NH_3)_4$ is only 33 per cent. A sample of commercial carbonate lost by 24 hours' exposure, according to Dalton, 50 per cent. of its weight: this makes it probable that it had the composition I find the carbonate to have at present, for when free from any water in addition to that in the formula, this is just its calculated loss by exposure. In cold moist weather the commercial carbonate appears to be slightly deliquescent, but in consequence of other changes it is difficult to decide this point conclusively.

Behaviour when Heated.—The commercial carbonate gets moist when heated; it is, of course, gradually dissipated. The products of its distillation will be afterwards described.

Behaviour with Water.—It dissolves in four parts of water at 15°, according to my experiments. Perfectly clean lumps were weighed and dropped into a weighed quantity of water (fresh boiled and cold) in a stoppered bottle; the bottle was kept in a place at a temperature always very near 15°, and was often agitated. In different experiments varying proportions were used. On cooling slightly the saturated solution, it deposited crystals of acid carbonate. Cooled in ice the deposit of crystals was still more copious, and consisted always of acid carbonate; although it has been stated* that the half-acid carbonate then crystallizes out. As above determined, its solubility accords with that of the acid carbonate it contains, namely, about half its weight. The solubility of the carbonate which used to be in commerce has been variously stated as lying between that of 1 in 2 of water, and 1 in 4 of water; I think it must have been less than this. A saturated solution, unlike one of the acid carbonate, or of the half-acid carbonate, does not act like a saturated solution of carbonic anhydride. The strongest hot solution I have been able to make is that of 1 in $1\frac{1}{2}$ of water. This was made by dropping this proportion of the carbonate, crushed small, suddenly into the hot water contained in a wide-mouthed bottle fitted with a caoutchouc stopper, then closing the bottle and keeping it hot in the water-bath at a temperature of about 65° C. Only a little carbonic anhydride was lost. When made, the stopper of the bottle containing it could be withdrawn without anything more than a very slight escape of bubbles. The old carbonate of commerce is stated in Berzelius's 'Lehrbuch'† to be soluble in twice its weight of water at 49° C.

A cold saturated solution of the old carbonate was stated by Griffiths‡ to boil at a temperature of 82° C. John Davy found such a solution to decompose at a lower temperature than this, bubbles beginning to appear at 49° C. I have tested the modern carbonate, and find a solution of it of 1 in 4 begins to effervesce, though only slightly, at 60° C., effervesces copiously at 75°, and continues to do so as the temperature rises, which it does rapidly. At 85°, or a little below, the products of effervescence, which before consisted almost entirely of carbonic anhydride, contain much ammonia, and begin to condense on the neck of the flask or retort. At 100° C. the solution has given off all the carbonate it contained, and is nothing but water (Griffiths). I have just stated that the cold saturated solution differs from the saturated solution of half-acid carbonate, in not behaving like a saturated solution of carbonic anhydride; and there can be no doubt that this fact, and that of the point of incipient effervescence in the two solutions when heated being different, are due in part to the difference in the ratio of the ammonia to the carbonic anhydride in them. The following experiment shows the effect of dilution upon the production of effervescence. Some of the same solution as that used in the previous experiment was mixed before heating with an equal bulk of water (freshly boiled and cooled), and then did not begin to effervesce until about 70° C., was only in full effervescence at 80° C. or higher, and only at 90° C. began to yield products of effervescence, which condensed in the neck of the flask. In both these experiments the heat was applied by a water-bath. Griffiths' statement must not be supposed to be so much at variance with that of J. Davy as the latter seemed to consider it; for Griffiths meant apparently by the boiling-point of this solution the point at which the products of the effervescence begin to be such as undergo condensation, and this would probably occur with the old carbonate at about 82° C.

The action of a saturated solution upon more commercial carbonate is well known to be the production of a sort of skeleton of the pieces of carbonate, consisting of the acid carbonate. I have only to add that by prolonged digestion I have found the particles of this mealy skeleton to grow into, or be replaced by, transparent crystals of the same substance.

I have examined the effects of heating the commercial carbonate with a little water, and have found that bubbles of carbonic anhydride escape through the solution from the undissolved lumps at a lower temperature than they escape from a cold saturated solution heated alone. Thus, from about 40°–45° C. very slight effervescence was visible, due probably to an escape of the air entangled in the pores of the carbonate. At 47° decided effervescence commenced; this became copious at from 54°–56°, and at this temperature crystals began to form in the neck of the flask. (In this and the preceding experiments the mouth of the flask, as I should have mentioned before, was loosely closed so as to prevent diffusion of the vapours given off.) Cooled down to 51° the escape of bubbles ceased. Heated again and kept at from 56°–60° effervescence went on again, the condensation of the vapours appeared to be complete, and the lumps which had originally been barely covered with water disappeared entirely in a couple of hours. During their solution they seemed to dissolve entire, for no temporary residue of acid carbonate or any loss of translucency in the lumps was seen. The products of the distillation were examined, and the results of the examination will be found among those of the examination of the products of distillation. The solution on cooling deposited crystals first of acid carbonate, and then of half-acid carbonate, determined to be such by their form. The mother-liquor was a very concentrated solution of normal carbonate, with a very little acid carbonate. Tested for carbamate the result was negative. A modification of this treatment of water with the commercial carbonate, by which the three ammonium carbonates can be obtained, has been several times referred to in this paper.

Behaviour with Alcohol.—It is well known that rectified spirit dissolves out carbamate from the commercial carbonate, leaving undissolved the acid carbonate. Hünefeld,* in 1836, heated the commercial carbonate with spirit of 90 per cent., and found that at 47·5° C. some bubbles began to rise from the lumps, that this phenomenon became quite evident at 50°, and that from 56° to 62° there was copious effervescence of nothing but carbonic anhydride. Above this temperature the gases escaping condensed in the neck of the retort as a neutral compound, and the distillate which now formed was a neutral solution. I have repeated the experiment of heating the carbonate at present in commerce with spirit of about 90 per cent., with somewhat modified results. Of the products of distillation I shall say nothing at present. Minute bubbles began to escape from the lumps at 41°; at 45° there was very evident effervescence from the lumps; at 50° there was copious effervescence with a simmering noise; at 51° the products of the effervescence began to condense; while at 53° the effervescence was exceedingly great. The temperatures observed by me as marking the stages of this phenomenon are, therefore, lower than those observed by Hünefeld. The heat was applied by means of a water-bath, and the flask was loosely closed by a caoutchouc stopper to pre-

* Pelouze et Frémy. 'Traité de Chimie,' vol. ii. p. 483 (1861).

† Vol. iii. p. 313.

‡ 'Quarterly Journal of Science' (1825), vol. xviii. p. 91. "On the Boiling-points of Saturated Solutions."

* Journ. für prakt. Chemie, vol. vii. p. 25.

vent diffusion. On keeping the spirit for some hours at 52°, effervescence continued, and there was little or no loss of spirit; at the end of the operation the neck of the flask had become only thinly encrusted with the products of the effervescence, and the carbonate had only partly dissolved. The lumps on removal appeared externally to be but little altered in structure. Internally, too, they were unchanged; for fragments yielded on analysis 54·51 per cent. of carbonic anhydride, and 32·22 per cent. of ammonia. The spirit proved to be a little weaker than before, dry pearl-ash separating a little water. It contained a little ammonium carbamate, still less ammonium carbonate, and a marked though small quantity of ammonia. Left at a temperature of about 0° for two days, it did not crystallize.

Behaviour with Ammonia.—Concentrated ammonia-water in the cold dissolves out carbamate, and converts the acid carbonate into normal carbonate, either by removing half its carbonic anhydride, or by combining with it an atom of water. The commercial carbonate digested at 20°–25° in a closed vessel with a saturated solution of ammonia, as already described in the case of the normal and acid carbonates, slowly dissolves in apparently unlimited quantity, and the solution deposits on cooling crystals of ammonium carbamate, and a very little normal carbonate. The reaction may be thus represented:—

$$(CO_2)_2OH_2(NH_3)_3 + NH_3 = 2CO_2(NH_3)_2 + OH_2.$$

Behaviour when Heated with Anhydrous Potassium Carbonate.—As already described, the gases evolved condense to carbamate, ammonia escaping, according to this equation:—

$$(CO_2)_2OH_2(NH_3)_3 \quad + \quad CO_3K_2$$

$$= 2CO_3KH + \overbrace{CO_2 + 2NH_3}^{\text{Forming carbamate.}} + HN_3.$$

The contents of the retort have been found, in accordance with this equation, to be more or less completely acid potassium carbonate.* For a short time after the mixture is made, ammonia is evolved in very small quantity at ordinary temperatures, and escapes in bubbles through the mercury into which the beak of the retort is made to dip, but this is probably due to the presence of a little moisture. It is only at from 50°–60° that a material reaction is set up; and here a phenomenon presents itself which is of considerable interest. Nothing but ammonia is given off, and by maintaining the heat at 60°, this evolution of ammonia can be nearly or quite terminated before any carbamate-forming gases come off. It is not until the temperature is carried to 65° that the formation of carbamate begins, and not until it is carried on towards and up to 80° that the whole of the carbamate is obtained. Hence the reaction occurs distinctly in two stages, according to the following equations:—

$$\begin{aligned}\text{1st stage: } & (CO_2)_2OH_2(NH_3)_3 + CO_3K_2\\ &= NH_3 + CO_2(NH_3)_2,\ 2CO_3KH.\\ \text{or } &= NH_3 + CO_2(NH_3)_2,\ CO_3KH + CO_3KH.\\ \text{2nd stage: } & CO_2(NH_3)_2,\ CO_3KH\\ &= \underbrace{CO_2 + 2NH_3}_{\text{To form carbamate.}} + CO_3KH.\end{aligned}$$

Further proof of a union of the acid potassium carbonate with ammonium carbamate is afforded by the facts that on distilling the commercial carbonate with calcium chloride, the components of the carbamate are driven off at a temperature of 52°–65°, and that on heating carbamate alone, it is converted into vapour at 59° or 60°; whereas in the present case the carbamate is not formed until the temperature reaches 65°, and passes on to 80°. The special interest of this point is its bearing on the difficult question as to whether the commercial "carbonate of ammonia" is a double salt or only a mixture of salts.

Behaviour when heated with Anhydrous Calcium Chloride.—At a temperature of 50°–52°, the mixture evolves gases, a part of which condenses as carbamate, that escaping being carbonic anhydride; from this temperature up to 60° or so, the reaction goes on steadily, but the escape of carbonic anhydride greatly diminishes; how far the rate of formation of carbamate also slackens I have had no means of determining. The residue in the retort consists of unchanged anhydrous calcium chloride, of calcium carbonate and ammonium chloride.

When solid calcium chloride, with about two atoms of water, is mixed in coarse powder with the commercial carbonate, the smell of ammonia entirely disappears; and soon after the mixture has been made it gets warm, swells up considerably, and evolves quantities of carbonic anhydride. When the action is over, on heating the mass to 50° or above, more carbonic anhydride is evolved. I happened in one case to be so fortunate as to mix the two in equivalent proportions. The consequence was that nothing was given off but carbonic anhydride and water. The residue was a porous mass of ammonium chloride and calcium carbonate. Treated with water, a solution was obtained which gave a faint precipitate with solution of ammonium carbonate and ammonia, and on the other hand a faint opalescence with calcium chloride. The insoluble matter was calcium carbonate.

(*To be continued.*)

* The commercial carbonate of ammonia and sodium carbonate heated together have been used as a source of ammonia and bicarbonate of sodium.

MALT EXTRACT.

BY ALBERT E. EBERT.

The present time in the history of pharmacy may rightly be styled the era of "scientific specialties." The latest efforts in this direction are malt extracts. Two classes of preparations, under this title, are met with in the market, having widely different properties; one variety may be classed among alcoholic beverages; the other is purely saccharine in nature. To the first belong the preparations of Hoff and of Koch, the latter bearing the name of Liebig. Hoff's extract has obtained a ready sale by aid of extensive advertising, a fact which is surprising, after the exposures made by Hager and Wittstein. These chemists determined it to be simply a good article of *brewer's beer*, having an alcoholic strength of about 3 per cent., with an addition of marshmallow root, coriander, star-anise and grains of paradise, sweetened with glycerine or sugar, flavoured with the oils of lemon and orange, and coloured with burnt sugar. Koch's preparation purports to be similar to Hoff's, with the prominent advantage, well set forth in the words of the proprietor as follows:—"Owing to the facilities we have in manufacturing in this country, we are enabled to sell Koch's extract at the astonishingly low rate of $3.00 per dozen, or 30 cents for a single bottle." He magnanimously offers to suffering humanity lager beer at only six times its retail value, while Hoff charges about 50 per cent. more for the same article! How thankful we should be for his fortunate "advantage," and we must also feel deeply grateful after perusing the circular which accompanies this great medicine:—"The most eminent medical authorities in Europe, as well as in this country, agree that this new tonic is the best *dietetic and healing remedy* known to modern science, combining both the merits of a nutritious and palatable beverage, and the virtues of an unfailing medicine for general diseases of the lungs, the chest and the throat, while to those in good health it serves as a *pleasant table drink*, promoting their digestion and restoring and invigorating their appetite—(for what?). This malt extract offers the most beneficial relief to the sick all in cases where the stomach, the lungs or the throat are affected."

The reader will say, "But medical men do not recommend such nostrums." In reply, we will state that we have had prescriptions for this beer from men who lay claim to a scientific training, and have in each case advised the patient or messenger to procure the same by the gallon at some saloon, where they may obtain it at first cost.

This proves the truth of the saying, "There's something in a name;" and malt extract is equally as good a term as the celebrated strengthening tonic, "Stomach Bitters," whose chief advantage is the quantity of alcohol hidden by the high-sounding titles, and made into a fancy tippling drink by the aid of a few bitter roots, herbs and spices. But the greatest shame of all is the frequent recommendations and endorsements by letters which are published by the factors of these vile nostrums, and scattered broadcast to the public; and these testimonials are frequently from men who occupy prominent positions in science,—yes, even teachers in medical colleges. But, alas! we were lately astounded by seeing such an endorsement from a gentleman occupying the chair of Pharmacy in the St. Louis College of Pharmacy. His private endorsement might have been overlooked, but when he attached to his name his position in the College, to give it extra weight, he gave an insult to the entire organization in which he holds the office of a teacher; the remedy of making a few examples by excommunication would go far towards stopping this prostitution of our profession to such base uses.

Of the second class of malt extracts, sometimes called Liebig's, we have seen two samples from German manufacturers, Ed. Loeflund and Dr. H. E. Linck, both of Stuttgart. They were put up in patent medicine style, each claiming originality in the process of manufacture. This point is questionable, as malt extract has been officinal in the London, Edinburgh and Belgium Pharmacopœias, and in long use in Germany under the name of malt sugar (*Gersten-zucker*).

Professor Liebig does not lay any claim to the discovery or introduction of this preparation. We have heard him, during his lectures, denounce this attachment of his name to these extracts, it having been done in opposition to his wishes by parties who hoped to increase their sales by this seeming endorsement of their articles. We have lately made the malt extract at the urgent request of physicians, and give herewith the process, so that pharmacists may prepare it themselves, instead of relying upon the specialist to supply it at exorbitant prices.

Take of Barley Malt, kiln dried, 10 lb. av.
Water, q. s.

The malt can be obtained at the malt-houses or breweries by the bushel; reduce it by means of the drug mill so that it will pass through a No. 20 sieve, and add to the meal a sufficient quantity of cold water to form with it a soft dough; then add about two gallons of hot water, and apply heat so as to raise the temperature of the mixture to 150°, or not to exceed 158°. Maintain this temperature, with occasional stirring, for several hours, or until the whole of the starch is converted (by means of the diastase of the malt) into dextrine and glucose. The absence of starch can be ascertained by the application of tinct. iodine to a small quantity of the liquor, when, if the starch has been wholly converted, no blue coloration will be evident. Then express the liquor rapidly, and pass it through a strainer. This is the most difficult part of the process, as it speedily clogs the strainer. This can be averted to some extent by making a pulp by means of water from common unsized paper, or filtering-paper, and mixing this pulp with the expressed liquid previous to straining. The perfectly clear fluid is finally to be evaporated, by means of a water-bath, to the consistence of a thick syrup, having the sp. gr. 1·500, or approximately one pint, weighing $1\frac{1}{2}$ lb. av.

This extract has an agreeably, syrupy taste, and contains, besides the sugar of the malt, dextrine, albumen, and the phosphates of the grain. In very hot summer weather it is liable to go into fermentation, but this can be prevented by the addition of a small quantity of glycerine.—*The Chicago Pharmacist.*

Suicide by Carbolic Acid.—An inquest was held a few days back upon the body of a servant girl, who was found by her master lying dead in her room. It appeared from the evidence that she had been in depressed spirits, and suffering from pains in her head, and had committed suicide by drinking a quantity of carbolic acid, which had been obtained for disinfecting purposes. The coroner, Dr. Lankester, said the public ought to be put on their guard respecting this compound.

The Royal Society Medals.—The following award of medals was made at the annual meeting of the Royal Society on Nov. 30th:—The Copley medal to Mr. James Prescott Joule, F.R.S., for his experimental researches on the dynamical theory of heat; a Royal Medal to Professor W. H. Miller, Foreign Secretary to the Society, for his researches and writings on mineralogy and crystallography, and his scientific labours in connection with the national standard of weight; a Royal Medal to Mr. Thomas Davidson, F.R.S., for his work on the recent and fossil brachiopoda; and the Romford Medal to M. Alfred Olivier des Cloizeaux, for his researches in mineral optics.

How to Apply Leeches.—A correspondent in the *Lancet* writes, that having had occasion to order a mustard-poultice for a patient, it became requisite to put some leeches on the same place. He was told that they fastened instantly, filled rapidly, and that the blood streamed afterwards into bread-poultices as if it would never stop. Now, whenever he orders leeches, he always has a mustard-poultice applied first, then the leeches (two or three instead of half-a-dozen), and then bread-poultices. The flow of blood is, however, sometimes so much greater than would be thought likely or possible, that it is necessary to add a few words of caution,—an adult female patient, of average strength, bled to fainting from only two leeches applied in this way.

Origin of Malaria.—*The British Medical Journal* in noticing a book by Dr. Taussig, alludes to the theory of Dr. Balestra, who considers the malaria prevalent at Rome to be due to the seeds of a microscopic alga constantly present in all marshes, for whose vegetation and propagation the necessary conditions are stagnant water, a high temperature, and the vicinity of decomposing vegetable matter. These spores, he says, can be introduced into the system by the stomach, lungs, or skin, but when brought into contact with a solution of either sulphite of soda, arsenic, or quinine, they lose all power of vegetation, and undergo a change of structure.

Almond Powder for Preparing Emulsions.—M. Ch. Menière suggests the following means of facilitating the dispensing of almond emulsions: Make an emulsion of almonds blanched, 50 grams, and water, then add 300 grams of sugar in powder, and evaporate with a gentle heat until the mixture assumes a pasty consistence; spread it upon plates, dry thoroughly by artificial heat, and reduce it to powder, adding five grams of pulverized tragacanth. To prepare the emulsions of the Codex, take of the powder 32·5 parts, and triturate with orange-flower water 10, common water 120 parts. According to M. Menière, an emulsion can thus be speedily prepared, and leaves nothing to be desired.—*Journ. de Pharmacie et de Chimie.*

Syrup of Iodide of Iron.—M. Jeannel has observed that the addition of $\frac{1}{5000}$ part of tartaric acid renders syrup of iron clear when it has decomposed, at the same time diminishing notably its inky taste.—*Bull. de la Soc. de Pharm. de Bordeaux.*

The Pharmaceutical Journal.

SATURDAY, DECEMBER 24, 1870.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes endorsed "Pharm. Journ."*

THE PROPOSED POISON REGULATIONS.

IN referring last week to the decision of the Council to submit a code of regulations for the keeping of Poisons to the Annual Meeting of the Society in May next, we felt constrained to express a hope that the prevailing divergence of opinion on this subject might not be allowed to damage the real interest (by which we meant the advancement) of Pharmacy as a craft. The letters which we publish this week evidently show that earnest attention is being directed to the subject. Several others, which have arrived too late for insertion in this number, also tell the same story. It cannot be denied that there is a great difference of opinion, and it will, we presume, be readily admitted, that both parties to the argument are honest, the one in advocating, the other in deprecating, any action in this matter. While abstaining from comment on the arguments brought forward by our correspondents, it seems that, in furtherance of the hope we expressed last week, it is our duty to urge upon members of the trade, for the sake of avoiding that mischance which struck us as possible, they should, in discussing this question, carefully dismiss from their minds every feeling of antagonism and, before the Annual Meeting, very carefully consider the proposition put to them by the Council,—a Council consisting of practical men, whose interests and mode of conducting business are identical with those of chemists and druggists in all parts of the country.

We think, too, that beyond mere *consideration*, there is ample time for *practical trial* of the methods proposed for storing poisons, and that such trial would enable both the advocates and opponents of regulations to speak more confidently as to the advantages or inconveniences attending those methods when the subject comes on for discussion in May next. There can be little doubt that there is a demand on the part of the public for some restrictions and that the officers of the Privy Council agree with and support that demand: moreover, our Council considers that the Pharmaceutical Society, in accepting the Pharmacy Act of 1868, also accepted the duty of promoting public safety and by implication, that of making regulations. It should be remembered, too, that the Council received instructions from the meeting of 1870 to consider this subject carefully, and present it again in 1871. It should also be borne in mind that, if we are to have regulations, no persons can be so well qualified to determine the nature of them as experienced men of our own body.

For all these reasons, therefore, we say, let the Council have credit for honesty and independence, and at least a fair hearing.

Having said thus much in the hope of confining controversy to its proper limits, we will conclude by again describing in detail the regulations as now proposed, noting also the alterations that have been made by the Committee, in the hope that our readers will test their applicability.

The first rule, and the only one to be universal, is that every poison shall be marked with its name, and shall bear, beyond that, a distinguishing mark which will be known to the dispenser as indicative of poison.

The alteration here is that the word "Poison," which it was feared would strike terror into the mind of customers, is exchanged for any mark a chemist may choose to employ, intelligible to himself and his assistants—say, a triangle, circle, or square.

We have then a proposition of three different and alternative modes in which poisons may be kept, and it should be distinctly understood the Committee does not recommend that a man should be compelled to select one of those three and apply it to all his poisons; such a course would be obviously impracticable. A chemist may apply any of the modes as best suited to his convenience; the first to one poison, the second or third to others.

These three modes of keeping poisons have not been altered in substance, but are now stated more clearly than formerly. It is proposed that poisons shall be kept either in—

(1.) A separate compartment for dangerous articles;

or,

(2.) Distinctive bottles or vessels;

or,

(3.) Bottles or vessels so tied over or secured that they cannot be opened by mere unstopping as the ordinary bottles are.

We observe that the proposal, to send out compounds, intended for external use in distinctive bottles, when they contain poisons, has been omitted from the new code. This alteration we understand was made by the Committee on account of difficulties which might arise as to procuring or keeping in stock at all times, a supply of such bottles, but notwithstanding this omission, we hope a custom so salutary and now so widely practised among druggists will not be discontinued.

THE POOR-LAW APOTHECARY-GENERAL FOR IRELAND.

In reply to several inquiries that have been made in connection with the above subject, we give, for the benefit of our readers, all the essential points contained in the general order of the Poor-Law Commissioners for Ireland; any further information would be supplied by the Commissioners on application by an intended candidate for the office, addressed to the Chief Clerk, Dublin.

The salary will be £500 per annum, with suitable apartments. Although this officer will be elected by the Guardians of the Unions, the Commissioners will have the power to discharge him.

The Poor-Law Apothecary will have to give security for the "due and faithful performance of his duties," in an amount not exceeding £5000.

The qualifications are—

"1. He shall be thirty years of age at least.

"2. He shall be a Licentiate of the Apothecaries' Hall of Ireland.

"3. He shall not, while holding the office of Poor-Law Unions Apothecary, be engaged or interested, either directly or indirectly, in any wholesale or retail trade of drugs, medicines, or medical or surgical appliances, or in any other trade or profession whatsoever."

The following is the copy of the mode of appointment:—

"On or before the 1st of January, in the year 1871, all candidates for the office of Poor-Law Unions Apothecary shall send their application and testimonials to us the said Commissioners, to be laid before the Guardians of each of the said Unions, who shall proceed at the second meeting after the receipt thereof to select the candidate of their choice in accordance with the rules prescribed for the appointment of officers after advertisement in the General Regulation Order, bearing date the 19th January, 1852, and shall report the result of such selection to us the said Commissioners, and the candidate selected by a majority of the Unions in the said schedule shall be deemed to be appointed the Poor-Law Unions Apothecary, and if no candidate shall have been selected by a majority of the whole number of Unions, so many of the candidates selected by the greatest number of Unions as shall together have been selected by a majority thereof, shall be again submitted to each Union, and the same process shall be repeated until one candidate shall have been selected by a majority of all the Unions named in the schedule."

There are about 160 Unions in Ireland, and they generally have weekly meetings of the Boards. We believe that the above contains all the necessary information that would be required by intended candidates. There are other officers to be appointed, but the Commissioners do not intend to open this question until after the election of the Apothecary, which is not likely to be finished until February, 1871.

THE BRITISH PHARMACOPŒIA IN CANADA.

In the November number of the *Canadian Pharmaceutical Journal* there is a curious commentary upon the statement made by Mr. Howden in his address at the last Evening Meeting, that wherever he went in the United States, the fact that he was a member of the Pharmaceutical Society of Great Britain secured for him the greatest kindness and the fullest information from every pharmacist with whom he came in contact. The Editor of that journal says that a letter had been received from a correspondent asking for information concerning the price of a work which he understood had been "recently published, and which, under the general title of *The British Pharmacopœia*, at once did away with the annoyance so often realized from the use of the different authorities representing the national colleges." The writer of the letter stated that he "went in strongly for progress," and that as he considered the publication of such a work to be a step in the right direction, he meant to obtain a copy of the Pharmacopœia at once, so as to be fully up to the times.

Of course it would not be fair to take such pharmaceutical Rip Van Winkleism as representing the general state of knowledge in the colony concerning our national Pharmacopœia, six years after its publication; neither, on the other hand, must it be taken for granted that the writer of the letter was far behind his neighbours, for it appears that he is a druggist doing a good business in a flourishing border town. Doubtless one of the causes of such a state of things is to be found in the absence, at present, of any authoritative direction that the British Pharmacopœia is the standard to be used; this evil it is proposed shall be remedied in the projected Canadian Pharmacy Bill; but another cause lies in the want of sufficient opportunities for obtaining sound pharmaceutical education. Besides these, there is undoubtedly another cause, viz. the strong influence which the United States Pharmacy exercises upon the Canadians. It is stated that if a prescription requiring tinct. arnicæ were to be sent to each druggist in Ontario, in nearly every case the United States' preparation would be used. There is also a tendency to favour the fluid extracts or concentrated remedies of that country, and to make use of the ingenious preparations which come under the category of "Elegant Pharmacy."

Whether the British Pharmacopœia be best suited to the wants of Canadian pharmacy, or whether Canada would be better off with a Pharmacopœia of her own, are points we are not at present prepared to discuss; but we think the fact with which we started is one that may not be without its use in toning down any exaggerated estimates that may have been formed as to the influence of English Pharmacy in America.

PHARMACY AND THE STATE.

To those who are zealous in their efforts to promote the interest of British Pharmacy and to those who have laboured at this work, the views expressed in the following quotation will be at once a stimulus and a reward. It is with great pleasure we record this acknowledgment that during the last thirty years the Society has done some service, and that the objects for which it was formed have not only been to some extent realized but also appreciated.

"The Appendix further contains Reports on a subject of great practical interest to the public—the examination of chemists and druggists prior to their being permitted to commence business. The report on the London examinations is by Dr. Greenhow, that on the Edinburgh examinations by Dr. Christison. In former times the business of a chemist and druggist was subject to no kind of restriction, and was even frequently added on to other trades, such as the sale of groceries, by persons who had no knowledge whatever of the characters of drugs, who were incapable of compounding a prescription, and who sometimes committed homicide by misadventure, from their ignorance of the dangerous commodities which they sold. The Pharmaceutical Society strove for many years to remedy these evils; and after carrying on for some time a system of voluntary examination, at last succeeded in procuring that this examination should be rendered obligatory upon all who deal in drugs. It is now so conducted as to assume three forms —the *major* and *minor* examinations, which are intended to be permanent, and the modified examination, which will be only temporary. The major examination admits those who pass it to be registered as "pharmaceutical chemists;" the minor, as "chemists and druggists;" and the modified admits those to be chemists and druggists who were fairly embarked in the vocation before the provisions of the Pharmacy Act became binding. The inspection of the examinations by men so eminent as Drs. Greenhow and Christison is a matter for which the medical department of the Privy Council deserves much commendation. The supply of medicines to the sick, once regarded as a proper function of those general medical practitioners who attend the great bulk of the community, has now been very generally abandoned by them, not only in great cities, but also in provincial towns and rural districts. Indications are not wanting that it will before long be abandoned altogether, and that medical men of all classes will limit themselves to prescribing the remedies which their patients require. A few years ago this could not have been done with safety, but now, thanks to the Pharmaceutical Society and its Act, a sick man will find almost everywhere a chemist who may be trusted to dispense any prescription, and who will have under his hand, save in exceptional cases, the preparations necessary for the purpose. It is not needful to follow the two inspectors into the details of their reports, but we have pleasure in recording the conclusion of Dr. Greenhow, "that the examinations are of such sort, and are conducted in such a manner as to constitute a sufficient guarantee to the public;" and that of Dr. Christison, that "the results of the examination seem to me satisfactory in every point of view." The Pharmaceutical Society could receive no more flattering testimony to the character and value of its labours."—*Times.*

Dr. Henry E. Armstrong has been appointed Professor of Chemistry at the London Institution, an office once held by Mr. W. R. Grove, Q.C., F.R.S., and subsequently by Mr. J. Alfred Wanklyn. Dr. Armstrong studied chemistry under Professors Hofmann, Frankland and Kolbe, and has been associated with Dr. Frankland and the late Dr. Matthiessen in original researches. We understand that this appointment is connected with a project for establishing Practical Chemistry classes in the laboratory of the London Institution.

A contribution of twenty guineas has been made to the Benevolent Fund by the Local Committee of the Pharmaceutical Conference lately held at Liverpool, out of the surplus of the local fund remaining after the expenses incurred had been paid.

Proceedings of the Pharmaceutical Society.

EXAMINATION IN LONDON.

December 21st, 1870.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Edwards, Gale, Garle, Hanbury, Haselden, Ince and Southall.

Dr. Greenhow was also present on behalf of the Privy Council.

Twenty Candidates presented themselves for examination, ten Major and ten Minor; the following passed and were duly registered:—

MAJOR (as Pharmaceutical Chemists).

*Skipper, Edward	London.
*Pick, Richard	Hull.
*Clark, Walter Beales	Leicester.
*Cross, William Gowen	Shrewsbury.
*Taylor, John William	Great Grimsby.
*Griffin, Thomas	Bromley.
Thompson, John Thomas	Richmond, Yorks.

MINOR (as Chemists and Druggists).

*Brown, James	Bideford.
*Davenport, Horace	London.
Field, Charles	Netley.
Morgan, William John	Kinver, Stourbridge.
Stoakes, Benjamin Maiden	Boston.
Sant, George	Atherstone.
Marks, Benjamin	Plymouth.
Spong, Douglas Morton	Bedford.
Skinner, Kenneth George Walrond	Christchurch.
Biddle, Charles John	Manchester.

The above names are arranged in order of merit.

---

* Passed with honours.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Fourth General Meeting of the present session was held at the Royal Institution, December 8th; the President, Mr. JOHN ABRAHAM, in the chair.

The minutes of the preceding meeting having been read, the PRESIDENT said he must correct the statement that he said he had always obtained 15 fluid ounces of distilled product in following the Pharmacopœia process for spirit of nitrous ether. He stated the contrary, but suggested that the fact might be owing to imperfect condensation, and that the loss might perhaps be obviated by putting the rectified spirit into the receiver instead of adding it subsequently. The alteration having been made, the minutes were confirmed.

Mr. S. G. HILDITCH exhibited four samples of products taken in the distillation of sp. æther. nitros., B. Ph.:

No. 1 being taken when (working on four times the B. Ph. quantity) two gallons had distilled over which contained 50 per cent. of nitrous ether ($C_2H_5NO_2$).

No. 2, when two gallons six pints had been collected, which contained 48 per cent. of $C_2H_5NO_2$.

No. 3. A fresh receiver was then adapted, and the distillation continued until one gallon had been collected; and on testing this with chloride of calcium, he could not get any separation of $C_2H_5NO_2$. The receiver was again changed, and heat (steam) being increased, the distillation was continued until nothing more would distil over. In this way he obtained forty-eight ounces of a liquid consisting principally of spirit and water, having a very disagreeable smell.

No. 4 represented this product.

The SECRETARY then read a letter which had been received by the President.

[The letter is essentially the same as the letter from Messrs. Fox to the Editor, already printed in the Journal, p. 479.]

The PRESIDENT said that it did not appear that Messrs. Fox complained that he had said anything which was not correct, but they objected to the inferences he had drawn from the facts. He had, however, nothing to withdraw. They had sent him a handbill, in which one of the testimonials referred to the fact that their preparation contained only 50 per cent. of cod-liver oil; but the handbill round the bottle which he had exhibited contained no such statement, and he could not but think that if they had wished it to be known that "palatable cod-liver oil" contained only half oil, the rest being sugar and water flavoured, they might have taken more effectual means to accomplish their purpose. Be that as it may, he had contented himself with showing the composition of the mixture, and that the label was so put on the bottle as to conceal the fact from all but careful examination. He also observed that gentlemen who called themselves Fellows of the Chemical Society, who professed to have analysed the oil, gave testimonials which did not convey the slightest idea of its composition, and left their readers to infer that it had been made palatable by some unobjectionable process. In the new testimonials which Messrs. Fox had sent with their letter, he observed very prominently the name of a gentleman whom he could not refer to except in terms of respect. It was Dr. A. H. Hassall, who, as a commissioner for the *Lancet*, had done so much to make known the composition of important articles when their names failed to do so. He says that flavouring and other ingredients have been added, but he does not tell us that they form one-half of the mixture. His (the President's) object was that this should be known to those who sold and to those who bought it.

Mr. EDWARD DAVIES, F.C.S., heartily agreed with the President, and showed that the oil was not and could not be *a combination*. He said that, knowing the whole system of testimonial-giving was thoroughly rotten, being applied wholesale instead of confined to the sample analysed, he was glad (as an analytical chemist) for the sake of his profession that this practice was confined to a few conspicuous individuals.

Mr. T. F. ABRAHAM said the oil professed to be patented.

The SECRETARY stated that Messrs. Fox had registered the word "palatable" as a trade mark, but this would be invalid if it could be proved that any one else had previously applied the term.

Mr. HILDITCH said he had been informed by legal gentlemen that many of these patents were of no more value than the paper upon which they were written, and gave instances where so-called patent processes were invalid.

Mr. ALFRED H. MASON, the Honorary Secretary, thought the oil should be condemned by pharmaceutists as an inelegant preparation, a decided separation being present, and no *combination*, as Messrs. Fox had stated in their letter. He had seen a short time ago in one of the New York medical journals a formulary for cod-liver oil cream.* The sample exhibited consisted of a solution of gum tragacanth (2 drachms being dissolved in 16 ounces of cold water), to which 50 per cent. of oil was added, flavoured with essence of lemon, essence of almonds and cassia, sweetened with syrup of tolu. This mixture did not show any separation, as the tragacanth broke up the oil into such minute particles that it was held in suspension, and it thus formed an elegant emulsion very pleasant to the palate.

Mr. REDFORD fully concurred with the remarks which had been made, and felt that there was not anything to withdraw from what had already been made public in the report of the proceedings of a former meeting.

Several other miscellaneous communications were made by Messrs. Hilditch, Tanner, Davies, T. F. Abraham, Redford, and Hallawell.

Before closing the meeting, the President gave a very interesting *résumé* of a paper he had heard read the previous evening at the Pharmaceutical Society's meeting by Mr. Howden, on "The State of Pharmacy in the United States."

After the usual votes of thanks were passed, the meeting adjourned.

Proceedings of Scientific Societies.

THE EXHIBITION OF CHEMICALS, DRUGS, ETC., AT THE RECENT MEETING OF THE AMERICAN PHARMACEUTICAL ASSOCIATION AT BALTIMORE.

Our space will not permit us to do justice to this attractive feature of the annual gatherings of the Association. Though the exhibition was hardly equal in variety and extent to the display made at the meeting of last year, in Chicago, it was exceedingly good, and the articles were arranged with most excellent taste, so that they might be seen to the best advantage. As usual, Messrs. Powers and Weightman, of Philadelphia, made the most attractive and valuable contribution, many of their specimens being in large quantities, a single vase containing upwards of 1000 dollars worth of sulphate of morphia. Many of their specimens were particularly remarked on account of their superior beauty.

Messrs. Charles T. White and Co., of New York, also made a most attractive display. This house is rapidly gaining a national reputation for the purity of its products, and certainly no one familiar with the appearance of fine chemicals could view their collection without being struck with the rare beauty of almost every article. They exhibited upwards of forty specimens, among them the salts of morphia, which they are largely manufac-

* I have since found that the article referred to was extracted from a letter signed "Emulsio," published in the *Chemist and Druggist* for April, 1870, p. 121.—A.H. MASON.

turing. It is needless to say that they were invariably admired.

Messrs. Rosengarten and Sons, Philadelphia, exhibited a case of fifty-six specimens of chemicals from their laboratory, including fine crystals of the hypophosphites of lime, soda, and potassa: piperine, permanganate of potassa, and a variety of salts of the alkaloids.

Messrs. Schering and Gatz, New York, exhibited thirty-two specimens, mostly of rare chemicals, produced by E. Schering, of Berlin.

Andrews and Thompson, of Baltimore, exhibited a variety of handsome chemicals,—among others were sesquichloride of chromium, scaled salts of iron, hypophosphite of manganese, and phosphate of manganese; also a living specimen of the Benne plant.

Messrs. Thomsen and Block, of Baltimore, contributed specimens of glacial phosphoric acid, valerianate of zinc, carbolic acid, nineteen varieties of fluid extracts, a number of essential oils, and a large collection of materia medica specimens.

The Baltimore chemical works exhibited specimens of acetate of lead, acetic acid, fine crystals of the iodide and bromide of potassium, and many other chemicals.

The Baltimore chrome works exhibited extensive specimens of bichromate of potassa, and the chrome ore from which it is prepared.

The display in the materia medica department was large and varied.

Messrs. M'Kesson and Robbins, New York, exhibited a very extensive collection of gums and gum-resins, in the whole and powdered state.

Messrs. B. O. and G. C. Wilson exhibited specimens of their herbs, pressed and unpressed, numbering about sixty. This firm have gained an enviable reputation for the quality of their goods; their herbs are deprived of the large stalks, and only the leaves and leaf-stalks are sent out of their establishment. Their specimens were excellent throughout.

Robert Shoemaker and Co., Philadelphia, exhibited an extensive variety of powdered drugs.

Dr. E. R. Squibb, Brooklyn—Two cases of rhubarb.

PHARMACEUTICAL AND OTHER SPECIMENS.

Messrs. Bullock and Crenshaw, Philadelphia, exhibited sugar-coated pills in great variety, and presenting the handsomest appearance, fully sustaining their well-deserved reputation.

Messrs. Mellor and Rittenhouse, Philadelphia, made an extensive display of fruit essences, solid and fluid extracts, etc.

Mr. S. Mason M'Collin, Philadelphia, exhibited a variety of spread plasters of excellent quality, and also court plaster, Breed's gutta-percha pessaries, and flavouring extracts, etc.

Messrs. Hance Brothers and White, Philadelphia—Solid and fluid extracts in great variety, fruit essences, and sugar-coated pills; also, a new pattern of a geared drug-mill for apothecaries' use, and Hance's percolator.

Mr. Robt. Platzer, Philadelphia, exhibited about fifty specimens of essential oils, many of them exceedingly rare; also, a number of foreign drugs.

E. Parrish and Son, Philadelphia, exhibited various pharmaceutical specimens, and also apparatus.

Mr. W. C. Bakes presented a new style of pestle and mortar machine, worked by hand power; also, various contrivances for facilitating the dispensing and preservation of medicines.

Mr. Wm. Warner, Philadelphia, exhibited a variety of sugar-coated pills.

Dr. W. H. Pile exhibited a variety of hydrometers, burettes, graduated measures, etc.

Mr. Charles Shivers, Philadelphia.—Samples of spread plasters in yard rolls.

Mr. Henry Troemner, Philadelphia, exhibited his improved drug mill and prescription scales.

Messrs. Burroughs Bros., Baltimore, exhibited a most extensive collection of fluid extracts of their own manufacture, including almost two hundred specimens.

Messrs. Sharpe and Dohme, Baltimore, made a creditable display of fluid extracts, syrups, etc.

Professor J. Farris Moore, Baltimore, also exhibited some fine specimens of fluid extracts and other pharmaceutical preparations.

Mr. N. Hynson Jennings, of Baltimore, exhibited a collection of specialities and toilet articles.

Messrs. S. Campbell and Co., Philadelphia, exhibited fluid extracts made by direct percolation, without evaporation; also a variety of elixirs, syrups, and toilet perfumes.

Mr. Geo. S. Dickey, San Francisco, contributed five samples of Monsel's salt, in scales, granules, and powder.

Messrs. Hartman, Laist and Co., Cincinnati, exhibited specimens of pure, inodorous glycerine, very beautiful in appearance; also, fine specimens of Epsom and Rochelle salts.

John Mathews, New York, placed on exhibition a magnificent draught stand for soda water, constructed of mottled marble, with silver ornamentations.

Glassware and shop furniture, in tasty and beautiful styles, and druggists' sundries, were exhibited by Messrs. J. Quinlan, New York; Adams and Drexel, Baltimore, and Whitehall, Tatum and Co., Philadelphia.

Messrs. Battley and Watts, London, England, exhibited samples of liquid extracts, prepared by the processes of the B. Ph.

Among the objects of great interest must be mentioned the microscopic specimens exhibited by Dr. F. Hoffman, of New York. The specimens were mostly illustrative of the materia medica, and were mounted by Mr. C. Rodig, of Hamburg, Germany.

In conclusion, we may say that the exhibition was most satisfactory, and reflected great credit upon the exhibitors, and also upon the members of the local Committee in Baltimore, who had made such ample and excellent provisions for the occasion.—*The Chicago Pharmacist.*

LINNEAN SOCIETY.

At the meeting held Dec. 15th, a paper was read on 'Sabadilla" (*Asagræa officinalis*, Lindl., *Sabadilla officinarum*, Mandt.), from Caracas, by A. Ernst. The writer remarked that it does not appear to be generally known that a considerable quantity of Sabadilla is exported from Caracas and Venezuela, amounting to from 3000 to 3500 quintals annually; almost the whole being sent to Hamburg. The plant is a very common one by the roadsides in Caracas, but the greatest part of the drug comes from the hilly regions in the south, where it grows at an elevation of from 3500 to 4000 ft. It was originally discovered in the Mexican Andes, and is not known elsewhere. Although not mentioned by Humboldt, it is, however, apparently indigenous in Venezuela. It flowers in August and September, while Humboldt was there in the dry season; and it is besides very local in its distribution. The writer bases his belief in its being indigenous on several circumstances. In the first place the spots where it grows are the most unlikely for it to have been planted; and it has no special means of easily spreading its seeds. There is no record of its introduction; yet it was known long before the seeds were first exported by German druggists. The Caracasian form differs slightly in the width of the leaves and a few other characters from the typical *A. officinalis*, of Mexico, and might be called *A. caracasana*, but the writers did not considerit specifically distinct. The bulbs contain numerous raphides of oxalate of lime.

In the discussion which followed, the PRESIDENT (Mr Bentham) agreed with the writer, that there was not sufficient ground for forming the Caracasian Sabadilla into a distinct species, especially as Lindley's description was drawn from dried specimens. Mr. HANBURY complained that the writer had not accompanied his paper with specimens of the plant. He said it was a mistake to suppose that pharmacologists are not aware that the drug is exported from Venezuela. The fact is mentioned by Flückiger, of Berne; while Berg and Schmidt even mention the difference between the two varieties.

Parliamentary and Law Proceedings.

SALE OF PATENT MEDICINES WITHOUT STAMP OR LICENCE.

On Tuesday, Dec. 13, John Marston, jun., of 44, Great Charles Street, Birmingham, appeared at the Derby Borough Police Court, in answer to a summons obtained by the excise officer, charging him with selling patent medicines without a licence, at 9, Sitwell Street, Derby.

The officer deposed that on the 24th of September he went to No. 9, Sitwell Street, and saw a brass plate on the outside, having on it the name of J. W. Hunter, and on an inner door the name of Dr. Hunter. When he entered the room, he saw a person named Manning, and asked for a box of red pills. Manning left the room and shortly afterwards returned with the box of pills and a book. Witness gave him 2*s.* 9*d.* for the pills, which were without the government stamp.

Thomas Place, supervisor, Birmingham, said that on the 7th October, he called at the establishment of Dr. Hunter, in Birmingham, and saw the defendant. The name of J. W. Hunter was on the door. The defendant informed him that his father had bought the business of Dr. Hunter some years ago, and that he had re-bought it of his father; and he also stated that he had agents in Nottingham and Derby, and that his Derby agent dispensed his medicines. Defendant informed him that on purchasing stamps at the Birmingham Stamp Office, he had applied for a licence, but was told that it was not the time for granting them, and that he should receive notice when that time arrived. He had not applied for a licence, however, and the present proceedings had been taken in consequence.

The defendant, who stated that Manning had acted without his authority, was fined £20, the full penalty for the offence, which the magistrates unanimously decided not to mitigate.—*Derby Mercury.*

POISONING BY ARSENIC IN IRELAND.

An inquest was held on Monday, December 12th, at Rahoon, upon the body of Mr. John Holton. It was stated in evidence by his wife that there had been a quarrel between her and the deceased on Friday while at a cattle fair. When he returned home he was retching very much, and she heard him say that he had taken two doses of poison. She thought he was under the influence of drink. Medical assistance was procured, but he died the following day.

Dr. Colahan stated that he found the deceased suffering from the effects of arsenic. He administered the usual antidotes and used the stomach-pump, but although the deceased was relieved considerably, he died from arsenical poisoning.

George Brokie deposed that he was an assistant to Mr. James M'Swinney, who kept a druggist's establishment as well as an apothecary's. On Friday night, a person whom he knew to be Holton, the deceased, came into the shop to purchase arsenic. Upon asking him what he wanted it for, he replied to poison rats. Witness said he considered him perfectly sober and sold him about a drachm of pure arsenic. He did not keep a book for the purpose of registering the sale of arsenic, but a couple of hours after the sale he entered it in the shop-blotter. The packet was marked "poison" on a red label and "arsenic" on the shop label. He cautioned the deceased to be careful with it.

Henry O'Reilly said he was an assistant in the establishment of Mr. Staunton. Holton, whom he knew, came into the shop, he thought on Friday; when witness began to quiz him about feeding-bottles. After a time, deceased, who was perfectly sober, said he wanted some arsenic to poison rats. Witness said he would give it to him if he would promise to be very cautious, and he told him the danger attending its use. He could not say whether he sold or gave it to him, or whether he received any money or not. It was pure arsenic, not mixed in any way with colouring-matter,—a perfectly white powder. He kept no register, nor did he enter it in any book. The packet was marked "poison" and "arsenic."

The jury returned a verdict that deceased died from the effects of arsenic administered by himself.—*Galway Vindicator.*

Obituary.

December 8, at his residence, 33, Rue Magnan, Paris, aged 36, ROBERT JOHN FOWLER. Mr. Fowler was born at Gloucester, and entered the profession of pharmacy by apprenticeship to Mr. Harvey, of Leeds. His tastes and pursuits had a strong bias towards experimental science, and photography was a subject to which he devoted much attention. The introduction of the collodion process produced a rapid revolution in photography, and its trade aspect developed proportionately, so that Mr. Fowler's energies were concentrated upon the new department of the business in which he was engaged. In the year 1860, Mr. Fowler became a partner in the firm of Harvey, Reynolds and Fowler, but repeated attacks of congestion of the lungs compelled him in about four years to relinquish this position and he settled in Paris, the climate of which appeared to suit him much better than that of England. He soon established a special kind of business as commission agent in matters relating to chemistry, pharmacy and experimental science, acting as the medium alike of importers and exporters. During the Paris Exhibition of 1867, he was the representative of a large number of English exhibitors, and his assistance was greatly appreciated by his countrymen. For several years Mr. Fowler held the post of Paris correspondent of the *British Journal of Photography*, his letters appearing almost weekly, and often giving the earliest information about discoveries in physical science generally, as well as the novelties of photography. We do not learn that Mr. Fowler's life was shortened by the effects of the siege. The mischief to the lungs had long since developed consumptive symptoms and his death occurred after a short and rather sudden accession of illness. He has left a widow and one or more young children, who of course are still shut up in the besieged city.

Review.

ELEMENTARY CHEMISTRY. By the Rev. H. MARTYN HART, M.A. 8vo, pp. 287. Cassell, Petter and Galpin.

We begin by praise because we intend to blame. This small volume is very nicely and clearly printed, neatly got up, the woodcuts are numerous and good, and the price is moderate. The author, too, has evidently taken pains with his writing; he is probably a good teacher, and certainly possesses the faculty of putting in a clear and intelligible form those things which he himself understands. But the fault we have to find is that he is not sufficiently instructed in the subject upon which he professes to write.

The impression we have derived from a careful examination of the little book before us is this: it is an abridgment, imperfectly effected, of Miller's Chemistry. It is, in fact, just such an epitome as a student reading that work would compile for his own use. But not only is there no originality displayed in the manner of treating the subject, in the arrangement of the matter, or in the illustrations made use of, but over all the book hangs that crude and superficial air, the appearance of which lets the cat out of the bag. Added to this, there are even quite early in its pages several very serious mis-statements. Not to cavil, we pass over the Introduction, and in Chapter II. we find, succeeding a table of the elements, the following passage:—"The numbers in the third column are the *combining weights*, or, as they are sometimes called, the *equivalent numbers* or *atomic weights*." And then a little further on:—"It is to be remembered then, that the *equivalent number* of any element signifies the relation in weight which the atom of that element bears to an atom of hydrogen; and since chemical compounds are formed by the union of atoms, the atomic weight will also represent the weight in which the element will enter into combination. Sometimes one, two or many atoms enter into the compound, so that whatever may be the quantity of the element, it must always be a multiple of the atomic weight; hence the name *combining weight*. And it very frequently happens that one element in a compound is replaced by another, one atom taking the place of another, the weight of one atom being equivalent to the weight of the other; hence the name *equivalent number*." Only a few lines lower down we are told that "a salt is a compound of an *acid* and a *base*." An acid is a body possessing a sour taste, and "is now defined to be a salt of hydrogen." "A base is a body which will combine with an acid to form a salt. The alkalies are the strongest bases. A base is generally the oxide of a metal." What a curious state of confusion must the author's mind have been in when he penned these sentences! We are only certain of this, that if a boy of sixteen presented himself at the London University Matriculation examination in such a condition of mental fog, he would inevitably be "spun" without mercy. Now that the teaching of science to boys and girls is becoming more and more the fashion, it behoves us to condemn uncompromisingly all that is not of the soundest and clearest. Let those schoolmasters who must needs be their own professors bear ever in mind that in proportion as the possession of practical and lucid scientific ideas is of greater importance than ever so critical an acquaintance with dead languages, so the slightest haziness in this department of mental culture is more pernicious than any number of imperfections in such an art as Latin versification.

