PROPOSED REGULATIONS FOR STORING OF POISONS.

Sir,—In the discussion on this subject several important points have not been touched upon; and, as it is now evident that the Privy Council intend something to be done, and that within a reasonable time, it would be wise on our parts to attend to it early, so as to prevent any further interference.

On a previous occasion, June, 1869, I advocated voluntary measures, but the time is now past for anything of that sort, and something compulsory must be agreed upon.

In my opinion we can easily gratify the public, without any inconvenience or much expense to ourselves, and it will be obviously to our interests to do so. It is more as a *placebo* to satisfy the wishes of our customers, who seem to have made up their minds about having some regulations of this kind, than for any other reason that further legislation is needed.

The Pharmacy Act, 1868, always appeared to me to expect further action by the Society; and I think we are under certain moral, if not legal obligations, to bring forward some scheme to be universally adopted.

There would be really very little difficulty in the matter if the regulations were confined to Part I., and to the sending out of poisonous applications in blue bottles or bottles covered with blue paper.* As to the argument that such precautions are not necessary, and that they ought, if compulsory, to apply equally to medical men, I attach very little weight to it, because every one who has had experience in the best dispensing houses knows that similar arrangements are there carried out, and also that medical men can, in many cases, avoid inquiry into their mistakes.

Good bold labels, and a separate compartment for all articles in Part I., and labelling lin. aconit. and belladon. for outward use to distinguish them from the tinctures, appear to me the measures best adapted to retailers; but to extend these precautions to articles in Part II. is only to bring ridicule on the Society and the whole trade. Let us all make up our minds to carry out fully some well-considered method, and, by sinking private feelings for the general good that would follow, we shall please the public and advance our interests as dispensers.

There is a growing feeling amongst the educated classes that medicines are better prepared by the chemist than the surgeon. If we can keep pace with the demands of the enlightened portion of the community for genuine medicines skilfully prepared, we can well afford to leave medical men free to do as they like.

Sandown, I. W. GEORGE BROWN.

Sir,—Although I cannot speak on the above subject from large practical experience, I have given some attention to the consideration of its bearings, both on the trade and the public, and am not at all surprised at the objections expressed in the Journal to the proposals of the Council. It is quite true, as "Nemo" observes in the number for Dec. 31, that cases of poisoning by "misadventure seldom" occur. But this does not, I think, show (as he seems to argue) that precautionary measures are not therefore requisite and advisable. The question is not whether such cases "seldom" occur, but whether they occur at all; whether anything can be done to prevent them. To my mind the question shapes itself thus: Has everything been done that can be done to prevent accidental poisoning by chemists? If not, then it is clearly a duty of the Legislature (and intermediately of the Council) to supply this deficiency. This is attempted in the present simple regulations, to which, I think, no chemist can reasonably object. They are not an infallible remedy against mistakes, but a further effort (in addition to qualification) to prevent them,—another link in the circle of duty which we owe, as a public body, to society.

"Prevention is" always "better than cure," but in cases of poisoning prevention is too frequently the only cure. The fatal draught once swallowed, no power, perhaps, can avert the sad results,—the loss, it may be, of a valuable life, and the ruin of the chemist, or at least the sacrifice, on his part, of a large sum of money, to say nothing of reputation. In how many cases would such results have been prevented by the rigid adoption of a few simple precautions like those now proposed? Let me select three "sample cases," in each of which, I believe, these precautions would have proved effectual. They are all recorded in the PHARMACEUTICAL JOURNAL for July, 1869, and each proved fatal. In the first of these, which resulted in the death of Mr. F. Grattan Guinness, it is next to certain that, had these compulsory precautions been in existence, the porter would not have filled the carbonate of ammonia bottle with cyanide of potassium. It is distinctly stated that "the jar had no label to it." It is true the assistant should have discovered the substitution, but the porter's error was the original cause of the accident, and would have been entirely met by the precautions now proposed. It was asserted at the inquiry that the rules of the establishment had, in this case, been departed from, and this fact clearly shows the advantage of uniform and compulsory regulations over those privately adopted. The former are far less likely to be neglected than the latter. To the second case referred to, which involved the death of Essex T. Williams, surgeon, a similar line of remark is applicable. Had the strychnia sent out by the "wholesale house in Bristol," in mistake for acetate of morphia, been originally prominently distinguished, it is hardly possible to suppose that it would have been supplied in error for the latter substance. The third case, in which strychnia was substituted for sugar, still more strikingly exhibits the value of precautionary measures. A chemist, who had on the very day of the accident, entered on a business, dispensed strychnia for saccharum. The chemist who had sold the business alleged that the labels had been mistaken, adding, "It was not customary for chemists to label their bottles 'Poison' in addition to the ordinary label as to the contents." It is clear enough that this mistake would not have occurred had the bottle containing strychnia been in some way distinguished from the rest. A parallel case to the above, in which strychnia also proved fatal, is recorded at page 728 of the PHARM. JOURNAL (Vol. XI.). In this case a surgeon dispensed the medicine. It was, however, stated on the inquiry that the surgeon "was not aware that there was any strychnia in a crystalline form in his surgery," and that "the bottle containing the poison was not properly labelled." The above cases (and, did time and space permit, others equally in point might be cited) show that poisoning by "misadventure" does not occur so "seldom" as could be wished, but quite often enough to render some restrictions necessary. Practically they suggest that the same or similar regulations should be applied to wholesale druggists and surgeons, as to dispensing chemists.

Such cases also furnish a reply to the observation of "Pharmaceutist" (page 537), "that the improved education now demanded is a sufficient safeguard to the public." Such a remark is altogether beside the question. If only educated, pharmaceutists and scientific men had the handling of poisons, restriction might be less necessary, but as we see in the case of Mr. Guinness, and as every one in the trade knows, these substances are constantly being manipulated by apprentices or porters, who are for the most part imperfectly educated, and the same remark will apply, probably, even to not a few assistants. The fact is, the qualification of the principals in Messrs. Oldham's establishment was far less capable of preventing the accident above referred to, than a few simple rules, regarded by all as compulsory, would have been. The same observation will apply in the case of mistakes which have occurred in other houses of the highest standing in the trade. Clearly enough qualification may have nothing to do with the matter. In neither of the above cases, where the principals made the blunder, was any question whatever raised respecting qualification. The present regulations are designed to meet sources of error against which no degree of qualification could render a man absolutely secure, either as regards himself, or especially as regards those in his employ. Education and a sense of responsibility, so far from rendering us independent of rules, teach us to frame good ones, and willingly and rigidly to abide by them.

Let me ask, in conclusion, how would these regulations, if adopted, practically affect the trade? Do not the alternatives

* As stated by the Editor in a recent number, this last is very important, for it will be found on examination that most of the accidents occur through mistakes or neglect of patients or attendants.

now offered and the suppression of the restriction touching liniments and angular bottles, so simplify them, as to render them generally applicable? The trade may, I imagine, be divided, as regards this question, into three sections. First, there are houses probably where these or similar regulations for storing poisons are already in force; this, we may presume, is the case in our principal metropolitan and provincial dispensing establishments, and here no material difficulty would be experienced. There is a second class who have virtually embodied these regulations in certain precautionary measures of their own, and such would willingly conform to those officially proposed. A third section still remains, not, I think, the most numerous, and certainly not the most influential, who have not adopted precautions of any kind in keeping poisons, but who (as Mr. Slipper naively observes), "If they find the bottles containing crystals of citric acid and sal. acetos. hugging each other, naturally and prudently(!) forbid the close connection." Such chemists "know better" than to be bound by a "hard and fast line." They act upon their knowledge and experience. Perhaps the instances given above will serve to show that the *laissez faire* policy, which this section of the trade so strongly advocates, is directly subversive of its own interests, as well as of the interests of the public, and help to explain the reason why the Council think it necessary to compel chemists to keep poisons in certain places or in distinctive bottles. From this section of the trade opposition must be expected, and ought to be vigorously met. But by a free and full discussion of the matter in the pages of the Journal, it may be hoped that many who at first opposed these regulations, will be led to see the advisability of adopting them.

Objections have been raised to the compulsory nature of the proposed regulations, but to be generally effective, I hold that they must be compulsory. This is evident from the existence of a section in the trade opposed to them (and which would still exist if reduced to a minority), and also from the fact that their effectiveness must largely depend on their faithful application by apprentices, assistants, or porters, on whom rules legally binding, would naturally have a greater hold than regulations merely recommended by the Society or enjoined by their employers. It might, perhaps, greatly facilitate the adoption of the present regulations, if the Society could devise and authorize a label to be stamped, "The Pharmaceutical Poison Label," and bearing the word "poison" in the centre in distinctive type; such label, exhibiting some bold device which would be at once recognized, to be made both in paper and metal; the latter form with holes for nails or string, to enable it to be conveniently affixed to casks or jars. If made in different sizes, the smallest bottle or pot or preparation of any kind, could easily have one attached. The value of one uniform safeguard label, universally understood and recognized throughout the trade, will be at once evident to all. I have said above that the proposed regulations should apply to wholesale druggists and surgeons as well as to chemists. Nor do I see why they should not or cannot; but if their extension to medical men and the wholesale trade involve any practical difficulty, this is certainly no reason why chemists should reject them. Shall we refuse to adopt a course suggested by prudence and warranted by reason and experience, merely because our neighbours won't? Let us set them a good example.

January 7th, 1871. M. P. S.

P.S. The use of the label above suggested, would probably be considered to meet the requirements of the second alternative regulation, applicable to articles which cannot be conveniently kept apart, especially if the label were made of sand-paper or other rough material, so as to be distinguishable by the touch. In the case of metal, a few holes punched in it would answer this purpose. Let me add, that it is quite possible that many chemists whose own arrangements are excellent, may, nevertheless object to compulsory regulations, but surely they are inconsistent with their own practice in doing so. I have just read Mr. Allman's letter in to-day's Journal and would here endorse his excellent remarks (as also those of "A Pharmaceutical Chemist" in the Number for December 24th). Mr. Vizer's reference to the "knives and lancets" is a pure absurdity. It is, however, important as touching Mr. Proctor's suggestion, that the regulations should be as simple as possible, otherwise they will be evaded. A rule too complex to be undeviatingly observed is worse than none. This question deserves, in my opinion, far more serious and dispassionate treatment than it has received in the letters of Mr. Beaton, Mr. Hampson, Mr. Vizer and other correspondents.

Sir,—In common with the majority of your readers, I have taken great interest in the discussion that has been kept up with so much spirit and, in the main, with such good sense.

We now stand in a different position respecting the question; the Council are not to have it all their own way. Much as I respect several individuals of that body, I should feel wanting in honesty did I not express my convictions upon the great topic. I have hitherto deferred doing so, but the letters of Messrs. Beaton, Hampson and Allman have brought me to bearings; the two former gentlemen fairly represent the gist of the whole affair, and advocate the dignity of our profession (if it be ever destined to such honorary title).

Presuming the object of Government to be the protection of the lives and health of her Majesty's subjects, there is ample scope for such benevolent intentions:—

1st. By commencing a system of practical sanitary reform.

2nd. By regulating the supply and quality of poisonous compounds by publicans and others.

3rd. By placing under strict surveillance unscrupulous and irresponsible railway directors, who sacrifice human life and limb with so much *sang froid.*

4th. To try and get hold of the fact (if it exists) that people can be made moral, careful and intelligent by Acts of Parliament for the prevention of such as the three cases of poisoning recorded in last week's Journal.

I can but repeat what has already been shrewdly advanced, that the intelligent chemist does not need legal intervention to keep him in the knowledge of the substances he makes and handles, any more than the accomplished surgeon requires watching as to how he operates with his knives and lancets,—the idea is preposterous and impertinent.

Mr. Allman's letter being chiefly personal, does not admit of remark, further than the acknowledgment that as a specimen of special pleading, it deserves the palm.

R. Goodwin Mumbray.

Pharmacy in Brighton.

Why do not the Pharmaceutical Chemists here study more the interests of their assistants, since the examinations of the Pharmaceutical Society have become so rigid? In this town, where we have more than fifty chemists in business and, on an average, two assistants in each shop, there is not either a school of pharmacy or any place where we can receive instruction. Why does not the Pharmaceutical Council appoint Local Secretaries, not merely for the purpose of conducting a preliminary examination (which is of no use to assistants), but also that they might exert themselves—particularly in a town like Brighton—to establish, with the help of their brother pharmaceutists, a school, or at least some place where assistants could meet for the purpose of instruction in the several branches of the profession? It is not every assistant who has money to repair to the great metropolis, and give his whole time to a pharmaceutical education; whereas at home he might get away one evening in the week and pay a fee for a course of lectures. I am sure if our Pharmaceutical Chemists were to exert themselves to establish a school of pharmacy, it would be strongly supported by the assistants in general.

A. Henley Attwater, Jun.

Wholesale Druggists' Assistants' Society.

Sir,—Concerning my abortive attempt to get the assistants in the wholesale drug trade to form themselves into a Mutual Improvement Association, allow me to remark that it took place as far back as the spring of 1867, and was prompted principally by seeing the rapid improvement which had for years been going forward in the ranks of the assistants in the retail trade, while the assistants in the wholesale trade were gradually sinking in the social scale, if we may judge from the fact that their employers found it necessary to look about for some means of protection against their delinquency. I need hardly allude to the difference which has always existed in the position of the wholesale and the retail druggists' assistant. While the latter are men who have passed through a regular apprenticeship, and for the most part reside with their employers, having access to the various works and journals appertaining to their calling and time to study them during the intervals of business, the great bulk of the former have never had an opportunity of pursuing any course of study; and, being engaged at business during fewer hours of the day, they are constantly employed at set duties, which allow them no time for reading during those hours. After business hours few, at present, have the means of acquiring that knowledge, which would be so easily attainable if there were a reading-room and library to which they could resort at any hour which suited their convenience. The periodical trade literature would cost but a trifle annually, and I know by past experience that the nucleus of a library is soon formed by donations from authors, publishers and employers, added to subscriptions got up among the members. It is also known that several of the *employés* in the trade are men whose attainments are such as would not fail to be most useful in the enlightenment of their less favoured brethren, could they be prevailed upon to join in the exposition of the useful trade and scientific knowledge which they possess.

Having communicated my idea of the desirableness of such an institution to three acquaintances holding a similar position in the trade to my own, it was determined that each of us should submit the following to his own private circle as the primary objects of a proposed Society, but our personal canvass was so very unsuccessful that the matter was abandoned after the second meeting at my private residence.

1st. To enroll any member of the wholesale drug trade who had been employed in any drug house for a period of five years as an associate of the Society, and to provide, in return for a small monthly subscription, a meeting and reading-room, to which every associate would have access at any time.

2nd. To institute a series of readings by those members of the Society able and willing to contribute articles of trade interest.

3rd. To facilitate the acquirement of trade knowledge by opening a register, in which any member might request the advice and information of the other members on any subject connected with the trade.

4th. To keep a record of all vacancies occurring in the trade, and to furnish employers with a ready means of at once selecting servants suitable to their wants.

5th. To undertake to expose and prosecute any dishonesty on the part of any of its members.

I may set down the failure of the movement—(1.) To the difficulty of getting a sufficient number of co-operators to promote it, by throwing in their energies and the small advance of cash (a few shillings each at most) necessary to set it going. (2.) An expression of fear that employers would misconstrue the aims of such an undertaking (3.) An apparent feeling of rivalry between the men of the various wholesale houses.

In making the above hurried jottings of what was a private effort to do good, I write in the hope that some one may now come forward with sufficient energy to ensure the success of so desirable an institution.

88, *Campbell Road, Bow,*
27th Dec. 1870.

O. Davies Owen.

Druggists' Charges.

Sir,—Having seen much in the Journal lately concerning the above, I beg to lay before your readers the state of things not many miles distant from Hull. Two cases have recently come under my notice I think worth making known. In the first, a 3 oz. bottle of drops was dispensed at a chemist's, and charged 2*s.* 6*d.* On taking the prescription to a Pharmaceutical Chemist by Examination, the patient was asked what had been the former charge. The reply was 2*s.* 6*d.* To which the pharmacist replied, "Oh! but we will let you have it for 9*d.*" There can only be one inference drawn from this, either that the chemist was actually a loser by the transaction or that the patient was the sufferer. The second case was that of an 8 and 6 oz. mixture, dispensed and charged respectively 2*s.* and 1*s.* 8*d.* The lady looked rather astonished, and was asked if she had paid less, the answer being that she had been charged 9*d.* each, but on going the second time was informed that they could not make them up again for the same price; the charge must be 1*s.* 9*d.* the two. The lady added that she did not mind giving more for them, providing they did her more good than the last, which had not done her any good. This was not to be wondered at, seeing that the bare retail price of the ingredients came to about 2*s.* 6*d.* for both bottles. If this state of things continue, I see no chance whatever of the rising generation of young chemists making a living.

One of the Rising Generation.

Obscure Prescriptions.

Sir,—The following enigmatical recipe was brought, some years ago, to a shop in a country town within fifty miles of London, to be "made up." I secured the original, of which I give a copy *verbatim et literatim*:—

Oil of koors ham
Oil of hope ham An
Oil of Anni seed
Oil of St. eppes.

The above recipe was distinctly and carefully written, but except the aniseed, we were unable to identify the ingredients. If "hope ham An" mean opium, the "oil" is still perplexing; the other ingredients seem quite apocryphal. The purpose of this mixture was to mix with food for cattle; the proportions being left to the judgment of the chemist, and it was judiciously compounded accordingly; not, however, without a shrewd suspicion that it was designed to excite in certain specimens of the equine race an unnatural taste for "Chaff," to the possible advantage of some preternaturally clever, but not overscrupulous "Johnny."

January 6th, 1871. F. D.

The Library.

Sir,—I have of late frequently heard the question asked by students at Bloomsbury Square, if it were not possible for the Library to be kept open an hour or two longer. If it were closed at eight o'clock, instead of six o'clock, as at present, I think it would meet the approval of the students generally; many of whom would gladly avail themselves of the advantages there offered, which they cannot obtain elsewhere. I would ask the Council, on their behalf, to take the matter into consideration.

I would also invite the opinion of gentlemen interested in the Monthly Evening Meetings, respecting the time fixed for their commencement, whether or not it is the most convenient for the majority of members and others? I know many gentlemen state they should attend much oftener, but being compelled to be home at a certain time, they are generally under the necessity of leaving before the conclusion of the meeting.

Dec. 12th, 1870. Student.

[*** Formerly the library was kept open as our correspondent recommends, but this arrangement was given up in consequence of the small number of readers using it in those hours. We would recommend "Student" to forward any suggestions he may have to make on the subject to the Council.—Ed. Ph. Journ.]

"*Indoctus*" (Bolton).—Cooley's 'Cyclopædia of Practical Receipts' may be obtained through any bookseller.

G. R.—The label sent would require to be stamped. Every reference to dose and medical treatment must be omitted.

D. Y. N. (Barnsley).—We do not undertake to give advice as to the study of midwifery. Our correspondent had better apply to the editor of one of the medical journals.

We have received, enclosed in a note from Southampton, the initials to which appear to be H. M., a contrivance by which a simple india-rubber band is used to secure the stopper of a poison-bottle after it is withdrawn, and so to attract the attention of the dispenser.

T. C. (Sheffield Moor).—We are obliged for your communication, but, as it stands, it would appear too much like an advertisement of a particular maker's preparation.

"*Alpha's*" wants will probably be supplied by the pump, unless he is joking.

"*Medicina.*"—The question as it stands is too vague for insertion.

Messrs. Coates and Walker.—The letter and stamps have been handed to the publishers. To secure insertion, all advertisements should be sent direct to Messrs. J. and A. Churchill, New Burlington Street.

Communications, Letters, etc., have been received from Mr. A. W. Bennett, Messrs. Cox and Co. (Brighton), Mr. J. Ince, Mr. H. J. Owen, Mr. S. R. Atkins (Salisbury), Mr. J. M'Cann, Mr. W. W. Stoddart (Bristol), "Conia" (Leeds), "Indoctus," "F. D.," "M. P. S.," "S. D." (Bow), "H." (Heckmondwike), "W. F. C." (Buckley), "E. F." (Folkestone).

PRESCRIPTIONS FOR PROVINCIAL ASSOCIATIONS.

BY JOSEPH INCE.

Some misunderstanding seems to prevail in the minds of students relative to this matter; they fear that the introduction of foreign formulæ in each assorted volume, may suggest eventually a catch examination question, or prove a trap to snare. Let me then say precisely what is the intention of this second (Provincial) collection. Two-thirds of each compilation are filled with general recipes, the reading of which will facilitate the knowledge of autograph prescriptions—the remaining third consists on purpose of specimens of pharmacy other than English—these serve as reference, or as things of literary curiosity and may prevent a pharmacist from sinking his existence in his immediate surroundings.

During the past week the following collections have been forwarded. I. (10), II. (38), III. (9), A. W. Gerrard, Guy's Hospital. From Preston a collection of twenty years by Thos. Dawson has arrived.

Amongst those received are some which seem to indicate a pharmacy differing from our own.

I.

℞ Extrait de Belladone, deux gros
Unguent Napolitain, un gros
Graise fraîche, une once
Tinture de Benzoin, un gros.
M.
Dec. 3, 1868. G. M.

Suppose the plan of direct teaching be adopted, then how this ordinary French ordonnance rises into importance! What is a *gros?* is Unguent Napolitain, correct? is Graise the correct spelling? how in French would you write Tr. Benzoin? what, according to the Codex is the composition of Ext. Belladonnæ, Onguent Napolitain, and Teinture de Benzoin?

II.

Donner à l'enfant une cuillerée à bouche de la potion suivante de 4 en 4 heures.
℞ Sel de Seignette, 30 grammes
Eau de Laurier cérise, 4 grammes
Sirop d'Ecorce d'orange, 30 grammes
Eau pure, 150 grammes.
Le 14 *juin* 1860.
VICTOR DE MÉRIC.

Make this also teach its own lesson—what is the correct English version of the directions which are as common as *horâ somni sumendus?* What is Sel de Seignette, and what are the respective English values of 30, 4, and 150 grammes? Why does the prescriber say *le* 14 *juin* instead of June the fourteenth?

From America we get many *pharmacal* illustrations, some including very recent remedial agents, as for instance

Sulpho-carbolate Zinc, ʒij
Water, ℥iv
M. Two teaspoonfuls to a pint of water.
Sig. for external use.

Not the least curious are the Pencil Prescriptions mostly written on the druggist's counter: these are retained by the pharmacist invariably, as also many others.

AMERICAN PENCIL PRESCRIPTION.
℞ Ext. Monesiæ ʒj
,, Nucis Vomic. gr. iv.
M. ft. pil. No. XX.

Another.
℞ Ol. Erigeronii ℥j
S. Take twenty drops four times a day.
D. W. C.

A third.
℞ Tinct. Gelsemin, ʒiij.
S. Fifteen drops three times a day.
GILLETTE.

℞ Gelsemin, gr. iv
Lupulin, gr. xxxij
M. ft. chart. No. 16.
Sig. Dose, 1 three times a day. RAY.

Now let us ask, though we are all familiar with Ext. Monesiæ, what are Ol. Erigeronii, Gelsemin and its Tincture?

GERMAN PRESCRIPTION.
℞ Tincturæ Aurantiar.
,, Chinæ Comp.
,, Mal*l*at. Ferri
,, Gentianæ
,, Ci*n*amomi
āā unc. semisse.
M. D. Sig. mane et vesperi cochlear. capt.

℞ Bromi Puri ʒij
Kali Hydrobromici ℥ss
Liniment. Opodeldoc ℥iv
Misce, fiat lege artis linimentum consistentiæ Balsami Opodeldoc. Detur ad vitr. epist. vitreo bene claus.
S. Bromine Liniment.
Sept. 19, 1855. DR. OSCAR PRIEGER.

This leads me once more to offer a needful explanation. The arranged Prescription-books when completed are designed to answer two purposes: the first—the essential one, to present a number of varied formulæ sufficient as far as one volume is concerned, to render a certain familiarity with medical instructions possible. One book cannot suffice, but it may form the commencement of a more extended series to be extended indefinitely hereafter by individual exertion; still this single folio will be manifestly better than none, while want of variety will, it is hoped, not be amongst the number of its defects. Here are a few examples in illustration:—the contractions often incorrect are copied from the originals.

℞ Lupulin gr. iv
Pulv. Camphoræ gr. x
Gelsemin gr. xxiij.
M. ft. chart. No. 20. Sig. Dose, 1 three times a day.

℞ Syrupi Wahoo ℥ss
,, Pini Palustris ℥iiiss
Brom. Ammo. ʒij
Mur. Ammo. ʒss
Chlorate Potass. ʒss.
M. S. A. Sig. One teaspoonful as required.
3 . 30 . 69. DR. HILDRETH.

℞ Podophyllin gr. iij
Ext. Colchic. Rad. Acet. gr. ij
,, Hyoscyami gr. v.
M. ft. *Pills* No. 8. Sig. Take j every three hours until bowels act freely.
RAY.

℞ Atropiæ Sulph. Neutral. gr. ij
Aquæ Destill. ℥ss.
M. S. A. Sig. Eye Drops.
4 . 3 . 69. DR. HILDRETH.

℞ Macrotin ℈j
Caulophyllin ℈ij
Ferri Per. Hydrogen ʒj.
M. ft. *Pills* No. 60. Sig. Dose, 1 three times a day after eating.

RAY.

℞ Tinct. Rad. Phytolaccæ,
„ Guaiaci, āā ℥j.
Misce. Sig. 1 teaspoonful in milk three times a day after meals.

HAMILL.

In Sciatica and Chronic Rheumatism.

This is dispensed by P. L. MILLEMAN, Graduate, Philadelphia College of Pharmacy:—

℞ Tinct. Belladonnæ,
Syr. Simplicis,
Aquæ, āā ℥jj.
Misce. Sig. Teaspoonful every hour or two.—R.

CHICAGO.

℞ Pulv. Rad. Rhei Chin.,
Sulphur Præcip.,
Salis Seignette,
Elæosach. Fœniculi, āā ℥ss.
M. ft. pulv. det. ad scatul.

℞. Panes azymos No. vj.

DR. FELIX SCHOON.

℞ Veratriæ pur. ℈ij
Ol. Olivæ ʒij
Ung. Sperm. ʒiij.
Mt. ft. ung.

℞ Ol. Caryoph. ʒij
Ung. Sperm. ʒiij.
M. ft. ung.

DR. TURNBULL.

Characteristic recipe of Sir CHARLES LOCOCK:—

℞ Liquoris Cinchonæ (Battley) ʒij
Sp. Ammoniæ Succinatæ ℈ij
Misturæ Camphoræ ℥iiiss
Tinct. Hyoscyami ʒiiss.
M. Sumat cochlear. max. j ex aquâ, primo mane et horâ 4 P.M.

℞ Camphoræ,
Extracti Aconiti, āā gr. ij.
M. ft. pilula omni nocte sumenda. Mitte iv.
Nov. 16, 1857. C. L.

A short formula of ERASMUS WILSON:—

℞ Ung. Hyd. Nitr. Ox.,
Ung. Odorat. āā ℥j.
M. ft. pomatum. A little to be well rubbed among the roots of the hair night and morning.

The second object contemplated is to show the practice of other countries, and in what different ways nations not our own exercise the healing art. For surely the aspiration of our students ranges higher than the passing an examination. Let it however, for the third time repeated, be clearly understood that these sometimes strangely written, recondite formulæ are not meant to perplex the young pharmacist, nor do they, as far as his examination is concerned, in the least influence the chances of his success.

Let me conclude by outlining an idea which one day may be realized. I propose the subsidiary direct teaching of practical pharmacy by means of autograph prescriptions precisely in the same manner as Oliver taught botany. His system is too well known to need description. He takes an actual flower, and *from* it and *on* it demonstrates its parts, indeed its whole history—why can we not from actual pharmacy obtain the same result? As far as my light goes, Oliver has revolutionized the study of botany; has made its commencement not a work of drudgery but pleasure, for in the case of many modern treatises the introductory chapters should be drafted into the Appendix. Pharmacy seems capable of being aided by the same sensible mode as by the one which Oliver, following the track of his predecessors adopted. Let a student take this characteristic formula of the late Dr. Bright.

℞ Liquor. Calcis lb. ss.

Sumat cochl. mag. ij, more exposito.

℞ Bismuthi Trisnitrat. ℈j
Acidi Hydrocyan. (Scheele) ♏viij.
Sodæ Sesquicarb. ℈iss
Tinct. Card. Comp. ʒij
Mucilaginis ℥ss
Infus. Aurant. ad ℥iv. M.

Fiat Mist. cujus sumat partem quartam ter dic. Applicetur Empl. Cantharidis scob. cord.

R. B.

Then let him set himself the following short examination, giving his answers *aloud* for his *vivâ voce*, or writing them in full.

1. Write out Prescription in correct Latin, with full terminations—give the construction of its nouns, verbs and adjectives.

2. What is liquor calcis—how made—what its use—what is its pharmaceutical history?

3. Bismuthi trisnitrat.—what is its chemical and pharmaceutical history? Describe the metal. What is the moot point of contention respecting its preparation as indicated in the British Pharmacopœia and the formula adopted by private manufacturers?

4. Hydrocyanic acid—how made? why called Scheele's? Official strength and chemical history, therapeutical applications internal and external.

So we might proceed, but space is valuable, and enough has been said already to mark out the idea.

Any student who, in the quiet of his own room, can faithfully go through this ordeal will be effectually saved from the slightest anxiety with regard to one part of his examination. Fifty formulæ, arranged by an intelligent tutor, with due regard to distinctive handwriting, working out in detail this rude sketch, would be an educational gain. Print, or still better, lithograph facsimile, would materially assist.

Meanwhile, when there are so many candidates for our examinations, nearly three hundred having presented themselves the first week in January, let us on our side as a Society representing Pharmacy meet them honourably; let us not ask these young aspirants to make bricks without straw; rather let us give them every facility for acquiring knowledge—and this, if help be not denied, will be the New Year's gift of London to the Country.

THE PRESENCE OF MANGANESE IN BEECH-NUTS.

BY DR. J. E. DE VRIJ.

In the introductory address of the chairman of the last Pharmaceutical Conference* at Liverpool, my attention was fixed by the following sentence:—"By some authors it has been denied that plants absorb from the earth such metals as are not absolutely essential to their nutrition. Experiments, however, afford strong evidence to the contrary. Mr. R. Warington (Journ. Chem. Soc. 1865) found in the ashes of the beech and birch 0·193 per cent. of manganese."

This quotation of Warington's investigation induces me to mention the fact observed by myself more than twenty years ago. As at that time the investigation of the ashes of plants occupied a great many chemists, I also analysed some ashes. Amongst them were the ashes of beech-nuts collected by me in the neighbourhood of Giessen, in Germany. As there exists a great quantity of manganese ore in that vicinity, the presence of a relatively large quantity of manganese in these ashes seemed to me quite natural. In 1847, being at the meeting of the British Association at Oxford, I visited the beautiful park of Blenheim, and collected there on that occasion some unripe beech-nuts. After returning home, I analysed their ashes and found also in these, although grown in a very different soil, the presence of a relatively large amount of manganese. A third analysis of the ashes of beech-nuts, collected in the wood of the Hague, confirmed the same fact. As I was accustomed to use the ashes of beech-nuts in my lectures to demonstrate the reagents for manganese, this fact has been fixed in my memory.

To Camphorate Blisters.—M. Deschamps d'Avallon has suggested, when it is desirable to camphorate a blister, this may be readily accomplished by dropping on its surface a few drops of a saturated solution of camphor in chloroform, made by adding two parts of the latter to four of the former.—*Journal de Pharmacie.*

---

* PHARM. JOURNAL, Sept. 17, 1870, p. 234.

PREPARATIONS OF CONIUM; THEIR CHARACTERS AND MEDICINAL VALUE.*

By John Harley, M.D.

In an able and exhaustive paper in the December number of the *Practitioner* for December, Dr. Harley records the results of a continuation of his researches upon the comparative value of the different preparations of *Conium*.† Although written principally for the information of the medical practitioner, it has considerable interest for the pharmacist.

Dr. Harley is of opinion that the only reliable test of the amount of active principle in a preparation of hemlock is physiological action, the alkaloid being so subtle and unstable that chemical reagents used for the quantitative determination of conia, when combined with the ordinary constituents of vegetable infusions, give most fallacious results. He says that any one acquainted with the physiological effects of conia may easily determine its amount by subjecting a nervous system of known power to its action, an experiment for which an hour will suffice.

Schroff has recently stated‡ (1) that the unripe fruit of one-year conium plants contains the smallest amount of conia; (2) that the unripe fruit of biennial plants contains the most conia, especially when the development of the fruit is advanced and near ripening; (3) that the perfectly ripe fruit, produced only by the biennial plants, stands in point of efficacy between these two. Dr. Harley says that he does not quite agree with all these particulars. He has found that conia stands to the ripe and unripe fruit pretty much in the same relation as opium does to the ripe and unripe fruit of the poppy. It abounds in the green pericarp, but gradually decreases as this becomes dry and brown. As to the statement that only biennial plants produce perfectly ripe fruit, he says that for four years he has kept up a little plantation of annual hemlock plants derived from the self-sown seed of a previous generation of annual plants.

The following were the preparations used in the experiments:—

Preparations of the Green Fruit.

1. *Tincture.*—Two samples were used; one distinguished as "London," prepared by macerating the fresh undried crushed annual fruit in proof-spirit, and percolating (℥vj yielded ℥xxvj of tincture); the other was made from dried American fruit according to the directions and in the proportions ordered in the B. P.

2. *Extract.*—Prepared by evaporating the tinctures to dryness over a water-bath, 1000 grain measures yielding 20 grains of bright yellowish-brown brittle extract, which became soft on exposure, from absorption of about 15 per cent. of water, and formed a translucent extract of the colour of Cape aloes. Treated with excess of potash, it assumed a gamboge colour, and evolved a powerful odour of conia.

3. *Fluid Extract.*—Prepared by Dr. Squibb, of Brooklyn, New York; a rich brown spirituous fluid of sp. gr. 0·992, one minim representing one grain of the green undried fruit. 1000 grain measures yielded 98 grains of extract, possessing the same physical characters as the preceding.

Preparations of the Fresh and Flowering Plant.

4. *Succus Conii*, B. P.—The author calls attention to the variability of this preparation according to the quantity of water contained in the plants. The colour, varying from that of pale sherry to dark Marsala wine, is an evidence of its strength, succus as dark as the latter being three times as strong as the palest variety. Two preparations were used; one intermediate in depth and colour, prepared from year to year by Mr. Buckle; the other, darker and stronger, prepared in the unusually dry season of 1865 by Messrs. Allen and Hanbury.

5. *Extractum Conii*, B. P.—The author says that 6 grains, the maximum dose of this preparation, cannot possibly contain more than 0·084 of a grain of conia, a quantity insufficient to produce hemlock effects in a child two years old; while 60 grains at least of the freshly-prepared extract are required to produce slight effects in the active, and 15 to 20 on the most enfeebled adult.

6. *Tincture.*—Prepared by Mr. Deane, of Clapham, from half-blown plants gathered in the last week in June, 1869, by exhausting 32 ounces (avoird.) of the herb, previously crushed in a mill, with rectified spirit until 53 ounces of tincture were obtained (= nearly 5 drachms of the fresh plant in f℥j). Of a grass-green tinge at first, but became brownish on keeping; sp. gr. ·940; 1000 grain-measures yielded 36 grains of light yellowish-brown extract, which absorbed 15 per cent. of water. During evaporation a quantity of green resin separated.

Preparations of the Dried Plant.

7. *Tincture.*—Prepared by Mr. Deane from similar plants to the preceding, dried in the open air, and used as soon as dry (16 ounces of the fresh herb yielded 4 ounces of the dry). In this preparation the directions of the P. L., 1851, were followed, *i. e.* 2½ ounces (avoird.) to 20 fluid ounces of rectified spirit. It retains a bright green tinge. A quantity of vivid emerald-green resin separated on evaporation. Sp. gr. ·940; 1000 grain-measures yielded 32 grains of extract, possessing the same general characters as the preceding, but more deliquescent, absorbing 25 per cent. of water.

8. *Fluid Extract.*—Prepared by Messrs. Clarke, Beasdale, Bell and Co., of York, from herbs gathered in the neighbourhood of York, at Midsummer, in the exceptionally hot and dry season of 1868. The roughly-ground leaves being exhausted by percolation of proof-spirit, the spirit was distilled off, and the extract evaporated until one fluid drachm equalled one drachm of the dry leaves (= ½ ounce of fresh herb). This is a dark yellowish-brown watery fluid of a rank hemlock odour, depositing much greenish-brown resin on the sides of the bottle. 1000 grain-measures yielded 195 grains of bright, orange-brown, brittle extract, rapidly absorbing water to the extent of 19 per cent.

9. *Benzoate of Conia.*—The author had had furnished to him by a member of a City firm of druggists a solution labelled "Benzoate of Conia; one drachm contains two grains. Dose, five to twenty drops;" and also samples of the solid substance. Failing to obtain from it any physiological effects, even when the dose was increased to 20 grains of the solid substance, he was induced to give it a thorough examination, which led him to the conclusion that the so-called benzoate of conia was an impure benzoate of soda, devoid of a trace of conia.

A neutral benzoate of conia is obtained by mixing equal proportions of solutions of conia and benzoic acid in dilute spirit, evaporating to dryness and preserving over sulphuric acid. The result is a clear bright amber-coloured body of the consistence of soft extract, with a faint conia odour, a bitter taste devoid of acridity, and forming with water an odourless solution. This substance and its aqueous solution, even when a thousand times diluted, evolves the odour of conia when supersaturated with potash; and this occurs in the presence of large quantities of either benzoic acid or benzoate of soda, showing that these bodies do not interfere with the nasal test for conia. Heated in a test-tube the benzoate runs, volatilizes and decomposes with evolution of white fumes, in which the odour of benzoic acid is masked by the more powerful one of conia.

* Abstracted from a paper by Dr. Harley, published in the *Practitioner* for December, 1870.

† See Pharm. Journ., 2nd ser., Vol. VIII. pp. 413, 452, 572, 601, 710; IX. 471.

‡ Wochenblät. der K. K. Gesellschaft der Aerzte in Wien, 1870, No. 1; and Pharm. Journ. No. 18, p. 348.

An acid benzoate was formed by the addition of two equivalents of the acid to one of conia. It resembled the preceding in its reactions, but was colourless, odourless, and less soluble in water. Attempts to combine more of the acid, so as to produce a dry salt, failed.

The following are the results of the experiments so far as they show the relative strength of the preparations. The drug was administered to persons familiar with the intoxicating effects of hemlock, and the doses were given as nearly as possible under similar conditions. The strength of the preparation was inferred by the extent of physiological action induced upon a system of known power.

1. The first experiment was made with Extractum Conii, B. P., and Succus Conii, B. P. (Buckle's). The relative value was—gr. xx extract = fʒij succus.

2. Extractum Conii, B. P. (prepared by Bell and Co. in 1867–8) and Succus Conii, B. P. (Buckle's).—gr. xl extract = fʒiv succus; gr. lx extract = fʒvj succus.

3. Extractum Conii, B. P., Succus Conii, B. P., and Tincture of Green Fruit (American, ℥ivss fruit yielding f℥x).—gr. xlv. extract = ʒivss succus = ♏80 tincture.

4. Succus Conii, B. P. (Buckle's, 1866) and Tincture of the Green Fruit (London ℥v in ℥xx).—ʒiv succus = ♏50 tincture.

10. Extractum Conii, B. P. (Bell's, 1868), Succus Conii, B. P.—gr. 40 extract = fʒiv succus.

11. Succus Conii, B. P. (Buckle's, 1867; the plant yielded 75 per cent. of juice) and Succus Conii, B. P. (Allen and Hanbury's, 1865; the plant yielded about 35 per cent. of juice).—ʒix of Buckle's = ʒiij of Allen and Hanbury's.

12. Extract of the Green Fruit (American) Tincture of the Green Fruit (American), and Succus Conii (Buckle's, 1867).—gr. iij extract = fʒiv tincture = ʒiv succus.

13. Succus Conii, B. P. (Buckle's, 1860) and Extract of the Green Fruit (London).)—ʒivss succus = gr. iij extract.

14. Squibb's Fluid Extract, Tincture of the Green Fruit (London), Succus Conii, B. P. (Buckle, 1866), Deane's Tincture of the Fresh Plant, Deane's Tincture of the Dry Plant, and Clarke and Co.'s Fluid Extract.—♏50 Squibb's fluid extract = ʒiss tincture green fruit = fʒv succus = ʒiijss to ʒiv Deane's tincture fresh plant = fʒj Deane's tincture dry plant = ʒiijss Clarke's fluid extract.

15. Squibb's Fluid Extract, Succus Conii, B. P. (Buckle's, 1867), Succus Conii, B. P. (Allen and Hanbury's, 1865), Tincture of the Green Fruit (London), Deane's Tincture of the Fresh Plant and Neutral Benzoate of Conia.—ʒj Squibb's fluid extract = ʒvj pale succus = ʒij dark succus = ʒiss tincture green fruit = ʒiv tincture fresh plant = ¾ gr. neutral benzoate.

16. Results similar to 14.

17. Results similar to 14, 15 and 16.

18. Succus Conii, B. P. (Buckle's, 1867) and Benzoate of Conia.—ʒvj succus = gr. ½ benzoate.

The author draws the following conclusions from his experiments:—

That the superiority of the green fruit over every other part of the plant, as the basis of the tincture and extract, is clear and decided. He considers the Pharmacopœia extract to be a scandal to the present state of medical knowledge, and that as soon as possible a spirituous extract of the green fruit should take its place.

That although the variability in strength of the succus is a drawback, this might be in great measure removed by the cultivation of the plant for medicinal use. At present the wild plant is gathered as soon as it makes the least show of flowering instead of being allowed to remain until the fruit begins to form.

Another grievance is the expensiveness of the succus. With the following remarks on this point Dr. Harley concludes his paper:—"This is a discredit to pharmacy, for hemlock is the rankest of our native weeds, and by an abundant yield of juice would well repay the room required for its growth; cultivation it requires none. If our pharmaceutists remain blind to their interests, medical men must help themselves, and annually rear a dozen plants in some waste spot of their garden. These will yield them a pound of green fruit, from which, with a very little trouble, may be made a tincture stronger than any juice that can be produced, and an extract, of which three grains would produce decided effects in most persons.

SAPONACEOUS PLANTS.

BY P. L. SIMMONDS.

Many plants in different countries furnish useful substitutes for soap to the natives, where there are no conveniences or materials for manufacturing the ordinary soap of commerce. Prominent among these are the soapworts, tropical plants belonging to the genus *Sapindus*. The Hindoos use the pulp of the fruit of *Sapindus detergens* for washing linen. Several of the species are used for the same purpose instead of soap, owing to the presence of the vegetable principle called saponine. The root and bark also of some species are said to be saponaceous. The capsule of *Sapindus emarginatus* has a detergent quality when bruised, forming suds if agitated in hot water. The natives of India used this as a soap for washing the hair, silk, etc. The berries of *Sapindus laurifolius*, another Indian species, are also saponaceous. The name of the genus *Sapindus* is merely altered from *Sapo-indicus*, Indian soap, the aril which surrounds the seed of *S. Saponaria* being used as soap in South America. According to Browne, the seed-vessels are very acrid; they lather freely in water, and will cleanse more linen than thirty times their weight of soap, but in time they corrode or burn the linen. This assertion, however, requires confirmation. Humboldt tells us that proceeding along the river Carenicuar, in the Gulf of Cariaco, he saw the native Indian women washing their linen with the fruit of this tree, there called the *Para para*. Saponaceous berries are also used in Java for washing. The fresh bark of the root *Monnina polystachia* (R. and P.), called *Yalhoi*, pounded and moulded into balls, is used by the Peruvians in place of soap.

Saponine exists in many other seeds and roots—in the legumes of *Acacia concinna*, in which a considerable trade is carried on in some parts of India, and in the root of *Vaccaria vulgaris*, *Agrostemma Githago*, and *Anagallis arvensis*. It also occurs in various species of *Dianthus* and *Lychnis*, and in the bark of *Silene inflata*. *Gypsophila struthium* is used by the Spaniards for scouring instead of soap. The bruised leaves of *Saponaria officinalis*, a native of England, forms a lather which much resembles that of soap, and is similarly efficacious in removing grease spots. The bark of *Quillaia saponaria* of Central America answers the same purpose, and is used as a detergent by wool dyers. It has been even imported largely into France, Belgium, etc., and sold in the shops as a cheap substitute for soap. The fruit of the *Bromelia Pinguin* has also been found useful as a soap substitute.

A vegetable soap was prepared some years ago in Jamaica from the leaves of the American aloe (*Agave Americana*), which was found as detergent as Castile soap for washing linen, and had the superior quality of mixing and forming a lather with salt water as well as fresh. Dr. Robinson, the naturalist, thus describes the process he adopted in 1767, and for which he was awarded a grant by the House of Assembly of Jamaica:—The lower leaves of the Curaca or Coratoe (*Agave Karatu*) were pressed between heavy rollers to express the juice, which, after being strained through a hair cloth, was merely inspissated by the action of the sun, or a slow fire, and cast into balls or cakes. The only precaution deemed necessary was to prevent the mixture of any unctuous materials, which destroyed the efficacy of the soap. Another vegetable soap, which has been found excellent for washing silk, etc., may be thus obtained:—To one part of the cake add one and a half part of the before-named *Agave Karatu*, macerated in one part of boiling water for twenty-four hours, and with the extract from this decoction mix 4 per cent of rosin.

In Peru, the leaves of the *Maguey Agave* are used instead of soap; the clothes are wetted, and then beaten with a leaf which has been crushed; a thick white froth is produced, and after rinsing the clothes are quite clean. The pulpy matter contained in the hard kernel of a tree called locally *Del Jaboncillo*, is also used there for the same purpose. On being mixed with water, it produces a white froth. In Brazil, soap is made from the ashes of the bassena or broom plant (*Sida lanceolata*), which abounds with alkali. There are also some barks and pods of native plants used for soaps in China. The soap plant (*Amole*) of California, *Phalangium pomeridianum*, is stated by Mr. Edwin Bryant to be exceedingly useful. The bulbous root, which is the saponaceous portion, resembles the onion, but possesses the quality of cleansing linen equal to any olive soap manufactured.

From a paper read before the Boston Society of Natural History, it appears that this soap plant grows all over California. The leaves make their appearance about the middle of November, or about six weeks after the rainy season has fairly set in; the plants never grow more than a foot high, and the leaves and stalk drop entirely off in May, though the bulbs remain in the ground all the summer without decaying. It is used to wash with, in all parts of the country, and, by those who know its virtues, it is preferred to the best of soap. The method of using it is merely to strip off the husk, dip the clothes into the water, and rub the bulb on them. It makes a thick lather, and smells not unlike brown soap.

At St. Nicholas, one of the Cape Verde Islands, they make a soap from the oil of the *Jatropha Curcas* seeds, and the ashes of the burnt papaw-tree leaf. The oil and ashes are mixed in an iron pot heated over a fire, and stirred until properly blended. When cool it is rolled up into balls about the size of a six pound shot, looking much like our mottled soap, and producing a very good lather.—*The Journal of Applied Science.*

PHYSOSTIGMA VENENOSUM.*

The *Physostigma venenosum*, or ordeal bean of Old Calabar, has of late been used medicinally. Its peculiar and powerful poisonous properties were long ago made known by Drs. Christison and Balfour, but we owe the fuller knowledge we now possess of its powers to the elaborate investigations of Dr. Fraser of Edinburgh, Dr. Robertson and other observers. The active principles of the bean quickly enter the blood and gradually produce general paralysis, which is due, according to Dr. Fraser, to changes effected in the spinal cord. In an animal poisoned by the bean the reflex functions of the cord are destroyed—"It acts on the spinal cord by destroying its power of conducting impressions." This results "in muscular paralysis, gradually extending to the respiratory apparatus, and producing death by asphyxia; and in a rapid paralysis of the heart, causing death by syncope. It also causes paralysis of muscular fibre, striped and unstriped." The knowledge obtained by these investigations led to the employment of the bean as a remedy in tetanus, and a considerable number of cases have been treated by it. Dr. Fraser has a high opinion of its value, and has reported twelve cases of tetanus treated by it, of which nine recovered. Many other cases of its administration in this disease have been reported in the various medical journals, English and foreign, and in not a few of these instances the patients have undoubtedly recovered; but the results, on the whole, have scarcely supported Dr. Fraser's estimate of the remedial value of the drug, while in some cases it has been suspected of doing harm rather than good, and of increasing the patient's danger by its paralysing action.* It has been observed, too, that in most of the cases of recovery the disease lasted about a month, just as in cases successfully treated with atropia, hydrate of chloral, and other remedies. The physostigma has been employed in other maladies. It is indisputably a weapon of great power, and must be used with great care and watchfulness: at the same time, in such a disease as tetanus, it must, as Dr. Fraser has insisted, be employed early. The Pharmacopœia contains two preparations, the powder and an extract; the first may be given by the mouth, in doses of from one to four grains for an adult; the extract, subcutaneously, in doses of one-tenth to one-third of a grain and more, the dosage being regulated by the effects.