BOOKS RECEIVED.

NOTE-BOOK OF MATERIA MEDICA, PHARMACOLOGY AND THERAPEUTICS. By R. E. SCORESBY-JACKSON, M.D., F.R.S.E., etc. Second Edition, Revised, Enlarged and brought down to the Present time, by ANGUS MACDONALD, M.A., formerly Lecturer on Mat. Med. and Therapeutics at Surgeons' Hall. Edinburgh: Maclachlan and Stewart, 64, South Bridge. London: Simpkin, Marshall and Co.

DIE PFLANZENSTOFFE IN CHEMISCHER, PHYSIOLOGISCHER, PHARMACOLOGISCHER UND TOXICOLOGISCHER HINSICHT. Für Aerzte, Apotheker, Chemiker und Pharmakologen bearbeitet von Dr. Aug. Husemann und Dr. Theod. Husemann. Dritte Lieferung (Bogen 34–51). Berlin. 1870. From the Editors, through Mr. Nutt.

INTRODUCTION TO THE STUDY OF INORGANIC CHEMISTRY. By WILLIAM ALLEN MILLER, M.D., D.C.L., LL.D. London: Longmans, Green and Co. 1871. From the Publishers.

The following journals have been received:—The 'British Medical Journal,' Dec. 17; the 'Medical Times and Gazette,' Dec. 17; the 'Lancet,' Dec. 17; the 'Medical Press and Circular,' Dec. 21; 'Nature,' Dec. 15; the 'Chemical News,' Dec. 16; 'Journal of the Society of Arts,' Dec. 15; 'Gardeners' Chronicle,' Dec. 17; the 'Grocer,' Dec. 17; the 'English Mechanic,' Dec. 16; the 'Produce Markets Review,' Dec. 17; the 'New York Druggists' Circular' for December; the 'Chicago Pharmacist' for December; 'Chesterfield and North Derbyshire Almanack,' 1871; the 'Galway Vindicator,' Dec. 14.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department*, 17, *Bloomsbury Square, W.C., and not to the Publishers.*

[63.]—GREEN FLUID FOR SHOW-BOTTLES.—The following gives an emerald green:—

Cupri Nitrat. ℥iij
Acid. Muriat. ℥iv
Acid. Nitric. ℥iv
Aq. Destil. Cong. ij.
Misce sec. art. W. J. P., *Hawkhurst.*

[66.]—CEMENT FOR INDIA-RUBBER.—*M.* and *S.* send the following:—

India-rubber ʒj
Gutta Percha ʒiv
Bisulphide of Carbon ℥iv. M.

[68.]—POT POURRI.—In reply to "*Iodi*" (Sudbury), *H. B.* (Scarborough) sends the following:—

Gum Benzoin ℥ij
Cloves ℥j
Styrax Cal. ℥ss
Cort. Cinnam. ʒij
Rad. Iridis ℥j

Roughly powdered together, then add—

Musk ʒss
Bay Salt Hij
Ol. Lavand. gtt. xx.

Mix.

℞. Lavender Flowers 1 lb.
Yellow Sandal-wood 4 lb.
Cloves 2 lb.
Nutmegs 2 lb.
Orange Peel 2 lb.
Lemon Peel 2 lb.
Cumin Seeds 1 lb.
Cinnamon 2 lb.
Juniper Berries 2 lb.
Rose Leaves 2 lb.
Musk ℈j. G. HEYWARD, *Croydon.*

[74.]—TOILET VINEGAR.—In reply to "*Reciprocate*" I forward you the following recipe:—

Ol. Neroli,
" Cloves,
" Lemon,
" Bergamot,
" Cedrat, ana ʒj
Otto Rose gtt. xx
Gum Benzoin ʒv
Balsam Tolu ℈j
S. V. R. Oiij.

Digest for six days and add—

Acid. Acet. Glacial. ℥iss
Ess. Ambergris gtt. x
" Musk gtt. x.

After twenty-four hours, add aq. destill. ℥x and filter.—H.B., *Scarborough.*

[77.]—DISPENSING.—Can any of your readers inform me how I can dispense the following mixture so as the result shall be, without filtering, perfectly clear? It has been dispensed in London, and every time a clear mixture was sent out. I have dispensed it some twenty or thirty times, and it has always been milky?

℞. Acid. Phosph. Dil. B. P. ʒiij
Ferri Cit. c. Quin. ʒj
Tinct. Nucis Vomicæ ʒj
Sp. Chloroformi ʒij
Aq. Destill. ad ℥vj.

Ft. mist. One tablespoonful to be taken in half a wine-glass of water, at eleven and five.—"EXHIBEATUR."

In reply to "*Exhibeatur*" I give it as my opinion that it is not possible to prepare the prescription faithfully and procure a clear mixture without filtering. Experiments hastily made in the course of business show that on the addition of the acid. phosph. dil. to the solution of ferri cit. quin., a deposit of ferri phosph. is the result, and on further adding the other ingredients there is a deposit of quinia. I have tried Mr. Harwood's method of dispensing the prescription, and find that, as by any other method, a precipitate is slowly deposited. Such a mixture ought certainly not to be filtered. —"Ego."

[82.]—COLOURS FOR CARBOYS.—The following, like the green sent last week, do not contain more than a few grains of solid matter in the gallon:—

BLUE.

Liq. Fer. Perch. Fort. ♏x
Potass. Prus. Flav. gr. x
Acid. Oxalic. ℥ij
Aq. Cong. i, vel q.s.

RED.

Liq. Fer. Perch. Fort. ♏x
Potass. Sulphocyanid. gr. x
Aq. Cong. i, vel q.s.

H. P. Hearder, *Plymouth.*

CRIMSON.

Iodi,
Potassii Iodidi, ana ℨss
Acidi Hydrochlorici ℥j
Aquæ ad Cj. M.

GREEN.

Cupri Sulph. ℨj
Potass. Bichrom. ℨss
Liq. Amm. Fort. ℥ij
Aquæ ad Cj. Misce.

Tried and found good by T. W. C., *Holbeach.*

RED.

Liquid magenta dye q. s.

This is a good colour, stands well, and can be easily deepened by the addition of a little more magenta.—Pestle and Mortar.

In answer to *M.'s* inquiries as to the best way to prepare colours for bottles, I beg to say, if he wishes for a perfectly clear solution, his better plan is to use a weak spirit, say 30 U.P., made by mixing two gallons of ordinary alcohol with three gallons of distilled water; but if this is too expensive, then use distilled water alone and filter.

Crimson.—Make a strong decoction of red poppy petals, and with acid. sulph. dil. to the required shade.

Blue.—Cupri sulph. 2 parts; acid. sulph. 1 part.—G. B. Clarke, *Woburn.*

[93.]—OVER-PROOF SPIRIT.—The term *proof* spirit was originally applied to a spirit of such a strength that when gunpowder was wetted with it and the mixture lighted, the spirit, after it had burned away, fired the gunpowder,—if it failed to do this it was considered *under* proof. At the present time, however, the strength of spirit is known by the quantity of absolute alcohol it contains, as indicated by its specific gravity; the proof spirit now recognized by the Excise is of a sp. gr. ·920 and contains 57 per cent. by volume of real alcohol. And when a spirit of a certain strength is named, such as 56 or 60 degrees *over* proof, it means that to every 100 parts of such spirit, 56 or 60 parts of water are to be added to reduce it to proof strength.—J. H. Baldock, *S. Norwood.*

Proof spirit, sp. gr. 0·920 is the standard by which the strength of spirit of wine is regulated by law in this country; hence, if spirit of wine be *stronger* and therefore *lighter* than proof spirit, it is said to be so much per cent. "*over*-proof;" and if *weaker* and consequently *heavier*, so much per cent. "*under*-proof."

The sense in which the Excise use the term *per cent.* is somewhat peculiar and is as follows, viz.:—100 gallons of spirit of wine at 56 per cent. over-proof (*Spiritus rectificatus* P. B. sp. gr. 0·8382 at 60° F.), contain as much alcohol as 156 gallons of proof spirit, *i. e.* 100 gallons require to be reduced with distilled water to 156 gallons to form proof spirit; 100 volumes of spirit of wine at 54 O.P. are diluted with distilled water to 154 volumes; and 100 volumes at 60 O.P. are diluted to 160 volumes, to form proof spirit.

A spirit of wine stated to be 10 per cent. "*under*-proof" signifies that 100 volumes contain as much alcohol as 90 volumes of proof spirit, and 100 volumes of spirit of wine at 30 per cent. "*under*-proof" contain the same quantity of alcohol as 70 volumes of proof spirit and so on.

In making *Spiritus tenuior*, P.B., by mixing five pints of rectified spirit with three pints of distilled water and well stirring the mixture, eight pints of proof spirit is *not* produced, owing to the evolution of heat and contraction of the fluid.

This deficiency—of about 4 oz. in the gallon—is usually made up with distilled water, and must be borne in mind in preparing tinctures, etc., containing proof spirit. *Spiritus tenuior* should be kept ready prepared and the specific gravity always carefully tested.—J. Saunders Seaman.

[99.]—SHEET LIGHTNING.—"*Pestle and Mortar*" (Dorking) wishes for a recipe for making sheet lightning.

[100.]—TOOTHACHE TINCTURE.—"*A Leech*" would be glad of a recipe for a good toothache tincture.

[101.]—CHERRY TOOTH-PASTE.—*W. L. G.* (St. Austell) would feel obliged if some correspondent would give him a recipe for a good cherry tooth-paste.

[102.]—CIVET, AMBERGRIS AND CASTOR.—*F. C.* is desirous of knowing whence we derive our supplies of civet, ambergris and castor, and the quantities imported during 1869.

[103.]—SEA-SICKNESS.—*P. Q.* would feel obliged for a formula of a reliable remedy for sea-sickness, not chloral hydrate.

[104.]—COUGH PILLS.—"*Pendennis*" wishes for a good recipe for cough pills.

[105.]—BLACK MIXTURE.—Will any of your readers supply me with a formula for black mixture for scour in cattle?—*Pendennis.*

[106.]—*M. P. S.* would be glad to know if chloral. hyd. and chloralis anhydr. are the same, and whether both names are used.

[107.]—ADDRESS.—*R. H.* wishes for the address of Dr. Natali, an Italian physician, living at Twickenham in the beginning of the year 1869.

[108.]—SUKKAR-UL-AUSHAR.—"This is the name of the Manna or saccharine substance produced by *Calotropis procera*, or some other species allied to it, in Arabia and Persia, which was formerly imported into India; but it is not found at all now in any bazaar, nor is it ever produced here, as far as my knowledge extends, by any species of *Calotropis.*" So says the 'Supplement to the Indian Pharmacopœia,' but can any correspondent, at home or abroad, vouch for the existence of such a substance at all, from personal experience, and not from books? Has any one ever seen sugar or manna, or any saccharine substance, obtained from any species of *Calotropis* or believed to have been obtained from such a source? If so, what is it like? whence procurable? and is it any other than the nidus of an insect (*Coleoptera*) which frequents the *Calotropis*?—C.

[109.]—TAMARISK MANNA.—Many a time and oft it has been asserted in books that a species of *Tamarix* yields manna. It is said to be accurately described by Diodorus Siculus. Some say it is produced by an insect and is found near Sinai. Others allude to Persia, and others that it is obtained plentifully near Jhang, in the Punjab. Can any correspondent affirm, upon his own knowledge, that there is such a substance at all as Tamarisk manna? because I begin to doubt whether there is not some mistake, and whether any manna is produced on Tamarisks.—C.

[110.]—PATENT MEDICINES.—A table was published some years ago in one of the scientific journals, giving a comparison of the composition of various well-known medicines, protected by letters-patent, as obtained by actual analysis of a sample, with the composition as given by the inventor in his specification. I am desirous of finding this table.—R. B. P.

Correspondence.

Proposed Regulations for Storing of Poisons.

In regard to this subject there is evidently still almost as great a divergence between the position taken by the Council and that held by the country members as there was before the last election of Council took place. As far as present evidences go, there appears little prospect of an agreement being arrived at by the time the Annual Meeting comes round, at which the subject will be again debated,—and, it is earnestly to be desired, debated with better effect than at the meeting in May last.

Mr. Flux, at that meeting, said "he must confess there was, in his opinion, no danger of a *mandamus* being issued calling upon the Society to pass these regulations; but, whether the public would not consider that the clause did impose an obligation to pass some regulations, and that, refusing to pass any, the subject was remitted back to the public to be dealt with as Parliament might in its wisdom think best, was a matter for the consideration of the members." And the members at the meeting practically indicated their willingness to take the consequences of the rejection rather than submit to the regulations then proposed. If the Council have other and more urgent reasons for pushing the adoption of some regulations, the members do not appear to be made sufficiently aware of the fact.

A clear statement of the reason why some regulations must be adopted, and an evident desire on the part of the Committee and the Council to meet as far as possible the objections which were raised against the previous code, would do much to remove the objections which I have reason to believe are still strongly felt by many of my provincial brethren.

Comparing the code as at present proposed with that previously discussed, it is certainly altered for the better; but comparing it with the remarks which were made at the discussion in May and with the correspondence that has been published since that time, I think it might have been modified still further, both with advantage to its efficiency and to the prospect of its ultimate adoption.

The main objection to the former code was that it was impracticable to put restrictions upon the mode of keeping many of the less potent preparations of cantharides, belladonna, opium, etc.; that it was unreasonable to put them under the same regulations which were requisite for the safe custody of strychnine and hydrocyanic acid, and futile to expect good results from the use of any danger-signals which would be too common from their extension to the whole of the numerous list of legal poisons.

It may be that the Committee do not feel empowered to select a short list of very dangerous articles, which might be kept under stringent regulations; but, if so, we think they would do well to make it fully known that they have not the power of making two sets of regulations to apply to the first and second parts of the schedule respectively, or to classify poisons according to any other mode which might be more practicable for their safe keeping.

Perhaps the publication of the debates in Council upon the subject would show that these points have been fairly considered and for good reasons laid aside; but the Council must not wonder at the continued opposition of the country members, so long as they give them no evidence that their suggestions have met with consideration before being rejected.

In the Journal for July 9, 1870, Mr. Wilkinson rejoices that the immediate danger of vexatious restrictions has passed away, and concludes his letter by saying, "If we must have regulations on the subject, they should be confined to a few of the more deadly and dangerous poisons and their names specified."

In the Journal for September 17, 1870, I protest against making the poison regulations abortive by becoming too common, and suggest, as a means of avoiding this, that "All poisons intended for internal use as medicines, the usual adult dose of which is less than one drachm, shall bear a label immediately under the name of the article stating the usual adult dose; and upon such articles the usual adult dose of which is less than, say 5 grains, there shall be added the label 'Poison,' immediately under the label indicating the dose;" and add, that if a poison-cupboard or other additional precaution is deemed necessary, it should only apply to such poisons, the usual adult dose of which does not exceed 5 grains; thus liberating the tincture and wine of opium, etc., from the poison-cupboard, and liberating paregoric elixir and syrup of poppies from any restriction regarding their storage.

In the number for October 8, 1870, Mr. Buckett, while declaring his preference that we should restrict our efforts for securing public safety to the proper education of all who sell and dispense poisons, also says, "Keeping dangerous articles in one particular place, such as a cupboard, is a precaution which, I think, should never be neglected, though the articles so treated would depend, in some degree, upon the class of business done." There is thus evidently a willingness on the part of some of the opponents of the late code of regulations to accept an amended code, if it can be made such as they have suggested would be practically useful and not excessively burdensome; and while I would urge upon the Council to prepare for submission to the Annual Meeting such a code of regulations as would disarm their late opponents, I would also gladly see the country members extend yet a little further their willingness to submit to regulations which are probably more dreaded in anticipation than objectionable in actual practice; this, however, with the understanding that in the meantime the Council show satisfactory grounds for the opinion which they seem to hold, that it is necessary at the present time to add some further regulations to those inherent in the Act. And that they either submit a further amended code of regulations, obviating, as far as possible, the objectionable features which, I think, have been amply pointed out during the discussion of the subject, both at the meetings of the Society and in the pages of the Journal.

11, *Grey Street, Newcastle.* Barnard Proctor.

Sir,—It appears to me that this proposal is likely again to cause much ill-feeling in our Society, and will probably lead to a distinct fight upon the question at the next election. I think every well-wisher to the Society will be anxious to see this avoided. The question then arises, what steps can be adopted to avoid the scandal of a split among ourselves? Perhaps the first amendment moved at the Council Meeting by Messrs. Brown and Woolley, would command the adhesion of a majority of the Pharmaceutical and Registered Chemists; but certainly their second proposal, that of ascertaining the opinion of chemists throughout the country before taking action, would command almost universal support. What I would therefore propose is that every local secretary should at once ascertain the opinions of all chemists in his district and forward them to the Council. I am prepared so to act here, and would recommend, where the local secretary declines to act, that some other member or registered chemist does the work. The feeling of all could be thus obtained in a few days, and would, no doubt, determine the action of the Council.

T. W. Gissing, *Local Secretary.*

Wakefield, Dec. 17*th*, 1870.

Sir,—The Chairman at the last Annual Meeting, in his opening remarks upon the question of "Poison Regulations," used the following words:—"I fail to gather from all the protests which have been sent up, any more logical objection to them than that of perhaps a natural dislike to being compelled to submit to any special code." Does it not strike the reason of any intelligent person that the real repugnance to these absurd regulations is based upon the most logical grounds possible, and is but the natural expression of minds possessing just appreciation of their own intelligence and responsibility?

Allow me to put a parallel case and to ask what would be the feeling of a gentleman, after receiving a good education, walking the hospital, going through the usual examinations and who in due course received his diploma authorizing him to practise,—were the same authorizing body to come to him and say, "Now, Sir, you have passed our examinations, you are fully qualified to practise, but before you do so, we must remind you that you must conform to our regulations as to the place and manner of keeping your knives and lancets, lest you should by mistake use the wrong one. You must also have each of those instruments distinctly engraved 'dangerous,' lest you should by chance forget the fact." What, I ask, would that gentleman say? what would he feel? Methinks I see the smile of sarcastic scorn with which he would view his interrogator, while with difficulty he restrains the utterance of an epithet not over-complimentary. Would his objection be logical? Would not his indignation be pardonable as well as reasonable?

I venture to think this is very much the position into which our Council seeks to put us by adhering to these would-be "Poison Regulations," over which we had so warm a discussion at the last Annual Meeting, the amended form of which you have published in this week's Journal. I grieve, as I look through the names of the gentlemen who felt it their duty (certainly not in the interests of their electors) to oppose the amendments moved by Messrs. Brown and Woolley, to see those whose judgment in most cases we dare not question, who yet, under the mistaken idea that because the Council at the time of the passing of the Pharmacy Bill thought proper to make certain unwise engagements, therefore the present Council is bound to endorse and to carry out those engagements, notwithstanding the universal expression of dissent by the whole body of independent chemists throughout the length and breadth of the land. Should the Council persist in enforcing these regulations, it will be our bounden duty to rise *en masse* against so unjustifiable an act.

The reluctance of the Council to solicit a cool expression of feeling on the part of the trade, which would have been the result of adopting Mr. Woolley's second amendment, reminds one irresistibly of the similar feeling manifested by our neighbours across the Channel; is it possible a similar feeling of distrust in their own position actuates both parties? If so, let our friends at Bloomsbury Square be wise and face the difficulty and act upon the verdict returned, and they will have no cause to regret the step; but supported by the unanimous voice of the trade, they will be in a position to explain to the Privy Council the impracticability of carrying out such measures, and further to show that the present educational standard required by law is a far more powerful safeguard than any penal enactment could possibly produce. On the other hand, should these gentlemen, forgetting their representative position, still consider themselves pledged to Government to carry out these regulations, then in the face of an adverse vote but one constitutional act remains open to them.

No one would regret more than myself any repetition of the excitement exhibited at our last Annual Meeting upon this question, but unless the Council will be wise in time, I fear the result will be inevitable, for assuredly the trade at large will not quietly submit to be thus unnecessarily saddled with a burden which neither the promoters nor ourselves could carry.

Two modes of action present themselves at the present crisis. The first rests with the Council itself, viz., the adoption of Mr. Woolley's motion at the next meeting of the Council to the effect "That it is desirable to obtain an expression of opinion from chemists throughout the country whether regulations for the keeping of poisons are desirable or not; the same to be obtained by circulars issued by the Secretary of the Society." The second would then be unnecessary; but in the event of the Council again rejecting it, I venture to suggest that the trade would be compelled in self-defence to take the matter into its own hands, and forthwith have petitions against the regulations signed in every town and duly forwarded to the Council. For many reasons the former would be far preferable, eminently so, as it would at once prevent the unnecessary excitement which must otherwise arise.

The one would be an act of becoming grace, the other an act of hostile necessity. EDWIN B. VIZER.

63, Lupus Street, Belgravia South,
December 19th, 1870.

Sir,—I had a slight hope, but not much expectation, that the discussion in the Council on the 7th instant would have produced a different result, and that we should hear no more of compulsory regulations; but the majority seem determined, if possible, to force them upon us. They certainly cannot be aware of the full scope and effect of the proposed measure, or they would not be so desirous of enforcing its adoption.

I do not hesitate to say that if the "Regulations" last proposed become law, every chemist and druggist in the country will be at the mercy of the Privy Council, and liable at any time to be struck off the Register, and compelled to discontinue his business if he fail to observe them. The first clause in the Pharmacy Act says, "It shall be unlawful for any person to sell or keep open shop for retailing poisons, or to use the title of Chemist and Druggist, unless registered under the Act, and conform to such regulations as to the keeping, dispensing and selling of such poisons as may from time to time be prescribed by the Pharmaceutical Society with the consent of the Privy Council."

Clause 15 says, "Any person who shall fail to conform to any regulation as to the keeping or selling of poisons made in pursuance of this Act, shall be liable to a penalty of £5."

Clause 26 says, "The Privy Council may direct the name of any person who is convicted of any offence against this Act, which, in their opinion, renders him unfit to be on the Register under this Act, to be erased from such Register, and it shall be the duty of the Registrar to erase the same accordingly." It is hardly credible that any one seeing the effects of these provisions would voluntarily subject himself to such a liability, yet that is what our Council propose to do for themselves and us.

We have been told that the Council are bound by the Act to make "regulations," but that I deny. The Act nowhere says that the Council shall make regulations, but it speaks of regulations that may "be prescribed by the Pharmaceutical Society." Now the word "may" is only used in the Act some six or seven times altogether, and in every other case in a permissive sense only, giving power to do something that may be necessary or desirable, but certainly not directing the thing to be done; surely if this be so, we have every right to conclude the word to be permissive in this instance likewise. But granting the intention to have been that the Society should prescribe regulations, I contend that it is the duty of the Council to strongly resist any Governmental pressure on the subject, and firmly refuse to submit either themselves or their constituents to a burden which they alone, of all the dealers in poisons, are required to bear.

The threat that, if we do not frame regulations, the Privy Council will do it for us, does not alarm me in the least. They have not the power to do so; a new Act of Parliament would be required for the purpose; and does any one imagine it possible to pass an Act that shall apply to chemists and druggists only, and leave every other dispenser of poisons to keep them in any way he thinks proper? If compulsory regulations are made at all, they must apply to every dispenser of poisons and not to us alone.

There is not a doubt that you have correctly estimated the terms of Mr. Hampson's letter, and that "open war and determined resistance to the action of the Council" is intended; if the Council will not fight our battle in this matter, we must fight the Council, and I have no fear that "the real interests of Pharmacy, as a craft," will either "be lost sight of or damaged" in the contest.

W. WILKINSON.

Cheetham Hill, December 19th, 1870.

Sir,—The majority of the Council has elaborated a new edition of the 'Poison Regulations,' which it intends to propose for adoption at the next Annual Meeting, and we have now before us the prospect of a renewal of last year's contest.

It is much to be hoped that the leaders of the opposition will on this occasion take stronger ground, and contend boldly—that all such regulations, however wide their terms, are objectionable in view of the consequences which must follow their adoption in a compulsory form; if it is not to be a mischievous sham—both a snare for ourselves and a delusion for the public—that no sufficient proof of their necessity in the past has been afforded, and that they must, under existing circumstances, become daily less necessary. Their warmest advocates recommend them only on the ground of expedience. Holding before our eyes the bugbear of the Privy Council, "We know," say they in effect, "the dose is nauseous; but swallow it now with a good grace, lest by-and-by you get one still more unpleasant." The valour of these gentlemen is too largely tempered with discretion. If we are true to ourselves, and act in concert, we have little to fear; but even should their most terrible prognostications prove well-founded, it will be better to suffer what we cannot avoid, after a manful resistance, than commit the absurdity of fashioning a yoke for our own shoulders, leaving free those of the whole body of general practitioners, which has, in truth, far more to answer for than ourselves.

Hampstead, Dec. 19*th*, 1870. CHARLES EVE.

Sir,—I rejoice to find that we are at last likely to obtain a settlement of this troublesome question, the Council having at their last meeting decided upon some simple regulations which they will propose for the adoption of the next Annual Meeting of the Pharmaceutical Society in May. The last Annual Meeting remitted this subject to their continued attention. We may rest assured that a Council elected so popularly as the present, and composed of good and trusted elements, will not have based their present conclusions upon rash or unconsidered grounds, and it is satisfactory to find that they were confirmed by a large majority of the Council.

Nevertheless, a note of war comes from Manchester! We may possibly expect another blast from Leeds. These cheerful notes will be useful in keeping the question warm until the opportunity of settling it comes. In the meantime let us hope that the several members of the great constituency in whose hands the decision rests, will be wise,—will not allow their judgment to be influenced by prejudice or partisanship, but will calmly and reasonably weigh the proposal the Council has made with so much care and deliberation.

That the chemists of Great Britain must submit to some regulations for the storage of poisons is not to be doubted. Those who are acquainted with the history of the Pharmacy Act of 1868 know that it was not only first named a Poison Act, but that no Bill would have been submitted to Parliament at that time but for the acknowledged necessity of observing further precautions in the use and keeping of poisons. The opportunity was adroitly taken to introduce into the measure security for the higher education of chemists, as one of the means supposed to promote the object in view. The gain to pharmacy was, and will yet be, immense. But that the primary object was the protection of the public from accidental and other poisoning, there cannot be a doubt.

The Act, however, was confessedly incomplete without additional precautions for the safe keeping of poisons; and the Privy Council, therefore, discreetly determined to lay upon the Pharmaceutical Society the obligation to provide such regulations as experience of the exigencies of the trade suggested. The Privy Council, urged on by constant articles in the public and medical journals, do now impress upon the Pharmaceutical Council very strongly the necessity for its action. The cry for some regulations has waxed so strong, that the Privy Council may propose some Bill to Parliament, should the present proposal be rejected, and that Bill might be most objectionable to us. The Council of the Pharmaceutical Society have, therefore, only performed a public duty, imposed upon them alike by honour and interest in conforming to these various demands.

In spite, however, of these obligations, the glorious liberty of the Englishman to do as he pleases with his own, is so strong in the chemist, that certain of them are prepared to defy Councils, National, Privy and Pharmaceutical, in order to maintain his unrestricted liberty with his poisons. It is, however, a fact that, to the limitations of law, we owe our truest freedom; and, in the observance of restraint, we find our highest interests and happiness. In this case, moreover, the chemist is the defendant; the Government and the public are the plaintiffs. It is surely in the interest of the defendant, that he should, whilst the golden opportunity lasts, make his own regulations.

The amended regulations which the Council now propose are extremely simple and will inconvenience nobody. It is admitted that most chemists in Great Britain already observe these regulations in one or other of their forms,—and thus testify that such regulations are necessary and practical in their character. The non-observers are those who seldom dispense a prescription at all, but vend a motley variety of medicines and drysalteries, in which pills, paint, cream of tartar, arsenic, sweets and laudanum are the representatives. If ever there was any class of men who ought to be subject to poison regulations, it is this. Yet even to them, the proposed poison regulations have no sting. They may, if they like, keep their cask of arsenic in one corner, secured with a padlock on the cover. They may keep their carboy of laudanum under the counter in another place, but capped with leather, or distinguished by some other sign; and all their choice and other deadly poisons—strychnine, aconitine, morphine and what not else—on some special shelf or division in the shop, and thus fulfil, without inconvenience, the regulations proposed.

One much paraded objection to any regulation is that it would necessitate the appointment of inspectors to enforce its observance. The idea is chimerical, were the regulations left to the Council of the Pharmaceutical Society; but possible, if enforced by special Act of Parliament.

The observance of approved regulations in the keeping of dangerous poisons would have this value, that their careful observance would, in the eye of the law, constitute a strong claim to favourable consideration in case of accident. It would also afford to the chemist a sense of security and satisfaction in the conduct of his business which he does not now possess. And as to the argument that any regulations are unfair which do not equally touch the dispensing surgeon and apothecary, this beneficial result would follow its partial application, viz. he that takes the physic would do so with much greater security if it were compounded by the chemist, than if it were made by the apothecary who observes no precaution in the protection of his clients from accident.

A PHARMACEUTICAL CHEMIST.

(For the proposed Poison Regulations, see PHARMACEUTICAL JOURNAL, Dec. 17th, p. 491.)

A POINT OF ETHICS.

Sir,—In answer to *two* of your correspondents, relative to the prescription dispensed by "Magnesia," No. 22, p. 437, allow me to say that I do know that "quinine" undissolved is "*not so*" bitter as in "solution," and frequently ordered so by medical men to their patients, but in the prescription alluded to the deposit was something more than "undissolved quinine," and, perhaps, more nauseous to a weak stomach. I still maintain the medical man in this instance forgot to add ac. sulph. dil. gtt. xij, having so frequently compounded nearly the *identical* prescription not only for *one person* but *several.*

I would ask your correspondent, D. T. W., of Bath, who thinks that medical men are "not so forgetful" as I wish to make them, what he thinks of the enclosed prescriptions that have come under my notice from "eminent medical men," and whether he would have compounded them (as they are written), or used his discretion and acted up to the best of his knowledge?—

℞. Morph. Mur. gr. i
Ext. Hyoscyam. gr. xij
Ft. Pil. h. s. s.

℞. Hydrarg. Bichlorid. gr. xviij.
Divid. in chart. xij, cap. i ter in dies.

Those are not solitary cases; truly they do require looking after as well as chemists.

Liverpool, Dec. 17*th*, 1870. CHEMICUS.

LIMITS OF THE MEDICINE STAMP DUTIES ACT.

Sir,—Having to prepare a bottle of "quinine wine" for a customer, I went to a respectable confectioner's for "orange wine;" it was old and not at all palatable. I did not purchase; he then recollected he had just received a case of "quinine wine," and opened it for me. On reading the label and enclosed handbill, I advised him not to sell any until I had written to Somerset House, as my notion was that it would require a stamp, and make it necessary that he should take out a Patent Medicine Licence. I this day received a very courteous reply, stating that quinine wine is not regarded as medicine within the meaning of the Medicine Stamp Duty Acts, etc.

Sheffield, Dec. 14*th*, 1870. HENRY HORNCASTLE.

THE PHARMACY ACT.

Sir,—I wish to inquire, through the medium of your Journal whether the Council of the "Pharmaceutical Society" have not acted contrary to the full meaning of the 'Pharmacy Act' in refusing to admit me as a member? What is the limit of the discretionary power, and are they not bound to a *just* reason for their decision?

ELIZABETH LEECH, *Registered Chemist and Druggist.*
Elm Villa, Broadwater, Worthing, Dec. 17*th*, 1870.

The Alleged Exorbitant Charge for Dispensing.

Sir,—I have been waiting to see if the editor of the *Lancet*, in answer to your letter of the 30th ult., would "make more fully known the facts of the particular overcharge" which led to this discussion. His only reply is a foot-note, which says, "our correspondent merely relates a fact regarding the conduct of an individual." The public and the daily press have, however, taken this to be a sample of the "extortionate charges" of chemists generally, and we have cut a very sorry figure indeed when compared with "lawyers, horsedealers and brigands." But as the *Lancet* deigns to give you no explanation, I now venture to inform you that the "druggist" who charged 24*s.* for 36 oz. of mixture, as narrated by "Prescriber," is a medical practitioner keeping an open shop. Comment is distasteful and unnecessary, but we may fairly complain that our reputation as a class has been damaged by an anonymous communication, and all discussion on the merits of the case stifled. The letter was written no doubt *bonâ fide*, but an important fact was unwittingly omitted, and the result is an injury which cannot be repaired. I venture to say that no chemist in the kingdom would charge more than 2*s.* for this particular 6 oz. mixture; the more universal price at shops of the highest respectability would be 1*s.* 6*d.*, and this fact may be gathered from "Prescriber's" own words. Having written thus much, my authority may be demanded, and it may, perhaps, save time if I say that the prescription was brought to me, and the price I quoted was 1*s.* 6*d.*; the bill complained of was afterwards put into my hands, and, I believe, that I characterized the charge as very exceptionally high and excessive.

Wigmore Street, Dec. 19*th*, 1870. Wm. Matthews.

Remedy for the Toothache.

Sir,—In the Journal of the 10th, page 466, you recommend carbolic acid to be applied to the inside of the tooth when the nerve is exposed. May I be allowed to suggest, as an efficient improvement and addition, which I have found very efficacious? viz. equal parts of collodion and Calvert's acid. carbolic. applied to the part affected, say twice a week, after nervous sensibility has ceased, then mastic and chloroform applied afterwards on cotton wool, have given permanent relief.

Sudbury, Dec. 17*th*, 1870. J. Barker.

Druggists' Charges.

Sir,—Druggists' charges have been a topic for some time, and although many letters have appeared, it does not seem that they have led to any definite result.

Several of your correspondents have complained of the cutting system carried on in some neighbourhoods, and naturally ask what is to be done to prevent such practice. They say prescriptions are frequently handed to them by persons to know the price, who, when informed on that point, reply that your neighbour Mr. So-and-so made it up for half the amount. I have had a good many years' experience in some of the first-class dispensing establishments, both in London and country, and have frequently experienced remarks of the same kind, and have, on many occasions, found that such statements were not correct. The remedy in a case of dispute is simple. First read the prescription, then state the cost, and, if disputed, don't give way, but leave the option in the hand of the customer. If informed that some other house has compounded it at a much lower price, advise that it be taken there. As to the truth of such a statement, you can judge from the respectability of the house. If it be one of any standing, it will be incorrect; if not, don't waste time by saying that drugs supplied there cannot be of the same genuine character that we use. If this system be carried out, it will, I believe, go far towards putting down the indiscriminate and mean practice of cutting. It is well known that a cutting house does not compound many prescriptions, in fact but few, for confidence is lost, and it is often found that a prescription comes back to the house from which, on account of charge, it had been taken. This I have several times experienced. As regards fixing prices for dispensing with a view to uniformity, it cannot be done, for physicians do not prescribe alike; some write very simple and inexpensive prescriptions, with eight doses in the eight-ounce bottle, then the usual charge will answer. Others, however, write for sixteen doses, while the ingredients are more costly. In these cases discretion and prudence must be exercised. Pepsine, quinine and other expensive drugs may be in large proportion, consequently the charge must be according.

The leading dispensing establishments, both in town and country, have prices which almost correspond, and, taking a conscientious view of such prices, I don't think they will be found at all exorbitant. Good houses are particular in having experienced hands that can do their work well, paying them good salaries in return, and are most careful that the drugs used are pure and genuine, consequently they ought to have a fair price for strictly carrying out their duties.

In Mr. Robert Howden's very elaborate paper, published in the Journal of Saturday last, we are informed of the prices obtained in the United States for dispensing; there the pharmacist generally charges about sixpence an ounce for medicines, that is, three shillings for a six-ounce mixture. These prices are considerably above ours, why should such be the case? Is pharmacy more of a profession there than in England? In Ireland the apothecaries' prices are also above ours; but I don't think the same complaints are heard there as we hear in London and the English provinces. In conclusion, I would beg to suggest that upon no account ought one pharmacist cut below another in dispensing prices. Let us try and follow each other as much as possible. This could easily be done by having one recognized private mark, and let the first house which compounds a prescription mark the price accordingly, and let all others who receive it afterfollow that price. This system is adopted by several good houses, and is found to be of great service when the mark is known. Some use the words "Mel Boracis," others some other term; but if we had one special mark to work from, the effect would be most beneficial. It would put a stop to the impositions which we so often find customers attempting.

Newcastle, Dec. 14*th*, 1870. John Dowling Allman.

Spiritus Ætheris Nitrosi.

Sir,—In the report of the Transactions of the Liverpool Chemists' Association, appearing in the Journal of the 10th instant, in the discussion upon Spiritus Ætheris Nitrosi, I am reported to have said, "I could not understand why a concentrated solution could not be made;" such a remark I did not make, and it is evidently a misunderstanding on the part of the Secretary taking his notes. On the contrary, I condemned the practice of wholesale houses supplying the article, not only because I found it impossible to obtain a solution, containing 80 per cent. of pure nitrous ether (which would be the required strength), but also, because it is impossible to keep a concentrated solution without its soon becoming strongly acid.

Absence from town precluded the possibility of my correcting the error at our last meeting, I shall therefore be glad if you will insert this in your next issue.

Dec. 14*th*, 1870. G. J. Rawland.

Information Wanted.

Sir,—I have received to-day a prescription with the following article in it—

Mag. Ferri et Quin. Sulph. ℥iss.

The above was written very distinctly, and had been obtained at Messrs. Hitchcocks, of Oxford; perhaps they, through your columns, would give some information as to the composition of the article. E. B.

L. V. D.—Persons passing the Modified Examination are not entitled to call themselves, or be addressed as, Pharmaceutical Chemists. Registered Chemists and Druggists may open as many branch establishments of their business as they please.

R. Hall (Camborne).—They may be obtained of any scientific instrument maker.

Pharmaceutical Chemist (Northampton), *W. R.* (Scarborough), *M. P. S.* (Southport), *Res Facta* (Bristol), are referred to the rule respecting anonymous communications.

E. Smith (Torquay).—Arrangements are being made for the issue of cases; we hope to be able to publish the details in our next number.

In consequence of press of matter, we are obliged to omit answers to several correspondents.

Communications, Letters, etc., have been received from Mr. H. Machon (Saffron Walden), Mr. J. B. Leslie (Sheffield), Mr. Barker (Sudbury), Mr. Malcham (Sheffield), Mr. H. Flint (Cork), Mr. Gregory (Stockton-on-Tees), Mr. Collier (Sheffield Moor), Mr. W. A. Thirlby, Mr. Fairlie (Glasgow), W. M. (Ramsgate), W. L. G. (St. Austell), A. (Carlisle), S. D. Q., "Grey Hairs," "Aliquis," "Kapha," "Nemo."

THE TRADE IN LEECHES.

BY P. L. SIMMONDS.

Although the commerce in leeches in this country has largely declined of late years, yet the demand elsewhere for this small red-blooded aquatic worm is so great as to afford employment to a considerable number of persons in breeding, catching, and selling them. France, which used to be the great emporium for much of the trade, has, within the last few months, had weightier matters to attend to than the collection and transit of leeches. Hence some few particulars and statistics of the trade, as it did exist, may not be without interest at the present time.

Among the works which I have consulted may be named 'Monographie des Hirudinées,' par Moquin-Tandon; 'Monographie des Sangsues Médicinales,' par Ch. Fermond, 508 pp., Baillière, Paris, 1854; 'Mémoire sur l'Hirudiniculture,' par A. Ph. Laurens, 1854; 'Nouvelle Monographie des Sangsues Médicinales,' par Dr. Ebrard, 494 pp., Paris, Baillière, 1857; 'Le Guide pratique des Éleveurs de Sangsues,' par L. Vayson; 'La Production des Sangsues,' par Jourdin: Paris, Hachette et Cie.

The commerce in leeches may be looked at in different points of view, as the sale, properly so called, the importation, export, nature of the commercial species sold, their price, falsification and transport, but full descriptions on all these would take up too much detail. Fermond enumerates seven varieties of the medicinal leech; so does Dr. Letheby. It is not necessary to give the specific details of these here. In this country only two kinds are usually reckoned fit for medicinal purposes, viz. the brown leech and the green leech; the former found sparingly in Great Britain, but abundantly in northern and central Europe. Dr. Letheby says the *Sanguisuga* may be known by one or both of two characters: they have a continuous longitudinal stripe of a yellow or orange colour along each margin or side of the body; and secondly, when the abdomen is of a lighter tint there should always be two lateral black stripes, one running down on either side. Every leech that does not present these, which may be called generic characters, should be rejected.

A communication to the Société Zoologique d'Acclimatation of Paris made known the existence in America of leeches possessing this valuable property, that they leave no mark on the skin to which they are applied, so that they must act not by biting but by suction. This curious fact is put beyond a doubt by the experiments made upon himself by Craveri, a learned Italian. M. de Filippi has placed these leeches in a new genus, which he terms *Hæmentaria*, and of which he describes three species, two belonging to Mexico and one to the river Amazon.

The following is the annual declared value of the leeches imported into this country in the last seventeen years. Formerly the largest quantity came from Hamburg, but of late years nearly all the imports were from France:—

1853	£27,068	1862	£9,455
1854	17,238	1863	12,393
1855	16,477	1864	9,028
1856	12,926	1865	13,314
1857	10,011	1866	12,866
1858	11,604	1867	8,999
1859	11,919	1868	8,876
1860	11,857	1869	7,067
1861	11,175		

This is the foreign import, and exclusive of any home supply obtained. It is difficult to arrive at numbers in such an article, but the value must represent at least two million leeches annually; indeed, some years ago it was stated that seven or eight millions were annually imported.

From official figures we find that the import of leeches into France annually from 1827 to 1836 was 34,050,682; and from 1837 to 1846, 18,538,041. The largest quantity was 57,491,000 in 1832; the official value of these being stated at 1,724,730 francs. In subsequent years the imports were greatly reduced, as the following figures will show:—

1847	11,790,840
1848	9,903,398
1849	11,112,000
1850	11,766,000
1851	13,058,500
1852	10,415,000

Adding the home collection and those fraudulently imported, the leeches annually employed in France may be taken at 30 millions; and many of these serve for use several times. According to L. Busquet, these 30 millions are differently made up, and he considers the largest portion are furnished from the native marshes. In 1851 (he states) we received 13,058,500 and exported 5,731,000, and therefore, of the imports 7,327,500 were retained for consumption; and as 30 millions are used, the home supply must have been 22,672,500 leeches, of which about a third were furnished by the department of the Gironde. France is now obliged to seek leeches from the adjacent countries, Switzerland, Belgium, the Sardinian States and Greece. Spain and Portugal, which used to export, are now obliged to draw supplies from abroad. It is the same in Italy. Tuscany exports some leeches, but they are considered of an inferior quality. Bohemia, which used to furnish supplies, now possesses only exhausted marshes. Hungary, so rich in leech morasses, commences to be impoverished of the kinds which the dealers used to send as far as the frontiers of Russia and Turkey, Poland and other countries in the north of Europe. Great Britain, which used to be rich in leeches, is now forced to draw supplies from France, Germany, and Portugal. It is by Bordeaux, Stettin, Hamburg and Lisbon that these supplies are drawn. Hamburg and Stettin each send about 150,000 per month.

Turkey still supplies leeches. In 1845 the shipments from Constantinople were 120 tubs; in 1846, 189; and in 1847, 108. In 1857, 475 packages and cases of leeches, valued at 287,000 piastres, were shipped from Smyrna.

The price has varied greatly in France. For fifty years, according to Fée ('Cours d'Histoire Naturelle'), they were sold at 12 to 15 francs the thousand; in 1815 they were double that price, and they gradually advanced to 150 and 200 francs. In 1849 and 1850 the hospitals at Paris bought them at 160 francs the thousand, but in 1851 the price rose to 240 francs. The price varies according to the size, quality and season. In 1854 it ranged from 150 to 190 francs the thousand. If with Vayson we take the mean price at 200 francs the thousand, we arrive at the gross annual value of £240,000 for leeches in France. The wholesale merchants will not, however, admit that the sum is so large.

Leeches are found to a great extent in the lakes of the north-west district of Morocco, called the Ghaib. They are shipped in the first instance to Gibraltar. In 1839 about 4 or 5 million leeches, valued at nearly £6000 sterling, were shipped from Morocco; and in the same year, from Tunis to France, leeches valued at 106,000 piastres. In 1843 their value seems to have greatly increased, for in that year 611,000 leeches (valued at £4889) were sent to England from Morocco, and 809,000, value £6358, to other countries. The quantity annually shipped from Tangier is said to be from 15 to 18 millions. Spain and France receive the greater part. The leech fisheries of Kaissaireh and other parts of the empire of Morocco are annually disposed of by the Government to the highest bidder. The right to collect leeches in these marshes was at first obtained for a few hundred pounds, but now purchasers pay heavily for the privilege. In 1856, £14,000 was paid for the monopoly of the collection and export.

Sixteen to seventeen thousand pounds' weight of leeches are obtained there annually. There was long a prejudice in France against the leeches of Algeria, as they were placed in the category of dragon-leeches, which were excluded by law from being used in the civil hospitals of France. The result, however, of experiments made in Algeria by order of Marshal Vaillant, and subsequently repeated in France under the eyes of many members of the Academy of Sciences, has fully established the fact that the African leeches are fully equal to any obtained in Europe, and therefore for the home supply of France recourse need not be had to the marshes of Turkey and Hungary. They are to be found plentiful in the marshes of Taguin, between Boghas and Traret, and a large commerce might be carried on in them with profit. Indeed, in the year 1865, 1,207,000 leeches were shipped from Algeria, of which 379,000, value £1516, came from Stora, Philippeville, and 11,923 from Bona.

The rearing of leeches in great natural marshes, or in marshes artificially made, forms an important branch of rural economy in France. M. Béchade, a farmer in the neighbourhood of Bordeaux, became a millionaire by transforming poor marshes, for which he could hardly pay a rent of 300 francs, into magnificent enclosures for leeches, now let for 25,000 francs. M. Jourdin ('La Pisciculture et la Production des Sangsues') refers to a Parisian capitalist who embarked in this species of industry, with the satisfactory result of a revenue of 15 for 1, that is to say, a leech which cost 25 centimes produced on an average 15 leeches a year, which could be sold at the same price, or, say 3 francs. Deducting at the most 5 centimes for expenses, there remains a gain of 2 francs 25 centimes when the operation is on a large scale. It is therefore credible that a marsh of 48 hectares should let for 25,000 francs, and that enormous fortunes should have been made by this new species of rural economy, which is alike useful to the public and beneficial to the private interest of those by whom it is prosecuted.

Lord Desart lately let a piece of marsh land of about 40 acres on his estate near Callan, Wexford, to a company of Frenchmen, who immediately fenced it in, and, having freely irrigated it from an adjoining stream, proceeded to sow it down under a leech crop. The "seed," if we may so express it, was contained in sacks, each holding 15,000 leeches, which were scattered from the hand just as corn is sown. Formerly, after becoming apathetic from use, leeches were thrown away, and new ones procured at a considerable cost; now, however, when no longer fit to be used, they are planted in beds in the rivers and ponds of France, and, being properly fed, soon resume their activity, and furnish the most beautiful cocoons.

Leeches abound in India and Ceylon, and we may yet get them even from those distant quarters. Dr. Carter read a paper some years ago before the Bombay Medical and Physical Society on the leeches of western India, in which he alluded to the Matheran, a terrestrial leech, the common leech being aquatic. This Matheran leech is about three-quarters of an inch long and of a reddish-brown colour, has a black line down its back, is covered with black spots, and has ten eyes arranged in a circle, with a smooth lip. The common leech, on the contrary, is olive-green in colour, has seven lines down the back, twelve eyes arranged quadrilaterally, and an uneven notched lip.

In Ceylon, where the varieties of leeches are more numerous than in any part of the world, the propagation of the sort used in phlebotomy is made a secret. In India, also, the leech propagators do all they can to keep the knowledge to themselves. Major Blenkinson, a good naturalist, succeeded, however, in propagating them in Scinde, to the great economy of Government in supplying the hospitals. Mr. J. Sparkes describes the plan, PHARMACEUTICAL JOURNAL, Vol. VI. p. 259.

Dr. Hooker, in his 'Himalayan Journal,' says that he found leeches swarmed in incredible profusion in the streams and damp grass and among the bushes. "They got into my hair (he adds), hung on my eyelids, and crawled up my legs and down my back. I repeatedly took upwards of a hundred from my legs, where the small ones used to collect in clusters on the instep. The sores which they produced were not healed for five months afterwards, and I retain the scars to the present day."

INTRODUCTION OF MAIZE INTO CHINA;*

(INDIAN CORN, *Zea Mays*, L.)

BY H. F. HANCE, PH.D., ETC., AND W. F. MAYERS, ESQ., F.R.G.S.

With Notices of the Plant by Chinese Authors.

In the summer of 1858, and therefore shortly before the collections of Mr. Charles Wright had furnished the text for Asa Gray's celebrated essay on the connection of the Japanese and Eastern-American Floras, the venerable Professor von Martius, of Munich, in a letter on the relations of the Asiatic and American continents, directed my attention to the inquiry whether there was any extant evidence of maize being a true native of Japan, adding that Siebold had stated it to be delineated in the arms of that empire.

At that time Japan was just emerging from the position of a *terra clausa;* no very comprehensive idea of the precise character of its flora and its connection with that of other countries, based on modern researches, was attainable, and, save a stray specimen here and there, its vegetable productions scarcely existed in herbaria except amongst the rich and unarranged treasures of the Leyden Museum. The

* Read before a meeting of the Linnean Society.

query excited my interest at the time, but partly from Thunberg noting under *Zea Mays* (Fl. Japon. 37), "Colitur prope Nagasaki, a Chinensibus forsan primum in regnum hocce illata," and partly owing to the incongruity which attached in my mind to the notion of armorial bearings amongst the Japanese,—though we now know that these exist, and that the feudal retainers of the powerful chieftains wear their badges precisely as did those of the mediæval barons,—the subject soon escaped my memory. Some months back, however, my attention was attracted by an advertisement in the London seedsmen's catalogues of a striped-leaved form, alleged to have been introduced from Japan, of *Zea Curagua*, a Chilian species (and probably the only other one of its genus) described about eighty years ago by Molina; but on what evidence a Japanese origin is assigned to this variety I have no means of ascertaining. About the same time also Mr. A. Ernst, of Caracas, wrote to me, requesting that I would, if possible, ascertain when maize was first known in this country.

In the 'Géographie Botanique' of M. Alph. de Candolle (ii. 942 *sqq.*) the distinguished author has given a very complete *résumé* of what was known respecting the introduction of this cereal, and, after a careful and lucid examination of all the data, has expressed his unhesitating conviction that it was brought from America, though from what part of that continent he considers very doubtful, inclining, however, rather in favour of Mexico. He expresses, moreover, a desire that reliable investigations should be made as to Bonafous' suspicion, that the grain was cultivated in China prior to the discovery of America,

The question whether, in common with *Phryma leptostachya, Panax quinquefolium, Tipularia discolor*, and some other plants, maize may claim Asia equally with America as its native country; or, failing probable grounds for such an opinion, whether trustworthy printed evidence exists of its cultivation in Asia antecedent to the second discovery of the great American continent at the close of the fifteenth century,—is evidently of the highest interest; and the Chinese nation boasting a rich historical literature, and in matters of antiquity having perhaps a right to look on Western records much as the Saïtic priests are represented in the Timæus to have regarded those of the Greeks, I felt convinced that the examination of native works, the statements in which relative to the sciences of observation have commanded the respect of such men as Arago, Humboldt and Biot, could not be wholly unproductive. I am not myself a Chinese scholar, but was so fortunate as to enlist in this inquiry the services of my friend Mr. W. F. Mayers, H.B.M. vice-consul at Canton, one of the most accomplished and learned of sinologues, and who besides enjoys exceptional advantages from being on amicable terms with all the high native officials at the southern capital. This gentleman had the kindness, at my request, to make inquiries of his Chinese literary acquaintances, and to undertake and execute himself a thorough examination of all the works treating of maize to which he could procure access, and the results are embodied in the accompanying memoir, the interest and value of which, as a contribution to the history of plants, all botanists will acknowledge. It was, through the writer's liberality, freely placed at my disposal, and is here given without a single alteration.