The physostigma has also the peculiar properties of causing very rapidly contraction of the iris, and altering the power of accommodation of the lens, and it has been largely used and proved of great value in ophthalmic practice. Its action on the iris was first pointed out by Dr. Fraser,† and first made use of by Dr. Argyll Robertson.‡ A very interesting communication on the subject, by Mr. J. Soelberg Wells, containing a description by Mr. Bowman of the effects of a solution of the bean on his own eye, was published in the *Medical Times and Gazette* in 1863.§ It may be applied by touching the inside of the eyelid with a solution, one minim of which equals four grains of the bean, or by placing within a minute portion of paper which has been saturated with a strong solution.

GLYCERINE SOLUTIONS OF PEPSIN AND OTHER SUBSTANCES.

BY LIONEL S. BEALE.

In *Nature* of December 29th, Professor M. Foster calls attention to the method of making glycerine extract of pepsin pursued by Von Wittich, and remarks with reason that the means hitherto adopted for preparing pepsin for medical purposes are clumsy and inefficient. There is, however, one exception, a mode of preparation which has long been in use, and which is by no means inefficient. This will be found to possess some practical advantages over the process of extracting the fresh mucous membrane with glycerine, while from it the glycerine solution can be prepared quite as pure and clear, and as strong as by maceration.

As long ago as 1858 ('Archives of Medicine,' vol. i. pp. 269–316) I described a method of obtaining the active digestive material from the pig's stomach, which answers perfectly, and has been employed in practice ever since. It simply consists in quickly drying the mucus expressed from the stomach glands upon glass plates.‖ The dried mucus is then powdered and kept in stoppered bottles. It retains its properties for years. Eight-tenths of a grain will dissolve *one hundred grains* of coagulated white of egg.

Now, from this powder is easily prepared by solution in distilled water a perfectly clear and colourless digestive fluid of great activity, which *can be readily filtered.*

‖ This pepsin is prepared for medical purposes by Messrs. Bullock and Reynolds, 3, Hanover Street, Hanover Square.

Some years ago I found great advantage from subjecting tissues to the action of a very small quantity of this solution in glycerine, and keeping the whole at the temperature of 100° for some hours. By this process the elements of the tissue were softened, and could be dissected from one another readily for examination under the highest magnifying powers.

No doubt there is much to be learnt concerning the nature of the action of such substances upon tissues by the use of glycerine solutions. For microscopical work glycerine is of more use than any other medium. Not only may various substances be removed from tissues, but others may be introduced, and the tissue subjected to the action of various reagents without destroying it. In fact, the action may be regulated with the greatest nicety. Nearly all the tests required in microscopical examination may be dissolved in glycerine ('How to Work with the Microscope,' p. 297, 1867) and tissues of the most delicate character may be preserved in it, and will retain their microscopic characters for years, *if care be taken to obtain the best and strongest glycerine.*—*Nature.*

THE SALE OF POISONS BY DRUGGISTS.

THE LAW IN THE STATE OF NEW YORK.

BY FRANCIS TILLOU, ESQ., COUNSELLOR-AT-LAW.

The sale of poison by druggists is regulated in the State of New York by statute.

By the Revised Statutes, vol. ii. p. 649, sec. 23, it is enacted that "Every apothecary, druggist, or other person who shall sell and deliver any arsenic, corrosive sublimate, prussic acid, or any other substance or liquid usually denominated poisonous, without having the word 'poison' written or printed upon a label attached to the phial, box, or parcel in which the same is sold, or who shall sell and deliver any tartar emetic without having the true name thereof written or printed upon a label attached to the phial, box, or parcel containing the same, shall upon conviction be adjudged guilty of a misdemeanour, and shall be punished by a fine not exceeding one hundred dollars."

By an Act to regulate the sale of poisons, chapter 442 of the laws of 1860, passed April 16, 1860, it was enacted by the first section of said Act, "that no person should sell or give any poison or poisonous substance, without recording, in a book to be kept for that purpose, the name of the person receiving said poison, his or her residence (together with the name and residence of some person as witness to such sale), excepting upon the written order or prescription of some regularly authorized practising physician, whose name must be attached to such order. Such book to be kept open for inspection."

But by an Act passed 1862, chapter 273 of the session laws of 1862, the above first section of the Act of 1860 was amended by leaving out the requisition for the name of a witness to the sale.

By the second section of the Act of 1860 it is further enacted that no person shall sell, give or dispose of any poison or poisonous substance, except upon the order or prescription of a regularly authorized practising physician, without attaching to the phial, box, or parcel containing such poisonous substance, a label with the name and residence of such person, and the word "poison" all printed upon it with *red ink*, together with the name of such poison, written or printed thereon in plain and legible characters.

By the third section of the Act of 1860, it was further enacted, "That the above provisions should apply to the following poisonous substances, excepting when sold in wholesale quantities of one pound or over, viz. arsenic and its various preparations, oxalic acid, corrosive sublimate, chloroform, sugar of lead, tartar emetic, opium and its preparations, oil of bitter almonds, cyanurets of potassium, mercury, silver, and zinc, deadly nightshade, henbane, poison hemlock, prussic acid, aconite and its various preparations, atropia and its salts, cantharides, croton oil, datura and its salts, delphinia and its salts, digitalis and its various preparations, nux vomica and its preparations, elaterium, ergot and its preparations, veratria and its salts, cannabis and its preparations."

By the Amendatory Act of 1862 this third section of the Act of 1860 was repealed.

By the fourth section of said Act of 1860, it is enacted that any person infringing any of the provisions of said Act shall, upon conviction, be deemed guilty of a misdemeanour, and shall be punished by a fine not exceeding fifty dollars.

By the fifth section of said Act of 1860, it is further enacted that said Act shall *only* apply to incorporated cities and villages having a population of one thousand inhabitants and upwards in this State.

By chapter 478 of the laws of 1869, an Act regulating the preparation of medical prescriptions was passed May 1, 1869.

By the first section of this Act of 1869, it is enacted that no person employed or in attendance at any drug store or apothecary shop shall prepare a medical prescription, unless he has served two years' apprenticeship in a drug store, or is a graduate of a medical college or a college of pharmacy, except under the direct supervision of some person possessing some one of the before-mentioned qualifications; nor shall any one having permanent charge as proprietor or otherwise of any store at which drugs are sold by retail, or at which medical prescriptions are put up for sale or use, permit the putting up or preparation thereof therein by any person, unless such person has served two years as apprentice in a retail drug store, or is a graduate of a medical college or a college of pharmacy.

And by the second section of the same Act, it is provided that any person violating the provisions of said Act shall be guilty of a misdemeanour, and shall be punished by a fine not exceeding one hundred dollars, or by imprisonment not to exceed six months in the county jail; and in case of death ensuing from such violation, the person offending shall be deemed guilty of felony, and be punished by a fine not less than one thousand dollars, nor more than five thousand dollars, or by imprisonment in State prison for a term of not less than two years, nor more than four years, or by both fine and imprisonment, in the discretion of the court.

By statute every man who by his culpable negligence causes the death of another, although without any intent to kill, is guilty of manslaughter. (2 R. S. 662, sec. 19.)

The foregoing seem to be all the existing statutory provisions on the subject.

A druggist who negligently sells a poison, labelled as a harmless drug, and thereby causes the death of a person to whom it is administered, is guilty of manslaughter.

So highly does the law value human life that it admits of no justification wherever life has been lost, and the carelessness or negligence of one person has contributed to the death of another.

And this rule applies not only when the death of one is occasioned by the negligent act of another, but where it is caused by the negligent omission of a duty to that other.

Besides the penalties imposed by statute, there is also a common law liability of the druggist for damages sustained by his negligence.

All persons who deal with deadly poisons are held to a strict accountability for their use.

The highest degree of care known amongst practical men must be used to prevent injury from the use of such poisons.

And one who sells poison labelled as an innocent drug is liable in damages to any person injured thereby, no matter through how many hands it may have passed.

A druggist is undoubtedly held to a special degree of responsibility for the erroneous use of poisons corresponding with his superior knowledge of the business.

Affixing a false label to a poison, and sending it into market in that condition so as thereby to mislead others and endanger human life, is an unlawful act for which the party guilty of the act is responsible, whether he did it wilfully or negligently, and to entitle the aggrieved party to his action in such case no privity is necessary except such as is created by the unlawful act and consequential injury. Privity of contract in such case is out of the question. For a duty violated by a druggist giving a false label is a duty not created by contract, but by law, every one being under an obligation to abstain from acts tending naturally and probably to endanger human life.

The injury is not rendered too remote to sustain a recovery because separated from the unlawful act by intervening events, however numerous or of whatever kind, provided they are the natural and probable consequences of the act.

And when the unlawful act is in its nature likely to produce the events which follow, as, for instance, a patient taking a poison instead of some harmless or different prescription than that intended, by reason of a false label of a druggist, the author of it may be treated as having caused the succeeding events, though they consisted of the acts of third persons. For the false label is a continuing authority or direction by the druggist for the use of the poison, and he is bound to indemnify against the acts which it was likely to cause when sold in that condition.

The foregoing propositions seem to be fully sustained by the case of Thomas *v.* Winchester, in the Court of Appeals.

That was an action brought to recover damages for negligently putting up, labelling, and selling as and for the "Extract of Dandelion" a jar of the "Extract of Belladonna," by means of which the plaintiff's wife, Mrs. Thomas, being sick, a dose of dandelion was prescribed by a physician, and a portion of the contents of the jar of belladonna was administered as and for the extract of dandelion, etc.

The facts of the case, briefly, were as follows:—

The defendant, Winchester, was engaged at 108, John Street, New York, in the manufacture and sale of certain vegetable extracts for medicinal purposes, and in the purchase and sale of others.

The extracts manufactured by him were put up in jars for sale, and those he purchased were put up by him in like manner.

The jars containing extracts manufactured by himself and those containing extracts purchased by him from others, were labelled alike—both were labelled as "prepared by A. Gilbert," a person in the employ of defendant.

The jar in question was labelled "½ *lb. Dandelion, prepared by A. Gilbert, No.* 108, *John Street, N.Y.;*" and in fact contained belladonna, and not dandelion.

The jar was sold by defendant to a wholesale druggist in New York, as and for the extract of dandelion. Dr. Foord, a physician and druggist at Cazenovia, Madison county, N. Y., purchased the article from the New York druggist, as and for the extract of dandelion.

Mrs. Thomas being ill, her physician prescribed a dose of dandelion. Her husband purchased what was believed to be the medicine prescribed, at the store of Dr. Foord. The medicine was taken from the jar in question and administered to Mrs. Thomas, who was thereby made dangerously ill, and the action was brought against Winchester and Gilbert to recover damages.

It appeared that the extract in the jar in question was not manufactured by defendant himself, but was purchased by him from another manufacturer or dealer, but labelled with Gilbert's labels, which labels were paid for by Winchester, and used in his business with his knowledge and assent.

It was objected, among other questions, that the action could not be sustained, as the defendant was the remote vendor of the article in question, and there was no connection, transaction, or privity between defendant and the plaintiff.

A verdict was rendered against the defendant Winchester; the defendant Gilbert being acquitted by direction of the Court.

The defendant Winchester appealed to Court of Appeals, and it was there held that a dealer in drugs and medicines, who carelessly labels a deadly poison as a harmless medicine, and sends it so labelled into market, is liable *to all persons* who, without fault on their part, are injured by using it as such medicine in consequence of the false label. That the liability of the dealer, in such case, arises, not out of any contract or direct privity between him and the person injured, but out of the duty which the law imposes upon him to avoid acts in their nature dangerous to the lives of others. He is liable, therefore, though the poisonous drug with such label may have passed through many intermediate sales before it reaches the hands of the person injured. That where such negligent act is done by an agent, the principal is liable for the injury caused thereby.

Although the defendant Gilbert was acquitted by the jury under direction of the Court, and judgment rendered against the defendant Winchester alone for damages, Judge Ruggles, in delivering the opinion of the Court of Appeals, said that "Gilbert, the defendant's agent, would have been punishable for manslaughter, if Mrs. Thomas had died in consequence of taking the falsely labelled medicine." (2 R. S. 662, § 17; Tessymond's Case; 1 Lewin's Crown Cases, 169; Regina *v.* Swindall; 2 Car. & Ker. 232.)

"Although the defendant Winchester may not be answerable criminally for the negligence of his agent, there can be no doubt of his liability in a civil action, in which the act of the agent is to be regarded as the act of the principal."

See the case fully reported in 6 New York (2 Selden) Reports, page 397, and the numerous authorities there cited and referred to.

The law regulating the sale of poison by druggists might be amended in this respect:—

Druggists should be required, in addition to the label of poison and the name of the poison, to name also the antidote to such poison, and give brief directions for administering the antidote. This should be printed or written plainly and legibly, so that in cases of poison being taken by accident or design, an antidote could be quickly administered without the delay of getting a physician; and no doubt many lives could thereby be saved.

The law of 1860 seems to be defective in limiting its application to incorporated cities and villages having a population of one thousand inhabitants and upwards.

It might with advantage be made general in its application throughout the State.—*Medical Record.*

SPIRITUS AMMONIÆ AROMATICUS.

The following are the results of the analyses of six samples of the above preparation, obtained from different druggists, published in the *Practitioner*:—

Nos.	Per cent. Alcohol by weight in volume.	Per cent. of Ammonia by weight in volume.
Brit. Pharm.	62·6	2·6

The Pharmaceutical Journal.

SATURDAY, JANUARY 21, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes endorsed "Pharm. Journ."*

PRESCRIPTIONS.

THE principal practical part of a pharmacist's duty being the compounding of recipes emanating from men supposed to know better than himself the therapeutical effects of the drugs employed, it would be presumptuous in the face of such a supposition for the pharmacist to add, alter, or subtract one iota from the prescriptions presented to him. And the grand basis of all social well-being in every relationship of life consisting in *sincerity*, how much more must it be self-evident that in life-and-death cases between patient, physician and prescriber, all should be actuated by the sincerest motives for the mutual good of each. Yet the pharmacist is often obliged to act as a check on the physician's involuntary mistakes, or occasional posological errors. One of the great sources of doubt and uneasiness to the most sincere and intelligent dispensers is the omission of terminations. Admitting the general public not to understand Latin, why mutilate it, rendering it more unintelligible to them and more puzzling to the dispenser. What can be more ambiguous than the everyday ℞. pot. chlor. or sodæ sulph. of ordinary prescription-writers? It is true that habit, experience, and above all, a knowledge, not only of the properties of medicines, but of their therapeutical uses, enable the dispenser in 99 cases out of 100 to skim over the difficulty, scarcely noticing it. But frequently the ambiguity and consequent responsibility become much greater.

This lax and undignified habit of abbreviating nearly every word has caused, and causes, innumerable mistakes. Why should, for instance, the dispenser use chlorate of potassium in a gargle where pot. chlor. is ordered? Common salt dissolved in water is a frequent domestic remedy for sore-throat, why should not chloride of potassium be equally efficacious? and why might not the physician wish to try it? A dispenser takes an unwarrantable amount of responsibility in selecting one salt in preference to the other. And the physician has no right to throw a shadow of that sort of responsibility on the druggist's shoulders. Moreover, these things occur so often that people are content to lie prone *in statu quo*, without ever trying in the least to improve the situation.

The habit of writing Latin prescriptions must be considered, on the whole, an advantageous one; for in countries where the vernacular is used as a medium of understanding between doctor and druggist, the tendency to revert to old-fashioned and even quite obsolete terms, causes quite as much misapprehension as abbreviated Latin does here. This is evidently done for exactly the same reason as obscure Latin is even openly sanctioned by some members of the profession, in order to prevent the patient from feeling nervous at the exhibition of opium or calomel. But sick people's faculties are often miraculously sharpened by curiosity, and experience proves that such awful names as *Sirop de Karabé* or protochloride of hydrargyrum, though even cautiously pronounced and declared safe and reliable medicines by the urbane chemist, will frighten nervous people ten times more than the names of drugs familiar to the ears of all intelligent persons.

Needless mysticism is the greatest fault of all, for it necessarily causes more mistakes at the dispenser's hands than is warranted by an increased privacy of inter-communication. An eminent English practitioner, whose prescriptions are to be found all over the Continent, always writes Syr. C. for simple syrup,—an anything but orthodox synonym, syrupus communis being used to designate treacle in the Prussian Pharmacopœia.* Could not a great amount of good be done to the pharmaceutical community at large if a few "sincere" dispensers in the large houses in town and country would quietly note any of these peculiarities and have them periodically published?

THE QUALITY OF DRUGS.

IT is announced in the *Practitioner* for January that, in consequence of complaints made by medical men as to the varying qualities of drugs, even when obtained from the most respectable shops, it is intended to commence an extensive examination of preparations of food and medicine, the results of which will be published in that journal. As a commencement, the results of a series of analyses of samples of sp. ammoniæ aromaticus are given. According to the British Pharmacopœia this preparation should contain 62·6 per cent. of alcohol by weight in volume, and 2·6 per cent. of ammonia by weight in volume. The quantities in the six specimens analysed ranged from 63·1 to 48·1 per cent. of alcohol and from 2·0 to 1·5 per cent. of ammonia.

It is unfortunate that this preparation should have been selected for the purpose of introducing the examinations contemplated by our contemporary, for it is one in reference to which there are

* "Syrupus communis—Gemeiner Syrup. Nonnisi syrupus in depurando saccharo Indico obtentus adhibeatur." —*Ph. Borussica*, p. 193.

great differences of practice. Several of our oldest and most respectable establishments have their own formulæ for this preparation, and they find it requisite to follow those formulæ in order to meet the demands of their customers. It is therefore by no means a legitimate inference that a deviation from the Pharmacopœia in the sal volatile bought at a shop of credit is to be regarded as indicating inferiority. This is not a matter of quality or of price, and before any one can justly assert that particular druggists improperly make use of preparations which do not conform to the Pharmacopœia, the examiner must be careful to make sure that he obtains from the vendors such preparations as they would use in dispensing and not for ordinary sale. There may be, without any impropriety, a great difference in this respect, not at all inconsistent with due adherence to the Pharmacopœia in all cases of dispensing.

The *Melbourne Argus* announces that, attention having been drawn of late to the evil results which follow the making up of medical prescriptions by druggists not sufficiently qualified, steps have been taken by the Pharmaceutical Society of Victoria to secure the passing of a Pharmacy Bill during the next session of Parliament. At a meeting of chemists and druggists recently held in Melbourne, it was decided that a Bill should be sketched out by the Council of the Society, and that the Government should be asked to draft it and adopt it. The object of the Bill will be to prevent, in future, any but thoroughly competent men from acting as chemists and druggists.

In Dr. Lankester's Annual Report of Inquests held by him in 1868-9, he calls attention to the fact that poison ranks third in frequency among the means of suicide. It appears also that a considerable change has taken place in the selection of poisons by intending suicides. He says that cyanide of potassium, which is used in enormous quantities by photographers, and may be purchased without difficulty, has been the poison most frequently used during the last seven years. Oxalic acid, which stands next, is used by shoemakers, saddlers, and harness-makers. The use of opium for the purposes of suicide is on the decline, owing to the difficulty of procuring a sufficient quantity of that drug. The same remark applies to hydrocyanic acid. Then comes oil of bitter almonds, rarely, if ever, the cause of accidental poisoning. Next sulphuric and hydrochloric acids, employed by metal-workers and brass-finishers. Vermin powders and preparations of strychnine stand lowest on the list, only two cases of poisoning by these agents having been recorded during the last seven years.

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

January 18th, 1871.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Edwards, Gale, Garle, Hanbury, Haselden, Ince and Southall.

FIRST, OR PRELIMINARY EXAMINATION.

Two hundred and ninety-eight Candidates were examined; the following two hundred and ten passed, and were registered as

APPRENTICES OR STUDENTS.

	Welcher, Robert Mitchell	Chatteris.
	Whitefoot, Thomas	Ludlow.
	Wilson, Thomas	Blackheath.
	Wright, John Henry	Leeds.

The following is a list of the towns in which the examinations were held, with the number of candidates annexed:—

Aberdeen	5	Lanark	1
Abingdon	1	Lancaster	2
Altrincham	1	Leeds	11
Andover	1	Leighton Buzzard	1
Ashton-under-Lyne	3	Lewes	1
Ashby-de-la-Zouch	2	Lincoln	2
Aylesbury	1	Liverpool	4
Barnstaple	4	London	37
Bath	1	Manchester	16
Belfast	3	Merthyr Tydfil	6
Bewdley	2	Newark	1
Birmingham	8	Newcastle-on-Tyne	2
Bolton	1	Newport (I. of W.)	1
Boston	3	Northampton	4
Bradford	3	Norwich	3
Bridgnorth	1	Nottingham	9
Brighton	1	Oxford	2
Bristol	4	Pembroke Dock	2
Bury St. Edmund's	2	Perth	1
Cambridge	1	Peterborough	3
Cardigan	2	Plymouth	3
Carlisle	4	Poole	4
Carmarthen	4	Portsmouth	2
Carnarvon	2	Reading	1
Cheltenham	1	Richmond	1
Chesterfield	1	Ripon	2
Colchester	1	Ruthin	1
Coventry	3	St. Austell	1
Darlington	2	St. Ives (Cornwall)	1
Derby	2	Scarborough	1
Devonport	1	Sheffield	1
Doncaster	5	Sleaford	1
Dorking	1	Southampton	1
Dover	4	South Shields	2
Dublin	1	Stafford	1
Dudley	1	Stamford	5
Durham	3	Stockport	4
Ellon	4	Stockton-on-Tees	2
Evesham	1	Stoke-on-Trent	1
Exeter	2	Stourbridge	2
Farnham	2	Stowmarket	2
Flint	1	Swansea	5
Forres	1	Taunton	5
Frome	1	Tenby	1
Grantham	1	Tewkesbury	1
Halifax	1	Thirsk	1
Hartlepool	1	Tiverton	1
Hereford	1	Torquay	1
Holywell	1	Truro	1
Horncastle	3	Wallingford	1
Huddersfield	2	Warrington	1
Hull	9	Wednesbury	3
Huntingdon	1	Whitehaven	1
Ipswich	1	Winchester	1
Kendal	1	Wolverhampton	2
Kidderminster	1	Worcester	1
King's Lynn	2	York	1

The Questions for Examination were as follows:—

Time allowed: Three Hours.

LATIN.

Translate into English two at least of the following sentences:

1. Flumen est Arar, quod per fines Æduorum et Sequanorum in Rhodanum influit incredibili lenitate, ita ut oculis, in utram partem fluat, judicari non possit: id Helvetii, ratibus ac lintribus junctis, transibant.

2. Quod si veteris contumeliæ oblivisci vellet; num etiam recentium injuriarum, quod eo invito, iter per provinciam per vim tentâssent, quod Æduos, quod Ambarros, quod Allobrogas vexâssent, memoriam deponere posse?

3. Fiat haustus, quartâ quâque horâ capiendus. Ut effectus sudorificus augeatur, adde singulis haustibus antimonii potassio-tartratis grani quartam partem.

4. Rosæ prius divulsæ aquam superinfunde, dein acidum immisce. Macera per horas duas, et liquorem cola; denique saccharum adjice.

5. Give the genitive and dative endings, singular number, of nouns of the fifth declension, and state the gender to which they belong.

6. Decline *idem*, the same.

7. In what case do you put a noun of time when it answers to "how long"? Give an example in Latin.

8. State to which conjugation each of the following verbs belongs, and give the second person singular, present tense, indicative mood: *debeo*, *repurgo*, *scribo*, and *audio*.

9. What case does *esse* take after it? Give an example.

ARITHMETIC.

10. Multiply 2710432 by 375.

11. If I gave £187. 3*s.* 3*d.* for 25 cwt. 3 qrs. 14 lb. of Senna, what did I pay per lb.?

12. Reduce $\frac{1\frac{1}{2}}{12}$ of $\frac{1\frac{3}{4}}{14}$ of $\frac{2\frac{1}{2}}{29}$ to a single fraction.

13. Add $5\frac{2}{3}$, $6\frac{7}{8}$, and $4\frac{1}{2}$ together.

14. What is the difference between three-tenths of an unit and 64 ten-thousandth parts of an unit?

ENGLISH.

15. Into how many parts is English grammar divided? Name them.

16. How many articles are there, and where are they used?

17. How do nouns ending in *ch* form the plural, also nouns ending in *ch* sounding *k*? Illustrate by examples.

18. Give the past tense and past participle of the following irregular verbs: fly, hew, drink, slay, and speak.

19. Correct the following: If she were the wittier, he were the wisest of all.

20. Write from 15 to 25 lines upon *one* only of the following subjects:—
   a. The importance of early mental cultivation.
   b. The advantages of having good companions.
   c. The blessings of peace.

Certificates presented by the undermentioned were accepted in lieu of this Examination:—

Richards, James Griffiths .... Newport, Mon.
Savell, Edward Pearce .... Southampton.
West, John Leaver .... Ashby-de-la-Zouch.
Wright, Conrad William .... Tewkesbury.

Four Candidates presented themselves for the Major Examination, and Sixteen for the Minor; the following passed, and were duly registered:—

MAJOR (as Pharmaceutical Chemists).

*Diaper, Albert .... Bury St. Edmunds.
*Reinhardt, William Tynedale .. Leeds.
Sherburn, Thomas .... Harrogate.
Sandiland, Robert Burgess, jun. Bicester.

MINOR (as Chemists and Druggists).

*Catterns, Heneage Parker .... London.
*Troake, Marler Hamilton .... Kingsbridge.
*Hughes, Evan Grismond ...... Llandilo.

---

* Passed with honours.

	*Humphry, Horatio	Southampton.
	*Brown, James	Ampthill.
	Overton, Charles Arthur	Horncastle.
	Smith, John Francis	Scarborough.
	Chitty, Frederick	Titchfield.
	Parker, John Samuel	Peterborough.
Equal.	Jones, Alfred	Northampton.
Equal.	Watmough, George Capes	Caistor.
	Atkinson, David	London.
	Francis, William	Carmarthen.
	Arundel, Matthew Henry	Penge.
	Coles, Samuel John	Liverpool.

The above names are arranged in order of merit.

* Passed with honours.

Provincial Transactions.

THE SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The Second Annual Meeting was held on Wednesday evening, January 11th, in the Rooms, Music Hall; Mr. Wilson, the President, in the chair.

The Secretary read the following Report:—

"In presenting the Second Annual Report, the Council have great pleasure in being able to offer their congratulations upon the prosperous condition of the Association. The number of Members and Associates shows a slight increase upon that of last year, the losses by resignations and death having been replaced by new Members; and we have every reason to believe that the third year will be commenced by a considerable addition to our numbers.

"The Council desire to acknowledge the services Mr. Ward has rendered to the Association by gratuitously giving a course of chemical lectures (prepared at great expense of time) to the students during the Summer Session. An attempt was also made to form a botanical class, but proved unsuccessful. At the ordinary monthly meetings lectures have been given upon—

"'The Detection of Poisons,' by W. Baker, Esq., F.C.S.

"'Nitrous Oxide, or Laughing Gas,' by Dr. Harrison, F.C.S.

"The Winter Session was inaugurated with an address by Dr. J. C. Hall, Oct. 19th, since which the following lectures have been given:—

"'The Nightshades,' by Dr. Griffiths.

"'The Laws of Heat,' by W. Baker, Esq., F.C.S.

"'The Dangerous Gases of Coal Mines,' by Mr. Bradwell, an Associate of the Society.

"It was decided to hold fortnightly meetings, trusting that Associates would be induced to read short 'Papers,' and to give opportunity for discussion; but, from unavoidable causes, they have not been carried out.

"A Latin Class, conducted by Mr. Fox, and a Chemical Class, by Mr. Allen, have been organized, and are now in active operation; the number in each being about twelve.

"Prizes have been offered by members of the Council, for which the students are invited to compete at the end of the course. Strenuous efforts have been made by the Council to extend the usefulness of the Association, by throwing open these classes to the Assistants and Apprentices of neighbouring towns; and, with that object, deputations of the Council visited Rotherham and Chesterfield, and canvassed all the chemists and druggists in those places.

"Notwithstanding adverse circumstances, their success was such as to augur well for the future of the Association; and the Council have every confidence that Sheffield will become the centre of pharmaceutical education for the district.

"The Council are indebted to Mr. James Allport, General Manager of the Midland Railway Company, for allowing the Chesterfield students to travel to and fro at reduced fares.

"The Library now contains many valuable works for study and reference; seventeen volumes have recently been purchased. The Pharmaceutical Journal, the gift of the Council of the Pharmaceutical Society, and the *Lancet* are now weekly placed upon the table of the reading-room.

"Valuable donations to the Library and Museum have been received from the President, Mr. E. Wilson, of a large Smee's galvanic battery; from Mr. Nathaniel Booth, Rotherham, of thirty-seven volumes of the *Lancet* and seven volumes of Bell's 'Surgery;' and from Messrs. Cubley and Preston of a small cabinet of mineral specimens.

"The Council, in retiring from office, solicit for their successors the support of the masters, not only in contributing to the funds of the Association, but by giving every facility for their assistants and apprentices to attend the classes and reading-room.

"They look back upon the operations of the past as very successful; they see an increasing desire on the part of the students to avail themselves of the advantages the Society offers; and they have every confidence that the educational department will be placed upon a firm basis."

Mr. Barber proposed, and Mr. Cubley seconded, that the Report, as now read, be confirmed. Carried unanimously.

The following officers were elected for the ensuing year:—*President:* Mr. J. T. Dobb. *Vice-Presidents:* Mr. G. B. Cocking and Mr. Horncastle. *Treasurer:* Mr. Radley. *Secretary:* Mr. H. W. Maleham. *Auditors:* Mr. Crawshaw and Mr. Priestley. *Council:* Messrs. Cubley, Hill, Huddlestone, Hudson, Preston, Ward, and Wilson.

Mr. COCKING proposed, and Mr. WILSON seconded, That Rule 12 shall be altered, and read as follows:—"That the ordinary monthly meetings for the transaction of business be held on the first Thursday in every month." Carried.

Messrs. Newham and Strain were elected Members, and Messrs. Jervis, Thwaites, Wood, Birch (Chesterfield), Aldred (Chesterfield), and Hesk (Rotherham), Associates.

Cordial votes of thanks to the retiring President, and each of the other officers, for their services during the past year, concluded the business of the meeting.

HALIFAX CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Annual Meeting of the members of the above Association was held last month, but with only a moderate attendance. After supper the Secretary commenced the business of the evening by reading the report, viz.

"The usual meetings in the early part of the year were mostly occupied in the consideration of the intention of the Council of the Pharmaceutical Society to introduce very stringent regulations in the storage and sale of poisons. These were unanimously disapproved of, and your Committee, in conjunction with many others, protested against them. These protests and agitations resulted in the defeat of the intended plan, and in such a change in the Council of the Society unequalled in its history.

"Two valuable papers have been read during the year: one on Materia Medica, by Mr. Shaw, and the other on the proposed Poison Regulations, by Mr. Brook. It is a subject of regret with your Committee that the number of papers have been so few; the chief cause of this is the slender attendance at the meetings, whilst the apathy of a great number of members gives no encouragement to those who are able and willing to undertake the preparation of an elaborate paper.

"During the year the Committee have succeeded in establishing a class in botany. The procuring of a suitable teacher was a matter of some difficulty which has been so well overcome, that the pupils express great confidence and satisfaction with the tutor. The Committee have decided to offer for competition a prize, to be awarded at the examination next month.. An effort has been made to form a class in materia medica, which only failed through the want of a suitable teacher. The classes in chemistry and Latin have this year improved in numbers and in regularity of attendance, and there is every reason to believe that at the examination in the ensuing spring, the young men will distinguish themselves. It is to be deeply regretted that there are many young men who do not avail themselves of these great advantages, a neglect which will seriously imperil their interests in the future, and which now prevents them being as reliable and useful in daily duties as they otherwise would be. Your Committee earnestly hope that this last consideration will have its weight with the members, and that they will insist upon every one of their young men attending these classes. Whilst the Committee have done their utmost to complete a thorough system of technical education, so that the future members of the trade will be men of undoubted stamp, they have not left untouched some of the grievances of the present members of the trade, and have succeeded in shortening the hours of business. A more uniform rate of retail charges has also received a large amount of attention, but the near approach of the Annual Meeting compelled its postponement till next year."

Mr. JESSOP proposed and Mr. BROOK seconded that the report as read be adopted. Carried.

Mr. SHAW proposed, and Mr. FARR seconded, that Mr. Stott be the President for the ensuing year.

Mr. STOTT in reply thanked them for the honour they had conferred upon him. He regretted that the continued indisposition of their late President prevented him from any longer occupying that position. He must express his great surprise that numbers of the members were simply content with their names being on the list, and very rarely attending any of the meetings. If there were larger attendance, and more earnestness displayed by the members, the Committee would possess greater influence in the removal of many trade grievances, and in advancing the education of their youths. During the year the principal novelty in medicine had been the discovery of the usefulness of chloral hydrate, on which he commented, as also on the various papers read before the Pharmaceutical Conference at Liverpool, and expressed his approval of the desire of the Association, that the names of Preparations should be truthful. With respect to patent medicines, he thought the trade was glutted with quackery, and he would rather see a diminution than an increase in that direction. He hoped a plan for regulation of poisons would be framed that would protect the public and be acceptable to the trade. Mr. Stott concluded his remarks by stating that the Committee should gladly have his assistance in furthering their efforts in the spread of technical education amongst their young men.

Mr. HEBDEN, Hon. Sec., regretted that his numerous engagements prevented him any longer filling the above post. He had great pleasure in moving that Mr. Brook be his successor, which was carried unanimously, as well as the election of Mr. J. Brierley as Treasurer.

The question as to how an increased interest and attendance at the monthly meetings could be brought about, after a long discussion, ended in the following motion being carried:—"That in the absence of pressing business at our meetings, each member in turn be expected to introduce matters of special interest to the trade, sufficient notice being given to prepare for such meeting."

A vote of thanks to Mr. Dyer for two years' services as President, to Mr. Hebden, as Hon. Sec., and to the President, brought the evening's proceedings to a close.

First Monthly Meeting, held January 12, 1871; Mr. JESSOP, Vice-President, in the chair.

Mr. HEBDEN introduced the subject of the late examination of the Botany Class, and presented the Report of the Examiner, Dr. Dougall. The Report stated there were six questions given, valued at 65 marks. Only one youth answered the six with any degree of correctness, gaining for himself 32 marks; the next highest number being 29. Mr. Hebden thought the students had hardly come up to the mark the Association could have wished, and advised that the prize offered to the successful pupil should be reduced in value to that originally intended.

Mr. FARR agreed with the last speaker, and suggested a more valuable one next Session.

Eventually Mr. JESSOP moved, and Mr. J. B. BRIERLEY seconded, "That a prize of not less value than 5*s.*, in the form of a scientific work, be presented to Wm. Ferrand, the successful pupil.

The question of forming a Materia Medica Class then engaged the attention of the members.

Mr. HEBDEN informed the meeting that Dr. Dougall had very handsomely offered his services to conduct it, if a sufficient number of members could be obtained. Several gentlemen expressed a strong desire that such a class should be formed, deeming it of more importance than botany, and as Dr. Synnott and Mr. Shaw have both kindly offered valuable prizes in connection with it, the latter gentleman having also volunteered to conduct an examination, it is thought a good class may be formed next Session.

The Treasurer presented a cash statement showing a balance in favour of the Association of £4. 5*s.* 3*d.*, which was ordered to be entered on the minutes of the Association. A vote of thanks to Dr. Dougall for his kindness in conducting the examination of the the students in botany ended the meeting.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Seventeenth Session.

The Seventh Meeting of the Session was held in Anderson's University on Wednesday evening the 11th inst.; Mr. T. Davison, President, in the chair. The Secretary announced receipt of the Pharmaceutical Journal and *Chicago Pharmacist* as donations. Messrs. James Dickie, Crocket, Brodie, M'Auley and Wallace were elected members.

R. Carter Moffat, Esq., Ph.D., F.R.S.S.A. (honorary member), then delivered a highly interesting lecture on "The Detection of Alum in Bread." He first explained some of the many processes recommended by chemists for this purpose, stating that for many years it was one of the most difficult problems to solve. He then went on to say, that some months ago he had been engaged, professionally, to report as to whether alum was really present in some breads, as alleged. His attention was thus drawn to the untrustworthiness of some of the tests and the awkwardness of others, and he endeavoured to remedy the matter if possible. After performing nearly two hundred experiments, however, the matter seemed to him as far from solution as ever. At length he came upon the process known as Mr. Horsley's, of Cheltenham, which recommends that a piece of bread be placed in vinegar for a short time, the vinegar then to be strained off, and a little ammonia added to the clear liquor, to neutralize the acid; an alcoholic solution of logwood was then to be added, which, it was stated, gave the liquor a blue coloration when alum was present. Fourteen loaves, besides some samples of flour, had been given him for analysis; and, according to Mr. Horsley's process, every one of these contained alum. But on experimenting further he (the lecturer) found that the blue coloration was produced when *no* alum was present, which led him to the discovery that by far the most reliable test for detecting the presence or non-presence of alum in bread or flour, was the simple alcoholic solution of logwood, without any of the burning, boiling, or other processes. He used 120 grains of ordinary chip logwood, and digested it for eighteen hours in 8 ounces of methylated spirit and filtered it. When the solution is brought in contact with bread or flour *free* from aluminum, a pale yellow or straw colour is produced, but if aluminum be present the colour turns out a dark red. With this test he had found that only *one* of the fourteen loaves contained alum, showing that this substance was not so extensively used for whitening bread as had been given out by many chemists and others. The lecturer performed some experiments in illustration of his subject, and at the conclusion was awarded a hearty vote of thanks.

The proposed poison regulations were then considered, and in course of a short discussion—in which the feeling semed to prevail that chemists generally could not object to regulations of some kind being made in regard to the keeping of poisons—it was thought advisable to oppose them becoming law in their present form, until such time as the Government should see fit to place the same restrictions upon surgeons and others who keep open shop for the dispensing of medicines. A member stated that he thought if the druggists would agree to the regulations independent of the surgeons altogether, the public would have greater confidence in going to the chemist for their drugs; but the idea was repudiated by most of the members, on the ground that surgeons who had shops never allowed their prescriptions to be dispensed elsewhere if they could avoid it; and further, because in many of the large towns in Scotland surgeons had the cream of the drug business in their own hands; in Glasgow particularly fully two-thirds of the drug retailers being medical practitioners who, it was understood, would be entirely exempt from the restrictions. The President and Secretary were instructed to communicate with some of the other associations, to ascertain what action was being taken by them in the matter, and also to write to the medical department of the Privy Council, explaining the position in which the Glasgow chemists will be placed in the event of the regulations, as at present proposed, becoming law. The discussion was then adjourned till next meeting.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

On Fermentation.

BY PROFESSOR A. W. WILLIAMSON, F.R.S.

Lecture IV.—continued.

Amongst the processes which are detrimental to the quality of wine, I have already mentioned the excess of air having access to it. That is the one which is most known, and against which people least need to be cautioned, but it has been found by wine-growers and wine-makers, especially in the case of higher-class wines, like those of Burgundy and some other districts, are liable to particular maladies which produce evils, each one quite peculiar and different from the others. Amongst these maladies, the first and simplest of all, is acetification, or the transformation of the alcohol into acetic acid. That is one which is so well known now, and so well understood, that, I think, wine-growers are well able to guard against it with tolerable completeness. By the use of a microscope, these little acetic cells on the surface of the liquid would at once be seen, and you would know, of course, that there would then be a tendency in the wine to pass over into acetic acid, and that, unless those cells are removed, or if they are present, unless oxygen be excluded,—because the presence of the cells does not of itself make the wine into vinegar, it is necessary that they should be present with a continuous supply of air,—so that if they are removed, or if you prevent a supply of air, that malady is arrested or cured. But there is another malady which is well known, and frequently spoken of amongst wine-growers as the "turning" of wine. It is a process which is, in its general features, something analogous to acetification, but chemically it is very different. When the wine is put into casks, it begins to give off gas, and in French they call it *la pousse;* it pushes out the ends of the casks, and, if a hole were made, the wine would be ejected with considerable force. M. Pasteur has examined not only the wine itself when undergoing this process, but also the deposit, the little solid particles which are present in it, and he has found two things which are correlative to one another,—in the first place, that there is always present in wine which is suffering from this malady certain little films, which can be seen quite distinctly by the microscope, and which are different from any particles found under any other conditions, and which he therefore believes to be little organic bodies, just as much as in the alcoholic ferment or acetic ferment, and he calls them the ferment of the turning or *la pousse.* That is one fact which is established. These little particles are compared in their structure to little bamboos, as they consist of little straight joints one at the end of the other, the length being considerably greater than the diameter; they are not little spherical matters, like the wine ferment, and their diameter is exceedingly small, being about the one-thousandth part of a millimetre. That is one fact which M. Pasteur has established, and the other is this, that while this process is going on, lactic acid is present; and his explanation of the malady consists in attributing it to the presence of this particular parasite in the wine, which is transforming the materials of it into lactic acid, with no doubt some other product, at the same time. Another malady which not unfrequently occurs in wine, is ropiness; and it is said that wine suffering acutely from this malady might almost be mistaken for oil, when poured from one vessel to another, so thickly does it flow. That peculiarity is attributed solely to the presence in it of a number of little films peculiar to it; but they are very different to the eye, and very different also in their functions from the films which constitute the active agency of the process I have just mentioned, that of turning. These little films are like little strings of beads, little spherical particles, a great number of them joined end to end. The particular nature of the transformation which the wine undergoes has not been investigated, but, as far as M. Pasteur's observations go, and they are very numerous and accurate, these little strings of beads are really active agents in that particular transformation which constitutes ropiness, and which destroys wine; for, if it cannot be arrested, the wine ceases to be drinkable, and becomes worthless. The fourth malady, which is also one of frequent occurrence, is one which produces a bitterness, and it is said that this malady is one to which wine is subject in its youth and also in its old age; that it sometimes occurs when wine is two or three years old, and sometimes, though in a less acute form, when it is very old. Here, also, a particular parasite is present, little organized particles, which have been minutely described and depicted, and they are found in various states, some differing very much from the others. Some pictures of the parasites which constitute the bitter ferment are like little branches with a number of little knobs or warts upon them, and some of them are clear and transparent, whilst others are coated with an incrustation. M. Pasteur, however, has already shown that the little knobs or warts upon them, and the incrustation which frequently occurs, are nothing else than foreign matter deposited upon them, that when the parasite dies it is liable to be encrusted, but that in a pure state it is clear and transparent. This parasite, when it occurs in young wine, renders it completely worthless, but when it occurs in old wine, it only gives such an amount of bitterness as is not fatal to the wine, and is, to a certain extent, exceedingly common, so that it is considered almost a natural accompaniment of old wine. Amongst the remedies for these processes is sulphurous acid, which, of course, would destroy parasites when they are present. We can quite understand that wine which has got germs of these little organic beings present in it is liable to undergo these injurious changes if the germs are allowed to develope themselves, but that it would be free from all such tendency if, by any poisonous material, the little germs or organisms were destroyed. We can also understand that any mechanical process of filtration, or of forming in the liquid a gelatinous mass which will subside and carry down with it any fine particles which may be present in suspension, but which are too light to settle of themselves, would effect the same object; and it is quite intelligible, that if Pasteur's view is correct, that these little solid particles are the active agents of those transformations, the processes which have commonly been in use for preventing the detriment of wine by such changes should be effectual; we can quite see why they ought and indeed must be effectual, but, at the same time, we cannot help seeing that they would be very liable to be incomplete. Of course, it is a matter of chance whether, if you form a precipitate in the liquid, the little light particles would all happen to be caught by some of this precipitate when going down. We should expect that any such process would be efficacious in diminishing the evil, but not in arresting it completely, and I believe that is exactly what is found by experience.

(*To be continued.*)

MEETINGS FOR THE ENSUING WEEK.

MONDAY ......*Medical Society,* at 9 P.M.
London Institution, at 4 P.M.—"On the First Principles of Biology." By Prof. Huxley.

TUESDAY ......*Royal Medical and Chirurgical Society,* at 8.30 P.M.

WEDNESDAY...*Society of Arts,* at 8 P.M.—"New Paper-making Materials and the Progress of the Paper Manufacture." By P. L. Simmonds.
London Institution, at 7 P.M.—Conversazione. "On Dust and Disease." By Prof. Tyndall.

THURSDAY......*Royal Society,* at 8.30 P.M.
London Institution, at 7.30. P.M.—"On the Action, Nature, and Detection of Poisons." By F. S. Barff.
London Chemists' Association, at 9.30 P.M.—"Preservation of Vegetable Substances." By E. Beynon.

FRIDAY ....*Royal Institution,* at 8 P.M.—Lecture by Professor Odling.
Quekett Club, at 8 P.M.

SATURDAY......*Royal Botanic Society,* at 3.45 P.M.

Parliamentary and Law Proceedings.

A Druggist acting as an Accoucheur.

At an inquest, held on Wednesday last, before the Brighton Borough Coroner, to inquire into the death of a young woman shortly after her confinement, evidence was given gravely implicating William Henry Funnell, a chemist and druggist.

The deceased, it appeared, had made an arrangement with Mr. Funnell to attend her during her confinement, it being alleged that he represented to her that he had been in the habit of attending night cases and cases of emergency for Mr. Tuke, surgeon, with whom he formerly lived as dispenser. When the time came, symptoms of unusual difficulty set in, with which he was evidently quite incompetent to cope. After the lapse of some time he called in skilled assistance, and the delivery was effected, but the patient died half an hour afterwards from exhaustion.

Medical evidence was given to the effect that although the case was an unusual one, it was one that a skilled practitioner would have recognized and treated accordingly. Mr. Tuke denied that Mr. Funnell was justified in saying that he attended his night cases. He said that Mr. Funnell did attend several labours for him, in cases of emergency, while acting as his dispenser, but he invariably saw the cases afterwards himself, and Mr. Funnell always referred to him if any symptoms appeared which he could not understand.

The jury returned a verdict that the deceased had died through not having had proper medical attendance until too late, and requested the coroner to censure Mr. Funnell for his conduct in the matter.

This the coroner did, telling him that the only reason why the jury refrained from sending him for trial on a charge of manslaughter was that the case was an unusual one, and that he had devoted a great deal of time to it. If the jury had been a severe, instead of a very kindly and lenient one, he would have been committed for trial on the criminal charge, and thus put in a position of great peril.—*Brighton Daily News.*

Singular Case of Poisoning by Arsenic.

An inquiry has just taken place into a supposed case of poisoning by arsenic, which resulted in a farmer named Knowles, living at Tipp's End, Upwell, near Wisbeach, being committed for trial for the manslaughter of the child of a labourer. According to the evidence, the prisoner had prepared a little more than a peck of wheat with arsenic for sowing. This he mixed with two bushels of clean wheat and sent the whole to a mill to be ground. After it had been ground a small quantity of Knowles's grist remained in the mill and was mixed with other grist. The result was that several persons, after partaking of food prepared with this flour were seized with violent pains and sickness; all, with the exception of the child, however, recovering. Arsenic was discovered in the stomach of deceased and in some of the food that remained. Medical evidence showed that the child was suffering from bronchitis, but that its death was accelerated by the poison.—*Daily News.*

Review.

Year-Book of Pharmacy and Transactions of the British Pharmaceutical Conference, 1870. Churchill and Sons.

The British Pharmaceutical Conference have undertaken a very useful duty in the compilation of this work. At the present time, when the art of Pharmacy is everywhere making such rapid strides, it is more than ever necessary that the English pharmacist should be fully acquainted with the labours of his fellows both at home and abroad. But the whole record of pharmaceutical progress is of necessity distributed through a host of periodicals, issued in different countries and printed in different languages.

To compile from these scattered sources an annual report, which shall include in one volume a summary of all pharmaceutical papers, processes, preparations and formulæ published throughout the world during each year, is the task which the Conference has undertaken; and every one of our readers will at once recognize its importance and value. At the present time no work of the kind exists in this country. 'The Year-Book of Pharmacy,' which was started some five or six years ago, has ceased to exist. The Conference have adopted the title and general scheme of that publication, but with much greater chance of success; and the executive members deserve great credit for the judgment and zeal with which they have commenced their new enterprise.

The present volume includes nearly six hundred octavo pages, but of this number one-half is devoted to the Proceedings of the Pharmaceutical Conference at the Liverpool meeting. Of this portion of the work we need say little, except that the papers contributed to that meeting, which are here printed in full, display a large amount of scientific ability on the part of the members, and constitute a most important addition to Pharmaceutical literature. The Year-Book proper contains a large number of excellent abstracts from many important papers bearing on Pharmacy which have been published either at home or abroad during the past year. While the advancement in the science of Pharmacy is thus recorded, the practical utility of the volume is enhanced by numerous useful formulæ, which have been collected from various sources. Every one will regret to learn that the delay which has occurred in the publication of this book has been due to the serious illness of its talented and kindly editor, Mr. J. C. Brough. It is, no doubt, to this cause that we must also attribute some of the defects which are noticeable in the work. The arrangement of the matter, especially bears evidence of great haste, and is certainly not well done. The first section deals exclusively with American Pharmacy and recipes. The second section is devoted to English and Continental Pharmacy; yet it includes a long list of syrups for American drinks copied from an American Journal, and much further on in the book many very characteristic American formulæ are to be found. An abstract, entitled "Turpentine as an Antidote to Phosphorus," occurs in the Materia Medica section (pape 90); another, headed "Poisoning by Phosphorus,—Turpentine the Antidote," is placed among things which "do not admit of classification," and may be found at page 283. No reference is made from one to the other, and even in the Index they are not brought together. It is unnecessary to quote further instances of what occurs frequently throughout the volume.

The present work brings together so much matter of real scientific and practical value in a convenient compass, that it will be an undoubted acquisition to every pharmaceutical library; nevertheless, it can scarcely be said that the full programme of the Conference has been realized. We shall hope to see succeeding volumes present a still more perfect record of English and foreign pharmacy. Experience will probably lead to a more judicious selection of material. Many papers relating strictly to Pharmaceutical subjects seem to have been overlooked, while some of the matter included would have been considerably improved by curtailment. A celebrated author has compared our modern periodical literature to an inch of soap beaten into a hogshead of lather. It should be the business of a Year-Book to present the soap in its solid form. At the same time, however, that we candidly criticize what we conceive to be the weak points of the present volume, we cordially recognize the ability which has been displayed in an arduous task, and we confidently predict a useful career for the Year-Book of Pharmacy.

BOOK RECEIVED.

On a Localized Outbreak of Typhoid Fever in Islington during the Months of July and August, 1870, traced to the use of Impure Milk. By Edward Ballard, M.D. London: J. and A. Churchill. 1870.

Obituary.

CHARLES GUSTAVUS BISCHOF.

This well-known German chemist and geologist died at Bonn on the 30th of November. He was born near Nuremberg, in Bavaria, on the 18th of January, 1792, and received his education in the University of Erlangen, where he applied himself at first to the study of mathematics and astronomy, but subsequently abandoning this branch of science, he turned his attention to chemistry, becoming one of the most distinguished pupils of Professor Hildebrandt. In 1819 he was appointed Professor of Chemistry and Technology in the University of Bonn. An enthusiastic geologist, Dr. Bischof sought to discover in molecular action certain geological phenomena. His most important works are 'Physico-Statistical Descriptions of the Fichtelgebirge Mountain,' published in 1817: 'The Mineral Springs of Volcanic Origin in France and Germany, and the Mineral Springs of Roisdorf,' and a 'Treatise on the Interior Heat of the Terrestrial Globe.' The latter work, which appeared at Leipsic in 1837, was "crowned" by the Scientific Society of Holland. Dr. Bischof was a constant contributor to various scientific journals. His memoir on the 'Mode of Preventing Explosions in Coal Mines,' published in 1840, gained the prize of the Academy of Brussels. Of his other works the best known are 'Popular Letters to a Lady on the Natural Sciences,' 2 vols., Pforzheim and Bonn, 1840 and 1849; and 'Elements of Chemical and Physical Geology,' Bonn, 1847–50, a revised edition of which was published in English by the Cavendish Society.—*Times.*

The following journals have been received:—The 'British Medical Journal,' Jan. 14; the 'Medical Times and Gazette,' Jan. 14; the 'Lancet,' Jan. 14; the 'Medical Press and Circular,' Jan. 18; 'Nature,' Jan. 12; the 'Chemical News,' Jan. 13; 'Journal of the Society of Arts,' Jan. 12; 'Gardeners' Chronicle,' Jan. 14; the 'Grocer,' Jan. 14; the 'English Mechanic,' Jan. 13; the 'Chemist and Druggist' for January; the 'Doctor' for January; the 'New York Druggists' Circular' for January; the 'Brighton Daily News' for Jan. 11.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department,* 17, *Bloomsbury Square, W.C., and not to the Publishers.*

[57.]—FLORIDA WATER.—As no other correspondent seems to have furnished "*Nemo*" (Sudbury) with a recipe for preparing Florida water, I send you the following from an American source:—

℞. Ol. Lavandulæ,
Ol. Bergamot,
Ol. Limonis, of each 2 drachms
Tincturæ Curcumæ,
Ol. Neroli, each 1 drachm
Ol. Mellissæ, 30 drops
Ol. Rosæ, 10 drops
Alcohol, 2 pints. LECTOR.

[94] and [111.]—YLANG YLANG.—The essence of *Ihlang-Ihlang* is distilled from the flowers of the *Unona odoratissima*, a large tree which grows in the Philippine Islands, the Straits of Malacca, and the Indian Archipelago. *Ihlang-Ihlang* (improperly spelt *Ylang-Ylang* by the Spanish residents) is the native *Tagal* name this tree bears in the Philippine Islands. The Malays call it *Kanonga*, and it is found described under that name in the works of Rumphius, an eminent botanist of the seventeenth century, who says that the smell of the flowers is so powerful that it scents the air for miles around. The flowers are flosculent and drooping, and of a greenish-yellow colour. They were first distilled by a chemist at Manilla, and yielded an essence of an exquisite odour, somewhat partaking of the jasmin and lilac, but still having a flavour *sui generis*. This essence is now largely manufactured, and used by the leading perfumers either pure or in compounds. It is made principally at Manilla and Singapore. The former is the finest, and costs when pure about £2 per ounce.—E. RIMMEL.

[123.]—ARNICA CERATE.—The British Homœopathic Pharmacopœia gives the following:—

Spermaceti, 3 oz.
White Wax, 6 oz.
Olive Oil, 14 fl. oz.

Add 1 drachm of medicated tincture to every 9 drachms of cerate and stir briskly until cold.—T. W. ROMANS, *Wakefield, January 14th*, 1871.

[125.]—SCIENTIFIC LIBRARY. — "*Stranger*" will have his wants supplied by the Educational Reading-room of the South Kensington Museum; open on Monday, Tuesday and Saturday from 10 a.m. till 10 p.m.—DELTA.

[128.]—AMANDINE.

℞. Ol. Amygdal. Dulc. Hiij
Syrup. Simplicis ℥ij
Sapon. Mollis Alb. ℥ss
Ol. Lavand. Ang.,
„ Bergam. Opt., ana ℥ss
„ Caryoph. ʒij

Rub the syrup and soap together in a perfectly clean mortar until the mixture is homogeneous. Mix the perfume with the oil and add *very gradually, stirring briskly until* thoroughly incorporated.

The following recipe will be found easier to make and much more efficacious for the purpose intended:—

℞. Mel. Ang. Opt. ℥iv
Ovi Vitell. No. ij
Pulv. Iridis ℥iss
Ol. Amygdal. Dulc. ℥iv
Otto Rosæ gtt. xij.

Mix the first three ingredients until they are a perfectly smooth paste, and add the oil (first mixed with the otto) slowly until the whole is combined.—H. A. WILLIAMSON.

[129.]—TALCA GUM is a variety of acacia gum. It consists of the siftings left from the finer sorts.—J. C.

[130.]—GERMAN YEAST.—Place ordinary beer yeast in a close canvas bag, and gently and gradually squeeze out the moisture in a screw-press until the remaining matter acquires the consistence of clay or soft cheese. In this state it must be preserved in close vessels or wrapped in waxed cloths.—M. N.

[131.]—MOUTH WASH.

℞. Rad. Krameriæ,
Gum. Myrrh. Opt., ana ℥ij
Caryophylli Olei ʒj
Sp. Vini Rect. Oij

Macerate fourteen days and filter.—H. A. WILLIAMSON.

[133.]—CAMPHOR CAKE.

℞. Gum. Camphoræ ℥ss
Ceræ Albæ,
Cetacei, ana ℥j
Ol. Amygdal. Dulc. ℥iv.

Dissolve the camphor in the oil previously warmed. Melt the wax and spermaceti in a water-bath; stir the whole together until nearly cold and pour into moulds.

H. A. WILLIAMSON.

In answer to "*Rusticus*" we give the following formulæ from the *New York Druggists' Circular* for the present month:—

(1.) Take of Spermaceti,
White Wax (pure), each 2 oz.
Almond or Olive Oil, ½ pint.

Melt them together by a gentle heat and add—

Camphor, cut small, 1 oz.

Stir the mixture until it is dissolved and then pour it into slightly-warmed moulds, which may be ounce gallipots or egg-cups with smooth bottoms. Hemispherical cakes will thus be formed.

(2.) Take of Clarified Suet, 1 lb.
Spermaceti, 3 oz.
White Wax, 2 oz.
Camphor, 1 oz.

Stir the mixture until it is dissolved and pour it into moulds as in the preceding.

Whiteness is a recommendation to camphor balls, therefore the materials used should be as free from colour as possible. They may be perfumed according to fancy.

[137.]—HAIR DYE.—I should be glad to be informed of a good recipe for hair-dye, or if some one will say what is used instead of ammon. hydrosulph. as application No. 1. —H.

[138.]—SYR. FERRI ET CALCIS SUPERPHOSPH. —Will any of the readers of the Journal oblige me with the formula for syr. ferri et calcis superphosph.?—IODI.

[*** See Mr. Gale's paper on the "Syrup of Superphosphate of Iron," etc., PHARM. JOURN., 2nd ser. Vol. I. p. 497. —ED. PH. JOURN.]

[139.]—SP. AMMONIÆ AROMATICUS.—I have some sp. ammon., B. P., received in September from a wholesale house in town, two Winchesters of which were not touched until this week. On the sides of each are deposited some very pretty crystals about the size of oxalic acid, I suppose owing to the severe cold. I shall be glad to hear if any other of your readers have observed the same in their sp. amm. ar. B. P., and if it is reduced in strength below the Pharmacopœia standard.—IODI.

[*** The crystals were probably carbonate of ammonia, and would redissolve on shaking and rise of temperature.— ED. PH. JOURN.]

[140.]—CHLORAL HYDRATE LOZENGES.—"*A Bookworm*" would be glad to receive a formula for making chloral hydrate lozenges.

[141.]—SP. CHLORAL HYDRATE.—"*A Bookworm*" also asks for a formula for sp. chloral hydrate.

Correspondence.

Proposed Regulations for Storing of Poisons.

Sir,—The all-absorbing topic with chemists appears to be the storing of poisons, and many of your correspondents write with some warmth upon the subject, feeling that their arrangements are being unnecessarily interfered with. Looking at the subject from all sides, I think the difficulty might soon be got over. No doubt those that are in a smaller way of business have comparatively as much convenience for storing as those who keep laudanum, arsenic, etc., in large quantities. The subject will be again brought forward, and thoroughly discussed at the General Meeting. It is very natural that a superior body of men should look with a deal of jealousy at being forced into anything; but it must not be forgotten that the Pharmaceutical Council are under an obligation to the Privy Council, consequent on the passing of the recent Pharmacy Act, to make some arrangements for the safe keeping and storing of poisons. Not that they think our body careless, but that the general public should know, as a rule, every precaution is taken to prevent accidental poisoning or otherwise. The Council have the matter left to them in a measure, and have invited opinions and discussion from the whole body of chemists, and have postponed the subject for a considerable time. I think it would be a great pity if, when the Privy Council call upon the Pharmaceutical Council for their plan, they had to say that the chemists, as a body, could agree to no plan. It then might be taken from their hands to those that did not know our requirements so well, and some regulations adopted which we might find rather troublesome of application. I think I may say, during my short experience, I recognize our body merging into a more homogeneous mass, and our opinions and feelings getting more in unison, and that our trade prices and seemingly troublesome poison regulations will disappear by being thoroughly discussed and ventilated.

W. Donaldson Boon.

King's Lynn, January 16th, 1871.

Sir,—May I be permitted to supplement the various suggestions for distinguishing poisonous articles by adding another? viz., that such things should be put into bottles rendered opaque, and that the labels should be hidden from view by a covering which must be lifted to enable the seeker to find the article; thus he would be compelled to read the label before using the substance, and a mistake would, under such circumstances, be highly blameable. All drawers, casks, boxes and parcels may be easily included in this system.

January 14th, 1871. Rus.

Sir,—In speaking of the above, I think some little regard ought to be paid to the feelings of others. In *M. P. S.'s* letter in your Journal of the 14th he is (I should hope) unthinkingly stirring up old grievances, which must indeed be most painful, both to Messrs. Oldham and the unfortunate "assistant" (in Mr. Guinness's case). Surely they have both suffered enough from their own feelings, without being again reminded of their misfortune through the medium of the only paper that has a circulation amongst nearly all the chemists in Great Britain and many abroad. Remarks might, I think, have been made just as striking without speaking of past and nearly forgotten misfortunes.

I am in no way connected with "Messrs. Oldham" or the "assistant," but have a little feeling for them. *M. P. S.* also remarks that "apprentices" and "porters" are, as a rule, uneducated. Now I think most of your readers will agree with me that the former are, as a rule, well educated, and the latter are, in many instances, better up in chemistry than many of those who are in a better position in the trade (this I know from experience), therefore they are competent to handle poisons. Fair Play.

Brighton, January 17th, 1870.

Pharmaceutical Ethics.

Sir,—I have read with much satisfaction your leading article of last Saturday on "Dispensing Charges and Alliances," and with your permission I will briefly express my views on the two matters therein discussed.

1st. *Dispensing Charges.*—That the average charge for dispensing is too low, I confidently assert, when we consider the pre-requisite education of a qualified dispenser, to which must be added the care, responsibility and the inevitable anxiety involved in our calling.

Further, there has, under the strain of competition, been a growing tendency during the last few years to reduce still lower these charges.

Unhappily, there are men amongst us possessing not an atom of that *esprit de corps* so essential to maintain and advance the respectability of pharmacy; willing to transact business on any terms, and sell at any prices, so long as the barest modicum of profits has been secured. The right course for wiser and better men to adopt towards such is simply to ignore them, but, unfortunately, the necessary courage so to do does not always exist,—the result is a depreciation of prices all round.

The plan I would advise my brother pharmaceutists to pursue is simply to fix their own scale of charges at what they deem an honourable range, and steadily hold thereto, through evil and through good report.

I am convinced that any attempt to bind by any local restrictive regulations the black sheep amongst us would be utterly useless. I would, however, suggest the possibility of a modified course of action being feasible, namely, that the pharmaceutists of any city or town anxious to advance the status of their business might most advantageously meet now and then for conference on trade questions, and thus agree to adopt, as far as practicable, a uniform standard of prices.

Even here some degree of latitude must be accorded to the varying circumstances of different localities. An East End chemist may be actuated by as pure and laudable principles as his West End brother, and yet find Belgravian prices will not acclimatize amongst his supporters; the parallel holds true in many a large provincial town.

The true solution of this difficulty is the one indicated in your article,—a *higher* but *elastic* scale of charges.

2nd. *Alliances.*—Whilst the former question affects two parties—the general public and ourselves, this affects also the medical profession.

These alliances may be broadly divided into two classes; the one demands and deserves unmitigated condemnation; I refer to the arrangement between a medical man and a particular chemist, by which, for a consideration, the prescriptions of the former invariably find their way to the establishment of the latter.

With regard to dispensing for medical men, the course of action is not so clearly defined, although I heartily accept the gist of your remarks.

Nothing can be more heart-breaking than the scale of remuneration (?) for dispensing between some chemists and their professional patrons, and where this work has been done by a competently trained and adequately paid staff, that it is unremunerative labour there can be no doubt.

Why, Sir, I have known a man as worthy and assiduous in his business as any man I ever knew, giving a surgeon credit for a four years' dispensing at a scale of charges that completely reversed the conditions of obligation, and yet such were the circumstances of the case, whilst wanting the money he was afraid to ask for it.

A clearer mutual recognition of the ground respectively occupied by the profession and pharmaceutists would lead to a better understanding of each other. The former should be paid for professional service only, the latter for physic.

If medical men really desire to see pharmacy advance its status without encroaching on professional ground, such a line of action would greatly facilitate it.

Hoping this expression of opinion may tend to elicit fuller discussion of such vital questions.

Salisbury, Jan. 11th, 1871. S. R. Atkins.

Sir,—I have read with considerable interest the article in last week's Journal on "Dispensing Charges and Alliances," and quite agree with you that perfect uniformity of prices for dispensing is neither practicable nor desirable.

On the second point referred to, viz. "Alliances," I will, with your permission, offer a few remarks; and, as I have done a considerable amount of contract dispensing, perhaps I cannot do better than give a little of my own experience.

Some years ago, I entered into an engagement with a medical firm to do their dispensing, which still continues, and I am not aware that I am taking any undue advantage of my brethren; I am on friendly terms with all of them that are likely to be affected by it. I have reason to believe that if I were to discontinue the contract, two or three of my immediate neighbours would be willing to take it. But supposing none of us would have it, would the dispensing fall to us in the regular way of prescriptions? No; the firm would at once do as they did formerly, employ a dispenser in their own surgery,—although they assure me they would only be too glad to give up dispensing altogether. But the custom of the town would not admit of it. They believe, and so do I, that my supplying the medicines instead of them is a step in the right, and not in the wrong, direction. It familiarizes the public with the practice, and induces the belief that the chemist, and not the medical man, is the proper person to apply to for medicines. I find that through such arrangements we often get opportunity of dispensing on our own account, which would not fall to us if the prescribers sent the medicines from their own surgeries. For instance, the patients will frequently say, "So-and-so is not my chemist; can't I get my medicines elsewhere?" and the reply is, "Certainly you can," and a prescription is at once given, which, of course, the patients have to pay for in the regular way. Altogether, from one cause or other, I feel sure that a very large number of prescriptions are given to the patients to get prepared where they may think proper, that would not be given them at all if the medicines were sent out by the doctors themselves.

I have recently had an interview with a chemist in a neighbouring town,—a gentleman who occupies a high position in the Pharmaceutical Society,—in reference to contract dispensing. I have given him a full account of the whole matter as far as concerns myself; and he is of opinion that such alliances are desirable in the interests of pharmacy, as at present constituted in this country.

Of course, we all know that it would be better to have the supply of medicines entirely in our own hands; at the same time, we are equally certain that at present we cannot have it so. E. F.

Spiritus Chloralis.

Sir,—In a paper read before the Liverpool Chemists' Association by Mr. A. H. Mason, and reported in your last number, occurs the following passage, which may lead to erroneous conclusions:—

"Spiritus chloralis is made by Savory and Moore. It has a very agreeable taste and smell, but I was not able to obtain any deposit upon evaporating a little."

A deduction likely to be drawn from this would be that the spiritus chloralis does not contain the pure German hydrate, which it does in the proportion of ten grains in the fluid drachm.

We know chloral hydrate easily crystallizes from some simple menstruums, such as spirit or water, but our preparation, as we state on the label, is a compound spirit, and the presence of volatile oils, glycerine, etc., in it prevents the crystallization of the chloral.

If the alkaline tests are applied to the spiritus chloralis, the chloroform will be seen forming and settling in a layer at the bottom, and if the alcohol present be estimated for what is dissolved again, or the alcohol carefully driven off *at a very low temperature*, the chloral may be estimated as chloroform.

Savory and Moore.

143, *New Bond Street, Jan. 7th*, 1871.

[***. We can only suppose the deduction feared by our correspondents to be possible in the case of persons ignorant of the fact that chloral hydrate is volatile below the boiling-point of water. We may state, however, that the sample of their spiritus chloralis sent here evidently contained a considerable amount of chloral, and on treatment with alkalies it yielded a quantity of chloroform corresponding with the specified strength of the preparation.—Ed. Ph. Journ.]

The Payment of Assistants.

Sir,—I have watched with deep interest the controversies carried on by our different pharmaceutical brethren upon the questions of obscure prescriptions, druggists' charges, the storing and keeping of poisons, and a multitude of other items, but there is one which has failed to attract attention. I am sure I speak the minds of my fellow-assistants when I say that our average salaries are less than those of any other class of assistants, without taking into consideration our extra outlay for study, books, etc. According to the present requirements of our Society, it would be vain for any one who wished to revel in the mysteries of our profession to make the attempt unless he could command at least £100 for premium, and he must also allot a similar sum for books, studies, clothes, etc. When he has terminated this monotonous stage of his life, and passed his examination, he rests with the comfortable assurance that his title will now secure to him a fair remuneration; but he finds that, while Pharmaceutical Chemists would undoubtedly prefer his services, they cannot see their way clear to give more than £40 and a free kit, as there are unqualified assistants that suit them equally well. He then sees his folly in wasting money which in many instances would give him a fair start in life. In support of my argument, and by way of conclusion, I may mention that I had occasion to visit one of our wealthy midland towns some twelve months ago. During my conversation with a friend of mine, it transpired that a Mr. I. required an assistant. Being at the time disengaged, I ventured to call upon him; and, after several questions having passed between us, as is customary, he asked me what salary I should require. I told him that my last stipend was £30, and that I did not care to engage under that sum (being then twenty-four years of age). He seemed completely bewildered, and, after duly staring me in the face, exclaimed, "What, £30! Then you must have had some considerable experience." As I did not care to engage for much less, and as these terms did not seem at all compatible, I retraced my steps, quite shocked, I can assure you. I omitted to mention that the gentleman in question was a member by examination, as set forth by divers diplomas exhibited in the windows.

January 7th, 1871. Fuissem.

A Suggestion.

Sir,—I shall feel obliged by your kindly allowing me, through the medium of your Journal, to suggest that wholesale druggists should not supply citrate of magnesia, glycerine, cochia pills, "et hoc genus omne," to any but those who are duly registered as chemists.

A brisk trade in these articles is carried on by hucksters in every village, to the injury of the legitimate chemist. They manage things better in France, where the *pharmacien* holds his proper position as determined by law.

D. Carroll, LL.B., Registered Chemist (Exam.).

Cerne Abbas.

R. G. (Slough).—We believe it is the custom in such cases to use the sp. chloroformi, B. P.

R. J. S.—We are unable to furnish you with the address applied for.

W. C. Tryon (Portsea).—The black colour is the result of a decomposition, of which an explanation will be found in any elementary work on chemistry.

S. Dean and *G. M.*—It may easily be obtained from any new or second-hand bookseller.

"*Xenophon*" has omitted to furnish his name.

W. G. (Wimborne).—Bentley's 'Manual of Botany' (Churchills) and Henfrey's 'Elementary Course of Botany' (Van Voorst).

*** In answer to several correspondents, we are able to announce that arrangements have been made for the issue of reading-cases, in sizes suited for holding three months' and six months' numbers of the Pharmaceutical Journal. Particulars will be announced next week.

Communications, Letters, etc., have been received from Mr. W. W. Stoddart (Bristol), Mr. W. D. Boon (Lynn), Mr. H. A. Williamson (Scarborough), Mr. P. L. Simmonds, "Soda-water," "Justitia," R. J. S. (Alfreton), M. S. P. (Swindon), G. M.

BRISTOL PHARMACOLOGY.

BY W. W. STODDART, F.C.S., F.G.S.

(*Continued from page* 483.)

PHANEROGAMIA.

Class I. Dicotyledones.—Subclass I. Thalamifloræ.

Nat. Ord. Ranunculaceæ.

Only two plants of this Order are named in the British Pharmacopœia, viz. Podophyllum and Aconitum, the latter being the only British plant, and therefore admissible in the present paper. In former times many more were made officinal, as Ranunculus, Delphinium, and Helleborus.

Aconitum Napellus (Linn.)

This beautiful but deadly plant, although originally an escape from the gardens, is in many places seen to grow thoroughly wild in the neighbourhood of Bristol. It may be gathered at Ashton, in the Leigh Woods, at Dundry, and at Shirehampton. Near the village of Stapleton is Frome Glen, a lonely and picturesque spot, where the river cuts its way through the new red sandstone and furnishes a luxuriant habitat for a long list of plants. The banks in many parts of the glen are completely hidden by Ferns and Mosses.

The rare *Asplenium lanceolatum* hangs from the rocky beds with its elegant fronds and scaly rachis. The *Lastrea dilatata* grows to a very large size, a giant among its sisters *Cystopteris*, *Polypodium*, *Aspidium*, *Athyrium* and *Ophioglossum*. In one part of the river the bank for twenty or thirty yards, and eight or ten feet high, is literally covered by tresses of *Fontinalis antipyretica*, a Moss with stems frequently two feet in length.

A small wood near this spot is a favorite resort of the author, and many delightful early mornings have been spent in it among the Anemone and Hyacinth, the stately Alder, and the pretty little Chrysosplenium. In their midst may be gathered the Aconite, growing luxuriantly, and often nearly a yard in height. Its dark green, deeply cut leaves show off the curious dark purple flowers. The petals are small and concealed within the calyx, which in this plant is the most conspicuous part of the flower. The upper sepal is much longer than the other, and shaped like a helmet, affording, as it were, a protection from the rain. This singularly-shaped sepal gives rise to its English name Monkshood, from a fancied resemblance to the hood of a monk's cowl. Indeed, the plant has had all kinds of epithets given to it, as helmet flower, wolf's bane, friar's cap, storm hat, and blue rocket.

Every part of the plant is probably poisonous to all animals, although Linnæus said that horses may eat the *dried* herb with impunity. In the B. P. the leaves are used for making extract, while the roots are used for the preparation of the tincture, liniment, and the fearful alkaloid aconitin.

Being a native of Italy and Greece, the virulent properties of the aconite were well known to the ancients. Theophrastus was the first to mention the word aconite (Hist. Plant. vol. ix. p. 16), but his description does not agree well with that of *Aconitum Napellus*, and it may therefore be a matter of doubt whether he alludes to the same plant.

Dioscorides and Ovid often mention aconite as a well-known poison. The latter in his description of the supposed Iron age, tells of its use in ridding a family of a troublesome relative.

"Lurida terribiles miscent aconita novercæ."

At the present day its administration is regarded with the greatest caution and infinitesimal dose.

The poisonous alkaloid aconitin is found in all parts of the plant, leaves, roots and seeds.

The roots are tapering and resemble those of many other vegetables; indeed, the specific name *Napellus* is derived from the similarity of the root to that of the wild turnip (Napus).

Aconitin ($C_{30}H_{47}NO_7$) exists in combination with aconitic acid ($C_6H_6O_6$). This acid is remarkable as being produced from citric acid when distilled at a high temperature; water, acetone and carbonic oxide are given off, and aconitic acid left.

$$\underset{\text{Citric acid.}}{C_6H_8O_7} - H_2O = \underset{\text{Aconitic acid.}}{C_6H_6O_6}$$

The B. P. process for the extraction of aconitin is similar to that of Dr. Headland or that of M. Stas. The alkaloid is first precipitated by an alkali, and afterwards dissolved out by ether. The student may easily prepare it for himself. To get a profitable result, it ought to be remembered that the smallest proportion of water must be employed before the addition of the ether, or the result will be materially affected, and lessened.

Mr. Morson also extracted another alkaloid from aconite, which he named napellin. The period when the roots contain the largest proportion of aconitin is when after flowering the leaves have just died off.

Analyses of the roots gathered at Frome Glen gave the following results, with the ether process:—

1 lb. av. of fresh root	before flowering	yielded	3·11 gr.
1 lb. av. ,,	after ,,	,,	7·97 ,,
1 lb. av. dried root bought in London		,,	31·98 ,,

The alkaloid thus produced when quite dry and powdered had a slightly brown colour, and possessed all the well-known qualities of aconitin mentioned in the B. P.

Nitric acid dissolved it without change of colour. Oxide of chromium was formed by the addition of sulphuric acid and bichromate of potassium. It was precipitated by tannic acid, terchloride of gold and iodine.

The difference between samples of aconitin is something inexplicable, except on the ground of adulteration. Delphinin and chalk have been mentioned as adulterating agents.

Aconitin is so deadly a poison, that Dr. Pereira was accustomed to say it could not be administered with safety, and that in one case an old lady was nearly killed by one-fiftieth of a grain. Dr. G. Bird mentions an instance in which a gentleman swallowed two grains and a half;—a sample of the extent to which adulteration has been carried.

Two well-authenticated cases of poisoning have occurred in Bristol. One at a convent, where an inmate had given to her, by mistake, forty minims of Fleming's tincture. Death ensued about four hours afterwards.

In the other case, a gentleman who had aconite-root used with roast beef instead of horse-radish. Mr. Herapath, who was the chemist employed in the investigation, calculated that one-twentieth of a grain of pure aconitin had been swallowed.

The proportion of aconitin in the leaves is very variable, so that the extractum aconiti must be also uncertain and not be depended on.

When making the extract, beautiful little octahedral crystals are often seen; these are aconitate of calcium.

Nat. Ord.. PAPAVERACEÆ.

The plants in this well-known Order are all herbaceous, and exude a milky juice having strong narcotic properties. One genus, *Chelidonium*, containing an alkaloid chelidonia, is not officinal, although Dr. Williams recommended its use, Its yellow juice is a popular remedy in the country for warts and corns. In the B. P. only two species of *Papaveraceæ* are named, both of which occur plentifully in the environs of Bristol.

Papaver somniferum (Linn.).

This plant is a native of Southern Europe and the shores of the Levant, but was probably introduced into England as a garden flower. Through the agency of birds and wind, the seeds have been scattered till, in a few places, the poppy may be considered as wild.

The only locality near Bristol, where *Papaver somniferum* can be said to grow in a wild state, is on the sandy shore of the Severn, near Westbury and Aust, upon the limestone beds of lias. The poppy likes a calcareous soil; the ashes of the seeds contain an unusual amount of lime, often nearly 35 per cent. Here, however, the plants do not attain a very large size, the capsules rarely exceeding the size of a walnut, the whole plant reaching the height of 12 or 14 inches. The flowers are handsome, usually white, with blue or purple veins. The leaves are glabrous and their peculiar bluish-green colour at once arrests the attention of the botanist.

The Poppy has been known as a narcotic from a very early period. Homer, who lived about nine hundred years before Christ, speaks of the poppy as a favourite garden plant, Il. viii. 306:—

> *Μήκων δ' ὣς ἑτέρωσε κάρη βάλεν, ἥ τ' ἐνὶ κήπῳ*
> *Καρπῷ βριθομένη.*

Virgil was evidently familiar with its appearance, when he says (Æn. ix. 436):—

> "Lassove papavera collo,
> Demisere caput, pluviâ cum forte gravantur."

Poppy juice (*μηκώνιον*) was the subject of a dispute between Diagoras and Hippocrates; the former condemning its use, while the latter extolled it.

The seeds of the poppy are used in Eastern countries by the confectioners and for sprinkling over cakes. They are very oily, and, when burnt, give off a disagreeable odour of fried bacon.

Horace in his 'Art of Poetry,' speaks of a distasteful flavour given to honey by the addition of poppies or more probably poppy-seeds:—

> "Sardo cum melle papaver offendunt."

The seeds contain 40 per cent. of a pale sweet oil. The cake remaining after pressure is highly nutritious as a cattle-food, containing 7 per cent. of nitrogen and 6·3 per cent. of phosphates of calcium and potassium. The black variety is sold under the name of maw seed, and used as a medicine for canaries. They are favourite objects for the binocular microscope, the surface being covered with hexagonal reticulations.

Poppy oil is often used for the adulteration of olive oil, and may be detected by the "beading" which appears when the oil is shaken, or still better by a solution of nitrate of mercury. The specific gravity of poppy oil is ·924, while that of olive oil is ·910.

The soluble matter or juice of the poppy is the most valuable agent. In China and Turkey it is considered indispensable. The Turk cannot do without his mash-allah, and the Tartar can subsist a long time without food, when taking a long journey, by making use of a few opium lozenges.

The B. P. orders the capsules to be gathered before being ripe. If M. Buchner's opinion be correct that the ripe capsules are the most narcotic, it would follow that the latter state would be the most desirable when making extr. papav.

The Bristol market is supplied from Westbury, in Wiltshire, where poppies are cultivated in large quantities.

The capsules of the wild plants from the Severn banks gave the dark red tint with $FeCl_3$, and an orange tint with NO_3, indicating meconic acid and morphia. They yielded an extract which produced 1·3 per cent. of morphia.

Mr. Groves says that in the ripe capsule there is a larger proportion of codein than in opium. The poppy capsule is a most instructive study for the student of structural botany. All true poppies have a *one-celled* ovary, although at first sight this statement may seem an erroneous one. On cutting a transverse section of one of the dried capsules, the placentation or attachment of the ovule is seen to be on the surface of the dissepiments (or vertical plates), and are, therefore, *parietal*, and not axial, as in the Foxglove or Orange. The dissepiments *do not reach the centre* of the capsule so as to make a multicellular ovary. Well may the poppy plant be prolific, for each capsule contains more than 32,000 seeds.

On the top of the capsule is the well-known cap or coronet, which is formed by the remains of sessile stigmas. Under this are small openings through which the seeds escape when the capsule reaches maturity.

The microscopic structure of the poppy capsule is very wonderful, and will amply repay any trouble taken in its examination. The knowledge is especially necessary for the detection of a very common adulteration of pulv. opii, where the quality is lowered by an admixture of the powdered capsules.

The outer surface (epicarp) is characterized by well-marked angular cells, with stomata, and strongly resembling a section of small fossil astreiform corals, and have broad, well-marked, cell-walls.

The inner surface (endocarp) is strangely different, although penetrated by the same stomata. The cells are very irregular and elongated; the thick walls have a beaded structure.

The dissepiments themselves have cells again completely different from either. They have the same size and general form as the endocarpal ones, but instead of the beaded configuration, they have carinated walls, with two series of pore-like dots, and, of course, devoid of stomata. Their appearance under a half-inch objective resembles, in an extraordinary degree, the little Fenestella, so frequently found fossil in the carboniferous limestone.

An excellent object for the low-power binocular is a transverse section of the dissepiment, showing the spermophore with the seed attached.

Very few of the articles of our materia medica can vie with the poppy and its products in profit and interest either to the chemist, botanist or microscopist.

Papaver Rhœas (Linn.).

This richly-coloured plant, the pest of our cornfields, is more especially abundant on the new red sandstone strata. It occurs more frequently in the South than the North of England. The capsules differ from those of *P. somniferum* in shape. They resemble the schoolboys' whip-top, with ten or more stigmatal rays in the coronet.

It is remarkable for its splendid red colour, which probably is the only useful property it possesses. The *P. Rhœas* is often confounded by the tyro with *P. dubium* and *P. Argemone*, but may be distinguished from the former by the shape of its capsule being globular and by the spreading bristles on the flower-stalk. From the latter it is instantly known by the smoothness of the capsule.

The colour of the petals of *P. Rhœas* is usually described as scarlet, but is in reality an exceedingly rich crimson. Treated by Riffard's process (*Journ. de Pharm.* vol. xii. p. 412), viz. by the action of ether and alcohol, the petals yielded a dark red colouring matter, which is deliquescent, insoluble in ether, but soluble in alcohol and water.

Acids partially destroy and chlorine quite decolorizes the red pigment. It is readily distinguished from the colouring matter of the rose and cabbage by becoming nearly black by alkalies, instead of the usual blue or green. The petals yield about 40 per cent. of Riffard's product.

According to Meier (*Repert. Pharm.* (3) vol. xli. p. 325) the red colouring matter of *P. Rhœas* consists of what he calls rhœadic and papaveric acids. The former differs from the latter by being precipitable by acetate of lead. Most likely, however, the true red colour has yet to be isolated.

In Bristol the syrup is much used as a popular remedy for measles, under the name of oil of kermes.

(*To be continued.*)

KAFUR KACHRI.

(*Hedychium spicatum*).

BY M. C. COOKE, M.A.

Many articles employed in Oriental medicine are still involved in great obscurity, so that it is impossible to state with any certainty whence they are originally derived, or what plants yield them. This seems to be pre-eminently the case with the products of Scitaminaceous plants. What can be more obscure than the sources of the different kinds of Zerumbet and Zedoary? and the Galangals are not satisfactorily determined, whilst Cardamoms were in a deplorable condition until Mr. D. Hanbury exerted himself to clear away some of the mystery which enshrouded them. Then there are other and minor products, undoubtedly belonging to the same Order of which we know exceedingly little, and doubt much. This is the case with the species of *Curcuma* which afford a starch of the nature of arrowroot. Who can identify, with any certainty, the sources of the *Curcuma* arrow-roots of India?

The *Kafur-kachri* of the bazaars of India is one of the substances which seem to be involved in the least obscurity; and though it is not of any great importance, a brief account of it may not be the less acceptable. The native names have been verified by Mr. Moodeen Sheriff, and may be relied upon. He gives Kafur-kachri, or Kapur-kachri, as the Hindustani name, the latter being also applied in Bengal and the Dukhan to the same substance. Vilayati-kachur is another Dukhani synonym; and the Tamil and Telugu names are respectively Shimai-kich-chilik-kizhangu, and Sima-kichchili-gaddalu, meaning "Europe or Foreign Long Zedoary."

On reference to the Indian Pharmacopœia, we find it stated that this is the Sitruttee of the bazaars, and was considered by Dr. Royle to be very probably the Sittarittee, or Lesser Galangal of Ainslie. The Supplement to the Pharmacopœia sets this question at rest, for it is declared that Sittarittie and Sutruttee, which are used in some works synonymously with Kafur-kachri as the Hindustani names of this root, are incorrect, because they belong as Tamil names to the Lesser Galangal, which is the product of a different plant. We may hereafter endeavour to clear up some of the doubts regarding the Galangals, so that it will be unnecessary to refer to them here.

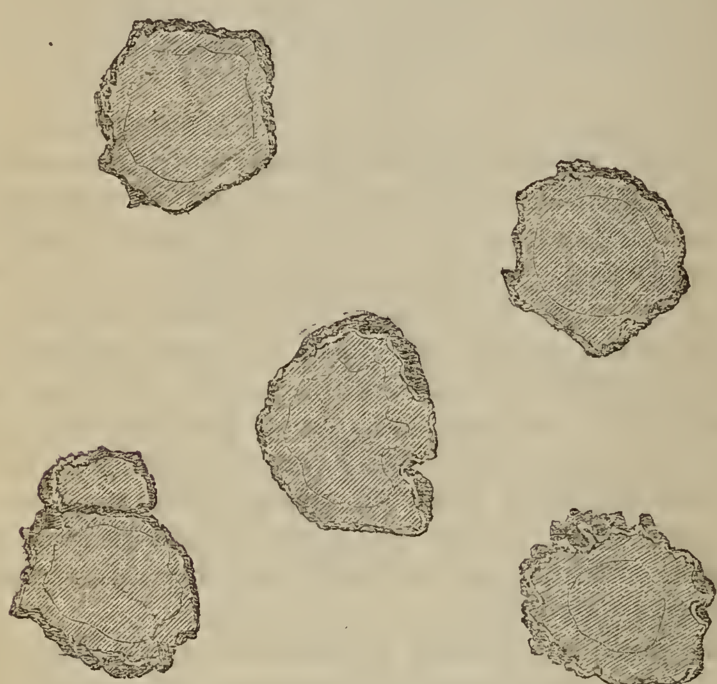
There is no reasonable ground for doubt that the Kafur-kachri is the root, or rhizome, of *Hedychium spicatum* (Smith), figured and described in the 'Botanical Magazine' (plate 2300), which is a native of the Himalayas.

The root when entire is reddish-brown, marked with white rings, bearing considerable resemblance to the true Sit-ruttee or Lesser Galangal, whence, perhaps, the confusion of names. It differs, however, from Galangal in being very white and friable, internally starchy in structure, fragrant, and slightly warm or aromatic in taste, but not peppery or pungent. In smell, taste and internal colour, as well as medicinal properties, it resembles the Long Zedoary; but neither in smell nor structure can the two be confounded after having been seen together. The peculiar, strong aromatic odour of the Kafur-kachri is, at any time, almost of itself sufficient to identify this drug; it is an odour never to be forgotten, and not to be confounded with any other. The starchy character of the substance of the root is so characteristic, that it cannot escape notice; the interior may be scraped away with a knife, or pounded into a white flour, as if it were nothing else but pure starch. Indeed, a little of this substance scraped with a penknife upon a slip of glass, in a drop of water, and submitted to the microscope, seems to consist as absolutely of starch granules as many prepared starches. The proportion of foreign matter is exceedingly small. The granules partake of the character of *Curcuma* arrow-root, except that they are

Starch of *Hedychium spicatum*.

somewhat smaller; that is, they are ovate or elliptical, rather regular in outline, but flattened, so that when seen sideways, they are lenticular, with rounded ends. At first a mounting of this starch seems to consist of two kinds of starch mixed together, but a few moments' examination soon proves that the narrow granules are only the broad ones set on edge.

The only form in which this drug is found in the bazaars is in circular slices, a line or a line and a half in thickness, and about the size of a "fourpenny piece," very white and friable internally, with a reddish-brown edge, and fragrant. Insects seem to



have a great partiality for it, especially weevils, as the bottles will soon testify, in which specimens are preserved, by the quantity of powder on the bottom.

The value of this drug as a remedial agent is probably very small. The great quantity of starch it contains would place it, perhaps, on an equality with other starchy rhizomes; but its properties as an aromatic stimulant would be surpassed by other common substances, and the merit it is supposed to possess as a tonic may be almost imaginary.

Dr. Stewart gives some additional uses for the plant in his recent work, and the range of growth which he found it to extend in the Himalayas. His observations are:—This plant is not uncommon in parts of the Punjab Himalayas up to near the Jhelam at least, at from 3500 to 7500 feet. Its large broad leaves are twisted and made into coarse mats for sleeping on, etc. The tuberous roots have, as "wild ginger," been tried by Europeans as a preserve, but without success. In Garhwal I was told they are used in washing the newly married; and Madden states that they are pounded with tobacco for the hookah. They are officinal under the above names, being considered tonic and stimulant. Honigberger is apparently in error in stating that they are only used in veterinary medicine. Cayley mentions that there is some import from the south of Lê, and export from the latter to Yarkand of *Kachur*, which is probably this, but may be *tekia kachur*, or *nar kuchar*, said to be the produce of *Curcuma Zerumbet*. Davies' trade report gives 25 maunds of *Kachur* as annually exported *viâ* Peshawur to Affghanistan.*

* Stewart's 'Punjab Plants,' pp. 239. Lahore, 1869.

CHINESE NATIVE OPIUM.

In confirmation of the remarks recently published in the Journal on the extensive production and consumption of native opium in China, the following details may be given. They are from a detailed report of an inland journey made by Mr. Moss at the expense of the Hongkong Chamber of Commerce, presented to the Chamber in November, 1870. The information is therefore recent, and may also be considered authentic. It is not likely to see the light in the official British consular reports for some time to come. Although all the foreign opium which is smoked in the country pierced by the West River is smuggled, and there is no means for estimating, even approximately, the quantity actually imported, it is impossible to arrive at any other conclusion than that in proportion to the consumption of the native drug it is trifling and unimportant. In the opium shops of Wuchaupu, and in all the towns to the westward, the foreign drug is rarely asked for, and that from Yunnan is exclusively smoked. What little foreign is used is Bengal, brought ball by ball up the river to Wuchau, and overland to the towns beyond from Yakpoi. Its price in the first week in July at the former city was 5 dollars per catty, or about 15 dollars per ball. At Tsunchaupu in June the price was dollars 5.10 per catty, and at Hwangchau a little over 5 dollars, or about 600 dollars per chest. The prepared drug was to be obtained at from 4 mace 8 candareens to 5 mace 5 candareens per tael weight, the average being about 5 mace per tael. Yunnan opium, on the other hand, was being retailed at from 3 mace 6 candareens to 4 mace per tael weight, according to its purity and quality. A common kind was purchasable at 3 mace. The raw drug is in round flat casks, about 6 inches in diameter by about 2 inches thick, weighing from 12 to 20 taels, and more or less adulterated with gritty, earthy matter. It was sold at from 18 to 20 taels per 100 taels weight; and old drug in the first week of July was selling at Wuchaupu at $12\frac{1}{2}$ taels. These rates were considered high. In the previous year the drug had been as low as 15 taels per 100 taels weight. From 15 to 20 taels per 100 taels weight is equivalent to 335 to 446 dollars per picul ($133\frac{1}{3}$ lb.).

Although it is smuggled into the country, and the very heavy exactions it is subjected to are evaded, the price of the Indian production, as compared with that of the native-grown commodity, is so high as practically to exclude it from consumption; and inquiry leads to the conclusion that, unless its price be reduced to approach closely to that of the latter, its superior quality, stronger flavour and greater narcotic power will fail to obtain for it an increased demand. It does not appear that foreign opium has ever been smoked in these regions by the bulk of the people; and if the statements of old smokers and of shopkeepers are to be credited,—and there seems to be no reason for discrediting them,—it cannot but be believed that for at least two generations native-grown opium only, from the province of Yunnan, has been almost solely consumed. There is nothing to show that its use has increased; on the contrary, it is obvious that the opposite must have been the case from the destruction of large cities, the diminution of the population generally over the country, consequent on the Taeping rebellion, and from the state of warfare which has existed during the past fifteen years and longer in the Yunnan Province, and which is reported to have devastated it. Considering the proximity of this portion of the empire to Canton, it is a significant fact that foreign opium has not entered into general use; and there can be no doubt that in the habituated taste of the native smokers the foreign drug has had to contend against an influence nearly, if not quite, as powerful as its own high cost.

The imputations which have been directed against the foreign trade in this article, in so far as it has affected this part of China, are disproved most convincingly by a journey up the West River. In no city, town or market village he enters will the traveller find the foreign opium consumed by the inhabitants; and in Kwangse, in only a few shops of the largest cities, will he succeed in meeting with it at all. The further he pushes inquiry the more firmly will he entertain the conviction that opium-smoking has been a habit common over the country from a period anterior to the present century, and that the supply has been met by native production. To impute its introduction into this portion of the country to the foreign opium trade is to assert what will appear to be positively contradicted by facts.

SYNTHESIS OF ALKALOIDS.

It has just been announced by Dr. Hugo Schiff, of Florence, that he has succeeded in obtaining by synthesis a product which possesses the characteristic properties contained in the active principle of hemlock (*Conium maculatum*), in fact identical with the alkaloid conia. When alcoholic ammonia acts upon butyraldehyd, at a temperature not above 100° C., two bases are produced, one of which, dibutyraldine, is represented by the following formula:—

$$\underbrace{C_8H_{17}NO}_{\text{Dibutyraldine.}} = \underbrace{2\,C_4H_8O}_{\text{Butyraldehyd.}} + NH_3 - H_2O.$$

By the dry distillation of dibutyraldine, there is obtained, among other products, a final one, which is the alkaloid in question. The following is the reaction that takes place:—

$$\underbrace{C_8H_{17}NO}_{\text{Dibutyraldine.}} = H_2O + \underbrace{C_8H_{15}N.}_{\text{Conia.}}$$

—*Journal of Botany.*

PODOPHYLLIN.*

Podophyllin, or the podophylli resina—a new purgative introduced into the British Pharmacopœia—comes to us from the United States, where it has for many years been largely used, and is obtained, by the action of rectified spirit, from the dried rhizoma of the American may-apple, or mandrake (the *Podophyllum peltatum*). It has a well-established repute as a purgative, and, from the character of the motions produced by it, has been called "vegetable mercury." When the proper dose for a patient has been found, it acts very efficiently, but different constitutions require different doses; a grain dose is rarely required, in many cases a sixth of a grain acts gently and efficiently, while others may require a dose of half a grain, though in not a few such a quantity would act violently. Authorities are not in accord as to its action. By many it is considered to be a powerful cholagogue, largely increasing the quantity of bile poured into the intestines; but while some assert that it excites increased secretion of bile, others say that its action as a cholagogue is only due to its stimulating the gall bladder to contract and expel its contents into the bowels. And again, others deny that it increases either the secretion or the excretion of bile. Dr. Anstie, who experimented with it on dogs and rats, came to the conclusion that it has no special action on the liver; and the Committee of the British Medical Association appointed to investigate the action of podophyllin on the liver reported that doses varying from two to eight grains, when given to dogs, diminished the solid constituents of the bile, whether they produced purgation or not; and that doses which produced purgation lessened both the fluid and the solid constituents.* It is difficult, however, not to believe the strong evidence given in its favour as a useful and powerful cholagogue in man—in conditions of disorder or disease, at any rate. American physicians of scientific repute hold it in great esteem as a cholagogue and general eliminative. Dr. Gardner says,† "I know no other substance which so certainly produced bilious evacuations when the liver is full of bile," and specially speaks of its value in jaundice, in the torpid liver of those who have resided in tropical climates, in gout, and in the constipation which often besets patients in phthisis. Dr. Ramskill,‡ after an extensive employment of it, reports, "As a cholagogue, it stands pre-eminent and alone—far before mercury or any other drug that I ever administered. . . . In very small doses it will procure an abundant flow of bile, and often induce its discharge by vomiting, before, or even sometimes without any purging." Dr. Sydney Ringer§ recommends it in the obstinate constipation which often follows an attack of diarrhœa in hand-fed infants. He uses an alcoholic solution of the resin, containing one grain to the drachm of alcohol, and of this one or two drops are given. It may be considered as having acquired a well-established reputation. In America|| it has been found, in small repeated doses, of great value as a deobstruent in scrofula, rheumatism, syphilis and other chronic diseases; and in England Dr. Marston,** of the Royal Artillery, and Dr. R. S. Sisson, have employed it in secondary syphilis as a substitute for mercury, with marked success.