I am far from maintaining that the evidence adduced is sufficient to establish the claims of Asia to rank as a native country of this cereal. But, for my own part, I am much disposed to coincide in a remark made to me by Mr. Mayers, "that the unhesitating statement of the Pun Ts'ao, as to its origin in the countries west of China, goes a considerable way towards establishing this origin, the assertion being so unqualified that I think it must be founded on antecedent evidence, although this is now untraceable." And I may add that, in my judgment, the remote date assigned by Chinese records to its introduction, and the circumstance that the introducer is unknown are irreconcilable with the supposition that it was brought to this country by the Portuguese, their first arrival here, under Fernand Perez d'Andrada, being, I believe, in 1517, and the earliest notice of maize in European literature dating later than 1530. To those, finally, who would urge the conflicting and erroneous opinions of the early European writers, as to the country whence maize found its way to the West, as a ground for regarding Chinese statements with equal distrust, I would answer that it is not logical to apply the same canons of criticism to Western and Chinese literature, the latter being, at the period in question, in a very different and comparatively far more advanced state of development.

Whampoa, 1867. H. F. H.

On the Introduction of Maize into China.

In answer to inquirers on this subject information has been sought from private sources and from the published works of Chinese authors. The following is a translation of a memorandum by Mei K'i-chao, the present Intendant of the Grain Revenue for the Province of Kwang-tung.

I. *Notes on Maize* (*Pao-ku*).

"*Pao-ku* is identical with *Yü Shŭ-shú*, or the jade-like Shŭ Millet.* The Complete Treatise concerning Agriculture† gives also the name of *Yü-mi*, or jade rice. The plant takes its name from the resemblance of the stem and leaves to those of the *Shŭ-shú*, or millet of Sz'-ch'wan (Barbadoes millet), compared with which, however, they are more fleshy and shorter. They also resemble the *I-i*, or *Coix lachryma*. From its lustrous white colour it obtains the name of "jade-like." It is also called *Yü Kao-liang*, and *Yu-mê*, or jade wheat. Also, from its seed having been brought originally from the country of Si-fan,‡ it is likewise called *Fan-mé*, or *Fan* wheat; and, having been formerly presented as tribute, it is also called imperial wheat, *Yü-mé*.§ Other names are in use, such as *Jung-shu*, or western pulse (*Jung* designating the territories to the westward of ancient China), and *Yü Shŭ-shú*, or jade millet of Sz'-ch'wan. The variety of these terms is due to the fact that the seed was introduced from abroad, so that at first it had no definite name;

* For note respecting this plant see *post*, p. 525.

† This work, entitled '*Nung Chêng Ts'üan Shu*, was the production of Sü Kwang-k'i, an enlightened statesman of the sixteenth and seventeenth century, noted for his friendship with the Romish missionaries. His treatise, above referred to, was laid before the Emperor Wan-li in A.D. 1619.

‡ The territory to the N.W. of Tibet has been known to the Chinese from the earliest times by the name of Si-fan, which has now, however, disappeared in favour of that of Inner Mongolia. The Si-fan (or Western-alien) territory borders on the present provinces of Sz'-ch'wan and Kan-su.

§ See *post*, section iv. note, p. 525.

but, as it can be used as farinaceous food, the terms rice, wheat, millet and pulse have been made use of.* The names *Pao-ku* (sheathed grain), *Su-mi* (millet rice), and *Pao-su* (sheathed millet), are the designations current in the southern provinces.

"The stem grows to a height of 3 or 4 feet (42 to 56 English inches) or upwards. At each joint a sheath is put forth, growing outwards from the side of the stem, in shape like the *Tsung* fish.† At the extremity of the sheath a beard of an inch or more in length is formed. The seeds are in size like those of the *Tz'* plant,‡ and are clustered together, enveloped in several layers of a white external covering. It flowers about the end of summer.

"The Pun Ts'ao§ classes this plant with the cereals (*Ku*), remarking that its grain has a sweet flavour, and that its medicinal qualities are aperient. In poor country places and remote districts it is occasionally used as food. In the neighbourhood of Peking its common name is *Yü-mi*, or jade rice.

"The seeds are ground into flour and mixed in the proportion of one-tenth or one-fifth with wheaten flour, to which it adds whiteness and an agreeable appearance; but no one uses it as food by itself, from fear of indigestion. The maize grown in the province of Kwang-tung is slightly different, having yellowish grains.

"It is said that maize abounds chiefly in the provinces of Yün-nan and Kwei-chow, where tradition asserts that it was brought from Cochin-china by Ma Fu-po,‖ but there is no genuine evidence to this effect, and confidence must not be rashly placed in the tradition. Examination of the two works above quoted, both published under the Ming dynasty, elicits only that the seed was first brought from Si-fan; but of the period at which this took place they say not a word. It is further noted that this grain was heretofore presented as tribute, but again no date is assigned. It is evident that its introduction must have taken place at a very early period; as, at the time when these works were compiled, no information could be procured."

* The writer appears in this passage to be seeking to make clear the fact that the maize plant, not being indigenous to China, has no authorized appellation sanctioned by the uses of antiquity, and that hence the names under which it is known are merely comparative and fluctuating, according to individual or local choice, although the obvious characteristics of the plant confine the selection within the range of cereal species.

† *Tsung-yü*, a species of *Sciræna*, the tapering body of which resembles in some degree the bract of the maize plant.

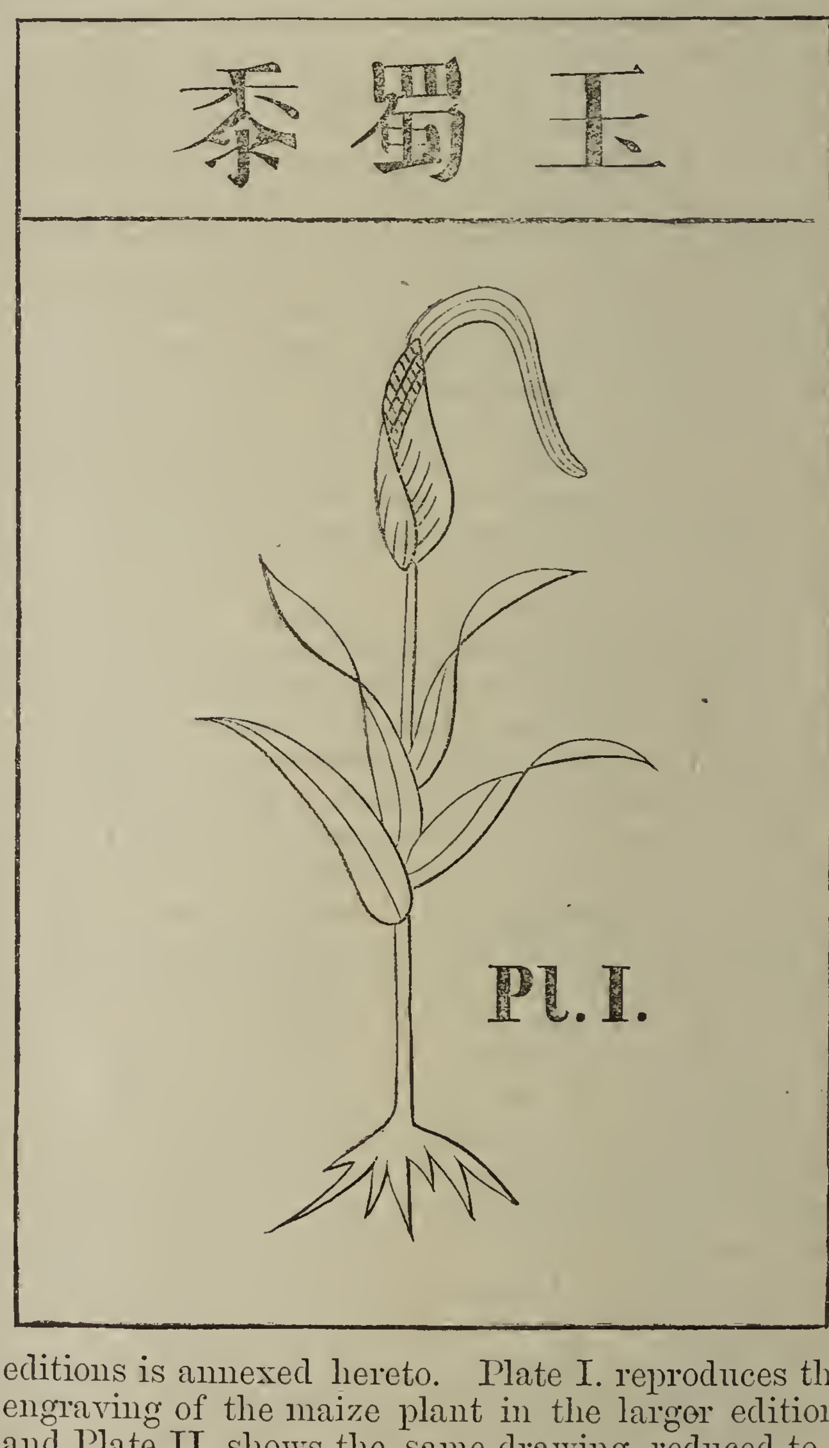
‡ *Tz'-shih*, an aquatic plant, resembling the nelumbium, cultivated for its seeds, which are used in medicine. In size and farinaceous appearance they are not unlike those of the maize plant. [This has been proved on further investigation to be *Euryale ferox*, Sal.—H. F. H.]

§ For note on the Pun Ts'ao and extracts respecting maize, see *post*.

‖ Ma Fu-po, or Ma Yüam, the celebrated general of Kwang Wu of the Eastern Ham dynasty, A.D. 30. It is noteworthy that Chinese history records an expedition, headed by Ma Yüan, against the Si-fan tribes, in A.D. 36, prior to the campaign in Cochin-china, with which his name is most commonly associated. If the maize plant was really brought from the Si-fan territories to the Western Provinces of China, as the native records assert, it may well have been among the results of this early expedition; whilst a confusion in the popular tradition as to its origin is also not unintelligible, in view of the constant connection of Ma Yüam's name with his famous victories in Cochin-china.

II. *Extract from the Pun Ts'ao, or Cyclopædia of Natural History.*

[*Note.*—The *Pun Ts'ao Kang-mu* was composed by Li Shih-chên during the latter half of the sixteenth century, but was not published until after his death, having been laid before the Emperor Wan-li by his son in A.D. 1597. It remains to this day the standard work of reference among the Chinese for all subjects relating to natural history and medicine; but the text of the original has been largely added to and reclassified by subsequent editors.* It has proved impossible to obtain a sight of an ancient copy of this work, and the extract translated below is taken from the edition of 1655, from which all later reprints have been made. The original plates are transferred to each edition, whether of octavo or duodecimo size; and a specimen from two of such



editions is annexed hereto. Plate I. reproduces the engraving of the maize plant in the larger edition, and Plate II. shows the same drawing, reduced to a smaller scale. Plate III. is a figure of the Barbadoes millet (for note respecting which, see next page).]

"*Yü-shŭ-shŭ*, common name *Yü-kao-liang*.

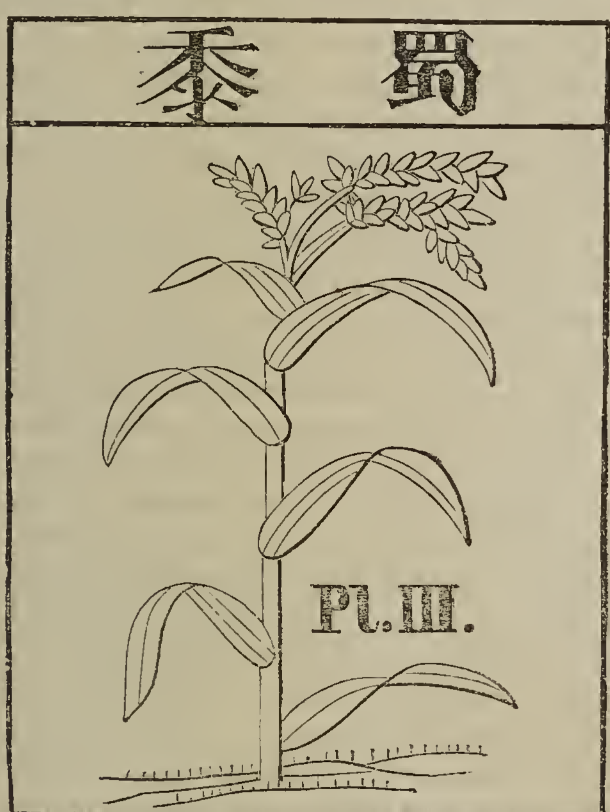
"The text of Li Shih-chên is as follows:†—The seed of the *Yü-shŭ-shŭ* came from the lands on the West, and it is cultivated by but few. Its stalk and

* Notwithstanding the additions to or reconstruction of the text by successive editors, the words of the original are, in accordance with invariable rule, both scrupulously preserved and carefully distinguished. Thus, in the modern editions of the Pun Ts'ao, the text of the author is specifically quoted at the head of subsequent additions or commentaries.

† See remarks in previous note.

leaf both resemble the *Shŭ-shŭ* (Barbadoes millet), but are more fleshy and shorter. They also resemble the *Coix lachryma;* the stalk grows to a height of 3

or 4 feet; it flowers in the sixth or seventh month, producing an ear like that of the *Pi-mé*. From the heart of the stalk there issues a sheath in shape like



the *Tsung* fish, from which a white waving beard grows out. After a time the sheath opens and the grain comes forth. The grains are clustered together, each one as large as a *Tsung* (?) [used as a generic term for palms] seed, and yellow and white in colour; they may be eaten baked or roasted. When roasted, they burst into a white flour-like mass, similar in appearance to that produced when rice of the glutinous kind is roasted."

III. The following are the references of the Pun Ts'ao with respect to the Barbadoes millet (*Sorghum vulgare*, Pers.):—

"The plant known as the Shŭ-shŭ, or millet of Sz'-ch'wan, has the following synonyms:—*Lu-ts'i*, reed grain; *Lu-sŭ*, reed millet; *Mu-tsi*, wood grain; *Ti-liang*, reed millet; *Kao-liang*, tall millet. Li Shih-chên observes: 'The Sz'-ch'wan millet was not much known in former times, but it abounds at present in the northern provinces.' The work called the '*Kwang-ya*,' gives the names *Ti-liang* and *Mu-tsi* (see above), on account of its belonging to the millet tribe; but from its growth to a height like that of the reeds called *Lu* and *Ti*, it has become popularly known by the various names given above. The seed was first introduced from the territory of Shŭ (the ancient name of the present province of Sz'-ch'wan, on the western frontier of the empire), whence it is called Sz'-ch'wan millet."

IV. Apart from the Pun Ts'ao, notices upon the present subject have also been sought in the '*Kê Chih King-yüan*,' or 'Mirror of Classified Research,' a vast cyclopædia of information in all departments of physical study practised by the Chinese, with references under each heading to antecedent works. This collection, in twenty-four volumes, was published in 1735 by Chên Yüan-lung. It contains no reference to maize under the name of *Yü Shŭ-shŭ*; but describes the plant as *Yü-mê* (imperial wheat),* in the following terms:—

"*Yü-mê*, or imperial wheat, originated in the Si-fan territory (the lands beyond the western frontier of China Proper), and its ancient name was *Fan-mê*, or 'wheat of the foreign lands of the West.' Having been offered among tribute, it has received the name of imperial wheat. In its stem and leaf it is the congener of the *Ts'i*, or panicled millet, and, in its flower, of rice. The sheath enclosing the ear is like a closed fist, but longer. The beard resembles red threads. The seed is like the grain of the *Tz* plant, but large, lustrous, and white. The flower blooms at the top of the plant, and the seed (ear?) grows out from the joints."

V. The same work from which the above notice is taken, contains a quotation from a historical work called '*Tu Yang Tsa Pien*,' or 'Miscellanies of Tu-yang,' throwing light on the practice of presenting new species of plants as tribute to the Emperor. The extract is as follows:—

"In the eighth year of Yüan-ho,† of the Tang dynasty, *Pi-mé*, clear green wheat, was offered as tribute by the kingdom of Ta-chên. In size it was larger than the wheat of China, and its seeds, both within and without, were of a clear green colour. Its scent was like that of the non-glutinous rice."

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Borax.—The principal form of native borax is the mineral *tincal* from India. [§ It is also made artificially by boiling together in proper proportions boracic acid and carbonate of soda.] The boracic acid is derived from the water of the lagoons, little lakes formed by the condensation of the steam of volcanic origin, which issues from the earth in several districts, particularly at Lardarello, in Tuscany. The water of these lagoons is evaporated by causing it to pass slowly down an inclined and terraced roof heated by the steam and vapours which issue below.

Borax is an abnormal salt, the constitution of

* See *ante*, reference from note, p. 523.

† The reign known as Yüan-ho commenced in A.D. 806.

which cannot be expressed by any simple formula. It may be noticed, however, that it contains the elements of two molecules of a metaborate, $NaBO_2$, with boracic anhydride B_2O_3; or, since it is probable that part of its water is constitutional, it may be represented as an acid metaborate with water of crystallization, $2(NaBO_2HBO_2)9H_2O$. Normal boracic acid is H_3BO_3; take from this the elements of water, H_2O, and metaboracic acid remains.

Borax presents a weak alkaline reaction with litmus paper. [§ A hot saturated solution when acidulated with any of the mineral acids lets fall as it cools a scaly crystalline deposit (boracic acid H_3BO_3), the solution of which in spirit burns with a green flame.

The boracic acid is produced thus:—

$$Na_2B_4O_7 + H_2SO_4 + 5H_2O = Na_2SO_4 + 4H_3BO_3.$$

Boracic acid is a very feeble acid, which decomposes carbonates but slowly in the cold; it reacts with turmeric as alkalies do. Upon this fact is founded an excellent test for its detection. The borate is mixed with a slight excess of hydrochloric acid and a piece of turmeric paper dipped into the solution. Upon drying the paper it appears of a reddish-brown colour, which becomes blue on moistening it with weak potash. Boracic acid is employed in the Pharmacopœia as a test for turmeric powder in rhubarb. Borax neutralizes acids to the same extent as an amount of sodic hydrate or carbonate containing the same quantity of sodium. Thus $Na_2B_4O_7 10H_2O$ will neutralize $H_2C_2O_4 2H_2O$; half a gram-molecule, or 191 grams, will, therefore, neutralize 1000 cubic centimetres of the volumetric solution of oxalic acid.

Bromum.—[§ A liquid non-metallic element obtained from sea-water and from some saline springs]; also, in small quantity from *kelp*, the ash of seaweed. From whatever source it is obtained, the same principle is adopted in its preparation. The liquids from which the most easily crystallizable salts have been removed are made to receive a current of chlorine gas. Chlorine has a greater affinity for metals than that possessed by bromine, consequently upon such treatment the bromides present undergo decomposition and the bromine is set free. Thus if bromide of magnesium be the salt operated upon, as is usually the case, the reaction proceeds thus:—

$$MgBr_2 + Cl_2 = MgCl_2 + Br_2.$$

Excess of chlorine is to be avoided or it combines with the liberated bromine. The liquors which are now brown are shaken up with ether, which dissolves out the bromine, and rising to the surface, carries it with it. Drawn off and shaken up with a solution of potash, the ether gives up the bromine to the potash, which, after it has been several times employed in the same way, becomes finally saturated with bromine and neutralized. On evaporating to dryness the solution of bromide and bromate of potassium thus obtained, heating the residue to destroy traces of brominated organic compounds, and finally distilling the residual bromide of potassium with sulphuric acid and black oxide of manganese, bromine is found in the receiver.

$$2KBr + MnO_2 + 3H_2SO_4 = Br_2 + 2KHSO_4 + MnSO_4 + 2H_2O.$$

[§ Bromine is a dark brownish-red, very volatile liquid, with a strong and disagreeable odour. Its specific gravity is 2·966. Agitated with solution of soda in such proportion that the fluid remains very slightly alkaline, it forms a colourless liquid:—

$$(6NaHO + 3Br_2 = \underset{\text{Bromide.}}{5NaBr} + \underset{\text{Bromate.}}{NaBrO_3} + 3H_2O),$$

which, if coloured by the further addition of a small quantity of the bromine, does not become blue on the subsequent addition of a cold solution of starch.] This last test is intended to indicate that the bromine is free from iodine, but it is quite useless for this purpose, and founded in error. If iodine were present in a sample of bromine, the whole of it would be converted into iodate which would not be decomposed by the addition of bromine.

$$6NaHO + IBr_5 = 5NaBr + NaIO_3 + 3H_2O.$$

To detect iodine in bromine, dissolve the sample in weak sulphurous acid, employed in such proportion as to produce a solution almost, but not quite, colourless. The whole of the bromine and part of the iodine will thus be converted into hydracids, a small quantity of the iodine remaining unchanged.

$$Br_2 + H_2O + SO_2H_2O = 2HBr + H_2SO_4,$$

and—

$$I_2 + H_2O + SO_2H_2O = 2HI + H_2SO_4.$$

It can then be recognized by starch.

The boiling-point of bromine is 145·4°, not 117° F., as stated in the Pharmacopœia.

Bromine, in its chemical relations, stands intermediate between chlorine and iodine. Its atomic weight 80 is very nearly the mean of 35·5 and 127, which are those of chlorine and iodine respectively. The crystalline form of the chloride, bromide, and iodide of any given metal is the same in nearly all cases. The elements themselves, though different in many characters, resemble each other closely in not a few. They all three form coloured vapours, with an odour which, when concentrated, is exceedingly irritating and corrosive, but when feeble, as when the vapour is diluted largely with air, reminds of the sea. Chlorine is a green gas, condensable to the liquid state; bromine is a very volatile liquid forming a brown vapour; iodine a solid, but volatile and producing a purple vapour. Each combines when in the gaseous state with an equal volume of hydrogen to form a colourless gas, which is very soluble in water, and forms a strongly acid solution.

THE COMBINATIONS OF CARBONIC ANHYDRIDE WITH AMMONIA AND WATER.

BY EDWARD DIVERS, M.D.

(*Concluded from page* 507.)

Products of the Distillation of Sal-Ammoniac with Chalk, with Potassium Carbonate and with Sodium Carbonate.

Sal-Ammoniac with Chalk.—I have already stated the collective evidence showing that when ammonium carbamate is volatilized, it is not converted into vapour of itself, but into a mixture of carbonic anhydride and ammonia. In the case of the carbonates of ammonium, the evidence of their decomposition into these gases and water when heated is still more conclusive, as some water is always obtained in the free state. The nature, therefore, of the products obtained by distilling a mixture of sal-ammoniac and chalk depends upon the behaviour of a mixture of water vapour and ammonia and carbonic anhydride gases; or, to go a step further, as these substances do not combine with each other until their temperature is much below the condensing-point of steam, and that, therefore, much of the water separates from the mixture in the liquid state, the nature of the products depends upon the reaction of equivalent quantities of moist carbonic anhydride and ammonia, and the behaviour of the product of this reaction with liquid water.

It is always stated that the products of the distillation of sal-ammoniac and chalk are the substance

$$(CO_3)_3(OH_2)_2(NH_3)_4,$$

water and ammonia gas; but I am not aware of the publication of any investigations on which this statement rests.

It would naturally be made on theoretical considerations, based on the ascertained composition of the carbonate as it appeared in commerce. All my own experiments on the subject, direct and indirect, prove it to be incorrect, and I am almost fully convinced that this statement is an incorrect one, and has been advanced upon theoretical grounds only.

In the distillation of a mixture of chalk and sal-ammoniac no ammonia escapes, the evolved gases entirely condensing. The carbonic anhydride and the ammonia combine to form ammonium carbamate, while the water is deposited in a free state. The carbamate and the water very slowly combine together. On redistilling these products, the commercial carbonate and free ammonia are the new products obtained, unless the distillation is carried on very slowly indeed. So that it is in the refining process that the commercial carbonate is obtained, and not in the primary operation.

Sal-ammoniac with Potassium or Sodium Carbonate.—When sal-ammoniac is distilled with either of these carbonates, the products are the same as when chalk is used, except that in the first part of the distillation some ammonia escapes. The evolution of the excess of ammonia is due to the unchanged carbonate of potassium or sodium combining with some of the carbonic anhydride and water, and forming acid carbonate.

Sal-ammoniac and Pearl-ash distilled with Aqueous Alcohol.—When pearl-ash, with fully its equivalent of sal-ammoniac, is distilled with aqueous alcohol, according to the directions of the London Pharmacopœia for preparing spiritus ammoniæ aromaticus, the first portions of the distillate soon deposit crystals in the receiver. By allowing a sufficient quantity of fluid to distil over, these crystals redissolve. The distillate, as a whole, is a solution of normal carbonate. The crystals deposited by the earliest portions of the distillate are very minute; but on letting stand some of the earlier portions of the distillate of such a strength as only to form crystals slowly, a good quantity of very thin, six-sided tables are deposited, which both by their appearance and behaviour on exposure to the air, prove to be half-acid carbonate. Acid carbonate is also formed. The mother-liquor is basic, or contains more than two atoms of ammonia to one of carbonic anhydride.

The spiritus ammoniæ aromaticus generally proves to contain caustic ammonia, and I think—I cannot speak with certainty—not unfrequently much less carbonate than it is intended to contain. By following the directions in the British Pharmacopœia, to use solution of ammonia and commercial carbonate instead of pearl-ash and sal-ammoniac, the formation of a spirit containing excess of ammonia is favoured, but to only a small extent. The spirit thus obtained is, of course, equally liable, if too strong in alcohol, to decompose into a basic solution and half-acid or acid carbonate, as I ascertained by preparing it. During the distillation crystals are apt to deposit in the neck of the retort, but they are soon dissolved again as the process goes on. The effects of distilling the commercial carbonate with aqueous alcohol and with water will be described presently.

Products of the Distillation of the Normal, the Acid, and the Half-acid Carbonates of Ammonium.

When the normal carbonate is distilled slowly enough, the products are carbamate and water, and, when the acid carbonate is similarly distilled, the product is the acid carbonate again; but when either the normal, the acid,* or the half-acid carbonate is distilled faster than the whole of the products of distillation can condense in the receiver, partial condensation takes place in such a way that *the carbonate of commerce is formed*, according to the respective equations—

$$2\,[CO_2 + 2\,OH_2 + 2\,NH_3] = (CO_2)_2OH_2(NH_3)_3 + 3\,OH_2 + NH_3$$
$$3\,[CO_2 + OH_2 + NH_3] = (CO_2)_2OH_2(NH_3)_3 + 2\,OH_2 + CO_2$$
$$3\,[3\,CO_2 + 4\,OH_2 + 4\,NH_3] = 4\,[(CO_2)_2OH_2(NH_3)_3] + 8\,OH_2 + CO_2.$$

Products of the Slow Distillation of the Commercial Carbonate of Ammonia.

On distilling the commercial carbonate very slowly, a thin film of liquid first condenses, which soon becomes a thin layer of crystals, probably of normal carbonate. Next, after a cessation in the volatilization, during which the temperature rises several degrees, some moist ammonium carbamate deposits. (This is really the first product of the distillation, the normal carbonate being only the product of the action of moisture—that adhering to the carbonate and to the retort and that in the air—on the ammonia and carbonic anhydride into which some of the carbamate of the commercial salt always passes when placed in a fresh volume of air.) After this, slightly moist commercial carbonate $[(CO_2)_2OH_2(NH_3)_3]$ is deposited, forming the great bulk of the products. Lastly, a very thin layer of moist and more acid carbonate is formed either by direct condensation or else by the action of water and carbonic anhydride on the superficial part of the commercial carbonate already deposited. When, therefore, the commercial carbonate is distilled very slowly indeed, the product consists principally of the same substance; by a more rapid distillation the product consists almost entirely of it.

Products of the Distillation of the Carbonate formerly in Commerce.—These have been examined by Rose. I have not succeeded in getting a carbonate of the composition the commercial substance used to have. But I have already shown that the main product obtained by Rose had the composition of the carbonate at present in commerce *plus* water. Unlike, therefore, the present carbonate, it yielded a product essentially different from itself by slow distillation. The remote part of the deposit was neutral.

Commercial Carbonate distilled with enough Water to cover it.—The effects of this distillation carried on at as low a heat as possible have been already described, so far as the changes in the retort are concerned. The deposit was formed by a distilling-heat of about 53° in a very warm condenser. It was moist and crystalline, and appeared qualitatively to be slightly ammoniacal acid-carbonate. Analysis proved it to be so.†

Commercial Carbonate distilled with Spirit of 90 *per cent.*—Hünefeld ascertained that by distilling commercial carbonate with spirit, a deposit condensed which was neutral in composition. I have repeated his experiment and have partly described the results.

It only remains to add here that the deposit, which was crystalline and saturated with aqueous alcohol, proved to be ammonium carbamate.

---

* The formation of the commercial carbonate from the acid-carbonate in this way was patented by F. Clarke Hills in 1846.

† Gossage patented, in 1855, the production of the acid-carbonate and a residual solution of the normal carbonate by distilling an aqueous solution of the commercial carbonate.

SANTONIN, AND ITS DETECTION IN THE URINE.*

BY WALTER G. SMITH, M.B.

Two singular effects are known to result from the administration of santonin in moderate doses, viz. visual derangements and a peculiar alteration in the colour of the urine. It is with the latter phenomenon that the author principally deals, but he gives personal testimony to the effect of santonin on the vision. Three hours after taking five grains of pure white santonin he became conscious, while reading, of a yellowish tint on the paper and a yellow haze in the air. His own hands, and the complexions of others, appeared of a sallow, unhealthy colour; and the evening sky, which was really of a pale lavender colour, seemed to be light green. Vision was not perfectly distinct for some hours, and was accompanied by a certain vagueness of definition.

Many substances, when taken into the stomach, visibly affect the characters of the urinary secretion in their transit through the system, and a number of vegetable colouring matters seem to pass unaltered into the urine. For example, madder communicates a red tint to the urine, and under the use of senna this secretion acquires the property of being reddened by ammonia. When rhubarb is administered it tinges the urine yellow or red, according as the reaction of that fluid is acid or alkaline. Carbolic acid, absorbed by the stomach, causes the urine to become greenish, and when freely applied to the skin has frequently developed a smoky or even black colour. Since the isolation of santonin by Kahler, forty years ago, it has almost entirely superseded santonica, and within the last twenty years has been largely and increasingly employed as a safe and efficient vermifuge. Various observers have noticed that the urine of persons under the influence of santonin is tinged of a saffron-yellow or greenish colour, and Giovanni and Ambroise state that it often induces apparent hematuria. The urine of some of the lower animals, *e. g.* rabbits, is similarly affected. As in the case of rhubarb, the shade of colour depends, no doubt, on the reaction of the urine, which is coloured yellow when acid, and purplish-red when alkaline.

The attention of the author was drawn to the subject by a case in which a boy aged five was given four grains of white santonin on the evening of August 18th last. Next morning the urine, which had been kept in a tall glass vessel, was of a bright pinkish-red. On the evening of the 19th, the boy took another four-grain dose. The urine passed soon after was of a greenish-yellow colour. A few drops of liq. ammoniæ immediately produced a clear red tint. The author then made a series of experiments on himself, the result being that he found the presence of santonin in the urine might be detected by the alkali test in periods varying from ten to fifty minutes after it had been taken, and that it was eliminated in from thirty to fifty hours.

A small quantity of saliva was several times tested, but always with negative results. It is stated that the serum of the blood is coloured yellow by a large dose. The colour of the urine was in all cases greenish-yellow, sometimes approaching a light saffron tint, the greenish hue being best seen by looking obliquely across the surface of the fluid. It resembled the urine of a person slightly jaundiced, and, like it, stained linen of a persistent light yellow. In two other respects also it curiously conformed to bilious urine. When nitric acid was dropped on a small quantity, a distinct purplish colour was brought out, which, however, was evanescent. Again, when sulphuric acid was added drop by drop, it developed a reddish-brown colour, changing to a deeper brown. No such effects were produced on the urine, when not under the influence of santonin. The sulphuric acid reaction was less ambiguous than the nitric acid, which might affect the colouring matter of normal urine somewhat similarly. These reactions, viewed in connection with the altered colour of the urine, show that it would be quite possible, from a hasty examination, to make an erroneous diagnosis of bile in the urine, and point to a possible fallacy in regard to the two most common clinical tests for bile.

The alkali test for the detection of santonin in the urine is a very striking one, and may be noticed both as to its character and its sensitiveness. It simply consists in the addition of an alkali to the urine, when a fine cherry red or crimson colour will immediately be developed, according to the amount of santonin present. The urine will respond to potash, soda, or ammonia, and also to lime or baryta water. If a globule of potassium be dropped on the urine, a bright-red track is left wherever the burning metal skims along the surface. At first ammonia was employed, and the colour is well brought out by pouring a few drops of liquor ammoniæ down the side of the test-tube, so as to float on the urine, when the red zone will appear sharply marked at the line of junction of the two liquids. But potash was afterwards found to be a more delicate reagent, and is better suited for general use. The red alkaline fluid is not bleached or altered by boiling, but the colour is at once destroyed by any acid, even carbonic acid gas. The subsequent addition of alkali restores the colour as before; hence it may be inferred that the colouring substance is not impaired or broken up by acids. Bicarbonate of sodium produced no immediate change, but on boiling for some time the reddish tint was gradually developed, and was discharged by continued boiling. Carbonate of sodium afforded similar results, except that it required longer boiling before the colour was discharged. Phosphate of sodium gave no result. The red-coloured stratum soon subsides to the lower part of the test-tube, carried down by the precipitated phosphates. Prolonged exposure to light in contact with excess of alkali bleaches out the colour, and chlorine at once dissipates it. Considering the sparing solubility of santonin, one part requiring 5000 parts of water at 17·5° C., the delicacy of the test will be apparent when it is stated that santonin was detected in the urine within ten minutes after 4 grs. were taken, and within an hour after but 1 gr. was taken. In one experiment the urine voided twenty-four hours after the dose gave a decided red colour with liq. potassæ, even when diluted with three parts of water.

For ordinary doses of from 3 to 6 grs. about two days are required for elimination, and it is to be remarked that the urinary coloration and reaction to the alkali test are more persistent than the phenomena connected with vision.

When the red liquid is examined with the spectroscope, the red, orange and yellow rays are transmitted, while the blue end of the spectrum is absorbed. In a more dilute state the red and blue rays are transmitted, and the centre of the spectrum is stopped. No characteristic absorption bands are produced. In order to determine the nature of the colouring material found in the urine, and to ascertain its behaviour with reagents as an aid towards its isolation, the following process was adopted at the suggestion of Dr. Emerson Reynolds:—About a pint of urine, passed after taking 4 grs. of santonin the preceding evening, was treated with neutral acetate of lead, avoiding excess, and then filtered. To the filtrate, neutralized by potash, basic acetate of lead was added so long as any precipitate was formed, and until the fluid became colourless. Neutralized, filtered, and washed. The yellow precipitate was transferred to a beaker, and decomposed by the cautious addition of dilute suphuric acid; spirit of wine was added, and the beaker set aside for twenty-four hours. Filtered; removed excess of sulphuric acid by barytic water, and filtered. The clear fluid now gave the pink reaction distinctly with potash, but ammonia had no longer any effect. The colouring

* Abstracted from a paper published in the *Dublin Quarterly Journal of Science* for November, 1870.

matter, therefore, was evidently set free, but the quantity at command was too small to admit of a more minute examination. The red alkaline filtrate gave a bulky precipitate with alum; but when this precipitate was filtered off, neither the precipitate nor the filtrate any longer afforded a trace of colour with potash. The liberated colouring substance does not seem to enter into combination with nitrate of silver, nor is it visibly affected by corrosive sublimate, sulphocyanide of potassium, chloride of gold, or bichromate of potassium. With persalts of iron it gives a permanent rich brown colour. From these experiments it may be gathered that the colouring material is tolerably stable, that it combines with *basic* acetate of lead, and can still be detected in that state of union by the potash test. It is highly probable that the colour-developing substance is a feeble acid derived from the intra-vascular oxidation of the santonin, and in support of such a view an experiment of Mialhe may be brought forward.

When santonin, in powder, is submitted to boiling nitric acid, a product is obtained which, after saturation, gives, with water, a greenish-yellow solution, analogous in appearance to that which urine assumes under the influence of santonin. This liquid, when treated with an alkaline base, immediately developes a deep orange-red coloration similar to that which urine secreted after the ingestion of santonin assumes with alkalies. This experiment has been repeated on the white and yellow forms of santonin, and with corresponding results; yet, though the reddened alkaline fluid gave an abundant yellow precipitate with basic acetate of lead, neither the precipitate nor its filtrate were any longer coloured by potash. Neither could any coloration be obtained on decomposing the lead precipitate with sulphuric acid, and testing the fluid decanted from the sulphate of lead with potash. If in these respects the artificial colouring matter fails in its analogy to the natural colouring substance in santonic urine, still Mialhe's experiment may be regarded as indicating the direction in which to seek for the cause of the natural phenomenon.

PRODUCTS OF THE ISLAND OF HAINAN.

BY R. SWINHOE.

The visitor from China is specially struck with the abundance of the cocoa-nut-tree—a tree not found in the latitude of Canton—which meets the eye on all points of the island coast. In spite of the winter monsoon, it flourishes best in the north-east corner of Hainan, in the district of Wênchang. Further in the interior, as the ground rises, the pine (*Pinus sinensis*) appears, and in some spots clumps of pine and topes of cocoa-nut grow side by side. The cocoa-nut also was found growing on the opposite shore of the Luichow peninsula, and on the small island of Naochow, off the right of the peninsula, in latitude 20° 45′. The cocoa-nut is not known in Formosa, excepting in one spot at the foot of the mountains, about twenty miles from the S.W. coast, where a few trees flourish, which there is good reason to believe were introduced by the Dutch. The areca was everywhere largely cultivated, as it is also in South China and Formosa. Fine banyans shaded the villages, growing to a large size. I observed three species—the ordinary *Ficus nitida*, a large-leaved species found also about Canton, and a species with small glabrous leaf and yellow berry—all equally grand and umbrageous trees. On the high-road to the capital and about the city itself two peculiar trees presented themselves—the one with black pods, ten inches long, hanging downwards all over it; the other, with long scimitar-shaped pods, twenty inches long, covered with an ochreous woolly down. Both these were new to me, and I brought home specimens of the pods, and submitted them to Mr. Bennett, of the British Museum, who pronounces the first an Asclepiadeous tree of an unknown species, and the latter a *Spathodea*, nearly related to *Spathodea stipulata*. Other village trees not often seen in China were the jack, the breadfruit, and the tamarind.

In the mountain forests the *Liquidambar formosana*, of Hance, was the commonest tree, associated with noble fig-trees of great variety and beauty. Palms also were abundant; on the higher ground the cocoa-nut giving place to fan-palms, caryota, phœnix, etc. The undergrowth was traversed in all directions by rattans and other tangles innumerable, so as entirely to impede passage through. The finest woods for fragrance and for sculpture are procured from the mountains of Hainan; and Du Halde, in his 'Histoire de la Chine,' states that the Emperor Keenlung had some carried to Pekin at immense cost to decorate a palace he was building for his sepulture. The most precious of these woods is the *hwa-le*, named by Europeans rose or violet-wood on account of its odour, which the Chinese procure by barter with the hill tribes. Then there is the *kao-kên*, or eagle wood, a very hard timber, a specimen of which I procured at Hoitow, and brought home for the Kew Museum. There is also a very fine and incorruptible yellow wood, columns of which, of a certain thickness, are priceless, and said to be reserved, as is the hwa-le, for the service of the Emperor. This yellow wood is much used in the island for building purposes, but I noticed that its bright colour soon fades when exposed to the light. One tree exudes an abundance of a gummy matter, which is brought down in large lumps to the west coast, and thence exported for sizing purposes. Another tree, probably the same as the *Aloexylum Agallochum* (Loureiro) of Cochin China, yields the "ching-heang," or fragrant wood, so much sought after by the Chinese for incense and for carving into ornaments. This is procurable in large quantities in Nychow city in the south end of the island, where the best kinds are sold for about 1*s.* an ounce, and the coarser kinds, used for burning, for about 6*d.* a pound. The Chinese did not know the tree, and could give no account of it, but Loureiro says that it is only the decayed parts of the tree that are so highly scented, and he attributes it to a disease. In the south also they have the tree which yields the "dragon's blood," and others with sweet-scented sap used for incense.

About the jungles of the south a species of *Alpinia*, with upright flower, lately described by Dr. Hance, her Majesty's Vice-Consul at Whampoa, as *A. officinarum*, grows wild, and its roots yield to trade the valuable drug galangal. Its berries, which are also used as a drug by the Chinese, and were described and figured by Mr. Daniel Hanbury in 1855, are infused and taken by the aborigines as a substitute for tea. The tea-plant is cultivated in Hainan by the Chinese, and a very coarse kind of tea prepared from it; but whether it is indigenous to the island or has been introduced, I was not able to ascertain. The fruits of the country are cocoa-nuts, areca or betel-nut, mangoes, indifferent oranges, limes, jackfruit, breadfruit, papaws, lichees, longans, jamboos, carambolas, bananas and tamarinds.—*The Field.*

Supposed Suicide by Carbolic Acid.—An inquest was held lately in Liverpool on the body of George Carey, a shipkeeper, who was found, apparently in a fit, in the cabin of a vessel in which he had been keeping watch. A bottle labelled "Carbolic Acid" was on the floor, with the cork drawn. He was taken to the Southern Hospital, where he died. His breath smelt strongly of carbolic acid, and it is supposed that he had taken a quantity of it from the bottle found on the cabin floor. No cause could be assigned for such an act, except that he had been fined in the morning for losing a tide watch. The jury returned an open verdict.

Effect of Coffee upon Iodine.—Hutet mentions that one grain of iodine, added to a teaspoonful of strong infusion of coffee, has no longer any taste or smell, and does not give the blue tinge to starch.—*Lancet.*

THE COMPARATIVE EFFICACY OF ANTISEPTICS.

Dr. F. Crace Calvert has performed two series of experiments in order to ascertain the comparative powers of various substances ordinarily used as antiseptics. The first consisted in placing in bottles (not corked) solutions of albumen and flour-paste. To these he added various proportions of some of the substances patronized at the present time as antiseptics, and the following table shows the time in which an offensive odour became sensible at a temperature from 70 to 80 degrees F.

Antiseptic employed.	Per cent. of antiseptic.	Albumen.	Flour-paste.
M'Dougall's disinfecting powder	5	11 days	25 days
Carbolic disinfecting powder	5	Sound	Sound
Chlor-Alum (made lately)	2	9 days	—
Chloride of zinc	2	15 days	—
Chloride of lime	5	16 days	14 days
Permanganate of potash	5	—	—
Tar oil	2	11 days	25 days
Carbolic acid	2	Sound	Sound
Cresylic acid	2	Sound	Sound
None	—	5 days	7 days

The above table he considers clearly to show that the only true antiseptics are carbolic and cresylic acids; and these results coincide with those obtained by Mr. William Crookes, F.R.S., Dr. Angus Smith, F.R.S., and Dr. Sansom. These two acids continued their action till the albumen solution and paste dried up. The second series had the object of ascertaining which of the undermentioned substances is most active in destroying germs, and preserving animal substance. At the bottom of wide-mouthed pint bottles, Dr. Calvert placed a known quantity of each of the antiseptics, suspending over them by a thread a piece of sound meat; and, by daily examination, it was easily ascertained when the meat became tainted or putrid.

Antiseptic used.	Became tainted.	Putrid.
Permanganate of potash	2 days	4 days
Chlor-Alum	2 "	10 "
M'Dougall's disinfecting powder	12 "	19 "
Chloride of lime	14 "	21 "
Tar oil	16 "	25 "
Chloride of zinc	19 "	—
Carbolic disinfecting powder	Did not become tainted, but dried up and became quite hard.	
Carbolic acid		
Cresylic acid		

—*British Medical Journal.*

DRUGGISTS' CHARGES.

The *British Medical Journal*, in commenting on this subject, makes the following remarks:—A great deal is being said just now in various places about the high charges of dispensing chemists, for the most part very unreasonably, and even mischievously. No one pretends to believe that the average income of the class of pharmaceutical chemists from their business is greater than that of other classes of retailers. It is well known to be less than the general average in businesses demanding a far less onerous training, and in which it is by no means so important that a highly instructed and conscientious class of men should be employed, and that they should be conveniently numerous and widely dispersed. It is of the first importance that the cheap and nasty system should not be encouraged in dispensing. Every one knows that he can buy a hat for nine shillings in one place, and for twenty-four shillings in another. He will not expect to have them of the same quality, unless he belong to the deluded race of bargain-hunters. A man can put up with a bad hat; or he can renew his purchase more frequently; but the immediate danger which he will suffer from stale infusions and extemporized makeshifts of the cheaper kinds for the most costly pharmacopœial preparations is not so easily estimated or repaired. Lucky if he escape without plaster of Paris in his sulphur, or if he get a tithe of quinine in his crystals of quinine and iron. The whole question, however, does not lie in that of the use of inferior, stale, or adulterated materials. The price of a bottle of medicine represents many things besides the ingredients: it represents skill, responsibility, character, and outward and material guarantees for all these. When a physician writes a prescription, the question is frequently asked, "Where shall I get it made up?" There are two usual ways of answering it; either to say, "Go to any respectable chemist in your neighbourhood;" or, if it be a prescription involving materials of special novelty, delicacy, or difficulty of perfect preparation, to name half-a-dozen establishments well known for their perfect arrangements, either of which can be selected. Then the importance of what we speak of as material guarantees is at once seen. There are in every large town some establishments where all the arrangements are obviously made so as to secure perfection, irrespective of cost. There are others where the special labours of the pharmaceutical chemist have been such as to inspire special confidence in his dispensing. These are all things to be paid for. Many of them are costly in themselves; all are valuable to prescribers and the public, and have a fair market-value. Druggists in poor neighbourhoods must suit their prices to the pockets of their customers. They are helped to do so by smaller shop-rents, a cheaper way of living, much less exigence and expenditure as to the elegancies of dispensing, and by consulting economy in every possible way in laying in their stock, and in the *personnel* and the arrangements of their establishments. With all this, they may resist the temptations to actual inferiority; but it is perfectly clear that the more costly arrangements, and the sole regard for perfection of material and method, are those things which we seek to secure for our patients, and which they have the greatest interest and desire to have, where they can afford to pay for them. We are not all concerned to defend druggists against charges of extortion, or to uphold a system of unduly high prices; but we feel assured that the danger lies chiefly in the other direction. We have more to guard against in the interests of effectual prescribing, in the interests of healing, and for the security of the public and ourselves, in dealing with cheap, than with dear druggists. Those medical practitioners who dispense their own medicines will certainly not be the last to recognize the truth of this proposition. Those who prescribe only well know how important it is for their patients to fall into the hands of conscientious and well-educated dispensers, who have studied their business, and charge a fair price, and supply fresh and honestly prepared medicines, without that single eye to cheese-paring which is characteristic of the cutting down system in retail businesses. Above all, it is certain that the worst evils of counter-practice go always hand in hand with cheap dispensing. If any success should attend an attempt to reduce dispensing to a system on which it could yield even smaller profits than it now does in the aggregate, the probable results, we think, would be greatly to diminish the number of places to which we could confidently allow our patients to apply for their medicines, and to degrade the practice of pharmacy to an injuriously low level. This would be both inconvenient and disastrous to all concerned. But we do not expect that any success will attend so ill-favoured and unreasonable a proposition.

The *Medical Times and Gazette* remarks that "The controversy which has been going on for some time past in the pages of two of our contemporaries is amusing, if not instructive. One result, however, may be gathered from it—viz. the accusers of pharmaceutists as overchargers know little or nothing of the matter; and the pharmaceutists are unnecessarily irate at a charge brought against them at once unfounded and absurd."

The Pharmaceutical Journal.

SATURDAY, DECEMBER 31, 1870.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes endorsed "Pharm. Journ."*

THE PROPOSED POISON REGULATIONS.

Our correspondence columns are again crowded with letters that have been forwarded on this subject, and we have been enabled to lay before our readers the following important communication:—

[Copy.]

"*Medical Department of the Privy Council Office,*
"23*rd December*, 1870.

"Sir,

"I am directed by my Lords of Her Majesty's Council to request that you will call the attention of your Council to the power which is, by the Pharmacy Act, 1868, given to the Pharmaceutical Society to make, with the consent of the Privy Council, regulations as to the keeping, dispensing, and selling of poisons.

"My Lords believe it to have been the opinion of Parliament that proper regulations in this matter are required for the protection of the public, and, as more than two years have elapsed since the passing of the Act without the Pharmaceutical Society having proposed any such regulations, my Lords think it right to inquire whether the Pharmaceutical Society intends, within any time you can specify, to propose such regulations to their Lordships. They direct me therefore to request that you will have the goodness to give me, at your earliest convenience, the information required by their Lordships.

"I am,
"Sir,
"Your obedient servant,
"John Simon.

"*The Registrar,*
"*Pharmaceutical Society.*"

Considering the near approach of the opening of Parliament, the importance of this official statement of the views held by the Privy Council will be apparent to our readers.

As further material for consideration by the readers of this Journal we also add the following extract from the editorial columns of the *Lancet* of last week.

"We are glad to observe that the Council of the Pharmaceutical Society have again decided to recommend to the Annual Meeting of the Society for its adoption certain specific regulations for the keeping of poisons. It is to be hoped that these, or similar regulations, will be accepted by the body of pharmaceutists as the solution of a much-vexed question. In the discussions which have from time to time taken place on the subject of accidental poisoning, public opinion has expressed itself in unmistakable terms in favour of the enforcement of precautionary measures of the nature of those now just formed by the Council of the Pharmaceutical Society, and which, indeed, are identical with those rejected by the Society last year. The public, moreover, will not be satisfied until some regulations of the kind are in force.

"A large amount of new blood was infused into the Council last year, and in such a way as to make it truly representative of the different interests of pharmaceutists; and it is this Council which calls upon the latter to accept certain alternative and compulsory plans for keeping poisons, viz. in separate "poison" compartments or drawers, or in bottles of a distinctive kind, or in vessels secured in such a way as to arrest the attention of the dispenser.

"It is with regret that we still observe in a few persons a spirit of antagonism to the acceptance of any regulation whatsoever for the keeping of poisons. We venture to hope, however, that they will find themselves in a very small minority at the approaching Annual Meeting of their Society. If the pharmaceutical body allows the present opportunity of legislating for themselves in the matter of the keeping of poisons (and thereby augmenting the confidence of the public towards themselves) to slip, they may find the tables turned against them, and the pressure of public opinion from without subjecting them to enactments of a still more stringent and, to them, even of a vexatious character."

MISNOMERS.

We take this opportunity of protesting against an instance of the abuse of names, which may be in itself harmless, though it is none the less a violation of the principle that the names given to things should be distinctive and not liable to be mistaken for each other. We refer to the application of the term "Chloralum" to a solution of muriate of alumina which is being introduced as an antiseptic and disinfectant by Professor Gamgee. Without wishing in any degree to disparage the usefulness of this material, we cannot omit to point out the great similarity between the name given to it and the term chloral—long before in use—as an objection which makes the term chloralum altogether inappropriate and inadmissible.