Its action as a purgative is rather uncertain, and is apt to be attended with griping, to prevent which it may be combined with small doses of henbane, belladonna, or cannabis indica; and its action is rendered more certain by giving compound colocynth or rhubarb pill, soap, or ipecacuanha with it.

THE GUAVA.

The guava is a tree which grows in tropical countries, and it is found principally in the West Indies. It is of the genus termed by botanists, *Psidium*, and is of two sorts, the *P. pomiferum* and *P. pyriferum*. The plant does not attain any considerable size, being generally about fifteen feet high, and it is of very delicate formation. The bark is quite thin, and of a light brown colour. It peels off in small portions when exposed to the sun; to prevent this, the trees are usually planted beneath others of a larger growth and hardier nature. The leaves are of an elliptic, lanceolate form. They are very distinctly marked by the fibres of which they are

** *Lancet*, January, 1864.

composed; they are of a dark green colour, and measure about 2½ inches. The flowers resemble those of the orange, and emit a strong perfume; the fruit is about the size of a small lemon; it is almost of the same shape and colour. The interior consists of a red pulpy substance, containing an innumerable quantity of small seeds somewhat larger than those of the fig. The rind of the fruit is of the consistency of that of an apple. Of this fruit the West Indians make several kinds of preserves,—the guava jelly, stewed guava, quake pear, and marmalade; the most lucrative is the guava jelly; the fruit is often eaten in its raw condition. The negroes are so fond of it that they are very wary and diligent in guarding the trees from robbery when they are bearing fruit.

The guava jelly is obtained by boiling the guavas with sugar and spices; and, after expressing the juice through a cloth, it is left to cool. Of course it undergoes minor processes, which I omit, they being inappropriate to the object of this paper.

The jelly is frequently bottled, but oftener it is put into small cylindrical boxes made of laminated pine board. A great quantity of this comfit is manufactured in Cuba, where it is termed "Jalea de guayaba," which is exported to the United States and Europe. Notwithstanding that a good deal is made in the smaller islands, they import quite a quantity of the Cuban jelly.

After the juice has been expressed from the guava, there remain the skins and the pulp containing the seeds; the latter is stewed and bottled, and it constitutes the stewed guava. This is generally partaken of with milk.

The skins are converted into the delicacy termed "quake pear," by a process varying slightly from the foregoing.

The guava marmalade is not frequently made. It consists of the guava grated and prepared in a peculiar manner.

Of the before-mentioned preserves, the marmalade is preferred by most connoisseurs. The small seeds in the stewed guava are very objectionable, the more so if one is subject to toothache, as they get into the cavities of decayed teeth, causing a great deal of suffering.

The natives of the West Indies are great herbalists; they convert almost any plant into medicine of some kind or other, and they have discovered several medicinal properties in the guava-tree and its complementary portions; what they are, I cannot pretend to say.

There is no distinction made between the name of the tree and that of the fruit in English, both being guava; the French term the tree *goyavier*, and the fruit *goyave*. Their respective terms in the Creole patois are *gyanbaum* and *gyan*.—*Druggists' Circular and Chemical Gazette.*

CHEMICAL EXAMINATION OF CONDENSED MILK.*

The *British Medical Journal* reports the following result of an analysis of the contents of a tin of Newnham's Condensed Milk:—

Water	19·0
Caseine	10·0
Ash	2·0
Fat, Milk-Sugar, Cane-Sugar	69·0
	100·0

The water was determined by drying at 212° F. The caseine was determined directly, the result being verified by the employment of Wanklyn, Chapman and Smith's ammonia process. The ash was determined by ignition. There appeared to be about as much fat as caseine. From the analysis it follows that the degree of condensation of Newnham's Condensed Milk is between three and four; that is to say, one pound of the condensed milk contains the solid constituents of from three to four pounds of fresh milk.

* See *ante*, No. 5, p. 89.

ANALYSIS OF MILK.

In making examinations of milk for sanitary or commercial purposes, it is customary to use determinations of specific gravity as indices of the *strength* of milk. It is, however, recognized that owing to the circumstance of cream being lighter than water, whilst skimmed milk is heavier, the indication of strength afforded by a determination of specific gravity is not very precise. Obviously, if, in addition to the specific gravity, the percentage of cream were taken, a connection could be applied so as to rectify the indication of strength derived from specific gravity. In the course of an examination of milk undertaken for the *Milk Journal*, the observation was made that there is another source of inaccuracy hitherto quite unsuspected. Skimmed milk consists mainly of water, caseine milk, sugar and a small quantity of mineral salts. Now, the exact molecular condition of the caseine influences the specific gravity of milk. In other words, samples of milk of the same strength will vary in specific gravity according to the exact molecular condition of the caseine. Especially are these changes in condition brought out if milk be kept for a while. This is illustrated by the following examples.

We do not intend on this occasion to enter fully into the subject of milk analysis, but we may state that plans commonly adopted are of little worth. We have had to notice the untrustworthiness of specific gravity determinations of milk,—that is to say, the danger of judging of the strength of milk by its specific gravity. To be of any value at all, the specific gravity determination must be made whilst the sample of milk is very fresh. After milk has been kept for two or three days, even in a closed vessel, its specific gravity falls in a very remarkable manner. The following examples exhibit this in an extreme form. The specimens of milk had been kept in corked bottles for four days:—

	Sp. gr. at 60° F.	Percentage of Solids dry, at 212° F.	Percentage of Ash.
Sample *a*	1·0004	11·34	0·94
„ *b*	0·9960	10·48	0·75
„ *c*	1·0184	8·92	0·66

Showing that the highest specific gravity sometimes accompanies the lowest percentage of solids. The reason of this want of correspondence between specific gravity and solid contents we have already explained. Meanwhile, in judging of the strength of milk, it is proposed to adhere to the method of evaporating to dryness in the water-bath, and weighing the residue.—*Milk Journal.*

THE HEAT DEVELOPED IN THE COMBINATION OF ACIDS AND BASES.*

BY THOMAS ANDREWS, M.D., F.R.S., HON. F.R.S.E.,
Vice-President of Queen's College, Belfast.

In a paper communicated to the Royal Irish Academy in 1841, I gave an account of a large number of experiments on the heat disengaged when acids and bases, taken in the state of dilute solution, enter into combination, and when bases, insoluble in water, are dissolved in dilute acids. The following general conclusions or laws were deduced from those experiments:—

Law 1.—The heat developed in the union of acids and bases is determined by the base and not by the acid, the same base producing, when combined with an equivalent of different acids, nearly the same quantity of heat; but different bases, different quantities.

* From the 'Transactions of the Royal Society of Edinburgh,' Session 1869–70.

Law 2.—When a neutral is converted into an acid salt, by combining with one or more atoms of acid, no change of temperature occurs.

Law 3.—When a neutral is converted into a basic salt, by combining with an additional proportion of base, the combination is accompanied with evolution of heat.*

Three years later I laid before the Royal Society of London the results of an experimental investigation of the heat developed when one base is substituted for another in chemical compounds. The law deduced from this inquiry is implicitly involved in the foregoing, of which it may indeed be regarded as a necessary consequence. It was enunciated in the following terms:—

Law 4.—When one base displaces another from any of its neutral combinations, the heat evolved or abstracted is always the same, whatever the acid element may be, provided the bases are the same.†

Finally, the law of metallic substitutions, first announced in the 'Philosophical Magazine' for August, 1844, was thus stated in a paper published in the 'Philosophical Transactions' for 1848.

Law 5.—When an equivalent of one and the same metal replaces another in a solution of any of its salts of the same order, the heat developed is always the same; but a change in either of the metals produces a different development of heat.

In 1845 a paper appeared by Graham on the heat disengaged in combinations, the second part of which refers to the heat produced when hydrate of potash is neutralized by different acids.‡ The results arrived at by this distinguished chemist exhibit a close agreement with those contained in my first communication to the Royal Irish Academy.

The concluding part of the elaborate memoir of MM. Favre and Silbermann on the heat disengaged in chemical actions is chiefly devoted to the same subject. A large number of experiments are described, which are nearly a repetition of those I had previously published. Their results bear a general resemblance to those given by myself in 1841, but they widely differ in the details. The authors of this able memoir fully recognize the accuracy of my fourth law, which asserts the equality of thermal effect when one base is substituted for another. "M. Andrews," they observe, "avait en effet établi que, quel que soit l'acide d'un sel, la quantité de chaleur dégagée par la substitution d'une base à une autre pour former un nouveau sel est la même, lorsque l'on considère les deux mêmes bases."§

In a preceding paragraph of the same memoir, the authors object to what they conceive to be my first law, and state that it is not in accordance with the results of their investigations. As the question is one of some importance, I may perhaps be permitted to quote the passage in the original language. "Ses conclusions, savoir: que la chaleur dégagée par l'équivalent d'une même base combinée aux divers acides est la même, ne s'accordent pas avec les résultats de nos recherches, et ne nous paraissent pas pouvoir être admises." No doubt, through inadvertence, MM. Favre and Silbermann have here given an inaccurate statement of my first law. It did not declare that precisely the same amount of heat is disengaged by all the acids in combining with the same base, but that the heat is determined by the base, "the same base producing, when combined with an equivalent of different acids, *nearly* the same quantity of heat." A comparison of the results of MM. Favre and Silbermann with those in my original memoir will show that I had fully recognized and described the deviations from the other acids, exhibited, on the one hand, in excess, by sulphuric acid, and on the other, in deficiency, by tartaric, citric and succinic acids. "If we refer," I remarked, in the original memoir of 1841, "to the first, second and fourth tables, as being the most extensive, from the large number of soluble compounds formed by potash, soda and ammonia, it will be observed that sulphuric acid developes from 0·8° to nearly 1° more than the mean heat given by the other acids; while tartaric, citric and succinic acids fall from 0·4° to 0·55° short of the same. A minute investigation of the influence of the disturbing sources of heat will no doubt discover the causes of these discrepancies. The high numbers for sulphuric acid are probably connected with that acid's well-known property of developing much heat when combining with successive atoms of water. All the other acids develope nearly the same amount of heat in combining with the same base, the greatest divergences from the mean quantity being, in the case of potash, + 0·24° and − 0·13°; in that of soda, + 0·26° and − 0·14°; and in that of ammonia, + 0·17° and − 0·05°. These differences are almost within the limits of the errors of experiment."*

But although there is a superficial agreement between my original results and those of MM. Favre and Silbermann, they will be found, when examined closely, to differ widely in detail and on points of great importance. I had found that oxalic acid disengages almost exactly the same amount of heat in combining with the soluble bases as hydrochloric, nitric and many other mineral acids, and this observation I have always regarded as one of the main foundations of Law 1. MM. Favre and Silbermann, on the contrary, have inferred from their experiments that "the following organic acids—oxalic, formic, valeric and citric—disengage sensibly the same quantity of heat, but it is less (*plus faible*) than that given by the foregoing mineral acids"—among which they enumerate the nitric and hydrochloric. According to my experiments, no distinction of this kind can be admitted between acids derived from the mineral and organic kingdom, inasmuch as oxalic acid developes at least as much heat in combining with the bases as hydrochloric, nitric and several other strong mineral acids.

The experiments to be described in this paper were made some years ago, but their publication has been deferred from accidental circumstances. I have, however, recently repeated a few of the more important of them, with a slightly modified form of apparatus. The solutions were taken in so dilute a state that the heat disengaged never exceeded 3·5° C. A standard solution of sulphuric acid was prepared and carefully analysed, by precipitating a given weight with a soluble salt of barium, and weighing the sulphate of barium. The strength of the alkaline solutions was adjusted with great care by means of this standard acid. The same solution of each alkali was employed in all the experiments, and the quantity used in each experiment was determined by careful weighing. The acid solution was of such a strength that, after being mixed with the alkali, an excess of two or three per cent. of acid was present. The alkaline solution was contained in a light glass vessel, in which a large platinum crucible holding the acid was carefully floated. By giving a rapid rotation, by means of a light stirrer, to the acid solution in the platinum crucible, a perfect equilibrium of temperature was soon established between the two liquids. The initial temperature of the solutions was usually about 1·5° below that of the air, and the final temperature of the mixture about 1·5° above it. The corrections for the heating and cooling action of the surrounding medium were determined with great care. The mechanical process of adding the acid to the alkaline solution produced no change of temperature, and as the heat disengaged in the combination raised the liquid almost instantly to the

* 'Transactions of the Royal Irish Academy,' vol. xix. p. 228.

† 'Philosophical Transactions' for 1844, p. 21.

‡ 'Memoirs of the Chemical Society,' vol. ii. p. 51.

§ 'Annales de Chimie et de Physique,' 3me série, xxxvii. p. 497 (1853).

* 'Transactions of the Royal Irish Academy,' vol. xix. p. 240.

maximum temperature, the whole correction required was for cooling. The first temperature was read one minute after the addition of the acid to the alkaline solution, the mixture being stirred during the whole of that time. If δ represents the correction, and ϵ the excess of temperature above the air in Centigrade degrees, the value of δ will be given by the following expression:—

$$\delta = \epsilon \times 0{\cdot}012^\circ.$$

As a proof of the accuracy of the method of mixture adopted in this inquiry, I may mention that, being desirous to know whether the dilute acids employed in these experiments produced any change of temperature when mixed with water, I made the experiment with nitric acid by the method just described, substituting water for the alkaline solution, with the unexpected result of a fall of 0·01°. On varying the conditions of the observation, so as to obtain a larger effect, it was ascertained not only that a diminution of temperature had actually occurred, but that the observed fall represented approximately its true amount. When hydrochloric acid of equivalent strength was diluted to the same extent, an elevation of temperature of 0·05° was produced.

The accuracy of experiments of this kind, where the whole thermal effect observed amounts only to 2° or 3°, depends greatly on the thermometer employed. Unless its indications are perfectly trustworthy in every part of the scale, the labour of the inquirer will only end in disappointment. I have therefore taken every precaution to secure this important object. The tube of the thermometer was calibrated and divided with care, according to an arbitrary scale, by means of a dividing instrument contrived for the purpose, and provided with a short screw of great accuracy made by Troughton and Simms. The divisions, etched finely on the glass, correspond to about 0·05° C., and the readings could be made with certainty to less than 0·01°. The division of the scale, corresponding to 0°, was determined from time to time in the usual way; and another point, about 30° C., was fixed by comparison with four other thermometers similarly constructed, whose scales extended from the freezing to the boiling-point of water. The readings of these four instruments, when reduced to degrees, rarely differed from each other within the limits to which they could be read, or 0·02°. The reservoir of the thermometer used in these experiments was 75 millimetres long, and, when immersed in the liquid, occupied nearly its entire depth.

As some uncertainty always exists with regard to the thermal equivalent of glass vessels, I made two sets of comparative experiments—one with a thickly-varnished copper vessel, and the other with a vessel of platinum. The mean result of these experiments coincided almost exactly with the result obtained when the glass vessel was employed.

The weight of the glass vessel which contained the alkaline solution was 58 grammes, and corresponded thermally to 11·4 grammes of the solutions formed. The thermal equivalent of the reservoir of the thermometer and of the stirrer was 0·9 gramme. The alkaline solution weighed 160 grammes, and contained the equivalent of 1·738 gramme of SO_3. The acid solution weighed 42·5 grammes. Hence the entire thermal value of the apparatus, in terms of the solution formed was:—

Solution	202·5
Glass vessel	11·4
Thermometer and stirrer . .	0·9
	214·8 grammes.

A correction (additive) of $\frac{1}{240}$ was made to the direct readings for the mercury in the stem of the thermometer. The results are given to thousandths of a degree, but this apparent minuteness is due to the reduction of the indications of the arbitrary scale to degrees.

The following table gives the mean results of the new experiments, the acids being arranged in the order of their thermal action:—

Acid.	Potash.	Soda.	Ammonia.
Sulphuric acid . . .	3·378°	3·353°	2·976°
Oxalic acid	3·058°	3·040°	2·648°
Hydrochloric acid . .	3·021°	2·982°	2·623°
Nitric acid	2·993°	2·929°	2·566°
Acetic acid	2·852°	2·832°	2·492°
Tartaric acid . . .	2·732°	2·710°	2·376°

It is interesting to observe how closely the results in the three vertical columns agree relatively with one another. The acids follow in the same order under each base, and even the differences in the amount of heat disengaged by the several acids in combining with the different bases approximate in many cases closely to one another. Thus the heat given out when sulphuric acid combines with potash exceeds that given out when oxalic acid combines with the same base by 0·320°, the corresponding differences in the case of soda and ammonia being 0·313° and 0·328°. If, in like manner, we compare the differences between the heat disengaged by the acetic and tartaric acids, we fall upon the numbers 0·120°, 0·122°, and 0·116°. Even in the case of oxalic, hydrochloric and nitric acids, which disengage so nearly the same amount of heat, the same order is observed with the three bases. It must be particularly remarked that the oxalic acid disengages from 0·022° to 0·058° more heat in combining with these bases than the hydrochloric acid, and from 0·065° to 0·111° more than the nitric acid. The conclusion of MM. Favre and Silbermann, that the organic acids (oxalic, formic, acetic, etc.) disengage sensibly less heat than the mineral acids, is thus entirely disproved; and the original results recorded in my work of 1841, according to which oxalic acid disengages at least as much heat as nitric, phosphoric, arsenic, hydrochloric, hydriodic, boracic and other mineral acids (with the exception of the sulphuric acid) are fully confirmed. Tartaric, citric and succinic acids, it is true (as was also shown in the same work), give out about $\frac{1}{14}$th less heat than the average of the other acids, but acetic and formic acids fall scarcely $\frac{1}{30}$th below the mean, and oxalic acid is always above it. These results, in all their main features, are fully corroborated by the experiments recorded in this paper, which were performed with a more perfect apparatus and a more exact thermometer than I had at my command in my earlier investigations. A reference to the same paper will show that while acids, differing so widely from one another as oxalic, phosphoric, arsenic, nitric, hydrochloric and boracic acids scarcely present any sensible difference in the quantities of heat which they disengage in combining with the bases; and while of the other acids examined sulphuric acid (and probably also sulphurous acid) presents an extreme deviation of about $\frac{1}{8}$th above the mean, and the tartaric acid group a deviation of about $\frac{1}{30}$th below it, the bases, on the contrary (and the subsequent researches of Favre and Silbermann have confirmed this result), differ altogether in thermal power from one another. Thus, equivalents of the oxides of magnesium and of silver give out 4·1° and 1·8° of heat respectively in combining with nitric acid, the former oxide having therefore 2·3 times the thermal power of the latter. Yet, as is well known, both these bases fully saturate the acid, and the resulting solutions are even neutral to test-paper. For these reasons I have no doubt whatever that the first law, as enunciated in 1841, is the expression of a true physical law, and that in the combination of acids and bases in presence of water the heat disengaged is determined by the base and not by the acid. It is true that in this, as in similar physical inquiries, experimental results cannot immediately be obtained free from complication or disturbing influences. The same remark applies to the experimental proof of the great law discovered by Dulong and Petit, which connects the specific heats and atomic weights of the elementary bodies, and also to that of the remarkable relations discovered by Kopp between the composition and boiling-points of many organic liquids. We have already seen an illustration of one of these disturbing influences in the fact that dilute nitric acid, when mixed with water, gives a slight fall of temperature, hydrochloric acid a rise; and the differences of specific heat in the solutions formed will, to a small extent, modify the results. But the cause of the higher thermal power of sulphuric acid I have not been able to discover, and future researches must decide whether it depends upon some disturbing cause, or (which is less probable) upon its possessing an exceptionally high thermal power. One condition is, however, essential, or Law 1 will not apply. The acid and base must be capable of combining when brought into contact, and of forming a stable compound. In the paper so often referred to, I showed that hydrocyanic acid and potash, which fail to fulfil this condition, do not disengage the normal amount of heat when mixed; and the same observation will doubtless be found to apply to a large number of metallic oxides which form unstable compounds with, and imperfectly neutralizes the bases.

As regards the experimental proofs of the other laws, even those of the fourth law, the truth of which is admitted by MM. Favre and Silbermann, they are only approximative, and here also we meet occasionally with peculiar and unexpected results. Thus, a slight fall of temperature occurs, as Hess showed long ago, in the conversion of the neutral sulphate of potash into the acid salt; and I found, as, indeed, might have been expected from their alkaline reaction, that in the conversion of the ordinary phosphates and arseniates into supersalts a disengagement of heat occurs, amounting to about one-seventh of that disengaged in the formation of the salts themselves. In other cases results, at first view startling and apparently anomalous, will be found to be strictly in accordance with the general principles already laid down. In the formation of double salts there is no disengagement of heat, a principle announced in 1841, and which ought perhaps to be enunciated as a distinct law, although it is implicitly involved in Law 2. Again, if tribasic phosphoric acid or arsenic acid is added in fractional portions to a solution of potash till the subsalts are formed, the heat disengaged on each addition of acid corresponds to the amount of acid added; but after this point has been reached the disengagement of heat follows a different law. Pyrophosphoric acid, on the other hand, behaves in the same way as nitric and most other acids when added in successive portions to solutions of potash or soda, equal increments of heat being evolved for equal additions of acid till the pyrophosphate of potash or soda is formed.*

Appendix.

In the following tables I have given the results described in this communication and those of 1841 in a form which admits of comparison with one another, and with those of MM. Favre and Silbermann. I have also added a few determinations recently made by M. Thomsen, of Copenhagen.† It will be seen that the original experiments of 1841 exhibit, on the whole, a fair agreement with those now communicated to the Society. From the small scale on which they were performed (the whole weight of the solutions after mixture being less than 30 grammes), the imperfect form of the apparatus, and the uncertainty of the thermometric indications, I have indeed been surprised to find them so near the truth. The results of MM. Favre and Silbermann do not exhibit the precision which might have been expected from the high character of those experimentalists, and from the accuracy of other parts of their great work. The mercurial calorimeter employed by them appears to have been little adapted to its purpose; but after making due allowance for its imperfections, I am at a loss to account for the serious errors into which they have fallen. M. Thomsen's experiments have evidently been made with care, and his results agree comparatively with my own; but the absolute amount of heat obtained by him falls far short of what I have found. It is, indeed, much easier to obtain results relatively than absolutely correct. The numbers given in this paper will, I believe, be found rarely to differ *relatively* more than $\frac{1}{200}$th from the truth, but they may hereafter require a small correction in respect of their *absolute* value. That correction can, however, be scarcely more than $\frac{1}{50}$th of the whole amount, and I have little doubt that the number, for example, given by Thomsen to express the heat disengaged in the combination of soda with nitric acid will prove to be as far below the true number as that given by MM. Favre and Silbermann is above it.

Preserved Meat.—There has lately been a trial of preserved meat from Rosario, in the Argentine Republic, with, it is stated, satisfactory results. Preservation was effected by immersion in bisulphite of lime, according to the process of Messrs. Medlock and Bailey, of Wolverhampton; and the meat was sealed up in a cask, in the presence of the British Consul at Rosario, on August 10th last, and brought by him to England in a recent steamer. It had, therefore, been kept four months, and had made a passage across the Line.—*Journal of the Society of Arts.*

Glycerine Inhalation in Croup.—Dr. Stehberger, of Mannheim, reports that he has successfully used inhalation of glycerine, through Siegle's apparatus, in the early stages of croup. The glycerine, if pure, is used unmixed; if not pure, it is diluted with a little water.—*British Medical Journal.*

THE CHEMISTS' BALL.

On Wednesday evening this social gathering, which now seems firmly established as an annual one, was held in Willis's Rooms, St. James's. The Ball was a complete success. There were upwards of four hundred persons present, and on no former occasion has the assembly been graced by the presence of so many ladies. Amongst the many guests there were the Lord Mayor and Miss Dakin; the Pharmaceutical Society was represented by the President and Vice-President; the Auditors of the Society by Mr. Barron; the Council by Mr. T. B. Groves and Mr. Bourdas; the Examiners by Mr. Allchin and Mr. M. Carteighe; the Educational Department by Professor Attfield and Mr. W. A. Tilden; and the other officials by the Secretary, Mr. R. Bremridge and Mr. Flux. The Supper, which was an elegant one, was served in three rooms, and the Committee must have been much gratified with the extremely pleasant manner in which everything connected with the Ball passed off.

In proposing the toast of the evening, the Lord Mayor said he was much gratified in having been asked to preside on this occasion, which he believed to be the fifth of the kind, and which was such an evident success. As the enjoyment of privileges always entailed duties, so the position which he then held involved the duty of observing the usual rule of this gathering, and proposing the one toast which was customary, viz. "Success to the Chemists' Ball." In doing so, he felt how much satisfaction was to be realized in the performance of duties, and he desired to take the opportunity of expressing his approval of such a gathering; for independent of the pleasure it afforded to all who took part in it, it was calculated to be eminently useful when regarded as an annual rallying-point of the members of our most important profession. He was glad also to learn that yet another object was served, and that the surplus proceeds of the Ball flowed "heaven-directed" to the poor. Though he was precluded by usage from adding to the one toast he now proposed, he could not, while surrounded by so much youth and beauty, abstain from making some reference to the presence of those without whom we should not be able to enjoy the pleasures of the evening, any more than we could dispense with their good offices in other matters. For this reason he would ask them to add three cheers to the toast of "Success to the Chemists' Ball."

After the cheering had subsided, Mr. Watson rose, and in a few words proposed that they should still further depart from the usual custom and show the appreciation of their presence there that evening by drinking to the health of the Lord Mayor and Miss Dakin.

After the toast had been honoured and the cheers given, the dancing was resumed and kept up with great spirit until a very late hour.

How to Fasten Rubber to Wood and Metal.—As rubber plates and rings are now-a-days almost exclusively used for making connections between steam and other pipes and apparatus, much annoyance is often experienced by the impossibility or imperfectness of an air-tight connection. This is obviated entirely by employing a cement which fastens alike well to the rubber and to the metal or wood. Such cement is prepared by a solution of shellac in ammonia. This is best made by soaking pulverized gum shellac in ten times its weight of strong ammonia, when a slimy mass is obtained, which, in three to four weeks, will become liquid without the use of hot water. This softens the rubber, and becomes, after volatilization of ammonia, hard and impermeable to gases and fluids.—*Druggists' Circular and Chemical Gazette.*

ANNUAL DINNER OF THE SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The Annual Dinner, in connection with the above Association, was held at Mr. Armfield's, Adelphi Hotel, on Thursday evening, the company numbering between forty and fifty. The chair was occupied by the President, Mr. J. T. Dobb, and the vice-chair by the Ex-President, Mr. Wilson.

The usual loyal and patriotic toasts having been proposed and honoured, Dr. Hall gave the toast of the evening, "Success to the Sheffield Pharmaceutical and Chemical Association," and, in the course of his remarks, congratulated the Association upon its prosperous condition. He alluded in graceful terms to the relationship which existed between the medical and pharmaceutical professions, how dependent one was upon the other, and at some length reviewed the sections of the Annual Report, which had been distributed that evening.

Several other toasts were proposed and duly honoured, after which the Chairman, in proposing the "Continued Success of the Pharmaceutical Society of Great Britain," said, What is the sphere of labour of our Sheffield Pharmaceutical and Chemical Association in its connection with the parent Society? To my mind the efforts of your Association should be devoted to extending and establishing the Library and Museum, to maintain and uphold, as far as our funds permit, our Latin, botanical and chemical classes, with the regular course of lectures. In the future looms a laboratory for practical chemistry, with an established teacher. With the support and approval of the Pharmaceutical Society these forces might be so utilized and brought to bear upon the education of those in this neighbourhood who are studying for the profession, as to be a great advantage to them. Sheffield is in the midst of a large and populous district, and could be made the centre of a district. The examiners of our Local Association might give certificates of competency in the examinations, and thus save the expense and time occupied in journeys to London for such a purpose. I do hope the day is not far distant when these desires will be realized, and that the Pharmaceutical Society will give us all the moral and material support in their power.

Veratrum Viride an Antidote to Opium.—E. H. Sholl, M.D., of Alabama, communicates to the *Philadelphia Medical and Surgical Reporter* a case of poisoning by morphia, which was cured by veratrum. The patient, a negro boy, aged fifteen years, had typhoid fever, and took an overdose of morphia, which had been prescribed for hiccup. It was followed by stertorous breathing, contracted pupils, and so forth. His mouth was prized open, and gtt. xviij Norwood's tincture poured in, "with two ounces of brandy." In one hour every symptom of poisoning had vanished.

Quinquina Chocolate.—Dr. Heuze, in *Les Mondes* of June last, says, he has succeeded in preparing an extract of Peruvian bark, so as to possess no unpleasant bitter taste, and this is mixed with pure chocolate paste, so as to form readily-portable, and, at the same time, an agreeable, dietetic medicine. This preparation is (thus it was stated at a meeting of the Central Imperial Society of Agriculture) considered superior to the sulphate of quinine.

Chloride of Zinc in Rods.—Dr. Köbner, of Breslau, describes (*Berlin. Klin. Wochenschr.*, no. 47, 1870) a method of making solid rods of chloride of zinc. Two parts of the chloride are fused with one part of nitrate of potash and formed into rods, which are kept in tinfoil in a well-stoppered bottle. They will last for a week. The combination forms, says Dr. Köbner, an excellent caustic, holding a place midway between nitrate of silver and caustic potash.—*British Medical Journal.*

The Pharmaceutical Journal.

SATURDAY, JANUARY 28, 1871.

PHARMACY IN IRELAND.

IT is probable that among the various matters claiming the attention of our legislators in the approaching Parliamentary Session, the Pharmacy Bill for Ireland, proposed by the Governor and Company of the Apothecaries' Hall, Dublin, will have a place. The Bill has been already printed in this Journal,* and doubtless has been read by many interested. It does not seem to have been regarded with much favour by the chemists and druggists of Ireland; but although an expression of opinion was invited, and a portion of our space offered for the discussion of the subject, only three letters have, up the present time, been received. Certainly it seems desirable that those whom the question most affects should not rest contented with merely protesting, but that before the time arrives for the discussion of the Bill in Parliament they should decide among themselves what course they ought to take.

That the state of affairs with regard to the practice of pharmacy in Ireland is anomalous has long been admitted. A chemist and druggist is allowed to vend drugs to any extent, but is absolutely prohibited, under fear of a heavy penalty, from making up a single prescription. That portion of the business is confined to members of the Apothecaries' Hall, who are also permitted to sell drugs.

The law, as it at present stands, simply creates a monopoly which cannot be defended on the ground that it favours the educated pharmacist, for a man, however well qualified to practise that calling, is not allowed to do so in Ireland unless he is a member of the particular body mentioned. He may have passed the examination of the Pharmaceutical Society of Great Britain and hold a diploma certifying that he is competent to dispense a prescription in England, Scotland, or Wales, but let him cross the St. George's Channel and set his foot in Ireland, and his diploma is of no avail. Surely that skill which is accounted sufficient in England would be equal to satisfying the requirements of the Irish public.

There is no reason why the law concerning pharmacy should not be assimilated in the three kingdoms. In doing this, it would be necessary to guard against the privilege of dispensing being accorded to any but those who are competent fully and conscientiously to carry out a prescriber's wishes. But this should be done with consideration. Men who have been many years in business, and who have a good practical knowledge of it, could hardly be expected to enter upon a curriculum of chemistry, botany and materia medica. Any examination that may be instituted should be capable of being modified to meet these and similar cases in Ireland; and persons who have once satisfied the requirements of the English law ought to be allowed to practise there without any further examination.

* No. 21, p. 405.

POISON REGULATIONS.

OUR readers will perceive that we have again some long communications on this subject, which deserve attention as representing various views. We have also during the last few weeks published some information as to the state of opinion and law in Canada and the State of New York respecting the sale of poisons. The present Journal contains a number of recent cases of poisoning, illustrating some of the modes in which accidents happen. Both these and the papers above referred to afford matter for reflection, though they cannot be expected to determine the regulation question. In regard to that, it appears there are some who maintain there should be regulations, some who maintain there should not be any, and others who declare they will not have them. Which of these three views is to rule the action of the Society is clearly a matter for decision by vote, and meanwhile we endeavour to fulfil our part by furnishing all available information on the subject.

An amusing instance of popular posology occurred this week in the report of a case of poisoning given by one of the London daily newspapers. It was there stated that death arose from an overdose of opium, "the deceased having taken a drachm and a half, whereas the full dose was only a drachm."

A CROWDED audience assembled in the theatre of the London Institution on the occasion of the Conversazione on Wednesday evening last, to hear Professor Tyndall lecture on "Dust and Disease." The discourse, which was a very eloquent one, was a repetition, with some variations, of his celebrated lecture on the same subject at the Royal Institution.

DISPENSING IN SURGERIES.

In calling the attention of our readers to the report, in another column, of a case of poisoning by an overdose of morphia, we wish to say that any remark that may be made will not be intended to apply to particular individuals. If the method of dispensing adopted in Mr. Dex Bean's surgery had been singular and unusual, probably we should have abstained from comment; but as, on the contrary, we believe it to be typical of what might be met with in hundreds of surgeries throughout the country, and these belonging to members of a body which, at times, is inclined to be rather exigent in its demands upon pharmacists, we are tempted to call attention to some of the facts of the case.

A child being ill, a medical gentleman who was called in, prescribed for it a mixture of solution of tartarized antimony, hydrate of chloral, and colouring matter. This mixture was supplied from his own surgery. A teaspoonful having been administered the child fell into a deep sleep, only disturbed by convulsions until its death. We do not think we shall be charged with unfairness if we say that here, in the ordinary course, there would have been an end of the affair. But it happened that the father, who is a chemist and druggist, recognized the appearance of narcotism in the child; and after its death he obtained an analysis of the portion of the mixture which remained, the result being that it was found that antimony which was ordered was absent, while morphia, which had not been ordered, was present.

As to the state of things which would allow of such a result. The prescription was left to be dispensed by a pupil who had been under tuition one year and three-quarters. Now we doubt whether there are many respectable pharmacies in which an apprentice in so early a stage would be entrusted with the responsible work of compounding prescriptions, certainly not without vigilant supervision. But what are the facts with regard to this young man? What is Mr. Dex Bean's own evidence on this point? "The drugs were left to be compounded by his assistant, John Simeon Dyson. No other person was authorized, or even able to compound the medicine. He had not interfered with the dispensing department for the last twelve months. He could not say where the bottle containing chloral was kept exactly. Mr. Dyson had had one and three-quarter years' practice in dispensing. He had dispensed, without supervision, sixteen months." Again, in answer to the question, "How many prescriptions has the young man Dyson made up?" the answer was, "Several thousands." And again, in answer to a question from the foreman of the jury as to the qualifications required in a dispenser, Mr. Dex Bean replied that dispensing was merely mechanical, and he did not think that previous education had much to do with it.

So that this young man, when he had only had five months' experience, was left to make up his employer's prescriptions without any supervision, since which time he has prepared several thousands! Such statements carry in them the strongest possible condemnation of a system under which it is possible for them to be made. The inference to be drawn from the occurrence by every candid mind, amongst medical men and pharmacists, must be, that it is their duty to do all in their power to hasten the time when dispensing as well as prescribing shall be performed only by men specially trained to each calling.

At the Evening Meeting of the Pharmaceutical Society on Wednesday next, a Lecture will be delivered by Dr. Carpenter, the subject being "The Microscope and its Revelations."

The *British Medical Journal*, referring to the paper by Mr. Ince in our last number, expresses an opinion that while the object is a good one, it is worth considering how far it accords with proper reticence and courtesy. It thinks that before putting such documents to a public use the permission of the writers should be asked, and if this were not possible, the signatures should be erased.

EXAMINATION IN EDINBURGH.

January 17th, 1871.

Present—Messrs. Ainslie, Aitken, Baildon, Brown, Buchanan, Kemp, Mackay and Young.

Twenty-four Candidates were examined, eleven for the First or Preliminary Examination, eight for the Minor, and five for the Modified; the following passed and were duly registered:—

FIRST, or PRELIMINARY (as Apprentices or Students).

Anderson, David Smith ...... Musselburgh.
Bray, William .... Dumfries.
Chislett, Charles .... Edinburgh.
Galloway, George, jun. ...... Inverness.
Gardner, William .... Inverkeithing.
M'Leish, Stewart Munn ...... Uddingston.
Meldrum, David .... Edinburgh.
Moffat, Alexander Dryden .... Glasgow.
Russell, James Bryce .... Glasgow.
Sharp, Robert Henry .... Portobello.

MINOR (as Chemists and Druggists).

Galloway, George, jun. ...... Inverness.
Giles, William .... Aberdeen.
M'Naught, Archibald .... Greenock.
Macpherson, Richard .... Greenock.
Veitch, John Wilson .... Dunse.

MODIFIED (as Chemists and Druggists).

Ewing, James .... Edinburgh.
Robinson, Jonathan Scott .... Rhyl.
Savage, James .... Bradford.
Stephen, John .... Aberdeen.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

On Friday, the 13th instant, the Third Monthly Lecture of the Session was delivered at the Philosophical Institution, by Herr Leipner. The subject was "The Pharmacist in Germany."

The lecturer drew a hasty sketch of the history of pharmacy from its birth in the dim ages, burdened and half-smothered with the myths of alchemy, through the time of its childhood, bolstered and protected by the operations of guilds and municipalities, to the dawning of the present century, when the period of its maturity as a living, independent branch of science was reached.

The social position of the pharmacist during these times he showed to have been pretty much as might have been expected from the varying amount of credit with which the art was practised. The enthusiast, the quack and the tradesman, each in turn, claimed him for his own; but, in proportion as his art had struggled through the disadvantages that at different periods surrounded it, and he had become the qualified practitioner of a liberal calling, his own status in society had advanced.

In drawing his present position, and the circumstances that now surrounded him, the lecturer found it necessary to give an outline of the educational system of the Germans. It appeared that every child of Germany was by law compelled to be educated in one of three grades of school, either in the first or elementary school, the course of study in which embraced only the elementary subjects; or in the second, the "real" school, which, in addition to the above, included French, English, chemistry, physics, algebra, mathematics, Latin, drawing, and more history, natural history, geography and arithmetic than taught in the elementary schools; or in the third, the gymnasium, which gives a purely classical education. From the sixth to the tenth year all children attend an elementary school, after which they may enter either a real school or a gymnasium.

The class from which the pharmacist most usually sprang generally affected the "real" school; hence, in commencing his special studies, the young pharmacist started with an already acquired knowledge of the elements of natural science and chemistry. At this period of his career he entered a pharmaceutical college, where he devoted himself to the sciences especially required in his future duties for a period of two to three years, and from which he was required to emerge by the process of an examination creditably passed. He then, for a definite time, entered the shop of some established pharmacist; after which he was considered qualified to become a master pharmacist upon his own account.

The number of establishments in a district was, by the municipal law of that district, limited; but the pharmacist was not allowed to take extreme advantage of this apparent monopoly, for the prices for dispensed medicines, and to a great extent for drugs also, were regulated by the authorities. The restrictions, therefore, upon perfect freedom of trade, which were so generally swept away at the beginning of the present century, were thus seen not to have been removed from the pharmacist, who always was, and still is, regarded as one of the servants of the State.

In a money point of view, perhaps, his remuneration might be deemed to be inadequate to his responsibilities; but he undoubtedly received more consideration from society than his comrade in England, and this, the lecturer thought, was mainly due to his higher scientific attainments.

The following were a few of the many opinions quoted by the lecturer:—

Professor Wackenroder, of Jena, thus defines the position of an apothecary (1851), "The German apothecaries are indirect servants of the State, therefore unsalaried and independent, who, under State supervision, by special permission practise an art, but enjoy the same right of property as every other citizen of the State."

Dr. Carl Müller, Professor at Halle, says, "In the present condition of German pharmacy one might well consider apothecaries as half State-institutions, the pharmacist himself, however, as a servant of the State, occupying an independent position, being a servant at his own risk, who does not cost the State anything, but who, nevertheless, gives to the State what can be required of a servant of the State."

Again, Buchner writes, "The objects of pharmacies prove that they are not free trades, but medical institutions, which have to subserve the general weal, and therefore cannot be managed *ad libitum*, but according to definite and general Government Institutions. The pharmacist cannot, therefore, be classed among the free tradespeople, nor among artisans or manufacturers or merchants, but in his functions occupies a position by the side of the physician among the functionaries of the public weal. In the free trades the egotistic principle is the ruling one. The tradesman always cares directly for himself and his own advantage; according to natural right he knows no other duties than those of every citizen of the State. The farmer may cultivate his field or let it lie fallow, just as he pleases or his sense of the advantages may dictate; the mechanic, the manufacturer produces his goods according to his own ideas, and directs his efforts into the channel of free-trade speculations. In like manner the merchant may open or shut his business, give up keeping any merchandise he pleases, or keep any article in various qualities, and sell it at different prices, as demand and luxury may dictate. The free tradesman therefore cares for others only indirectly, being directly only mindful of his own advantage. The servant of the State, however, the medical man, the pharmacist, in short, every one serving the State, cares directly for the nation, and the State, indirectly only for himself and his family; for he must always act as the State and the public good may dictate, must sacrifice his comforts, private advantages, nay, even his life, for the public welfare. He receives from the State definite instructions, and must solemnly subscribe to such instructions."

Proceedings of Scientific Societies.

LINNEAN SOCIETY.

January 19th, Mr. DANIEL HANBURY, F.R.S., F.L.S., read some "Historical Notes on the *Radix Galangæ* of Pharmacy." The drug known as Galangal has been an object of trade for many centuries between Europe and the East. It is a stimulant and pungent aromatic of the nature of ginger, which it might be used to replace; but the many virtues ascribed to it by the ancients must be ignored. It was apparently unknown to the Greeks and Romans; its introduction into Europe was due to the Arabians, in whose writings it is frequently mentioned, being an ingredient of the compound medicines then in use. This is as early as the tenth and eleventh centuries; in the fifteenth century it was already in common use in Europe. In 1563, it was first pointed out that there are two kinds of Galangal, the smaller kind or *Radix Galangæ minoris*, obtained from China, and the larger kind from Java. The latter, the *Alpinia Galanga*, Willd., is not known in Europe; the former, named by Dr. Hance *Alpinia officinarum*, is alone seen in European commerce. It is used, to a considerable extent, in the East as a substitute for ginger. Considerable quantities are annually sold in London, but entirely for shipment to the Continent, a large quantity being consumed in Russia. It is used by brewers, and also for the purpose of giving an aromatic flavour to vinegar. By the Tartars it is used as a tea, and in some places as a cattle medicine. During last year 2300 cwt. were exported from China.

SOCIETY OF ARTS.

On Fermentation.

BY PROFESSOR A. W. WILLIAMSON, F.R.S.

Lecture IV.—concluded.

M. Pasteur has introduced a process which, I gather from his statements, has already been adopted by a considerable number of wine-growers and merchants, which goes to the root of the matter in such a way as to leave nothing to chance, for he has proceeded upon the knowledge previously acquired by his accurate and masterly experiments, regarding the nature of all these little organisms, and the conditions which are favourable to their development, and which are destructive of them. He finds that when wine is heated to near the boiling-point, in any vessel in which it may be enclosed, and left in that vessel to cool, it may then be kept (provided the vessel be not opened) for any length of time without undergoing any of these deleterious changes. He finds also that so high a temperature as that I have named is not absolutely necessary, but that even if wine, which on keeping would be subject to the malady of acetification or ropiness, be heated to a temperature of 60° Centigrade (that is, about 140° in the clumsy and inconvenient scale which is still, I am sorry to say, in common use in this country), it will kill these organisms completely; and the experiment is so easily performed that any of you may do it with a very moderate amount of care. You ought to perform the experiment with several bottles at the same time, and to keep some similar bottles in the original state, in order to observe the difference. In the month of September, when I last saw M. Pasteur, he gave me several bottles of wine, some of which were in their original state, whilst the others had, after bottling, been heated to a temperature of 60°, or a little more. I have not yet opened any of them, but I have some of each sort here, and we will presently see what has been the result of the treatment. I ought to say that they have not been kept with proper precautions, for, on opening the case, I found that it had been left in such a position that the bottles had been standing with their necks upwards, which is not very favourable to the preservation of the wine. The experiment is so simple, that it is worth while for everybody to perform it. You should take some light wine, which you have reason to believe will not keep well; the bottles should not be too tightly corked, and there should be a little space left below the cork. You put several of these bottles into a vessel of water, cautiously if the water be warm, to avoid breaking them, and with them one bottle full of water, uncorked, you then warm the whole very gradually, until you find, by inserting a thermometer into the open bottle of water, that the temperature is up to 140° Fahrenheit; you then allow the whole to cool slowly. The corks are generally lifted a little by the expansion of the liquid and air within the bottles, and will require to be struck in again to their proper place. The same operation is performed on a large scale by wine-growers and merchants in France, in casks, and several contrivances have been described for the purpose. The simplest of all is to put a cask, with its bung upwards, into any convenient vessel of water, so placing it that the top of the cask is just above the water. The water surrounding the cask is then warmed gradually until it is found, by lifting the bung and inserting a thermometer, that the wine is of a temperature 60° or 70° Centigrade. The bung is then closed, and the whole allowed to cool. Another form of apparatus has been figured in a late book of M. Pasteur's on acetification, which consists of a cask with one of its ends removed, and replaced by a sort of double bottom of metal. This cask is then put on the fire, so that the water in the false bottom may be heated, and raise the temperature of the wine in the cask above, without danger of burning it. M. Pasteur recommends that when the wine has reached the right temperature it should be allowed to run, while still hot, into the cask into which it is to be kept, so that any little germs which may be present there may be as much heated as the wine which comes in contact with them. He heats the wine in this operation to about 65° or 70°, but he says there is reason to believe that even 50° is sufficient. Upon all occasions on which it has been tested it has been found that the little parasites which are present, and which are the seeds of the maladies of which we have been speaking—and, no doubt, other organisms—are changed in such a manner as to be practically dead. Whether they are susceptible of being revived is another thing. It is not known, and it is not affirmed that there are no germs which might not, by contact with oxygen, be afterwards brought into life; but practically there are no organisms in the wine, after that temperature has been applied to it, capable of growing in the closed vessel in which it is kept. M. Pasteur says that if the wine were, after that treatment, bottled, he would expect that some bottles would contain wine which would spoil, whereas the greater number probably would not, the reason being that the wine, on its passage from the cask to the bottle, would be liable to get some little germs from the air which possibly might retain some vitality, which would be stimulated by the oxygen. Therefore, all he affirms is, that when the wine is kept in the same vessel in which it was heated, it undergoes no further change whatever.

With regard to the ordinary process of aerating wine by keeping it in bottles, I should like to show you an experiment which illustrates, in a very simple way, what is a very familiar well-known fact. Every one who has had occasion to keep wine knows what an immense difference there is if you keep a bottle standing upwards or lying down. The difference is of this kind. If it stands upwards, the cork is dry, and air has access at a very rapid rate to the contents of the bottle, and the wine gets oxidized and spoilt; whereas, when the bottle is left lying down, the cork is wet, and the air has access much less rapidly,—in fact, only at such a low rate as is suitable for mellowing and improving the wine. I have here a couple of glass tubes, both open at one end, and closed at the upper end by a porous substance, which I may call a cork—it is, in fact, a cork made of plaster of Paris, a particularly porous substance,—one cork being wetted, so that the pores are full of water, whilst the other has been carefully kept dry, and this one is covered for the present with a little cap to prevent the access of the air. Here, in another vessel, is a mixture which is giving off hydrogen gas, which is passing upwards into these two tubes, one with a wet cork and one with a dry one. After a minute or two, both tubes will be full of pretty nearly pure hydrogen, and then we will remove them, and put the lower ends into this jar containing a coloured liquid. Most of you know that this porous substance allows hydrogen to pass through it more rapidly even than the air which is now outside passes in, and therefore as the hydrogen passes out of these tubes more rapidly than the air comes in, the liquid will be sucked up in the tubes, and we shall have a measure of the rate at which our gas passes through the wet cork and the dry cork, by noticing the difference in the rise of the liquid in the two tubes. If it passes quicker through the dry cork than the wet one, we shall find that the liquid will rise more rapidly in that tube, and I think you will find that the difference will be very great indeed. They are now both standing in the coloured liquid, and already there is a perceptible rise in the tube with the dry plug; but in the other one I cannot yet see the liquid at all. So it is in the simple case of a wine bottle. If the cork of a bottle is wetted, so as to allow an exceedingly slow diffusion of air through the contents, the wine gets very slowly oxidized, and undergoes only that gradual transformation which is wanted; whereas, in the other case, it is turned sour and spoilt by too rapid oxidation.

I could gladly have entered upon many other facts and considerations which belong to this subject, but one must stop somewhere. I cannot, however, part from you without expressing my very strong sense of the debt which we owe to that great investigator whom I have already quoted so many times. I think there are few precedents of research so fruitful as those of M. Pasteur, if we consider, not only the theoretical importance, I mean with regard to our knowledge of the processes of life, and the origin of life, of his investigations regarding germs in the air, and these processes of fermentation; but if we take into account also the fact that he has succeeded in working out one of the most complete practical applications of it in a process like wine-making and keeping,—we cannot refrain from admiring the truly perfect adaptation of the highest science to a useful purpose. I will now proceed to open these two sets of bottles, some of which have been heated and some not, and I hope the result will be satisfactory.

The samples of wine were then tasted by the audience, the difference being most remarkable, not only in taste, but also in colour and general appearance.

At the conclusion of the lecture, Mr. Foster, the secretary, proposed a vote of thanks to Professor Williamson, which was carried with acclamation, and suitably acknowledged.

LONDON INSTITUTION.

On Wednesday evening, Professor Tyndall delivered his interesting lecture on "Dust and Disease," in the theatre of the London Institution, Finsbury Circus. The theatre was filled with an audience of ladies and gentlemen, who seemed quite absorbed in the interesting experiments and the important facts brought under their notice. As the lecture is a repetition, with some slight variations, of the one which was delivered some time ago by the learned professor at the Royal Institution, it would be superfluous to enter into a repetition of details, but it may be generally stated that the object of the paper was to show that "dust" existed in abundance in the atmosphere; that, mixed with this "dust" were "germs" which were the origin of vegetable and even animal existence; that these were most injurious to health, and that it was now becoming an object with surgeons, and especially with Mr. Lister, of Edinburgh, to endeavour to prevent the entrance of these germs into the human body, in which, if they once got a lodgment, they produced fermentation and putrefaction. The air could be purified by strong heat, by chemical processes, and by filtration. The application of the latter method had already been productive of much good in certain trades. The lecturer was greatly applauded at the conclusion of his lecture, which lasted over an hour.—*Daily News.*

MEETINGS FOR THE ENSUING WEEK.

MONDAY ......*Medical Society*, at 9 P.M.
London Institution, at 4 P.M.—"The First Principles of Biology" (Educational Course). By Prof. Huxley.

Parliamentary and Law Proceedings.

DEATH FROM AN OVERDOSE OF MORPHIA.

On Wednesday, January 18th, an inquest was held at Mossley on the body of a child eleven months old, the daughter of Mr. Henry Jones, chemist and druggist. On the 15th of December the child, being unwell, was seen by Mr. Dex Bean, surgeon, of Mossley, who intimated his intention of prescribing for it, and that a mixture would be supplied from his surgery. Upon returning home that gentleman, following his usual custom, wrote out a prescription in a book kept for the purpose. The ingredients ordered were two drachms of solution of tartarized antimony with syrup of hydrate of chloral, and colouring matter. This prescription was left to be compounded by his pupil, Mr. John Simeon Dyson, who had been employed in the surgery a year and three-quarters. Upon receiving the mixture, Mrs. Jones gave a teaspoonful of it to the child, who five minutes afterwards fell into a deep sleep. Mr. Bean, calling in the afternoon, noticed that the child was breathing very heavily, and had it removed from the cradle where it had been placed, when Mr. Jones, who was present, immediately exclaimed that the child was narcotized. It appeared to be perfectly comatose; remedies were applied without effect; convulsions followed, and the child died the following morning. After the death, Mr. Bean and Mr. Jones experimented upon a cat with some of the contents of the bottle. The cat was not affected until nearly an hour afterwards; it then became almost motionless, lying on the floor, discharging saliva from its mouth, and there appeared to be a contraction of the pupils of the cat's eyes. The animal recovered, however, and Mr. Jones's suspicions being somewhat allayed, the child was buried. After the burial he obtained an analysis of the contents of the bottle, upon the receipt of which he communicated with the coroner, and the body was exhumed.

At the inquest Mr. Bean, in his evidence, stated that in the surgery he kept a solution of hydrochlorate of morphia. The quantity of morphia he always used himself and directed Mr. Dyson to use was four grains to an ounce of water. The drugs were left to be compounded by his assistant, Mr. Dyson. No other person was authorized, or even able to compound the medicine. He had not interfered with the dispensing department for the last twelve months. He could not say where the bottle containing chloral was kept exactly. Mr. Dyson had had one and three-quarter years' experience in dispensing. The solution of morphia was kept in a violet-blue glass bottle with glass stopper. The solution of antimony was kept in a white flint-glass ounce bottle. In answer to questions put to the witness by a solicitor who was present on the part of Mr. Dyson, he said that Mr. Dyson had made up thousands of prescriptions, and had exhibited such an amount of knowledge of his profession as to cause no fear. He had often examined him as to his knowledge of the drugs he dispensed. Mr. Dyson had made them up without supervision for sixteen months. He considered the art of dispensing to be merely mechanical, and that the previous education of a person would not have much to do with it.

Mr. Edward Davies, F.C.S., of the Royal Institution, Liverpool, described the result of an analysis made of the contents of the bottle. He found chloral, morphia, sugar and some colouring matter, which he believed to be cochineal. He tested for antimony, but found none. On one occasion, when making experiments, he gave three grains of sulphate of morphia to a cat, and it produced no perceptible effect upon it. He could not say exactly how small a quantity of morphia would kill a child; but as the result of reading he should say that one-eighth of a grain would be sufficient. In the mixture he analysed there would be about one-fifteenth of a grain in each spoonful. The effects of a dose would depend, in a great measure on the idiosyncrasy of the recipient.

Mr. Bean, after hearing this evidence, said that he thought the comatose state had been produced by the morphia.

In consequence of Mr. Bean expressing an opinion that it would be difficult, from the decomposition of the body, to ascertain the actual cause of death, the jury decided not to order a *post-mortem* examination, and returned a verdict that the death occurred from misadventure, to which they added an expression of regret that the investigation had not taken place sooner.—*The Oldham Chronicle.*

Seizure of Worthless Tea in Dublin.

Some time since, in the London papers, there appeared an account of a vessel landing in that port, having on board a cargo of what is termed "lye tea." The cargo was condemned in London, but it seems to have found its way to Dublin, for in the Southern Divisional Court Mr. Norwood and J. O. Byrne applied for an order that some unsound tea should be destroyed. It was sold by auction in the Commercial Buildings, but the purchaser had it examined by the City analyst. The tea was found to be utterly worthless and useless. The Public Health Committee were apprehensive lest this kind of tea should get into circulation. Mr. Barton made an order for its destruction.

Sale of Petroleum without a Licence.

At Sheffield, on Monday the 16th inst., Mr. John T. Dobb, druggist, appeared in answer to a summons charging him with selling petroleum without having a licence. In September, 1869, Mr. Dobb applied at the town clerk's office for two licences for the sale of petroleum at his shops in West Bar and Meadow Street respectively. Mr. Dobb was not satisfied with the licences granted and desired to be allowed to sell two hundred gallons; this permission the General Purposes Committee of the Town Council would not grant. Mr. Dobb declined to take the licences for forty gallons, and since last September has been selling petroleum without holding a licence at all. He was fined £1 and costs.—*Grocer.*

Supposed Death from Subcutaneous Injection of Morphia.

An inquest has been held at Manchester on the body of Mr. Sutcliffe, late Physician's-Assistant at the Royal Infirmary, who was found dead. As it was generally reported that he was in the habit of using morphia by subcutaneous injection, a *post-mortem* examination was made.

Dr. Buckley deposed that there was no morbid disease sufficient to cause death. The liver and kidneys were diseased; the other organs were in a healthy state, but congested. There was also congestion of the membranes of the brain. He found no traces of morphia in the stomach. He understood that deceased had been in the habit of taking subcutaneous doses of morphia, and a dose acting on a depressed system might be fatal. A solution of morphia and a morphia syringe had been found in the deceased's room. The latter article might have been used, though he did not think it had. From what he knew of deceased, he did not think he would have intentionally taken an overdose of morphia.

The jury returned a verdict of "Death from toxæmia, aggravated by a dose of morphia taken as medicine to produce sleep."—*Medical Times and Gazette.*

Death from an Overdose of Opium.

An inquest was held recently at Mitcheldean on the body of Mrs. Masson, the wife of a surgeon. It appeared from the evidence that the deceased had suffered severely from neuralgia, and frequently took opium to relieve the pain. On the occurrence of the last attack she seems to have taken an overdose. Two hours afterwards she fell into a comatose state, and died within forty-two hours. A verdict in accordance with the evidence was returned.—*Standard.*

Review.

On a Localized Outbreak of Typhoid Fever in Islington during the Months of July and August 1870, traced to the Use of Impure Milk. By Edward Ballard, M.D. London: Churchills.

This interesting Report of Dr. Ballard's, read originally before the Association of Medical Officers of Health, and which has since appeared in a more or less complete form in several of the medical journals, has now been printed and published, in a pamphlet form, for that association, in compliance with a resolution passed, after the paper was read, by the members present. The subject of the paper, although at the first glance purely medical, is really one of such wide-spread interest, treated in so masterly a manner, that we gladly take the opportunity of its publication in a separate form to give a brief *résumé* of it, referring those of our readers who may desire fuller details to the pamphlet itself.

A serious outbreak of typhoid fever having occurred within a limited area in the parish of Islington, which is under the sanitary supervision of Dr. Ballard, he was induced to make a thorough investigation for the causes which led to so startling an event. In the course of his inquiries he found that between July 3rd and September 10th, 168 individuals, living in sixty-seven houses in this district, had suffered more or less severe attacks of typhoid fever, of whom twenty-six died. The area of the district in which these cases occurred is described as being the third part of the segment of a little more than half a circle, the radius of which is a quarter of a mile, formed by the North London Railway passing through it. Within the same period, in the whole of the rest of the parish (consisting of 3127 acres) there were twenty fatal cases.

To the inquiry, how did the disease originate? four different answers were suggested. These were—(1) some alterations made in the railway cutting by which an extensive surface of fresh earth had been exposed, and, it was alleged, several old sewers and drains had been cut across; (2) the smell proceeding from the dung-shoot in a large yard where several hundred horses were kept; (3) various local causes existing in the several houses invaded by the fever; and (4) the milk supplied by a tradesman in the neighbourhood.

Careful investigations, based upon the first three suggestions were made; but it was found that although they might possibly have been sufficient to account for a small proportion of the cases, yet that neither individually nor collectively were they sufficient to explain the large number that had occurred.

The fourth suggestion, that the disease had its origin in the supply of milk by a certain tradesman, was made under the following circumstances:—A lady, in whose family fever had occurred, was informed that four families of her acquaintance were also suffering from it. She remembered that she herself had, some little time before, changed her milkman, and had likewise induced these friends of hers to adopt the same tradesman. She formed her conclusions accordingly, and imparted them to her medical attendant. It happened that that gentleman had attended the family of this very milkman. He made some cautious inquiries, and found that out of eleven families, members of which were under his care for typhoid fever, ten of them were supplied with milk from the same source. This discovery being communicated to Dr. Ballard, led to further inquiries, resulting in the establishment of an evident connection between the cases of fever which had occurred, and the supply of milk from this particular dairy.

We have not space here to reproduce the evidence which led to this conviction, but will content ourselves with quoting a description of how the typhoid "picked out, as it were, the customers of this dairy in particular streets and rows of houses. Thus, in one long road, and a street issuing from it, at a distance of a mile or more from the dairy, it supplied three families; of these, two had typhoid. It supplied two families in a street with about thirty houses; one suffered from typhoid, in the other died an old lady from 'choleraic diarrhœa.' It supplied four families in a new neighbourhood of about seventy houses; three of these families had typhoid. It supplied four families in a crescent with twenty-five houses; all four had typhoid (in one only a single mild case occurred). It supplied four families in a row of nine houses; typhoid occurred in two of them, and in the other two, cases of a mild febrile character (not enumerated) occurred. It supplied four families in two opposite rows of houses, altogether about sixty-seven; three of them had typhoid happen in them. It supplied four families in a square with fifty-nine houses; all four had cases of typhoid happen in them, etc. And these were, so far as I can ascertain, the only cases in these several localities."

It is curious to notice how in families that were attacked, women and children, as those who ordinarily consume most milk, were the first to suffer.

"Thus, in the family living at the cowyard, the daughter, while engaged as a nurse in a situation, alone got the dairy milk with regularity, and she was the first attacked; the second case in this house (her mother) was a month later. In a family consisting of the father and mother, who never took any milk at any time, two servants and four children, all had typhoid, except the father and mother, the children commencing. In another family, consisting of mother, two servants, three girls and a boy of seventeen, one of the girls and the boy took milk porridge daily at breakfast; the other girls, with the mother, took little milk comparatively. The servants, complaining that the beer was sour, asked permission to have milk instead of beer. The girl and boy who ate porridge and the two servants were alone attacked. In another family, where a daughter aged eighteen and a son aged five years were attacked, the daughter, I was told, was a great drinker of milk, and she was attacked a fortnight before the son. In a house occupied by several families, using one privy, and where the drain-smells from an over-filled cesspool were very offensive, only one elderly man and woman were attacked. They alone drank milk from the dairy; the other families, being poor, had never any milk at all and altogether escaped. In another family, the only person attacked was a young girl, who, being in delicate health, took more milk than all the rest of the family. Mr. Clifton also told me of a case of typhoid, which is not enumerated here, in the person of a young lady whose family was supplied by some other purveyor, but who fancied to drink daily a glass of milk from the dairy in question. No one else in the house ever took this milk, and she alone suffered."

It is very significant that those families who lived in houses in which local causes of fever existed were the first to suffer.

And now having discovered the vehicle by which the fever was spread, and having narrowed the limits of the search, Dr. Ballard set to work with fresh zeal. By a process of exclusion he eliminated many possible and probable causes, and at length was led to the conclusion that the source of all the mischief lay in an underground water-tank. Upon this tank being exposed, it appeared that the wood of which it was made had rotted; and that by various rat burrows it was brought into connection with two drains, so that it was possible that under certain circumstances the sewage ran into the tank. The chief difficulty that now arose was the assertion that this water was never used to mix with the milk, but only for the horses, washing the cans, and general cleaning purposes. Even supposing this to have been the case, there would be a small quantity of the foul water left in the cans after washing, and considering the small admixture of sewage that will poison a well, and the fact that milk is a substance which has remarkable relations to chemical ferments, the author is disposed to think that sufficient of the poison would have existed in it to account for what occurred. But we think that it is hardly necessary to fall back upon so slight a cause, as although the statement of the family, "that if ever any water was added it was from the tap," might be true as to the rule, there may have been exceptions to it in practice, and the pump connected with the tank was so situated that it could not be seen from the master's house. At any rate, we do not see in what other way the following fact, ascertained since the reading of the paper is to be accounted for, as the drainings of the cans would have been as likely to affect one sort of milk as the other.

"In a street of about fifty villa residences, two of the houses only were supplied from the dairy. In only one of these did typhoid occur. The family consisted of the father and mother; three boys, aged two, four and five years; a baby, aged ten months; two servants and a governess. Two kinds of milk were supplied to the house from the dairy—namely, ordinary milk at fourpence per quart, and 'babies' milk' at fivepence. Only the baby got the latter. It was better than the ordinary milk, as 'it threw up more cream.' It kept well. The master of the house, on one occasion before the outbreak, had the curiosity to examine the ordinary milk with the sp. gr. galactometer, and following the directions accompanying the instrument, inferred that one-fourth of the bulk was added water. The youngest boy took most milk, but all three boys had bread and milk for breakfast. The boys and the mother were ill in the country, whither the family had gone for their summer trip. The youngest boy was the first attacked, on July 17, and was taken out of town the next day. The baby remained well, as also did the father, the governess and one servant. Of all the family, one servant only remained at home and continued to use the milk. She was taken ill about August 1 and had a sharp attack of typhoid. At the other house in this street, the part of the family at home during June, July and August was the father, mother and one servant. At this house nothing but 'babies' milk' was taken in, the extra price being habitually paid. No fever occurred at this house."

With this quotation we close, having given a brief outline of the subject of the pamphlet, but again recommending those of our readers who wish for further details to obtain it, and read it for themselves.

Method and Medicine. An Essay. By Balthazar W. Foster, M.D. London: Churchills. 1870.

A Manual of Structural Botany, for the Use of Classes, Schools, and Private Students. By M. C. Cooke, M.A. With upwards of 200 Illustrations. Third Edition. London: Robert Hardwicke.

The following journals have been received:—The 'British Medical Journal,' Jan. 21; the 'Medical Times and Gazette,' Jan. 21; the 'Lancet,' Jan. 21; the 'Medical Press and Circular,' Jan. 25; 'Nature,' Jan. 19; the 'Chemical News,' Jan. 20; 'Journal of the Society of Arts,' Jan. 19; 'Gardeners' Chronicle,' Jan. 21; the 'Grocer,' Jan. 21; the 'Produce Markets Review,' Jan. 21; the 'English Mechanic,' Jan. 20; the 'Photographic Journal' for January; the 'Chemists and Druggists' Advocate' for January; 'Transactions of the Odontological Society' for January; 'Proceedings of the National Association for the Promotion of Social Science,' Jan. 12; the 'Manchester Courier,' Jan. 19; the 'Manchester Examiner,' Jan. 19; the 'Ashton Standard,' Jan. 21; the 'Oldham Chronicle,' Jan. 12.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department*, 17, *Bloomsbury Square, W.C., and not to the Publishers.*

[99.]—SHEET LIGHTNING.—"*Pestle and Mortar*" can prepare "Sheet Lightning" by following the directions of the B. P. for the preparation of pyroxylin, substituting paper for the cotton, and immersing it for a little longer time in the mixed acids. The best paper I have been able to procure for the purpose is Swedish filtering-paper, but should prefer a thinner paper, somewhat resembling "cigarette" paper, if able to obtain it sufficiently large. For blue fire, soak afterwards in a weak solution of chloride of copper; for red, use chloride of strontium.—H. J. BACON.

[115.]—MARKING-INK.—I have found the written portion sometimes destroyed, and have attributed it to want of care in heating the fabric, supposing the destruction to be caused by the letters on becoming dark rapidly absorbing heat, and thus charring before the white and unwritten part becomes discoloured. Perhaps also the effect may be heightened by the evolution of oxygen gas arising from the decomposition.—H. J. BACON.

[124.]—AFRICAN SAFFRON.—In answer to *X. Q. Z.* as to the source of the so-called African saffron, I beg to inform him that a correspondent of the *New York Druggists' Circular* lately suggested that it might possibly be derived from the *Lyperea crocea*, a South African plant, which is said to closely resemble saffron. But at a recent meeting of the Philadelphia College of Pharmacy, reported in the *Chicago Pharmacist* for December, a sample of this so-called African saffron was exhibited by Professor Maisch, obtained from the Chicago market, which upon examination proved to be *Carthamus tinctorius* (Safflower) in a broken and discoloured condition.—F. R. B. P.

[131.]—MOUTH WASH.—An excellent astringent lotion for the mouth can be made as follows:—

℞. Boracis ʒiss
Mel. Ang. ʒvj
Tinct. Pyrethri ℥ss
Tinct. Myrrhæ ʒiij
Aq. Fl. Aurant. ℥ij
Aq. Rosæ ad ℥vi.

"GIVE AND TAKE."

H. W. G. will find the following a first-class remedy:—

P. Aluminis ʒj
S. V. R. ʒj
Tr. Myrrhæ Simp. ad ℥ij.

To be used with a camel-hair brush after meals.—H. H. READ.

℞. Borax,
Alum,
Bay Salt, each ʒj
Sp. Camph.,
Tinct. Myrrh, each ʒj
Sp. Armoraciæ ℥ij.

M. Shake occasionally for a day or two, then filter. A teaspoonful in a wine-glassful of water, to rinse the mouth after cleaning the teeth, or at any time.—W. W.

[132.]—COUGH BALLS FOR HORSES.

℞. Antim. Tart.,
Digitalis, ana ʒss
Pot. Nitrat. ʒiss
Picis Liquidæ, q.s. ft. Bol.

Omni Nocte.—W. W.

℞. Rad. Scillæ 2 dr.
Gum. Ammoniaci 4 dr.
Ipecacuanhæ,
Opii, ana 4 dr.
Pimentæ 1 oz.
Bals. Sulphur. 4 oz.
Sapon. Castil. 2 oz.
Theriacæ q.s.
Ft. massæ pro Bol. no. vj.

One twice a day. W. W.

℞. Pulv. Scillæ ʒvj
Gum. Ammoniac. ℥ij ʒij
Gum. Opii ʒiij
Ol. Anisi ʒj

Mix and divide in six balls. M. S. P.

The following is a good form:

℞. Antim. Sulphurat. ʒiij
Camphor ʒj
Sulph. Flor. ʒij
Antim. Tart. ʒj
Sapo Mollis, q.s.

Ft. bol.

One every night or every other night.—R. ROGERS.

[133.]—CAMPHOR BALLS.

℞. Cetacei ʒiij
Ceræ Albæ ʒiv
Ol. Amygd. ℥j
Rad. Anchusæ, si opus sit.

Melt, then add—

Camphor. (Pulv.) ʒiij

Pour into small gallipots, so as to form hemispherical cakes.

W. W.

℞. Cocoa-nut Oil, 8 oz.
White Wax, 3 oz.
Camphor, $1\frac{1}{2}$ oz.

Melt the oil and wax together, and add the camphor previously pulverized.—S. D.

[135.]—ESSENCE OF JARGONELLE PEAR.—Acetate of Amylene is sold under this name. It is made by distilling a mixture of 1 part oil of grain, 2 pot. acet., 1 oil of vitriol. Wash the diluted liquid with alkaline water, agitate with chloride of calcium, and re-distil from litharge.—W. W.

[136.]—DISPENSING (SIGMA):

℞ Potassæ Chloratis ʒiv
Tinct. Ferri ʒiv
Aquæ ad iij. M.

"One teaspoonful in water three times daily."

It is impossible with that quantity of water to dissolve more than two-thirds of the chlorate of potash. Even boiling the chlorate of potash with the solution will not suffice, as it immediately re-crystallizes on cooling.—HENRY H. READ.

[*** The chlorate of potash should be rubbed down with the water, and a "shake-the-bottle" label affixed.—ED. PH. J.]

[142.]—CRIMSON MARKING-INK.—Can any of your readers give a formula for a good *stable* "crimson marking-ink?" I know the formula in PHARMACEUTICAL JOURNAL (Second Series, Vol. V. p. 188), but it has the disadvantage of degenerating in colour, in the course of a few weeks, to a dull brown shade.—R. G. H.

[143.]—DISPENSING.—I received to-day the following to dispense:—

℞. Collodion
Chloroform. pur., ana ʒij.

M. Paint the irritable parts every night with a camel-hair brush.

Can any of your readers inform me how I am to dispense it, so as to produce the result required? I have my experience of it, and so also had some one else, for it had been dispensed before *somehow*.—"VIATOR."

[145.]—GINGER ALE (AERATED).—Can any one give me a good recipe for making the above?—SODA-WATER.

Correspondence.

Proposed Regulations for Storing of Poisons.

Sir,—The storm of opposition which the proposed regulations for the keeping of poisons have evoked seems to have been noticed with amazement by the medical journals, and will probably excite the surprise and contempt of the House of Commons if the subject should come before them. That anything so simple and easy as an enactment which amounts to this, that certain deadly poisons named in a schedule, by the careless use and sale of which accidents have continually happened to human life, should be either kept separately in the way most convenient to the dealer, or, if not, marked distinctly from other things, should be so obstinately resisted,—will be one of the curiosities of pharmaceutical literature when the question is settled. The Council, too, are unreasonably assailed, as if they wished to force these regulations upon the trade against their will, in utter forgetfulness apparently that they were ordered to prepare them by the last annual meeting, and that the next will no doubt demand obedience to those directions.

We hear it vaunted loudly by some that such scientific men as chemists should be above legal restraint, but the gentlemen who make this assertion forget that there are a very large number of chemists and druggists placed upon the register who have never been examined at all, and who have equal right with themselves to sell and use the objectionable articles. The Council have been obliged by law to give this privilege to thousands, merely because they had kept open shop for the making up of prescriptions before the passing of the Act. Very many of these, there is reason to fear, are both careless in the way they carry on their business, and very ill-qualified to conduct it rightly. And those who so loudly put themselves forth as the types of the legal sellers of poisons should know that they are a minority, and a small one, of those to whom the regulations will apply. Mr. Vizer writes as though he had quite set the matter at rest with his typical surgeon and his lancets, etc., but, so far as argument in his letter goes, it is sufficient to say that if it were possible to show that in consequence of the negligence of medical men human life had been sacrificed until a cry of reprobation and alarm arose from every quarter, that it was sacrificed now and might probably be so in time to come, then it would be the duty of the Legislature to regulate the use of lancets, etc., in the hands of surgeons, whatsoever examinations they might have passed, and although they might have half-a-dozen letters of distinction appended to their names.

Some of your correspondents are indignant because the restrictions do not apply to medical men, but we have nothing to do with medical men; we have to regulate our own affairs, and if we have the good sense to do this properly we shall not have them to regulate ours.

Mr. Proctor, whose name always carries deserved weight with it, says that the only fault of the regulation is that it does not provide for the different grades of caution which the articles may require, so that morphia, etc., may be shut up in a cupboard, while such a thing is impracticable for syrup of poppies, etc.; but I maintain that this variety is the very thing which is given. You may seclude the most dangerous articles as closely as you please, whilst a different bottle or a capped one, or one with a mark upon it, will suffice for those which are mingled with the others. A more weighty objection—and the only weighty one that I can find—is this, that you introduce the thin edge of the wedge, which will lead to inspection and annoyance from public officers.

But those proposed will no more introduce the wedge than the last regulations did. We are living already under regulations as to how we shall sell poison, and neither the Privy Council nor any one else can set on foot inspection without an Act of Parliament, a thing wholly unlikely as long as we act up to the requirements of the Act we have already. But if, indeed, we refuse to do this, the Privy Council (backed by the Government) will most assuredly take the work into their own hands; and can any one who has observed the temper of Parliament, the press, the medical profession and the current of public opinion, doubt how it will be done? Does any one who has marked the career of former Poison Bills suppose that such an Act as we should have would be content with the few articles in schedules A and B? or that it would leave us the freedom which the present regulations afford? We may well dread inspectors, indeed, if the matter passes into the hands of a committee of the House of Commons. Look at the Petroleum Act. Suppose the dealers in this should say, We are men of considerable experience in business, we have much property at stake, we know best how to manage our own affairs, and these regulations are very troublesome and have caused many of us inconvenience and loss. Would not the reply be something of this kind? Very probably they may, but do you suppose we pass Acts of Parliament to please petroleum dealers? We have to consider what is best for the public and what regulations ensure safety to them. If those we have ordered are what you practise, so much the better; if not, you had better conform to them without delay. And if the legal restrictions pinched us pretty sharply, as no doubt they would, should we get any to pity us? Would they not say you have only yourselves to thank, they serve you right; you had the extraordinary opportunity afforded you of making rules to suit yourselves, and you were guilty of most extraordinary folly in refusing to do so.

It is, of course, in the power of the next Annual Meeting to talk great things and refuse to accept any regulations at all, and the Council will then probably transmit the answer to their Lordships and hand the matter over to them; but if the advocates of this proceeding imagine that thus poison regulations will come to an end, no greater mistake will ever have been made. If anything is certain it is this, that whether we like it or no, the Privy Council are determined that the intention of the Legislature shall be fully carried out, and that either with our consent or against it, poison regulations shall be made.

Opifex.

Sir,—The precipitate publication of Mr. Simon's letter having failed to produce the effect doubtless intended (viz., that of silencing our opposition) by those who were in such a terrible hurry to publish it to the members before it was even known officially to the Council, it seems now to be the cue of the "regulation" advocates (who, by the way, mostly write anonymously) to say that when the Pharmacy Act was passed, it was an understanding with the Government that the Society should make some regulations on the subject, and thus endeavour to convince us that we are morally bound to make a yoke for our own necks and a rod for our own backs, now they find that threats of governmental interference do not alarm us. This appeal to our moral sense is being pressed rather strongly into the service, but only to meet the same fate as the threat of parliamentary compulsion. If ever there were any understanding of the sort, it was kept remarkably secret and made known only to a very select few; the great bulk of the trade being certainly totally unacquainted with any such arrangement, and are not, and will not, be compelled to acknowledge as a duty that of which they had no cognizance.

In the Journal of December 24th there is a letter signed "Pharmaceutical Chemist" which contains some extraordinary statements. I always understood, as did most other people, and it was always so stated by the Pharmaceutical Council both in the Journal and elsewhere, that their primary object in promoting the Act was to secure the higher education of chemists, and that the poison clauses were introduced entirely against their wish in consequence of the action of other parties, whereas his statement would make it appear that the facts are exactly contrary. The preamble of the Act says "It is expedient for the safety of the public . . . that chemists and druggists should possess a competent knowledge of their business . . . and should be duly examined as to their practical knowledge;" and there is not one word in the Act to bear out his assertion that "opportunity was adroitly taken to introduce into the measure security for the higher education of chemists," but exactly the contrary; nor can I admit that "the primary object was the protection of the public from accidental and other poisoning" by means of poison schedules and regulations, as he would have us to believe.

As to the cry for some regulations, having waxed strong, the only outcry has been a few articles in a newspaper or two and in the medical journals (of course); but that the public have made any demand in the matter I utterly deny, and challenge "Pharmaceutical Chemist" to give a single instance of any such demand, except from newspaper writers and official persons.

With regard to the question of inspection, I would ask, are the proposed regulations intended to be observed or not? If not, it is useless making them; but if they are to be enforced, what other means is there but that of inspectors, unless we are to suffer the visits of a common informer like our Canadian brethren (see PHARM. JOURN. of Jan. 7th) whose case I commend to the consideration of all those desirous of adding to the annoyances we are already subjected to?

W. WILKINSON.

Cheetham Hill, January 24th, 1871.

MORE FETTERS.

Sir,—Time was when the greater included the less. The Pharmacy Act secured for the public of the future an educated body of chemists. In so doing, it provided the best possible guarantee against mistakes dangerous to life; but, no sooner has it become the law of the land, than a cry arises for more poison regulations. "Allow me to suggest more fetters," exclaims the medical officer of the Privy Council. "By all means!" reply half the chemists of the country.

As a humble unit of the other half, I ask leave to protest against the encumbrance, as altogether supererogatory, and a most strange instance of a requisition outliving the circumstances that gave it birth. The thing required is done; it was comprehended in the larger action already accomplished. To puzzle our heads about more poison regulations now, is to imitate the philosopher who, after providing a most ample entrance hole for the cat, was uneasy until he had contrived a small one for the kitten.

The public will be as safe with properly qualified chemists as they are with properly qualified medical men, whose dispensing arrangements, by the way, are so much less complete and precautionary.

I trust, therefore, the many reasonable objections to further restrictions will be represented with such force and persistency, that neither the Privy Council nor Parliament will wish to interfere with the method adopted by each examined and certified chemist, in performing the responsible duties of his profession.

Glastonbury. T. MAYHEW.

A DANGEROUS PRESCRIPTION.

Sir,—I had this morning brought to me a prescription, of which the following is a *verbatim* copy:—

℞. Tinct. Camph. Co. ℥vj
Acid. Hydrocyan. Scheele's ʒij
Glycerini ℥j
Aquæ ad ℥vj.
Sumat ℥ss 4tis horis.

It was for an old and regular customer; the medicine was wanted at once; and it was impossible at the time to communicate with the prescriber. What ought I to have done under the circumstances?

I am not sure that I did the right thing, but I used as much of Scheele's acid as I dare, viz. minims 20, and altered the prescription to that effect.

It makes one shudder to think what would have been the effect if this prescription had fallen into the hands of a raw apprentice.

In the course of twenty years' experience in a fair dispensing business, I can call to mind many cases where the prescriber has been at fault. SIGMA.

Pendleton, January 20th, 1871.

YORK CHEMISTS' ASSOCIATION.

Sir,—In looking through Mr. Schacht's excellent paper on "The Local Means of Pharmaceutical Education," I find mention of the "York Chemists' Association." My reason for thus troubling you is to ask, Is there such an Association, and (if there is) what are its objects?

I believe there formerly was one (hence Mr. Schacht's statement), but I think it is now extinct. If I should be mistaken in this supposition it is only natural, as it has kept itself so very, very quiet since the passing of the Pharmacy Act, that it is the only conclusion one could arrive at. Perhaps some of your readers can inform me; if they will, they will oblige

Bootham, York, Jan. 23rd, 1871. EXCELSIOR.

CHLORAL.

Sir,—As you have published in your paper an article written by Mr. Mason, containing remarks about the chloral-hydrate manufactured by us, which is calculated to injure our reputation considerably, we request you to insert at the same place in your paper the enclosed analysis of our chloral-hydrate, which will at once demonstrate the incorrectness, to use no other expression, of Mr. Mason's statement.

We shall send you a full refutation of the statement contained in the above article as soon as we have received the papers to which reference is made by Mr. Mason, but in the meantime request you to publish this letter at once, as a longer silence might increase the mischief already done.

Hanover, January 20th, 1871. E. DE HAEN AND CO.

[*** We willingly insert Messrs. De Haen's letter, and shall give due attention to the result of analysis which they have forwarded, and any further communication on the subject. The paper they refer to was published entirely on the author's responsibility as a statement of experimental results; and, as the question raised is one of great importance, we shall be glad to make known such additional data as may be useful for deciding the relative value of the chloral hydrate of various makers,—always providing that such data have direct reference to those points of interest with which pharmacists are properly concerned.—ED. PHARM. JOURN.]

DISPENSING ALLIANCES.

Sir,—Without entering on the question as to whether the prescriber is entitled to the lion's share of remuneration, or as to the relative status, expense of education, etc., of medical men and pharmaceutists,—I will simply state the understanding subsisting between myself and my brother, who is a chemist residing near me.

He dispenses my prescriptions at the usual "surgeon's prices," for which I pay him punctually every quarter, so my patients have but one account to meet, and that only at Christmas.

I have no interest in what are called "family articles,"—such as castor oil, cod-liver oil, linseed meal, extract of meat, etc.; these being paid for in the usual way.

You will observe that, under this arrangement, all "trade risks" are borne by the medical practitioner. And I can safely affirm that during the past two years I have attended numerous cases wherein I see no chance of being repaid for my outlay in medicines, much less for professional attendance; not to mention such trifles as a world-wide experience and a modest skill of twenty years' standing and cultivation.

Nevertheless, I for one regard this arrangement as "a step in the right direction," viz. towards laws which shall prohibit the practice of dispensing drugs by medical men, and of prescribing on the part of pharmaceutists.

For, when once dispensing is confined to pharmaceutists, I believe it will result in great convenience to the public, both in town and in country places. Under such a system, a chemist or a person possessing technical knowledge, would be required in every large village, wherein he would probably combine the duties of postmaster, telegraphist, etc.

THE QUALITY OF CHLORAL HYDRATE.

BY B. H. PAUL, PH.D.

Considering the importance of the question that has been raised as to this preparation and as to the substitution for it of another compound of chloral—the alcoholate—possessing therapeutic properties different from those of true chloral hydrate, it seemed to me worth while to make an examination of some samples as they are met with in the market and in use by dispensers.

The data given by Mr. Mason in the paper read by him before the Liverpool Chemists' Association on the 22nd December, and subsequently published in this Journal, would appear to indicate at least the existence of a very great dissimilarity in the chloral preparations manufactured by different firms; for even on the assumption that the samples referred to by Mr. Mason were all choral hydrate, the data he gives as the results of his analyses would indicate an inferiority of some samples to the extent of 20 per cent. as compared with others, besides at the same time suggesting the possibility that some of these samples might consist of chloral alcoholate.

For the objects necessary to be kept in view in this Journal, it does not appear to me either requisite or desirable that, in considering the question as to the quality of chloral preparations, there should be any reference by name either to the particular makers or dealers from whom certain samples have been obtained. The great point is to ascertain whether any such variation in quality as that pointed to by Mr. Mason's results does really prevail, so as to be of practical importance in regard to the medicinal use of this drug. I shall, therefore, abstain from any mention of names either of the manufacturer or others from whom I have obtained samples for examination, and will content myself with stating my results merely in reference to numbers and to the characters of the preparations operated upon.

Adopting the ammonia test originally suggested by Mr. Williams, and since worked out in detail by Mr. Umney, I have applied it to the examination of twelve samples of chloral preparations which were obtained from various sources, and were all furnished to me as being chloral hydrate representing the supply now in the market.

Each of these samples was treated in the manner described by Mr. Umney, a somewhat smaller quantity, however, being taken for the experiment.

According to the composition of pure chloral hydrate, 100 grains of it should yield in this way 72·2 grains of chloroform, or 72·2 per cent. by weight. That quality of chloroform having the density of 1·497 would be in volume 48·2 grain-measures, so that 100 grains of pure chloral hydrate should yield by decomposition with ammonia, that measure of chloroform.

In like manner 100 grains of the compound of chloral with alcohol would by decomposition with ammonia yield 61·75 grains of chloroform, or 61·75 per cent. by weight, this being in volume 41·2 grain-measures.

The following are the results I have obtained for 100 grains of each preparation examined:—

No. of Sample.	Characters.	Volume of Chloroform obtained. Grain-measures.	Equal to Grains weight.	Percentage of Chloroform by weight.
1.	White amorphous dry lumps	46·1	69·1	69·10
2.	Hard transparent fragments of crystals	48·0	71·8	71·86
3.	Thin translucent crystalline cake	48·0	71·8	71·86
4.	White opaque cake, apparently not quite dry, especially at one surface	42·0	62·8	62·87
5.	Very small crystals, aggregated into translucent lumps, with a slightly moist appearance	47·0	70·3	70·36
6.	White semitranslucent cake, with slightly moist appearance	48·0	71·8	71·86
7.	Translucent crystalline cake, consisting of small scaly crystals, moist and greasy to the touch	47·5	71·1	71·10
8.	Large tabular crystals, like chlorate of potash	44·0	64·8	64·86
9.	Translucent lumps, consisting of scaly crystals, slightly moist to the touch	45·0	67·3	67·36
10.	Small acicular crystals, apparently breaking up into scales when rubbed in the hand, slightly moist to the touch	47·0	70·3	70·30
11.	White opaque lumps, resembling effloresced carbonate of ammonia, with distinct crystalline fracture, translucent at the interior and greasy to the touch	46·5	69·4	69·40
12.	Chloral alcoholate*	37·5	56·1	56·13
13.	Pure chloral alcoholate	41·2	61·7	61·76
14.	Pure chloral hydrate	48·2	72·2	72·20

* For the specimens I am indebted to Mr. John Williams.

These results differ widely from those reported by Mr. Mason, and it will be seen that, so far as the samples I have obtained represent the chloral preparations of commerce, there does not seem to be a very great difference of quality if the yield of chloroform be taken as a criterion.

To a certain extent I believe this may be done; but at the same time, on looking over the results given in the table, it will be seen that those samples which consisted of crystals almost invariably gave the largest amount of chloroform.

This fact, together with the more definite character of the crystallized chloral hydrate, as compared with the cake, induces me to suggest that, for dispensing purposes, the material should always be used in the state of crystal. I do not believe that the difference in price would be anything worth regarding as an obstacle to that practice; but in making this suggestion it is necessary to particularize the kind of crystal to which I refer, for there are several kinds of crystallized or crystalline chloral preparations. That which I believe to be the purest, presents commonly the appearance of ordinary alum broken into fragments about the size of grains of paradise (in one instance I have met with very definitely formed crystals resembling sulphate of potash); the fragments are perfectly transparent, free from powder, possessing very little odour, and when turned out upon the hand they feel dry and do not become moist by exposure.

This appears to be the form in which chloral hydrate is most definite and uniform, and, therefore, best suited for dispensing purposes, quite independently of its being obtained from any particular maker.

But there are several other varieties of crystals: sometimes the preparation is in the form of minute acicular crystals, like chloride of ammonium; sometimes it has the appearance of chlorate of potash, and sometimes it is in definite needle-shaped crystals, like oxalate of ammonia. Very frequently these crystals are more or less moist in appearance, and on exposure this character becomes more marked. The definite needle-shaped crystals last mentioned are, I believe, characteristic of the alcoholate. I have only met with one sample of this kind in commerce, and have not yet obtained a sufficient quantity of it for analysis. As regards the other acicular and tabular crystals, however, they appear to be decidedly inferior to that form of crystallized chloral hydrate described above, and they do not seem to be very much preferable to the cake.

Still none of the samples give results at all approximating to those which would be obtained from alcoholate, nor does it appear that any of the samples examined contained less than 87 per cent. of chloral hydrate. In the case of that sample which gave the lowest result, there was a copious separation of a flocculent humus-like substance between the chloroform and the supernatant liquid, and that obscured the true volume of the chloroform layer. The same deposit was found to some extent in testing other samples.

According to the analysis made by Mr. Eugene De Haen, and referred to last week in the letter from Messrs. De Haen, the choral hydrate they make gives the following results:—

Boiling-point.	Chloroform Layer (after the List of Mr. Mason).	Quantity of Chloroform produced from 500 grains of the Chloral compound by weight.	General Remarks.
Centigr. 97°	Grain-measures 240	353 grains, or 71 per cent.	A crystalline cake (crystal) soluble in water, ether, alcohol; insoluble in chloroform, etc.; has all attributes of a really chemically pure chloral-hydrate.

Since writing the above Messrs. Domeier have forwarded a letter, which appears in the Correspondence columns, and the results of two analyses by Dr. Versmann, which are as follow:—

Samples.	Boiling-point.	Chloroform layers, grain-measures.	Quantity of Chloroform from 500 grains hydrate by weight.	Corresponding to percentage of pure chloral hydrate.	General Remarks.
Crystals . .	96° to 97° C.	235 grs.	357·8 grs. or 70·3 p. c.	97·43 p. c.	Fine white crystals, slightly deliquescent, dissolved very freely in water, dissolves in alcohol, ether, etc., not quite insoluble in chloroform.
Cake . . .	96° to 97° C.	232 grs.	347·3 grs. or 69·4 p. c.	96·20 p. c.	White opaque cake, not quite dry, readily soluble in water, alcohol, ether, etc., not quite insoluble in chloroform. Both begin to solidify after having been melted at 49° C.; specific gravity of liquid at that temperature is 1·610.

Both samples are pure chloral hydrate, which have by exposure to air attracted some moisture, which is the cause of the deficiencies in the percentage.

After decomposition with ammonia and separation of chloroform, no crystals of iodoform could be obtained from the solution, proving the absence of any alcohol.

In reference to Mr. Abraham's remarks on the ammonia test as reported in the proceedings of the Liverpool Chemists' Association, I may remark that care must be taken to ensure completion of the reaction before reading off the volume of chloroform. Of course the temperature to which the tubes have to be heated must be regulated by the nature of the product. A temperature of 100° F. maintained for three or four hours is quite enough. Meanwhile, the tubes should be well shaken. If these precautions be not observed, probably very little chloroform may be produced, or it may happen that the chloroform-layer appears to be much larger than it ought to be. In such cases it will be found that after some hours rest, crystals separate from the chloroform. This latter circumstance is due to incomplete decomposition of the chloral hydrate and its solution in the chloroform produced, apparently with increase of volume. On heating a tube in this condition, the recommencement of the reaction will be at once apparent, and after cooling, the chloroform layer will be found reduced to its true volume.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

CERII OXALAS.—$Ce\,C_2\,O_4\;3\,H_2\,O$.

[§ A salt which may be obtained as a precipitate by adding solution of oxalate of ammonia to a soluble salt of cerium.] The chloride may be employed.

[§ A white granular powder, insoluble in water, decomposed at a dull red heat into a reddish-brown powder (a mixture of $Ce\,O$ and $Ce_2\,O_3$), which dissolves completely and without effervescence in boiling hydrochloric acid, and the resulting solution gives with solution of sulphate of potash a white crystalline precipitate (of double sulphate of cerium and potassium). If the salt be boiled with solution of potash and filtered, the filtrate is not affected by solution of chloride of ammonium (showing the absence of alumina); but when supersaturated with acetic acid it gives with chloride of calcium a white precipitate (oxalate of calcium) which is soluble in hydrochloric acid. Ten grains when incinerated lose 5·2 grains in weight.] That is, a residue of oxide weighing 4·8 grains is left. If it consisted solely of cerous oxide $Ce\,O$, the residue would weigh 4·6 grains, but a small quantity of peroxide is always formed; thus the slight increase in weight is accounted for.

CHLOROFORMUM.—$C\,H\,Cl_3$.

Into a capacious still is introduced a quantity of rectified spirit diluted with much water. Heat is applied, and when the temperature reaches 100° F., a mixture of slaked lime and chlorinated lime is added. When the mixture commences to froth, the fire is removed, and in a short time the process is complete. There is no necessity for continuing the application of heat any length of time, as the whole of the chloroform comes over at the commencement.

The product is purified by washing it first with water, then with strong sulphuric acid; finally it is dried and purified from traces of acid by redistilling it from a mixture of chloride of calcium and dry slaked lime.

Chlorinated lime is an agent capable of acting by supplying either oxygen or chlorine. Thus it may split in a manner represented by either of the two following equations—

$$Ca\,Cl\,O\,Cl = Ca\,Cl_2 \quad + \quad O.$$
$$\text{or } Ca\,Cl\,O\,Cl = Ca\,O \quad + \quad Cl_2.$$

In the production of chloroform it acts both ways. First the alcohol is believed to lose hydrogen and become converted into aldehyd,

$$C_2H_6O + O = C_2H_4O + H_2O.$$

Then the aldehyd is acted upon by the chlorine from another portion giving chloral, which in its turn is decomposed by the lime into chloroform and calcic formate.

$$\underset{\text{Aldehyd.}}{C_2H_4O} + 3\,Cl_2 = \underset{\text{Chloral.}}{C_2HCl_3O} + 3\,H\,Cl.$$

$$2\,\underset{\text{Chloral.}}{C_2HCl_3O} + Ca\,2\,H\,O = \underset{\text{Formate of Calcium.}}{Ca\,2\,C\,H\,O_2} + 2\,\underset{\text{Chloroform.}}{C\,H\,Cl_3}.$$

The chloroform distils over, the formate remains mixed with the excess of lime and water in the retort. The slaked lime employed is not absolutely necessary, but prevents irregularities in the decomposition.

The foregoing explanation of the reaction is rendered probable by what we know of chloral. This body in the form of hydrate is now familiar to every one. It is made by passing dry chlorine gas into absolute alcohol.

$$\underset{\text{Alcohol.}}{C_2H_6O} + 4\,Cl_2 = \underset{\text{Chloral.}}{C_2H\,Cl_3\,O} + 5\,H\,Cl.$$

When treated by alkalies it breaks up as shown in the equation already given. Ammonia is employed when it is desired to test it quantitatively. By the amount of chloroform produced, the proportion of real chloral present can easily be calculated.

The sulphuric acid employed to purify chloroform must be free from all traces of oxides of nitrogen; for it has been shown that the apparently spontaneous decomposition to which chloroform is sometimes subject is to be attributed to contamination of this kind.

The best indication that chloroform is free from noxious impurities is that it evaporates from the hand without leaving a residue or odour of any kind. Admixture of spirit would be indicated by the specific gravity.

Chloroform is still sometimes called perchloride of formyl, in accordance with the supposition that it is a chloride of an assumed radicle $(C\,H)'''$, formyl, the existence of which is doubtful. All the different views which may be held respecting the constitution of chloroform in reality amount to one and the same thing; in this body we have an atom of quadrivalent carbon united with and saturated by the four univalent atoms, one of hydrogen and three of chlorine.

By dissolving chloroform in spirit of wine acidulated with hydrochloric acid, to which a few drops of perchloride of platinum have been added, and digesting the mixture upon granulated zinc in a flask to which a Liebig's condenser is attached, dichloride of methylene is gradually produced, and distils over.

$$C\,H\,Cl_3 + H_2 = C\,H_2\,Cl_2 + H\,Cl.$$

Dichloride of methylene has been tried with some success as an anæsthetic, but its production in quantity is uncertain and difficult.

By submitting chloroform to the action of excess of chlorine, a liquid, tetrachloride (formerly called bichloride) of carbon, $C\,Cl_4$, is produced.

These bodies form part of a series which well illustrates the law of "substitution;" for they may all be formed simultaneously by the action of chlorine upon marsh gas,—the atoms of hydrogen in that body being one after the other replaced by equivalent chlorine atoms.