There is the more reason for urging this objection, since the use of a hyphen between the two syllables would obviate the difficulty, especially if a capital letter were used for the initial of the second syllable. We therefore suggest that it would be advantageous to the prospects of this material if its name were always written Chlor-Alum, and pronounced in such a manner as not to be confounded with chloral.

PRESCRIPTIONS FOR PROVINCIAL ASSOCIATIONS.

We have been requested by Mr. Joseph Ince to make known his thankful acknowledgment of the receipt of sixty assorted prescriptions, contributed by Mr. Albert Ebert, of Chicago, and we willingly comply with his request.

The London collection is now finished, but 876 still remain to complete the provincial series. A few words of explanation may be of service.

Both collections (London and Provincial) are under the direct sanction and personal approval of the Council and the London Board of Examiners.

They are in no way the private speculation of any individual collector—being in fact the free gift of the Pharmaceutical Society. Owing to the pressure of other engagements the task of arrangement has been abeyance during the months of November and December, but once more the work is in course of active progress.

It is hoped that each of the twelve volumes forwarded to the Country will represent a small library in itself, as no single collection will contain more than a divisional assortment of recipes kindly forwarded. The books have been bound and prepared by the Messrs. FISHER, who supply King's College, London, and many artists' firms: the insertion of the formulæ is intrusted to skilful hands. Each separate compilation will if possible illustrate the Pharmacy of England, America, France and Germany. Surely when the vessel is so near the haven where it would be, none will hesitate to lend a helping hand in order that it should pass the bar.

An easy but questionable reputation might have been gained for rapid execution, had each folio been carelessly filled up, but this has been resolutely avoided. Mr. INCE asks respectfully but earnestly, that as only 876 recipes are required, he may be allowed to finish the original design in all its integrity. The last report is as follows:—(*December*) I. Chicago—(60) II.—(11) III. (6) IV.—(23) total 100. Aid from Italy is expected daily.

The Examiners require a student to recognize objects constituting what is termed Materia Medica, as well as specimens illustrative of Chemistry—he must also show a certain familiar acquaintance with plants dried and fresh. To acquire this practical knowledge ample facilities are provided—an attempt has of late been made, in London most successfully, that the same aid may be within the reach of every learner with regard to accuracy and facility in understanding the directions of the Medical Profession, How large a share these Autograph Formulæ have in direct teaching can scarcely be conceived.

IMPORTS.

WE venture to think that the returns of the Board of Trade for 1869, as published in our columns last week, must have contained much that was interesting to pharmacists generally, many of whom, like ourselves, in perusing the list of imports officially called "other articles," must have been furnished with material for thought and reflection. The import of ether in quantity of nearly two thousand three hundred gallons (16,550 lb.) much impressed us.

Although we have little doubt that a considerable portion of this ether (manufactured entirely from pure alcohol) was exported "in bond," or in other words was consigned to the various depots of shipment under the eye of the Customs, without passing out of the bonded warehouses in which it was landed for reception into the private stores of the owners; —nevertheless we are aware that a large quantity paid the duty of twenty-five shillings a gallon, and was thereby made free to compete with the ether manufactured in this country from pure spirit of wine.

Now, let it not be thought that we purpose writing against competition generally, for we fully acknowledge that nothing can surpass, or even equal it, for bringing prices to a proper average; but we do say that the competition produced by this import is not fair, inasmuch as the advantages of the parties concerned are unequal.

On the Continent alcohol is (in quantity) of the market value of fivepence a pound. In Great Britain its cost, even of production, is ten times that amount.

Now, as few processes are conducted without some loss being entailed before the final product is brought into a state of purity, it does not require an expert to see that one might safely class such a volatile body as ether among those manufactures likely to be conducted with considerable losses.

This is of the greatest concern to the operator in this country, for, although he may take immense pains in perfecting his apparatus in order to reduce his loss to minimum, he is still at a disadvantage as compared with the Continental manufacturer in the ratio of ten to one, for he is compelled to sustain a loss upon "duty paid" spirit, while the other has the boon of "free spirit." The result is that pure ether can be offered in quantity in Germany at *ninepence* a pound, a rate at which ether cannot be made for the arts from methylated alcohol.

If asked for a remedy, we should suggest that either the Legislature grant permission to make ether from pure spirit, previous to its duty being paid, or upon which a "drawback"* has been allowed, in laboratories under Excise supervision, the duty being finally paid upon the product perfected; or to put a somewhat higher duty than the present upon imported ether, taking as a precedent the extra duty of *fivepence* per gallon proof (10*s.* 5*d.*) imposed upon foreign spirit, as compared with spirit of home manufacture (10*s.*). Such an arrangement would afford a protection to our manufacturers, and still leave room for healthy competition.

While we write upon this subject, we cannot refrain touching upon a kindred one,—*the manufacture of alcohol.* The remarks of the previous case are equally applicable; but, in addition, the evil in the latter is greater and without a parallel in the former, inasmuch as the Excise allow anhydrous ether to be freely made from methylated spirit, but will not allow anhydrous alcohol manufactured from the same spirit to be made or sold.

* A refunding of the money paid as duty, such as is practised when spirit is methylated.

Until most recently, alcohol was manufactured either by the Pharmacopœia process or by a modification of it; now, however, its production has been entirely discontinued, on account of its cost being much in excess of the market value of imported alcohol *duty paid.*

The injustice here seems to us to be the levy of duty at the ordinary rate of foreign spirit (ten shillings and fivepence per proof gallon), no cognizance being taken of the home manufacturer's loss in bringing his alcohol to such a strength,—which loss, although probably not in excess of that of his competitor, is upon *duty paid* as compared with *free spirit.*

Every one knows that our legislators care but little for private interests, their wish being to serve the public only; all, however, will agree that it should be no less their perpetual aim to offer the greatest advantages in their power to the arts.

In the case before us they have not only ignored the home manufacturer, but have at least put great restrictions upon that important branch of science, photography.

Our contemporary, the *British Medical Journal*, condemns the proposed appointment of an Apothecary-General for Ireland, on the ground that such a post will afford opportunities for unlimited jobbing and will leave no room for appeal. It is suggested that a better course would be to appoint inspectors, who should see that the contracts are properly drawn out for medicines and drugs, and that they are supplied of good quality and at a fair price.

Proceedings of the Pharmaceutical Society.

EXAMINATION IN LONDON.

December 23*rd*, 1870.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Edwards, Garle, Hanbury, Haselden, Ince and Southall.

Twenty-three Candidates presented themselves for examination; the following passed and were duly registered:—

MINOR (as Chemists and Druggists).

*Hadley, Thomas .... Hereford.
*Freeman, Ernest .... Stourbridge.
*Pickering, Samuel Whaley .. Chester.
*Gower, Alfred John .... Tonbridge.
*Fowler, William Ratcliffe .... Ipswich.
*Fegan, John .... Exeter.
Weaver, Edwin Thomas .... London.
Tebbutt, Edwin .... Hemel Hempstead.
Equal. { Braddock, James .... Manchester.
Equal. { Marden, George .... Fareham.
Holmes, Charles Joseph .... Kingston.
Woolstencroft, Joseph ...... Northwich.
Griffin, Alfred William ...... Havant.
Hannaford, William .... Peterborough.
Watson, Horace .... Laceby.
David, John .... Newport, Mon.
Burn, Henry .... London.
Butler, William Harsant .... Frome.

The above names are arranged in order of merit.

* Passed with honours.

FIRST, OR PRELIMINARY EXAMINATION.

The Certificate of Examination of the undermentioned by the University of Cambridge was accepted in lieu of the Preliminary Examination.

Keeling, Charles James ...... Stafford.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The members of this Association inaugurated their connection with Anderson's University on the evening of Wednesday the 7th inst.; Mr. T. Davison, President, presiding. The attendance was very large. After the ordinary business had been transacted, Mr. W. R. Kermath submitted his motion, of which he had previously given notice, in regard to the compiling of a dispensing price list. The motion was seconded by Mr. David P. Walker, and carried unanimously. Twelve gentlemen were appointed a committee, with full powers to prepare a suitable price list to be ready for distribution at the next meeting of the Association. A new code of rules was then discussed and agreed upon.

The Fifth Meeting of the Session was held in Anderson's University on Wednesday evening the 14th inst.; the President in the chair. The usual business having been transacted, Professor Hennedy delivered the second of his course of lectures on 'The Histology of Plants,' which was of a very interesting and instructive nature. After the lecture the following gentlemen were unanimously elected honorary members of the Association, viz. Drs. A. M. Robertson and R. C. Moffat, James M'Donald, Esq., James Taylor, Esq., Robert R. Hatrick, Esq., and Roger Hennedy, Esq. A paper on 'Volumetrical Analysis' was announced for next meeting.

The Sixth Meeting of the Session was held in Anderson's University, December 21st. In the absence of the President, Mr. Brodie, Vice-President, occupied the chair. The minutes of last meeting having been read and approved of, Mr. Joseph Duncan, Ph.C., was elected a member.

Mr. James L. Macmillan then read a paper on "Volumetrical Analysis," which he treated in a very elaborate and painstaking manner. In course of his remarks he referred to the great need for every chemist being able to analyse his own drugs when required, owing partly to the fact that inferior articles were often sent into the market for sale, and partly because even in the best regulated houses mistakes occurred, and analysis was often the most convenient way of getting the matter cleared up. He explained at length the B. Ph. process, and described the method for making several of the solutions, also the apparatus required. After performing some experiments in testing, he drew attention to the value of the burette, and concluded by urging the younger members especially to practise analysis for themselves.

In course of a short discussion which followed, Dr. Moffat recommended Sutton's work on volumetrical analysis as being less complicated than that of the B. Ph. process, and better suited not only to the amateur analyst, but for all practical purposes in the laboratory.

The Chairman complimented Mr. Macmillan for the instructive manner in which the paper had been delivered, and proposed a vote of thanks for the information conveyed, which was heartily responded to.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The Third General Monthly Meeting was held in the Rooms, Music Hall, on Wednesday, December 14th; Mr. WILSON, the President, in the chair. A lecture upon "The Laws of Heat" was given by an honorary member of the Society, W. Baker, Esq., F.C.S. It was of a very interesting and suggestive nature, illustrated by experiments, and elicited much applause. The following is a short abstract:—

Heat is only known to us by its effects. We are familiar with the sensation of heat; we observe that it causes a change of volume in matter, that it renders bodies luminous and so forth. Heat may be conveniently studied under two heads, absorbed heat and radiant heat. Sensible heat is measured by thermometers; but it must be borne in mind that what we really observe is the expansion of a liquid or gas in making use of such instruments, and the requirements for a good thermometer are not easily fulfilled. Allowance must be made for the expansion of the glass as well as the fluid it contains. The meaning of 212° Fahr. must not be lost sight of; it is really the temperature at which water boils under a barometric pressure of 29·905 at London.

The dilatation of solids, liquids and gases was noticed, and the superiority of air thermometers shown by the fact that the coefficient of expansion of all gases was practically the same; hence all air thermometers are comparable one with another. The applications of a knowledge of these laws of expansion were shown to be extremely numerous in the arts. The quantity of heat was measured in various ways, and constituted a separate chapter on heat called calorimetry. The combustion of a weighed quantity of fuel under water by means of a mixture of potassic chlorate was shown to raise a certain bulk of water so many degrees, and thus furnish a practical measure of its calorific value,—the unit of heat being 1 lb. of water raised from 32° to 33° Fahr. The change of specific heat upon compression was noticed and illustrated. The general facts attending liquefaction and solidification, and the effects of heat, stored up as it were in a liquid, were shown to have important effects upon our climate. One ton of water upon freezing was stated to give out sufficient heat to raise one ton of water from 32° to 174° Fahr. Development of heat upon solidification was illustrated by the sudden crystallization of a solution of sodic sulphate, which had been previously cooled in a flask; upon removing the cork the contents became a mass of crystals in a few seconds, and the heat could be observed by an immersed thermometer. Hope's experiment upon the changes of density of water near its freezing-point was mentioned.

The phenomena of evaporation, ebullition and the spheroidal condition of fluids were described. Conductivity of heat in metal bars was illustrated by attaching light balls by means of wax to the bars and heating the ends. The superior conductivity of copper over iron was thus easily perceived. Finally, the general laws of radiant heat were enunciated, and the effect of concentrating the radiant heat from a hot ball upon an air thermometer, shown to be very considerable at a distance of many feet.

At its conclusion a cordial vote of thanks to Mr. Baker was proposed by Mr. WILSON, seconded by Mr. DOBB, and carried unanimously. In consequence of the lateness of the hour no further business was done.

BRISTOL PHARMACEUTICAL ASSOCIATION.

On Friday, December 16th, the second monthly lecture of the current session in connection with the above Association was delivered by their Professor of Chemistry, THOMAS COOMBER, Esq., F.C.S. The subject was "Heat," and the following notes indicate the range and order of the phenomena treated of by the lecturer.

Introductory.—A current of electricity controls the position of a proximate magnetic needle. Such a current is established by the addition or subtraction of heat from two different metals in contact. This arrangement used in conjunction with the magnetic needle becomes therefore a thermoscope.

(1.) An experimental inquiry into the nature of heat.

(2.) Observation of the effects of heat upon matter. (*a.*) Change of volume. Experiments to study this change on solid, liquid and gaseous bodies. Thermometers. The Trevelyan instrument. Observation of the exceptional deportment of water. (*b.*) Change of temperature. Experiment to illustrate the dissimilar capacities of different bodies for heat. (*c.*) Change of physical condition. Latent heat of vapours and liquids. Effects of congelation.

(3.) Study of the modes by which heat may be transmitted. (*a.*) By conduction. Experiments to show that dissimilar bodies conduct heat at different rates, and that liquids are sluggish conductors. (*b.*) By convection. Experimental illustrations of this mode of transmitting heat. (*c.*) By radiation. It may be shown by experiment that heat travels in straight lines, that the angle of reflection is equal to the angle of incidence, and that dissimilar surfaces radiate at different rates.

SOCIETY OF ARTS.*

ON FERMENTATION.

BY PROFESSOR A. W. WILLIAMSON, F.R.S.

Lecture IV.

We had occasion last week to notice the effect of the atmosphere on processes of fermentation in several instances. I mentioned, among other things bearing on that question, an experiment of Gay-Lussac, in which he squeezed some very ripe berries of the grape under mercury, and kept them, with due precautions for the exclusion, as far as he knew, of everything except the grape-juice; he kept this expressed juice for some time quiescent, and then introduced a bubble of air, or a bubble of oxygen, the active substance of air, but he subjected the air or the oxygen, before introducing it into this juice, to various strong influences, which must have destroyed any vital organism in it; and he found that the mere addition of the air to the quiescent juice caused a process of fermentation to commence and a formation of organisms to begin, that they developed themselves, and that the liquid fermented in the usual way. The fact of the fermentation commencing is, if we bear in mind the general results of M. Pasteur's researches, to be attributed to the presence in the mercury or in the grape-juice, or somewhere or other in the substances present, of bodies which, by the mere access of oxygen, were stimulated so as to develope themselves into these little vital cells. It is now known, I may say, that there are in mercury, unless it is purified with extraordinary precautions, always present some such organisms, capable of developing themselves under such influences; and it is probable, I will not say more than that, for I do not know, that in the grape-juice there may also be similar germs present. The functions of oxygen appear from that experiment—which has since been confirmed by other observers—to be essential, at all events, to the initiation of the process, and there is, in that respect, a remarkable analogy, which I think is interesting to recall to mind, with the action of oxygen

* Cantor Lectures.

on other bodies, as shown by an experiment made by Humboldt many years ago. He got some grains of wheat from Egyptian mummies, which had been so long at rest that they were not inclined to grow, in fact, they could not be got to grow in the ordinary way. However, he stimulated them to activity by immersing them in a little chlorine water. It is well known to chemists that chlorine in the presence of water does oxidize, or cause the oxygen to separate and pass over to common organic substances capable of combining with it. Humboldt actually stimulated these sleepy wheat grains to life, so that they grew and germinated, and their descendants are still in existence, by the mere action of oxygen developed in that way.

In the processes of wine-making and wine-keeping, the presence of air is one of the most important matters which have to be considered, and there has prevailed, and I ought to say there still prevails, to a certain extent, a difference of opinion regarding the functions of oxygen in these processes. On the one hand, it is known, as a matter of fact, that processes of fermentation are performed under conditions such as that air has access to the substance. No actual wine or beer-making has yet been performed on a large scale on such conditions as to exclude oxygen. On the other hand, the experiments of Gay-Lussac established clearly that it is necessary. In some cases, however, in wine-making, it has been thought desirable to facilitate the access of air to the substance; while other wine-makers think, on the contrary, that in the first process as little air should be present as possible; but there has always been some. The juice first expressed from the grapes has been very carefully examined with regard to the gases contained in it. If air has access to it, it is always necessary to know, in order to judge whether the air acts upon it, whether the air is dissolved by it, and whether, if dissolved by it, it is still to be found in the grape-juice as such, or whether it has undergone combination. Now, every case of the examination of must, or fresh grape-juice, which is not fermented, has shown that it contains a considerable quantity of gas, but no case has been established of free oxygen being present in it. Carbonic acid gas is present in it in a considerable quantity, and also nitrogen, in proof that air had had access to it, but the oxygen which was taken up at the same time with the nitrogen from the air, was not to be got out from that must again. It had been taken up, and it had entered into combination with the substance, so that all the oxygen present was actually combined chemically with it. In that respect a good many observations have been made by various chemists, but I ought especially to quote those of M. Pasteur, which are exceedingly careful and valuable. He has shown that this substance not only eats oxygen, but digests it. The oxygen is not to be found in it as such. It is only present in the form of a compound, which is formed by its action on the organic matters there present. Then, when the wine-juice has been expressed, and when it has been allowed to remain some time in a suitable place, so as to undergo fermentation, with a considerable variety of treatment in different places with regard to air, for in some places it is thought desirable that the fermentation should be allowed to take place in open vessels, or in vessels to which the air can have access as freely as possible, whereas in other cases special care is taken to cover as completely as possible the vessels in which the fermentation is taking place, so that the air may have as little access as possible to the fermenting substance,—and I believe it is impossible to give any one general rule with regard to the best process for all cases of fermentation, because the materials which are subjected to fermentation vary so considerably; they differ from one another in their composition so materially, and there are also other circumstances which are different,—for instance, the temperature, which has an important influence. Not only is the temperature in some localities higher than in others, but other circumstances are also different, and it would not be right to say, because air is found to be perfectly useless in some well-established cases during fermentation, that for that reason, it ought to be excluded, or even that it may be excluded, in all other cases of apparently similar fermentation. As far as a general rule can be laid down from present experience, I think it does appear certain that oxygen plays no part in the process after the first expression of the juice. Once the fermentation has commenced, it appears to go on as well if air is excluded from the substance as if air has access to it. There is, however, one circumstance which is considered by persons of considerable experience to be important in this matter, and which I ought therefore to mention, viz., that when fermentation takes place at a low temperature—and some fermentations are, with great care, kept at a low temperature—the products are found to be superior if the whole process is carried on, the temperature being kept exceedingly low, and in those cases it appears that an open vessel is certainly not in any degree detrimental. It is customary, in fact, to use an open tub when the temperature is low; and, on the contrary, it is usual to use a partially closed vessel, of course allowing for the escape of carbonic acid, when the temperature is comparatively high. When the first vinous fermentation has completed itself, it is customary, in the wine-growing countries, to put the still active liquid into casks, and the slower process of fermentation then goes on, which lasts a considerable time. During this second fermentation, there is very much the same kind of condition present as in the first, and there is always formed, in this subsequent fermentation, a considerable quantity of deposit, which is afterwards removed with much care; either the supernatant liquid is carefully decanted, or, in some cases, it is removed by a process of rough filtration. The subsequent treatment of the wine, I mean the keeping of it in casks or cellars, and the subsequent keeping in bottles—and these two processes of keeping it in casks and keeping it in bottles are quite distinct,—are not usually considered as forming part of the process of wine-making. It appears, however, from the investigations of M. Pasteur, that changes take place in the composition and the materials by these processes, which really are as essential to the composition of the product as any other part of it, and that they ought to be considered as later parts of the process of wine-making. In fact, the process of wine-keeping is, in theory, not to be separated from the process of wine-making, the keeping being a process making it more perfect than it was when first turned out of the fermenting vessels. Common experience corroborates that in a very remarkable way. Everybody knows the difference there is between new and old wine, and the changes which take place when the wine is being kept constitute certainly one of the most important parts of the general subject of wine-making. Wine, when its fermentation has been completed, is found to absorb air with considerable rapidity and avidity, and when endeavours are made to get out from this wine again the air which has been dissolved in it, it is found that some kinds of wine allow it to go, or part with it again, whilst other wines do not; and in this respect, a distinctive test is found between the qualities of the wine; for by observing this difference in the facility with which they give up the air which they have dissolved, and by comparing that with the qualities of wines in each case, a remarkable generalization has been arrived at. In this matter I speak upon the authority of others, for I have not confirmed it by my own observations. But all that I do know fully corroborates it. The rule is this, that whereas low-class wines, which people will not pay much for, give up again almost completely the air which they have dissolved, superior kinds of wine do not give it up again, they only give up the nitrogen, and hold the oxygen fast. The oxygen, which is dissolved in both cases, is held firmly, or is digested by the high-class wines; but it is not digested, but simply eaten by low-class wines. Observations have been made in this direction by a great many observers, especially Berthelot and Pasteur, to whom we owe most decisive results in this respect.

(*To be continued.*)

MEETINGS FOR THE ENSUING WEEK.

MONDAY, *Medical Society*, at 8 P.M.

WEDNESDAY, *Pharmaceutical Society of Great Britain*, at 8.30 P.M.—Adjourned Discussion on Mr. Howden's paper, "Notes on Pharmacy in America."—"Notes on Australian Opium." By J. S. WARD.

BOOK RECEIVED.

A LABORATORY TEXT-BOOK OF PRACTICAL CHEMISTRY, OR INTRODUCTION TO QUALITATIVE ANALYSIS. A Guide to the Course of Practical Instruction given in the Laboratories of the Royal College of Chemistry. By W. G. VALENTIN, F.C.S. London: John Churchill and Sons. 1871.

Parliamentary and Law Proceedings.

ATTEMPTED POISONING BY A "VERMIN KILLER."

At the Norfolk winter assizes Hannah Willmet was charged with administering poison to the infant child of her master. It appeared that her master had purchased some "vermin killer," which he had carefully put away out of the reach of his children. The prisoner obtained possession of this, and administered some of it to the child. She confessed to putting her finger into the mixture, and then putting it into the child's mouth. She said that she wished she had not done it, but that if there had been no addition to the family she would have been better able to do her work. The infant's mouth was wiped by its mother with a piece of rag, which was deeply stained with blue.

Mr. Sutton, analytical chemist, Norwich, by whom the jar of vermin killer and the rag had been examined, said that he found phosphorus in both. The mixture in the jar consisted of phosphorus, fat and malt flour, containing about one part in forty of phosphorus.

The prisoner was found guilty, and sentenced to six months' imprisonment.

Obituary.

We regret to have to announce the death of Mr. T. W. GISSING, Pharmaceutical Chemist, of Wakefield, which took place after a few days' illness, on Wednesday, the 28th inst. Mr. Gissing was one of the gentlemen nominated at the last election of Council, and a letter from his pen on the Poison Question appeared in this Journal as recently as last week.

The following journals have been received:—The 'British Medical Journal,' Dec. 24; the 'Medical Times and Gazette,' Dec. 24; the 'Lancet,' Dec. 24; the 'Medical Press and Circular,' Dec. 28; 'Nature,' Dec. 22; the 'Chemical News,' Dec. 23; 'Journal of the Society of Arts,' Dec. 22; 'Gardeners' Chronicle,' Dec. 24; the 'Grocer,' Dec. 24; the 'English Mechanic,' Dec. 23; the 'Produce Markets Review,' Dec. 24; the 'Philadelphia Medical and Surgical Reporter,' Nos. 716–718; 'Vierteljahresschrift für Praktische Pharmacie' for December; the 'Food Journal' for January.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department,* 17, *Bloomsbury Square, W.C., and not to the Publishers.*

[63.]—GREEN FLUID FOR SHOW-BOTTLES.—I beg to offer a good form, inexpensive and easily made.

Cupri Sulph. ℥i.

Rub down in mortar and add liq. ammoniæ *fort.*, q. s., at once a very dark blue will be produced; then add aqua to a suitable colour. Add a little potass. bichrom. if a green is required; lastly filter.—CHEMICUS.

[75.]—DECAYED TEETH.—Ol. Caryoph. with a few drops of ac. nitric. pur. Mix well and apply on wool.—CHEMICUS.

[77.]—DISPENSING.—It is impossible for "*Exhibeatur*" to make his mixture otherwise than milky, but he will find, on allowing it to stand for an hour or two, after dispensing it in the ordinary way, that the precipitate will re-dissolve and it will become quite clear.—A. CARTER.

[102.]—CIVET, AMBERGRIS AND CASTOR.—*F. C.* will, I think, find in Rimmel's 'Book of Perfumes' detailed information about civet and ambergris. The imports of these are very small; of ambergris in some years none at all, and in others about a hundred ounces. Castor is the only one of the three enumerated officially in the Board of Trade returns of imports. We received in 1869 2408 lb., valued at £742, nearly all from the Hudson's Bay territories in North America.—P. L. S.

[111.]—YLANG-YLANG.—"*Utile,*" in answer to "*Chemicus*" in No. 22, gave an excellent recipe for a lasting perfume containing "ylang-ylang," the composition of which is greatly desired by ALPHA.

[112.]—HORSE AND CATTLE SPICE.—*W. R.* (Scarborough) would be glad of a good recipe for horse and cattle spice for feeding purposes.

[113.]—DISPENSING.—Will some of your readers kindly inform me the best mode of dispensing the following prescription, and if it is possible to get a mixture of decent appearance?

R. Liq. Hydrarg. Perchlor. ℥ij
Potassii Iodid. ʒij
Tinct. Quinæ Co. ℥iss
Syr. Aurant. ℥j
Aquæ Dest. ad ℥vj.
M. ft. mist.

S. D.

[114.]—ARECA NUT TOOTH-PASTE. — "*Scilla*" would be glad to hear of a good formula for this tooth-paste.

[115.]—MARKING INKS.—I shall be glad to be informed of the best method of preparing and using aniline marking ink, and to know whether it effectually answers the purpose. Also the cause of carefully prepared silver inks making holes in the fabric, this being sometimes asserted.—Q.

[116.]—DISPENSING.—I wish to learn the correct method of dispensing the following prescription, and also what appearance it should present:—

R. Ferri Citrat. ʒj
Sp. Ammon. Ar. ʒiv
Potass. Bromid. ʒiv
Aq. ad ℥ij.
M. f. guttæ.

Capt. coch. j min. bis die ex aq. cyatho vinario.

I suppose it is unnecessary to remark that the *ammonio-citrate* is not intended; this I know for certainty, as the prescriber is, I understand, in the habit of frequently writing a similar prescription.—F. G. G.

Correspondence.

Proposed Regulations for Storing of Poisons.

Sir,—The Council having determined by a majority of 10 to 4 to recommend to the members at their next annual meeting the adoption of the proposed regulations for the storing of poisons, it now remains for the members themselves to give expression of approval or otherwise in the Journal or by letters to the Secretary. Messrs. Vizer, Wilkinson, Eve and others have already done so. The present manifestation is decidedly against the compulsory adoption of any regulations; and believing, as I do, that this feeling will be found very general throughout the country districts, there need be no unseemly exhibition at the annual meeting as some of your correspondents seem to imply; but a simple resolution, either to modify or negative the recommendation of the Council, would, no doubt, meet with the support it deserved. There seems to be an impression that the Privy Council expect the Council to take some action respecting the storing of poisons. However, I cannot think that either the Pharmaceutical Council or the Privy Council would interpose any obstacles to the generally-expressed opinion of the members. I concur with much that has been said in favour of non-interference; the educational legislative measures already obtained and self-interest are sufficient guarantees to ensure every precaution being taken to avoid mistakes.

Another Pharmaceutical Chemist.

Sir,—I am sorry to see from the report of the proceedings of the Council that the majority think it necessary to compel Pharmaceutical Chemists to keep poisons in certain places set apart for that purpose or in distinctive bottles, and I want to know the reason why. Have any deaths occurred or has any injury to health been recorded in Great Britain since January 1st, 1869, which would have been prevented by any regulations for storing poisons? I am inclined to think the Council have no stand-point from which to start their proposition.

I read the Journal regularly and the daily papers, and I do not recollect one instance within the last two years where the proposed regulations and restrictions would have been of any use. If before the passing of the Pharmacy and Poisons Bill many deaths were caused through the negligence in storing and carelessness in selling poisons, the present fact that such accidents have been reduced to a minimum, if not to *nil*, since the Act came into force, appears to me to be a most forcible argument to "let us alone." We chemists require no "hard and fast line" drawn for us in this matter. If we find the bottles containing crystals of citric acid and sal acetos. hugging each other, we naturally and prudently forbid the close connection; we do not keep our tinct. opii bottle by the side of haust. nigr., decoct. sarsæ co., or tinct. myrrhæ co.; we do not store strychnia, morphia *et id genus omne* in similar bottles and on the same shelf with p. antim. co., hyd. subchlorid. and antim. tart. In a business like mine, we do not keep our penny packets (pennyworths we are obliged to sell) of precipitate, red and white, in the same drawer with jalap and rhubarb, or Epsom salts near oxalic acid, or sugar of lead and cream of tartar in close proximity. We know better, and we act upon our knowledge and experience, because it is our interest to avoid the penalties which must fall upon the careless and ignorant.

I am one of those who think we owe much to the gentlemen of the Council who devote their time and intellect to the management of our affairs, and in most matters connected with our Society are well fitted to lead and guide; but on this subject I am so entirely opposed to them, that I have ventured to intrude my opinions on your notice.

December 21st, 1870. James Slipper.

Sir,—Will you allow me a few remarks with regard to the keeping and storing of poisons? I quite agree with the sentiments contained in Mr. Hampson's letter. I presume it is the feeling of the majority of our brethren that the improved education now demanded is a sufficient safeguard to the public, and that each chemist should be guided by his sense of responsibility.

In my own case I have always used precautionary measures, and did so many years before the Pharmacy Bill passed, and I am sure it was the usage in all respectable establishments in my locality.

If it is true that the Government are putting a pressure on the Council of our Society, I should like a member of the former to visit our town, containing a population of half-a-million, where fully one-half of its drug retailers are surgeons; it would show him (after inspection) the folly of adding or desiring to add vexatious restrictions upon properly-qualified men, and exempting those who are allowed to manage their businesses as they think fit, leaving them the greater part of the day under the care of boys and girls, who cannot be expected to adhere to the requirements of the Pharmacy Act, or feel its responsibility.

I am justified in saying that mistakes are necessarily numerous. It therefore seems to me odd that such a state of matters should exist. If a surgeon or doctor wishes to become a druggist, why should he stand exempt from our penalties and restrictions? We must of necessity employ well-paid assistants to take charge in our absence; should they not be compelled and expected to do so likewise, if the public are to be protected? Until the Privy Council begin to use the right end of the rod, it seems to me absurd to push the matter further so far as the city of Glasgow is concerned.

Glasgow, December 21st. Pharmaceutist.

Sir,—The storing of poisons being again an object of discussion, allow me to recommend to the members of our Society the expediency of avoiding any very loud expression, either of assent or dissent, to any proposals put before them.

Views expressed through the medium of the Journal or circulated among ourselves as a body, would be much preferable to any open demonstration.

The public is often slow in arriving at facts where legal questions are concerned, and might feel disposed to view those who support measures for regulating the storage of poisons as supporting regulations for "incapables;" at the same time those who are noisy in advocating resistance to any regulations whatever might be thought reckless.

Chemists have certainly some claim to exemption from forced details in business which are not absolutely necessary, for what with the Poison Act, the Petroleum Act and the Excise supervision, quite sufficient is known of the "powers above."

To ventilate our grievances too much before the public would be a confession that hitherto all our rectitude had been a matter of chance, and public alarm would follow. We have some anomalies in the sale of poisons which our customers cannot at present comprehend, and to attract further public attention to what we ourselves at present confess to be a chaotic state would be suicidal, so far as our reputations go. The necessity for fresh "leading-strings" would not confirm our supporters in an opinion that we were capable of running alone.

It must be expected that opinions will diverge here as elsewhere, but the less they diverge into public notice, the better for us.

It is unfortunately a position which none can envy us—that of being repeatedly told that we cannot manage our own professional affairs after the sacrifice of time and money in attempting to learn how so to do; but if we let our friends outside know our grief, we shall be only extending our troubles rather than settling them.

M.P.S. (by election).

Brighton, December 24th, 1870.

Sir,—The regulations for storing poisons, scheduled by the recent Pharmacy Act, 1868, are now so much simplified that no reasonable person can complain of their being oppressive, or unduly interfering with the dispatch of business or requirements of trade.

I would suggest that each individual should look at the question from a broad point of view, and not as affecting any particular branch, adapting the regulations to the best of his ability, according to the circumstance of each case.

What can be easier than for the retail chemist who has a cupboard in the shop or wareroom where he probably already keeps strychnine, aconite, atropine, cantharides, prussic acid, etc., to add in addition to the name of the article in the vessel a distinctive label such as I have enclosed, with the word "*Toxicum*" written or printed legibly on a plain gummed label, placed on a larger piece of pink capping paper, showing a border beyond which must strike the eye, and attach a band of glass paper to the ends of it, going round the back of the bottle, or vessel, just above the bottom, where the hand would take hold when required for use?

Here there would be two safeguards at once, a distinctive white label on a red ground in front to catch the eye, and a rough surface detected by the touch.

These precautions may be adapted to large or small packages, either in the cupboard, on the shop shelves, or in warerooms; and where bottles or packages are not in every-day use, an additional precaution of tying over, or fastening down by a simple contrivance, would obviate every difficulty, put an end to this unseemly controversy, and meet the requirements of a wholesome regulation.

This inexpensive method every chemist can at once carry into effect for himself, by the aid of pen, paper and gum pot.

I trust our brethren will be unanimous, and adopt the regulations in a spirit of fairness; for captious resistance will inevitably lead to further legislation on the subject and enlargement of the schedule of poisonous articles.

A FOUNDER OF THE PHARMACEUTICAL SOCIETY.

Dec. 24th, 1870.

Sir,—As this poison question is again being brought prominently forward, I should like to be permitted to state in the columns of the Journal my own personal experience in reference to this subject before and after adopting precautionary measures in the storing, keeping and dispensing of poisons.

I have always felt one of the greatest drawbacks to the profession of pharmacy to be the possibility of some very serious mistake being made in the dispensing of dangerous drugs and chemicals, even when carried out by thoroughly qualified assistants. This always pressed heavily and unremittingly upon my mind before adopting precautions. But some six years since I separated the most dangerous of these medicines, such as strychnine, aconitine, hydrocyanic acid, liq. arsenicalis, and placed them in a small lock-up case, with each article distinctly labelled "poison;" whilst to the preparations of opium, morphia, and tr. belladonnæ and analogous drugs, I used caps of india-rubber, which from their elasticity required no fastening, and marked each cap with the word "poison." I can with truth say that considerable relief accrued to my mind from a conviction that an additional element of security against mistakes had thus been introduced.

Probably most of my brother pharmacists have more or less felt oppressed by our great responsibility, especially in connection with the dispensing of poisons; I believe this simple precaution would relieve them as it has done me from a considerable part of this, and frequently prevent the occurrence of serious mistakes; whilst at the same time it would meet the wishes of the Council, to whom surely some deference is due, composed as it is of some of the leading men connected with the Pharmaceutical Society, as well as being a representative body.

Of the other alternate proposals, viz. 1st. A separate compartment for dangerous articles, it is evident that this is next to impossible in a great many small shops for want of space. Or 2ndly. Distinctive bottles or vessels would involve considerable outlay, which would press heavily in businesses where the returns are small and inadequately remunerative for the skill and labour employed, which is unfortunately too often the case.

Edinburgh, Dec. 26th, 1870. H. C. BAILDON.

Sir,—As a very old member of the craft, allow me to say one word on the subject now agitating it. I do not see anything very hard in our being obliged to submit to such simple regulations as were last set forth by the Council, in itself. But I do see something very hard, very unjust, and contrary to the spirit of fairplay, so much loved by all Englishmen, and which is such a characteristic of English legislation, if all persons who dispense poisons are not equally compelled to submit to the same regulations. If there is to be one law for one class of her Majesty's subjects, and another law for another class, then I would oppose the Council's action through thick and thin.

If the Council will only seek to extend their regulations to all persons alike, without fear or favour, they would disarm a great deal of opposition.

Manchester, Dec. 27th. A LOVER OF FAIRPLAY.

Sir,—The above subject is of so much importance to us as a body that I will not offer an apology for asking you to grant me a small space for a few remarks, which I hope may be regarded as relevant to its discussion.

The whole subject appears to me to be embraced in the following questions:—(1.) Are these proposed regulations needed? (2.) Under what circumstances is it sought to impose that which is justly regarded as an unwise interference with an arrangement which has hitherto worked well? (3.) If we adopt the course which appears favourable to our parent Society, and reduce ourselves to the position of mere automatons, requiring no thought or consideration in the execution of our duties, shall we under this proposed new order of things, in the event of error, still be responsible and liable to damages? Finally, if these regulations eventually come into force, will it tend to elevate us in the estimation of the thinking public?

First, I will endeavour to prove that they are not needed. If these innovations are meant to prevent poisoning by misadventure, it seems to argue that this calamity is of frequent occurrence; but is this so? I think not. Indeed, so seldom does it happen (and, be it remembered, that we have no means of sheltering ourselves behind a curtain of obscurity), that when a case is brought before us we stand aghast, and inquire, How did it occur? Very rarely indeed by the chemist in compounding his prescriptions, as he becomes, by force of habit, a thoughtful and reflecting man, well knowing his great responsibilities, and as a rule is most conscientious in the fulfilment of his duties. It may more frequently be traced to the unwise parsimony of medical men, who order liq. strychniæ to be taken in five-drop doses, and thereby make the uninformed public their own dispensers, with what result I need not say. Facts are stronger than theories. Considering the number of potent poisons which many of us have daily to manipulate, our various duties interspersed with interruptions which often annoy, it argues much for our present order and arrangements, combined with energy and concentration of mind, that a less number of accidents could not occur, unless we were suddenly to arrive at a state of perfection; but, as this condition is not common to man, I take it that we are not likely at present to attain this point.

Secondly, the time for introducing this arbitrary measure appears most unfavourable and inopportune. If chemists, as a whole, were less competent in their particular sphere than other tradesmen or even professional men,—or if they, being incompetent, set their faces rigidly against reform, or persistently refused any measure which would tend to increase the public confidence; or, if poisoning by misadventure were of more frequent occurrence than formerly,—there might be a colouring of plausibility for thus introducing a measure which, to say the least, will be exceedingly onerous and excessively distasteful. But, if we look calmly into the facts, we shall soon perceive the very opposite of that which I purposely placed in the subjunctive mood. Who were most anxious for the passing of the Pharmacy Bill of 1868? The chemists, Sir. Who were most anxious that this Bill should be complete and effective, and the standard of education such as would entitle us to the respect of all? The chemists. To whose interest is it that all our plans should be well matured and well arranged, promote unity of action, cohesion and strength, and thereby avoid our greatest enemy—internal dissension? I say again, the chemists. While I believe that the Pharmaceutical Society are especially desirous of watching over our interests, and doing all in their power for our united good, I do hope that their great zeal will not lead them into the greatest of all errors, viz. that of doing too much.

Thirdly, the chemist must always be inevitably responsible to the public for the manner in which he conducts his most important duties. But, may I ask, is it wise to attempt to introduce any measure which will have for its object the simplifying (or more properly mystifying) of our present arrangements, and which will necessitate engrafting a new set of ideas upon our dull sensibilities? If this plan should be enlarged upon, we may soon find that, instead of labels to our bottles, we shall have to learn that a bottle with one angle means one thing, with two angles another, three angles another; and when our angles are exhausted, we shall fly to colours as another order of insignia, until the public will begin to doubt whether beings with such peculiar tendencies, and grotesque ideas, are quite the proper persons to trust with their lives; and some of our dear friends, who envy our wealth because of our overcharges, will not forget to point out to their patients, who pay them for their physic as well as their advice, that these changes have been considered necessary by the authorities, in order, if possible, to avoid the many and fatal blunders into which we are so constantly falling.

Finally, if we allow this measure to pass without raising our voices in opposition, and showing clearly and logically the ground of our objection, our moral and intellectual force must be weak indeed; and the public will not be slow to learn that those who exhibit such inability to manage their own affairs must be equally incompetent to undertake, and carry on successfully, the important interests of others.

Although I have gone over this subject very superficially, I fear you will regard it as extremely prolix; yet I beg you will accept it, with all its faults, as an earnest conviction of one deeply interested. NEMO.

INFORMATION WANTED.

Sir,—In answer to *E. B.*, p. 520 of your last Journal, I beg to state that magnes. ferri et quinæ sulph. is composed of 1 gr. of sulphate of quinine, 3 grs. sulphate of iron, and 16 grs. of sulphate of magnesia in each 20 grs. of the compound salt. G. S.

Renfrew, December 29th, 1870.

Sir,—We perceive in the Journal of the 24th inst. an undated and anonymous communication wherein our name is introduced as having compounded a prescription containing "Mag. Ferri et Quin. Sulph." and evidently treating it as a nostrum of our own.

The prescription in question was sent to us a short time since by a customer, to be dispensed. Not having the foregoing preparation, we wrote to our firm in Bruton Street, Berkeley Square, to procure it, which they did, at the Apothecaries' Company in Berners Street.

We now beg to make the following remarks: some individual (evidently "*E. B.*") went to our establishment in Bruton Street, last week (we believe on the 21st), and asked if they had a preparation of magnetic iron and quinine; he was told they had not; he then produced the identical prescription we had made up at Oxford, and was politely told it was a compound of the sulphates of magnesia, iron and quinine, and where he could obtain it; we were therefore extremely surprised to see his uncalled-for letter, especially as it is our invariable practice to give every information which may be desired of us.

It is evident that your correspondent has a sinister motive in view, for after taking the trouble to translate the prescription for him, which he was unable to do, and to tell him where he could procure the medicine, it is too bad that he should drag our names in such an invidious manner into print.

Oxford, Dec. 27th, 1870. HITCHCOCK AND SONS.

[*** The letter of our correspondent *E. B.* was inserted at the moment of going to press, and under the belief that it was a *boná fide* request for information. We do not now perceive that it was otherwise, or that there was any intention to annoy Messrs. Hitchcock.—ED. PH. JOURN.]

PHARMACY IN IRELAND.

Sir,—In their efforts to secure rights analogous to, and a basis as nearly as possible resembling, that which governs the Pharmaceutical Society of Great Britain, the Chemists and Druggists' Association of Ireland would deem it a favour if the members of that Society, individually or as a body, if occasion require, would exercise their influence with members of Parliament on the introduction into Parliament of the draft Pharmacy Act of the Apothecaries' Hall Company of Ireland. We look on the said Draft Act, as at present compiled, as unjust,—a barrier to the future progress of our Association, in its ultimate working a monopoly, and in no way likely to supply the grievous want so ably filled by the Pharmaceutical Society of Great Britain.

The importance of the subject to us, Sir, will be, I trust, a sufficient excuse for trespassing so much on your valuable space.

HENRY FLINT.

Laboratory, 108, *Patrick Street, Cork.*

A POINT OF ETHICS.

Sir,—"*Chemicus*" will be good enough to remember that the point at issue is not the mode of dispensing prescriptions containing morphia, etc.

He has not yet disproved the assertion that acid. sulph. dil. is not to be added to a mixture containing quinine unless specified.

There are eminent medical men here and elsewhere that frequently specify that the quinine is not to be dissolved unless specially ordered.

Bath, Dec. 27th, 1870. D. T. W.

Sir,—With reference to the prescription alluded to by "*Magnesia,*" I see that "*Chemicus*" still adheres to his assertion that the medical man forgot to add the acid. sulph. dil., and as proof is wanting, I think it best to give him the benefit of the doubt; but I quite agree with you that your correspondents were not justified in adding acid. sulph. dil.

If such was allowable, it would produce a rivalry amongst dispensers, as to who could supply the same medicine so as to present the most elegant appearance, regardless of the wishes of the prescriber or the comfort of his patients. I quite agree with "*Chemicus*" that a dispenser is justified, and in duty bound, to use his discretion in compounding a medical man's prescription (for medical men, like ourselves, are often pressed for time, and a slip of the pen might be productive of serious results); but he has no business to touch it up to suit his own fancy, and if any alteration be necessary, it is his duty to refer to the medical man. About a month ago the following prescription was handed to me to be dispensed, and was supplied accordingly:—

℞. Potassæ Chlor. ℈ij
Quinæ Sulph. gr. viij
Acid. Sulph. Dil. ʒi
Syr. Limonis ℥j
Aquæ ad ℥viij
M. ℥j 4tis horis.

When the medicine was finished, the same person brought the empty bottle and presented a prescription containing the same ingredients as the above, minus the acid. sulph. dil.

It immediately occurred to me that the acid had been forgotten, especially as the medical man sometimes prescribed acid. citric. with chlorate of potash and quinine, but as I had not an opportunity of referring to him, I felt bound to dispense the prescription as ordered, and of course I did so.

A few days after I happened to mention the circumstance to the medical man, who told me that he omitted to add the acid, as his patient complained of the medicine causing irritation of the bowels, and that the omission had produced a satisfactory result.

Imagine the annoyance of the medical man and the discomfort of his patient if I had presumed to act upon the suggestion of "*Chemicus of twenty years' standing.*"

Darlington, Dec. 26th, 1870. J. SWENDEN.

DISPENSING CHARGES.

Sir,—There can be no doubt that the plan proposed by "W. Wilkinson" in last week's Journal is most valuable, and would tend to lessen the great evil of different charges for the same prescription when dispensed at different shops; but still I fancy it would meet but half the difficulty. I have been in business for over twenty years, and in a town of about 7000 inhabitants. There are two chemists besides myself; often they undersell me and as often I undersell them, not intentionally on my part, and I am willing to believe not on theirs; but how is it to be avoided? For all trade communication between us we might as well live fifty miles apart: and I see no chance of effecting a better state of things till all in a town or district will agree to meet, say once a month, and, sinking all petty jealousies, talk over business matters in an amicable and friendly spirit. If this could be brought about, I am sure the evils so often complained of in your Journal would be much lessened.

Just to give an example of low charges. Some time since a commercial traveller (in the drapery line) brought me a prescription for an 8 oz. mixture, and on calling for it a little time afterwards, put down a shilling on the counter. I said I could not possibly charge less than 1*s.* 6*d.* for it. "Oh," said he, "I never pay more than a shilling." I insisted on the fairness of my charge, and the result has been that from that time I have dispensed but very few prescriptions from the hotel at which he was staying (the leading one in the town), whereas before I continually did so.

GREY HAIRS.

Bridport, Dec. 17th, 1870.

Sir,—The price-mark recommended by the Manchester Chemists' Association, and a dozen others adopted by leading firms, seem to have two defects, which should be supplied previous to general adoption. There is no "repeater," nor any provision for expressing the cypher. The letter "W," naturally suggesting the idea of reduplication, answers well as a repeater, and the cypher may be expressed by any letter not otherwise used.

I would, however, suggest two alternative schemes. There is a system of artificial aid to memory, somewhat extensively known in schools, which makes use of all the consonants. It has the advantage of various letters to express figures above five. I append the system.

1	t	Consisting mainly of *one* stroke.
2	n	" " *two* "
3	m	" " three "
4	r	Fourth letter of *four*, which has *four* letters.
5	l	In Roman numerals suggests *five* decads.
6	d	Supposed to resemble a reversed six.
7	c g k q	The "K" sounds.
8	b h v	Consonants in "beehive." H is the *eighth* letter of the alphabet, and its name suggests sound of *eight*.
9	p f	Consonants above and below the line.
10	y	Has a *two*fold connection as consonant and vowel, and represents *two* figures.
0	s x z	A circular figure, represented by letters suggesting sound of circle, cipher and zero.
	w	Repeating whatever letter has preceded it.

The Greek method of notation recommends itself by its classic use, as distinct from a merely fanciful scheme, and its exposition would be found in any Greek grammar. It is to be regretted, for the sake of the general benefit resulting from its study, and especially because it is the language *par excellence* of scientific nomenclature, that all chemists are not fairly acquainted with the Greek language; it would, however, require a very slight effort on the part of such an intelligent class to acquire a dozen characters. If desirable, shillings might be expressed by capitals, and pence by small letters, avoiding the intervening stroke, and the appearance to the public of a price.

HENRY H. POLLARD.

Ryde, I. W., December 20th, 1870.

OBSCURE PRESCRIPTIONS.

Sir,—I have perused with peculiar interest the correspondence and your remarks thereon which have appeared in the late numbers of the Journal respecting the obscure writing of physicians and surgeons. Having had very considerable experience—much more than falls to the lot of most men—in a large dispensing house in London, I can with some authority bear testimony and endorse all that your correspondent, "*M.P.S. by election,*" has advanced with reference to the slovenly and loose manner in which the great majority of medical men are in the habit of writing their prescriptions, which in justice to the patient, as well as to the dispenser, ought to be clearly and distinctly written. To my mind it is all fiddle-faddle about the "Latinity" of the prescription; it matters not to the patient if some of the terminations are written *ā* when they should be *æ*, or if there should be one or two *i*'s. It is not as if every prescription written was to be subjected to the criticism of an Oxford professor. Any one can understand what is meant by tinct. belladon. Never mind the termination; the all-important thing to be observed by the writer should be that when he orders tinct. belladon. it is so clearly inscribed that it cannot be mistaken for anything else by the dispenser. With respect to the gross blunders occasionally made by even the most eminent medical men, I have seen very many, some of which would have proved fatal to the patient at the first dose had the prescription been dispensed as actually written. What would be considered trifling errors or omissions, such as quantities left out, vehicle not mentioned, pills no number, and many other little inaccuracies, I found of almost daily occurrence.

A few words respecting the possibility of a case occurring when it would be of importance the patient should not be cognizant of the drugs he is taking. I have had many applications from medical men to suggest some means by which this might be overcome. As an instance, a lady had been taking for some time "liq. Fowleri" and with great benefit unfortunately one day she pushed the question as to what this "Fowleri" meant. Very reluctantly I told her it was a preparation of arsenic; nothing could persuade her afterwards to continue its use from the fear of being poisoned, as some one had told her that arsenic was cumulative in the system. In another instance, a gentleman travelled some sixty miles from the country to consult a medical man in London; two names having been submitted to him by the local apothecary, he called on me and asked my opinion which of the two I considered best. They both happened to be of equal calibre, so I told him he could not do wrong in consulting either, the one in the City and the other at the West-End. He returned in a few hours and presented me with the City doctor's prescription, at the same time observing he was not satisfied. He desired me to read over the articles prescribed (he is a dabbler in physic); having done so, he asked my opinion, what should I consider the ailment of the patient? I unhesitatingly told him, judging from the general run of prescribers, it might be for a slight cold, etc., as it would induce perspiration, etc. (it was composed of pot. nit., vin. ipecac., liq. amm. acet., mist. camph. and also a mild aperient pill, h. s.). He took the prescription from my hand, remarking he was sure from the questions asked, the doctor knew nothing of what he was about, also that none of the ingredients ordered ever suited him; at the same time, to my surprise, handing me another prescription, written by the West-End doctor, desiring to be informed what he had ordered. When I told him it was a very mild dose of "strychnine" and other things he would not hear anything more about it, as he assured me he was determined, if possible, to die a "natural death." The most laughable part of the story remains to be told; he then asked me to prescribe something for him: this I politely declined, telling him if he was not satisfied with the advice of two eminent doctors, mine would be of no service to him. In both these cases, had it been possible to keep from them what drugs they were taking, both might have been benefited. It must not be supposed I could advocate the plan adopted by Mr. Bradshaw, nothing can warrant such practice; a patient consults a doctor and pays his guinea for the prescription,—if he refuse to take the medicine prescribed because he objects to some particular ingredient or otherwise, it is his own business, but the prescription itself ought to be as plainly written as A B C, and in accordance with the B. P.

CHLORAL.

Hydrate—Alcoholate—Tests—Therapeutical Value—Pharmaceutical Preparations.*

BY ALFRED H. MASON.

The principal object of this paper is to show that the hydrate of chloral of commerce is not all pure hydrate of chloral, but that other compounds have been put upon the market. I have examined samples, obtained from different sources, varying very seriously in the proportion of chloroform they produce upon decomposition with alkaline reagents, and I feel it a moral duty to pharmaceutists to advise them of these facts. When it is considered that one agent alone in London has disposed of twenty-two thousand pounds' weight † during the past twelve months, it is certainly high time for us to be alive to the necessity of dispensing a guaranteed article.

Chloral, C_2Cl_3HO, is formed by the prolonged action of chlorine upon absolute alcohol.‡ To prepare it, the current of chlorine must be kept up as long as hydrochloric acid gas continues to escape, and the product is to be agitated with three times its volume of concentrated sulphuric acid. On gently warming this mixture in a water-bath, the impure chloral separates as an oily liquid, which floats on the surface of the acid; it is purified by distillation from fresh sulphuric acid, and afterwards from a small quantity of quicklime, which must be kept completely covered by the liquid until the end of the operation. The chemical reactions which take place in its formation were described in a valuable paper by Mr. Henry Sugden Evans, of London, last session.

Chloral is a thin, oily, colourless liquid, of peculiar and penetrating odour, which excites tears, and it has but little taste.

Liebreich says,§ if chloral be left in contact with concentrated sulphuric acid, it is transformed into polymeric insoluble chloral; this body is more easily purified, since it is not soluble in alkalies or acids, and it may be treated a long time with these substances without decomposing. Warm this insoluble chloral, and it converts itself into soluble chloral. The sp. gr. of soluble chloral is 1·502. By degrees it thickens, and is sometimes transformed suddenly into soluble chloral evolving a large amount of heat.

When we mix anhydrous chloral with water, we obtain in a short time acicular crystals of hydrate of chloral, this body being distinguished from ordinary chloral by containing one molecule of water. Its formula is $C_2Cl_3HO + H_2O$.

This method is the one alone authorized by Dr. Liebreich, of Berlin,‖ who took out a patent in July, 1869, for the sole use for anæsthetic purposes of chloral, hydrate of chloral, and trichloroacetic acid, $(C_2HCl_3O_2)$.

The physiological and therapeutical experiments made by Liebreich led to the introduction of this product as a medicinal agent, and since he has published his formula,* with the results of his experiments, I think we should fix upon his method as the OFFICINAL one. The superiority of the hydrate of chloral manufactured under his supervision I shall prove to you (i. e., *if the larger proportion of chloroform produced by alkaline reagents from the chloral compound employed* is to be the test, which is, I think, self-evident). He tells us that numerous experiments show that this method is far the most trustworthy.

Chloral is obtained in other ways; for instance, by the method of Stædeler, from starch, by distillation with hydrochloric acid and dioxide of manganese, formic acid, carbonic acid and other bodies accompanying it; but Liebreich states he has made experiments with this preparation and finds it is not to be depended upon in its action, from the great difficulty of preventing the formation of other compounds, especially chlorides of carbon, which serve to contaminate the chloral and render its administration dangerous.

It was contended by M. J. Personne† that the hydrate of chloral described by M. Roussin as pure, was nothing more than a compound of chloral and alcohol. Differences being observed in the physical properties of the preparation made by Liebreich and that made by Roussin, it was found that they were two entirely distinct compounds, which was fully confirmed by an appeal to analysis. Theoretically, hydrate of chloral should contain 64·35 per cent. of chlorine. M. Personne found that the preparation he had made contained 63·79 per cent., whilst a sample of that made by M. Roussin yielded only 54·89 per cent. Following this indication, Personne endeavoured to ascertain by experiments whether the hydrate of chloral prepared by Roussin did, or did not, contain alcohol. The results were very satisfactory in proving the presence of this compound. Further, by combining anhydrous chloral and absolute alcohol in proper proportions, Personne was enabled to prepare synthetically a substance having properties entirely similar to those of the supposed hydrate of chloral prepared by Roussin.

It is this preparation, alcoholate of chloral, represented by $C_2Cl_3HO + C_2H_6O$, that we meet with in commerce, also hydrated alcoholate of chloral, which are not to be trusted as therapeutic agents according to the system laid down by Liebreich.

At a meeting of the Pharmaceutical Society, Mr. John Williams suggested that an alkaline reagent would show the percentage of chloroform the chloral preparation would produce. Mr. Charles Umney has also made some very valuable experiments, and instituted what is now known to pharmacists as "the ammonia process" for testing hydrate of chloral. The mode of operating, and the results of his experiments, are published in the PHARMACEUTICAL JOURNAL.

I find that hydrate of chloral is insoluble in *cold* chloroform, tetrachloride of carbon, turpentine and bisulphide of carbon, but on the application of heat, solution is effected. The hydrate is, however, perfectly soluble in cold water, ether (·735) and absolute alcohol (·805); after the application of heat, and upon cooling, the hydrate separates in beautiful crystals, generally needles, but from bisulphide of

---

* Read at a meeting of the Liverpool Chemists' Association, held December 22nd, 1870.

† This includes both kinds of hydrate of chloral, as distinguished *now* by the agents themselves,—guaranteed and unguaranteed.

† *Journal de Pharmacie et de Chimie.*

carbon in prisms. True hydrate of chloral is not acted upon by nitrate of silver or by acids.

Alcoholate of chloral is perfectly *soluble* in chloroform, ether, tetrachloride of carbon, absolute alcohol, turpentine, and bisulphide of carbon, and upon heating does not present any change, nor can I produce crystals from these alcoholic solutions. Why, I do not quite understand. In cold water alcoholate of chloral is nearly insoluble; and I venture to suggest this as a *simple* test for these two forms of chloral compound.

If twenty grains of the chloral compound is *soluble* in thirty minims of cold chloroform, it is not a hydrate; on the other hand, if the same quantity of chloral compound is *insoluble* in chloroform, I should consider it a hydrate,—solubility in cold chloroform and partial insolubility in cold water being quite sufficient test to lead *to doubt;* and so in proportion to the solubility, should I judge the probable quantity of chloroform which the ammonia process would yield.

Now if the theory of Liebreich, that the hydrate of chloral coming in contact with the alkalies in the blood evolves chloroform in the human system, be correct, a moment's glance will soon convince you of the immense superiority of samples No. 1, 2 and 3, and the decided obligation that pharmacists should dispense this manufacture only until it can be shown that hydrate of chloral of equal composition may be procured elsewhere.

Therapeutical Value.—If we review the pages of the medical journals for the therapeutical effects of hydrate of chloral, we shall find many cases where its action has been attended with marvellous results. There does seem not a little danger of its being erected into a kind of panacea for all the ills that flesh is heir to, of its true worth and fame suffering from too indiscriminate use, and from the administration of some of the impure compounds which are being supplied. Its value, however, is too real for actual collapse by its abuse; but its repute may be, and doubtless has been, dangerously compromised.

We find it employed in cases of "maniacal paroxysms," "delirium tremens," "traumatic tetanus," chorea, diarrhœa, whooping cough, convulsions (epileptic or otherwise), with more or less benefit; it allays vomiting, and prevents sea-sickness; in puerperal mania it is well reported of; in fact, as a sleep compeller it is, in a very large number of cases, unrivalled; for while in power opium alone can be compared with it, there is this superiority to opium, that its use entails no unpleasant after symptoms, no headache, no nausea, no anorexia, no constipation, whilst

Sample No.	Manufacturers, or by whom supplied.		Boiling Point.	Chloroform Layer.	Percentage of Chloroform produced from 500 grains of the chloral compound.	General Remarks.
			Centigr.	Grains.		
1	Hydrate of Chloral, prepared under the supervision of Dr. Liebreich, by Dr. Martius and Dr. P. Mendelssohn Bartholdy, of Berlin.	Cake.	97°	240	357·6 grains, or 71 p.c. (71·5)	A crystalline cake, white, easily powdered, with an agreeable melon odour, slightly pungent. Soluble in water, ether, alcohol; insoluble in chloroform, carbon tetrachlor.; partially soluble in turpentine, and bisulph. carbon without heat. With heat, dissolves and, on cooling, needle crystals are formed, except in the case of bisulph. carb., which seems, as it were, to gelatinize it.
2		Powder.	96·5°	240	357·6 grains, or 71 p.c. (71·5)	A white powder. Results same as above.
3		Crystal.	98°	235	351·7 grains, or 70 p.c. (70·3)	Bright rhomboid crystals, melon smell, more pungent. Results as above.
4	Manufactured by Messrs. De Hane and Co., Hanover.—Cake.		100·5°	190	283·1 grains, or 57 p.c. (56·6)	Semi-transparent crystalline cake, rather hard, slightly deliquescent, much more pungent smell, caustic. Soluble in water, ether (with slight effervescence), alcohol; insoluble in chloroform, carbon tetrachlor., bisulph. carbon, and turpentine (slightly), without heat; with heat, soluble in all, and upon cooling crystallizes.
5	From Messrs. T. Morson and Son, London.—Crystal.		100°	190	283·1 grains, or 57 p.c. (56·6)	Thin, deliquescent, colourless, crystalline plates (in appearance resembling potass. chlor.), slightly pungent, melon smell. Soluble in water (with argent. nit. shows slight opalescence), ether, alcohol; insoluble in chloroform, carb. tetrachlor., turpentine, bisulph. carb., etc.
6	Manufactured by Messrs. Dunn, Squire and Co., London.—Cake.		100°	190	283·1 grains, or 57 p.c. (56·6)	Hard, thick flakes, very white, pungent melon smell. Soluble in water, ether (but soon turbid), carbon tetrachlor. (on heating separated), alcohol (heat no change); insoluble in chloroform, turpentine (with heat deposit at the bottom of the tube), bisulph. carb.; separates, and heat will not combine.
7	Supplied by Messrs. Schoetensack and Co., London.—Cake.		100·5°	190	283·1 grains, or 57 p.c. (56·6)	Hard white crystal cakes, very pungent. Soluble in water, alcohol, ether (with slight effervescence), partly soluble in turpentine, bisulph. carb.; insoluble in chloroform. On the application of heat, when cooled the ether solution shows fine needle crystals, the bisulph. carb. solution solidifies.
8	Manufactured by Messrs. De Hane and Co.—Crystal.		105°	185	275·6 grains, or 56 p.c. (55·6)	A white crystalline powder, slightly deliquescent. Soluble in water, ether, alcohol; insoluble in chloroform, carbon tetrachlor., turpentine, bisulph. carbon.
9	Manufactured by Messrs. Gehe and Co., Dresden.—Crystal.		110°	180	268·2 grains, or 54 p.c. (53·6)	Transparent needle crystals, caustic, rather deliquescent, slight smell. Very soluble in chloroform, ether, carbon tetrachlor. (crystals formed again without heat), alcohol, turpentine and bisulph. carbon (crystallizes at bottom), partly soluble in water.

the sleep it produces is gentle, calm and continued; at least, this is the general rule, but, of course there are exceptions, and medical men complain that its administration is attended with uncertain results, and that its quality is not so good as it was when first introduced, and can anything justify these assertions more than the foregoing results; but even with true hydrate of chloral we must expect to find exceptional cases so long as human beings differ so greatly in temperament, constitution, and sensibility to the action of medicine.

That hydrate of chloral ought to be perfectly pure when used in medicine is unquestionable; the substitution of alcoholate is quite sufficient to produce most of the ill effects attributed to chloral. In fact, instead of being a hypnotic, it has a tendency to produce mental excitement, as ordinary stimulants.

The dose of hydrate of chloral is from 5 grains to 30 or 40 grains, according to the purpose for which it is required. A case is on record where 100 grains were taken accidentally without any evil results; but I am informed that there is danger in continued small doses. Very unexpected results have, in a few instances, occurred. And here I would strongly caution pharmaceutists not to prescribe its use themselves, or supply it to the public without the sanction of a medical man.

Hydrate of chloral has been successfully administered as an antidote to strychnia.

Hydrate of chloral cannot, in consequence of its chemical properties, be administered in the shape of pills or in the form of powder; it is, therefore, necessary almost to confine its use to solutions. For dispensing purposes, Liebreich recommends a solution of the hydrate in its own weight of water. In small doses it can be given without the addition of a corrective, but simply dissolved in distilled water.

There are several pharmaceutical preparations in which the hydrate of chloral is disguised, or its taste modified, in various ways. Of the syrups containing 10 grains of Liebreich's hydrate in each dram, one made with syrup. pruni virg. is used in America; it is most palatable. Another is made with syr. tolu; others with syr. flor. aurant., syrup. cort. aurant. (as suggested by Liebreich). Another is flavoured with almonds (Ferris). There is also a draught containing half dram chloral, with syrup tolu, tinct. ginger and peppermint water. Lozenges containing 1 grain hydrate of chloral in each are manufactured by Messrs. Meggeson and Co.

Spiritus chloralis is made by Savory and Moore. It has a very agreeable taste and smell, but I was not able to obtain any deposit upon evaporating a little.

Limousin's capsules are known to contain alcoholate of chloral, because true hydrate cannot be secured in a gelatinous envelope.

In prescribing and dispensing hydrate of chloral, it should be borne in mind that no corrective with alkaline reaction can be employed with it, because such an administration would bring about the transformation of the substance.

In concluding this paper, I must add that I have no interest whatever in putting forward the claims of Liebreich's manufacture, further than a feeling of moral duty to the medical profession, pharmacists and the public, together with the *conviction* that other manufactures which have come under my notice do not attain the desired standard. It appears that the importers of this article now know a guaranteed hydrate of chloral and an unguaranteed hydrate of chloral. There is a guarantee to the consumer, which is the protection of the hydrate manufactured under Leibreich's supervision; this is a registered trade mark. It is offered in three forms—cake, crystal and powder; but the action of the cake is more to be relied upon. Each product should be kept in well-stoppered bottles. The large quantity which the bottles with the registered trade mark contain is, I think, a drawback to its more universal application; and I think, if the agents of this manufacture could be induced to supply it in smaller bottles,—say from 1 oz. upwards,—with the registered label on each bottle, and could produce it at a cost more in proportion with the competition, they would not only further the objects of the discoverer by more satisfactory and uniform results being produced, but also benefit mankind in general.

NOTE ON AUSTRALIAN OPIUM.*

BY J. S. WARD.

The large sum paid as duty on all opium imported into Australia has caused the experiment of growing poppies for the production of opium to be tried for two or three years in different parts of the colony of Victoria with good success. The product has been of a tolerably uniform quality, and the samples have yielded variable quantities of morphia.

The sample of which I shall treat was sent by Mr. Francis, a Melbourne pharmaceutist, formerly with Messrs. J. Bell and Co., 338, Oxford Street, to Mr. T. H. Hills. I have been requested by the latter gentleman to examine it and lay the result before this meeting.

But before going into particulars as to its quality, I shall read an extract from Mr. Francis' letter referring to the cultivation of the poppies and the collection of this opium:—

"The poppies, from which the present sample was extracted, were grown in Gipps Land, a vast tract of country forming the south-east portion of the colony of Victoria. The land taken up was one quarter acre. The plants were placed nine inches apart, in rows two feet six inches from each other. They were planted in July, the opium was extracted in the December following. Each plant attained a height of from five to six feet, the number of capsules on each averaging ten. The mode of gathering was as follows:—The capsules were nicked in the afternoon of the day by one person, another following immediately after, gathering the drops as they fell. The liquor, being very thick, was then placed in tin dishes and exposed to the sun till a proper consistence was attained. The gross yield of opium from the quarter acre of the consistence of the sample sent was 14 lbs. weight. You will notice that the mode of collecting is somewhat different to that spoken of by Pereira, and it was found better to collect towards evening than in the morning, on account of the heavy morning dews.

"I have seen other samples of opium prepared and grown in the colony, but got up more closely to resemble the ordinary article of commerce; they compared very unfavourably with the one sent.

"I might, perhaps, mention that I paid 52*s.* per lb. for the opium; but I bought it rather on account of its novelty than for any other reason. I have not

* Read at the Evening Meeting of the Pharmaceutical Society, Jan. 4, 1871.

yet used it in business, nor tested it, so as to arrive at my conclusions as to its commercial value.

"All imported opium is subject to a duty of 10*s.* per lb."

This opium, when first received, was of a light brown colour, and in appearance like a well-made hard extract; but on keeping became like other opiums, much harder and darker; when quite dry, it breaks with a smooth regular fracture. These characters are explained by its being a pure dried juice.

Its odour, which is very fine and marked, is similar to that of Smyrna opium, but scarcely so powerful. Cold water takes up 46 per cent. of soluble matter. A tincture made according to the Pharmacopœia is of a very light colour, being no darker than the tincture of myrrh.

The most important character of this sample is its richness in morphia. On submitting it to quantitative analysis I obtained the following result:—

Morphia	9 per cent.
Narcotine	4 " "
Meconic Acid	6 " "

I have not examined it for any other alkaloids, not having a sufficient quantity of the sample to work on. I can only find one report of an analysis of this opium, namely, by Mr. Bosisto, of Richmond, who, in a paper read before the Royal Society at Melbourne, stated that it contained 10 per cent, of morphia and 3 of narcotine.

By these characters, it will be seen that Gipps Land opium will compare favourably with the best Smyrna; and it cannot, I think, be doubted that its more extensive cultivation in this district would prove a source of large increase to the revenue of the colony, and, consequently, of great advantage to its inhabitants, while, at the same time, it will supply us with another new and important source of this valuable drug.

THE NAMES OF THE CINCHONA ALKALOIDS.

BY DR. J. E. DE VRIJ.

In No. 18, of October 29th, 1870, of this Journal, I found, on page 342, an article upon Java cinchona bark, abstracted from Herr Jobst's paper in *Neues Jahrbuch für Pharmacie*, xxxiv. 18, which induces me to make a few remarks.

If anybody not thoroughly acquainted with the chemistry of the cinchona alkaloids, in reading this paper, compares the results obtained by Professor Gunning and by Herr Jobst, he will very probably suppose that there exists much discrepancy between the results of these two chemists; as the one found (for instance) in Java Calisaya bark much quinidine, whilst the other found therein no quinidine, but conchinine, etc. The cause of this apparent discrepancy is that Professor Gunning, like the majority of chemists, calls the alkaloid discovered by Henry and Delondre, and later admirably well described by Pasteur, *quinidine;* whilst Herr Jobst uses for this alkaloid the name of *conchinine,* which name was given to it about two years ago by O. Hesse. If this chemist had discovered the alkaloid in question, I should have no objection to the name; but as the name quinidine has, since it has been confirmed by the investigations of Pasteur, been accepted by the majority of chemists, and particularly by Mr. Howard in his celebrated 'Quinology,' I consider it in the interest of this branch of science not to alter the name which it has now borne more than thirty years. In the same paper Herr Jobst uses the name of quinidine for what the majority of chemists, and also Mr. Howard in his 'Quinology,' call cinchonidine. I hope that the Editor of this Journal will agree with me on this topic, and for the convenience of the readers always use the names of quinidine and cinchonidine, as they have been used since 1848 by Pasteur and the majority of chemists.

The Hague, December 10th, 1870.

GLYCERINE EXTRACTS OF PEPSINE AND OTHER FERMENTS.*

Mr. M. Foster reports, in *Nature*, the result of a repetition of some experiments, published a short time ago by Von Wittich in *Pflüger's Archiv*, upon the isolation of pepsine and other so-called ferments by means of concentrated glycerine.

After washing the mucous membrane of a pig's stomach, it was freed as much as possible from water, minced, bruised, and covered with pure glycerine. Having stood twenty-four hours, a few drops of the glycerine, diluted with acidulated water, digested fibrin rapidly. This process was repeated four times, each resulting extract manifesting strong peptic powers. Treated, after filtration, with an excess of alcohol, these extracts gave a slight precipitate, which, separated by filtration and redissolved in acidulated water, was strongly peptic.

Salivary gland and pancreas yielded to glycerine a starch-converting ferment, and a "laden" pancreas gave a ferment digesting fibrin in an alkaline medium. Ungerminated barley gave up a non-proteid diastase; almonds a ferment acting on amygdalin.

The author thinks that glycerine offers advantages in the investigation of this subject not presented by any other medium, as the extracts remain unchanged for a long time, while the tissues, being little altered after exhaustion of their ferment by repeated treatment with glycerine, may be examined under conditions hitherto impossible. He claims that these results are also of practical value in the preparation of the so-called pepsin for medical purposes; as by glycerine a pure palatable peptic liquid, apparently keeping any length of time and certain in its action, can easily be obtained.

IODOFORM.

BY J. HENRY CARSTENS, M.D.

Teriodide of formyl, or sesqui-iodide of carbon as it was formerly called, has a chemical composition of CHI_3. It was discovered in the year 1822 by Sérullas, who procured it by adding chlorinated lime to an alcoholic solution of iodide of potassium. Claimed by Dumas to be analogous to formic acid, the iodine taking the place of the oxygen (also chloroform and the like preparations).

A good method for making this compound is given by Wittstein. Two parts of carbonate of potash, two parts of iodine, one part of alcohol, and five of water, are mixed in a retort, which is then heated by means of a water-bath till the contents are perfectly colourless. After the retort has cooled, the liquid is poured into a beaker and allowed to settle. The yellow scaly mass is then collected on a filter, washed thoroughly with water,

* See *ante*, p. 403.

and dried between filter-paper. Reaction (according to new nomenclature) :—$6(K_2CO_3) + 16I + 2(C_2H_5HO)$. Five atoms of oxygen of the carbonate of potash join $2(C_2H_5HO)$, forming $2(HCHO_2) + 3(H_2O) + 2(CH)$; $2(HCHO_2)$ combines with $K_2O = 2(KCHO_2, H_2O)$; $10K + 10I = 10$ (KI); while 6I and the $2(CH)$ of the alcohol form $(2CHI_3)$, carbonic acid escaping.

According to this, the gain of iodoform would be 38 per cent.; but the reaction never takes place so completely, and we must remember that all these changes take place at once, and that iodoform is very volatile (must never be made in an open vessel); the alcohol evaporates, and must be used in larger quantities; the excess of carb. of potash does not retard, but seems to increase the reaction.

By using six ounces of iodine only one ounce of iodoform is collected, or about 17 per cent. It would therefore be very expensive if we could not make use of the filtrate for making iodide of potassium. This liquid contains, besides traces of iodoform, the balance of the iodine as iodate of potash and iodide of potassium, and also formate and carbonate of potash.

Evaporate this solution to dryness and triturate with one-eighth of its weight of charcoal, and then heat to redness for a short time in an iron crucible, then digest in alcohol and filter; the residue is carbonate of potash, while the filtered solution contains the iodide of potassium; the alcoholic solution is evaporated and allowed to crystallize. By this means no iodine is lost, and teriodide of formyl ought to be not more expensive than iodine.

Iodoform appears in the shape of yellow, shining, six-sided scales, with a spicy odour (like saffron or iodine and chloroform); is volatile at ordinary temperature. Almost insoluble in water (one part in 13,000), but more soluble in alcohol (one part in 80). If it be used in a mixture, it is necessary to avoid alcoholic solution of potash, which decomposes it, forming formate of potash and iodide of potassium :—

$$CHI_3 + 2(K_2O) = KCHO_2 + 3KI.$$

Besides the well-known effects of iodine and its preparation, iodoform has the advantage of the former preparation of being stronger and more uniform in its action on the system; that is, does not corrode, nor act as a local irritant, and that, therefore, it may be given uninterruptedly. It is anodyne, and, consequently, often useful in neuralgia; producing also a local and partial anæsthesia of the colon. It has less anæsthetic powers than chloroform, although recommended by Eugenio Franchino (*Gaz. Sard.* 28, 1858) as a general anæsthetic in place of chloroform. First used by English physicians in form of ointment for exanthema; used by Litchfield in porrigo and lepra; by Glover for psoriasis, impetigo, scabies, etc.; also recommended for croup (internally), and used with good success (*Monthly Journal, Feb.*, 1848). On the recommendation of Moretin and Mouzard (*l'Union*, 1857), used as a local anæsthetic, in the form of suppositories, in the prostate; it also seems to relieve tenesmus, easing defecation.

Iodoform has lately been prominently brought to the notice of physicians in the United States as a remedy for chronic ulcers (Proc. Penn. State Med. Soc. 1868), obstinate neuralgia, scrofula, strumous ophthalmia, consumption, and even in cancer is stated to have relieved the excruciating pain of this malignant disease, without seeming to arrest the same (*Medical and Surgical Reporter*, Phil., vol. xvi. xvii. xviii.). It is also a valuable dressing in chancre.

It is best administered in pill form, one to two grains, three times a day. Quevenne's iron may often be advantageously added. Externally it is used as an ointment, one-half to one drachm of iodoform to one ounce of lard, or it is dissolved in hot alcohol and glycerine added; these to be used *pro re natâ.—Detroit Rev. of Medicine.*

APOMORPHIA.*

Apomorphia, a very curious organic base, was discovered by the late Dr. Matthiessen and Mr. C. M. A. Wright, while experimenting in the laboratory of St. Bartholomew's Hospital, in April, and reported on to the Clinical Society by Dr. Gee, in May, 1869.† It is obtained by submitting the chloride of morphia for several hours to the action of strong hydrochloric acid at a high temperature. The result is the chloride of apomorphia, from which the base may be obtained without difficulty; but as it is very unstable, the salt has been used. Chemically the base, apomorphia, differs from morphia by containing the elements of a molecule of water less. Its chloride is a white crystalline powder, soluble in thirty parts of cold, and in much less of warm water. As a medicine it possesses most remarkable emetic powers, acting rapidly and certainly. Dr. Gee says, "We have never yet failed to produce vomiting when we wished to do so, and by a single dose." The salt is free from all local irritant properties, and can therefore be used hypodermically; its dose is very small—one-fifth of a grain by the mouth, or one-tenth of a grain hypodermically, acting rapidly and freely; and its action is not accompanied or followed by any ill effects. "The vomiting," Dr. Gee says, "seems, in most cases, to be critical, as it were, and put an end to itself; there is no subsequent nausea."

The only other information on the use of this salt is a short communication from Dr. F. M. Pierce, who confirms Dr. Gee's statements. He says, "It is the most speedy and most certain emetic known—the tenth of a grain of the chloride, or even less, is the dose required. It may be given safely to children, and acts more rapidly when hypodermically administered" than when given by the mouth.

Should it turn out that the drug has no other medicinal value than as an emetic, it will be a most important addition to the materia medica. No other emetic can be administered hypodermically; and all others are bulky in dose, very uncertain in action, and produce distressing nausea and depression.

THE KATIPO, OR POISON SPIDER OF NEW ZEALAND.

BY DR. WRIGHT.

The author, in a paper communicated by him to the *Medical Times and Gazette*, reports the case of a man who, while employed in carrying firewood which had been stacked in some sedge or coarse grass, was bitten by a katipo on the shoulder. Within an hour, upon attempting to eat his dinner, he found that he could not open his mouth, and was scarcely able to articulate in consequence of stiffness about the jaws. He immediately applied to Dr. Wright for medical assistance, but was scarcely able to make himself understood. Upon examination of the spot the surface was found to be raised to an extent as large round as a teacup. This swelling was white, and surrounded by a halo of red not unlike an exaggerated wheal of the nettle-rash. He complained of considerable pain in the part. During the examination he became faint and almost pulseless, his countenance and body assumed a hue of extreme pallor, his extremities were cold and flaccid, his respiration almost ceased, and there were fears that he was about to expire. Ammonia was applied to the wound, and ammonia and water combined with brandy, in considerable doses, administered; but it was upwards of two hours before the man was sufficiently recovered to return home. Several days elapsed before he was able to resume work, in consequence of great lassitude and nervous depression.

* Abstracted from a series of papers on the "Progress of Therapeutics," published in the *Medical Times and Gazette*.

† *Transactions of the Clinical Society*, vol. ii. 1869, p. 166.

The information concerning this insect which the author has been able to obtain is to the following effect:—The katipo is a small spider, from half to three-quarters of an inch in diameter, measured across the body and legs. There are said to be two kinds, one with a dark glossy brown or black spherical body and compact legs, found amongst dead wood in gardens, or with a slight web among the rafters of lofts and outbuildings; the other, which is the most poisonous, has a black body with a vermilion spot upon its back, and inhabits the sandy beaches of the seacoast, taking refuge among the driftwood and roots of sedge or rushes found there. The author considers the poison to be of a narcotico-irritant nature, similar in its effects to those recorded as following the bite of the tarantula.

In corroboration of the nature of the accident, an account of three cases of katipo bites met with by the Rev. Mr. Chapman, a missionary to the Maori race in the interior of New Zealand, is appended. In one case a native girl was bitten near the beach, and, although ammonia was applied, and wine and other nourishment given, died after lingering two months. In the second, a boy was bitten in the thigh, and did not recover for nearly six months. In the third case the sufferer was a native chief, with whom the missionary was travelling. We give the account of it in his own words:—"We were travelling together up the coast from Whatakane, and, halting to dine, he seated himself upon a large tuft of sedge. He had not been sitting many minutes before he sprang upon his feet, saying he had been badly bitten by a katipo on the upper part of the thigh. I directed him to lie down; I then dissolved some carbonate of soda in a very small quantity of water, and, adding to this some brandy from my flask, quickly made a crucial incision over the part bitten, squeezed out forcibly the blood, and rubbed in this antacid solution, keeping up this action for ten minutes, when he said he no longer felt the pain. He remarked on rising, 'Had you not been with me, I should have had a long illness.' Only two or three minutes could have elapsed after the bite before a spot about the size of the top of the little finger appeared, of a peculiar white colour, in strong contrast with the dusky shade of Toke's skin. He was very careful to secure all the blood I had forced out of the wound I had made by absorbing it in a piece of rag torn from his shirt. This relic, now so doubly sacred, he carried into the middle of a swamp close by, and I saw him stamping it down into the ground very violently, to preserve it from possible desecration."

SWEET TINCTURE OF RHUBARB.

Take of Rhubarb, bruised,
Liquorice Root, bruised, of each 2 ounces.
Aniseed, bruised,
Sugar, of each 1 ounce.
Diluted Alcohol, 2 pints.

Macerate for fourteen days, express and filter.—*New York Druggists' Circular.*

BOTANY IN MEDICAL SCHOOLS.

In an introductory lecture, delivered by Mr. Leo Grindon at the opening of the current session of the Manchester School of Medicine, the lecturer, alluding to the utility of a knowledge of materia medica, remarked that it would especially ill become him to undervalue the right use of drugs, since the germ of the science of botany was found in the study of the vegetable portion of the materia medica by the pupils of Aristotle; and although an eminent physiologist and lecturer had quite recently expressed his opinion that both chemistry and botany should be omitted from the curriculum of study in medical schools, he could not but exclaim, God forbid that the day should ever come when it should be said that medicine was unfaithful to its first love, and that the allegiance of more than 2000 years had come to an end. It might be that Professor Huxley objected rather to the particular portion of botany to which the student was too often required to give his first attention,—an attention quite as frequently repelled by it as allured. The student who was wishful to learn how to distinguish *Dulcamara* from *Belladonna*, and to possess clear notions of the general aspect of deleterious plants as contrasted with harmless ones, could not be expected to feel either gratification or encouragement in minute details respecting *Phyllotaxy* and *Bothrenchyma.* To the student, botany so initiated may well seem a useless burden, and he (the lecturer) could not see how the student was helped towards the practical knowledge of pharmaceutical and poisonous plants by being saturated with minute vegetable anatomy. Vegetable histology was one of the noblest pastimes of every true botanist, and a large acquaintance with it was one of the special ornaments of his profession, but to commence with it was to enter the temple through the roof instead of the portico. He did not believe that Professor Huxley or any one else could deem it superfluous that the medical student, in addition to receiving a good groundwork of structural botany, with its complement of physiology, should be shown, as in their Manchester school, specimens, or other intelligible illustrations of every plant mentioned in the Pharmacopœia, and of every plant the name of which cropped up periodically in connection with deaths by accidental poisoning. That the practical department of botany involved in its teaching far more labour and anxiety of preparation than was needed for illustrations of histology might account for the preference given to the latter; and if teachers were not able or willing to undertake that labour, it certainly was a reasonable question,—had not botany better be out of the curriculum?—*Gardeners' Chronicle.*

Tinted Honey.—A specimen of rose-coloured honey has been presented by Messrs. Fortnum and Mason to the Food Department of the South Kensington Museum. It is of great beauty and delicacy. The comb is virgin, the wax almost white, the honey limpid, pure and of the colour of pale red currant jelly. The secret of its production is not revealed, except that it is the result of artificial feeding. The *Gardeners' Chronicle*, after alluding to the various opinions held as to the change which honey undergoes between the time of its being taken from the nectary and that of its being deposited in the comb, remarks that honey from white clover has a greenish-white hue, that from heather a rich golden yellow, and no doubt other colours might be observed according as certain flowers are in particular abundance. It is even possible that feeding the bees upon currant or raspberry jelly or jam would answer the purpose equally well. But it is clear that this step in the refinement of honey being reached, we shall not stop here. With the help of the chemist, the beekeeper will be able to turn out, in a few weeks, to order, honey of any hue, blue, pea-green, orange, or apricot-coloured, or even,—by a little ingenious manipulation of the present system of hives, which will allow of any part of the comb being shut off or made accessible to the bees at pleasure,—a parti-coloured honey, arranged in artistic patterns and devices.

Wax-Varnish.—Benzine will dissolve a large proportion of wax, especially when heated to the boiling-point, which can be easily effected without danger of explosion, by placing a bottle containing the liquid in water heated to between 150° to 200° F. The solution, however, will deposit a cloudy sediment upon cooling. Nevertheless, it can be readily used for producing wax paper, or, in fact, for all manipulations where the object is to produce a thin uniform coating of wax on any foreign substance. The benzine evaporates completely within a few hours without leaving a trace of smell behind. The best solvent, however, I found to be bisulphide of carbon. This substance readily produces a concentrated clear solution of wax, even without the aid of heat, and evaporates so quickly, that wax paper produced by its aid is ready for use within a few minutes after being impregnated. The latter manipulation should be performed quickly and on both sides by means of a soft sponge. This solution will be found especially adapted for coating gypsum statuettes and other similar work. It may also be used for closing up small cracks in furniture prior to being varnished or painted, as also for bedsteads to exclude bed-bugs. For the former purpose it may be coloured to harmonize with the furniture. The use of this "Wax-Varnish" will be found very convenient, especially during the summer months, when gas stoves and charcoal furnaces are in general use, which will not produce the uniform heat over a large surface that is necessary to make good wax paper according to the usual plan.—*Hermann Koch, in Druggists' Circular.*

Test for Chloric Acid, by M. R. Bœttger.—Three years ago M. Braun described an extremely delicate test for nitrates and nitric acid; it depended upon the intense red coloration produced by these bodies upon sulphate of aniline dissolved in sulphuric acid. M. Bœttger suggests the same reaction for the detection of chloric acid and the chlorates. The smallest possible trace of a chlorate introduced into the solution of sulphate of aniline in sulphuric acid will develope almost instantaneously a blue colour throughout the mass.—*Journ. de Pharmacie et de Chimie.*

Flavour for Chloral Hydrate.—A correspondent of the *New York Druggists' Circular* says that the taste of chloral hydrate may be successfully disguised by the addition to a solution of the chloral of a little simple syrup and a few drops of oil of sassafras.

Tin-lined Water Pipes.—In an article upon the subject of the poisoning of water by pipes used for domestic purposes, the *Boston Journal of Chemistry* warns its readers against the tin-lined pipes lately introduced, which it asserts are dangerous because (1) tin by itself is often more readily attacked and dissolved by water than is lead; (2) where there is water contact between lead and tin, both metals are dissolved with increased rapidity. It adds that galvanized pipe is just as dangerous, for in this case salts of zinc are formed and gradually dissolved.—*Food Journal.*

Poisoning by a Disinfectant.—A fatal mistake occurred on Monday, December 26, at Winchmore Hill. Mrs. Gardiner, of Edmonton, having called to see her sister, Mrs. Eaton, whose family had been suffering from small-pox, was invited to partake of a glass of rum. After drinking a small quantity she complained of the taste, saying that it was very hot. Her sister then tried a little diluted with water. Shortly afterwards both ladies were taken seriously ill, when it was found that instead of rum, they had been drinking a disinfecting fluid kept in the house by order of the doctor. Mrs. Gardiner lived only a few hours, and her sister lies in a very dangerous state.—*Standard.*

Poisoning by Tincture of Squills.—A case of poisoning has occurred at Penzance, the particulars of which are as follows:—The wife of a miner being ill a messenger was sent to Mr. Chenhalls' surgery for some medicine. While preparing it, Mr. Chenhalls found he had not sufficient tincture of squills. He therefore asked the messenger, who is rather deaf, to take a bottle to a chemist's and have it filled for him. Instead, however, of returning with the filled bottle to Mr. Chenhalls, the messenger gave it to the patient's little boy, requesting him to tell his mother to take the same quantity as before. The patient did so, drinking nearly an ounce of the tincture. Mr. Chenhalls, finding the messenger did not return, acted promptly when he discovered the mistake, but nothing could prevent death.—*Times.*

Botanizing in Honolulu.—A correspondent in Honolulu, after making a botanical tour in the Kaala range, writes, "Botanizing on this island is not without considerable danger. Only imagine descending a steep decline of 70°, which had to be done chiefly by swinging from the roots of one tree to the branches of the next one below, and that at the height of 2000 feet above the deep gorge beneath our feet." Nature, however, seems in all cases to provide a reward for her admirers who voluntarily expose themselves to such dangers for the purpose of bringing to the eye of science her numerous hidden beauties, for the writer continues to say, he was not a little surprised by the discovery of a violet with splendid snow-white waxy flowers, some of which were almost half an inch in diameter and exquisitely perfumed. He considers it probably a variety of *Viola Chamissoniana*, which he found in its ordinary state lower down in the forest; but the pure white flowers, stretching out their long peduncles above the surrounding low undergrowth and luxuriating in the full sunshine of an azure blue sky, far exceed in beauty those of *V. Chamissoniana*, which are of the ordinary violet colour.—*Nature.*

Poisoning by Mistake.—An inquest was held on Monday, January 2, in Bell Street, Edgeware Road, upon the body of a child two days old, to whom a dose of laudanum had been given by the nurse in mistake for castor oil. As soon as the error was discovered, medical assistance was obtained, but the child died twelve hours afterwards. A verdict of death from misadventure was returned.—*Standard.*

THE SALE OF POISONS IN CANADA.

At the Toronto Police Court, on Friday, November 25, twenty-five druggists were charged with having sold poison contrary to the law. *The Canadian Pharmaceutical Journal* has the following editorial remarks concerning this prosecution:—

"Many of our readers will, by this time, have learned of the recent prosecution of a number of our city druggists for alleged infraction of the law regarding the sale of poisons. The case is one of considerable interest to all classes of the community, and to druggists especially so. Nor is this interest of a purely local nature, inasmuch as the statute relates to all parts of the province, and should the decision, which is now pending, be rendered in favour of the prosecution, it is probable that druggists in other cities and towns would soon have to suffer a like humiliation with their Toronto brethren, by becoming a prey to the treachery of that most despicable of creatures,—a common informer.

"Some time during the middle of last month, the notorious informer, Mason, accompanied by one of his satellites, made a circuit of the drug stores of the city, and from twenty-five of these establishments succeeded in obtaining, by virtue of various artful misrepresentations, quantities of laudanum varying from forty minims to an ounce. Information was at once lodged with the police magistrate, and the offenders were, in due course, brought before that functionary. As the information was in all cases the same, it was proposed to try one as a test, which was accordingly done. From the evidence of the informer, it appears that the laudanum was procured with considerable difficulty, and it was not until the purchaser gave full particulars as to the purpose for which he wanted it, urging, as a reason, that his rest had for several nights been broken, that the druggist consented to let him have the quantity required,—a little over half an ounce. The question arose as to whether laudanum came within the meaning of the statute in being 'a deadly poison.' A number of witnesses, including Professor Croft and Dr. Lizars, were examined, but all agreed in their testimony that laudanum could not be so regarded, and could not, with propriety, be classed in the same category with arsenic, corrosive sublimate and strychnia. The case was remanded from day to day, but nothing contradictory to this was elicited. The magistrate declined giving judgment when the evidence was concluded, and although nearly three weeks have elapsed, the decision has not yet been rendered.

"It is not for us to say what the end of the case may be, but *from the evidence taken*, we certainly think that the point upon which the case appears to turn is clearly made out, and that laudanum cannot be considered a deadly poison, in the same light with poisons such as strychnia and arsenic. That the intent of the law is to include poisons such as these, and these only, will be apparent from a consideration of the following quotation from the Act in question:—

"'No apothecary, chemist, druggist, vendor of medicine or other person shall sell or deliver any arsenic, corrosive sublimate, strychnine, or other poison, mineral or vegetable, simple or composite, commonly known as a deadly poison (or which being incautiously or secretly administered may cause immediate death), to any person who does not then produce and deliver a certificate or note from some person duly licensed to practise as a physician or surgeon, or some priest or minister of religion, resident in the locality, addressed to such druggist, etc., and mentioning the name, calling, or profession of the person requiring such poison; and stating the purpose for which it is required, and that it ought to be sold to the persons requiring the same; and such certificate or note shall be kept by the persons selling or delivering such poison as his justification for so doing.'

"What is a deadly poison? This is a question somewhat difficult to answer. It is true we might give a general definition of the term, which might convey its commonly understood acceptance, but this definition might be widely incorrect. Happily, in this difficulty, the framers of the statute have plainly indicated what they, at least, understood by the term; that is—a poison 'which being incautiously or secretly administered may cause immediate death.' Certainly laudanum cannot come under this designation, for we know that 'immediate death' has never been known to result from its use, even in the most enormous quantities, and in all cases a sufficient time elapses for the exhibition of the proper remedies. Some persons have endeavoured to assign a wider and more general meaning to the term as used in the Act. Thus, an erudite correspondent of the *Globe* informs the readers of that paper that a deadly poison is one 'that will kill,' 'or produce death in man.' A moment's reflection shows this to be erroneous, but, assuming it to be correct, we might find hundreds of articles in a druggist's stock which might be classed under the term. The mere enumeration of these would be sufficient to show their character, but let us go to fields less promising and find what the grocer does in the 'deadly poison' line. Take one of the commoner articles—saltpetre—we find that in doses of one ounce it will prove fatal, and instances of such a termination have been recorded (Wood and Bache); cream of tartar, four or five teaspoonfuls have been found a fatal dose for an adult (Taylor's 'Medical Jurisprudence'); essence of ratafia, a teaspoonful is a fatal dose,—a case of poisoning by this quantity is reported in the *Lancet* in 1841; cayenne pepper, one ounce of which would cause death as certainly as a like quantity of laudanum. We might enumerate a number of similar instances, or might allude to alcoholic liquors which are, as a rule, comparatively slow in their action, but nevertheless remarkably sure; but think we have adduced sufficient to show that if a deadly poison is one which will produce death in man, and that such is the meaning of the term as used in the Act, the informer Mason need not in future confine his attention exclusively to druggists.

"We do not, at present, intend to pursue this subject further, but shall postpone our remarks until a legal decision has been given. In the meantime, we do not wish it to be understood that we treat the matter of the sale of poisons, with undue laxity; we hold to quite the contrary, and think that every legal obligation compatible with the lawful use of dangerous substances, should be laid down and enforced with the utmost rigour, but we believe that the present law is altogether insufficient for the purpose for which it was intended, as demonstrated by the fact that for over ten years it has remained a dead letter on our statute books, and when it is ultimately revived, it is only for the purpose of extorting money from one of the most respectable classes of the community, and placing it in the hands of one whose very avocation is a by-word and a disgrace.

"The most impracticable and pernicious feature of the present law is that of requiring a physician or minister's certificate as authority for the sale of poison (let the rendering of the word be what it may). On this subject one of the *Globe's* correspondents very sensibly remarks, 'Is a doctor or a minister any better qualified than a druggist to determine the uses to which a person may apply poison after having purchased it? Or, do they keep any record of the name, occupation, residence, etc., of those to whom they grant these certificates? I believe the answer—No! will apply to both these questions. And I also believe that there is no druggist in the dominion who would knowingly and willingly contravene the law as it now exists, if he could avoid it. But the thing is impossible! There is scarcely any article in the whole Pharmacopœia which can strictly be termed "innocuous," and one-half of the stock usually found on the shelves of a drug-store might easily be termed "poisons." So that keeping to the precise letter of the law, a druggist would be compelled to give up his business and say with the Moor, "Othello's occupation's gone," or by infringing it, as in the instance now on trial, place himself at the mercy of any one who through spite or impecuniosity may see fit to visit him with the terrors of the law.'

"The druggist is the party with whom the responsibility of the sale of poisons should rest. The nature of his calling presupposes an intimate knowledge of their properties and uses; of these matters he is certainly a better judge than the priest or minister. His standing in the community is, as far as morality is concerned, as high as any. Care and watchfulness form an essential part of his education, and, in this respect, he is not a whit behind the physician. We are not unduly sounding the praises of the class we represent, for we find that others entertain an equally high estimate of the character of the profession. On this subject a city contemporary editorially remarks: 'As a rule the educated druggist is one of the most careful of traders. A high sense of responsibility governs his proceedings, whether dispensing or retailing his goods. Not a few of them can point to occasions on which even the physician's prescription has been corrected, and a catastrophe arising from a slip of the M. D.'s pen, averted by the watchfulness and intelligence of the dispenser.' Let the druggist be allowed to use his own discretion in regard to the sale of poisons, and in thus assuming the guardianship of the public safety, we are sure that the welfare of the community will not suffer.

"In speaking to druggists it is needless for us to remark that the passing of the proposed Pharmacy Act, as amended at the last sitting of the Legislature, would prove an effectual remedy for the evils and inconveniences with which both druggist and people are now harassed. It would ensure adequate qualification on the part of those engaged in selling poisons, and at the same time guarantee all that the law can ask in regard to their sale. We hope that druggists, as well as lovers of good order, will do all in their power to promote the passing of this measure, by representing to members of the House, with whom they may have influence, the true state of affairs and the great necessity for putting this vexed question of poisons on a just and solid basis."

The Pharmaceutical Journal.

SATURDAY, JANUARY 7, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes endorsed "Pharm. Journ."*

THE OPENING YEAR.

THOUGH the present number is neither the commencement nor the conclusion of a volume, the fact of its being the first to appear this year will, we hope, be received as a sufficient excuse for a brief allusion to some of those points of pharmaceutical interest which may be expected to constitute for us characteristic features of the year now opening.

First, in regard to the general organization of pharmacy, as a business in which the interests of the public demand above all things certified competence in those who practise it, we may expect that measures will be taken to secure for Ireland the same advantages as we now enjoy in other parts of the United Kingdom.

In the matter of education, which is now engaging the earnest attention of all classes of the community, we may expect that pharmacists will be no exception; but that the means by which rising members of the trade may acquire that thorough knowledge of chemistry, botany and the materia medica, which is as essential to an accomplished pharmacist as the practical training gained during apprenticeship, may be developed and made still more generally accessible than they are at present.

Within the year now opening we may also expect the Pharmaceutical Society to take an important step in reference to the storing of poisons, by deciding whether or not it will prescribe regulations for that purpose. In this respect the forthcoming Annual Meeting of the Society will probably be one of unusual interest.

The alteration of the laws relating to patent medicine stamps and licences, will probably be dealt with during this year.

Among the prominent events of the year, the second meeting of the Conference, north of the Tweed, must not be forgotten, and while the fact that it is to be in Edinburgh will be an earnest of its brilliancy to all who know Scotland, it will be especially so to all who remember the success of the meeting at Dundee.

Last, but not least, we may be permitted to hope that within the present year any question which may remain as to the desirability of altering this Journal from a monthly to a weekly issue may be disposed of. We will also take this opportunity of addressing ourselves to all who are interested in the success of this Journal, as the property of the Society and the organ of its Council, to solicit from them such individual assistance as they can afford, with the object of rendering it a worthy representative of British pharmacy. There are probably few, if any journals connected with pharmacy which enjoy such advantages as this one, but we are inclined to believe that its general character no less than its utility might still be largely enhanced by the freer cooperation of those practically engaged in the business of pharmacy throughout the country.

We desire to return hearty thanks to those who have spontaneously come forward and given their help by contributing information, news and comments on matters of interest to the trade. We hope such contributions will still continue, and that they will become more general under the conviction that they may tend to the good of the entire body.

Nor must we forget to thank some grumblers who have favoured us with complaints which we have found both useful and beneficial in their influence, for we fully recognize the obligation of making this Journal generally acceptable and interesting, while at the same time endeavouring to perform the duty of elevating and leading opinion in all matters with which it is concerned.

In conclusion, therefore, we ask not only for the assistance of all who approve our endeavours, but also for the complaints of those who disapprove or are unsatisfied, and if these requests be responded to as we desire they may be, we do not doubt that the new year will be as prosperous for the Journal as we hope it will be for all its readers.

DISPENSING CHARGES AND ALLIANCES.

WE think the Pharmaceutical Society would lose influence if it responded to the suggestion of correspondents by promulgating a scale of dispensing charges. We by no means underrate the importance of the question of proper remuneration, but unless we were prepared to advocate uniformity of price (which appears to us eminently calculated to repress the best kind of emulation), we must leave the actual determination of prices to the judgment and good sense of the parties concerned.

Fixed rates are not, according to our experience, adopted by other trades, and the difficulty of assessing them is increased by the semi-professional nature of dispensing operations, in which personal qualification and reputation become positive elements of market value. In the professions there is still greater elasticity, and we see that one barrister will demand a hundred guineas for services which another would willingly render for ten, without concluding that the first is extortionate or the other unprofessional. If we offer any advice at all upon this tender topic, it will be to recommend our readers to follow the barrister's example, to be a little more independent of the conduct of others, and to have more confidence in right principles of business, which it should be their object to discover and to practise.

But while we hold ourselves apart from the contentions of Mr. A. with his neighbour Mr. B., we are thoroughly cognizant of the points involved, viz. the honour and credit as well as the pecuniary interests of Pharmacy; and in promotion of these objects we propose to divert our readers' attention from a personal to a general discussion upon which an expression of opinion may exercise some beneficial effect:—we have in view the alliances more or less overt between members of the medical profession and pharmaceutists.

It would be impossible to specify the many forms under which these alliances exist. Some have recently been brought to view in the correspondence columns of this Journal, and have elicited the disapproval of the medical profession as well as of our own body. Whatever the precise character of the compact may be, the essential feature is that the doctor hands his patients over to a particular chemist, and in some shape or other receives a premium for so doing. We will speak only of the more avowed and, to our thinking, the least objectionable arrangement, where the doctor is the ostensible purveyor of the medicines, the chemist acting as his dispenser or agent. In these cases the doctor receives the full remuneration for work *which he does not do*, while the pharmaceutist is preposterously underpaid for the work which he does,—only receiving, in fact, about half the remuneration to which he is fairly entitled for his services.