Marsh gas or methyl hydride . .	$\overbrace{H\,H\,H\,H}^{C}$
Methyl chloride or methyl-hydrochloric ether	$\overbrace{H\,H\,H\,Cl}^{C}$
Methylene dichloride	$\overbrace{H\,H\,Cl\,Cl}^{C}$
Chloroform	$\overbrace{H\,Cl\,Cl\,Cl}^{C}$
Carbon tetrachloride	$\overbrace{Cl\,Cl\,Cl\,Cl}^{C}$

THE ADULTERATION OF SAFFRON.

BY JOHN INGHAM.

Notwithstanding the recent remarks that have been made by different writers upon the adulteration of saffron, there seems to be no improvement in the article as met with in commerce.

I hope that this additional exposure of the enormous extent to which the adulteration is practised, may be a step towards putting a stop to it, by concentrating the attention of the trade more fully upon the subject.

Towards the close of last year I ordered a small quantity of crocus sativus opt. from one of the oldest drug firms in London, a house whose drugs generally are to be relied upon for purity as much as those of any other firm; yet the saffron supplied at the rate of 56*s*. per lb. contained from forty to forty-five per cent. of impurity. Bearing in mind Mr. Daniel Hanbury's remarks on this article, I determined to examine what I had. On close scrutiny with the naked eye I could see it had *much* foreign matter attached to it; on applying a little HCl brisk effervescence immediately commenced.

In order to ascertain to what extent the fraud had been carried and what was the adulterant, I took 1 drachm of the saffron and washed it two or three times with water in a beaker, mixed the washings, allowed the precipitate to deposit, and decanted off the clear liquid. The sediment, when dried till it ceased to lose weight, weighed *twenty-seven grains*. Surprised to find so large an amount, I thought that some heavier adulterant than carbonate of calcium, perhaps sulphate of barium, might have been employed also. On treatment with HCl, brisk effervescence ensued, and the greater part was dissolved. This portion was easily proved to be nothing more than carbonate of calcium. The portion insoluble in HCl was equally so in aqua regia. I endeavoured to treat in the usual manner for insoluble sulphates as also for silica, but was unable, with the means at my command, to obtain sufficient heat to fuse it when mixed with a proper flux. From its appearance to the eye I think it is only sand. The quantity compared with the chalk was small, it may probably have been a mechanical impurity in the latter. After such a result I hardly anticipated finding that there was a still greater sophistication, yet I felt curious to continue my investigation a step further.

Placing a small portion upon the surface of some hot water, I soon perceived some yellowish portions, which I had previously taken for stamens, unfolding themselves, looking very like ligulate florets; in my readiness to believe, I nearly mistook them for such; they were, however, only stamens. These constituted fully 1 per cent. I do not know the origin of this saffron, but I should think it is a very bad specimen of the worst Alicante Mr. Hanbury examined. From the immense time and labour requisite for the gathering of saffron, it must of necessity always be a costly article; and so long as there is a ready market for such qualities as have lately been selling, doubtless the supply will be kept up, and be very profitable to those primarily concerned.

The remedy is chiefly in our own hands; if we refuse to use, or have anything to do with such qualities, it will soon be found more remunerative to supply a genuine article, even if a higher price must be charged. I am no advocate for cheapness if any advantage is to be gained by higher prices; yet, in conclusion, I cannot help reiterating what has often been said before, that a drug so costly and of so little therapeutical value should be, as soon as possible, ordered much less than it is in our Pharmacopœia, or be altogether expunged from it.

THE COMPOSITION OF THE FERRIC IODATES.

BY CHICHESTER A. BELL, M.B.

The ferric biniodate having been recently proposed as an addition to our list of medicines, and successfully employed by many physicians in Dublin, it appeared desirable to investigate the chemistry of a substance which seems destined to come into more general use. The compound hitherto employed, however, is both expensive and tedious to prepare, and is, moreover, liable to decomposition, although very much more stable than the ferrous iodide as a substitute for which it was introduced. With the view, therefore, of devising a more simple and rapid mode of preparing it, or of finding some similar and equally efficacious compound, a few experiments were undertaken, and with the following results:—

There appear to exist, at least three well-defined compounds of ferric oxide and iodic anhydride. One of these, the biniodate, is formed by precipitating a solution of iron alum by one of potassic or sodic iodate added in excess. This is the compound recently proposed for use in medicine, and to it the formula $Fe_2O_3, 2I_2O_5, 8H_2O$ has been correctly assigned. When first precipitated it is of a yellow or yellowish-brown colour; but it soon becomes darker on exposure to air, at the same time evolving an odour of iodine. If now to a solution of ferrous iodide one of potassic chlorate be added, and then an excess of strong nitric acid, upon heating the mixture a fine yellow precipitate is produced. The formation of this substance is often remarkable, the iodine which was at first set free disappearing suddenly when the yellow precipitate appears. The composition of this precipitate corresponds to the formula $Fe_2O_3, 3I_2O_5$ or $Fe''' 3IO_3$. It is, therefore, a normal iodate. It contains 9·64 per cent. of iron and 65·57 per cent. of iodine, while the percentages of iron and iodine in the crystallized ferrous iodide of the Pharmacopœia are about 15 and 67. It is scarcely soluble in cold water and dissolves with difficulty even in strong nitric acid. Like other iodates it is readily attacked by warm moderately dilute hydrochloric acid, chlorine gas being produced. Boiling water takes up from it both ferric oxide and iodic anhydride, a basic salt remaining undissolved. It is destitute of both flavour and odour. It possesses the advantage over the preceding compound of being anhydrous and perfectly stable. The most suitable proportions for its preparation seem to be, 2 parts iodine converted in the usual manner into ferrous iodide in solution in 5 or 6 parts water, 2 parts potassic chlorate dissolved in a small amount of hot water, and $1\frac{1}{2}$ parts strong nitric acid.

When only a small quantity of nitric acid is added and the mixture heated to boiling, a considerable amount of iodine escapes, while a deep red precipitate is formed. The composition of this precipitate, when dried at 212° F., appears to be normally Fe_2O_3, I_2O_5. It soon, however, decomposes, even during washing, and the proportion of iodic anhydride is accordingly liable to vary. Prepared with a larger quantity of nitric acid its colour is lighter, while it contains a greater percentage of iodic anhydride. When the amount of acid is not quite sufficient to cause the formation of the normal salt, the resulting precipitate is probably a mixture of normal and basic iodates. Digestion with warm dilute nitric acid converts any of these basic mixtures into the neutral compound.

Of these three ferric iodates the normal compound would seem the best suited for medical use in consequence of its great stability. The iodates as a class undoubtedly require further examination.

THE APPLICATION OF DISINFECTANTS.

Now that smallpox, fever and other contagious diseases are prevalent amongst us, the knowledge of how to apply the substances which are used as disinfectants is of much importance. The chemist, as the vendor, is often consulted as to the best way of using a certain disinfectant, and having ascertained the purpose for which it is required, should be able to give a judicious and ready reply.

First among disinfectants is carbolic acid. Its universal adaptability, its extensive use in most of the metropolitan hospitals, and during the cattle plague, entitle it to this rank. It has advantages which no other disinfectant can boast of, being capable of application either as a fluid or as a vapour; the fluid not injuring the fabric to which it is applied, and the vapour when breathed being comparatively harmless.

There are several ways of applying this substance. In solution, a good strength is one part of the crystallized acid to thirty of water. This is suitable for sprinkling the floor, clothing, bedding, etc. A very good way of using it is to keep clothes continually wetted with it, and suspend them in the room. For pouring down drains and the immersion of linen and other infected articles, one in fifty is strong enough. As vapour it may be evolved by keeping a solution of the first strength constantly evaporating; or another more simple and effectual method is to make a fire-shovel hot and pour upon it a little of the strong solution at regular intervals. The patient and those in attendance should likewise wash with carbolized soap.

Manganate and permanganate of potash are valuable as disinfectants and deodorizers on account of their oxidizing powers in the presence of organic matter. The Pharmacopœia solution of the permanganate is strong enough for all the purposes to which it can be applied. If the patient drinks much water, a few drops of this solution in each glassful will do good. As a wash for the mouth, one drachm to an ounce is a suitable strength. All utensils for the reception of evacuations should be charged with this solution. For sprinkling the floors, clothing and bedding, and pouring down drains, two drams to the ounce should be used. A weaker solution is very useful for rinsing the hands.

Chlorinated lime is a substance so well known, and its application so simple, that most persons are instructed in its use; its cheapness recommends it to the poorer classes, and, I believe, its use is generally appreciated by them. In places where it is strewn, it should be renewed every twenty-four hours, as by that time it generally loses its freshness. A portion of it placed in a pail of water for the washing of floors is a wise precaution at all times.

Sulphurous acid gas is liberated by burning sulphur. It is a powerful destroyer of the germs of contagion, but owing to its deleterious and suffocating odour it cannot be introduced in any quantity to the room of a sick person; nevertheless, it is very useful.

Mr. Startin, the senior surgeon to the Hospital for Diseases of the Skin, Blackfriars, in a communication to the *British Medical Journal*, recommends the following method of fumigation to be used for the purpose of preventing the spread of contagious diseases. For disinfecting beds and bedding, a warming-pan or some other suitable utensil, containing a few live embers, upon which a teaspoonful or two of flowers of sulphur has been thrown, should be passed to and fro between the sheets until the combustion of the sulphur is complete. After a few minutes the patient may enter the bed. Should the fumes prove too stimulating for his respiratory organs, they may be intercepted by holding a loosely folded damp handkerchief before the mouth until they have subsided. To disinfect clothing it should be lightly sponged or sprinkled with water containing well-mingled milk of sulphur, in the proportion of a teaspoonful to a pint of water, and then ironed with a flat iron, heated to a temperature sufficient to volatilize the sulphur without burning the clothing. This process should be repeated according to the extent and duration of the infection.

Dr. Walter Fergus, writing to the same journal, says that he has found the readiest method of developing sulphurous acid fumes to be by igniting two parts of flowers of sulphur and one of powdered charcoal on any incombustible surface, such as a saucer or a bit of tin. He says also that sulphurous acid is not so much an irritant as it has the appearance of being. An atmosphere highly charged with it may be breathed with very small inconvenience, which soon passes off. Dr. Fergus has used it with benefit in cases of the affection known as "hay-fever."

A correspondent says, in reference to the above method, that it is open to several objections. He much questions whether a patient could remain in the room after the burning of two teaspoonfuls of sulphur; under any circumstances it would produce a most irritating cough, even if the wet handkerchief were applied to the mouth, as there is a limit to the absorption of this gas by moisture. The hot cinders are not necessary for its ignition, the sulphur will readily take fire, and burn on the application of a lucifer match.

The disinfecting properties of chlorine are well known. It can be eliminated by the action of hydrochloric acid on chlorinated lime, or sulphuric acid on peroxide of manganese and salt. From its poisonous properties it is open to the same objections as sulphurous acid; the same rules may be observed for its application.

In conclusion, we give the following list of precautions adopted in a recent case of typhus fever. When the medical attendant discovered the nature of the case, he ordered immediate disinfection with carbolic acid and Condy's fluids. The room in which the patient lay was stripped of the whole of its furniture, leaving nothing that was not required for the use of the patient. The floor was then washed with a solution of chlorinated lime, and afterwards well sprinkled with solution of carbolic acid one to thirty. Cloths kept wet with this solution were suspended in the room, and the bedding was lightly sprinkled. Three times a day, at regular intervals, a drachm of the strong acid was poured upon a hot fire-shovel and moved about the room. All clothing, bedding, etc., when removed from the patient, was immersed in a solution of the acid one to fifty. He was washed with carbolized soap. All utensils for the reception of evacuations were kept charged with Condy's fluids; a weaker solution of the same was used as a gargle. This plan was strictly followed for three days, when the patient sank and died. As soon as possible after death the fireplace and windows were securely closed, and a tablespoontul of sulphur placed in a vessel and ignited. The door was then closed, and the room left in this condition three hours, after which the windows were opened from the exterior. Soon afterwards the remains were placed in a shell containing charcoal. The paper was then stripped from the walls, and the sulphur process again repeated. The room was kept closed in this condition for two days, when the body was removed.

As destroyers of atmospherical germs of contagion, sulphurous acid and chlorine are perhaps the best agents; but, in consequence of their irritating effects, their application is much restricted in the sick-chamber.

THE SALTS OF CERIUM AND OF LITHIA.*

The salts of cerium were first introduced as remedial agents by the late Sir J. Y. Simpson,† and the oxalate was admitted into the second edition of the British Pharmacopœia. Sir J. Y. Simpson considered them to possess sedative and tonic properties, which make them useful substitutes for bismuth, hydrocyanic acid and nitrate of silver. He used them with marked advantage in "chronic intestinal eruption," in irritable dyspepsia, attended with gastrodynia, pyrosis, and chronic vomiting, and in the vomiting of pregnancy. In epilepsy and other allied convulsive diseases in which the nitrate of silver has been frequently employed, the salts of cerium possess the advantage over the nitrate of silver, that they may be persevered with without any fear of discolouring the skin. The oxalate has obtained a great reputation as a remedy in obstinate vomiting, especially in the vomiting of pregnancy.

The remedy possesses the great advantages of smallness of dose (gr. iij–v) and freedom from taste and smell.

Lithia and its salts were also introduced into the British Pharmacopœia of 1864. More than thirty years ago, Mr. Ure and some other authorities called attention to the remarkable solvent powers which the carbonate of lithia possessed over uric acid calculi—powers which much exceed those possessed by the other alkaline carbonates,—and suggested the injection of solutions of the carbonate of lithia into the bladder, with the object of dissolving calculi formed wholly or in part of uric acid. But it was Dr. Garrod who introduced the lithia salts into medical practice. Extending the experiments of Mr. Ure, etc., he found that the carbonate of lithia could completely remove gouty deposits of urate of soda from cartilages incrusted by them, while carbonate of potash acted less strongly on them, and carbonate of soda left them unaltered. This encouraged him to make trial of the lithia salts clinically, and with highly satisfactory results. He found them of great value for keeping uric acid in solution during its passage through the urinary organs, and for preventing its deposition in the structures of the body; it seems, also, that they may be of service in removing gouty concretions when formed. The carbonate is a much more powerful diuretic than the salts of potash or soda, and may be given with great advantage, as a prophylactic, in chronic gout, calculus, etc. Its dose is from three to six grains, and is best given in a state of free dilution. The value of the lithia salts, especially the carbonate, has been widely recognized. The lithia springs of Baden Baden ‡ have gained a considerable reputation, and Professor Roscoe has found lithium in the thermal waters of Bath. Dr. Garrod has stated that he has known a few, but a very few, instances "in which the long-continued use of the drug has appeared to cause symptoms referable to the nervous system, as shaking or trembling of one hand, which has disappeared on the omission of the remedy." §

THE USE OF PREPARATIONS OF CARBOLIC ACID IN SMALL-POX EPIDEMICS.

Although carbolic acid is not a preservative enabling us to dispense with vaccination, it is nevertheless a disinfecting agent which it is advisable to employ as a prophylactic. In a hygienic point of view it is thought worth while to call attention to two new preparations, or rather two different forms of the same preparation, which are due to MM. Dubarth and Rolle.

The best method of employing carbolic acid as a disinfectant, according to M. Dubarth, is to mix it with a coarse powder, which being saturated with it so divides the acid as to present the largest possible surface for evaporation. For this purpose powdered brick affords an excellent vehicle, at once convenient and easy in its use.

The following is the manner in which he prepares this mixture, to which he has given the name of "Dubarth's Disinfectant."

Powdered Brick	5 kil.
Carbolic Acid	250 gr.

Dissolve the acid in a sufficient quantity of alcohol and then mix. A thin layer of this powder spread upon a plate, frequently stirred and slightly damped, produces at the ordinary temperature a much larger quantity of antimiasmatic vapours than would be given off by any solution of carbolic acid. It is superior to the solutions of permanganate of potash, its effects being more constant and more certain.

The following is the method proposed by M. Rolle for making carbolicized cigarettes:—

Powdered Plaster	100
Carbolic Acid	20

Dissolve the carbolic acid with a sufficient quantity of alcohol, and sprinkle with this solution the granulated plaster. Stir with a spatula in order to secure an equal distribution of the active substance, then introduce the granules into the hollow portion of a quill, of which the ends are closed with a little wadding, as is done in the case of camphor cigarettes.

As an agent in the treatment of confirmed small-pox, carbolic acid has been largely experimented with since the first trials by M. Chauffard, with results proportionate to the gravity of the evil. Professor Godefroy, of Rennes, has had three cases of small-pox, in which he has obtained such satisfactory results by the use of it, that he has published the particulars in the *Revue de Thérapeutique Médico-Chirurgicale.*

The first was the case of an unvaccinated adult, suffering from semiconfluent small-pox. The prescription ordered was—

Mixture of Acacia (Potion gommeuse, Fr. Codex)	125 grammes.
Crystallized Carbolic Acid	1 ,,

Two tablespoonfuls to be taken every two hours.

The following lotion was to be applied every hour to the face and hands:—

Crystallized Carbolic Acid .	5 grammes.
Distilled Water	500 ,,

There was no suppuration.

The second case was that of a confluent variolic eruption. The same treatment was adopted. There was no suppuration.

The third case was an infant of eighteen months. The eruption was moderate. Without ceasing to suck, this child took a teaspoonful of a solution of 30 centigrammes. The hands were bathed with a lotion made according to the formula previously given. It recovered.

It is well to remark that these three cases were too slight to decide in favour of the efficacy of carbolic acid; but they at least prove that the acid can be administered without inconvenience.—*Echo Médical et Pharmaceutique Belge.*

DR. LANKESTER'S REPORT FOR 1870.

It appears from an analysis contained in this Report that in cases of suicide, women, as a rule, prefer taking poison and drowning themselves. Of twenty-three cases of female suicide in 1868–9, six were from poison and ten from drowning. Men, on the other hand, adopt the more violent methods, such as cutting their throats, hanging, jumping out of windows, etc.

With regard to poisons, the third on the list of means of suicide in proportion to their frequency, it will be seen "that during the past seven years the most frequent deaths have arisen from cyanide of potassium. This is a most deadly and certain poison. It can be bought of almost any druggist or seller of photographic chemicals, without any questions being asked. It is used in immense quantities by photographers, and every amateur photographer possesses a certain quantity in his stores. It is well known in families where it is sold and used as a poison. It is in this way the most readily accessible, and perhaps the best known of all poisons, as it is generally labelled, when sold, as 'poison.' On this account it seems to offer a terrible temptation to those inclined to commit suicide. Thus the word 'poison' only acts as a preventive of accidental poisoning, for persons disposed to commit suicide might know nothing of the properties of a substance unless it was thus labelled. In a recent case of poisoning by Calvert's carbolic acid, used for disinfecting purposes, the bottle containing it not being labelled 'poison,' the mistress of a family told her servant she must be very careful of the acid as it was a strong poison. The consequence was that the girl got up in the night and swallowed a quantity of the carbolic acid, and was found dead the next morning. Labelling poisons 'poison' will not prevent suicide, nor will any restriction on the sale of poisons prevent suicide. The only restriction that can be of any service is on the sale of poisons, which may easily be administered to other persons on account of the small bulk or absence of any physical property, and which can be easily employed for the purposes of murder. There is no doubt that writing the word 'poison' frequently prevents accidental poisoning, but I am of opinion that nothing will prevent this amongst ignorant and careless people but the sending out of poisonous substances in bottles or boxes that should at once be recognized by the sight and feeling as devoted to the reception of poisons alone.

"The next most frequent agent used in suicidal poisoning is oxalic acid. This is used by saddlers and harness-makers, shoemakers, and also for certain household purposes. Just as photographers and their wives and families poison themselves by cyanide of potassium, so shoemakers and saddlers and their wives and families poison themselves with oxalic acid. It is seldom taken by mistake or used for purposes of murder; it is usually sold with the word 'poison' written on it, and is well-known as a tolerably efficacious poison. I say tolerably, because I believe cases of recovery from oxalic acid poisoning are much more frequent than from cyanide of potassium.

"After these two instances come the preparation of opium. These cases are not so numerous as formerly, and even my tables seem to point to a decrease. The facility of obtaining cyanide of potassium and oxalic acid may explain this. The chemist and druggist is very careful over the sale of laudanum, selling it only in small quantities, and then only to persons whom he supposes are not going to misuse it. But in the great majority of cases where persons take laudanum for suicidal purposes, they have bought it in small quantities and added them together, and thus have taken sufficient to effect their object. But a large number of the cases of poisoning by opium or its preparations arise in druggists' shops and medical men's dispensaries, to which servants or others desirous of committing suicide have access.

"This is more so the case with hydrocyanic or prussic acid. In nearly every instance of suicide by poisoning with this agent, it has occurred with medical men, druggists, or their families and servants. It may be bought, but great precautions are taken in the sale, and its sale and use is almost entirely confined to chemists who make it, druggists who sell it and medical men who employ it.

"Poisoning by oil of bitter almonds comes next. It is used as a scent and also employed to flavour food. The few cases which have occurred during the last seven years are principally amongst servants and courtesans. It is easily procured in druggists' shops. It should, however, be known that the essential oil of bitter almonds is not a poison, and it is only when it is impure and contains hydrocyanic or prussic acid that it acts as a poison. I have never held, that I recollect, an inquest in a case of accidental poisoning from oil of bitter almonds, as it is never taken in sufficient quantity when used as an article of diet. It is, however, an unpleasant fact to know that you may be taking a dose of hydrocyanic when eating a custard at dinner.

"Following oil of bitter almonds in the number of their victims are sulphuric and hydrochloric acids. These articles are known in commerce as oil of vitriol and spirit of salt, and are used for various purposes and by various workers. They are known to be poisonous, but they are generally known also to kill by their caustic action on the flesh of the body. The death which follows the swallowing either of them is most agonizing and cruel, the victim frequently not dying for some hours, or even days, after taking them. They are employed by persons who are too poor or too ignorant to have recourse to anything else. The drunken brass-finisher, or his wife, or any other artisan who works at his business with these materials, in the moment of frenzy, seize on one or other of these acids which may be nearest to them, and thus finish their existence by one of the most painful deaths that man can die.

"The last substance mentioned is strychnia. It is contained in powders sold for the destruction of vermin. In the two cases recorded the strychnia has been taken in this way."

POISONING BY BATTLE'S VERMIN KILLER.

We have been favoured by a correspondent with the following account of a case of poisoning by Battle's Vermin Killer, that has come under his notice:—*Jan.* 7, 1870, 12.30. I was called to Mrs. —, who I was told was dying. On arriving I found her in tetanic convulsions and quite asphyxiated. She recovered from the convulsions just after my arrival, when her father told me she had taken a 3*d*. packet of Battle's Vermin Killer. She gave me the key of her box, where I found one empty and another full packet of the above poison. She said she had taken it thirty minutes before. I immediately ordered her a mustard emetic, and hastened back for antidotes. On arriving again in about five minutes, I found she had vomited a quantity of green fluid, and that another convulsion was just commencing. I gave her a few whiffs of chloroform, which relieved it, and then another emetic mixed in strong coffee. About 12.45 I administered "ʒij of chloral hydr." in a little starch as an injection, after which she had "*no more convulsions*" and slept, waking up every hour till 5 next morning. On seeing her about 9 she said she had only a little pain in her legs, and felt rather languid. The next day she was out of bed, sat up, and is now perfectly recovered.

COUGH REMEDIES.

As at this season of the year, and more especially the present year, succeeding to the great and long-continued heat of last summer and autumn, coughs, colds and catarrhs, and all of this class of affections of the bronchial membrane of the air-passages are prevailing to an unusual extent, it will be found convenient to be able to turn readily to a well-established formula that may afford relief to persons thus affected, and perhaps have the good fortune to make a cure. Therefore, to that end—

1. Take Syrup of Squills,
Syrup of Ipecacuanha,
Camphorated Tinct. of Opium, of each, 1 oz.

M. Dose, a teaspoonful for an adult every three hours.

It promotes expectoration and causes relaxation.

2. Take Syrup of Wild Cherry Bark, 3 fl. oz.
Syrup of Tolu, 1 fl. oz.
Prussic Acid, diluted, 16 minims.

M. Dose for an adult, a dessert-spoonful every three hours. Tonic and sedative, and is highly useful in consumption.

3. Take Syrup of Gum Arabic, 4 fl. oz.
Muriate of Morphia, 1 gr.
Oil of Sassafras, 1 drop.

M. Dose, a teaspoonful every three hours.

This is like Dr. Jackson's well-known "Pectoral Syrup."

4. Take Powdered Ext. of Liquorice,
Powdered Gum Arabic, of each, 2 drms.
Hot Water, 4 fl. oz.

Make a mixture and add—
Spirit of Nitrous Ether, 1 fl. drm.
Antimonial Wine, 2 fl. drms.
Tincture of Opium, 40 minims.

M. A tablespoonful for a dose.

This is an excellent remedy in the early stages of catarrh; it is the well-known *Brown Mixture*, or the "mistura glycyrrhizæ composita" of the U. S. Pharmacopœia.

5. Take Decoction of Senega, 4 fl. oz.
Syrup of Ipecac. 1 fl. oz.
Syrup of Squills, ½ fl. oz.
Tartrate of Antimony, 1 gr.

M. A teaspoonful for children two years of age and over. This is often given in croup.

6. Take Gum Ammoniac,
Ext. of Liquorice, of each, 2 drms.
Vinegar of Squills, ½ fl. oz.
Fennel Water, 5½ fl. oz.

M. Dose, a teaspoonful for an adult every two hours.

A stimulating expectorant in chronic bronchitis and catarrh.

7. Take Muriate of Ammonia, ½ oz.
Powdered Gum Arabic, 2 drms.
Powdered Ext. of Liquorice, 3 drms.
Water, 6½ fl. oz.
Spirits of Nitrous Ether, 1½ fl. drm.
Vinegar of Squills, 3 fl. drms.

M. A dessert-spoonful every two hours.

A stimulating expectorant and alterative, and may be given in the advanced stage of bronchial disease.

8. Take Copaiba,
Balsam of Tolu,
Powdered Gum Arabic, of each, ½ oz.
Water, 6 oz.
Aromatic Sulph. Acid, 20 minims.

Make a mixture by well rubbing together.

Dose, a tablespoonful. Given in chronic catarrh and bronchitis.

9. Take Hypophosphite of Lime, 6 drms.
Hypophosphite of Soda,
Hypophosphite of Potash, of each, 2 drms.

Dissolve, strain and add—
Hot Water, 10 fl. oz.
Sugar, 14 fl. oz.

Dissolve, with a mild heat, strain and add—
Orange-flower Water, ½ fl. oz.

M. Dose, a teaspoonful every three hours.

The hypophosphites are recommended by Dr. Churchill in phthisis and bronchitic consumption.—*The New York Druggists' Circular.*

Eye Seed.—A correspondent in the *Gardeners' Chronicle*, says that some years ago, being on a tour in North Wales, he saw a plant—which some of his friends who were with him knew as Clary, and others as Wild Sage—growing plentifully in the ruins of Denbigh Castle. The man who was in charge of the ruins gathered some of the berries, and recommended them to the party as a wonderful cure for eye disease. His mixed Welsh and English was difficult to understand, but the point appeared to be that the seed was good for checking inflammation, and might be placed whole under the eyelids without doing harm. The plants appeared to agree with the description in Loudon's 'Encyclopædia of Plants' of the wild Clary, the *Salvia Verbenaca;* they were labiate, about a foot high, and the flowers were of a bluish purple. The time of the year was about the beginning of July.

Female Pharmaceutists in Holland.—According to the editor of the *Pharmaceutische Zeitung*, at the examination for pharmaceutical assistants recently held in Amsterdam, nine female candidates made application, five of whom had been educated there at the industrial school. The commission of examination was fully satisfied of their capability. The *Pharmaceutical Weekly* of Holland reiterates the views expressed on a former occasion, that these girls (Meisjes) are not adapted for city pharmacies, but that in the country, where the prescription business is naturally limited to certain hours, and where they could find time for improvement in domestic duties, they might become useful and valuable assistants.—*American Journal of Pharmacy.*

Chloride of Lime as a Cargo.—The National Company's steamship 'England,' which sailed for New York on the 12th instant, put back into Queenstown under the following circumstances. During a gale several barrels of chloride of lime, which formed part of the cargo, burst, the fumes arising from which compelled the firemen to leave the stokehole. With considerable difficulty, the men employed in the duty being nearly suffocated, five barrels were got on deck and thrown overboard. It was then deemed prudent for the safety of the passengers that the vessel should not continue her voyage. Several bucketfuls of rats were found dead from the effects of the lime.—*Standard.*

Examination of the Bark of Coprosma grandifolia for Alkaloids.—Mr. Skey, analyst to the Geological Survey of New Zealand, reports that he has examined a specimen of the *Coprosma grandifolia* and found that alkaloids generally, and those of the quinia group particularly, are either entirely absent, or present only in so minute a quantity that the bark has no value as a drug on that account. The bark examined was bright yellow on its inner surface, very bitter and had a slightly hot, pungent flavour. Mr. Skey considers it the bitterest of any of the barks of that family that he had seen. The method adopted for the examination was as follows:—A decoction of 200 grammes of the pulverized bark in weak hydrochloric acid was slowly evaporated to half an ounce and then filtered. The filtrate yielded no precipitate with sulphocyanide of mercury, sulphocyanide of zinc or tannic acid. These reagents give dense precipitates in a very weak decoction of the common grey bark.—*Chemical News.*

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 4, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BETTS SUITS.

The present number contains a report of the proceedings before the Lord Chancellor upon the Appeal presented by Mr. Betts for a reversal of the decision given by Vice-Chancellor James. Mr. Betts has again failed, and it may now, we hope, be anticipated that the last has been heard of his remarkable pretensions.

As upon the former occasion the case was not disposed of upon the general question whether if Mr. Betts had proved an infinitesimal and innocent infringement, he would have been entitled to an injunction and damages, or in short would have been justified in filing his twenty-five Bills. The Plaintiff's counsel, in fact, failed to establish any case of infringement, and the Lord Chancellor upon that ground rejected the application. It will be well for the result of the case not to be misunderstood in these respects, because nothing has happened in the course of the proceedings to encourage a retailer in knowingly dealing in, or using even to the most limited extent, any article made in infringement of patent or other protected rights.

The judgment of the Vice-Chancellor (Third Series, Vol. I. p. 32) evidently discouraged suits against innocent persons until after reasonable warning given to them, followed by continued infringement of rights; the judgment of the Lord Chancellor is not at variance with those views, and, indeed, remarks (not reported) made by his Lordship during the arguments were in accord with the Vice-Chancellor's expressions on the subject.

The course of the contest illustrates the advantage resulting from mutual help; it is impossible to keep out of view the probabilities that a wealthy experienced and resolute litigant such as Mr. Betts might have had an easy victory against the twenty-five (and possibly more) Defendants, had each been left unaided. Upon the actual result we may once more congratulate the Defence Committee and all parties interested.

Some light was thrown upon a development of the pernicious system of "coaching," adopted by some teachers in preparing pupils for certain examinations, by a case that came before the magistrate at Bow Street on Friday last. Charles Gerrard, described as a teacher, living in Lincoln's Inn Fields, together with another man, were charged with inciting a person in the employ of Messrs. Rivington, the printers, to steal an early proof of one of the examination papers of the Apothecaries Hall. It appeared that the prisoners had been for some time trying to obtain a copy, and at length, by arrangement with the police, the proof-puller was allowed to supply them with two copies, for which he received ten pounds. A detective then immediately arrested the prisoners, while the proofs were in their hands. They were both committed for trial.

It is announced by the Committee of Publication of the *American Journal of Pharmacy* that an Index to the forty-two published volumes of that journal is being prepared, and that it will be published if a sufficient number of subscribers can be obtained within six months.

Mr. Jabez Hogg has been appointed Surgeon to the Royal Westminster Ophthalmic Hospital, in succession to Mr. Hancock, Vice-President and Examiner of the Royal College of Surgeons.

The Catalogue of the Class of the Philadelphia College of Pharmacy for the Forty-ninth Session, 1870–71, numbers one hundred and ninety-eight names.

It is interesting to note that in a recent case the use of a poison label nearly contributed to produce the result it was intended to avert. A woman, wishing to commit suicide, drank a considerable quantity of a lotion from a bottle which was labelled poison, in the hope of effecting her object. As it happened, however, the lotion was a very harmless one, a quart of which would not have hurt her, and so the desired result was not obtained.

At a meeting of the Executive Committee of the British Pharmaceutical Conference, the Secretaries stated that the financial position of the Conference was such as to warrant them in providing for the production of a Year-Book for 1871. The Committee of Publication were accordingly instructed to make arrangements for its issue. Mr. Charles H. Wood, F.C.S., was elected Editor. A vote of thanks was ordered to be conveyed to Mr. Joseph Ince for his services in editing, at a short notice and much personal inconvenience, the Year-Book for 1870.

Proceedings of the Pharmaceutical Society.

MEETING AT EDINBURGH.

The Second Meeting of the present Session of the North British Branch of the Pharmaceutical Society was held at Edinburgh on Monday, 23rd January; Mr. W. Aitken, President, in the chair.

Professor Balfour delivered a lecture on ipecacuanha root (*Cephaelis Ipecacuanha*). He referred to it as a valuable remedy in disorders of the mucous membrane, of the bronchial tubes, etc., but more especially in dysentery. In India it formed, when combined with opium, as valuable a remedy in cases of dysentery as quinine in fevers. He stated that, owing to the careless manner in which the natives collected the root, the plant was rapidly decreasing in Brazil, and that the British Government were now taking active steps to have it introduced and cultivated in India. For this purpose a great number of young plants are being propagated at the Royal Botanic Garden under the care of Mr. M'Nab. There are evidently two varieties of the plant; one has been growing in the garden for at least forty years, while the other was only sent to the garden in a living state about a year ago by Dr. Gunning, from the neighbourhood of Rio Janeiro. The old plant is that which was described and figured by Sir William Hooker in the *Botanical Magazine*, as having been sent to him from Mr. Makoy, Liége. The leaves of this plant are more leathery in their texture; their form more elliptical or oval; their apex less pointed and their edges wavy; there are fewer hairs on the surface and the stem is more shrubby than in Dr. Gunning's recently-imported plant. It also flowers readily after a year's cultivation from slips and the style is short. The Rio de Janeiro plant has not yet produced flowers at the garden, and therefore a full description cannot yet be given. The Professor then gave a history of the ipecacuan plant from its earliest mention by Michael Trestram, who called it Igpecaya or Pigaya, up to the present time. He described the mode in which the root was collected and dried. The gatherers of the *poaya* (the name applied by the natives to all roots used as ipecacuan) are called poayeros, and a skilled poayero can gather in the course of a day about thirty pounds of root. Under the name Ipecacuan many plants are mentioned belonging to different genera, or even to different natural orders. All of them, however, agree in possessing more or less emetic qualities. A figure of the ipecacuan plant was given by Piso in the 'Travels in Brazil,' undertaken by himself and Marcgrave, but it was not such as to enable botanists to determine the genus and species. At that time all annular emetic roots got the name of ipecacuan, and the different kinds were distinguished by their colour: thus we had brown, grey, red, black and white ipecacuan. The first accurate scientific description of it was by Brotero, in the Linnean Society's 'Transactions' for 1800, and subsequently a full account was published by Achille Richard in his thesis on the 'Natural History of Ipecacuan.' Professor Balfour gave a full botanical description of the true ipecacuan plant and showed its relation to other plants in the same natural order. He also gave descriptions of the following plants, used in different parts of the world as ipecacuan:—*Psychotria emetica* (striated ipecacuan), *Richardsonia scabra* (white ipecacuan), *Ionidium ipecacuanha* (false Brazilian ipecacuan), *Manettia cordifolia*, *Euphorbia ipecacuanha*, *Polygala poaya* and *Tylophora asmatica*.

The lecture was illustrated by a beautiful series of large water-coloured drawings, executed by Mrs. Balfour, of the various plants referred to and their structure; by sections under microscopes, prepared by Mr. Sadler; by dried specimens from the University Herbarium, and by living plants from the Royal Botanic Garden.

On the motion of the President, seconded by Dr. A. M'Donald, a cordial vote of thanks was given to Professor Balfour for his interesting and instructive lecture.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The Second Meeting of the Session was held on Monday evening, November 14th, 1870; Mr. William Smeeton in the chair.

Messrs. George William Highmoor, Thomas Edward Parkinson, and George William Roberts were duly elected Associates of the Society.

A vote of thanks was unanimously passed to Messrs. Southall, Son and Dymond, of Birmingham, for their valuable present to the Association of a box containing specimens of the organic constituents mentioned in the British Pharmacopœia.

After an alteration of Rule number 4, Mr. Edward Thompson was elected Vice-President.

Mr. Smeeton, the President, then favoured the meeting with an address. He strongly urged and inculcated upon Associates the duty of acquiring information, and of laying in a solid stock of knowledge, so as to be able to pass their examination with credit. Several phases of education were touched upon, and after a free conversation a vote of thanks was passed to the chairman.

The Third Meeting of the Session was held on Thursday evening, December 22nd, 1870; Mr. E. Thompson, the Vice-President, in the chair.

Mr. Samuel Jefferson, F.C.S., was duly elected a member of the Association, and Messrs. George Iredale and Frederick Plint were elected Associates.

The paper of the evening, on "The History of a Fungus," was then read by Mr. James Abbott. The lecturer explained the views of botanists and mycologists with regard to the cell-formation and reproductive characteristics of fungi, and then proceeded to enlarge upon the latest accepted theory of botanists on the formation of ergot in rye. The medicinal and poisonous properties of ergot were also remarked upon. The lecture was amply illustrated by diagrams and specimens, and after an animated discussion a vote of thanks was passed to Mr. Abbott for his highly useful discourse.

The Fourth Meeting of the Session was held on Wednesday evening, January 25th. Owing to the absence of the President and the Vice-President, Mr. John Day was called to the chair.

Mr. John Henry Wright was elected an Associate.

The Secretary then introduced the subject, "Dispensing; or, Who ought to do it?" The reader of the paper first endeavoured to define the terms dispensing and medicine, and then assumed that two classes only could be supposed equal to the duties of dispensing, viz. the medical and pharmaceutical professions. He afterwards entered into certain abstract and practical arguments to prove that chemists were better qualified to dispense than surgeons. The Secretary also brought forward facts and arguments to prove that the public interest and safety would be materially advantaged by placing the dispensing of the whole country in the hands of the chemists. During a friendly discussion, it was proposed to appoint a deputation from the Association to wait upon the officers of the Leeds Medical School, to point out to those gentlemen the desirableness of dispensing duties being performed in the future by chemists and druggists alone.

It was ultimately proposed by Mr. E. Brown, seconded by Mr. E. F. Atkinson, supported by Mr. Crosby, and carried, that the Secretary be desired to lay the subject before the Committee, and that the Committee be requested to report upon the matter at the next monthly meeting.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Sixth General Meeting was held at the Royal Institution, on Thursday evening, January 19th; the President, Mr. John Abraham, in the chair.

Several donations to the Library and Museum were announced.

Mr. John Shaw announced that he had been authorized by the Local Committee of the British Pharmaceutical Conference to place £32. 15*s.* 4*d.* (the balance of the fund raised to entertain their pharmaceutical brethren in September last) to the funds of the Association.

Mr. Edward Davies, F.C.S., drew attention to the case of accidental poisoning at Mossley, and detailed the result of his analysis of the medicine administered to the child, the detection of morphia, etc. He also made some remarks upon the evidence given at the inquest, and the experience of the physician's assistant as a dispenser.

The Secretary called attention to the report, published in the *Lancet* of 14th January, of Dr. Lankester upon the inquests held in Great Britain in 1868–69 upon suicidal cases, and thought regulations for the storing of poisons by chemists could not prevent such cases of poisoning as those mentioned.

Mr. Thomas F. Abrahams stated that the results of Mr. Mason's experiments, as detailed by him in his paper, read at the last meeting, induced him to make a few experiments, which he described.

The first trial was with some of Liebreich's chloral. The percentage of chloroform produced was by weight 71.

The second was with some of the crystal chloral (Sample No. 5). The quantity of chloroform produced was so small that he did not estimate it.

The third was with the *same* chloral (crystal), and the quantity of chloroform produced was by weight about 70 per cent.

The fourth trial was made with samples of Liebreich's and the crystals simultaneously. The same quantities were used. The tubes were of about the same diameter (possibly a matter of some importance), and were placed in the same jug at the same time.

The quantities of chloroform produced were, as nearly as possible, identical, viz. 70 to 71 per cent. by weight.

The chloroform layer from Liebreich's chloral deposited a white crystalline mass. That from the crystals did not deposit, but was more deeply coloured.

The conclusions he drew from these experiments were, that the crystal chloral, as far as this mode of testing shows, is quite equal to Liebreich's, and that the instructions given by Mr. Umney are insufficient, in that they do not prescribe the temperature of the water into which the tubes are to be plunged.

He intended, however, to make a further trial, and use more care in the manipulation.

A discussion followed, in which Messrs. Davies, Abraham, and the Secretary took part.

Mr. Alexander Fraser read an interesting and practical paper, giving the results of his experiments with some officinal and non-officinal remedies, concentrated infusions, etc. He condemned the practice of those who would, by *private judgment*, substitute cheaper medicines for officinal ones; and illustrated several common instances where this is done.

A short discussion followed.

A vote of thanks was passed to the author, and the members adjourned.

BRADFORD CHEMISTS' ASSOCIATION.

The Annual Meeting was held at the Freemasons' Rooms, Salem Street, on Tuesday evening, January 24th; Mr. M. Rogerson, the President, in the chair.

The Secretary, Mr. H. G. Rogerson, gave the Report:—

"The present meeting signalizes the close of the second year of the Society's existence, a year which, though not one of marked activity, can nevertheless scarcely be said to have been barren of desirable results. The roll of the Society's members shows, unfortunately, a decrease in their numbers, four having resigned, and there being no counterbalance to their loss in newly-acquired members. That of the Associates, from removal from town and other inevitable causes, gives a defection as compared with last year of thirteen, but the accession of nine new Associates goes far to compensate for their loss.

"The Preliminary Examination of the Pharmaceutical Society has been passed by five of the students, the Modified by two, and the Minor and Major each by one.

"During the year a course of lectures on botany was delivered by Mr. Louis Miall, the attendance at which, though at first satisfactory, fell off materially before the termination of the series.

"The Council determined in October last to discontinue the employment of a *special* lecturer on chemistry, and to lighten their expenditure by transferring the students to the chemistry class of the Philosophical Society, a course upon which they may be congratulated, since from some influence or other the number attending that class has dwindled down to eleven.

"In April last the Society was instrumental in recording the objections held by the chemists of Bradford, in common with those of most other towns, against the regulations for the storing of poisons then proposed to be submitted for the sanction of the Legislature.

"A sum of £16. 7*s.* 6*d.* was subscribed through the Society's agency in October last for the relief of the sick and wounded in war.

"Dr. Parkinson was the Society's delegate at the recent Pharmaceutical Conference,—Mr. Rimmington, nominated as his colleague, being unable to attend that assembly.

"It is hoped that the present year may witness a larger attendance at the general meetings than heretofore, there being many manifest advantages, apart from the actual transaction of business, in frequent gatherings of members of the trade. For may not such meetings tend to smooth down prejudices, and prove a potent means of causing sentiments of friendship and brotherhood to supersede the feelings of petty rivalry that undeniably have too often had a cherished existence."

The Report having been adopted, the following officers of the Society were elected:—*President:* Mr. F. M. Rimmington. *Vice-President:* Mr. Joseph Hick. *Treasurer:* Mr. Thomas Harrison. *Secretary:* Mr. W. Newsholme *Council:* Messrs. Bell, Cockshot, Parkinson, Ph.D. Whitehouse.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Eighth Meeting of the Session was held in Anderson's University, on Wednesday evening last, the 25th January; Mr. T. Davison, President, in the chair. The large hall was filled in every part.

Messrs. Thomas Hart (Govan), John Dunlop, W. Halley, A. Miller, and M'Donald were elected members.

Mr. J. Fergus Wilson afterwards brought forward the motion of which he had previously given notice, on "Early Closing."

Mr. Fairlie seconded the motion, on the condition that the appointment of the committee be postponed till after the festival, which was unanimously agreed to.

Dr. Moffatt made some remarks on the properties and uses of the new antiseptic, "Chlor-alum," which were highly appreciated by the members.

Mr. W. Crocket was appointed Treasurer in room of Mr. Cassells, who has been obliged to leave the city.

The discussion on the proposed poison regulations, which was adjourned at last meeting, was then proceeded with.

The President read a copy of a letter he had sent to the Medical Department of the Privy Council, with the reply from Mr. Simon, of which the following are copies:—

"71, *St. Vincent Street, Glasgow*,
"16*th January*, 1871.

"Sir,—As President of the Glasgow Chemists and Druggists' Association, permit me to direct the attention of the Right Hon. the Lords of her Majesty's Privy Council as to the keeping, dispensing and selling poisons.

"Glasgow, with a population of over 500,000 inhabitants, has about sixty pharmaceutical chemists and chemists and druggists, and about 120 physicians and surgeons, who keep open shop for the retailing, dispensing, and compounding of poisons.

"The proposed regulations for the keeping of poisons will *only* apply to the sixty pharmaceutical chemists and chemists and druggists, the 120 physicians and surgeons who keep open shop being exempt from the operation of the Pharmacy Act, 1868, by the Amended Act, 11th August, 1869.

"As the regulations for keeping, dispensing, and selling of poisons are required for the protection of the public, may I hereby suggest that the Right Hon. the Lords of her Majesty's Privy Council co-operate with the Council of the Pharmaceutical Society, and obtain a Bill that will *include* under the Pharmacy Act physicians, surgeons, hospital infirmaries, dispensaries, and *all* who keep open shop for the selling, dispensing and compounding of poisons.

"The opposition to compulsory regulations by chemists and druggists throughout the country is almost entirely owing to the liberty granted to physicians, etc., who keep open shop to act as they think proper.

"I am, Sir,
"Your obedient servant,
"Thomas Davison.

"John Simon, Esq., F.R.S., D.C.L.,
"*Medical Department, Privy Council Office*,
"8, *Richmond Terrace, Whitehall, S.W.*"

(Reply):—

"Medical Department of the Privy Council Office,
"*January 24th*, 1871.

"Sir,

"I am directed by the Lords of her Majesty's Council to acknowledge the receipt of your letter suggesting the propriety of extending the operation of the Pharmacy Act, so far as concerns regulations to be made under it as to the keeping, selling, etc. of poisons to physicians, surgeons and others, who keep open shop for the sale and dispensing of poisons.

"My Lords direct me to say that should an opportunity occur for such legislation as you propose, your suggestion shall have the most careful consideration.

"I am, Sir,
"Your obedient Servant,
"John Simon.

"T. Davison, Esq.
"71, St. Vincent Street,
"Glasgow."

The President, after reading the letters, said he would leave it to the members to decide what further steps should be taken.

Mr. John M'Millan said he thought from the tone of Mr. Simon's reply, the Privy Council were not going to be so pressing in their demands for regulations as was at first anticipated; he thought it was a few of the members of the Pharmaceutical Society who were anxious that some action should be taken in the matter, but he said it was unjust to make the regulations compulsory upon chemists who, in the great majority of cases, gave their whole attention to business, while physicians and others who had shops, and who gave little or no attention to the dispensing part of their business, should be entirely exempt. It had always been his opinion that surgeons who had shops would be exempt from the regulations, although some chemists maintained the contrary, and the fact that no reference was made to that point in Mr. Simon's letter, he thought confirmed his opinions. He would advocate that the regulations in their present form be opposed.

Mr. Kermath said he looked upon the whole affair as a good farce. How were the regulations to be made compulsory? There has been no mention of how they were to be enforced, whether by the aid of inspectors, or if that duty was to devolve upon the local secretaries; and further, was there to be a punishment or fine put upon those who did not comply with them? These are things which ought to be inquired into, and until they were satisfactorily cleared up, all compulsory regulations opposed. For his own part he took every precaution, having Silverlock's label attached to every poison in his establishment, and he kept the more dangerous poisons at the back of other bottles on a high shelf where it was impossible for an assistant to reach them without knowing what he was about; and from what he had seen among the chemists of Scotland, there was far more care taken with poisons by them, than by many physicians who had shops, and who left them from day to day in the hands of youths or girls.

Mr. Paterson said he thought the regulations should be opposed in their present form, but the memorial should be got up in a different manner from the one sent up to the Council last year. He thought it did not receive the attention it would have got had it emanated from the whole trade instead of from the Association only; he therefore suggested that if a memorial be drawn up, an opportunity be given to all chemists in and around Glasgow to sign it for themselves.

After several other members had expressed their opinion, Mr. J. M. Fairlie (Hon. Secretary) moved "That a committee be appointed to draw up a strong memorial against the regulations in their present form, together with a statement of objections, to be presented to the Council of the Pharmaceutical Society at their Annual Meeting in May next, and that an opportunity be given to all chemists wishing to sign the memorial before that time."