What then is the operation of arrangements such as these, and how do they affect the interests of pharmacy collectively and of individual pharmaceutists? These questions deserve the thoughtful consideration of our readers. Obviously the effect is to lessen the remuneration fairly earned by pharmaceutical labour, in order that the lion's share may be appropriated by members of the medical profession to whom it does not legitimately belong, thus realizing that interested dream of the *Lancet*, which recently aroused so much pharmaceutical indignation. Why is it then that pharmaceutists will give themselves up in detail to that which they repudiate in gross? We fear that it is because they have not sufficient *esprit de corps* to refrain from snatching a selfish advantage at the general expense. But does it even yield a selfish advantage? We think not. Speaking with competent knowledge of the large percentage to which the working charges upon dispensing trade amount, we state our deliberate conviction that the customary prices of this sort of dispensing do not pay; and we know that this conclusion has been arrived at by many who have made the experiment. But if it does not pay in itself, it may be said that it brings other business which does pay, and is thus indirectly advantageous. Assuming it to be so, we are directed to the unfair operation of the system upon neighbouring chemists, who are compelled to see their own legitimate connection poached upon by an occult competition against which there is no defence, and we can imagine the jealousies which may and do arise from this cause; for such is the daily experience of those who are brought within the baleful influence of these combinations. A Nemesis does, however, attend them; for the faculty as a body have a reasonable mistrust of chemists who are too closely identified with this or that individual practitioner. Of course medical men recommend those pharmacies in which they have most confidence, and it is quite right that they should do so. We are no friends to artificial restrictions, and we claim a reciprocal freedom for our members who are often consulted as to the skill and reputation of professional men. Provided that no self-interest underlies these recommendations, the public is benefited, and no one has any just ground of complaint. Nor would we interfere with medical men who dispense their own medicines, which is often a matter of necessity to meet the circumstances of a scattered population. We do not expect that the practice of dispensing will be altogether given up by the medical profession; but in the interest of pharmacy we desire to see it reduced to its minimum, and we think that considerable diminution might take place without inconvenience to the profession or to the public. Unfortunately pharmaceutists have lent themselves to the perpetuation of the custom by these very alliances of which we have spoken, and by means of which they preserve the whole profit of the business to the doctor, who, being anxious to relieve himself from this irksome duty, would otherwise probably abandon it altogether.

We are aware that in the foregoing remarks we have only reproduced facts already familiarly known to our readers. It has not been our object to advance anything new, but to invite serious reflection upon an old abuse, and we trust that a laudable *esprit de corps* will bring such influence to bear upon this really important subject as will serve (not suddenly but surely) to put an end to a custom which is injurious to pharmacy, unjust to pharmaceutists and a fruitful source of misunderstanding and jealousy.

The programme of the London Chemists' Association for the next three months includes papers on the following subjects:—"The Preservation of Vegetable Substances," by Mr. E. Beynon; "Belladonna and its preparations," by Mr. R. Pick; "Filtration," by Mr. De Putron; "Structural Botany," by Mr. J. H. Jessop; and "Phosphoric Acid," by Mr. G. Brownen. The Annual Dinner will take place on Thursday next.

Proceedings of the Pharmaceutical Society.

PHARMACEUTICAL MEETING.

Wednesday, January 4th, 1871.

MR. HASELDEN, VICE-PRESIDENT, IN THE CHAIR.

The SECRETARY read the following list of Donations to the Library and Museum:—

Liebig's Familiar Letters on Chemistry, fourth edition: from Mr. Daniel Hanbury,—On Santonin and its Detection in the Urine: from Walter G. Smith, M.B.,—An Address on certain aspects of Medical Reform: from Mr. John Jaap,—Journal of the London Institution, first number: from the Institution,—Large specimen of Arsenious Acid, manufactured by Messrs. Drayton and Co., of Cornwall; also, Two Leaden Bullets found in a sample of Turkey opium: presented by Mr. Slater, of Romsey,—Specimen of the bark of *Cinchona Pahudiana* grown in the Darjeeling Plantations, India, and offered for sale in London: presented by Mr. J. E. Howard,—Specimens of a large parcel of bark obtained from *Cinchona succirubra* and *officinalis* grown in Ceylon and offered for sale in London: presented by Messrs. Jenkins and Phillips, Lime Street, City,—Specimens of *Pakoe kidang*, being the hairy stipes of *Alsophila lurida* of Hasskarl from Java: presented by Mr. Hanbury.

Professor ATTFIELD drew attention to a large photograph of the members of the American Pharmaceutical Association, which met last year at Chicago, a copy of which had also been presented to the British Pharmaceutical Conference. It was sent by Mr. Ebert, with the greeting of the Chicago College of Pharmacy.

Mr. HOWDEN remarked, with reference to the photograph sent by Mr. Ebert, that one of the leading pharmacists in Chicago, Mr. Buck, was an Englishman, a native of Rochester, and a member by examination of the Society.

Mr. HANBURY, referring to the specimens of *Pakoe kidang*, said they were the stipes of a large species of fern, covered with peculiar golden-brown hairs that formed a very pretty object under the microscope. This hairy substance was extensively used in Java and the adjacent parts as a mechanical styptic, but he was not aware that the plant possessed any active medicinal properties.

PHARMACY IN AMERICA.—*Adjourned Discussion.*

Mr. HOWDEN said there were one or two points of detail, with reference to pharmacy in America, to which he might allude as an introduction to the evening's discussion. First, he would mention a very ingenious and pretty device, in common use in the States, for washing soda-water tumblers, which, owing to the shortness of the hot season in England, might not be worth while to introduce here, but would doubtless find its way into Continental cities and warm latitudes. On almost every soda-water counter in America was to be seen a silver or plated salver, surrounded by perhaps a dozen inverted tumblers, upon the inside of each of which played a jet of water, so arranged as to strike the inside of the glass obliquely, and so communicate to it a rotary motion, it being balanced on the centre. The weight of the tumbler acts on the stopcock through which the jet flows, so that on the removal of the glass there is no escape. Another curious thing to an Englishman, in connection with pharmacy in America, was that no coin of any kind ever passed over the counter, payment for everything being made in bank-notes or greenbacks.

When visiting the College of Pharmacy in Philadelphia, he heard a very interesting lecture from Professor Parish, the subject being "Specific Gravities." The lecturer particularly impressed upon the students the importance of taking proper precautions in ascertaining specific gravities,—the fact being that it is customary for physicians to request pharmacists to perform analyses of the urine of patients suffering from diabetes and similar diseases, proper fees of course being charged. Professor Parish also called his attention to a drug extensively used in America for coughs, etc., which he thought might advantageously be introduced into English medicine, viz. Wild Cherry Bark, or *Prunus Virginiana*. It was used in the form of a syrup, many hundred gallons being consumed, and its advantages were that it combined the properties of a pectoral and tonic medicine. He also called his attention to syrup of ipecacuanha made by treating the powder with spirits of wine, distilling off the superfluous alcohol until the residue became thick, then adding acetic acid and water, boiling, and adding sugar to the liquor when cool. This was recommended as superior to ipecacuanha wine. With reference to the subject of specific gravities, it had occurred to him that, whereas the specific gravities of all the preparations in the Pharmacopœia were given at a temperature of 60°, it would be very difficult to test them in that way in many parts of the world. No doubt 60° was a very convenient standard in England, but now that the art of pharmacy was extending all over the world, it must be remembered that many of their brethren were placed under great disadvantages in that respect, as he had had opportunities of noticing in America. In many cities there the temperature was never below 90° in the summer; while at a place called Minniapolis, to which it was usual to send patients afflicted with phthisis, the thermometer during the winter often stood as low as 45° below zero, the mercury freezing in the bulb. Now there was a growing practice in the States of buying drugs not from wholesale dealers, but from a class of men who might be called brokers, who sold by sample and delivered the goods in small original packages as imported. It was of great importance to the chemists that they should be able properly to test the purity and strength of the remedies thus furnished them; and, therefore, it appeared to him that it would be a great boon not only to Americans, but also to chemists in the colonies and various parts of the world if tables were issued under the authority of the Pharmaceutical Society, giving the specific gravities of the more important articles of the materia medica at temperatures ranging from 32° to 100°. Such tables might be found here and there, but they were incomplete and without authority. In conclusion, he desired to recommend every member of the Society, as far as opportunity allowed, to exercise hospitality towards the large number of strangers of their own profession who were constantly visiting London. He had met with so much kindness when travelling through the States that he could not but contrast the two national characteristics in this respect. Not that an Englishman's heart was not warm, but he often did not take proper means to let the heat radiate. He did not allude to knife-and-fork hospitality, but to a readiness to sacrifice time, and take a little trouble to show a stranger those objects in London which would be most interesting to him, such as Kew Gardens, the Botanic Gardens, and their own Museum and Library. If this were carried out more extensively both by the individual members and by the Society itself, he believed it would have the effect of raising up a number of friends throughout the world to remember the kindness which had been shown them throughout their lives.

Professor ATTFIELD said Mr. Howden was perhaps not aware that in nearly every London hospital a notice was exhibited informing strangers and visitors that they were invited to inspect the arrangements, and that if they would be good enough to make themselves known all possible attention would be offered them. In their own Institution scarcely a week passed, and sometimes not a day in a week, in which some stranger was not shown everything he desired to see by one of the officers. Perhaps as much had not been done as might be in pointing out the objects of interest in the metropolis, but it must be remembered that London was a large city. It might, however, be desirable that such a notice as he had described, should be exhibited in the hall, so that any stranger would at once see on entering that he would be welcomed and that every attention would be afforded.

Mr. Carteighe desired to know if the figures given in Mr. Howden's address—as printed, with regard to the salaries paid to assistants—were strictly accurate, because, although £100 to £250 as a maximum seemed high compared to what was paid in England, yet when the different circumstances and arrangements were taken into account, and the enormous expense of rent, food, etc., he did not think assistants in America had much to boast of. Again, with reference to the practice of prescribing, he had been much pleased at learning that every prescription went to the druggist, who received them by tens and hundreds daily, but since then he had seen in the *Medical Times* an abstract from a paper read before the King's County Medical Society in New York, in which the author complained much in the same strain as medical men did in England, of the large amount of prescribing done by druggists, at the same time acknowledging that a certain section of the medical profession were in the habit of compounding their own drugs. He wished, therefore, to ask Mr. Howden whether it was not possible that in his travels he had come in contact only with the *élite* of the pharmacists and of the medical profession, and so obtained an impression which did not quite adequately represent the facts with regard to the majority of the trade.

Mr. Howden said he had taken great pains to establish the accuracy of his facts, from the time he entered the States until he left. In every place he visited he inquired, not of one but of several pharmacists the amounts they paid their chief clerks, and the figures were those quoted by Mr. Carteighe. As a rule, the outside limit was £200 a year; but in Chicago, and one or two large and wealthy cities, this sum might be exceeded. With reference to the other question, he had been assured most emphatically over and over again, without a dissentient voice, that pharmacists had nothing to do with dispensing; that they steadily discountenanced it. At the same time it was admitted that there was sometimes a difficulty in preventing the younger men from prescribing for persons with trifling maladies; but, as a rule, prescribing was avoided both by principals and assistants. If done at all, it was practised by the less prosperous members of the trade, who carried on business in obscure districts, but they were not countenanced in so doing by the more respectable members of the profession. On the other hand, some of the less successful members of the medical profession encroached somewhat upon pharmacists' prerogatives, some of them being partners in drug stores, if they did not keep them themselves. Still this was done on a very small scale relatively, and generally in outlying districts, where civilization had not yet been thoroughly established.

Mr. Hanbury asked if he had correctly understood that druggists were in the habit of keeping original prescriptions, furnishing the patient with a copy if he required it? He did not think such a practice could be followed in this country.

Mr. Howden said it had been the practice in America from the earliest times for the chemist to retain the prescription, but not to furnish a copy; thus the first person who dispensed a prescription retained a sort of proprietorship in it. This was one of the points on which the Americans prided themselves on being ahead of the old country.

Professor Bentley said the thanks of the Society were due to Mr. Howden for the practical details and interesting information he had given with regard to pharmacy in America. Nothing could be more interesting or useful than for gentlemen who had travelled to come forward and give the result of their experience, and he believed that high as Pharmacy stood in this country, there was much to be learned from other nations. He cordially concurred in the remarks which had been made with regard to showing hospitality to strangers, but every one who knew that Society would be perfectly aware that immediately on entering the doors and asking for the Secretary or any of the officers, they would at once meet with every courtesy and attention. In times past the same facilities had not been afforded. Now, however, the doors were thrown open, and they expected that every pharmacist, from whatever country he came, would walk in and make himself as much at home as might be. Perhaps, however, it would be well if a notice were inserted in the Journal, that visitors from abroad would have the *entrée*, and that every facility would be given to persons desirous of information. There was, no doubt, much to be learned from America in the way of new remedies; for instance, podophyllum had been in constant use in America long before it was introduced to this country, but it was now becoming appreciated, and had been included in the Pharmacopœia. The same with regard to the remedy mentioned by Mr. Howden, *Prunus Virginiana*, which was much approved of by those who had tried it, particularly the Scotch physicians. He would therefore repeat a remark which he had often made before, that it was very desirable in issuing new editions of the Pharmacopœia, to follow the plan adopted in America, and issue a "secondary list" of new remedies which had not yet been experimented on and thoroughly approved. By this means new remedies had an opportunity of being tested; if they were worthless, they would soon be thrown on one side; if they were valuable, they would take their places in the regular list in future. He wished to know if he had correctly understood Mr. Howden that it was the practice of physicians, when they wished to test the urine or any other secretion of their patients, to hand it over to the pharmacist instead of doing it themselves.

Mr. Howden said he inferred from the minute instructions given to the students that this was the practice. It must be remembered that in America every one was called a physician who practised medicine, many not having any diploma at all.

Professor Bentley said he did not think any competent physician would do as was suggested.

Professor Attfield said that during the past four or five years he had had a very large number of applications from different pharmacists throughout the kingdom for short directions which would enable them to take the specific gravity of and otherwise chemically test urine for medical men, so that it was evident there was demand in this country for such knowledge on the part of chemists. This had induced him to write a short article, which was published in the 'Chemist's Almanac' for 1870, and in his own 'Manual of Chemistry,' and to his knowledge it had been extensively made use of. It was well known that medical men had not always the opportunities of testing specimens of urine, and that it could be more quickly done by instructing the patient to take it to a neighbouring chemist than by themselves taking home the specimen and testing it in their own surgeries. With regard to the temperatures at which specific gravity was taken, there could be no doubt that a table, such as Mr. Howden had referred to, showing the specific gravity of official articles at three or four different temperatures, would be very useful. Such data were given with regard to certain matters in several works on chemistry, and if this were carried out for most of the official articles it would be one of the most useful tables that could be compiled. This work could be well undertaken by any young pharmacist who was anxious to distinguish himself, and it might well form the subject of a paper at any future meeting. Similar work had been done by an associate of that Society a short time ago. He referred to the table compiled by Mr., now Dr. Watts, who was then an associate, which showed the strength of solutions of phosphoric acid of different specific gravities, and that table had since been introduced into nearly all the text-books of chemistry recently published.

Mr. Howden said it must be remembered taking specific gravity was not entirely an intellectual feat; it could not be done by means of any formula of proportion. A table to be useful throughout the world could only be arrived at by actual experiment, and frequent experiment on each substance, because the capacity of the bottle altered with the temperature, and no formula could meet that.

Professor Attfield said a much greater difficulty was this, that whereas the expansion of all gases for equal increments or decrements of temperature was the same, the expansion of liquids varied with almost every substance, and hence the experiment would have to be performed with every separate liquid included in the table.

The Chairman said he quite concurred with what had been said as to the usefulness of such a table. With regard to hospitality and attention shown to foreign visitors, he did not think Mr. Howden intended to convey that there was any lack on the part, either of their Society or the public institutions in this country, but rather that sufficient public notice was not given of their desires in that respect. Last year Professor Soubeiran visited the institution, attended the examinations for an hour or two, and afterwards visited the Conversazione at South Kensington Museum; and it was constantly the case during the session, that they had visitors attending the examinations and the other work of the institution. He thought, however, it might be possible to make it more publicly known that visitors would be welcomed.

Note on Australian Opium.

The Chairman then called upon Mr. J. S. Ward to read a paper giving the results of an examination of a specimen of Australian-grown opium. The paper will be found printed *in extenso* at p. 543.

Mr. Hanbury said he did not quite catch whether the juice which exuded after the scarification of the capsules was allowed to harden on them before it was collected. It would also be interesting to know whether the capsules were scarified longitudinally, or transversely as was done in Turkey.

Mr. Ward said he had no information beyond that contained in the letter which he had read; but as it stated that a person followed immediately after the one nicking to collect the drops, he should say it was collected when in a soft state.

Professor Bentley said on first exuding, the liquid would be absolute juice, and would be, he should imagine, very difficult to collect.

The Chairman said the opium question was very interesting just at present, on account of the high price of the article. No doubt there was a large demand for its use on the Continent, and anything which would lead to a diminution of price would be of great advantage to every one.

Mr. Howden said one reason for the increase of price was to be found in the enormous consumption in the United States, there being one firm in Philadelphia alone which could sweep the whole of the London market. With reference to the cultivation of opium in Australia, it was very much to be desired that experiments on the growth of plants in various climates and countries should be encouraged, but the results should be regarded with considerable suspicion until the medicinal virtues of the product could be accurately ascertained. The climatic difference in the growth of plants was something enormous, and in some cases it entirely altered the nature of the production. For instance, henbane and belladonna produced very valuable remedies when grown in this country, but in the United States the same plants had no medicinal value whatever. The cereals were, of all plants in the vegetable kingdom, those which bore transplanting with the least injury, growing with wonderful success in all parts of the world; indeed, it is well known that corn from Dantzic, the coast of Chili and Australia was absolutely better than that grown by the best English farmers. But this, however, was not the case with many other plants, and in the matter of drugs careful experiment was necessary to verify the results.

The Chairman asked if the consumption of opium had increased rapidly in the United States, because the price had gone up all at once, and, in fact, had been higher at one time than it was now?

Mr. Howden said large portions of the interior of the American continent were perfectly level, so that you could ride for hundreds of miles over land as flat as the table. The nature of the soil was most prolific, producing most wonderfully fine root-crops; but, as might be expected, the drainage was indifferent, and he had been painfully conscious of the presence of sulphuretted hydrogen gas, not in particular localities, but over areas many miles in extent. This naturally produced ague and low forms of fever, and from some occult reason it was quite certain that wherever this tendency existed the consumption of opium kept pace with it. This was seen in our own eastern counties, where laudanum and opium were used to a much greater extent than in the hilly districts. No doubt when these districts become more thoroughly civilized, and better systems of drainage were adopted, the consumption of opium might decrease.

Professor Bentley said there was really not much information in the paper on the most important point, viz. whether opium could be profitably cultivated in Australia? Even in England it could be produced sometimes of very fair quality, and he believed there were specimens in the Museum which had been found to contain 10 per cent. or more of morphia. The point was not whether a particular specimen could be produced, but whether on the average of summers there was such an amount of light and heat as would enable the cultivator to grow it to commercial advantage. The question raised by Mr. Howden was one of great interest and importance, viz. the influence of climate, culture and soil on the growth of medicinal plants; and he did not know anything more likely to yield useful results than a series of experiments on this subject; but they must be carried out with the greatest care and exactitude. He believed that much of the uncertainty of the action of medicines, in consequence of which blame had sometimes been thrown on chemists in times past, was due to the difference in the plants supplied to them. It was well known that a plant grown in one district would differ very materially in its properties from those grown in another.

Mr. Butt asked if the opium were analysed in a dry state, or when of the usual consistence of Smyrna opium, as this would make a considerable difference in the percentage of morphia.

Mr. Ward said he analysed it towards the end of August, when it was quite soft.

Mr. Hardcastle asked if it had ever been decided which variety of the poppy was best for opium-producing purposes, regard being had to quantity or quality or both.

Professor Bentley said there were only two main varieties used, the white and the black, and opinions varied as to which was the best. The white was more largely cultivated in some districts, but, as far as he knew, careful investigators were unable to find any appreciable difference between the two.

Mr. Umney said if the cultivation of the poppy could be carried on in Australia on a large scale, a quarter of an acre yielding 14 lb. of opium, it would be a fine speculation, as the land would realize from £70 to £80 per acre.

Professor Bentley said there was the seed in addition, which in India paid all the expense of cultivation.

Mr. Carteighe said he was sure Mr. Ward would not go away under the impression that the criticisms passed upon his paper had any personal bearing, since they were founded on the lack of information furnished by his correspondent. At the same time, it could not be denied that the paper lost much of its value from this cause, and Mr. Ward would be doing good service if he would obtain from Mr. Francis further details, which no doubt that gentleman would be happy to furnish.

The Chairman announced that on February 1st and March 1st Dr. Carpenter would give two lectures on the microscope.

Vinum Ferri.

Professor Attfield said he proposed at the next available meeting to read a paper on "Certain Precautions to be Observed in Making Wine of Iron." He should be glad to hear, in the meantime, from any one who had met with new difficulties in preparing this article. It was well known that during the last year or two malt liquors had had a very small quantity of solution of bisulphite of lime added to them, which had proved serviceable in preventing alteration, and it would seem that the process had been extended to wine, especially the cheaper kinds of sherry. The consequence was, that when this was used for making wine of iron, a reduction of the sulphite took place, sulphuretted hydrogen was generated and the sample was spoiled.

Mr. Butt said he had found it impossible to avoid the disagreeable sulphuretted hydrogen smell, although he had tried iron wire, iron filings, iron borings, and different samples of sherry.

Mr. Howden inquired if the sherry had been taken from the wood or from bottle, because it was known that bisulphite of lime was used to a great extent in bottling both wine and beer.

Mr. Butt said he had used it from the bottle and from the wood, and both low and high priced sherries, and always with the same result. It appeared, therefore, that the bisulphite was used both in this country and abroad. They used what was called "the sulphur match" in this country, to bring round inferior wines, to a great extent.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Fifth General Meeting of this Association was held at the Royal Institution on Thursday evening, December 22nd; the President, Mr. John Abraham, in the chair. There was a numerous attendance. The minutes of the previous meeting were read and confirmed. Mr. Joseph Roberts was elected a member. Mr. W. T. Case was elected an associate.

Donations of the *Chicago Pharmaceutist*, *New York Druggists' Circular*, *Pharmaceutical Journal*, were announced.

The Honorary Secretary, Mr. Alfred H. Mason, read a paper upon "Chloral Hydrate, Alcoholate, Tests, Therapeutical Value, Pharmaceutical Preparations." (See p. 541.)

The President said the members were much indebted to the author for the paper they had just heard. He did not know that there was so much difference in the samples of hydrate of chloral which were offered for sale; he confessed he felt it was still a medicine of which little was known. He had always purchased his supplies from the first houses, without reference to price, and thought he was getting the right thing.

Dr. Nevins, Lecturer on Materia Medica, etc. at the Royal Infirmary School of Medicine, Honorary Member of the Association, said, that lately he had found that in administering hydrate of chloral, in any form, it produces unpleasant results upon the patients, nausea, headache, sickness, and sometimes vomiting. When the hydrate was first introduced none of these symptoms were present; but he thought the paper they had just heard would somewhat explain this. He drew attention to the fact that the administration of hydrate of chloral in many cases caused great languor and depression. He found it necessary to guard against too long continued doses, as sometimes, quite unexpectedly, unfavourable symptoms presented themselves. Of course the effects of hydrate of chloral differed like those of any other medicine, with different constitutions. He also called attention to the large quantity of caustic alkali used to set free the chloroform, and said he thought it impossible that as much alkali would be found in the blood of a patient.

Mr. Edward Davies, F.C.S., said the subject was one of great importance, and he was very much struck with the serious differences between the salts examined, which had been laid before them. Theoretically the products of decomposition of the alcoholate would be very different from the hydrate of chloral. He urged that in order to obtain a good result one article alone should be used in dispensing. He thought they were much indebted to Mr. Mason for bringing forward proof that there was a great deal of alcoholate of chloral in the market. The two preparations should not be indiscriminately used for the same class of cases. If any one wanted to ascertain whether alcoholate of chloral was a good remedy in other cases, well and good, but he thought it very probable that medical practitioners were now using alcoholate where formerly they used hydrate of chloral, and because they found ill effects where formerly they found benefit, they were apt to decry the hydrate of chloral.

The President spoke of the manufacture of chloral, and much doubted whether any was made in this country. He believed it was all imported from abroad, principally from Germany.

Mr. A. H. Mason said some crude hydrate of chloral had been recrystallized here, as he had been furnished with a small sample, but not sufficient to carry through the course of his experiments. Messrs. Dunn, Squire, and Co. advertised in the medical papers that they were manufacturers, and they had kindly supplied him with samples of the crude and cake hydrate of chloral, of which he had already spoken.

A short discussion followed, in which several members took part.

The President moved a vote of thanks to Mr. Mason for his interesting and instructive paper, which was seconded, in very complimentary terms, by Dr. Nevins, and carried unanimously.

Mr. Mason acknowledged the vote, and the meeting adjourned.

Proceedings of Scientific Societies.

ONTARIO COLLEGE OF PHARMACY.

At the regular November Meeting of this Society, an informal conversation took place upon the criminal prosecution of nearly all the Toronto druggists for selling laudanum contrary to the "Poisons Act." Eventually it was resolved to adjourn the meeting until after the magistrate's decision.

At the adjourned meeting the President said that, although the magistrate's decision had been twice postponed, it had been thought best to call the members together, as the Ontario Legislature had assembled, and it would be advisable to take action with regard to the proposed Pharmacy Bill.

After discussion, it was decided that as most of the members of the Society were non-resident in Toronto, the Society could do nothing with respect to the prosecution, but must leave it for the druggists of Toronto to deal with as they might think best.

Mr. R. W. Elliott said the Pharmacy Bill was crowded out last session, partly through a press of railway business and partly through the supineness of the gentleman who had charge of it. It was for the meeting to say whether it would be advisable to place it in other hands.

A committee was appointed to confer with the Attorney-General, and take such action as they might deem best for obtaining the desired legislation.

PHOTOGRAPHIC SOCIETY OF LONDON.

December 13, 1870.

On Xylonite, a Material applicable to Photographic Purposes.

BY DANIEL SPILL.

The name "Xylonite" is taken from the Greek word *xulon*, "wood," and the material upon which this name has been bestowed is derived from wood or woody fibres. These are converted, by the action of mixed nitric and sulphuric acids, into a rough form of xyloidine, which, being subsequently dissolved into a species of collodion, constitutes the base of a further manufacture.

The material was first introduced to the notice of the public, at the International Exhibition of 1862, by Mr. Alexander Parkes, of Birmingham, at which time it had not yet become an article of commerce; subsequently it was manufactured on a commercial scale, and introduced to the world for a short time under the name of "Parkesine" (named after the inventor). The manufacture having been much improved, and the patented solvents and machinery almost entirely remodelled, it was considered advisable that the name should also be changed, and "Xylonite," as being more appropriate for a derivative of xyloidine, was adopted.

The soluble base of this manufacture may be made from any wood or woody fibre, or fibre-producing grasses, old rags, waste from cotton or flax mills, old rope, starch, Esparto grass, "half-stuff" of the paper-makers, etc., but preferably using waste fibrous material from cotton and flax mills. Either of these substances which may be chosen should be first freed from all extraneous matter by boiling with alkali or soap and water, well washed, and dried, so as to leave nothing but a nearly pure fibre for the subsequent treatment. A bath composed of one part, by weight, of concentrated nitric acid, four parts of concentrated sulphuric acid, and one of water, having been prepared and cooled to about 70° or 80° F., a weighed quantity of the purified vegetable fibres is then immersed therein for a period of from one to fifteen minutes or longer, according to the degree of solubility required. The next step is to remove the uncombined acids as quickly as possible, either by draining or pressure (the latter preferred), and then wash quickly in a copious supply of water until the last washings are neutral to test-paper. If the fibre should at this stage retain any colouring-matter (which is not unfrequently the case), it may be submitted to the action of any of the ordinary bleaching agents without injury to the chemical condition of the xyloidine, which, after it has been carefully dried at a low temperature or by pressure (the latter being preferred), will be ready for dissolving. The solvents commonly employed in the preparation of photographic collodion are too expensive to permit of their use in the xylonite manufacture. The volatile solvents mostly used are wood-spirit, alcohol, aldehyde, mineral naphtha, benzole, and other hydrocarbons; and the non-volatile or fixed solvents are oil and camphor, or natural camphor-oil, linseed, castor, and other vegetable oils. The introduction of these fixed solvents is an important improvement and economy in the manufacture of xylonite, obviating much loss by evaporation and inconvenience arising from contraction of the material. To prepare these solvents, take, say, 100 parts of castor-oil and heat to about 250° or 300° F., then dissolve therein about 50 parts of camphor; while in the heated condition add the xyloidine, which readily dissolves into a stiff paste, and is then ready for a subsequent process. The condition of xylonite may be varied from the flexibility of morocco leather to the hardness of ivory or stone by the judicious combination of xyloidine, oil, and pigments.

Practically it is not necessary to dry the xyloidine thoroughly before dissolving it; pressure alone will remove 90 per cent. of its moisture; in this state it is quite uninflammable, even when held in contact with fire, and yet will readily dissolve in the before-mentioned solvents. Five parts of solvent will reduce one part of xyloidine into a stiff paste by stirring alone; but to blend the materials more perfectly the mixture is masticated or ground between rollers until the incorporation is completed; it is next removed into a strong vessel having a perforated bottom covered with a finely-woven wire sieve, which vessel is then placed beneath the piston of a powerful press, and the paste is thereby forced through the sieve, in order to strain it from all mechanical impurities or undissolved particles of xyloidine. This purified xyloidine is next removed, weighed, and the requisite quantity of oil or pigments added thereto, and then passed to a heated masticator or grinding-rolls, or into a retort provided with mechanical stirrers, which, for volatile solvents, are enclosed in an air-tight casing, the latter being in connection with a condenser and vacuum apparatus during the process of mastication or agitation. The volatile solvents are evaporated by the heat and vacuum, and conveyed away to a condenser for future use. When non-volatile solvents are used, the last-named apparatus is not required, heat and mastication being sufficient. When the paste is masticated into a very stiff condition, it is removed into a powerful calendering-machine, where it is rolled into sheets of any required thickness, after which it is placed in a seasoning-room heated to 100–120° F. for periods varying from fifteen to thirty days, when it is ready for use.

When preparing hard compounds with the non-volatile solvents it is necessary to use oxidized oil, such as linseed-oil, which will dry and become hard in the process of seasoning. The flexible kinds are prepared with cotton-seed-oil or castor-oil, which will *not* become hard. For coating or waterproofing fabrics, the paste may be applied in a semifluid condition with an ordinary india-rubber spreading-knife or machine, or it may be applied in a very stiff paste by the aid of calender-rolls.

In preparing non-actinic sheets for photographic purposes, no pigments are used, but semitransparent colours only, such as will arrest the passage of the chemical rays, and furnish a material suitable for windows of the dark-room in place of the ordinary yellow glass, but of sufficient depth of colour to arrest *all* the actinic rays of sunlight. In this state the sheets are flexible, durable and light. Spread upon fabrics it forms a waterproof material, useful for photographic field-tents, giving the operator an abundance of light of perfectly non-actinic quality, thus having a "dark" room combined with a considerable amount of light for personal comfort, and avoiding the use of yellow glass windows altogether. The applications for the material outside the photographic world are almost innumerable; a few of them may be instanced, viz. insulation and protection of telegraph-wire, coating fabrics for waterproof garments, making artificial leather for furniture-covering and book-binding, writing-tablets, substitutes for ivory, bone, horn, tortoiseshell, hard woods, marble, etc., knife-handles, friction and gear-wheels, also bearings for machinery, spinner's bosses, billiard-balls, pianoforte keys, walking-stick and umbrella handles, etc.

It may be turned in a lathe or wrought by the cabinet-maker's or brass-finisher's tools; can be embossed or moulded by heat and pressure, and may be polished like ivory, wood or stone. It is unaffected by atmospheric influences, heat, water, or grease.

The low combustibility of the xyloidine may be demonstrated by firing a portion on a plate, when it will burn slowly, leaving a considerable amount of carbonaceous residue.

MEETINGS FOR THE ENSUING WEEK.

MONDAY ......*Medical Society*, at 9 P.M.
TUESDAY ......*Royal Medical and Chirurgical*, at 8.30 P.M.
Photographic Society, at 8 P.M.
WEDNESDAY *Microscopical Society*, at 8 P.M.

Parliamentary and Law Proceedings.

ADULTERATION OF LARD.

In a late trial at Liverpool in which the plaintiff sought to recover the price of some lard which the defendant had returned as unfit for food, evidence for the defence was given by an analytical chemist that some of the bladders he had analysed contained a mixture of lard, mutton fat, rape oil and water, the latter in the proportion of 19 per cent. The Court ordered the plaintiff to take back the lard without payment.—*Food Journal.*

THE SALE OF LAUDANUM.

At an inquest held at Woodbridge on the body of a young woman, whose death was reported to have been caused by laudanum, evidence was given to the following effect:—

Harriett Thompson, a child aged twelve years, said that the previous morning the deceased had called her and asked her to go to Mr. Betts's, the chemist. She gave her sixpence, a piece of paper and a small bottle. A young man at the chemist's filled the bottle with something brown. There was a paper with printing on it stuck on the bottle. She could not read. She had often been to Mr. Betts's for the same kind of stuff, sometimes every day.

James Hartridge, apprentice to Mr. Betts, said he remembered a little child coming to the shop with a phial labelled "Laudanum." She asked for sixpennyworth, which quantity he put into the phial. It was also labelled "Poison." He took the laudanum out of the bottle from which they usually supplied people of that description. He had been with Mr. Betts only three months, and could not say the strength of the laudanum supplied. He had once or twice previously supplied the same child with laudanum. She had told him it was for Mr. Disbury.

John Betts, pharmaceutical chemist, said that on the previous Saturday the deceased had been supplied by him with fourpennyworth of laudanum. He had, on several occasions supplied her with sixpennyworth at a time, on the plea that she wanted it to ease the pain from which her mother, who was bedridden, was suffering. The laudanum supplied was half the strength of the London Pharmacopœia. It was not necessary to register the sale of laudanum of that strength.

Mr. Marshall, surgeon, said that he had made a *post mortem* examination of the body, and was of opinion that death had resulted from the diseased state of the liver and heart. He did not detect the smell of laudanum or any other poison. Had she taken the quantity stated to have been procured on the day of her death, he believed he should have detected it.

The jury returned a verdict of "Death from natural causes."—*Woodbridge Reporter.*

Obituary.

THOMAS WALLER GISSING.

OB. DECEMBER 28, 1870, ÆTAT. 41.

Our last number informed our readers of the sudden removal by death of a pharmacist known and esteemed by many of them, one whose life and character were distinguished by qualities which claim from his professional brethren a more detailed record. Such men as the late Mr. Gissing are, in a sense, the natural outcome of the calling of pharmacy, which, by introducing physical or natural history science to a congenial mind, often supplies the needed motive for action—action directed by the strong common sense belonging to trade in its best aspect, and when united to a capability of enthusiasm, soon associating kindred spirits with itself. It is from these social aggregations that we reap the fruit of progress, for man resembles the single palm-tree that bears no fruit when standing isolated from its fellows.

Thomas Waller Gissing was born at Halesworth, in Suffolk, on August 2, 1829, and there he received his education. He was apprenticed to a chemist and druggist at Ipswich, and afterwards held situations as an assistant in Leicester, Worcester and Salisbury. During a large portion of this period, Mr. Gissing was engaged in the business of Messrs. Whitfield and Son, of Worcester, and the PHARMACEUTICAL JOURNAL furnishes evidence of his active interest in botany at this time, as he established at Worcester a flourishing branch of the Phytological Club, which had its head-quarters at 17, Bloomsbury Square.

In the year 1856, Mr. Gissing succeeded to the business of Mr. M. B. Flick, at Wakefield, and how he spent the subsequent period is recorded by the *Wakefield Free Press*, as follows:—"We know of no tradesman who in the short space of fourteen years has done as much for the public, or done it so well, or gained such a position in the esteem of the town, or who has so well deserved the respect of all classes in the borough, as Mr. Gissing."

Amidst the claims of a business which demanded close personal attention, he found much time for his favourite pursuit of field-botany, and published two small works upon the local Flora, entitled 'The Ferns of Wakefield and Neighbourhood,' and 'Materials for a Flora of Wakefield.' He was an early riser, and often did a day's work before some men left their beds.

In 1857 he was placed upon the Committee of the Mechanics' Institution, and was at once recognized as one of its most energetic and intelligent members, subsequently taking the post of Honorary Librarian. He was a Member of Council of the Chamber of Commerce, the Secretary of the Wakefield Book Society, and an earnest working member of the Microscopical Society. The Industrial and Fine Art Exhibition, held in Wakefield in 1865, enjoyed a remarkable success, which was due to the well-directed efforts of a small band of voluntary workers accustomed to co-operate, and of these, none was more active than Mr. Gissing. The Lancasterian School, the Clayton Hospital and School of Art were institutions in the management of which he occupied a leading position. Mr. Gissing took a lively interest in politics on the Liberal side, and was a member of the Town Council; his last public act, on December

16, being to vote for the establishment of a School Board in the borough.

Mr. Gissing was Local Secretary of the Pharmaceutical Society, and was ever watchful of the interests of his profession, giving a zealous co-operation in promoting measures aimed at by the Society. His conduct in this position combined loyalty to the Society with independence of thought. It is not generally known that when the Pharmacy Act of 1868 was passing through Parliament, Mr. Gissing discovered that in the Bill first presented, two-thirds of the members of Council were to be drawn from London, only seven members being allotted to the rest of Great Britain. He energetically pointed this out in a quarter where his remonstrances received full sympathy, and an appeal being promptly made to the Local Secretaries throughout the kingdom, their opinions showed such unanimity that the Council removed the obnoxious clause. It can hardly be doubted that had Mr. Gissing's life been spared, he would before long have been elected on the Council of the Pharmaceutical Society. He was nominated at the elections of 1869 and 1870, and was almost successful on each occasion.

For a few years Mr. Gissing had suffered from what he believed to be chronic inflammation of the windpipe, which caused him considerable inconvenience and pain, especially in winter. An attack of cold confined him to the house for a few days, but his illness became suddenly alarming to his family, and he died on Wednesday morning, December 28th. He leaves a widow and five children, between thirteen and four years of age.

The funeral took place at the borough cemetery, when the Corporation, the members of the various committees to which Mr. Gissing belonged, and a large number of his fellow-townsmen testified, by their presence, their esteem for his memory.

The following journals have been received:—The 'British Medical Journal,' Dec. 31; the 'Medical Times and Gazette,' Dec. 31; the 'Lancet,' Dec. 31; the 'Medical Press and Circular,' Jan. 4; 'Nature,' Dec. 29; the 'Chemical News,' Dec. 30; 'Journal of the Society of Arts,' Dec. 29; 'Gardeners' Chronicle,' Dec. 31; the 'Grocer,' Dec. 31; the 'English Mechanic,' Dec. 30; the 'Journal of Applied Science' for January; the 'Canadian Pharmaceutical Journal' for December; the 'Woodbridge Reporter,' Dec. 30; 'Wakefield Free Press,' Dec. 31; 'Transactions of the Odontological Society' for December; the 'Educational Times' for January.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[34.]—AQ. CAMPH.—*C. U.* gives the following formula for a preparation that will serve for making aq. camph. extemporaneously:—

Camphor 1 oz.
S. V. R. (56 per cent.) 26 oz.

Dilute with 15 parts of water to make camphor mixture.

[*** Owing to the presence of spirit in camphor water so prepared, it would not be, strictly speaking, aqua camphoræ, B. P.—Ed. Ph. Journ.]

[56.]—HAIR-WASH.

℞. Glycerini ℥ij
Tinct. Myrrh. ℥j
Eau de Cologne ℥j
Tinct. Cantharid. ʒss
Aq. Destillat. ℥xxiv.
M. H. Q. S.

[93.]—PROOF-SPIRIT should *not* be made as directed by one of your correspondents, by adding to 100 parts of spirit at 56 *over proof* 56 parts of water, notwithstanding such a statement is to be found in standard works on pharmacy. A mixture in such proportions would be 2·9 over proof. When a spirit is said to be 56 *or* 60 *degrees over proof*, it means that to 100 parts of such spirit sufficient water should be added to make the product measure, when the contraction in volume has taken place, 156 or 160 parts at 60° F. The contraction in volume in mixing alcohol and water is not constant, but varies considerably when different proportions are taken. The maximum contraction is *almost* attained in making proof-spirit, in which case it is 2½ per cent. The British Pharmacopœia indicates that to 5 parts of alcohol, ·838 (56 overproof) 3 parts of water should be added (100 : 60). On no account should a further addition of water be made in making proof-spirit according to these directions, as another of your correspondents says is usually done in the proportion of 4 oz. to the gallon, or the spirit will be 2·3 under proof.—Chas. Umney.

PROPOSED REGULATIONS FOR STORING OF POISONS.

Sir,—What ever could have moved the Lords of her Majesty's Privy Council to make the interesting inquiry touching the keeping, dispensing and selling of poisons? Surely they are confounding the serious loss of life which has occurred recently through railway negligence with accidental poisoning. I cannot otherwise understand their anxiety at this holiday time, seeing that no death for a very long period has been reported as arising out of a chemist's neglect or inadvertence. It certainly may help the Council of the Pharmaceutical Society in their high aims of compelling the use of curious cupboards and funny bottles with poison! poison! poison! staring you in the face, till you are so familiar with the word that its influence will be lost.

After the many powerful letters which have appeared in the Journal, showing the absurdity and folly of poison regulations, I feel it is of no use to argue any more upon the subject, but be present at the next General Meeting of the Society, there make your voice heard, resolved to vote only for members of the Council who will pledge themselves to resist the proposed offensive regulations, proclaiming us to society as wholly incompetent for the responsibility which our profession involves!

Kilburn, Jan. 2nd, 1871. JOHN BEATON.

Sir,—By the publication of Dr. Simon's letter from the Medical Department of the Privy Council, the kind of pressure—which to the outside world has apparently put to flight the sagacity of the Pharmaceutical Council—is exhibited to the members themselves. Whether this mighty and portentous missive be a genuinely unsolicited production, to be held *in terrorem* over the heads of refractory members I do not know. We have, however, now the issue placed before us, and if we rouse ourselves I do not fear the result. The position of those opposed to compulsory dispensing poison regulations, with their concomitant corps of inspectors, is, I believe, sufficiently unassailable to withstand, not only most searching criticism, but even parliamentary discussion if this undesirable ordeal be brought about. We have simply at this particular crisis to face the difficulty which the injudicious action of the Council has produced, and defeat any further attempt at Governmental trade restriction. The Pharmaceutical Council seems to think itself bound, either by coercive influence or by an imaginary sense of obligation, to move in this matter; yet if the Pharmacy Act be consulted, it will be found that the introduction of additional regulations is perfectly optional, and in no way obligatory.

The settlement of this question, if no fairer mode be proposed, will be made at the next May meeting by those who are able to attend to give their votes, but how many are there who cannot possibly be present to resist or approve? Anything like a majority of the members, however anxious they may be to vote, will not be present. Hence how flagrantly unjust is this process of arriving at a decision! Is it really needful for us to make a humble and dutiful pilgrimage to Bloomsbury Square, at a sacrifice of time and money, to record our votes? The well-to-do magnates of the trade may be able to afford the time and money, but there are many whose voice in this matter is worthy of being heard who, simply from economic reasons, will not be able to attend. The voting in London in May, if it takes place, will not give a just reflex of the opinions of the members. The greater the distance from London, the fewer the votes that will be recorded. What objection is there to the issuing of voting-papers to every member of the Pharmaceutical Society, so that every member may be enabled to exercise his rightful influence in the settlement of the vexed question? By this means, and by this alone, is it possible to obtain the opinion of the members. If the Council honestly desire, as in duty bound they should, to elicit the opinions of the whole of the members, and if they do not wrongfully wish to carry with a high hand their unwise resolve as to the *compulsory* poison regulations, spite of protest and threatening discord, they will at their next meeting at once decide to use voting-papers instead of the arbitrary decision of an annual meeting.

Manchester, Jan. 3rd, 1871. ROBT. HAMPSON.

Sir,—The keeping and storing of poisons is now a matter of much importance, indeed it is perhaps one of the subjects that interests and concerns the whole trade more than any other. Therefore I trust a few further remarks on this controversy may not be unacceptable. In the first place I will say, it is with sincere regret that I find there are such dissensions on this matter; and although much has been written and said, we are still in a state of unsettlement from so many entertaining such different and tenacious opinions.

The Journal of Dec. 21st contains some very elaborate letters concerning the matter, the writers of which are well known for their many contributions to the Journal; but, strange to observe, each one holds widely different opinions.

Mr. Edwin B. Vizer's letter occupies a good space, but I must frankly remark that it seems more eloquent than logical; and in my opinion, his views, instead of leading to anything of service, are most inconsistent, or, if I might use a political phrase, they are perhaps ultra-radical.

I do not wish to review his letter as a critic would do, but what I wish to point out is the error he labours under in desiring to take up so much of the Journal in putting forth ideas that are not at all compatible with the subject.

He says, "Allow me to put a parallel case, and to ask what would be the feeling of a gentleman after receiving a good education, walking the hospital, going through the usual examination, and who in due course received his diploma authorizing him to practise, were the same authorizing body to come to him and say, 'Now, Sir, you have passed our examinations, you are fully qualified to practise, but before you do so, we must remind you that you must conform to our regulations as to the place and manner of keeping your knives and lancets, lest you should by mistake use the wrong one. You must also have each of these instruments distinctly engraved "dangerous," lest you should by chance forget the fact.'" I glean from this that Mr. Vizer does not deem it expedient that any act or rule is necessary to guide or control those who pass an examination, and, if he had the ruling, he would annihilate it *in toto.* But he must either forget, or he has not been aware, that all who keep open shops for the dispensing and compounding of medicines, are unfortunately not individuals of his ability and qualifications.

Many indeed, although registered as dispensing chemists, have never passed examinations, and I presume this is one of the special reasons which actuate the Council in urging the necessity of a law, to act as a preventive, as far as possible, of the deplorable accidents which have so frequently happened, and which must necessarily raise the indignation of the public against pharmacists in general.

How Mr. Vizer can offer the keeping of a surgeon's knives or lancets as a parallel case with that of storing virulent poisons seems to me ridiculously absurd. I cannot perceive any similarity whatever. If the surgeon should use the wrong knife or lancet, in all probability the harm would be but little; but if the pharmacist should use the wrong powder, such as strychnine for sugar, the mischief is irreparable. The majority of the trade, too, will admit, I think, that there cannot be a doubt as to the actual necessity of an Act for the storing and safe keeping of poisons. I know there is a sort of jealousy entertained by some parties, as this Act does not apply to surgeons, but why should such envy exist? Surgeons are not ruled by the Pharmaceutical Society. They have an Act of their own to practise under, and they consider themselves quite apart from the pharmacist. It also must be borne in mind that the surgery is quite a different kind of place to the pharmaceutical establishment. We may find two or three poisons in the former, while in the latter we have (or should have) all that the "Materia Medica," or Pharmacopœia, contains. Besides, the dispensing in the private surgery is totally different from that of the pharmaceutical establishment.

Therefore, as to having an Act for keeping and storing of poisons, I emphatically say it is necessary. I feel confident, too, that if something is definitely fixed upon, the change will benefit the whole trade. I might add that, as far as I can perceive, the law now in use has raised us considerably in the estimation of the public, for when they are assured that we have such precautions they feel a perfect safety in receiving medicines dispensed by us.

The present arrangement of keeping poisons in a separate apartment or cupboard is, no doubt, to a great extent, a satisfactory precaution; but it must have an improvement, as the dangers are equally bad as, if not worse than, that of mixing them with the usual drugs.

We have had several suggestions on this point. A very useful and practical one came from Mr. Proctor. He recommended "that all poisons intended for internal use as medicines, the usual adult dose of which is less than one drachm, shall bear a label immediately under the name of the article, stating the usual adult dose; and upon such articles the usual adult dose of which is less than, say 5 grains, there shall be added the label 'Poison!' immediately under the label indicating the dose." He also suggests, "that if a poison-cupboard or other additional precaution be deemed necessary, it should only apply to such poisons the adult dose of which does not exceed 5 grains, thus liberating the tincture and wine of opium, etc., from the poison-cupboard, and liberating paregoric elixir and syrup of poppies from any restriction regarding their storage."

In the many suggestions we have had, this seems to be the one that is the most useful, and the one which should be specially laid before the Council for their consideration at the next discussion on this very important subject.

What can be a safer guide to the dispenser, than to have the bottle distinctly labelled with the dose, and the word "poison" placed as prominently as suggested by him?

The doses of medicines are very apt to escape the memory of the most careful; but having it constantly before him is of the utmost importance. He knows then that the quantity he puts in a mixture is safe.

To this very useful suggestion I would wish to add another. In the keeping of the cupboard, one very necessary thing ought to be attended to, that is, the bottles which contain powders of a similar appearance, ought to be of a different character. For instance, strychnine, morphia and emetic tartar, ought to be more conspicuous than those less dangerous. The same rule should also apply to liquids; Scheele's hydrocyanic acid ought to be in a different-coloured bottle from that of the acid of the B. P. strength.

To arrive at some definite result respecting this most important and very necessary Act, we must put aside antagonism and petty prejudices, and ask ourselves whether the rules are so very troublesome that we cannot carry them out. We must do our utmost to assist the Council as much as possible, and let us bear in mind that they are a body of practical and intelligent men, anxious to promote our welfare and raise us to something higher than we have hitherto been. I had commenced this letter early last week, with the intention of submitting it to you for insertion in last week's Journal, but Christmas festivities interfered with my finishing it. I trust, however, it is not too late to point out to Mr. Vizer the mistake he has made.

January 3rd, 1871. JOHN DOWLING ALLMAN.

INFUSIONS.

Sir,—I have only now seen Mr. Allchin's paper on Infusions, which appeared in your Journal of the 17th inst. I hope you will allow me space for a few words on this subject, and they shall be as few as possible, for the matter lies (as I conceive) in a nutshell.

It seems to be generally agreed by several writers on the subject in your Journal, that fresh infusions are to be preferred to those of a concentrated form. I think if this be conceded, it can only be when those infusions really are made fresh daily; at least, one can only be sure of it then. I know very well what frequently happens when freshly made infusions are bottled and put on one side till they are wanted. They may be, and no doubt are, very good sometimes, when wanted a day or two afterwards; but I know they are very often kept in that way too long, and sometimes until they are unfit for use, and there is so great a temptation to use them (no concentrated infusion, perhaps, being at hand) when they are, at all events, in a partly decomposed state. Surely a carefully prepared concentrated infusion must be better than that.

I know it is all very well in theory to talk of using none but freshly-made infusions, but it cannot always be, save in houses doing a large dispensing business. They can and they do, no doubt, make those fresh infusions every morning which are likely to be wanted during the day, and their large daily consumption of such warrants them and repays them for so doing; but chemists in general cannot do this. It would be a great loss to them were they to make fresh infusions daily and throw away those not used, and so in self-defence they must use concentrated infusions. I say in self-defence, and thus it is so. A person, for instance, takes a prescription to one of the large dispensing houses, and has a mixture made up containing some ordinary infusion. The mixture is made at once, and the customer takes it away with him. Some day, when again wanting that mixture, he takes the prescription to some other chemist, who tells him it will take an hour or so to prepare. The customer is, of course, very much surprised, and probably all the explanation in the world will fail to convince him but that this chemist is "a muff," and though he may consent to have his mixture made there then, he determines not to go to that shop again. So it is to meet this, or rather to prevent this, chemists, not doing a dispensing business which will warrant them in keeping fresh infusions ready, must use concentrated infusions to enable them to compete with the larger houses.