Mr. Fairlie said that the great argument in favour of the regulations was, that they were for the protection of the public; but if so, why are chemists and druggists *only* required to adopt them? Some say, "Why do chemists wish to interfere with medical men? We have nothing to do with them; we have only to regulate our own affairs." This is all very true; I do not think there is a druggist in the kingdom who would interfere with a medical man in the performance of his professional duties; what we want is that when a medical man becomes a druggist, when he opens a shop for the sale and compounding of drugs, that he shall be under the same restrictions as ourselves. There is no unbiassed medical practitioner who keeps open shop that could object to being put upon the same footing, in this respect, as the druggist; and it seems to me to be the fault of the Council of the Pharmaceutical Society that they have not asked the co-operation of the medical department of Her Majesty's Council to get the regulations made so as to put all who keep open shop for the dispensing of medicines in the same position. Mr. Simon's reply says, that "should an opportunity occur," etc. I think we ought to do all we can to put the opportunity in their way, by getting the regulations rejected in May next. There are to be no voting-papers allowed; but if every association or every town in the kingdom would endeavour to send up one or two members, there would be no doubt the *Lancet's* hope, that we should be in a minority, would be reversed. The responsibility will then lie with the Privy Council, or probably with Parliament itself, and there is no doubt but that we shall receive every justice at the hands of the representatives of the people.

Mr. J. F. Wilson asked if medical men who had shops would be allowed to sign the memorial, as he was sure that the medical gentlemen whom he believed he represented would gladly do so.

The President stated there could be no objection to him signing it as a druggist, as the memorial was expected to come from druggists only.

Mr. M'Millan seconded the motion, which was unanimously agreed to, and an influential committee afterwards appointed to carry it out.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of Executive Committee.

February 1st, 1871.

Distribution of the Year-Book for 1870.—The Secretaries reported that early copies of the Year-Book had been sent for review to the Pharmaceutical Journal and *Chemist and Druggist* on the 12th of January, and that since that date books had been issued to members as fast as parcels had come in from the binders. The whole of the edition (2000) had not yet been received, the printers expressing their "regret that the volumes had not been completed more rapidly;" sufficient, however, had come to hand to enable the secretaries to post the last batch of orders for delivery to the publishers on January 31st. The local secretaries of the Conference had kindly undertaken to deliver members' copies in the respective towns and districts, and the London wholesale houses had courteously accepted secretaries' parcels for enclosure; still delay on the part of the binders, and the difficulty of getting in all the subscriptions, had caused much inconvenience. The Secretaries were instructed to make direct application for subscriptions in September this year and in future, and to take steps for obtaining an increased number of members, with the especial object of securing sufficient funds to admit of the next annual volume being sent post-free direct to every subscriber.

A Year-Book for 1871.—The Secretaries stated that the financial position of the Conference was such as to warrant the executive in providing for the production of a Year-Book for 1871. A resolution was thereupon proposed by Mr. Carteighe, seconded by Mr. Williams, and carried,—

"That the Committee of Publication be instructed to make arrangements for the issue of a Year-Book of Pharmacy for 1871."

Appointment of Editor.—Three applications for the Editorship having been read, and ballots taken, the Chairman announced that Mr. C. H. Wood was the successful candidate. The following resolution was passed:—

"That Mr. Charles H. Wood, F.C.S., be now elected Editor of the Year-Book of Pharmacy. That the manuscript of the Year-Book be placed in the hands of the Committee on or before July 31st, 1871."

Presentation Copies of the Year-Book.—Daniel Hanbury, F.R.S., and Professor Attfield were appointed a Sub-Committee to revise the list of persons, presented with gratis copies of the publications of the Conference.

Recognition of the Labours of Mr. Joseph Ince, Vice-President of the Conference.—Proposed by Mr. Hanbury, seconded by Mr. Matthews, and carried unanimously,—

"That the cordial thanks of the Executive Committee of the British Pharmaceutical Conference be conveyed to Mr. Joseph Ince for his valuable services in editing, at a very brief notice and at much personal inconvenience, the Year-Book of Pharmacy for 1870."

Election of Members.—Several new members were elected, a list of whom will be given next week.

Candidates for Membership.—Gentlemen sending in their names to the London Secretary, Professor Attfield, 17, Bloomsbury Square, W.C., and enclosing the subscription, 5*s.*, and 7½*d.* for postage (in stamps, or Post-Office Order, payable to John Attfield at the Bloomsbury Office), will receive by return of post a copy of the Year-Book.

ROYAL INSTITUTION.

On Friday evening, January 20, Professor Tyndall delivered a lecture at the Royal Institution upon the "Scattering of Light," which was, in point of fact, a discourse upon domestic water supply. The Professor commenced by exhibiting the impurities of London air, the motes of a sunbeam, by the light of the electric lamp, and explained to his audience that what they saw was not air, but suspended particles, capable of being dissipated or removed, and that, when so removed, the track of the beam through the air itself would be invisible. He next related that he had accompanied the eclipse expedition to Oran, and that on his return, having been disappointed as regards the special object of his journey, he had sought to turn his opportunities to account by investigating the causes of the varying tints presented by sea water. After paying a warm tribute to the zeal and kindliness with which his wishes had been furthered by the captain and officers of Her Majesty's ship 'Urgent,' he described the way in which a series of nineteen bottles had been filled between Gibraltar and Spithead, and the results of an examination of them by the electric light. The bottles were themselves on the table, but were not placed in the beam before the audience, since the original differences among them had been diminished by subsidence. The general tendency of the examination was to show that the yellowish water of coasts and harbours held in suspension a large quantity of particles; that the particles in the green water were less abundant and in finer division; and that the blue water of the deep ocean was comparatively free. Professor Tyndall explained the blue or even blue-black of the depths, by displaying the prismatic spectrum on the screen, and by quenching it, at first partially and with regard to certain colours, and afterwards absolutely, by a succession of cells of increasing thickness, containing a solution of permanganate of potash, or of sulphate of copper. He said that when a beam of light entered the sea, the heat rays were absorbed by the surface, the red rays by a very superficial layer of water, the green rays next, and ultimately the blue. If, however, the light encountered particles, these would reflect the green rays to an observer; while, in the absence of particles, the green rays would continue their course till they were wholly quenched. Water of great depth and absolute purity would thus appear entirely black, like a sea of ink, and would reflect no light beyond a glimmer from its surface. The Professor exhibited a white dinner-plate, to which a rope was attached, and which he was in the habit of having cast overboard and towed from the 'Urgent,' and which always appeared green, and he also described the appearances seen on looking down the screw-well of the ship, where the water was seen by turns green—with the screw-blades as a background—and then dark blue, with the ocean depths for a background. The white plate, which appeared as a green object when towed under water, would, he said, if ground to powder and scattered cause the portion in which this powder was suspended to return a general green reflection. Having in this way established that the visibility of the track of a beam through water depended upon particles by which the light was reflected, Professor Tyndall next placed before the electric lamp a succession of nine bottles, containing samples of the water supplied to their customers by the various London water companies. The turbidity revealed was in every case sufficient to make the audience regard water as a very undesirable beverage. That of the Lambeth Company displayed pre-eminence of a bad kind; that of the Kent Company was by far the clearest; the West Middlesex Company stood second in order of merit, and among the rest there was little to choose. With a reticence more eloquent than words, the lecturer avoided expressing opinions about the dirt that he exhibited; and he also expressly mentioned that pellucidity was no proof of the absence of soluble impurities. He also showed that to cleanse water from suspended dirt was a very difficult matter; and exhibited four specimens of distilled water, a specimen once filtered by Mr. Lipscombe, a specimen that had gone through a silicated carbon filter, and a specimen four times filtered through bibulous paper in the Royal Institution Laboratory. These were clear when compared with the water of the companies, but the track of the beam was plainly visible in all. A specimen of water from the Lake of Geneva was then exhibited in illustration of great natural purity, and here a faint blue line only could be seen. This brought Professor Tyndall to the practical conclusion at which he had been aiming, namely, to an account of the water supply yielded by the English chalk formations. He characterized this as being of the greatest attainable purity, inexhaustible in quantity, and easily accessible for the supply of the Metropolis. He described its natural hardness as being such as to render it unfit for domestic use, but explained that by Clark's process this hardness could be entirely removed at the central works, and that the water might be delivered in London at a uniform temperature, free from organic impurity or suspended particles, and so soft as to be perfectly adapted for all household purposes. He described Clark's process, and illustrated it before the audience, and finally showed actual results by producing a bottle of water from Canterbury, derived from the chalk, and softened in the manner described. By the side of this was a similar bottle containing the water supplied to the Institution, and the two were illuminated together by way of contrast. The difference was like that between pea-soup and crystal. Professor Tyndall then read a portion of the report made some years ago by the late Professors Graham and Miller, and by Professor Hofmann, upon the admirable qualities of this chalk-water, when artificially softened, upon its fitness for the supply of the Metropolis, and upon the impolicy of allowing it to pass into private hands, and concluded by saying that every word that he had read he desired fully and cordially to endorse.—*Times.*

PHILADELPHIA COLLEGE OF PHARMACY.

A special meeting of the College was held on Monday, Dec. 5, to receive the report of the Committee appointed to consider the business interests of the *American Journal of Pharmacy.* The following recommendations of the Committee were, after consideration, adopted (1) That the business pertaining to the journal shall be transacted at the College building; (2) that the journal shall be published monthly; (3) that a business editor be appointed to attend to the advertisements, the distribution and the accounts; and (4) that the treasurer of the publishing committee be authorized to draw on the treasurer of the College for the prime cost of the journals supplied to members.

On Tuesday, Dec. 27, the ordinary meeting of the College was held. The following communication was read:—

TO THE PHILADELPHIA COLLEGE OF PHARMACY.

Fellow Members,—It is now thirty-four years since my connection with the *American Journal of Pharmacy* as a contributor commenced, and about twenty-five years as co-editor and editor.

During this period time and labour have been freely given to make the work a continuous record of the progress of pharmacy at home and abroad. For many years it was a labour of love, and despite the great sacrifice of time occasioned by contributing to its pages, the labour was cheerfully given. Of latter years a change has occurred in this respect: the work has been continued regularly as a matter of duty, but it has ceased to be a pleasure. Under these circumstances, I desire to carry out an intention entertained for several years, and withdraw from the editorship.

In order to give the College time to select a successor, I have deemed it best to offer this my resignation at this meeting, to take effect at the annual meeting in March, when the stated time for electing an editor arrives.

Meanwhile every effort will be made to introduce the new order of things adopted at the special meeting of the present month, and to start the journal as a monthly in its three first numbers, hoping that the College will then be ready to release me from further duty.

I need hardly say that it has required some effort on my part to thus voluntarily resign a position fraught with so many pleasant memories, and which has brought me in contact with a large number of professional brethren beyond the pale of our College, yet after deliberate consideration I believe duty to myself requires the step to be taken, not doubting that under the auspices of a new editor the Publishing Committee will be able to report a flourishing condition of the journal at the end of the coming year.

Respectfully,

December 27th, 1870. WILLIAM PROCTOR, Jun.

The resignation of Mr. Proctor caused great regret among the members. A Committee was appointed to report to the next meeting the name of a suitable person to succeed him in the office of editor.

Frames for the engraving of Jacob Bell and the photograph of the Plough Court Laboratory, received from Mr. Daniel Hanbury, were presented by Mr. W. Procter, jun.

MEETINGS FOR THE ENSUING WEEK.

MONDAY ......*Medical Society*, at 8 P.M.
London Institution, at 4 P.M.—"The First Principles of Biology" (Educational Course). By Prof. Huxley.

TUESDAY ......*Royal Institution*, at 3 P.M.—"The Nutrition of Animals." By Professor Foster.

WEDNESDAY ...*Society of Arts*, at 8 P.M.—"Ornamentation considered as a 'High Art.'" By Dr. Christopher Dresser.
Microscopical Society, at 8 P.M.

THURSDAY......*Royal Society*, at 8.30 P.M.
Royal Institution, at 3 P.M.—"Davy's Discoveries in Chemistry." By Professor Odling.
London Institution, at 7.30 P.M.—"The Action, Nature and Detection of Poisons." By F. S. Barff.
London Chemists' Association, at 9.30 P.M.—"Remarks on Structural Botany." By J. H. Jessop.

FRIDAY ....*Royal Institution*, at 9 P.M.—"Fallacies connected with Ships and Guns." By E. J. Reed.
Quekett Club, at 8 P.M.

SATURDAY......*Royal Botanic Society*, at 3.45 P.M.

The following journals have been received:—The 'British Medical Journal,' Jan. 28; the 'Medical Times and Gazette,' Jan. 28; the 'Lancet,' Jan. 28; the 'Medical Press and Circular,' Feb. 1; 'Nature,' Jan. 26; the 'Chemical News,' Jan. 27; 'Journal of the Society of Arts,' Jan. 26; 'Gardeners' Chronicle,' Jan. 28; the 'Grocer,' Jan. 28; the 'Produce Markets Review,' Jan. 28; the 'English Mechanic,' Jan. 27; the 'American Journal of Pharmacy' for January; the 'Western Gazette,' Jan. 27; the 'Macclesfield Courier,' Jan. 28.

Parliamentary and Law Proceedings.

THE BETTS SUITS.

LORD CHANCELLOR'S COURT, 30*th January*, 1871.

Betts *v.* Willmott.

This was an appeal by the plaintiff against a decree dismissing his bill with costs, made by the Vice-Chancellor James, on the 28th June, 1870, reported in the PHARMACEUTICAL JOURNAL, 3rd series, Vol. I. p. 32.

The plaintiff had, by an order of the Lord Chancellor dated 3rd August, 1870, become bound in the suits *Betts* v. *Potts*, v. *Cleaver*, v. *Field*, v. *Brooks*, v. *Foster*, v. *Pratt*, v. *Stevenson*, v. *Smith*, v. *Hall*, v. *Hart*, v. *Ellis*, v. *Warin*, v. *Cooper* and v. *Preston* to abide the result of the appeal in *Betts* v. *Willmott*.

Mr. Willcock, Q.C., Mr. Grove, Q.C., and Mr. Everitt appeared in support of the appeal—Mr. Kay, Q.C., Mr. Eddis, Q.C., and Mr. Langley, for the respondent.

The LORD CHANCELLOR, at the close of the appellant's case, and without calling upon the respondent's counsel, delivered judgment.

Mr. Kay, I think, not having heard you, the case has been established by Mr. Betts, upon whom the *onus* is thrown, that you are making an indirect use of his invention, but he is bound to prove two things, one of which, it appears to me (not having heard your argument upon it), he has proved, namely, that there is a use of his invention. But the question is, whether it is an unauthorized use. It appears to me, the *onus* being thrown on Mr. Betts to prove that he has not discharged himself of it, he has to show that this thing you are using is not manufactured by him. That he attempted to do, in the first instance, by an affidavit in which he says it has not his private mark.

Mr. Kay.—He does not even swear that, my Lord.

The Lord Chancellor.—I took that rather from the Vice-Chancellor's judgment. Therefore he says, *primá facie*, "I did not make this," but what turns out upon cross-examination is this. He says, when cross-examined, that he is not only the manufacturer of this article in England, but that it is manufactured abroad by him in two different manufactories. It appears he bought up, at Paris, a business where the article was manufactured in the name of Espinasse, and he continued afterwards to carry on the business there, through the medium of Espinasse, who was acting as his paid agent, and therefore, for all purposes, Espinasse is the plaintiff in the suit. Being cross-examined further as to what is the actual condition of the thing so manufactured by him, and having made the admission that there is a manufacture of this article in Paris, he thus continues in his cross-examination, "I cannot answer whether the capsules A. B. and C., mentioned in the same affidavit, are or have ever been in my possession. If they are, my solicitor has them. I cannot now produce the Exhibit numbered 210. The eleven bottles now produced and marked as Exhibits 263, 201," (and a number of others) "are the several bottles I rely on in eleven of my several suits. I don't know whether the Exhibit No. 210, did or not correspond, in external appearance, with these eleven. The exhibits numbered 204 and 207 being infringements, I have no doubt No. 210 did correspond, in external appearance, with them, but I cannot compare them with a thing which is not present. After examining the capsules on the eleven Exhibits, and those on the Exhibits numbered respectively 211 and 401, I cannot say by whom those capsules were manufactured." Then he is asked, "Will you pledge your oath whether those capsules were or not manufactured by your house of Espinasse?" Answer, "I believe they are infringements, and that they are not of the house of Espinasse. I found this my belief on this, that Rimmel's dies, in Paris, do not correspond, as I have been informed, with the stampings on those, but I will not swear that they do not correspond exactly." Then a little lower down he says this, "I do not know whether it is the fact that Dupré's capsules supplied to Rimmel bore Dupré's name upon them," and at line 52, he says, "I will not swear that each of the capsules on the eleven Exhibits, and on those numbered 211 and 401, was not made by my house of Espinasse, or that they were not sold and delivered by that house to Eugene Rimmel." That is the part which, to my mind, creates the great difficulty in the plaintiff's case. Unluckily 210 itself has been lost, but we cannot help that, and we cannot, therefore, deal with that specially. He will not pledge himself to say that there is any real distinction between 210 and the others which are exhibited. As to those others which are made Exhibits, he says, "I have sworn that they were not manufactured by me, but I will not take upon myself to say that they were not manufactured by my house in Paris, or were not sold by that house to Rimmel."

That being so, the onus, I apprehend, being on the plaintiff to show that not merely is the thing made his own patented article, but that it has been unlawfully sold, he must be prepared to swear distinctly that it is not manufactured by him or his agents. Take this case. Supposing he had three houses of manufacture,—one in the north of England, one in the west of England, and one in London. I apprehend it would be his duty in making out his case before a jury to come forward and prove not only by his London agent that the article was of the same description as the patented article, but he would have to show it was not made by himself; and, for that purpose, he would have to call persons who had the control of his house in the north, also of his house in London, and also of his house in the west, to prove that no such articles were made by them. As things of a similar description are sold by millions, and are sold for the purpose of being distributed in every shop throughout the whole length and breadth of the land, it would be extremely improbable—not impossible, but a matter of considerable difficulty—for the persons who, from time to time, purchased not the capsules themselves but the bottles covered with the capsules, not being buyers of capsules wholesale, but purchasers as part of their stock in trade of a variety of bottles at a time, sometimes one bottle of one article, and sometimes twenty bottles of another article,—it would be impossible for them to go round to the whole trade and trace these bottles through the variety of persons into whose possession they might have got, in order to show that they could be traced up to the plaintiff's manufactory, without the Court in the least requiring it in the first instance; there should be the plaintiff's oath. If he takes that oath, and throws the onus on the defendants, they must meet it as best they may, but the oath of the plaintiff would be required to show that he had not manufactured that thing which had got into the hands of the particular defendant who is brought before the Court. This plaintiff discharged that duty in the first instance by saying, "I did not manufacture that particular thing;" but on cross-examination he says, "when I made that affidavit I did not intend to describe it in that way as not having come out of my manufactory in France, and I will not swear that now." The Vice-Chancellor's observations are certainly somewhat strong upon this gentleman, and I do not know quite that I should myself make the same strong observations, because the gentleman may possibly have had in his mind that view of the law which has been submitted by his counsel; and I quite agree with Mr. Grove that an argument might have been presented on that point, although I do not remember such a point having been brought before the Court before, or that the circumstances ever occurred which could give rise to such an argument; the point is this—supposing a man to have a patent in France and a patent in Belgium and a patent in England, and he establishes manufactories in each place for the manufacture of his patented article, then it is said that if he sells the patented article in France, it is for the French market, and it does not justify a person buying the article in France and bringing it over to England, and he cannot be allowed to use that article so made in France in England. Then Mr. Grove put the case of his having assigned his English patent (sold it to somebody), and continuing the manufacture in France, and said, would not the importer of any article sold in France come within the doctrine of *Caldwell* v. *Vanvlissingen?*

No doubt in the case so put he would, because the licence to sell, which vested originally in the patentee, would then be vested in his assignee, and therefore no licence in England given by the original patentee after a sale could authorize the making of the article; so of course, in exactly the same way, no sale at all by the original patentee in France, who is also the original patentee in England, could defeat the rights of the original patentee in England, or defeat the rights of a person purchasing from him in France. In other words, it comes almost within the doctrine of leave and licence, and leave and licence would not be effectual in such a case; and is it any more effectual in the other case, where a man carries on the three manufactories himself, and himself disposes of the article abroad? I apprehend if he disposes of the article abroad, unless it can be shown, not that there is some clear injunction to his agents or the like, but that there is some clear communication to the party to whom the article is sold, the person who has the sole right of vending in England, if he chooses to sell the goods in France, or Belgium, or England, or in any other quarter of the globe, the persons who purchase of him transfers with the goods necessarily the licence to use the goods which he has so sold. When a man has purchased an article he intends to have the control of it, and there must be some clear and explicit agreement to the contrary proved as against the purchaser of the article to justify the vendor in saying, I have not given you my licence for the sale of the article. He cannot prevent the purchaser using it wherever he pleases as against the person with regard to whom he is entitled to use it. He cannot use it against his assignee without a previous assignment of the patent, because no previous assignment of the patent would confer that right; but he can use it against the person who himself is the owner and proprietor, and has the power of conferring a complete right on him by the sale of the article. If this gentleman is unable to show that these things which he charges the defendant with having used are not used unlawfully,—if he cannot show that to be the case, I apprehend that, without establishing that he has not himself sold the very article the use of which he now seeks to prohibit, he cannot succeed by way of injunction in this Court any more than he would in an action at law. Therefore on that ground, although I do not quite follow the reasoning of the Vice-Chancellor on the subject, the decision being right, the petition of appeal will have to be dismissed with costs.

Deaths Supposed to Result from Excessive Doses of Chloral Hydrate.

An inquest has been held at South Petherton to inquire into the circumstances attending the death of Mrs. Masters, the wife of the Rev. J. P. Masters.

It appeared from the evidence that the deceased had for seven years suffered from violent hysterical attacks, for which she had at one time been recommended the use of stimulants. In consequence, however, of their effect upon her, under the advice of Dr. Norris these had been given up, and that gentleman prescribed for her draughts containing 30 to 40 grains of chloral. This offended Mrs. Masters very much, and eventually she went to consult Mr. Sanders, chemist, of Ilminster.

In his evidence Mr. Sanders said he was asked by Mr. Masters to prescribe for deceased when she would not take the draughts which Mr. Norris sent her. He did so, and, knowing of a similar case at Ilminster, in which chloral was used by Dr. Mules with success, put up draughts for her, containing 30 to 36 grains of that medicine. He had been told by Mr. Masters that she could not bear any preparation of opium. He had made up these draughts within the last two or three months. He had put up, perhaps, four-and-twenty. He understood that deceased did not take these draughts at the same time that she was taking those of Dr. Norris.

Occasionally deceased would take Mr. Sanders's draughts in the morning instead of at night. As she became very fond of the draughts, they were carefully guarded. This greatly excited her, and she insisted upon having them, and occasionally would take one of Mr. Sanders's draughts after taking one of Dr. Norris's. On Tuesday, the 8th January, upon going to bed she took one of Dr. Norris's draughts. About midnight she awoke, and asked for another. At first it was refused, but she became so violent that it was given to pacify her. She afterwards had a third, which caused sickness, and a fourth. On Wednesday she had three more, followed by much sickness; and on the Thursday morning, her husband, having left her for a short time, found her dead upon his return. As Dr. Norris said that he could not state positively the cause of death, a *post-mortem* examination was ordered.

Upon the resumption of the inquiry, Dr. Norris read a report of an analysis of the stomach and other portions of the body, made by Mr. Stoddart, chemist, of Bristol. Mr. Stoddart commented on the fact that decomposition had not taken place, although more than a week had elapsed since death. This he attributed to the effects of chloroform, a small quantity of which he found in the tissues. Dr. Norris said he commenced giving Mrs. Masters chloral in the summer of 1870, after ascertaining that various other sedatives did not suit her. The draughts he gave consisted of 40 grains. He had administered chloral extensively for two years past. If sufficient time was allowed for it to pass off it could not do any harm, as it did not remain in the system. On Monday, 9th instant, he sent Mrs. Masters a mixture of six doses, each dose of which contained 10 grains of chloral. If given in small quantities, chloral eased pain but did not induce sleep. According to the evidence given by Mr. Masters, deceased had taken 260 grains of chloral within thirty-five hours of her death, 112 grains of which had been administered within twelve hours of death. His opinion was that on the nights of January 10th and 11th she must have taken excessive doses of chloral, which prevented any chance of rallying from the prostrating effects of excessive vomiting on the morning of her decease, and probably produced syncope, from which he believed deceased died.

The jury, after a long consultation, returned a verdict, "That the deceased died from syncope produced by excessive vomiting, of the cause of which there is not sufficient evidence to satisfy the jury."—*The Western Gazette.*

On Monday last an inquest was held at Whittlebury, Northamptonshire, to inquire into the death of the Rev. L. Froome, rector of that village. The deceased had gone to bed on the previous Thursday evening apparently in good health and spirits, and on the following morning had been found dead in his bed. He had been accustomed for some time past to take opiates in consequence of suffering from sleeplessness. Latterly he had used chloral hydrate. It appeared from the evidence that he had taken an overdose of this drug, which had resulted in his death. The jury returned a verdict, "That the deceased came by his death by inadvertently taking too large a dose of a medicine called chloral hydrate.—*Times.*

[128.]—AMANDINE.—In answer to *J. P.* the following recipe for amandine is furnished by "*Rusticus*:"—

Bitter Almonds (blanched), 4 oz.

Beat them in a mortar, with a small quantity of water, to a smooth paste and add—

Orris Root, in fine powder,
Soap, in fine powder, each 1 oz.
Glycerole of Starch, 2 oz.
Clarified Honey, 1 oz.
Oil of Bitter Almonds, 5 drops
Oil of Lavender, ½ fl. drm.
Oil of Bergamot, 1 fl. drm.
Tincture of Cochineal, *q. s.* to colour.

Mix.

Blanch 12 oz. of bitter almonds and beat them in a mortar with a small quantity of rose or other water to a smooth paste; then add 7 oz. of rice flour, 3 oz. of bean flour, 1 oz. of orris powder, and when perfectly mixed, ½ oz. of carbonate of potash, dissolved in rose water; again beat together and add 3 oz. of spirituous essence of jessamine, 2 drops of oil of rhodium and one of neroli.—BEASLEY.

Take of Fine Pale Honey (or strong syrup) 4 oz.
White Soft Soap made from Lard and Potash, 2 oz.

Mix them thoroughly in a Wedgwood mortar, adding, if necessary, two or three teaspoonfuls of solution of potash, so as to produce a thoroughly homogeneous paste.

To this add and rub in by degrees and very gradually,—

Oil of Almonds 3½ lbs.
Previously mixed and scented with
Essential Oil of Almonds,
Essence of Bergamot, of each, 3 drms.
Oil of Cloves,
Balsam of Peru, of each, 1½ drm.,

and continue the trituration until the whole assumes the appearance of a rich transparent jelly. Finally, put the paste into pots or wide-mouthed bottles.

[*Note.*—The balsam ought to be triturated with a little of the almond oil, warm, before adding it to the rest, and after all the scents are added, the oil should be allowed to settle for two or three days and the clear portion only used.]

In using, a lump of amandine the size of a large pea is rubbed with a few drops of warm water, and the rich white lather applied to the hands, face, neck, etc. In a short time the skin may be wiped with a soft napkin.

Amandine may be *glycerinated* by adding one ounce of the best glycerine for every pound of oil to be used.

[134.]—BEESWAX.—The ordinary process for refining crude beeswax is to melt the wax with about five per cent. of water in a bright copper or stoneware boiler. When the whole is perfectly liquid and has boiled for some minutes, oil of vitriol, in the proportion of five or six fluid ounces to every cwt. of wax, is sprinkled over the whole surface of the wax. Great care is required during this operation, as the wax froths up and will run over the sides of the vessel if not carefully watched. The wax is then covered over and left to settle until cool enough for moulding, when it is gently skimmed off with a hot ladle, care being taken not to disturb the sediment. When no more can be drawn off, the impurities (mostly bees) are scraped from its under side, and the scraped cake remelted and strained through canvas into a mould. When wax has a poor colour it is sometimes improved by dissolving a small quantity of roll annatto in the melted wax, according to the shade required.—COOLEY.

Storage of Poisons.

Sir,—I am not surprised at the number of letters you continue to receive upon this subject, for it is one of the utmost importance, and our conduct in this matter will undoubtedly have very great influence upon our future status and welfare.

In the letter from the Medical Department of the Privy Council to the Registrar, there occurs this passage, "My Lords believe it to have been the opinion of Parliament that proper regulations in this matter are required for the protection of the public." These are serious and weighty words, and the whole tendency of modern legislation on matters connected with health being towards State supervision and control, there can be no doubt that before long some action will be taken in this matter, and it would be neither grateful nor wise of us to oppose it,—ungrateful because we have already received privileges in connection with this subject, and impolitic because our opposition would most assuredly be unsuccessful,—and, if compulsory enactments are to be made, it were surely better that they were framed by ourselves, acquainted with all the bearings and difficulties of the question, than to have an Act forced upon us by others comparatively ignorant of the subject.

And I would ask what are the special difficulties in the matter? What hardship can there possibly be in compelling the less careful to adopt those simple and necessary precautions which prudent pharmacists have already voluntarily established? To the skilful and careful they are no impediment, while to those who are not so, they act as a safeguard and check; even the occasional visit of an inspector, although to a certain extent unpleasant, can have no terrors for those who respect the law and carry out its provisions. Schools, workshops and factories are inspected, and any medical man who takes a lunatic patient into his house, is subjected to a monthly examination of his premises ten times more inquisitorial and unpleasant than any we shall have to endure.

After long and careful consideration of the subject, I am convinced that some compulsory regulations must be proposed by ourselves, or they will be forced upon us by the Government, and that, though there may be some difficulties, there will be also some advantages arising from State supervision and recognition.

In conclusion, I would suggest that the matter be put into the hands of a Committee of six or seven gentlemen, appointed by the Council or by a general meeting of the members convened for that purpose.

January, 1871. Frederick Andrews.

Sir,—Since the commencement of the correspondence on "The Storing of Poisons," we have been favoured with the views of many writers as to the merits and demerits of the proposed regulations, a very small majority being against compulsory legislation. Now, judging from the letters of this majority, it seems to me that their principal objection to the proposed movement is, because it is compulsory; they do not like the idea of being compelled to do now what they should have done voluntarily perhaps years ago, and strongly object to having any measure pushed down their throats as it were. I am glad to see some of your correspondents take an opposite view of the case; and one at least there is who speaks as emphatically in favour of the compulsory idea as any of the objectors do against it.

After reading this mass of correspondence, I do not feel my ideas particularly enlightened as to the demerits of regulations; and I remain much as before, impressed with the necessity, or rather desirability, of some such measure. I would suggest that it be left to the Council to recommend most strongly, and with all the force of their influence, the adoption of such a measure; and if afterwards this is found insufficient, then to make it compulsory; and when made compulsory on us, common-sense demands that it should be equally binding on dispensing surgeons, as it is in their surgeries that most of the accidents from careless dispensing take place. Indeed, so lately as the 20th of this month a case is reported in the *Liverpool Daily Courier*, where death resulted from the use of morphia instead of another drug, the medicine being compounded by a youth whose experience of the nature and properties of drugs was limited to a year and three-quarters; and had one of the precautions recommended by the Council been adopted, the child's life would in all probability have been saved. In these proposed regulations I see nothing to call forth such emphatic protests against their use. Were we tied down to any one of the three, the case would be different; but such a very wide latitude of choice is allowed, that I can hardly conceive anything but downright obstinacy refusing to adopt them. For my own part, I have used a similar plan for some years past without any inconvenience; for instance, tr. opii, ac. oxalic, with one or two others of a like class and in frequent use, are relegated to a part of the shop where there is no possibility of their being taken in mistake for others, being also marked "Poison." Atropia, strychnia and other powerful poisons are under lock and key; liq. arsenical., corrosive sublimate and arsenic occupy their usual places on the shelves, but securely capped, with a large red paper star, as well as "Poison," pasted on the bottles, so that there is no chance of danger in that quarter, while some are in octagonal and coloured bottles; so here are all three plans in use.

One consideration seems to have been lost sight of by all your correspondents. Were these regulations made on behalf of principals alone they might, to a greater extent, be thought unnecessary, as, from constant familiarity and the most moderate exercise of prudence, we are able, generally speaking, to avoid error; but most of us employ assistance in the conduct of business; some have apprentices and assistants constantly, and others as a temporary relief; and it is almost impossible that they will have the same familiarity with the arrangements of the shop, and the same prudential motives to guide them. To me it seems useless to say that the improved education of the druggist is the best safeguard; at present it is not, further than he himself is concerned. When all druggists and their assistants shall be examined pharmaceutical chemists, and when no apprentices or pupils are taken,—which, of course, is an absurdity,—then it may be. To a druggist who thinks he is being hoaxed when asked for "seed lac;" to another who confesses his ignorance as to ammonia alum, and, though he may see it daily, says he has none; and to another who advertises "oatmeal soap and all other French chemicals" (these have all come under my own notice recently),—such regulations may be needful. Taking into consideration the little inconvenience such a measure would be to ourselves,—nay, the convenience it would be, if taken in a right spirit,—and the satisfaction that would be afforded to the public mind, I intend to give it my hearty support.

T. H. Hustwick.

Liverpool, January 25th, 1871.

[*** We do not suppose our correspondent is singular in practising some such precautions as those he mentions; indeed, we should rather expect to find them adopted, according to circumstances, in all well-regulated establishments, and by all pharmacists who have received an education such as would ensure their competency and a due sense of their responsibilities.—Ed. Pharm. Journ.]

Sir,—I have read with pleasure the correspondence which has been going on in your columns for some time respecting the "compulsory" keeping of poisons. It is very creditable that it has been conducted in so fair a manner. Some of the letters have been very ably written, and all of them have shown that the writers are really in earnest. On calmly reviewing the correspondence, I think it must be confessed that the opponents of compulsion have the best of it; *cui bono*, I would ask? I cannot see that its advocates have yet advanced sufficient reason for compulsion. What are the facts? How many deaths have occurred through the carelessness of chemists during the last twelve months or during even the last twelve years? Of the few accidental poisonings which have occurred, the majority have been caused by medical men who dispense, or rather send out their own medicine. I cannot but think that the "protection of the public, like many other cries of the present day, has been pushed a little too far and become stale.

The general public have become so familiarized with that awful word "Poison," that already it has lost more than half its power as a caution. There never was a greater mistake than compelling us to mark "Poison" on such articles as paregoric, syr. poppies, infants' preservative, *et id genus omne.* The Committee of Pharmacy have attempted too much, and have defeated their object,—" the safety of the public." One is reminded of Shakspeare's

"Vaulting ambition, which overleaps itself,
And falls on t'other side."

Personally I am decidedly opposed to any compulsion whatever. We have quite enough with the patent medicine licence, spirit licence, methylated-spirit licence and petroleum licence without inviting a set of inspectors to visit us at unseasonable hours. I am vain enough to think that I can manage my own business without the intervention of the Council, and charitable enough to suppose that the great majority of my brethren can do the same. Few have been connected with the Society longer than I have; and no one has a greater respect for the Council, several of whom are personally known to me. I have always been taught to respect those who are "set in authority over us," and know the truth and value of what Mr. Bagnet says, viz. that "discipline must be maintained;" still there is a limit beyond which it would be unwise to proceed, and I would advise the Council to pause in time. Let them ascertain the real feeling of the members by sending out voting-papers to every Pharmaceutical Chemist in the kingdom. I shall be perfectly content to abide by the result, whatever it may be; but I do not feel inclined to put myself to considerable expense and much inconvenience at the simple dictation of the Council. I have hitherto been content to be a very silent member indeed, but it is the last strain, etc., and I think it behoves all who have an opinion on this subject, to boldly give expression to it before the annual meeting.

January 30*th*, 1871. SYDNEY TAYLOR.

Sir,—Is your correspondent, who shields himself in the obscurity of "*Opifex*," a *bonâ fide* chemist?

I am tempted to make this inquiry from the total want of respect and consideration he has shown for our brethren, charging "very many with carelessness in the way they carry on their business, and as very ill-qualified to conduct it rightly," and then sneering at our friend Mr. Vizer's analogy to the surgeon and his lancets, passing by his powerful arguments against poison regulations and fixing upon the weak point of his letter. I certainly regret Mr. Vizer did not apply a more forcible comparison; for instance, suppose the Council of the Royal College of Physicians, in concert with the Privy Council, proposed to make it imperative that every person who died under the treatment of a general practitioner should be subject to an inquest held by a medical tribunal,—the profession would to a man vehemently resist such a scandal upon their qualification.

"*Opifex*" speaks too of the amazement expressed by the medical journals at our opposition and the probability of our exciting the contempt of the House of Commons, and goes on to say if we continue to resist the proposed simple enactment "we shall be one of the curiosities of pharmaceutical literature," but what our opposition has to do with literature I cannot comprehend. I have conversed with many medical men upon this subject, and they have all expressed surprise that any chemist should be willing to place such a yoke upon his neck; and as to the House of Commons, it is all a phantom.

When the Council first introduced the subject, in Vol. XI. second series, No. 7, p. 377, there was no mention of the Privy Council nor House of Commons, who have more important duties than troubling themselves about poison cupboards.

I hope in future those who write upon this subject will subscribe their names, that we may know who would yoke us to their bondage, and those whom we may honour as the champions of our liberty. JOHN BEATON.

Kilburn, January 30*th*, 1871.

Sir,—The case reported in the PHARMACEUTICAL JOURNAL last week is worth notice, especially by one who shelters himself under the common-place signature *M. P. S.*

A Mr. Jones, chemist, druggist and stationer, of Mossley, Lancashire, sent for a medical man to attend his infant daughter. The medicine prescribed was compounded by a lad employed in the surgery, who substituted morphia for some other remedy. The first dose proved fatal. Surely, if educated and experienced pharmacists are to be coerced by law, subjected to the decisions of country magistrates or the tender mercies of common informers, other dispensers of medicine, whether in public or private establishments, should be included in the same regulations.

As regards blunders, inadvertencies and acts of carelessness, I am confident that they take place in our shops less frequently than elsewhere. Physicians themselves are not exempt from occasional errors, proof of which I have in my possession—several letters from eminent men thanking me for the judgment shown in dispensing prescriptions, which, had they been made up literally must have killed the patient. I write this after an experience of more than thirty years, and hope that *M. P. S.* will, before again addressing you, obtain a little more of that in which he acknowledges himself so deficient. R. GOODWIN MUMBRAY.

Richmond, S.W.

Sir,—It appears to me that the weak point in the proposed poison regulations is the fact that they apply to many comparatively mild preparations a system suited only for really dangerous articles. What can be more absurd than to place liq. ergotæ and tinct. canthar. under such stringent rules? How could crude opium or ergot possibly be mistaken for any other drug?

If the first regulation be applied to all poisons, and the second only to those which are really dangerous, I venture to think the difficulties of the subject might be met.

Jan. 30*th*, 1871. "PROVINCIAL."

CHLORAL HYDRATE.

Sir,—Messrs. E. De Haen and Co., of Hanover, justly complained, in a note you published last week, of certain statements in Mr. Mason's paper of January 7th, on chloral hydrate, which would make it appear that samples obtained by him as Messrs. De Haen's chloral hydrate were in reality chloral alcoholate.

Such statements, groundless and unjustifiable as they are, are calculated to do serious injury; and as the matter has now been fully investigated, we, as Messrs. De Haen's agents here, beg to hand you a copy of Dr. Versmann's analysis of the article in question.

The analysis proves that the compound manufactured by Messrs. E. De Haen and Co. and brought into the English market by us, is good chloral hydrate and nothing else; it is not chloral alcoholate.

There is no doubt Mr. Mason wishes to show, and he plainly states so, that from a variety of samples representing different manufactures, the product of one particular firm only is to be relied upon, and that all the other manufacturers offer the alcoholate under the name of the hydrate.

This is a very grave accusation, because the alcoholate is not a mere impurity or bye-product in the manufacture of the hydrate; it must be made on purpose, and the manufacturer selling it under the name of hydrate, must do so with the knowledge of committing a fraud,—and Messrs. E. De Haen, amongst other manufacturers, are accused of this fraud.

We must here be satisfied with proving the utter absence of truth in Mr. Mason's analysis as far as Messrs. E. De Haen and Co. are concerned, and we do so:—

1. By producing Dr. Versmann's detailed examination of samples representing large quantities.
2. By an extract of a letter received from Mr. Umney, who writes:—"I have on several occasions during the past year examined specimens of hydrate of chloral as consigned to you by Messrs. E. De Haen and Co., and have always found them to be hydrate, and never alcoholate, of chloral."
3. By Mr. Mason's own conflicting evidence. He states our cake yields 57 per cent. of chloroform, our crystals 56 per cent. Both cake and crystals are therefore represented as inferior to alcoholate; but by the solubility in water and insolubility in chloroform, he shows them to be hydrates. His own statements contradict each other, and prove how much value may be attached to his analysis.
4. By Mr. Mason's own confession. In answer to our inquiry how the samples had been obtained he writes: "I had the verbal declaration that this was De Haen's manufacture (I am morally certain of this), but much to my surprise, I learn this morning that the manufacturer of the cake is Saame, of Göttingen.

This statement of facts will, we trust, suffice to demonstrate how unsuccessful and untrustworthy Mr. Mason's attempt at scientific investigation is, and as by the reprinting in your Journal of Mr. Mason's paper serious injury may have been done, we request, in justice to the house we represent and to ourselves, the insertion of this letter and enclosed analysis of Dr. Versmann. DOMEIER AND CO.

"*London, E.C., January 30th*, 1871.

"Gentlemen,—I beg to submit to you the result of my examination of samples of chloral hydrate manufactured by Messrs. De Haen and Co. of Hanover, and received from you for analysis.

"I selected these samples from a large stock at your warehouse; they fairly represent about 4 cwt. of chloral hydrate in crystals, put up in 1-lb. bottles, and 16 cwt. in cakes, put up in jars of about 12 to 14 lb. each.

"The object of this examination was not only to determine the degree of purity of the articles, but especially to prove the presence or absence of chloral alcoholate.

"I have compressed the results of my examination in the subjoined table,* and I feel justified in stating that the chemical reactions and physical properties of the samples unmistakably prove both the crystals and the cake to be genuine and good marketable chloral hydrate, not inferior to the product of any other manufacturer, and perfectly free from chloral alcoholate.

"I have the honour to be, gentlemen,

"Your obedient servant,

"FRED. VERSMANN.

"*Messrs. Domeier and Co.,*

"*47, Basinghall Street.*"

THE SALE OF DRUGS BY GROCERS, ETC.

Sir,—I was very glad to see your correspondent, Mr. Carroll, bring before the notice of the trade the great injury done to legitimate chemists by hucksters selling popular medicines. Some months ago you kindly inserted a letter of mine on the same subject; this was written in the hope that other correspondents would take the matter up, and agitate until something definite was decided on by the Council.

This evil has been considerably increased since the passing of the Pharmacy Act; before that date the grocer or smaller shopkeeper had a certain vague notion that it was wrong to sell medicines, but now, thanks to the smaller wholesale houses and registered chemists, unworthy of the name, they are sufficiently well-informed to know that they may retail any drug or chemical compound under the sun, so long as it is not of a poisonous nature; and, moreover, as these persons on an average sell their articles at 50 per cent. less than the respectable chemist, they are compelled to buy the vilest trash imaginable. Many of them still continue to sell laudanum, anodyne cordial, infants' mixture, etc., articles which formerly contained veritable opium; but now the large-hearted wholesale dealer in his kindly endeavour to shield his innocent customers from the consequence of legal action, omits that essential drug and compounds his tinct. opii from caramel and a small portion of catechu, his anodyne from treacle-and-water flavoured with some essential oil, his mixture from chalk and English rhubarb; these articles, from the large part played by that necessary and cheap ingredient oxy. cum hydro, bear a very nice profit, which of course is a great incentive to the manufacturer to push this branch of his business. The sp. æther. nit., of which a large quantity is retailed at 2*d*. per oz. by these people, would probably require the services of a very high-class chemist to analyse, or, perhaps, it would be imperative to invent a new hydrometer to take the specific gravity.

Another consequence deducible from this great imperfection in the Pharmacy Act is, that herbalists, Coffinites, etc., who were formerly content to keep within the bounds of their proper businesses, have now branched out into selling castor oil, sweet nitre, magnesia, etc., knowing they can do so with impunity.

In the face of this grievance, one is apt to ask the pertinent question, What is the actual advantage of paying a large premium, passing a long apprenticeship, expending a large amount of time and money in books, lectures, etc., and ultimately making a *début* as a full-fledged pharmaceutist? He can dispense physicians' prescriptions, certainly, but unfortunately, with the majority of English chemists, this hardly pays rent and taxes; he can also sell poisons, but here, again, the average sum total taken in poisonous articles, forms but a small portion of the day's receipts; it appears, therefore, that the major portion of an ordinary country chemist's business is still open to the competition of the world, our boasted Pharmacy Act notwithstanding.

Mr. Carroll truly observes, "They manage things better in France, where the pharmacien holds his proper position as determined by law." There, a paternal government recognizing the fact that a pharmacien must undergo a laborious and expensive course of training before being qualified for his post, a circumstance unconnected with any other trade, endeavours to protect him as much as possible from undue competition; in fact, puts the hen-coop over the chickens to prevent the fox preying on them.

The remedy for this grievance is very simple, and would be easily applied, viz. make it penal for any person, not being a registered chemist, to sell any medicine intended for internal or external use, a law at present in force in every country in Europe except our own.

I trust some of your many able correspondents will give this subject the consideration it deserves.

A COUNTRY M. P. S.

Sheffield, January 26th, 1871.

P.S. I was much amused to-day by seeing in a grocer's window a large box, the label printed in bold black type, announcing the contents to be "Aunty Billy's Pills." Had the late A. Ward been a member of this pill-mongering firm, surely he would have added "this is rote sarcastical."

* The results are given on p. 62.

J. North (Reading).—The Pharmaceutical Society cannot be made a medium for the transaction of bookselling business.

J. Thomas.—We are much obliged to our correspondent for the enclosure.

G. C.—We do not know of any method for the artificial production of the oil.

M. P. S. G. B.—Cresylic acid is, like carbolic acid, a constituent of the coal-tar from gas-works; and we believe it may be obtained from any maker of carbolic acid.

"*Inquirer*" (Barnstaple).—We think that the "Balm" label would render the article liable to duty; the other label, which simply gives the dose of a pharmacopœial preparation, without reference to the treatment of any disease, would not.

W. A. (Hammersmith).—We think that No. 1 would come under the decision of the revenue authorities, that the words "Cough Lozenge" do not involve the payment of duty; but that the introduction of the other lines in No. 2 and No. 3, mentioning the diseases for which the article is recommended, and the dose, would render it liable. You had better communicate with the Revenue authorities at Somerset House.

Carolus and *Q.* are referred to the paper by Mr. Gale, in which the subject is fully treated of, already published in the PHARM. JOURN. 2nd ser. Vol. I. p. 497.

Chloral Hydrate.—At the moment of going to press we have received a letter from Messrs. Schætensack, in which they complain that the results contained in Mr. Mason's paper, and relating to the chloral hydrate, which they import, do not correctly represent its quality. They also state that they have submitted their chloral hydrate to analysis, and that they purpose communicating the results to the Journal. We shall be happy to do anything in our power for giving publicity to any well-founded reclamation, but the letter sent by Messrs. Schætensack for publication has reached us too late for insertion.—ED. PHARM. JOURN.

Meal Worms and Insects.—To. J. G. O.—The ravages in your packet of Embden groats have been made by the *Tenebrio molitor*, Linn., a small beetle, whose larva is known as the meal-worm. Westwood says it frequents bakehouses, corn-mills, granaries, ship-biscuit stores, and similar places, and does much damage by devouring meal, bran, flour, and occasionally cloth and wood.—J. A.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Agnew, Mr. C. R. C. Titchborne, Mr. G. H. Cockerell, Mr. J. North, Mr. S. Kellam (Galveston), Mr. J. Robbins, Mr. T. Hopkinson, Mr. F. Warnford, Mr. J. S. P. Rowe, Mr. S. Hallam, Mr. J. D. Allman, Mr. T. C. Jones, Mr. G. V. Druce, Mr. H. J. Church, Mr. R. G. Mumbray, Mr. G. Morgan, Mr. J. B. Bayley, Mr. J. Wain, N. C., J. T. N., A. THE MICROSCOPE AND ITS REVELATIONS.*

BY W. B. CARPENTER, M.D., F.R.S., F.G.S., F.L.S.