There can be no doubt, I think, that infusions can be so prepared as to contain all the extractive matter of the material employed in a concentrated form. Medical practitioners as a rule use them in the concentrated form, and find them answer admirably; and if vegetable extracts are to be believed in at all, I cannot see why they should be prescribed without hesitation in pills, etc., and a concentrated infusion, which is, of course, not nearly so concentrated a preparation as an extract, should be objected to. For my own part I believe the best plan would be to recognize concentrated infusions at once in our Pharmacopœia. They are partially so, I know, by the introduction of the formulæ for ext. cinchonæ liq., ext. Pareiræ liq., etc., but I venture to think if concentrated infusions generally were recognized there, it would put an end to much uncertainty in the matter; it would lead to more uniformity in dispensing, and it would, on the whole, be more satisfactory alike to the prescriber, to the dispenser and to the patient.

HENRY AYSCOUGH THOMPSON.

22, *Worship St., Finsbury Sq., London, E.C.*
27th December, 1870.

PRESCRIBING AND DISPENSING.

Sir,—I presume the time is approaching when medical men will no more be their own dispensers than architects their own builders. The anomalous position of prescribers and pharmacists is doomed, but good service may yet be done in clearing the way.

Are medical men gainers by dispensing? I doubt it much. Dispensing implies a stock of medicine and implements, the value of which is money sunk;—it often implies the salary of an assistant; it always implies employment inconsistent with the duties of a prescriber. Again, it deprives medical men of the support of pharmacists, and gives them opposing interests. Who loses most by this false position? Surely prescribers. Medical men can doubtless do much for chemists, but chemists can do more for medical men. What chemist, possessing in any degree the confidence of the public, does not know that scarcely a day passes when he could not transfer an applicant to the doctor? Make it his interest to do so,—or rather make it unfair that he should do otherwise —and the desired revolution would soon be effected. The practice arising from this altogether new class of patients would more than compensate prescribers for loss of profit on medicine.

These things will doubtless for some time be said and resaid with more or less force before all that is included in the new position of pharmacy, as a recognized and legalized branch of the medical profession, is understood and appreciated. A slow crystallization is however going on, which will gradually assign to the treaters of disease and the preparers of remedies their due form and position. When the process shall have been completed, the substantial benefits of the change, to both parties, will be too apparent to leave an atom of regret for the "good old times" that will have come to an end. T. M.

Glastonbury.

A POINT OF ETHICS.

Sir,—The only way to settle the matter in dispute relative to the prescription dispensed by "Magnesia" would be for him to ask the medical man if he intended to add "ac. sulph. dil." to the mixture. In all my experience in different towns, extending over thirty-six years, I never knew a doctor "but one" to order quinine in a mixture without adding a *little* ac. sulph. dil., "or other acids," to dissolve it, excepting in the case of "inf. rosæ c. quina" or "pills." *D. T. W.* will be kind enough to remember that he charged me with wishing to make the medical men appear more forgetful than they are, therefore I gave him the *two* prescriptions to inspect, and those "not solitary cases."

Liverpool, Dec. 31st, 1870. CHEMICUS.

LISTS OF DRUGS.

Sir,—If any of your readers, especially among wholesale druggists, could furnish me with two or three *stock-books*,—I mean manuscript-priced inventories of drugs,—dating from the early part of the present century, say 1800 to 1825, I should feel much indebted to them. I have some lists of the previous century.

Clapham Common, S.W., 4th January. DANIEL HANBURY.

DISPENSING CHARGES.

Sir,—I had the following prescription brought me this afternoon to dispense. It was marked on the side thus:—

℞.	Tinct. Camph. Comp.,	2
	Syr. Scillæ, ana ℥ss	1
	Acid. Sulph. Dil. ʒiij	1
	Tinct. Digitalis ʒj	1
		—
	Aquæ ℥viss	5

A tablespoonful thrice a day.

As it was for a working man, I thought I would be very reasonable in my charge, and only asked 1*s*. He told me he could get it made up in Newcastle for 5*d*. I refused to make it for that money, so he paid the shilling, but most likely will go to the "cheap man" next time.

Chester-le-Street, Dec. 28th, 1870. A. P. S.

MAG. FERRI ET QUIN. SULPH.

Sir,—My intention in writing to your Journal was to obtain information, and certainly not to annoy Messrs. Hitchcocks. In explanation I will state the facts.

The porter of a chemist brought the prescription, and asked for the article, which he said he was told was kept here (Apothecaries' Hall, Blackfriars). Hence the mistake. I did not go to Bruton Street, nor did I send any one else; but the same prescription has been brought to me by another chemist, also with a request for the article, within the last few days.

I am obliged to *G. S.* for the formula for the drug, which I am since informed was to be seen in a late number of the *Lancet.*

December 31st, 1870. E. B.

Fox's Palatable Oils.—Messrs. Fox, in the letter that they have forwarded, express their opinion that the "Liverpool Chemists' Association has stepped beyond its province, and made remarks without regard to their accuracy and without a sufficient knowledge of the matter they were handling." They dispute the remarks made by the President at the meeting on the 8th December, and add that, since they depend more particularly upon the medical profession to recommend their preparations, they had only sent to medical men the circulars stating what proportion of oil was contained in those preparations. They also state that they hold two patents for these preparations, and that they consider the decided separation of the oil from the other ingredients as a recommendation, inasmuch as it enables medical men to perceive with ease the actual amount of oil. They prefer that their preparations should be in this respect excluded from what is termed "elegant" pharmacy.

Inquirer.—No.

S. N. (Dorchester).—Colenso's Arithmetic.

Nemo.—Consult the papers on Liquor Taraxaci, by Bentley (PHARM. JOURN. 2nd ser. i. 402) and Squire (Brande's 'Materia Medica'). The difference in the appearance of the specimens is probably due to their having been prepared at different seasons of the year. We should prefer the darker for dispensing purposes.

D. D.—We think our correspondent might perhaps obtain a better result by using a calico filter instead of a paper one.

"*Guaco.*"—The iodine will be in a free state. The alkalies present are not in a condition to combine with it. The plants mentioned contain sulphur.

"*Vindex.*"—We do not think that formulæ for proprietary medicines are to be obtained through the medium of the Notes and Queries columns.

J. E. (Cromer).—The following is the formula for a syrup of lactate of iron proposed by M. Cap:—

℞. Lactate of Iron, 1 drm.
White Sugar, 12½ oz.
Boiling Distilled Water, 6½ fl. oz.

Rub the salt to powder with half an ounce of the sugar, and dissolve the mixture quickly in the boiling water. Pour the solution into a matrass placed on a sand-bath, and add to it the rest of the sugar in small pieces. When the sugar is dissolved, filter the syrup, and as soon as cold transfer it to well-stoppered bottles. This syrup has a very light amber colour, and contains about four grains of the salt to the fluid ounce. Dose from two to four fluid drachms.

J. T. Greenwood (Louth).—Distil a known quantity with caustic lime and as much water as may be necessary, collecting the distillate by careful condensation; then determine the ammonia by titration with a standard acid, or by adding a slight excess of hydrochloric acid, and evaporating to dryness, so as to weigh the chloride of ammonium.

John Gregory (Stockton-on-Tees).—The indications afforded by the tests you refer to are scarcely to be relied upon unless the operator has a large empirical familiarity with the results produced under various conditions. Probably the oil referred to was mixed with some substance that resinified on exposure to the atmosphere. This admixture might be accidental or otherwise, and in either case the presence of a very small amount of such substance might be sufficient to give rise to the rose tint observed,—so that this result could not *alone* be relied upon as indicating inferiority or adulteration of the sample in question.

"*Anxietas.*"—We have given full consideration to your suggestion, but we do not regard this Journal as the proper medium for giving such educational aid as that referred to. Moreover, the plan proposed is so admirably carried out in another journal, that we should be in no small degree poaching upon its preserves, if we were to adopt the same course. At the same time, we are much obliged for the suggestion, and will take this opportunity of saying that we should be very glad if members of the trade would more generally communicate their opinions and wishes in regard to such matters as it is the province of this Journal to deal with. In many cases that would be a means of rendering good service to the general interests of pharmacy and of our Society.

"*Inquirer.*"—We cannot furnish you with the address asked for.

"*Veritas.*"—We are unable to give the information concerning the proprietary medicine referred to.

A Student (Harwich).—See PHARM. JOURN. o. s. Vol. XII. for full information on the subject.

W. A. Thirlby.—In order to promote oxidation and facilitate solution of the iron.

C. J. Cann (Greenwich).—Prussiate of potash is exempt from being included in the words "cyanide of potassium and all metallic cyanides," partly because it is not a cyanide but a *ferrocyanide*, chiefly, however, because it is, as a matter of fact, not a poisonous substance.

J. B. Leslie (Sheffield) who expresses his dissent from our Answers to Correspondents in No. 19 and 20, will find in the foregoing answer a solution of his difficulty.

G. Wellborn.—(1.) See Ure's 'Dictionary,' art. "Yeast, Artificial." (2.) The rise of temperature, in the one case, and the fall of temperature in the other, are due respectively to the facts that heat is evolved in the one case, while it is rendered latent in the other. In the former case there is reason to believe that something like chemical combination takes place, resulting in the production of a hydrated salt, while in the latter case the change is merely physical, or the heat rendered latent in the liquefaction of the salt exceeds in amount any heat that may be evolved as a result of chemical combination between the salt and water.

S. D.—Hooper's 'Medical Dictionary' and Mayne's 'Medical Vocabulary' (Churchills).

COMMUNICATIONS, LETTERS, etc., have been received from Mr. A. H. Hale (Ramsgate), Mr. H. B. Brady (Newcastle), Mr. C. R. C. Tichborne (Dublin), P. L. Simmonds, A Stranger, "A. P. S.," "M. P. S."

"ANDREW BOORDE, of Physyche Doctor."

In all Mr. Ince's 'Century of Old Books,'—we speak with reservation, in that we are only partially acquainted even with their titles as yet,—there may possibly not be found one more edifying and amusing than a volume recently issued by the Early English Text Society, containing a reprint of some of the principal works of Dr. Andrew Boorde.* But apart from general interest or antiquarian value, this book has a peculiar claim on the notice of those to whom familiarity with medicines and dietary in the nineteenth century affords common meeting ground with an exponent of the theory and practice of the sixteenth in the same particulars.

Of Andrew Boorde himself not much is known. Some of our readers may perhaps not even recognize his name, others probably will know nothing more than the ill-natured tradition that he was a court physician in Henry the Eighth's time, in whose wandering habits and strange modes of pursuing his avocation the word "Merry Andrew," as applied to the odd being, half mountebank half quack doctor, still sometimes seen at a country fair, had its origin. Mr. Furnivall tells us something more, but not half as much as we should like to know.

We gather from the summary prefacing the reprints, that he was born some time before the year 1490, that he was brought up at Oxford, and admitted, whilst still under age, as a Carthusian monk. He appears to have been "dispensed" of his vows in 1521, in order to be made Suffragan Bishop of Chichester, and to have made use of his liberation by going abroad to study medicine. During succeeding years he made several foreign pilgrimages, extending his travels much further than was common in those days, (to all the universities and approved schools within the precinct of Christendom, he himself says,) and in 1536 we find him practising and studying medicine at Glasgow. After his last Continental tour Boorde settled at Winchester, and probably spent the remainder of his days partly in that city, where he had amassed some property, and partly in London. His end could hardly have been a happy one. Accused by his enemies of immorality, he was imprisoned in the Fleet, and the last information we have concerning him is found in his will, dated from his place of confinement, April 25, 1549.

Mr. Furnivall's first quotations are from the 'Breuyary.' Their phraseology is delightfully quaint, and they serve to give us an idea both of Boorde's theories as to the origin of various distempers and his actual practice as a physician. The specimens selected by the editor generally refer to psychological disorders, and the treatment in these cases is based upon hygiene rather than medicine. Still there are a number of sections devoted to material ills, such as itch, palsy, asthma, stone, chilblains, excoriations, and sundry cutaneous affections, of which the following may be taken as a specimen:—

Boorde's treatment of Itch:—A good pair of Nails.

"¶ The .292. Chapitre doth shewe of Itchynge. *Prurigo* is the latin word. In Englyshe it is named itching of a mans body, skyn, or fleshe,

¶ The cause of this impedimente.

¶ This impediment doth come of corrupcion of euyll bloud, the which wolde be out of the fleshe; it may also come of fleume myxt with corrupt bloud, the which doth putrifie the fleshe and so consequently the skyn.

☞ A remedy.

This I do aduertise euery man for this matter to ordeyne or prepare a good payre of nayles to crache and clawe and to rent & teare the skynne and the fleshe, that the corrupt bloud maye runne out of the fleshe; and vse than purgacions and stuphes & sweates; and beware, reuerberate not the cause inwarde with no oyntment, nor clawe not the skyn with fyshye fyngers, but washe the handes to bedwarde."—P. 97.

Or the following:—

Boorde's treatment of Palsy.

"☞ Fyrst, vse a good dyet, and eate no contagious meates; and yf nede be vse clysters, and anoynt the body with the oyles of Laury and Camomyll; but whether the Palsy be vniuersal or perticuler, I do anoynte the body with the oyle of Turpentine compounde with Aqua Vite, and vse frications or rubbynges with the handes, as one wolde rub with grece an olde payre of Botes, not hurtynge the skyn nor the pacient. And I do gyue the pacient Treacle with the pouder of Peper or els Mitridatum with Peper; or els take of Diatriapiperion. And if one wyll, he may rub the pacient with the rotes of Lylyes, brayed or stamped; after that use dry stuphes as the pacient is able to abyde. Or els, take a Foxe, with the skynne and all the body quartered, and with the herte, lyuer and lunges, and the fatnes of the intrayles, stones and kidnes, sethe it longe in runnynge water with Calamynt and Balme and Carawayes, and bath the pacient in the water of it; and the smell of a Foxe is good for the Palsy."—P. 99.

He does not approve of sending for the "duly qualified medical man" for small ailments, but trusts much to nature. For instance, speaking of some affection of the eyes, he says,—

"I myght here shewe of many salubriouse medecines, but the best medecine that I knowe is to lette the matter alone, and medle nat with it, but were before the eyes a pece of blacke sarcenet and eate neyther garlycke nor onyons nor drynke no wynes nor stronge ale, and it will were away."—P. 101.

He has, nevertheless, a genuine belief in physic properly administered, and his prescriptions often show a definiteness of purpose which, if we may judge by samples we have recently had to print in our pages, the modern prescriber might at times imitate with advantage.

The 'First Boke of the Introduction of Knowledge' hardly concerns us, and though highly entertaining, we must pass it by with the editor's remark, that "It is the original of Murray's and all other

---

* The First Boke of the INTRODUCTION OF KNOWLEDGE made by ANDREW BORDE of Physyche Doctor (1547).—A Compendyous Regyment or A DYETARY OF HELTH made in Mountpyllier, compyled by ANDREWE BOORDE of Physyche Doctour (1542).—BARNES in the DEFENCE OF THE BERDE: a Treatyse made, answerynge the Treatyse of Doctor Borde upon Berdes (1542 or 3).

Edited, with a Life of Andrew Boorde and large Extracts from his Breuyary, by F. J. Furnivall, M.A., Trin. Hall, Camb.

LONDON: Published for the Early English Text Society, N. Trübner and Co. 1870.

English Handbooks of Europe." A good deal of it is in verse, and it seeks to inform its readers on matters of Continental travel, with some foreshadowing even of the polyglot phrases of the modern tourist's guide.

The "Dyetary of Helth" is a complete system of regimen, not only as its title would impart, for people already sound in body, but for those afflicted with disorders of divers sorts. It begins by directing how and where a man should build his house; how order his household so as to live in quietness; how the head of a house should exercise himself for the health of his soul and body; and how order himself in sleeping, in watching and in apparel. Surfeiting is shown to do much harm to nature, but "abstynence is the chyfest medyson of all medysons." A number of chapters are devoted to the consideration of the virtues of various forms of diet, whether meat or drink, and many of the conclusions would startle the modern physiological chemist; then follow dissertations on roots, herbs, fruits and spices. We quote the following as a contribution to therapeutics:—

"Pennyryall doth purge melancoly and doth comforte the stomacke & the spyrites of man. Isope (hyssop) clenseth viscus fleume, & is good for the breste and for the lunges. Roosmary is good for palses, and for the fallynge syckenes, and for the cowghe, and good agaynst colde. Roses be a cordyall, and doth comforte the herte & the brayne."

The diet of men should differ according to their temperaments, the sanguine, the phlegmatic, the choleric, and the melancholy, will each find a chapter for his guidance. In times of epidemics and pestilence an additional precaution is needed in the form of fumigation, and a formula for a sort of incense is given. Then follow the diets for gouty and leprous patients, for the stone, colic, fever, dropsy, ague, and the like. And lastly,

"The xl. Chapytre doth shewe an order or a fasshyon how a sycke man shulde be ordered, And how a sycke man shuld be vsed that is lykely to dye."

We would gladly dwell on the curious glimpse this book affords us of the practice of medicine in the time of the Tudors. In Mr. Furnivall's estimate of his author every thoughtful student will concur. "I think," says he, "the reader will find Andrew Boorde worth knowing, a man at times of great seriousness and earnestness, yet withal of a pleasant humour; reproving his countrymen's vices and ridiculing their follies; exhorting them to prepare for their latter end and yet to enliven their present days by honest mirth. A man eager to search out and know the truth of things, restless in that search, wandering far and often to see for himself. Yet a man bound by many superstitions of the time, though free from many. * * * Sound at the core, a pleasant companion in many of England's most memorable days, worthy, with all his faults, of respect and regard from our Victorian time." But our space at present permits no more than to thank Mr. Furnivall and the Early English Text Society for the results of their labour, and to bestow a passing word of admiration upon Mr. W. H. Hooper's masterly reproductions of the droll wood-cuts that adorned the original works.

H. B. Brady.

METHYLATED SPIRIT.

BY P. L. SIMMONDS.

It is curious to trace the progress that has been made in the use of methylated spirit since it was first introduced about fifteen or sixteen years ago, as given in the detailed reports of the Commissioners of Inland Revenue. The high price of duty-paid spirit in this country not only repressed scientific research, but seriously interfered with trade, by compelling manufacturers to resort to cheaper and inferior substitutes for spirits, which injured the character of the goods, and, in some instances, made it doubtful whether the manufacturers in this country could much longer compete with those on the Continent, where the duty on spirit is inconsiderable.

In the year 1853, a gentleman who had obtained a patent for an artificial lubricant as a substitute for sperm oil, applied to the Lords of the Treasury to be allowed to use spirit in the manufacture of his lubricant, duty free, or at least at a reduced rate. After a careful examination of his invention, it was found that the spirit was rendered unfit for drinking, and that it could not by any process be restored to its original purity. A mixture of 10 per cent. of purified wood naphtha with spirit of wine effects the object. An Act was consequently passed in 1855 allowing such a mixture to be used duty free. Although there was good reason to believe that the methylated spirit would be so unpalatable that it would effectually repel ordinary drinkers, yet as it was not, in a peculiar degree, pernicious to health, it was impossible to predict what might be the result if such a means of intoxication at a cheap rate were readily accessible to habitual drunkards. It was, therefore, deemed necessary to impose such conditions on the use of methylated spirit as would guard against its possible perversion to purposes for which it was not intended. Persons who wished to use this spirit were required to make a written application to the Board, and to engage under bond that it should be properly applied. They were then furnished with forms of requisition, by means of which they could at pleasure obtain such quantities as they might require, not being less than ten gallons at a time. These regulations still apply in cases in which the spirit is required to be used in quantities greater than can be met by supplies not exceeding one gallon at a time, but by Act 31 & 32 Vict. c. 124, the minimum quantity that may be supplied at one time is reduced to 5 gallons.

The following are the principal purposes to which the spirit was at first applied:—Making furniture polish, varnishes and lacquers; dissolving resins for hat manufacturers; manufacturing hypospem oil, chloroform, sulphuric, nitric and chloric ethers, sweet spirit of nitre, fulminating powder and transparent soaps; extracting vegetable alkaloids, such as quinine, morphine, etc.; making soap liniment and extracts required in veterinary medicines; preparing gold-beaters' skin, floating mariners' compasses and filling spirit-levels; preserving objects of natural history, and in chemical and anatomical researches.

It was not at first allowed to be adopted as a source of heat or light for domestic purposes. In order, however, to accommodate a large class of work-people, known as French polishers, the spirit was permitted to be sold in smaller quantities than those prescribed by the Act, on condition that a certain proportion of shellac or other resin was dissolved in it, so as to make the preparation which is technically termed "polish," from its being employed to complete the polishing of the goods. There cannot be a doubt that this measure has been very beneficial in its operation.

Besides the direct encouragement which it has given to scientific research and to manufacturing industry, it has materially lessened the demoralizing practice of illicit distillation which was carried on (in London at least) principally for the supply of persons who use spirits as a solvent for gum resins, or in the manufacture of ethers or spirits of nitre.

In 1861, sufficient experience having been gained to warrant the conclusion that there was no danger of the preparation being converted into a beverage, some of the restrictions on its sale and use were removed. In July of that year an Act was passed which enabled any one (other than persons dealing in excisable liquors) to obtain a licence for retailing methylated spirit in quantities not exceeding one gallon at a time, and removing, in respect to the small quantities sold under such licence, the restrictions which confined its use to the various processes connected with the arts and manufactures.

It may now be purchased in small quantities for domestic use, and is largely consumed in a great variety of appliances to luxury and comfort, from the spirit lamp on the breakfast table to the singeing apparatus in the stable. The duty on the retail licence which was first fixed at £2. 2*s.*, was in 1867 (by the 30 & 31 Vict. c. 90) reduced to 10*s.*

Methylated spirit has found an extensive application in the preparation of the brilliant new dyes which were introduced about ten years ago. The French had long been in the habit of using alcohol in dyeing, but the high duty on spirit in this country formerly acted as a complete prohibition of their use for this purpose, and enabled the French to maintain an undoubted superiority.

In 1863 the high price of turpentine, caused by the war in America, led to an attempt to use rum as a substitute for it in paint. As it was represented that the methylation of rum for that purpose would be a great boon to the West Indian colonies, by affording an outlet to inferior produce, which was scarcely saleable as beverage, the authority of Parliament was obtained for allowing the mixture of rum in bonded warehouses with wood naphtha. The expectation of its utility as a substitute was not realized. The same Act legalized the exportation of methylated spirit.

Up to the year 1866 the consumption of methylated spirit had, by an almost regular progression, continued to increase, rising from 218,103 gallons in 1856 to 1,070,897 gallons in 1865. The fraudulent practice of making a compound of methylated spirit, which under the pretence of being used as a medicine, was in reality sold as a stimulant in the place of ordinary spirits, although not extensively prevailing, had, in 1866, become an increasing practice, and from every point of view, it appeared most desirable that it should be suppressed. It was also intimately connected with the application of methylated spirit to purposes for which it was never intended, though not expressly prohibited, namely, the preparation of tinctures and of medicines for internal use, an application of that spirit which the Pharmaceutical Society considered highly objectionable.

It was therefore necessary to resort to legislation, and to prohibit entirely the use of methylated spirit in any preparation which could be used internally as a medicine. Sulphuric ether and chloroform, on account of their being used extensively in arts and manufactures, were excepted from the prohibition above specified. Methylated spirit may also still be employed as a solvent or agent in the production of medicines, provided no spirit or derivative thereof shall remain after the completion of the process. In addition to this prohibition, it has been found advisable to impose a legal restraint upon any alteration in the character of the compound known as "finish," except by the introduction of more resin or colouring matter.

The object is to prevent "finish," which may be procured in unlimited quantity by the general public without certificate or a compliance with any forms, being applied to other than its legitimate purposes, that of a polish for furniture.

Attempts have at times been made to purify and render drinkable the methylated spirit, but apparently without success. The presence of the required portion of gum-resin in finish was considered to be a sufficient safeguard to the revenue, but there is no doubt that large quantities of finish were turned to improper account, either by covering the nauseous flavour with aromatics or by distillation with acids, which effected a conversion into potable ethers.

As an additional security to the revenue therefore, as well as to ensure the using of the finish for none but the approved purposes in the arts, a provision in the law was made to the preceding effect. This legislation has checked consumption to a considerable extent, by confining it to legitimate purposes. In the year ending March 1866, 1,070,897 gallons were used; 1867, 1,031,214; 1868, 854,844; 1869, 885,957. This decline probably represents the extent to which this spirit was applied either to fraudulent purposes, or to those such as the preparation of medicines for internal use to which its application was undesirable.

The increase in the last year may be fairly considered as representing the natural growth of a legitimate consumption. The number of licences granted to makers in 1869 was only 6 in England, 2 in Scotland, and 1 in Ireland. The retailers who had licences, however, numbered 991 in England, 148 in Scotland, and 41 in Ireland.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Cadmii Iodidum.—[§ It may be formed by direct combination of iodine and cadmium in the presence of water.] Cadmium is a metal which accompanies zinc in its ores, and resembles it in many respects very closely, but is more volatile. It is also distinguished by giving a yellow sulphide when sulphuretted hydrogen is passed into any of its acid solutions, and this yellow precipitate is not soluble in sulphide of ammonium. The latter character separates it from the sulphide of arsenic, which is of a similar colour. [§ Iodide of cadmium, in addition to the preceding reactions, gives a white gelatinous precipitate with excess of solution of potash, the filtrate from which is unaffected by sulphide of ammonium.] If any zinc compound were present the filtrate would retain it, and would give white sulphide of zinc on the addition of sulphide of ammonium. [§ Ten grains dissolved in water and nitrate of silver added in excess, give a precipitate which, when washed with water and afterwards with half an ounce of solution of ammonia and dried, weighs 12·5 grains.] The precipitate is, of course, iodide of silver, and the object of washing it with ammonia is to remove adhering traces of the cadmium salt. It should be remembered that the precipitate is not absolutely insoluble in ammonia. Since CdI_2 is the formula of iodide of cadmium, it will yield 2 molecules of AgI. 366 parts of iodide of cadmium give then 470 parts of iodide of silver; 10 grains will therefore yield, theoretically, 12·84 grains.

Calcii Chloridum.—[§ It may be formed by neutralizing hydrochloric acid with carbonate of lime, adding a little solution of chlorinated lime and slaked lime to the solution, filtering, evaporating until it becomes solid, and finally drying the salt at about 400°.]

The object of this process is to remove from the salt ferric oxide and alumina, which are very commonly present. When thus prepared, the product answers to the Pharmacopœia test. [§ The aqueous solution is not precipitated by the addition of limewater.]

Calcis Carbonas præcipitata.—Solutions of chloride of calcium and carbonate of soda are mixed together, the precipitate collected, well washed and dried at 212°:—

$$CaCl_2 + Na_2CO_3 = Ca\,CO_3 + 2\,NaCl.$$

See *Creta Præparata.*

Calcis Hydras.—The operation of slaking lime is familiar to every one. In operating upon small quantities hot water is best. Slaked lime should not be exposed to the air for any length of time, as it absorbs carbonic anhydride, becoming converted into carbonate.

Very pure lime, free from the alumina, iron, silica and alkaline chlorides commonly present in the ordinary kind, is now prepared commercially from marble, and can be procured at a cheap rate.

Calcis Phosphas.—Bone ash is digested in diluted hydrochloric acid, and the filtered liquid mixed with solution of ammonia in slight excess. The precipitated phosphate is to be thoroughly washed with hot water. Bone ash is composed of:—

Tricalcic phosphate . . .	$Ca_3 2PO_4$	
Monocalcic phosphate . .	$CaHPO_4$	
Calcic carbonate	$CaCO_3$	
Magnesic phosphate . .	$MgHPO_4$	traces.
Calcic fluoride	CaF_2.	traces.

Mixed with particles of carbonaceous matter. When treated with hydrochloric acid, all dissolve except the particles of carbon and sandy matters that are generally present. On filtering the solution and adding ammonia, the chloride of calcium, which was formed by the solution of the carbonate, supplies calcium to the monocalcic phosphate, and thus a precipitate, composed chiefly of $Ca_3 2PO_4$, is produced. For detection of phosphate of lime, see Bism. Subnitras.

Calx.—See Calcis Hydras.

Calx Chlorata.—[§ A product obtained by exposing slaked lime to the action of chlorine gas as long as the latter is absorbed. It possesses bleaching and disinfecting properties.] This compound is very commonly represented as a mixture of hypochlorite and chloride of calcium—

$$2\,CaO + 2\,Cl_2 = \underset{\text{Hypochlorite.}}{Ca\,2\,ClO} + \underset{\text{Chloride.}}{Ca\,Cl_2}.$$

Many of its characters, however, indicate that this view cannot be correct. Thus, it is not so soluble in water as it should be on such a supposition; it is not particularly deliquescent, and yields but a small amount of chloride of calcium when treated with spirit. It is more probably a compound intermediate between the chloride and hypochlorite, the constitution of which may be represented by the following formulæ:—

$$\underset{\substack{\text{Chloride}\\ \text{of Calcium.}}}{Ca''\begin{cases}Cl\\Cl\end{cases}} \qquad \underset{\substack{\text{Calx}\\ \text{Chlorata.}}}{Ca''\begin{cases}Cl\\(ClO)'\end{cases}} \qquad \underset{\substack{\text{Hypochlorite}\\ \text{of Calcium.}}}{Ca''\begin{cases}(ClO)'\\(ClO)'\end{cases}}$$

[§ The solution evolves chlorine copiously upon the addition of oxalic acid, and deposits at the same time oxalate of lime.]

$$CaClClO + H_2C_2O_4 = CaC_2O_4 + H_2O + Cl_2.$$

[§ 1 gram mixed with 3 grams of iodide of potassium, and dissolved in 4 fluid ounces of water, produces, when acidulated with 2 fluid drams of hydrochloric acid, a reddish solution, which requires for the discharge of its colour at least 85 cubic centimetres of the volumetric solution of hyposulphite of soda, corresponding to 30 per cent. of chlorine liberated by the hydrochloric acid.] The action of the hydrochloric acid on the chlorinated lime is this:—

$$Ca\,ClClO + 2\,HCl = Ca\,Cl_2 + H_2O + Cl_2,$$

and each atom of chlorine thus produced liberates an atom of iodine from the iodide of potassium. When that salt is present, therefore, in sufficient quantity, part of it is decomposed, and not chlorine, but iodine, is set free—

$$Ca\,ClClO + 2\,HCl + 2\,KI$$
$$= Ca\,Cl_2 + H_2O + 2\,KCl + I_2.$$

The amount of iodine is then determined by the employment of the solution of hyposulphite of soda. This is made by dissolving 1 molecule (248 grams) of the crystallized salt in water, and making the solution measure 10,000 cubic centimetres. This quantity would therefore be sufficient to decolorize 1 atom, or 127 grams, of iodine.

$$\underset{\text{Hyposulphite.}}{2\,Na_2S_2O_3\,5\,H_2O} + \underset{\text{Iodine.}}{I_2}$$
$$= \underset{\text{Iodide.}}{2\,NaI} + \underset{\substack{\text{Tetrathionate}\\ \text{of Sodium.}}}{Na_2S_4O_6} + 5\,H_2O.$$

If 85 cubic centimetres are necessary to decolorize the iodine set free by 1 gram of the calx chlorata, this indicates 1·0795 gram of iodine, and consequently an equivalent quantity, or ·30175 of Cl,—

10,000 : 85 : : 35·5 grams of chlorine,

equivalent to 127 grams of iodine: ·30175 gram, the chlorine available from 1 gram of calx chlorata.

Since 1 gram yields ·30175 of Cl, 100 grams yield 30·175. This is the same as saying 30 per cent.

THE EXTRACTION OF THE POISONOUS PRINCIPLE OF THE TUTU PLANT (CORIARIA RUSCIFOLIA).

BY W. SKEY,

Analyst to the Geological Survey of New Zealand.

A great many experiments have, from time to time, been made upon the Tutu plant, with the object of extracting the formidable poison known by sad experience to exist therein; but, as is well known, these attempts have been always unsuccessful, and have, besides, completely failed to discover anything at all definite as to the chemical or physical character of the poison.

Among these experiments is a series I made while connected with the Geological Survey Department of Otago, a notice of which appeared in the "Jurors' Report for the New Zealand Exhibition of 1865," the only result, however, being to prepare the way for future inquiry, which was promised at the time.

The Tutu plant does not grow in the neighbourhood of Wellington in any quantity, hence I have been greatly delayed in fulfilling my promise, much against my will; but recently a large quantity of the seed of this plant has been kindly presented to the Survey, for this particular purpose, by Mr. H. H. Travers, and upon this I at once commenced operations.

The plan I adopted was to separate, as well as I could, all the more immediate proximate constituents of the seed (in which the poison is known to exist), and to test each likely one by itself, in its effects upon the animal economy.

First, I extracted a portion of the finely-ground seed with cold water, and another portion with weakly acidified water, and treated them separately by a new process, now much in vogue, for the separation of alkaloids (Rogers and Girwood), all the evaporations being conducted at a temperature not exceeding 90° F.

The residuum from these processes was very small, and gave no indications of the presence of alkaloids to the proper tests; it consisted almost wholly of gummy matters.

The result seemed to dispose of all that was soluble in water or weak acids, and, to a certain extent, impugned the correctness of the general idea that this poison is of the nature of an alkaloid.

The part of the seed insoluble in these reagents was next examined.

Alcohol was passed through this repeatedly and the extract evaporated, when a large quantity of a greenish-red coloured substance discovered itself. This, treated with ether, separated into two parts, one a green-coloured oil, soluble therein, the other a resinous substance quite insoluble in this menstruum.

The resinoid substance was reserved for after-examination, and the oil at once tested in regard to its effects on the animal economy.

For this purpose I administered about five minims of it to a full-grown cat, after a twelve hours' fast; the oil acted as an emetic in a short time, and the greater portion of it was vomited. In half an hour, however, the animal showed signs of uneasiness, and convulsive twitches of the ears and eyes, together with a forward jerking of the head, took place, also much frothing of the mouth, culminating in a convulsive fit, in about one hour after the dose was administered. After a little while this fit passed off, only the twitches and forward jerkings continuing; but a second very severe fit, of short duration, occurred in about one hour afterwards, after which the cat gradually rallied. These symptoms agreed generally with those exhibited by cattle and sheep when poisoned by this plant.

Although I have made but one experiment, I think it will be allowed that the result of this has fairly proved that the poison of the seed, and so, by a very proper inference, the poison of the plant generally—since I find an oily substance throughout it—exists in this oil, if it is not the oil itself. It therefore now only remains to be ascertained whether this oil is a single proximate substance or a mixture or compound of such, and if the latter, which is, or which are, the active ones concerned in the production of these phenomena I have described. Unfortunately, I had not sufficient of the oil to allow me to test this properly, but I am in hopes of having it shortly, as I have been promised a large quantity of these seeds from Taranaki.

The following are the characteristics of this oil, as ascertained up to the present time.

Somewhat viscid at common temperature, but flowing freely at a little above this; colour, pale green; reaction, acid; taste, bland; burns away readily with much flame; scarcely volatile without decomposition; soluble in ether, alcohol, chloroform, and strong acetic acid; insoluble in hydrochloric or nitric acid; also insoluble in water; does not dry when long exposed to the air.

When boiled with solutions of the caustic alkalies there is much frothing, but only a portion of the oil dissolves, even when the boiling is continued for many hours; the portion dissolved was found to be saponified. The whole of the oil is, however, soluble in a cold alcoholic solution of potash, without yielding a precipitate when admixed with water; hence it is probable that all the acid portion of the oil is really saponifiable,—that which was unsaponifiable, in the first instance, being a product of the metamorphosis of a portion of the normal oil by the process employed.

When the oil is heated to the decomposing-point, a substance is given off having the pungent odour of acrolein, a substance characteristic of the presence of glycerine, or oxide of lipyle, the base of common fatty bodies.

Heated with caustic alkalies, either in the wet or the dry way, there are no alkaline vapours evolved, but in the latter case an odorous oil forms, probably œnanthylic acid.

From the reaction of this oil, here described, it evidently belongs to the series of non-drying fixed oils; in its solubility in alcohol or acetic acid, it bears a remarkable resemblance to castor oil, the only other fixed oil which I find to be wholly soluble in acetic acid. Now, castor oil, it will be remembered, is a very peculiar oil. It does not contain any of the acids of the common oils or fats, but in place of them, two very singular acids, quite peculiar, I believe, to this variety of oil; hence I conceive the acid part of this oil of Tutu to be also quite distinct from the ordinary fatty acids; to be, in all probability, peculiar to it; and to one or more of these acids I should ascribe the poisonous effects of the oil.

If further experiments should confirm the correctness of the views here stated, this case will, I conceive, become invested with an interest beyond that immediately under our notice, since it will offer another instance in which a non-nitrogenous oily principle is proved to affect the system like a neurotic poison, this class of poisons being almost always alkaloids, or at least nitrogenous substances.

Now it will be remembered there are several poisonous plants in Europe which have, hitherto, refused to yield any pure poisonous principle to chemical processes, but then these processes have been, as a general rule, I believe, especially for the detection of alkaloids. With this case to point, therefore, it does seem in the highest degree probable that, in some of these cases, at least, the poisonous effects may be due to a non-nitrogenous oil, not yet isolated or examined. In view of this I have recommended the subject for examination to a friend of mine residing in England, so that I expect in a few months to hear something more of this, or else to have selections of seeds, etc., from the plants I have named in my letter, so that I can inquire into this subject myself.*

* Since this paper was read, I learn from the *Chemical News* (vol. xx. p. 70) that M. Van Ankum has discovered

With regard to antidotes for administration to animals, etc., poisoned with the Tutu plant, I should be inclined to think that, in addition to emetics and purgatives, very dilute acids would be beneficial, since, by preventing saponification of the oil, they would tend to keep it insoluble and therefore inert.

As being somewhat related to the subject, I may state that the seed of the Karaka-tree (*Corynocarpus lævigata*), which is also of a poisonous nature, has refused, in a similar manner, to yield any alkaloid to my processes, but it gives up an oil to alcohol, which resembles the above in some of its reactions. It seems to exercise a specific effect upon the animal economy when administered in small doses, inducing at first great uneasiness, and afterwards restless, unwilling sleep, with sudden starting. Unfortunately I had not sufficient of it to get any decisive results.

This oil is also soluble in alcohol, acetic acid, ether and in hydrochloric acid.

It is very bitter, and feebly soluble in water.

In one important respect it differs from the oil of Tutu. It evolves ammonia when boiled with potash, thus, in regard to its composition, allying itself to the alkaloids, though in its reactions apparently distinct.—*Chemical News.*

the poisonous principle of the *Cicuta virosa* to be an essential oil, of formula $C_{10}H_8$, but "could not find any alkaloid in this plant at all." This was one of the plants especially selected for examination in the communication alluded to.

IMPROVED METHOD OF PRODUCING HYDROGEN GAS.

MM. Tessié du Motay and Maréchal, who have lately discovered a mode of obtaining cheap oxygen for illuminating and medical purposes from the manganates of soda, have sought a more practical and economical method of producing hydrogen by the decomposition of water by means of carbon, and they have discovered the following method, which has given the most extraordinary results. Alkaline and earthy alkaline hydrates, such as the hydrate of potash, soda, strontium, baryta, chalk, etc., mixed with charcoal, coke, anthracite, pit coal, peat, etc., and heated to a red heat, are decomposed into carbonic acid and hydrogen, without further loss of heat than that due to the production of the carbonic acid and hydrogen. The hydrates of potash, soda, etc., and more especially the hydrates of chalk or lime, decomposed by the coal into hydrogen and carbonic acid, can be used indefinitely in this process, provided they are moistened each time with water, so as to reproduce the decomposed hydrates. In this operation, the hydrogen gas is generated without any special production of steam, and may thus be produced without any other generating apparatus than the retorts themselves. These retorts, not being exposed to the direct action of the steam, are not subject to any interior alteration or damage. It follows, therefore, that the hydrogen gas produced by the decomposition of the above-named hydrates by means of carbon can be generated at a very small cost, and with the same facility as carburetted hydrogens from the distillation of pit-coal or rather organic hydro-carbon matter. These alkaline and earthy alkaline hydrates may be mixed with the different mineral or vegetable combustibles, either in a definite chemical proportion, or without a fixed or determinate proportion, and in any suitable distilling or heating apparatus, in order to produce, when heated to a red heat, hydrogen gas for illuminating and heating purposes. The advantage of the production of hydrogen as cheaply as oxygen, which has been obtained, is likely to create a revolution in many industries, and especially in metallurgy. A cheap method of producing a great heat in order to reduce metals, such as platinum, gold, silver, and iron, has long been sought for in Europe, where the oxyhydric blowpipe is now used to melt the platinum in a calcium crucible. By this discovery it becomes possible to obtain an immense heat which could be regulated by a simple tap. Enamellers and porcelain makers may thus get rid of one of their greatest troubles.—*Journal of the Society of Arts.*

PHARMACEUTICAL NOTES.

BY ALBERT E. EBERT.

On several occasions we have been requested by physicians to prepare pills from the oil of yellow sandalwood, each containing from five to ten drops. This we accomplished to the satisfaction of both prescriber and patient, by the following method:—

Take of Oil of Yellow Sandal Wood,
Yellow Wax, each half a troy ounce.

Melt the wax in a capsule and weigh into it the oil of sandal wood; mix and stir until cold, then roll out the mass, and divide it into 80 pills, by means of the pill-machine or pill-tile, in the same manner as an ordinary mass, and sprinkle with marshmallow-root powder. Each pill contains three grains, or about five drops of the oil. The excipient is unobjectionable, as it is readily soluble in the juices of the stomach. In the same manner we have made pills of the oils of cubebs, black pepper and fleabane.

Tincture of Calabar bean is frequently prescribed, and there is considerable variation in its strength as dispensed by different pharmacists. We have been accustomed to prepare the tincture, using one part of bean to ten of liquid, the menstruum consisting of alcohol, three parts, and water, one part. The bean, previously reduced to a fine powder, is macerated for several days with the water, the alcohol is then added, and the whole is allowed to macerate eight days longer. Finally, the mixture is thrown upon a filter, and when the liquid has ceased to pass, pour upon the residue sufficiency of the alcoholic menstruum to make up the original measure. It is difficult, by means of the mortar and pestle, to reduce the whole of the calabar bean to the requisite degree of fineness; besides, by this means much waste of the valuable material must occur. To avoid these difficulties, we have resorted to the goodwife's sanctum and appropriated that piece of apparatus so indispensable to a cup of good coffee, namely, the coffee mill, which we have found to answer to a charm the purpose of reducing the Calabar bean without incurring loss and without waste of time. We can heartily recommend the purchase of such a mill for use in reducing small quantities of many hard drugs, as stramonium and colchicum seed, etc.

Extract of Calabar bean is quoted by certain manufacturers of pharmacal preparations at $1.25 per ounce. Having had some demand for the article we undertook to prepare the article, and after thoroughly exhausting the bean, upon evaporation of the solution, were surprised to find the yield of extract to be but a trifle over one troy ounce from sixteen troy ounces of the bean. We find that other manipulators have obtained even smaller results. The query naturally arises, how can any manufacturer find it profitable to furnish the extract at $1.25 per ounce, when it requires one pound of material, costing $4 to obtain that quantity, to say nothing of the cost of menstruum, labour, etc.?

The dose of the tincture, as usually prescribed, is fifteen drops; that would indicate the dose of the extract to be about one-twentieth of a grain.

Lard is an article constantly required in galenical pharmacy, and upon its purity and freedom from rancidity depends, in great measure, the preparation of such ointments and cerates as will be creditable to the careful dispenser. Lard of the requisite quality is within the reach of all who will take the trouble to render it from the "leaf lard," which, in the proper season, is always obtainable. The difficulty in the way is the preservation of a sufficient supply from season to season without its becoming rancid. Many suggestions have been made by different writers, having in view the preservation of lard, by such means as the addition of gum resins, balsams, or solutions of the same, etc., but all are liable to some objection. The best and simplest method of accomplishing the desired end that has come under our notice is that followed in the Apothecaries' Hall, at Glasgow, Scotland, where the freshly-prepared lard is filled into bladders, which are afterwards tied at their necks and suspended in a cool cellar.

Savin Cerate.—This excellent irritant cerate is but little used at present; indeed, so seldom is it prescribed, that the dispenser is apt to find to his dismay his stock on hand, injured by exposure and age. It is preferable, therefore, to prepare this cerate extemporaneously, when required, and this can be readily done by keeping for the purpose the oleo-resin of savin, prepared by exhausting the leaves with ether, and evaporating according to the U. S. P. formula for the cerate. By weighing the oleo-resin, and ascertaining the proportionate amount appropriate to each ounce of cerate, the two may be mixed whenever required.

Ointment of Iodide of Sulphur.—The direction of the Pharmacopœia "to reduce the iodide of sulphur to a fine powder, with a little of the lard," has not proved practicable in our hands, as by the process we have failed to reduce the iodide to the fine state of division essential to a good ointment. Several modifications have been proposed, as triturating with small quantities of alcohol, ether, chloroform, and bisulphide of carbon; but these substances have little solvent action on the iodide; the use of the iodide of potassium has also been suggested, but this decomposes the iodide and hence is objectionable. Oil of turpentine has been used, but we have found the best success attending the use of the oil of lavender as a solvent—a few drops being sufficient, and there can be no reasonable objection to this addition.

To secure dispatch in the mixing of extracts with ointments and cerates, we keep such extracts as belladonna, stramonium, opium and arnica, in a fluid condition, by means of equal parts of water and glycerin. The diluted glycerin is added to its own weight of extract, and when the latter is prescribed in combination with a cerate, it, of course, is only necessary to substitute for the extract double its weight of the liquefied article.

It is of frequent occurrence that prescribers direct large quantities of watery or alcoholic solutions to be mixed with ointments or cerates. The best means of incorporating the greatest possible quantity is to melt the fatty matter and stir in the solution.

Tannic acid is seldom found in the matter of such purity as to form a clear solution. To facilitate the dispensing of solutions of this acid, we are accustomed to keep on hand a clear standard solution, preserved by glycerin. It is prepared by dissolving the tannin in a small quantity of water, filtering the solution, adding a weight of glycerin equal to that of tannic acid employed, and evaporating the fluid to such an extent that each part of tannin is represented by two parts by weight of the solution.

Suppositories.—When moulds of block tin are used, the main point necessary to secure success is to have the moulds *thoroughly chilled* by ice before the addition of the melted material; when this is observed, there is no difficulty in removing the suppositories with ease and within a few minutes.

Rose Water.—When this is prepared from the oil by rubbing with magnesia and adding water, a certain loss of oil occurs (absorbed by the magnesia) and the resulting water will not give clear solutions with nitrate of silver, owing to the solution of a minute quantity of the carbonate of magnesia, or of saline matters contaminating the latter, or both. A better method, and which, of course, yields a pure product, is to drop the oil into boiling distilled water and incorporate by agitation. Other medicated waters may be prepared in a similar manner. —*The Chicago Pharmacist.*

BROMIDE OF POTASSIUM.*

In 1826 M. Barthez and MM. Andral and Fournet published the results of researches made by them into the physiological and therapeutical action of bromine and of the bromide of potassium.† They reported that bromine possessed the power of rapidly removing pain in joints affected by chronic arthritis, and of lessening the swelling, immobility and deformity. M. Pourché, of Montpellier, also had found the bromide of service in the treatment of bronchocele, and in scrofulous affections.‡ MM. Puche, Huette and Rames attributed to this salt an anæsthetic action; and M. Thielmann, a Russian physician, asserted that it exercises a marked sedative action upon the organs of generation. In 1836 it was introduced into the London Pharmacopœia in consequence of the great success that had followed its use by Dr. Williams, of St. Thomas's Hospital, in cases of enlarged spleen. It did not prove equally useful in the hands of other practitioners. The observations of M. Thielmann and others bore but little fruit till they fell under the notice of Sir Charles Locock and led him to try the bromide of potassium in cases of "hysterical epilepsy." In 1857 Sir Charles stated to the Medical and Chirurgical Society that he had given the drug, in ten-grain doses, in fourteen or fifteen cases of epilepsy, and that the drug had proved eminently useful.§ Since then the bromide has become a very "fashionable" medicine, and in consequence has been misused and overrated, and credited with recoveries with which it had in reality no other relation than one of time. As a consequence of this, the pendulum of opinion has in some minds swung to the opposite extreme; and there are to be found those who doubt whether the drug possesses any real remedial powers at all. There can, however, be no doubt that when "mixed with brains" it is a medicine of very real and great value.

Its *mode of action* can hardly yet be defined with clearness and certainty. Many observers have reported on it, but their conclusions have in several cases been perplexingly contradictory. At present the conclusions arrived at by Dr. Robert Amory‖ seem most satisfactorily to explain its therapeutical properties. He considers, from his experiments, that the effects of the drug are produced by its direct action on the blood-vessels, or the vaso-motor system which controls the action of those vessels, and that this action can account for and explain all the physiological and therapeutical actions of the drug. He reports that the bromide is easily absorbed by the mucous membranes and by the skin, provided that the water in which it is dissolved is below the temperature of 75° Fahrenheit; that its elimination is conducted by the skin and kidneys, and that in therapeutical doses it is not eliminated by the intestines or the lungs; that it passes out of the skin without decomposition; that the larger the doses the more intense and enduring is the action on the vaso-motor system; and that its action upon the general nervous system is secondary to and dependent upon that of the vaso-motor nerves. Dr. Russell Reynolds also, in a valuable and instructive paper on "The Therapeutic Uses of Bromide of Potassium,"** records his opinion that the specific action of the drug "is exercised on the system of vaso-motor nerves, and that it acts upon that system as a sedative."

---

* Abstracted from a series of papers on the Progress of Therapeutical Science in the *Medical Times and Gazette.*

† *Journal de Chim. Méd.*, etc., t. v. p. 214.

‡ *Ibid.*, t. iv. p. 594.

§ *Medical Times and Gazette*, vol. i. p. 525, 1857.

‖ *American Journal of Medical Sciences*, 1869.

** *Practitioner*, vol. i. pp. 5–17.

As a medicine, the highest value of the bromide lies in its remedial powers over epilepsy. On this point the general experience of the profession agrees pretty closely with that of Dr. R. Reynolds, who asserts that, in the vast majority of cases it is of signal service, and that, while it absolutely cures very many cases, it rarely fails to diminish notably the number of attacks where it does not cure.

In many disorders producing or accompanied by mental disturbance or sleeplessness the drug renders very great service.

In delirium tremens it has also proved of great service, calming the delirium, producing sleep, and removing delusions.

The bromide of potassium possesses yet further this advantage, that it can be given without any danger whatever. Certain inconveniences and discomforts may attend its exhibition, but no dangers. Thus, it not infrequently excites acne or acneiform eruptions on the face or other parts; but, *en revanche*, acne of long standing has sometimes entirely disappeared during its exhibition. In full doses, very rarely in moderate doses, the drug may induce redness of the palate, epigastric heat, œdema of the lining membrane of the mouth, and salivation, drowsiness, confusion of mind, depression, failure of memory in a remarkable degree, and weakness of the arms and legs; but all these evils entirely disappear on the discontinuance of the drug. No permanent ill-effects have ever been observed to follow its employment.

Vegetable Wax in Japan.—From the notes of a short tour through the eastern parts of the provinces of Echigo, Iwashiro and Uzea, made in June and July of the present year by one of H.M.'s Consuls in Japan, we extract the following:—"In passing through Yazawa and some other villages, we found hemp, said to be of good quality, grown in frequent localities on the way, and vegetable wax trees in abundance. I was informed at Tsugawa that the extraction of lacquer from the same tree is prohibited there, the tree being reserved for the production of wax. As the lacquer is obtained by making incisions in the bark of the tree while young, the result of which is the death of the tree before coming to full maturity, both products can hardly be obtained from the same tree. This appears to be the reason for the prohibition. At Yonezawa, on the other hand, the extraction of lacquer from the tree is permitted, the result of which is, that little vegetable wax is produced there. I observed that many of the trees in the neighbourhood of Tsugawa had been injured, apparently, by the severity of last winter." The trees here alluded to are those belonging to the genus *Rhus*,—the most important wax-producing species in Japan being *R. succedanea*, L., the bulk of the varnish being yielded by *R. vernicifera*, Dec. The wax is obtained from the small fruits, while the varnish is procured by tapping the trees. The species met with at Tsugawa must have been *R. succedanea*, as this species yields both wax and varnish. Several other species also yield varnish more or less in China and Japan. Little is known about the preparations of this varnish as used in the ancient lacquer-work of the Japanese; and it is said that the modern workers in this article in Japan have themselves lost the secret of its preparation.—*Nature.*

Petroleum.—The year's business in refined American oil has been on a most enormous scale, the exports from the United States up to the 16th of December, 1870, reaching the total of 3,254,374 barrels, against 2,496,046 barrels for the whole of 1869, although the shipments of 1869 were in excess of any former year. It would thus appear that the supply is almost inexhaustible; and as the value of the year's shipments is about £8,000,000, it will be seen how important a part petroleum plays in the world's commerce. It is deplorable that the Act of 1868 should, as it most undoubtedly does, seriously interfere with the growth of the trade in this country. The dealers of the United Kingdom are harassed by laws that have no parallel either in America or the great consuming countries of the Continent. Meantime, the English public continue to pay higher prices than the inhabitants of more distant countries, who are not forced to import a special article, while the really dangerous petroleum spirit, or benzoline, is still admitted into our ports in growing quantities. The range during the past twelve months was from 1*s.* 5*d.* per gallon to 1*s.* 11*d.*; and closing prices are 1*s.* 6¼*d.* for contract quality, and 1*s.* 6½*d.* to 1*s.* 6¾*d.* for fine.—*Messrs. Phillips and Webb's 'Trade Report for* 1870.'

APOTHECARY-GENERAL (IRELAND).

Our readers will be well satisfied to learn that, at the last moment, even after the date of the appointment had been fixed, the Commissioners, who, as we hinted last week, had changed their minds, communicated to the conference of the Poor-Law Guardians of the North and South Dublin Unions, held on Friday, Jan. 6th, that they would not press this appointment in its present form. The suggestion of inspection which we proposed will probably be adopted. They do not appear to consider now that the qualification of apothecary will be a *sine quâ non*, as it might have the effect of excluding eminently qualified individuals from competition. If the principle of inspection be adopted, there can hardly be less than four inspectors, one for each province, considering that the number of dispensary stations and workhouses in Ireland is over twelve hundred. The Commissioners add that the subject will probably be brought before Parliament. We counsel the Poor-law medical officers of Ireland to see that their county representatives bring their claims not only for the holding of the appointment, but also for assisting in the appointing of these inspectors, before the members of Parliament for each county. In this first step towards promotion in Irish Poor-Law service, they may rely on the political co-operation of both the British Medical Association and the Poor-Law Medical Officers' Association of England. —*British Medical Journal.*

DRUG MARKET NOTES.

The following were among the parcels of drugs offered for sale last week:—

Aloes,—Cape, 149 cases; Barbadoes, 54 kegs; Socotrine, 45 boxes; East Indian, 23 packages.

Castor Oil, 498 cases.

Senna,—Tinnevelly, 90 bales; Alexandrian, 20 bales.

Galls,—Bussorah, 64 sacks; Turkey, 173 bags.

Talca Gum, 31 bales.

Nux Vomica, 186 bags.

Cardamoms,—Malabar, 6 cases; Madras, 3 cases.

Ipecacuanha, 13 serons; Carthagena, 6 barrels.

Canella Alba, 20 cases.

Cascarilla Bark, 50 sacks.

Colocynth, Turkey, 20 packages.

Bark,—Soft Columbian, 107 serons; Calisaya, 68 serons; Pitayo, 31 serons; Crown and Carthagena, 86 serons.

Jalap, 42 bales and 2 bags.

Gum Benjamin, 96 cases.

Ergot of Rye, 6 cases.

Tonquin Beans, 6 bags.

China Vermilion, 9 boxes.

Squills, 20 bags.

Calabar Beans, 1 barrel.

Chamomile Flowers, 20 bales.

Senega Root, 7 bales.

The Pharmaceutical Journal.

SATURDAY, JANUARY 14, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes endorsed* "*Pharm. Journ.*"

THE YEAR-BOOK OF PHARMACY.

WE are glad to be able to announce that the 'Year-Book of Pharmacy' for 1870 is now ready for delivery. It forms a handsome octavo volume of about 600 pages, containing a large quantity of information that cannot fail to be interesting and useful to every pharmacist.

With respect to the delivery of the Year-Book, the following card is being issued to metropolitan members, and to the residents in towns which contribute less than three names to the roll of the Conference:—

"On signing this card, and presenting it to Messrs. J. and A. CHURCHILL, publishers, 11, New Burlington Street, London, W., you will be supplied with one copy of the 'Year-Book of Pharmacy and Transactions of the British Pharmaceutical Conference, 1870.' If you wish the book to be forwarded, please to send with the card full directions as to route, and also enclose to Messrs. CHURCHILL stamps in prepayment of carriage. It can be sent by post for 7½*d*.

"Gentlemen joining the Conference before June 30, 1871, and paying the yearly subscription (5*s.* by cash, P.O.O., or stamps, to the London General Secretary, Professor ATTFIELD, 17, Bloomsbury Square, W.C.) will be entitled to a copy. Price to non-subscribers, 7*s.* 6*d.*"

To all other towns the volumes will be consigned, chiefly through the courtesy of wholesale houses, to the care of the local secretary, who will forward them to the members. The local secretaries are those gentlemen who formerly were local treasurers, and who have done so much to promote the success of the Conference. They have been relieved of the labour of collecting subscriptions by the appointment of a paid assistant to the London Secretary, and by the necessity, in view of the issue of the Year-Book, of direct relations being established between the financial officer and each member. According to a regulation of the committee, the work is to be supplied only to members who have paid the annual subscription. Considering the resources of the Conference, this rule is clearly indispensable.

We hope that the Executive of the British Pharmaceutical Conference will have the active assistance of every person who desires the well-being of Pharmacy, in their efforts to supply a want long felt in this country, and in which England stands almost alone, namely, the annual issue of such a Year-Book.

THE CHEMISTS' BALL.

THIS annual gathering, which resembles in its pleasant associations the meetings of the British Pharmaceutical Conference, is announced to take place on Wednesday, the 25th of January. The list of stewards, growing year by year, presents on this occasion a most imposing array of well-known names, and includes among others the President, Vice-President, Treasurer and Professors of the Pharmaceutical Society, a sufficient testimony to the propriety and good taste which have characterized all previous *réunions*, and a guarantee of the success of this year's assembly. The Committee are exerting themselves most laudably in making the necessary arrangements, and the LORD MAYOR, himself a druggist, has consented to be Patron. Tickets, Lady's, 10*s.* 6*d.*; Gentleman's, 17*s.* 6*d.*, including supper, wine and refreshments, may be obtained of any member of the Committee, of Mr. THOMAS BILLING, Hon. Treasurer, 143, New Bond Street, W., and Mr. T. D. WATSON, Hon. Sec., 46, Halton Road, Canonbury Square, N.

SALE OF POISONS ACT IN IRELAND.

THE first case of prosecution under this Act seems to have taken place in Galway, in connection with the death of a Mr. HOLTON. From the *Daily Express* correspondent, it would seem that the magistrates of the Galway Petty Session inflicted penalties in two cases.

Messrs. STAUNTON and M'SWINEY, two well-known and respectable apothecaries, were each separately summoned for selling poison without registering it in a book which should have been kept for this purpose. The occurrence which was the occasion of these summonses, was one in which a rich farmer of Galway, named HOLTON, having had some family misunderstanding, purchased poison from the apothecaries above named, and having drunk it, was found dead next day.* The police under the direction of F. W. CULLEN, Sub-inspector, issued summonses, and the defendants were each fined 5*s.* and costs. Mr. GREEN, one of the magistrates present, expressed his opinion that a heavier penalty should be imposed.

POOR-LAW UNIONS APOTHECARY FOR IRELAND.

IT is not the intention of the Poor-Law Commissioners to proceed with the Union Apothecary Order in its present shape. This is due to the opposition of about one-third of the Guardians. Of the 163 unions in Ireland, 45, including the North Dublin, South Dublin, Cork and Belfast, had passed resolutions adverse to the arrangement proposed; nearly the same number had expressed themselves in favour of it, and the remainder had accepted it without expressing any opinion.

* See *ante*, p. 514.

It had been suggested that the limitation requiring the qualification of an apothecary in the manager of the general depot was unnecessary, and had the effect of excluding eminently qualified individuals from competition. The general feeling is, that such a man should be an analytical chemist of position, possessing a thorough knowledge of the manufacturing and manipulating of drugs and chemicals.

The Commissioners have stated that they intend producing another scheme, as every one has acknowledged the desirability of some action being taken in this matter.

MEDICINES FOR THE IRISH UNIONS.

The following is the text of the letter issued by the Poor Law Commissioners of Ireland, revoking their previous sealed order for the appointment of an Apothecary-General to the Poor Law Unions of Ireland, in whose hands were to be concentrated the whole of the contracts for drugs and medical necessaries throughout Ireland:—

"POOR LAW UNIONS APOTHECARY.

"Poor Law Commission Office, Dublin,
"*5th January*, 1871.

"Sir,—Adverting to their recent order for the appointment of a poor law unions apothecary, the Commissioners for Administering the Laws for Relief of the Poor in Ireland desire to inform the guardians that the time having now arrived for taking the first steps in execution of the order, they have determined not to proceed with it in its present shape. So much complaint has been made of the quality of the medicines supplied for use in workhouses and dispensaries that the Commissioners anticipated a general acquiescence on the parts of the Boards of Guardians in the adoption of an arrangement which appeared eminently calculated to secure good and reliable medicines in future for the treatment of the sick poor. Of the 163 unions in Ireland, however, 45, including North Dublin, South Dublin, Cork, and Belfast, have passed resolutions adverse to the arrangement proposed, nearly the same number have expressed themselves in favour of it, and the remainder have accepted it without expressing any opinion. Under these circumstances it is not the intention of the Commissioners to force the adoption of this arrangement upon so many unions adverse to the principle involved. Suggestions have been made which, in the event of their issuing an amended order, it will be the duty of the Commissioners in the meantime to consider. For example, the mode of appointment laid down in the order is objected to, and a competitive examination of candidates suggested instead; but in the present state of the law the Commissioners do not feel themselves to be authorized to withdraw the direct appointment from the Boards of Guardians of the unions united for that purpose, though possibly some different mode of making it may be adopted. It has also been suggested that the limitation requiring the qualification of 'apothecary' in the manager of the general depot was unnecessary, and had the effect of excluding eminently qualified individuals from competition; this point will also receive attention in the preparation of any amended order. The application of the co-operative principle to the poor law unions which would have been effected by this order in regard to drugs was probably not contemplated in the Irish Poor Law Act of 1838; and although that Act contains powers enabling Boards of Guardians to purchase supplies in common, and to appoint a common officer for the purpose, it may be found desirable to bring the subject under the consideration of Parliament before any further steps are taken.

"By order of the Commissioners.
"B. Banks, Chief Clerk.

"To the Clerk of each Union."

It will be observed that the withdrawal is not unconditional, and it has been resolved by the guardians to appoint a "Vigilance Committee" to watch whatever steps the Commissioners may take in the matter, whether by sealed orders or seeking additional legislation. It seems to be the intention of the Commissioners to lay the future appointment (probably inspectional) open to analytical chemists and pharmacists of repute.

The executor of the late Mr. Cole, of Hampstead, has written to say that it will be his duty to pay over to the Benevolent Fund of the Pharmaceutical Society a bequest of nineteen guineas out of that gentleman's estate.

It will be seen by reference to page 571 that Mr. John Carr, of 171, High Holborn, has been chosen by the Council to fill the vacancy caused by the resignation of Mr. Cornelius Hanbury.

The necessity of examining drugs supplied to workhouse dispensaries is illustrated by Dr. Leeper, of Keady, who states that he has been supplied with train-oil for cod-liver oil; opium so impure as to be almost useless; muriated tincture of iron unfit for use; spirits of wine, which should be 56 over-proof, not quite 10 over-proof; tinctures which mouldered, and ointments unfit for use. The *British Medical Journal*, after the above statement, adds, "There is at present no inspection in England any more than in Ireland, and it will be eminently necessary to provide it in the new metropolitan dispensaries. We suggest this subject to the attention of the Poor Law Board."

The third volume of the *Chicago Pharmacist* having been completed, it is announced that an alteration will be effected in its future appearance, by the use of "solid" instead of "leaded" type, and the omission of the "prices current." It is calculated that these changes will give room for about one-third more matter, without increasing the size of the Journal.

We are glad to notice that the suggestion that a hyphen should be used to separate the syllables in the name of the new disinfectant, Chlor-alum, was adopted last week in the columns of the *Lancet*.

We learn from *Nature* that the cultivation of cinchona has so fully succeeded in the Neilgherry hills, in India, that the first shipment of bark from a private plantation, to the extent of 4000 lb., is taking place.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

January 4th, 1871.

MR. SANDFORD, PRESIDENT, IN THE CHAIR.

MR. HASELDEN, VICE-PRESIDENT.

Present—Messrs. Bourdas, Dymond, Evans, Hills, Savage and Williams.

The minutes of the last meeting were read and confirmed.

The President reported that arrangements had been made with Dr. Carpenter for the delivery of two lectures on the Microscope and its Revelations, on Wednesday, the 1st February, and Wednesday, the 1st March, instead of the usual evening discussions on those dates.

Mr. Cornelius Hanbury's Successor.

Resolved unanimously—That Mr. John Carr, of 171, High Holborn, be elected a Member of this Council, in place of Mr. Hanbury resigned.

The following letter having been read:—

"14, *George Street, Croydon, January 2nd*, 1870.

"Sir,—Mr. Charles Coles, late of 1, King's College Road, South Hampstead, deceased, by his will, left a legacy of £19. 19*s*. to the Benevolent Fund of the Pharmaceutical Society of Great Britain. I am the acting executor under his will; as soon as I have realized the estate, I shall have pleasure in sending you a cheque for the amount.

"Yours faithfully,
"Wm. F. Coles.

"*To* E. Bremridge, Esq."

It was resolved—That this Council desire to express their condolence with the relatives of the late Mr. Charles Coles, of Hampstead, who was for many years an active member of the Society, and wish at the same time to acknowledge the receipt of his executor's letter announcing a legacy of nineteen guineas bequeathed by him to the Benevolent Fund.

The following letter was also read:—

"*Liverpool, 21st December*, 1870.

"My dear Sir,—In compliance with a resolution of the Local Committee of the Pharmaceutical Conference, recently held in Liverpool, I have the pleasure of forwarding to you a cheque for twenty guineas (being a portion of the surplus of the Local Fund remaining over and above the expenses incurred), to be applied to the Benevolent Fund of the Pharmaceutical Society.

"Yours faithfully,
"John Shaw,
"*Treasurer*.

"*To* E. Bremridge, Esq., *Secretary, Pharmaceutical Society, London*."

Resolved—That the best thanks of the Council are due and hereby tendered to the Local Committee at Liverpool of the British Pharmaceutical Conference for 1870, for their donation of twenty guineas to the Benevolent Fund of this Society.

The Report and recommendations of the Finance Committee were received and adopted.

Resolved—That the Report and recommendations of the Parliamentary Committee be received and adopted.

Resolved—That the Registrar be directed, and is hereby authorized, to erase from the Register of Chemists and Druggists the name of Edward Moore, of Chippenham.

Resolved—That the Registrar be requested to give the Society's Solicitors the necessary instructions to proceed against Edward Charles Whisken, of Welshpool, for continuing to use the title of Chemist and Druggist, and retail poisons, his name having been erased from the Register.

The Report of the Library, Museum and Laboratory Committee was read and received.

The following letter was read:—

[Copy.]

"*Medical Department of the Privy Council Office*,
"*23rd December*, 1870.

"Sir,—I am directed by my Lords of her Majesty's Council to request that you will call the attention of your Council to the power which is, by the Pharmacy Act, 1868, given to the Pharmaceutical Society to make, with the consent of the Privy Council, regulations as to the keeping, dispensing, and selling of poisons.

"My Lords believe it to have been the opinion of Parliament that proper regulations in this matter are required for the protection of the public, and, as more than two years have elapsed since the passing of the Act without the Pharmaceutical Society having proposed any such regulations, my Lords think it right to inquire whether the Pharmaceutical Society intends, within any time you can specify, to propose such regulations to their Lordships. They direct me, therefore, to request that you will have the goodness to give me, at your earliest convenience, the information required by their Lordships.

"I am, Sir,
"Your obedient servant,
"John Simon.

"*The Registrar, Pharmaceutical Society*."

Resolved—That the letter from the Medical Officer of the Privy Council, addressed to the Registrar respecting the storing of poisons, be received and entered on the Minutes, with the Registrar's reply thereto.

REPORT OF THE BOARD OF EXAMINERS.

December, 1870.

England and Wales.

	Candidates examined.	Candidates passed.	Candidates failed.
December 21, Major	10	7	3
" " Minor	10	10	0
" 23, "	23	18	5
	43	35	8

Preliminary Examination.—1 Certificate approved.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be respectively granted a Diploma stamped with the seal of the Society:—

Chase, Thomas, jun. ....London.
Clark, Walter Beales ....Leicester.
Cross, William Gowen........Shrewsbury.
Griffin, Thomas ....Bromley.
Haydon, William Frederic....Blandford.
Ingham, John ....Upper Tooting.
Mason, Philip Henry ....Norwich.
Metcalfe, Edmund Henry ....Richmond.
Paton, James................Edinburgh.
Pick, Richard ....Hull.
Robinson, James ....Darlington.
Skipper, Edward ....London.
Taylor, John William........Great Grimsby.
Thompson, John Thomas ....Richmond.
Young, Joseph ....Leicester.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be elected Members:—

Barton, Henry	St. Ives.
Chase, Thomas, jun.	London.
Clarke, Walter Beales	Leicester.
Conder, George	London.
Ingham, John	Upper Tooting.
Jones, Hugh Lloyd	Victoria, British Columbia.
Machin, Frederick John	Huyton.
Manby, Walter Edward	Southampton.
Metcalfe, Edmund Henry	Richmond.
Moss, John	London.
Pick, Richard	Northallerton.
Pilley, Henry Thomas	Boston.
Strickland, George Hodgson	Yarm.
Thompson, John Thomas	Richmond.
Webb, Edward Alfred	Redstone Manor, Redhill.

Resolved—That the following registered Chemists and Druggists be elected Members of the Society:—

TOWN.	NAME.
Barnsley	Billington, Frederick.
Barrow-in-Furness	Sansom, Edwin.
Bettws-y-Coed	Jones, Owen Lloyd.
Bridport	Coppock, Henry Jones.
Brighton	Leech, William.
Bristol	Townsend, Charles.
Evesham	Pumphrey, John.
Hawkhurst	Stainburn, Joseph.
Ilford	Beal, Edmund John.
Largs	Fraser, Alexander.
Leeds	Exley, George.
Newcastle-on-Tyne	Welch, Thomas.
Portsea	Liddiard, William.
Shildon	Veitch, Thomas D.
Swansea	Layng, Thomas B.
Tonbridge	Gower, Alfred.
Usk	Jones, David Lewis.

Resolved—That the following, having passed their respective examinations, be elected "Associates in business":—

MINOR.

Durrant, George Reynolds	Hertford.
Fisher, Richard	Preston.
Keightley, Joseph	Tunstall.

MODIFIED.

Foulds, Astley Cooper	Nuneaton.
Frobisher, Frederick	Birmingham.
Graham, Monkhouse	Middlesborough-on-Tees.
Herron, Archibald James	Margate.
Lucas, William	Manchester.
Moody, Alfred	Landport.
Pattinson, Michael Hind	Carlisle.
Rees, David	Llanidloes.
Williams, John	Birmingham.
Williams, William	Llanfyllin.

Resolved—That the following, having passed their respective examinations, be elected Associates:—

MINOR.

Blyton, John	Liverpool.
Collishaw, John	Nottingham.
Brewis, Thomas	Rothbury.
Darby, Samuel Aldred	Reading.
David, John	Newport, Mon.
Dawson, William Powell	Horncastle.
Field, Charles	Netley.
Fowler, William Ratcliffe	Ipswich.
Rieveley, Charles	Birkenhead.
Skinner, Kenneth G. W.	Christchurch.
Stoakes, Benjamin Maidens	Boston.
Sweetman, Robert	Warwick.

MODIFIED.

Allsop, George Walter	Birmingham.
Argue, James	Yeovil.
Biggleston, Edwin Radford	Exeter.
Bond, Edward	Reading.
Bond, John	Okehampton.
Chapman, Josiah Thomas	Hulme.
Clement, John Radford	Ashton-under-Lyne.
Day, John Charles Thomas	Clifton.
Harvey, Henry	Wakefield.
Owen, Robert Henry	Rhyl.
Passingham, George William	London.
Philpots, George Payne	Leyton Green.
Pratt, Thomas Henry	Newbury.
Richardson, Alexander	London.
Simms, Robert John	Burnham.
Snell, Charles Henry	Plymouth.
Wavell, Edward	London.
Wigginton, Henry Beecher	Liverpool.
Wilson, Clement Fisher	Bury.

The following were appointed Local Secretaries to the Society:—

Bideford	Thomas Hogg.
Belfast	Oswald A. Reade.
Frome	Wm. B. Harvey.

Resolved—That Mr. L. S. Hughes be re-appointed Collector for London and suburbs for the ensuing year.

A member having paid the arrears of his subscription, together with the usual fine imposed, was restored to Membership.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The Second General Meeting of this Society was held on Friday evening, Nov. 11th; the President, Mr. Atherton, in the chair.

Various donations to the Library and Museum were announced and a vote of thanks recorded to the respective donors.

Five new Associates were proposed, after which Mr. Mayfield read his Introductory Address to the students of the Pharmacy and Materia Medica Class.

The Third General Meeting of the Association was held in the rooms of the Society on Friday evening, the 16th Dec., the chair being filled by Mr. Fitz Hugh, the Vice-President.

Members only were invited, many of whom were present. The election of the five candidates proposed at the last meeting was unanimously carried.

Mr. W. H. Parker proposed certain suggestions for the immediate formation of a museum, which was at once agreed to by the following gentleman undertaking to supply specimens as under:—

Barks	Mr. Fitz Hugh.
Seeds and Fruits	„ W. H. Parker.
Leaves	„ White.
Gums and Gum Resins	„ Mayfield.
Some dried specimens	„ J. S. Jenkins.

Afterwards Mr. Potts exhibited and explained various pharmaceutical novelties.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Third ordinary Monthly Meeting of the Session was held in the Memorial Hall, Albert Square, on Friday evening, January 6th. Tea was served at seven o'clock, after which the chair was taken by Mr. W. S. Brown, the President.

The following donations were acknowledged:—The *Pharmaceutical Journal*, weekly, from the Society; the *Pharmacist*, from the Chicago College of Pharmacy, U.S.; Dr. Thorpe's 'Chemical Problems,' from the Author.

Mr. Louis Siebold, Lecturer on Pharmacy in Owens College, then delivered an interesting address on the subject of "Pharmaceutical Examinations." A resolution was afterwards passed, requesting Mr. Siebold to prepare his lecture for publication in a substantial form.

A paper by Mr. Hampson "On the Importance of some Knowledge of Anatomy and Physiology to the Pharmacist," was announced for the February Meeting.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

On Fermentation.

BY PROFESSOR A. W. WILLIAMSON, F.R.S.

Lecture IV.—continued.

In the process of making wine, there are a considerable number of operations which are occasionally considered rather extraneous to normal wine-making, and are by many persons classed amongst frauds. Materials are sometimes used in aid of the natural constituents of the grape-juice, materials which contribute to the quality of the product; some of them by adding materials to it, but others simply removing from the substances bodies which are not wanted in it. And I must say that it does appear to me a great error to object to the introduction of any new conditions which may be found to effect an improvement in the product. I do not think it is reasonable to suppose, because wine is only known by the vulgar as fermented grape-juice, that for that reason nothing but grape-juice ought ever to be used in the manufacture. I think it would be desirable—in fact, it ought to be almost compulsory—that persons should state what materials are present in substances which they sell to the public; but, I think, with that safeguard, it would be right to leave manufacturers perfectly free to employ whatever materials they might find most conducive to the elaboration of their products. In some countries, grape-juice is exceedingly rich in acid and poor in sugar (and I think a good deal of wine is rather of that class), and wine-makers in such districts find that their stuff is more drinkable if some of the acid present in it can be removed before it is sent out. They therefore put into the must, in fermenting the wine, some chalk, and the lime which is present in the chalk combines with the tartaric acid and takes it out of the liquid. Thus, the sour liquid is rendered less sour, and certainly that is not, in any degree, or to any extent whatever, a fraudulent admixture. Nothing is added, but only an unpleasant substance is taken from it. It also happens in precisely the same districts, that from the paucity of sugar which is present in the grape-juice, the wine is too weak in alcohol; and that to meet the requirements of consumers, many wine-makers now add sugar in the process. Now sugar is one of the natural and proper constituents of grape-juice, and if the grapes contain too little of it, it does seem quite proper and desirable that more should be added. However, in the subsequent making of wine, there are several other processes which are less natural than these, and about which some greater difference of opinion may possibly prevail; and one of the commonest, not only amongst wine-makers, but also amongst wine-consumers, is the process of fining. In order to establish the effect and the meaning of this process, I think we must trace back the history of wine from the time in which it is first put into casks by those who produce it to the time at which it gets into the hands of consumers. It is customary—I cannot say whether it is universal or not, but I believe it to be so almost—to put new wine into new casks; and in the better districts oak casks are used. New wood is far more porous than old wood when used for such a purpose; and of course the wine, when put into the cask, sinks into the wood, so that the outer surface is moistened, and allows some of the water and alcohol, and the various volatile materials to evaporate. In fact, the wine diminishes during the first year of keeping in wood very rapidly, by a process of evaporation. But this is not all. Whilst the water and alcohols are evaporating from the outer surface, air is dissolved by the liquid which is in the wood. Air actually diffuses itself through the wet wood into the body of the wine in the cask; and what is more than this, the water and alcohol which go out are replaced by something. The cask does not collapse, nor is there a vacuum produced above the liquid. The wood is always sufficiently leaky for air to come into it, and there is always a space left above the wine. Wine-makers are, therefore, in the habit of filling up their wine-casks periodically. In some districts in France, they are filled up in the first year three times, at three different periods; and, in the second year, they are filled up only twice, but only at perfectly definite periods or seasons, which have been found, for those particular wines, to be most advantageous. But each time the wine, if examined carefully, is found to have undergone, not only what we chemists should call a process of concentration, the solid substances dissolved in the liquid of course always remaining behind, the proportion of liquid being diminished, but, at the same time, it has undergone other changes, that is, there is a deposit formed from it. Some of the bodies present in it, either by themselves or by forming compounds with others added to them, form a sediment, and in the wine-growing districts it is customary, and I have no doubt necessary, to decant the wine and pour it off carefully from the deposit many times, for the presence of the deposit, if continued in the wine, would be injurious to the future changes which it has to undergo. When this comes into the hands of the consumer, there is suspended in the substance of the wine some of this deposit,—some solid particles which might be got to settle down, but which could not easily be removed completely by any process of mere subsidence, and the processes of fining, which are exceedingly various, have for their object the more complete removal of these solid particles by forming compounds with them. In some cases, the process consists in forming what I might call a sort of mordant, or something like a process of dyeing, in which a gelatinous compound is formed in the body of the liquid, which carries down with it a good deal of colouring matter, which it encloses, and which does, while going down, take with it a number of little filaments and cells which were floating in the liquid, and which were so exceedingly light that they would not have settled and could not have been removed otherwise. This point is particularly important in relation to a process which I shall presently mention. In some cases, it has been thought the wine contained too much albuminous matter. The theory of fermentation which was held for a long time, and which we considered at one of our previous meetings, consisted in attributing the process to the decomposition of the albuminous matter which is present in the fermenting liquid. It was supposed that there was too much of this albuminous matter present, and that it remained and was inclined to do further work. One process which has been adopted to a considerable extent in the champagne districts, where that was supposed to occur, consisted in adding tannin, a substance which I have already spoken of, which carries down a good many albuminous bodies, forming a precipitate with them, and with these no doubt carries down the solids which may be in suspension. Then another process, which really bears a considerable resemblance to this one in principle, although not in form, is that of sulphuring, using sulphur in the casks, which, of course, you would understand at once, exerts an antiseptic action. It is, in fact, a process which consists in producing a material which is, in plain English, a poison to any germs which may happen to be present, whose action must consist, as far as it goes, in arresting the vitality,—in stopping any work which they were doing. M. Berthelot, who has made many accurate experiments regarding the composition of wine and the changes which it undergoes, subjected some wine to the action of a known quantity of air, and by examining the wine afterwards he was led to the conclusion that air is an unmixed evil to wine when once it is fully made. There are certainly many general observations which everybody must have had occasion to make which agree with that. If we open a bottle of wine and use half of it, especially if we leave a bottle of light wine open for some little time, everybody knows that it deteriorates in quality, and becomes flat, or even sour. In a great many cases, it is found that there is a development on the surface of the wine, and if you were to examine it carefully you would easily see, especially in light French or German wines, a pellicle—in fact, the vinegar cells; and their presence must have the effect of promoting the oxidation of the wine. M. Berthelot's experiments confirm the general observation, which everybody makes more or less definitely, that air is noxious to wine when present in any quantity. But M. Pasteur has arrived at precisely the opposite result. I do not mean to say that he says air cannot do harm, but that what is hurtful in air is the excess of it, or the too rapid rate of its action. He lays down the principle that every ripening of wine, or the process by which young and crude wine is changed into good old wine, consists in a process of slow oxidation; that is its very essence, and that without that, a crude young wine cannot be mellowed or transformed into a good old wine. The evidence which he gives for his conclusion is exceedingly simple, and I must say it appears to me exceedingly conclusive. He has, for the purpose of keeping wine with air, and for the purpose of keeping it without air, resorted to appliances which are far more effectual than those generally resorted to in common life. You may be aware that a cork, even what we should consider a good cork, does not completely prevent the communication of external air with liquids in a bottle. I do not suppose many people can know how much air passes in and through a cork, but the quantity is very great. M. Pasteur sealed up some young green wine, by putting it into a glass vessel, and then he melted up the neck, so that he had no air present with it. He then kept it for a considerable time, and he found that this wine, even after years' keeping, was as green and as young as at first; that wine kept under conditions such as that air could have no access to it did not undergo, to any extent, the change which was wanting, and that it did not improve by keeping. He then sealed up, in a similar vessel, some wine with air, and he subjected the wine, with a known quantity of air, to various influences which were calculated to accelerate the action of the air upon it, and amongst these I ought specially to mention that of light. He took some small vessels made of perfectly clear glass, and sealed up his wine, various qualities of it, in these little vessels with air, and then exposed them to the sunshine in the south of France. He found that the oxygen of the air was totally dissolved, and that, when he examined the air, the oxygen had gone, but he found that his wine then did pass over rapidly into a state exceedingly like that into which it passes by the ordinary process of keeping in bottle. It lost its harshness, and became like old wine, which it resembled very greatly in its quality, and also in its composition the older kind of wines. At the same time, he found that there was formed in such quality of wine a considerable amount of deposit, and his explanation of the way in which oxygen acts so as to improve the quality of the wine, is this, that it serves gradually to take away from the wine various substances which are present in it, and that the deposit is due to an oxidation of the colouring matters present, which have an unpleasant, astringent, harsh taste, and it also consists in acting upon the alcohol of the wine and upon the various organic liquids in it in a similar manner. This result is certainly one of very great importance; for if the process of improving wine requires the action of oxygen, and if, on the other hand, the action of oxygen may do much harm,—I mean if all the good has to come from the oxygen, and if all the worst evils come from oxygen,—and that really is the position in which the question stands upon our present evidence, it must be of the greatest importance to ascertain what are the conditions under which the beneficial action can be exercised, and what are those under which its detrimental influence occurs. In that respect, both of the observers I have mentioned, and others also, have established some remarkable facts, but in order to appreciate them duly, it will be necessary for you to know something of the general character of compounds to which I must now make allusion. When we were examining the process of oxidation, I spoke to you of alcohol as a substance eminently capable of undergoing oxidation, and showed you how readily it could be burnt to a much smaller extent than that to which we are in the habit of burning it. I had to mention ordinary acetic acid as being a product of a shorter combustion. Here is a vinegar-plant which is oxidizing under alcohol, and there is an intermediate body which I have not yet spoken to you about specially. Here in this, I have some of it dissolved in alcohol. It is a substance which, in the strong state in which I have it here, has rather a sickly odour, and it was named by Liebig, to whom we owe some of the first and most accurate facts in relation to it, aldehyde, a name serving to recall one of the most important facts about it, viz. that it is alcohol from which hydrogen has been taken away. If you were to take away from alcohol some of its hydrogen, you would have aldehyde,—it is alcohol minus one-third of hydrogen, and it is, therefore, alcohol de-hydrogenized, and that is the origin of the term. When wines are undergoing very slow oxidation, it appears that aldehyde and other bodies analogous to it are formed. A great deal of evidence has been adduced of this, but I ought to mention that as yet one link in the chain of evidence is wanting, which chemists are always anxious to get in proof of their conclusions, that is, the substance itself, in a pure state, has not been obtained from wine. Still, the proof is so far conclusive that we are prepared to admit it provisionally. One fact which I mentioned to you just now is very remarkable, as part of the evidence, viz. that wines which are particularly good, either by keeping or by their own composition, combine with oxygen which is dissolved in them. Now, aldehyde is particularly greedy of oxygen. If you were to dissolve in the aldehyde in this bottle some air, and if you were to try to get the air out of the alcohol again, you would find that you could get the nitrogen of the air out again completely if you went properly to work, but you could not get the oxygen out. The oxygen is laid hold of and digested so rapidly by the aldehyde that it is no longer to be recovered, after even a very short interval of time.

I might show you one case of the avidity with which this aldehyde absorbs oxygen. On putting into a glass a solution of nitrate of silver, and then adding a little ammonia, we should find, on pouring into it a little of this aldehyde dissolved in oxygen, there would be a deposit of metallic silver around the inside of the glass. This is a very common and easy way of ascertaining whether in a mixture any body of this class is present. The ammonia liberates the oxide of silver from the nitrate, and the aldehyde acts by taking away the oxygen and precipitating the silver, and in this way we get evidence of the greediness with which aldehyde takes up oxygen. There are several other interesting reactions of this aldehyde, and amongst them I ought specially to mention one which was discovered some few years ago by some very distinguished Itatian chemists, the action of which is most exact and clear for removing aldehydes from any substance in which they are present; that is, their combination with alkaline bisulphites. This common aldehyde, and every body of the same class, combines with bisulphite, and forms very definite crystalline compounds, by which they are very easily detected and removed.

When we oxidize alcohol very slowly and gradually, we are able to get aldehyde formed from it; and, in the ordinary process of keeping wine, when it undergoes that slow oxidization which Pasteur affirms to be the proper process, aldehydes are proved to be present in it; but, together with them, there are a considerable number of other bodies, which we are in the habit of calling ethers. I have spoken to you already about some ethers; for instance, the compound which sulphuric acid forms with alcohol, that is a kind of ether, although it is not one of the bodies we are commonly in the habit of so describing. Ethers represent a class of bodies which are certainly amongst the most pleasant of chemistry. I have a good many here; one is the commonest of all; it is the ether which is, I believe, present, to judge by the flavour at any rate, in the celebrated *Lachryma Christi*. It is a body which I might describe as a salt. It is a salt formed whenever hydric acetate, the hydrogen salt of acetic acid, is present for a sufficiently long time in alcohol. Whilst the alcohol of the wine is becoming oxidized, and whilst aldehydes are being formed from it, there is also formed some acetic acid, and also probably some valerianic acid, butyric acid and others analogous, which are formed by the oxidation of the bodies present with the alcohol. All these acids, while undergoing the process by which they are formed, combine with the alcohol and bodies like it and form these ethers; and it has been already shown that, at all events, in some cases the aroma of the wine is dependent upon the presence of bodies of this kind. One of the most remarkable processes of manufacture of bodies of the kind which has been successfully performed of late, is the process of preparing artificial ether, for the purpose of imparting to alcoholic liquids the same flavour, aroma, or bouquet which they are found to possess when made from the same natural substance; for instance, oil of brandy is got from the skins and seeds of the grape which are left when the grape-juice has been pressed out. They are fermented, and a quantity of alcohol and aromatic substances are formed by the fermentation, and this forms the so-called oil of brandy, which is used for making brandy artificially; that is, common corn spirit is flavoured with it, and sold as genuine cognac. In like manner, various kinds of these acids have been made, and there is now in Germany a manufactory for making butyric acid on a large scale from sugar; it is then made into this ether, which is a very fragrant substance, and then in small quantities it is used for flavouring various alcoholic liquids, in imitation of natural products which naturally would possess the same substance or a similar one in them.

(*To be continued.*)

MEETINGS FOR THE ENSUING WEEK.

MONDAY ......*Medical Society*, at 9 P.M.
WEDNESDAY...*Society of Arts*, at 8 P.M.—"How Meat is Preserved." By R. Jones.
THURSDAY ...*Royal Society*, at 8.30 P.M.
Linnean Society, at 8 P.M.
Chemical Society, at 8 P.M.
Royal Institution, at 8 P.M.—Lecture by Dr. Odling.

Parliamentary and Law Proceedings.

SUPPOSED MISTAKE.

At an inquest upon the body of Bartholomew Hodgkinson, a joiner, living at Preston, a certain amount of doubt arose as to the composition of a pill that had been administered to him.

The wife stated that deceased had met with an accident while at his work by which his leg was broken. Mr. Lund, of Manchester, attended him but prescribed no medicine. The only medicine he took was prescribed by Dr. Haldan. On the night before his death he took a pill and went to sleep and never woke afterwards.

Dr. Haldan said that he attended the deceased, who was suffering from a compound fracture of the leg. He considered it a case of very great danger. At the end of a fortnight the pulse had risen to 144. On the suggestion of Dr. Spence a pill was given to the deceased, containing sulphate of quinine. Twelve pills were ordered, one to be given every four hours. He died the next morning, but the pill could not have had any effect one way or the other.

Thomas Sharples, assistant to Dr. Haldan, said that the pills were made, according to the prescription, of quinine and extract of gentian. There was about a grain and a third of quinine in each pill.

A juryman said it would be advisable to have the pills analysed.

The coroner said that he should not like to incur the expense of an analysis unless they thought one essentially necessary.

A juryman said that although he had not the least doubt of the doctor's fidelity, he thought that the pills might have been mixed improperly but at the same time not purposely.

At first there were eight jurymen in favour of an analysis to four against, but after considerable discussion a verdict was returned to the effect that the death had been caused by the accident.—*The Preston Herald.*

POISONOUS CONFECTIONERY.

Several traders have been brought up at the Southern Divisional Court, Dublin, on a charge of having used poisonous ingredients in the preparation of various sweetmeats. Sugarsticks of a yellow colour were found to contain chromate of lead; lozenges were coloured with vermilion (bisulphide of mercury), and other articles were adulterated with from 10 to 12 per cent. of *terra alba*, a form of fuller's earth, most injurious to children. Dr. Cameron, the city analyst, who had experimented on the different articles mentioned, suggested the employment of saffron and cochineal, both harmless substances, instead of the hurtful chrome and vermilion. The traders were fined, and had to pay all costs.—*Medical Times and Gazette.*

Lead Poisoning.—The fact that metallic ice-pitchers corrode very rapidly, especially the solder of the joints, having been noticed by Mr. S. Dana Hayes, of Massachusetts, he was induced to investigate the cause, when he found that such corrosion was due to the action of alkalies upon the sides of the vessel,—generally made of Britannia metal, German silver and copper,—by which a galvanic action was set up and the lead in the solder decomposed.—*American Chemist.*

Reviews.

INTRODUCTION TO THE STUDY OF INORGANIC CHEMISTRY. By WILLIAM ALLEN MILLER, M.D., D.C.L. Longmans, Green and Co. 1871.

A LABORATORY TEXT-BOOK OF PRACTICAL CHEMISTRY. By WILLIAM G. VALENTIN, F.C.S. John Churchill and Sons. 1871.

We are really gratified in being able to announce and welcome these two books. They come to us most opportunely, for they fulfil, almost as perfectly as if they had been compiled in that design, the desire which we have already expressed in the columns of this Journal. It has often appeared to us that the usual text-books set before young students of chemistry introduce far too much of technicality into their language and mode of handling the subject at the commencement; a character more progressive seemed to us desirable. The little introductory treatise now before us, the work of the late much-lamented Professor Miller, relieves us of a difficulty we have often been placed in when requested to recommend an elementary book. The opening chapter, describing the scope and aim of chemistry, is very good; but our readers will gain a better idea of the style and plan of the work from the following extracts out of the short preface, than from a description of our own:—

"This book is written expressly for beginners. In order that they should really understand the statements which it contains, it will be necessary for them to begin at the beginning, and to go straight through it. Among other reasons for adopting this course, it is to be noted that it is impossible to avoid the use of technical terms in discussing a scientific subject; since we often have to deal with matters for which no expressions are in use in ordinary language.

"The student is strongly advised never to omit the performance of any experiment which he has the means of making. No useful knowledge of chemistry can be acquired by any one unless he constantly makes experiments as he proceeds with the study."

In this last remark we concur heartily. In order to indicate the methods adopted, detailed directions for upwards of two hundred and fifty experiments, mostly of a simple nature, are dispersed through the book; but of course an intelligent lad, as he makes progress, will devise many others for himself.

It is a question which may occur to some people, whether it is advisable to commence so early the employment of chemical notation. We are, however, of opinion that it is decidedly an advantage to use it, in a simple form, from the very first; by doing so, the precision which ought to characterize all scientific work is constantly impressed upon the mind.

To render it complete, there should have been added at the end of each chapter a series of questions. We hope this will be thought of in a future edition.

We have much pleasure in cordially commending this little volume to all who desire to acquire a solid groundwork of general principles.

Those who wish to go a step further, and not only to master the fundamental principles, but to gain also an acquaintance with some of the details of laboratory practice, will do well to choose Mr. Valentin's 'Text-Book' as their guide. It forms a fitting sequel to that of Professor Miller. The idea upon which it is based is the same. The arrangement of the book, too, is similar; but the student is led further. He is taught, not only to make experiments, but to draw from them correct inferences; and from the facts which he thus learns, and the conclusions flowing from them, he is introduced to theory.

Mr. Valentin, of course, makes exclusive use of the system of notation introduced by Dr. Frankland and founded upon the notion of quantivalence or atomicity. This system is easily intelligible. The atom of any given element is found by experiment to be capable of combining with a certain number of atoms of hydrogen or of any other element, chlorine for instance, which can replace hydrogen atom for atom. Although this number is apparently variable for almost all the elements, yet in each case there is a maximum point at which the atom which forms, as it were, the nucleus, is *saturated*. Thus oxygen is certainly a *dyad*, because it combines with either two atoms of hydrogen, or with one of hydrogen and one of the *monad* potassium, or with two atoms of potassium. In caustic potash the hydrogen and potassium are held together by the intervention of the oxygen. The potassium and hydrogen alone have no power to unite. In water the two atoms of hydrogen are linked by the same agency. When such an atom as that of oxygen, which is multivalent, is supplied with a number of monad or univalent atoms or their representatives, which are insufficient to satisfy its combining capacities, the resulting group is unsaturated. It has a tendency to combine with other bodies which may complete its saturation. Thus although ammonia, NH_3, is capable of existing alone, it nevertheless has a tendency to combine with hydrochloric acid or some other body which is capable of completing the molecule. This is explained by saying that nitrogen is quinquevalent, and therefore is not satisfied with three atoms of hydrogen. Dr. Frankland distinguishes by thick type, the element which in any compound possesses the greatest number of what he calls bonds, that is, units of combining power. This same element is also, as a rule, placed first in the formula. Thus water is written $\mathbf{O}H_2$. Carbonic anhydride, which contains the quadrivalent element carbon, with the bivalent oxygen, is $\mathbf{C}O_2$. Trihydric phosphate, or common phosphoric acid, is, by the same rule, $\mathbf{P}O(HO)_3$ or $\mathbf{P}OHo_3$. Dr. Frankland's formulæ are therefore all constitutional formulæ, that is, they pretend to express not only the relative proportions of the elements in a compound, or even the number of atoms in the molecule of that compound, but the actual order in which its constituent parts are fitted together. Though it must be admitted there is already considerable foundation for such a system, it ought in the present unsatisfactory state of the science to be used with due caution and, we think, alternatively with one less pretentious. Whilst we fully admit the value of constitutional formulæ as helps to teaching we have no sympathy with any of the graphic systems which have been introduced, and we are glad to perceive that Mr. Valentin accords to them quite a subordinate position in his pages. We cannot help commending very highly the arrangement as well as the details of this manual, and the author's expressed desire to lead his pupils "to generalize and to systematize," seems to be very successfully carried out. In the part devoted to qualitative analysis, the methods recommended are, we believe, both practical and accurate. A number of well-devised questions follow each chapter.

In conclusion, we here record our conviction that Mr. Valentin's Text-Book is the best laboratory guide to practical chemistry at present in existence.

BOOK RECEIVED.

YEAR-BOOK OF PHARMACY: comprising Abstracts of Papers relating to Pharmacy, Materia Medica, Therapeutics and Chemistry, contributed to British and Foreign Journals, from July 1, 1869, to June 30, 1870, with the Proceedings of the British Pharmaceutical Conference at the Seventh Annual Meeting, held at Liverpool, September, 1870.

The following journals have been received:—The 'British Medical Journal,' Jan. 7; the 'Medical Times and Gazette,' Jan. 7; the 'Lancet,' Jan. 7; the 'Medical Press and Circular,' Jan. 11; 'Nature,' Jan. 5; the 'Chemical News,' Jan. 6; 'Journal of the Society of Arts,' Jan. 5; 'Gardeners' Chronicle,' Jan. 7; the 'Grocer,' Jan. 7; the 'English Mechanic,' Jan. 6; the 'Chemists and Druggists' Advocate' for December; the 'Chicago Pharmacist' for December; the 'Florist and Pomologist' for January; the 'Milk Journal' for January; the 'Journal of the London Institution' for January.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department*, 17, *Bloomsbury Square, W.C., and not to the Publishers.*

[6.]—ESSENCE OF COFFEE.—This is a highly concentrated infusion of coffee, prepared by percolation with boiling water, and then quickly evaporated to about one-third or one-fourth of its bulk. Sometimes it is mixed with a thick aqueous extract of chicory and syrup of burnt sugar, so as to give the whole the consistence of treacle. The proportions of the dry ingredients used should be—

Coffee . . . . 4 parts.
Chicory . . . . . . 2 „
Burnt Sugar . . . . 1 part.

It should be kept in well-corked bottles in a cool place.—COOLEY.

[81.]—SYRUP OF TAMARINDS.—In answer to your correspondent "*Medicus*," I beg to furnish the following recipe for a syrup of tamarinds:—

Tamarinds . . . . . . 100 parts.
Sugar . . . . 500 „
Orange-Flower Water . . 6 „

Boil the tamarinds for some time with a sufficiency of water; add the sugar to the resulting decoction, and clarify the syrup with the white of an egg. The orange-flower water should be added when the syrup is cool.—ALEMBIC.

[92.]—FLEXIBLE VARNISH.

India-rubber (cut small), 1½ oz.
Chloroform, Ether (washed), or Bisulphuret of Carbon, 1 pint.

Digest in the cold until the solution is complete. It dries as soon as it is laid on. Pure gutta-percha may be substituted for india-rubber.—X. Q. Z.

[101.]—CHERRY TOOTH-PASTE.—A very good cherry tooth-paste is made as follows. It has the advantage of not fermenting:—

R. Lap. Pumicis Levig.,
P. Iridis, ana ℥ij
P. Myrrh. ℥ss
Mellis ℥iv
Lake Liquor to colour.

When mixed, add—

Ol. Caryoph. ʒiss
Ess. Limonis ʒiss
Otto Rosæ gtt. viij. S. D.

[104.]—COUGH PILLS.

R. Antim. P. Tart. gr. iss
Ext. Hyoscy. gr. xviij
Morph. Mur. gr. ½
Pulv. Glycyr. q. s. ft. pil. xij.

Capt. j nocte maneque.—W. W.

[117.]—WATCH OIL.—Ol. Amygdal. Dulc. is the best for either purpose.—W. W.

[120.]—EMBOSSING STAMP.—*A. H. Hale* can procure the kind of Press he requires from any of my establishments.—W. MATHER.

[121.] SYRUPUS CROCI.

R. Croci Stig. ʒj
Aq. Bullient. lb. j
Sacch. Alb. lb. ij.

M. Infuse the saffron in the water for some time in a warm place, then add the sugar, and slowly simmer for a time, then strain. If to be kept, add a little S. V. R.—W. W.

[122.]—PERFUMED LIQUID AMMONIA.

R. Otto Rosæ gtt. ij
Ol. Lavand. gtt. xx
„ Verbenæ gtt. ij
„ Limonis gtt. xx
„ Caryoph.,
Ess. Moschi, ana gtt. x
„ Jasmin. gtt. vj
S. V. R. ℥ss
Liq. Amm. Fort. ℥iij. MEDICINA.

R. Ol. Lavand. Ang.,
Ess. Bergamot,
Ess. Limonis, ana ʒj
Caryophyll. ʒss
Camphor ℥ss
Ammoniated Alcohol ℥xij

M. Macerate for a week, and filter.—W. W.

R. Ess. Ambergris,
Ess. Musk, ana ℥ss
Otto of Rose ♏xx
Oil Lavend. ʒj
Ammoniated Alcohol ℥x

M., et adde—

Liq. Ammon. Fortis ℥x.—W. W.

[123.]—ARNICA CERATE.—*M. P. S.* would be glad of the proper form (if there is one) for making "Arnica Cerate."

[124.]—AFRICAN SAFFRON.—Can any one give information as to the source of the so-called African saffron?—X. Q. Z.

[125.]—SCIENTIFIC LIBRARY.—"*A Stranger*" would feel obliged to any one who could kindly inform him of a good library containing scientific and other works, and chiefly open at nights for reading.

[126.]—TEETOTALLERS' SYRUP.—Can any reader inform me what is the composition of the "syrup" used by teetotallers?—W. B.

[127.]—BURLING INK.—Can any one favour me with a recipe for "Burling" ink? It must be blue-black, and a great portion of the colouring matter in a dissolved state. Such an ink is used by clothmakers for marking any portion of cotton in the cloth that has failed to take the dye properly?—CONIA.

[128.]—AMANDINE.—*J. P.* would thank any of our readers who would furnish him with a good recipe for making amandine for whitening the hands and preserving them from chapping.

[129.]—TALCA GUM.—Will any reader kindly give me some information concerning the source from which talca gum is obtained?—STUDENT.

[130.]—GERMAN YEAST.—*G. W.* would be thankful for good directions for the manufacture of German yeast.

[131.]—MOUTH WASH.—*H. W. G.* would be thankful for a recipe for a good wash for the mouth, to be used as a remedy for soft and spongy gums.