The modern microscope may, I think, be regarded under three aspects—as an instrument of scientific discovery, as an educational instrument, and as an instrument for affording an almost endless amount of rational recreation. I do not intend this evening to enlarge upon the first of these uses, because, as I understand, the object with which I was asked to bring the subject before you was that I might specially dilate upon the educational advantages, and the use of the instrument as a means of rational recreation. I hold it extremely important that every young man should learn, not only how to work but how to play. I think that to find a means of constant and attractive recreation, and especially one which combines the double character of quiet work at home and occupation for any amount of time, and, on the other hand, which will occasionally give a zest and interest to a walk abroad, is to find that which is one of the very best appliances that any home can have. I have found it so myself from my own boyhood, for I may say that the modern microscope and I have grown up together. It was just about as I was entering on my own educational course that that remarkable improvement was effected which I shall presently describe to you as the achromatization of the microscope. It was the introduction of the achromatic principle, which had already been applied to the microscope, which converted it from a mere scientific toy, for really it was very little better, into an instrument quite on a par with the most costly and elaborate telescope, as a means of scientific research. As I have said, the microscope and I have, in some sense, grown up together; and it is an instrument, from my own experiences of its uses, in all its aspects most precious in my eyes. It is known to most of you that I have made certain branches of microscopic research the main study of my own life, and I have also felt its advantages in the education of my own children so highly, that I do not think there is any single means of education that, on the whole, I estimate so much. It gives that special training which none of our ordinary studies do give, that is, the development of habits of careful and accurate observation, and in addition to that, the habit of reasoning upon observation. Those two directions of the mind, the training and discipline of the observing powers, and with that the training and discipline of the power of reasoning upon observation, I think distinguish scientific study, rightly pursued, from all our ordinary means of educational discipline; as, for instance, the study of classics or mathematics, which latter reasons entirely on abstractions, and is confined to reasoning of a particular kind, limited in a narrow groove, as it were. Here, however, we have a training of the faculties of discerning the probable, the improbable, the certain and the uncertain,—in fact, all that kind of discipline which, in the ordinary walks of life, is so extremely valuable. Thus, as I have said, to those young people who have been trained in this habit, who have learnt the value of it, and who desire a rational occupation of their spare time, and something which shall give an attraction to the ordinary work of life, nothing can be superior to the microscope.

These are the reasons, therefore, for which I advocate, and have often advocated, the use of the microscope, especially here, where I know there are a large number of young men who are closely confined during the day in business avocations, and who yet have more or less time to spare in the evening, one great advantage of microscopic study being, that it may be carried on as well by lamplight as by daylight, with the exception of certain advantages which daylight has; but, on the other hand, lamplight has its advantages, and for much of my own study I prefer it, because it is more manageable, and can be easily adjusted to exactly what is required.

A few words, in the first place, upon the microscope itself. I shall not dwell upon its general philosophical principles, presuming that you are acquainted with the general construction of the ordinary microscope. All that I shall endeavour to explain to you is the great improvements to which I have referred under the term achromatization. Achromatic means destroying colour. It does not mean that the microscope does not show the colour of the objects submitted to it, but that it does not show any false colours, or any which do not belong to the object. The old microscope was constructed in this manner:—The object-glass screwed at the lower end of the tube, and then an eye-piece at the upper end, that eye-piece consisting of two or more lenses. Now, the object-glass of the old microscope was a simple lens, an ordinary double concave lens; but the simple lens was employed as an object-glass, and a compound microscope gives extremely false effects. In the first place, the spherical curvature of its two surfaces does not bring the rays of the central part and the spherical, or outside part of the lens to the same focus; and therefore, if the lens have a large aperture, you have a great amount of what is called spherical aberration; that is, the rays that come through the central part and the rays that come through the spherical portion do not meet in the same focus. Therefore, if you focus it for one, all the other rays produce a sort of foggy effect. Then, besides that spherical aberration, every such lens acts as a prism in dispersing the colour, producing that kind of effect which you see with any ordinary prism, or with the cut-glass prisms on a chandelier, which are so cut for the express purpose of producing prismatic refractions. Therefore, every object seen through such a microscope had fringes of colour produced by the dispersion of the coloured rays. In order to reduce this to the minimum amount, it was necessary to contract the aperture, and accordingly the object-glass of the old microscope had an extremely narrow aperture; it was brought down to merely the central portion of the lens; and even with that, although the spherical aberration could be considerably reduced, yet there was always achromatic aberration, and the greater in proportion to the power. This defect had long previously been corrected in telescopic lenses. The large object-glass of telescopes was constructed by the union of flint and coarse glass, and the corners were ground in such a manner as to correct almost entirely both the spherical aberration and the achromatic. But it was considered quite chimerical to attempt to apply the same principle to lenses so small as the object-glass of a microscope. It was considered that the manipulative skill of those who had to grind these glasses was never likely to succeed in producing combinations which curves

* Delivered at the Evening Meeting of the Pharmaceutical Society of Great Britain, February 1, 1871.

should answer the same purpose with microscopes which these large lenses do with the telescope, the principle of construction in the two instruments being the reverse of each other in this respect. The power of the telescope is gained by a long tube and an object-glass with a long focus, and to get a very powerful telescope you require a very large lens, the limit there being the size of the flint glass that can be produced of sufficiently good quality. I believe at the present time object-glasses for telescopes are being made twenty-five inches in diameter, and that is the largest yet produced. On the other hand, in the microscope the power is gained by diminishing the focal length of the lens, and, in diminishing the length, the lenses themselves must be made upon a more minute scale. I shall not go through the successive steps of the process by which these powers were obtained, but it is interesting to mark that men of science in different countries were at work about the same time, in conjunction with mechanicians of skill in glass grinding, in producing achromatic lenses for the microscope. Dr. Goring, in London, within my own recollection, set Mr. Tully, who at that time was a celebrated maker of telescopic lenses, to work upon what would now be called a very low power for the microscope; and I remember very well hearing at the time that Mr. Tully, after long and numerous trials, succeeded in producing what we should now call a very inferior lens; and that, upon Dr. Goring asking what he had to pay for it, Mr. Tully said he could not estimate his time, at the very least, at less than £50. Lenses far superior to that can now be bought for about 15*s*. At the same time Professor Secchi, in Italy, and M. Chevalier, in Paris, were at work on the subject, and they produced achromatic lenses of higher power than those of Mr. Tully. Not long after that, a most estimable man, not long since deceased, Mr. Joseph Jackson Lister, applied very considerable mathematical powers to the investigation of the means of combining these lenses. It was soon found that the telescope plan did not answer at all for the microscope; that is, the plan of having the flint glass concave between two convex lenses of crown, was not effective for the microscope, but a much better effect was produced by combining two or three pairs of lenses,—a flint concave and a crown convex,—and that is the mode of construction which since that time has been adopted. Dr. Bentley has kindly lent me a diagram, showing the plan of construction adopted in object-glasses at the present time. Here are three pairs, concave of flint and convex of crown. The different curves are ground with very great care and accuracy, in such a manner as to correct both the spherical and the achromatic aberration, that is, to bring the rays of the central and peripheral parts of the lens to the same focus, and thus correct the spherical aberration and prevent any foggy appearance, and, at the same time, prevent any achromatic aberration, so that there shall be no false colours in any part of the object, and especially at its edges. There are different plans of combination. Some makers put a single lens in front, and a combination of three behind. There are different combinations for different powers, and different makers have their different methods, but they all go on the same principle; and at the present time the most extraordinary accuracy in workmanship has succeeded in producing lenses of a degree of minuteness that can scarcely be conceived. Messrs. Powell and Leyland have produced a combination lens of only a fiftieth part of an inch focus. I suppose the largest of the three does not exceed in size an ordinary pin's head, whilst the smallest must be scarcely larger than a pin's point, certainly not larger than a pin hole in a piece of paper. The practical skill which our mechanics have acquired has enabled them gradually to cheapen the construction, and this is a matter of great importance to those who desire to use the instrument as one of recreation and education. I may take some little credit to myself for having promoted this object, for in the year 1851, after the Great Exhibition, I induced the Society of Arts to offer a prize for a three-guinea achromatic microscope. I was laughed at excessively for thinking that an achromatic microscope could be made for three guineas, all the London makers saying it was entirely out of the question. The few first-rate makers then in the trade would have considered it lowering their reputation to condescend to anything of the kind. There were, however, second-rate, or perhaps, you may say, third-rate makers, who thought it worth their while to see what could be done. A jury was appointed by the Society of Arts, of which I was a member, and we selected a microscope made by Mr. Field, of Birmingham, a well-known manufacturing optician, and he informed me five or six years ago that over two thousand of these microscopes had been sold; and I dare say since that time more than double the number have been disposed of. That was the beginning of an improvement which has gone on continuously since; and makers both in London and the country are continually bringing under my notice microscopes, and especially achromatic microscopes, of cheaper construction and offered at lower prices. They are now beginning to feel what I have been preaching for a long time, that the best lenses for ordinary use are not those which serve best to display what are called test objects. I have sometimes likened the difference between these instruments to that between an ordinary roadster and a racehorse. You do not use a thoroughbred racehorse for ordinary every-day work, and, on the other hand, a roadster has qualities which, though they do not enable him to run races, make him a very useful animal. It is just the same with regard to these different qualities of lenses. There are certain achromatic combinations which are very costly, as they require a marvellous precision and finish, and which, therefore, it is impossible to make cheap. On the other hand, there are some combinations of what is called a much lower angle of aperture which are really best for ordinary use, which give the best view of an object, and which can be made at much less expense than the others. Very recently there have been imported into this country from Berlin a series of achromatic lenses of different powers at most extraordinarily low prices. They are known as Gimlach's lenses; and, having examined several of them, I have been really astonished at the excellence of the work that is produced in comparison with the price. For example, a lens of about one-third of an inch focus, costing 18*s*., is quite equal to a lens which I gave one of our best makers four guineas for a few years since. You may now have a microscope for £5 which I should have been most thankful in my earlier days to have given £20 for,—I mean with regard to its applicability to working purposes.

In the instrument itself there have been various improvements. One of those I have now before me is a very excellent example of the ordinary pattern of a student's microscope,—one which is capable of having various appliances added to it, which make it a very useful instrument. There are two plans of construction which I think it well to mention, because I very much hope that the direction that microscope-makers will take is that exemplified in one of these, and which I maintain to be the right one,—most instruments up to the present time being constructed on what I consider a wrong principle, mechanically and practically. In this microscope, which is constructed on what is called the Ross model,—it having been produced by Mr. Ross, I believe the grandfather of the gentleman lately dead,—the body or tube of the microscope is fixed at the bottom into an arm; then there is a transverse arm that is supported upon a rack stem. Now I apprehend a very great object in all microscopes is to obtain steadiness in the object; that is, that when you look through the microscope the object shall not seem to dance. The reason of this dancing is that the eye-piece has a tremulous motion which the object itself has not. If the whole microscope moves together, and the motion is equal in every part, you have no apparent motion of the object. For instance, during the last three years, during each summer of which I have been using the microscope on board ship, I fixed my instrument well down to the table, if the ship was rolling much, holding the leg of the table between my knees, and so fixing myself securely; and during the whole of the time this instrument has been my companion, and I have found so extremely little tremulous motion, even under the most trying circumstances, when the steamer has been going at full speed against a head sea, that I hardly perceived any of that objectionable motion in the object, the microscope and my eye going together. If there is no motion of any one part upon the other, the object will remain stationary; but if the eye-piece moves more than the object itself, then the object will appear to dance. Now my friend and colleague Dr. Wyville Thomson had with him a microscope constructed on the Ross model, and I found that I could work with my instrument under these trying circumstances with a power about four times that which he could; that is to say, the tremulousness of mine with a quarter-inch focus, which is a high magnifying power, was not greater than he found with a lens of one inch focus. This was the practical proof of the superiority of the one method of construction over the other, and I think all who have any knowledge of mechanics will see at once the superiority of this model. All metal-work has a certain elasticity about it, especially a drawn tube such as that of which the microscope body is made; the consequence is, that when the centre of movement is at the bottom of the tube, from which springs the rack upon which is placed the object-glass, there is the whole length of the tube to vibrate backwards and forwards. On the other hand, in this plan, which was devised by the late Mr. Jackson, of Spitalfields, the body is supported on a solid limb about the middle of its length, and a solid limb is carried down which supports the stage; and the body being thus supported about the middle, the vibration is equally distributed, so that there is practically hardly any vibration at all. My conviction is very strong, that if it had not been that early microscope makers had got up their patterns on this model of Mr. Ross's, they would soon have abandoned it; but we know that when manufacturers once get a stock of patterns they are loth to change them, and I am afraid I shall not live to see this improved plan brought into general use. Messrs. Smith and Beck, however, have adopted Mr. Jackson's model, and some of the makers who have been educated in their workshop have followed. I hope I shall not be considered to be dealing unfairly by other makers if I mention that the maker of this instrument, Mr. Crouch, also makes a student's microscope on the same plan, about the same size as this Ross model, which I consider much superior, the body being supported in this more stable manner. I mention this with the more confidence, because I know his instruments are now coming into general credit. My friend Professor Michael Foster, of Cambridge, lately of University College, who is now organizing a physiological laboratory there, has informed me that he finds Crouch's microscope a most satisfactory instrument. I am speaking now merely of the plan of construction, which I consider far superior, and I hope in time all makers will adopt it.

The other great improvement which the microscope has more recently sustained is the introduction of the binocular principle, which is simply the adaptation of the principle of the stereoscope. I shall not go into the history of the manner in which this was worked out, though it is very curious and interesting, and I have been a party to it from the very commencement, having in my possession one of the first to which it was successfully applied. We all in England now use the plan devised by my friend Mr. Wenham, and for those who, like myself, work with lower powers, and who are in the habit of looking much more at opaque solid objects than flat transparent ones, the binocular is a comfort I can scarcely describe. The difference in the fatigue which it produces, not only of visual but of mental fatigue, would surprise you, perhaps, but it is easily accounted for. When one has to estimate the form of a solid object with an ordinary single-bodied microscope, it is necessary to focus it up and down, in order to form by that means an idea of the projection of one part and the sinking in of another. The binocular gives you that unmistakable representation immediately; you have not to think about it at all,—you cannot help seeing it, any more than I can help seeing that this instrument before me is a solid form. I therefore always strongly recommend a binocular microscope to those who are really desirous of possessing a good instrument; and the cost is now so very much reduced, that it is really far better to incur it at the beginning, and to add the objectives gradually, if your means are limited, than to begin with an ordinary single-tube microscope and have to change it at a subsequent time. The value of the binocular is now becoming more and more appreciated. Several of my scientific friends who use the instrument merely as a means of research, rather laughed at me for my enthusiasm about it, and said they did not find any particular benefit in it, but one after the other they are gradually coming to the same view. For instance, last night Mr. George Busk was at my house, when he said he had lately had an opportunity of working with the binocular, and had come to the conclusion that he could not do without it.

Thus much must, I think, suffice with regard to the instrument itself. I would advise those who may be thinking of beginning microscopic inquiry to be satisfied with lower powers in the first instance. Learn to use them well with any ordinary objects you may pick up, as, for instance, the different parts of a fly or a plant simply laid upon a black or white ground, as the case may be, light coloured objects being best seen on a black ground, and dark objects on a light ground. Lay these objects in this way on a black or white ground and study the characters of the different parts, the management of the light and the mode of using the instrument, before you attempt to deal with higher powers. By this means you will save yourself a great deal of trouble and be going through a very valuable education. The lower powers are now made specially with educational microscopes; in fact, it was a special point which I insisted on with the Society of Arts microscope, that there should be a lower power of this kind, and I recommend all those who are commencing the study to begin with learning the use of them. You will find it wonderful how many plain ordinary objects, that come under your cognizance every day, may be seen in quite a new aspect, even by the use of these low powers.

We will now begin the exposition of the use of the microscope, by speaking of one of the most familiar of all objects,—a piece of chalk. I thought I could not do better than introduce this to you in its natural history aspect, because it is one you are all familiar with in its common every-day appearance. It will, perhaps, interest you rather more when I connect it with the work upon which I am myself engaged. For example, in this little box upon the table is a piece of what we may call modern chalk, which is now being formed on the bed of the Atlantic. This was brought up a year and a half ago from a depth of nearly three miles, 2435 fathoms. We brought up about 1½ cwt. of this in our largest deep dredges; and I venture to say that any of you looking at this would see no difference at all between it and an ordinary piece of chalk, except that it is a little browner, but still many varieties of common chalk are quite as brown as this. The microscope has shown that chalk is commonly composed of the remains of minute shells; sometimes the shells are found in great abundance, perfect as we find in this globigerina mud, as we call it. These shells are so small that they could scarcely be seen by the naked eye,—a single shell on a black ground would appear as the merest white point, and thousands of them would be required to weigh a grain; yet the aggregation of these, that is now going on at the bottom of the Atlantic, is forming an immense area of chalky deposit, the thickness of which we do not know. We know, however, the thickness of that which has been raised in the chalk cliffs of Dover, for example, and in the centre of Europe generally, which is several thousand feet in many instances; and you may, therefore, conceive what a vast lapse of time must have been required for the accumulation of such a deposit. We believe that the *Globigerinæ*, now living on the bed of the Atlantic, are the lineal descendants of those which formed the chalk in England and Europe generally, but that, when that was under water, it is very probable that there was dry land in what is now the bed of the Atlantic. We know, geologically, that there is every probability that oscillations have existed in past times, such as we know to be going on at the present very slowly. Mr. Darwin, many years ago, first brought himself the high reputation which now attaches to his name, quite irrespective of the peculiar theories called Darwinism, by the observations that he made during the voyage of the 'Beagle' on the coral formations of the Southern seas, when he showed that there are great areas of subsidence over which the bottom of the ocean is sinking very gradually, and, on the other hand, that there are areas of elevation, where very recently coral ridges have been brought up above the surface of the ocean, forming cliffs. The great mass of the continent of Europe, having the form of chalk, must have been lifted up in that manner; and, on the other hand, there is every probability that at the same time the bed of the Atlantic was going down, and that these little *Globigerinæ* gradually migrated from one part to another; and that, therefore, those now covering the bed of the Atlantic are the lineal descendants of those who lived in Europe during the chalk period; there is no difference whatever between them. We found from particular specimens of chalk, for it is not all chalk that shows the perfect shells, just the same differences that you will find in different specimens of old chalk. The larger part of both consists of granules of extreme minuteness, requiring high powers of the microscope to study them fully; they have been termed coccoliths and coccospheres. My friend Mr. Huxley first discovered the coccoliths in an examination of the soundings taken for the first Atlantic cable; they were afterwards recognized by Mr. Sorby in the chalk, and they were also found by Dr. Wallich; so that we have this correspondence, not merely in the *Globigerinæ*, but also in these curious little bodies which seem to be related to that very widely-diffused animal substance that you have heard a great deal about lately under the name of protoplasm. I see in the last number of *Vanity Fair*, which contains a most characteristic likeness of Professor Huxley,—caricatured certainly, but still showing at once his great power and good humour in a most remarkable manner,—a statement that he invented protoplasm. Of course, nothing can be more ridiculous than such a statement, for protoplasm had been talked of for twenty years before Professor Huxley mentioned it, and he himself would be the first to disclaim any such appropriation; but it is a remarkable fact that just at the time when I was out on the first of my deep-sea expeditions, Professor Huxley, in a communication to the British Association at Norwich, referred to an examination he had made of some of the soundings made for the Atlantic cable, in which he found that these coccoliths and coccospheres were diffused through a layer of protoplasm that does not belong to the *Globigerinæ*, and this I have been myself able to confirm, and to ascertain that this mud which we brought up is, so to speak, a living mass. The whole of it is alive; not that it is merely a collection or aggregation of individuals of the *Globigerinæ*, but that the peculiar tenacity which we observed in this mud, its stickiness and the difficulty we found in passing it through a sieve, all corresponded with his view, that the whole of the mud is a mass of protoplasm, through which the *Globigerinæ* are distributed, and to which these minute bodies belong. A very eminent observer in France, Dr. Ecker, has lately come to a conclusion of a similar kind, by his own examination of this very material, that this is a general characteristic of the chalk both of old and recent formation; they correspond precisely in all their particulars.

With regard to the other animals that are found imbedded in it, those fossils which give the particular geological character to the epoch, it is not my intention to say anything more than merely to mention that whilst a great number of these have undoubtedly become extinct, of those which flourished during the cretaceous period when the great chalk deposits of Europe were being formed, we have found a considerable number, and the researches of our American friends in the Gulf of Mexico are adding largely to the number of forms which exist in the old chalk deposit, so that we believe these to be the descendants, though modified in the lapse of time, of those which flourished during that period. There is some discussion at present going on as to how far my friend Dr. Wyville Thomson was right in his assertion, that we may be considered as still living in the cretaceous period. He enunciated that doctrine on the basis I have mentioned to you, that there is every probability that this great chalk formation going on in the bed of the Atlantic is continuous with that which formed the Dover cliffs and the great chalk deposits of central Europe, and that a large proportion of the animals that are now found in their deposit may be regarded as the descendants of those which flourished during the cretaceous period. But as Sir Charles Lyell has very justly pointed out in his recent book, 'The Students' Manual of Geology,' the termination of what we are accustomed to call the geological cretaceous period was marked by the disappearance of so many types of which the fossil remains are found in the old chalk, that geologically it must be considered as the conclusion of that period. This is really very much a question of words after all, like the question which I remember some twenty years ago agitated our law courts, arising out of a claim to very valuable property which had been purchased with a view to making paraffine oil, and the question was whether a certain substance was or was not coal. Almost all the chemists and geologists in England and a great many mineralogists were carried down to Edinburgh to give evidence on the subject, but the difficulty was to define what was coal. And so the difficulty here is to define what is meant by a geological period. All I care about is to have it admitted that this modern chalk deposit is not a mere repetition of the old chalk, but is a continuation of it on a different area; many of the animals having migrated into that area, while on the other hand, many no doubt have died out.

Now I am anxious to show you what is the nature of the animalcules of which this *Globigerina* is an example, because among the many efforts of modern microscopic study I do not know anything more remarkable or more important in its general bearing on physiological doctrines than the proper appreciation of the nature of their—I can scarcely call it structure or organization, for it is a remarkable fact that they have nothing that can be called organization or structure. In some way they make these beautiful shells, but the soft body of the animal that makes them is apparently destitute entirely of anything that can be called organization. That I shall now explain to you. On the wall are some drawings of these creatures, and amongst them you see some remarkably regular forms. Here is a piece of nummulitic limestone, of which the pyramids of Egypt are built, and you notice the regular manner in which the nummulites or small discs, so called from being in appearance like small pieces of money, are arranged, the whole surface being divided regularly into chambers, which are grouped in a spiral starting from a centre. We find several forms of that kind here, in the *Cristellaria*, the shells of which are formed of sand. The creatures have not the power of exuding a shelly substance from their bodies, but they make a calcareous shell by gluing together grains of sand, and building them up with extreme regularity in their spiral forms. They are very much like a nautilus; and I remember the time when they were universally reputed to be minute nautili, and were always so arranged, as for instance, in Cuvier's 'Animal Kingdom,' under the Cephalopods. But an eminent French naturalist, who, if my impression is correct, was a pharmacien, residing somewhere on the seacoast of Brittany, M. de Jardin, applied himself to the study of these bodies, and after some time he came to a conclusion, which has been since confirmed by the most careful and prolonged scrutiny. He degraded these animals at once from being amongst the highest of the invertebrate subkingdom, the Cephalopods, of which the nautilus stands at the top (the highest organization below fishes), down to the very lowest, and he was perfectly right in so doing. He found that the body of these animals consists of nothing but a soft jelly-like substance, which we now call protoplasm. He called it sarcode, which was a very good name, meaning something which is like flesh and answers the purpose, but is not flesh—a sort of rudimentary flesh. The word protoplasm was first invented by the botanists, and we now know that the sarcode of De Jardin and the protoplasm of the botanists are the same thing exactly. This sarcode itself can be obtained when we have the fresh animals by just dissolving the shell in acid, and we then get the sarcode body; here are representations of them seen both as opaque and as transparent objects. You see it has nothing like a structure or organization, but consists of separate little balls, so to speak, or segments progressively increasing. The original animal was the smallest of these segments, and it formed one chamber or shell; then by a gradually growing-up process which I shall describe, it has formed another segment, which in its turn formed a shell around it; then another larger segment, and so on. We find generally, from eight to twelve or more of these segments in one *Globigerina*. Then any further increase will take place in such a manner that the bud will separate and give rise to a new and distinct individual. That, however, is not necessarily so, for I shall presently show you that in a remarkable fossil which has been discovered within the last few years in Canada, the *Eozoön Canadense*, which is the earliest of which we have any knowledge, the extension takes place continuously by what is called continuous germination, the difference being just that between a plant and a tree. A plant has a limited growth. It does not increase by budding beyond a certain extent, and an annual plant dies at the end of the year, and there is an end of it, as an individual, though its seed may spring up again. On the other hand, a tree goes on putting out fresh buds every year; old parts gradually die away, but new and fresh parts come into existence by this extension from the original primordial stock. In the same way it is quite conceivable, as you will at once see, that the bottom of the ocean might be covered with one continuous mass of shell-deposit, produced by this protoplasm or sarcode, which is covering it at the present time; whilst on the other hand, this little *Globigerina*, instead of producing one continuous extension, produces an enormous aggregate of what we are accustomed to call separate individuals; simply because when a certain number is reached, the next bud is detached and begins a new shell, instead of going on in connection with the old one.

Our best knowledge of the nature of these animals is derived from the study of some of the fresh-water forms, which are within the reach of every one. The Hampstead ponds are full of them. They were formerly called *Protei*, from the extraordinary variety of shapes which they present while being observed, but they are now called *Amœbæ*. And we need not even go up to the Hampstead ponds for a specimen, for there is a very interesting paper in the last number of the *Quarterly Microscopic Journal*, by an Italian priest residing in London, who, following up some observations made in Germany, has found that these *Amœbæ* are almost universally present, not only amongst the stems of aquatic plants, etc., but that even on pulling out a bit of moss from a damp wall and shaking it in water, some of these *Amœbæ* are detached. It is a new and rather peculiar type, varying a little from the ordinary forms, but affording a most ready means of study within the reach of every one. Sometimes even you may find a bit of moss between the paving-stones in a back street which will afford you specimens for examination.

This *Amœba* I hold to be one of the most interesting of all microscopic objects, because it presents us with the phenomena of life in the most elementary form possible. It is a little bit of animated jelly, changing its form continually, and having nothing that can be considered an organization save this, that the outside of it is a little more dense than the inside. There is no skin, no definite membrane, but the exterior surface is like stiff jelly, while the interior is more like thin jelly; in fact, it is almost liquid. One of the most curious phenomena connected with it is the continual movement of particles in the interior. If you have some of these under the field of the microscope, you observe a continual agitation of the particles in the interior; this agitation will then appear to proceed in a certain direction, and will elongate itself into a sort of finger-like process, into which the body will appear to be drawn: then, perhaps, another will shoot out in another part, and gradually the body will follow and be drawn into that and so on; and in this manner it will gradually travel over the field of the microscope. It is by means of this movement that the creature gets its food. It comes in contact with some particle that may serve as nourishment to it; this particle penetrates the substance of the body through any part of the exterior, and this proves distinctly that there is no membrane. A mouth extemporizes itself anywhere, the particle is taken in, and when inside it becomes subject to this continual current that is moving about it. It thus undergoes a kind of digestion, and if there is any hard part left in this particle, after a time it works its way out through the surface again and is left behind. The body moves away from it and it gets out through the last edge of the surface-film and is thus extruded, so that an anus is extemporized as well as a mouth. In this manner this creature is continually travelling here and there, taking in articles which it has the power of appropriating, and thus, without anything that can be called organs, it performs all the functions of life. It takes in food without a mouth, it digests it without anything which can be called a stomach, and it gets rid of inappropriate matter without anything which can be called intestines or an anus. It moves without muscles or a nervous system, and it propagates itself by subdivision. Indeed, there is some reason to think that it goes through a very curious process of conjugation: two little bodies meeting together, become fused into a mass which is the commencement of a new set of generations. Upon that point, however, further observations are very much wanted—and observation extends over several months—to see whether a winter change takes place in them as it does in many animalcules, a preparation for a sort of torpid condition, which shall give place to renewed activity in the spring. This is a point on which any one with sufficient perseverance, who will devote himself to this branch of the inquiry, may really do very good scientific work, and at the same time he cannot fail to interest himself exceedingly.

This is the simplest and most elementary form of life; and I shall surprise you, perhaps, when I tell you that there are certain corpuscles floating about in the blood-vessels, the white or colourless corpuscles, which extremely resemble these *Amœbæ*. If you draw a drop of blood and put it under a sufficiently high power of the microscope, and by a little application of heat keep it at about the temperature of the body, covering it with glass so as to prevent evaporation (not, however, pressing too much upon it), you will find in the midst of the red corpuscles,—which you know are disposed to run together in piles, like pieces of money,—in the clear spaces left between, you will find what are known as the white or colourless corpuscles of the blood, and if you observe them attentively you will see the same kind of movement in the interior, and the same changes of form as are noticed in *Amœbæ*. They put out finger-like processes in one direction and then in another, though they do not move so much over the field of the microscope as the *Amœbæ*. They are, however, essentially organisms of the same character. What their purpose is I do not purpose now to discuss, but merely mention the fact.

In the Hampstead ponds and many other collections of water you will find some other forms which are known as "sun animalcules." These are much more stationary, and get their food in a different way to the *Amœbæ*. They send out long, straight extensions, and we do not find the interior soft liquid passing into digitations, but they send out these rays, which frequently are glutinous on the surface, and they entangle minute animalcules which come in their way, just as an insect is entangled in a spider's web. The other rays bend towards the one which has got hold of anything and coalesce with it; there is a kind of attraction amongst them, and some of the body, perhaps, will extend itself towards it, in the manner represented in this diagram. A film is sent out which completely invests the animalcule, and in this way it is gradually drawn into the body, where it is subjected to the digestive process. This is a very beautiful and curious animalcule, if you have an opportunity of observing it with a sufficiently high power. It does not move from place to place, but remains perfectly stationary under the microscope; but you will see the constant action of these long processes, and the continual circulation of little granules inside, which seem to move along one side and then back along the other. Sometimes two processes meet, and the granules pass along the one and back along the other.

Both these are freshwater forms, which there is no difficulty in procuring, if you persevere in your search; but I will now proceed briefly to indicate some of the marine forms and show you wherein the difference consists. The marine forms, such as that which forms the *Globigerina*-shell, live by putting out threads of extreme delicacy through minute apertures in their shells. This *Globigerina*-shell is studded all over with extremely minute apertures, about the $\frac{1}{6000}$ or $\frac{1}{8000}$ part of an inch in diameter; in some of the *Nummulites* the diameter is less than $\frac{1}{10000}$ inch, yet through these there pass out these exceedingly delicate threads, which extend themselves around the shell. I have lately succeeded in getting some of these types with the threads extended, and I have been able to mount them as preparations, and very beautiful objects they make. These threads form a sort of animated spider's web; they cannot take in anything large, as you see, by the fact that they come out of these minute apertures, but they extend, and then they coalesce with one another sometimes, which shows that there is no membrane upon them; they are simply nervous threads, like those spun from a spider's web. They coalesce occasionally into a mass, which forms a fresh centre of departure, and in this way particles of extreme minuteness are continually being entrapped. But what is more, and I believe that is the usual mode of nourishment, it presents a very large and extended surface of sarcode, which is, I believe, always absorbing from the sea-water the protoplasm which is diffused through it, in a very dilute condition. For our researches, of which I gave an account to the Royal Society last year (and chemical research has also tended to prove the same thing), indicate that the whole mass of sea-water is to be considered as a sort of very weak broth; that is to say, in every gallon of sea-water there is so much protoplasm diffused, and that protoplasm is the result of the surface life of animals and plants. For instance, take the great Sargassa Sea, which lies in the inner circle of the Gulf Stream, the circle around which the Gulf Stream curves: in that sea there is an immense amount of floating seaweed, which is always giving off to the water this sort of gelatinous exudation; and whereas it was formerly supposed that the organic matter, which my friend Dr. Frankland found in the water around our own coasts, was merely the result of the washing down of the organic matter in rivers, and from the shore-life of shells, crabs, and so on,—we find that water brought up from the greatest depths in mid-ocean contains just the same proportion of organic matter as the surface water near to our own shores. There is evidence, therefore, of the universal diffusion of elementary organic matter, so to speak, throughout the ocean. At the bottom of the ocean no vegetation can exist, because there is no light, none, at least, that can produce vegetation, and we find no evidence of vegetative action; and you all know, I presume, that these organic compounds all begin in the first instance with vegetative life; and, therefore, our belief is that it is the vegetative and animated life on the surface which is constantly giving off to the sea this protoplasmic substance that is thus diffused through it, and becomes the food of the immense mass of life at the bottom, which again supports animals of much higher organization. For instance, at these great depths we found star-fish of very high forms, which had their stomachs filled with *Globigerinæ*. Given *Globigerinæ*, anything else can live; but how do the *Globigerinæ* live? Our theory is, that they and all other animals of that kind living at great depths are supported by this wonderful protoplasmic substance present in the water in contact with it, which it is constantly absorbing and turning into sarcode.

I may here just refer to the diagrams on the wall, which represent some of the more remarkable forms we have met with, composed of sand grains glued together and arranged in many cases, as you see, with the most extraordinary regularity and finish. One, you see, is in a tri-radiate form, the rays being always straight; but sometimes there are four, and sometimes one is aborted. These are formed of sand cemented together with phosphate of iron. I have dissolved several of them in a rather strong solution of nitric acid to separate the sand grains; and my friend Professor Williamson has been kind enough to determine that the solution contains phosphoric acid and iron. One of these affords a very interesting illustration of a fossil type, which I worked at two or three years ago in conjunction with Mr. Brady, of Newcastle, with reference to which we contributed a paper to the 'Philosophical Transactions.' It is one of the large fossil foraminifera, the larger forms of which, approaching the size of a small cricket ball, are found not only in the green-sand near Cambridge, but also in the Isle of Wight. My friend Mr. Brady had in his possession some remarkable fossils of the same kind, although growing on a different plan, which were brought by the late Mr. Loftus from the neighbourhood of Persia; they are now deposited in the Museum at Newcastle. These, though framed on a different geometrical plan—one being built up of concentric spheres, while the other is a spiral winding round a long axis—are essentially the same in their structure, and are built up of sand grains, as represented in the diagram. Mr. Brady's *Loftusia* would be just the same if, instead of being a flat spire, it was elongated. Some of the specimens I have myself examined have been two and a half inches long, and there is one in the British Museum nearly three inches. This will give you some idea of the enormous size these creatures attained in former periods.

Now, in conclusion, I will briefly direct your attention to an example of foraminiferal structure, which is probably the most interesting of any yet revealed to us, viz. the very wonderful *Eozoön Canadense*, of which I have a very beautiful specimen in my hand. This is found in what are called the Laurentian rocks, in Canada. The Laurentian formation is the earliest kind of stratified rocks at present known. I say at present, because Sir William Logan, by whom it has been examined and described, says it contains pebbles of older rocks, and that he does not at all despair of discovering some older state of stratified rocks. At present, however, it is the oldest known, just as the Silurian strata of Sir Roderick Murchison were twenty or twenty-five years ago. Of the relative position of these Laurentian rocks you may judge when I tell you that they are about as far below the Silurian in geological order, and certainly in the time that must have elapsed between their formation, as the Silurian rocks are below the present time. The oldest previously known would come about the middle of the series. And when we consider that the older strata below are much harder, and must have taken a much longer time to form, the probability is that the lapse of time between the two must have been many times as great. The structure of this formation is that which is known as serpentine limestone. Serpentine is a silicate of magnesia, and limestone is carbonate of lime. Serpentine marble is composed of a series of alternate laminæ of carbonate of lime and green serpentine. The existence of this regular structure and this alternation of carbonate of lime and of serpentine impressed upon Sir William Logan the belief that it had an organic origin; but for a long time no specimens were found that yielded any evidence of this origin. About six or seven years ago, however, specimens were found which were examined by my friend Dr. Dawson, Principal of M'Gill College, Montreal, a most excellent microscopist and palæontologist. He had a knowledge of my own researches in foraminifera, and was well acquainted with the treatise which I published on this subject some years ago, and I had chanced to send him a year or two previously some of my own sections and microscopic objects, which happened to be just what was required to give him the clue to the interpretation of these stratifications. In making sections of this stratum, he found distinct evidence in the calcareous layers of shelly structure. Here is a diagram, showing what the structure would be if it were possible to dissolve out the serpentine, and leave only the calcareous layers. It has just the appearance of nummulites, with curious extensions into the solid layers between them, and these extensions are filled with prolongations of internal serpentine. In another diagram you see the ramifications of the serpentine which occupies these extensions. This is an ideal drawing, because we cannot dissolve away the serpentine and leave the carbonate of lime, but we can dissolve the carbonate of lime very easily and leave the serpentine. We thus get an internal cast or mould, showing the original form of the body which filled it.

The key to all this is furnished by the discovery which was made some years ago by Professor Ehrenberg, that the greensands of various geological periods are distinctly composed, in great part, of the internal casts of foraminifera. There, for instance, is the body of a *Globigerina*. Supposing that body, when dead and decaying, becomes entirely replaced by a green silicate; then dissolve away the *Globigerinæ*, and you will get a little mass exactly resembling the *Globigerinæ* in green silicate. That is exactly what is found in the green sandstone, and that process is going on at the present time. The examination of dredgings in different parts has shown that this process is going on at the bottom of the sea at the present time. Only a few months ago my friend Captain Spratt, who executed some years ago important dredgings in the Ægean Sea, placed in my hand some foraminiferous sand, and certainly the indications I saw in it led me to suspect that this change had taken place in many foraminifera. I put them into very dilute acid, and got a most perfect and beautiful series of internal casts, exactly corresponding with various forms which have already been found in the greensand. That gives the clue to the interpretation of this formation. We have a calcareous shell in the living state, with all the cavities filled with sarcode, and one chamber budding off from another continuously, not like the *Globigerina*, having a certain regular plan and then ceasing, but growing by continuous extension as corals do in making a coral reef. This chamber is filled with serpentine, which extends also into the minute peculiar cells which form what I call the nummuline layer. When we dissolve away the carbonate of lime, we leave here a set of little needles of serpentine, standing up side by side, or sometimes passing off into a brush-like form; and sometimes a smooth layer is formed by the smooth ends of the little fasciculi of silicate, just like the pile of velvet. But in particular parts we find that a number of these tubes run together and form pencil-like brushes that exactly correspond with what have been found in recent shells of the same kind. There is, in fact, no point in the structure of this *Eozoön*, which is so called, as indicating the dawn of life, which does not find its parallel in recent foraminifera. Having examined into the matter, I have come to the conclusion that Dr. Dawson was perfectly right in the view he had taken of the subject, and I was able, by having thinner and more perfect sections than he had, soon to determine the question of this nummuline layer, which completed the proof which was already all but perfect in my estimation. Still there are certain gentlemen who, from time to time, renew the discussion upon the matter when I am not present to reply to them, as was lately done at the Liverpool meeting of the British Association. Yet I venture to say that all the most eminent scientific authorities are fully satisfied with the view that was originally put forward by Dr. Dawson, and supported by myself, also by Mr. Parker, Mr. Rymer Jones, Mr. Brady, and all those who have most carefully examined it, and who are considered authorities on foraminiferous structure, and these views I have no question whatever will ultimately prevail. I may say, also, that those gentlemen who are the best authorities on the microscopic structure of minerals are entirely at one with us. Mr. Sorby, of Sheffield, who is by far the highest authority upon certain points of mineral structure, Mr. David Forbes, who is a great authority on the microscopic structure of minerals, and Mr. Maskelyne,—all say that this cannot be a mineral; that there is nothing that can account for the peculiar character that this structure shows that we know anything of in mineralogy, and there are certain facts which are quite inconsistent. I may just mention one of them, because I find it most satisfactory to any one who knows anything at all about the structure of minerals. It is this, that the Eozoön-rock shows, as many of them do, recent and fossil, distinct planes of crystalline cleavage. This has been long known. The spines of the *Cidaris* have a distinct crystalline axis; in fact, there is sometimes great difficulty in sawing them across, because the least turn of the saw will cause it to splinter off by crystalline cleavage. It has never happened to myself, but I am informed that many of the bags of gall-nuts which are sent over from the Levant very often contain a number of the curious large club-shaped fossil spines of the *Cidaris*, being put in fraudulently to add to the weight. Any of you who come across any of these curious fossils will find that you can cleave them in the proper direction, like a piece of calcareous spar; yet, nevertheless, they have a most beautiful and elaborate organic structure. The existence of crystallization has led many persons into the mistake of thinking that the structure of this rock cannot possibly be organic. There can, however, be no greater mistake, for we are constantly finding crystalline structure in recent as well as fossil calcareous organisms, and these large spines of the fossil *Cidaris* cleave very readily. The point is this: it is maintained by Messrs. King and Rowney that this beautiful arborescent structure, which is a magnified view of what would fill these canals,—that this, which we get by dissolving away the carbonate of lime, consists of mere mineral infiltrations. Now, the fact that was first pointed out to me by Mr. Jordan, I have found most particularly satisfactory to every gentleman who has gone into the question, and who is enough of a mineralogist to appreciate its importance. It is this, that these ramifications pass across the planes of cleavage, which they would not do if they were mineral infiltrations. I believe every mineralogist will at once say that that is perfectly conclusive against their being by any possibility mere inorganic infiltrations; that nothing but organic structure could in this manner produce a ramification of one mineral in the interior of another, a ramification of serpentine in the interior of carbonate of lime passing against its crystalline plane.

This cursory notice of this remarkable rock, for it covers hundreds of square miles in the Laurentian district, must conclude the little sketch I have endeavoured to give you this evening of the chief points of interest with regard to the structure of the foraminifera, but I may just mention one little incident which may give it a special interest for you, if, as I hope, I may be successful in inoculating some of you with a taste for microscopic study. If any of you are disposed to begin the study of the foraminifera, and will get the sponge merchants to give you the sand that they shake out of the sponges when these come over, you will find an immense variety of foraminifera, which will give you plenty of occupation; and there is nothing more easy to begin upon than this sponge sand. The incident I am about to relate I do not mention with any view to the *cui bono?* or with an idea of helping you to raise yourselves in life, because I do not think raising oneself in life is at all the first object in existence; I think the cultivation of one's own powers is the first object. However, to my tale. Some years ago, when I was first paying attention to this subject, a friend asked me if I knew Mr. A. B., who was at work on the same subject. I had not heard of Mr. A. B., who was a hard-working general practitioner, who had what is known as a guinea midwifery practice in a suburb of London. However, I called on this gentleman, and found him an enthusiastic student of natural history, but at the same time he was thoroughly and honestly devoted to his profession. I found that he had made a large collection of foraminifera in the manner I have mentioned, by getting the sponge merchants to allow him to shake out the sand which the sponges generally contain; and he had also gone down to Ratcliff Highway, and got the wholesale dealers in shells to allow him to scrape off some of the foraminifera which attach themselves to the large foliated shells of the East Indian seas, and which often afford some very curious types. In this way he had been working most patiently, employing every spare five minutes of his time; but I found he had been working on what I considered an entirely wrong basis. That is to say, he was following the then most recent authority, that of D'Orbigny, who was making every different form a species. Here, for instance, are two varieties represented, which are now classed as the same species, but which were then called distinct genera. We have now a perfect gradation from one to the other, so that it is impossible to draw a line between them. I invited him to spend an evening with me, and go through one type, and at the close of our interview he acknowledged that he had been working on a wrong plan, and said he should in future follow out the ideas I had given him. Since that time he has been one of my most valued and esteemed *collaborateurs;* and not only has he worked in the most successful manner upon this particular group, but he has followed another study requiring great devotion and care, and great dexterity of manipulation. He has since, through the valuable series of observations which he has communicated to scientific societies, been elected, and on his very first application, a Fellow of the Royal Society,—a distinction of very high value, because only fifteen are elected every year from forty-five or fifty candidates; and in the first or second year afterwards he received the gold medal, one of the highest honours the Royal Society can bestow. I am glad also to be able to say that that scientific distinction, instead of injuring him in his profession, has been of essential service to him. I mention this to show you how, from a very humble beginning, a man may, by simply employing odds and ends of time,—for my friend never had an idle five minutes in the day,—attain to a high position in science. There is no position in life in which this study may not be pursued; and it affords an object of interest, which is one of the greatest comforts to any man of active and busy life,—the comfort of turning to something which forms a quiet occupation at once engaging the eye and the mind without any effort, and which tends more than anything else to distract one from the cares and fatigues of this busy London life, which all of us more or less are engaged in. I can assure you, from my own experience, that microscopic study is for this purpose the best kind of recreation I am acquainted with.

Over-doses of Chloral Hydrate.—*The Medical Times and Gazette* mentions several cases which tend to show that chloral hydrate may prove fatal when administered in too large a dose. One, taken from the *New York Journal of Psychological Medicine*, was that of a lady, exceedingly nervous, who had been subjected unavailingly to a great variety of treatment. At last chloral hydrate was given in six cumulative doses of thirty grains each. The sleep so induced, although every effort was made to arouse her, ended in death. The cerebral vessels were enormously congested. The patient had previously been taking bromide of potassium. In one of our metropolitan hospitals a fatal issue has followed the administration of a large dose of chloral; but here the patient was in an exhausted state from a severe operation. In Philadelphia a woman swallowed an enormous quantity of the drug (460 grains it is believed). The symptoms were very severe, but remedies being applied promptly she recovered.

DR. RICHARDSON ON CHLORAL HYDRATE.

Dr. Richardson, in his lecture on Tuesday last, opened with a short and special series of observations on the recent fatal or assumed fatal cases from the use of the hydrate of chloral, and discussed certain important questions in respect to the action and the effects of chloral, on which he had recently been consulted by members of the medical profession. To a first question whether the practice of taking the hydrate without medical advice or direction was becoming at all general amongst the public, he gave a direct affirmative answer. He held that, in professional hands, now that its action is better understood and the novelty of its application has worn off, the employment of the hydrate is less than it was some months ago; while the practice of resorting to it by the public is on the increase, and a new class of cases is thereby becoming known, marked by particular symptoms and assuming, in some instances, a serious character.

As showing the extent to which the hydrate is now employed, Dr. Richardson said he had been able to estimate that nearly 50 tons of the agent had been used in England in the last eighteen months.

On the question, what is a dangerous and what a fatal dose of the hydrate, the lecturer computed that 120 grains was a dangerous and 180 grains a fatal dose; he cited a case of recovery from a dose of 120 grains, but the symptoms were very prolonged and the risk great.

Another question related to the quantity of the hydrate that might be given in small and repeated doses during a limited time, say of twenty-four hours. The answer to this was, that an adult person could not decompose and eliminate more than from five to seven grains of the hydrate per hour, and that it was therefore not prudent to administer more than 120 grains in the time suggested, viz. twenty-four hours. On a fourth question, whether the frequent administration of hydrate of chloral lessened or increased the danger of administration, the argument ran to the effect that frequency of administration, while it might increase the confidence of those who took the drug, in respect to its safety, actually increased the danger. To use a technical phrase, there was danger by frequent repetition of "accumulation," while the power of the body to dispose of the agent by diffusion, decomposition and elimination, became sensibly reduced. A striking contrast was here struck between the actions of opium and hydrate of chloral, by which it was shown that the latter cannot, like the former, be gradually increased except in the most limited degree, without immediate danger. Three other questions were noticed at length, having reference to the symptoms and pathological conditions incident to the prolonged use of the hydrate; the chemical tests for it in the tissues in cases of poisoning by it, and the *post-mortem* appearances in cases where it proved fatal after administration in many successive doses. These points, which excited much interest in an audience, composed almost exclusively of medical men, are of less moment to our own readers than the subjects we have briefly noticed above.

It will be recollected that Dr. Richardson was the first physician in England who experimented and reported on the action of chloral hydrate, after Liebreich's discovery of its properties, his report having been prepared at the request of the biological section of the British Association for the Advancement of Science, and read at the Annual Meeting of the Association at Exeter, in 1869.

SUNDERLAND CHEMISTS' ASSOCIATION.

The Annual Dinner of the above Society was held on Wednesday evening, Jan. 25th, at the Crown and Sceptre Hotel, and was numerously attended by the members. The chair was occupied by the President, W. Thompson, Esq., and Mr. Harrison Thompson filled the vice-chair.

As the meeting was intended to partake more of a social than a business character, the only toast proposed was by the Chairman, who said he ought not to let that opportunity pass of publicly thanking Messrs. Nicholson and Sharp, and the other gentlemen, whether present or absent, who had devoted a considerable amount of time and labour to getting up lectures and readings, and arranging the business of the society, not forgetting their Treasurer, Mr. Robinson, whose duties were, perhaps, the most onerous of all. These gentlemen responded, speaking hopefully of the progress of the society, Mr. Sharp stating that the last meeting had been undoubtedly the best attended and most successful of any that had been held.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The Annual Supper of the members of this Association was held at the Wellington Hotel, Granby Street, on Thursday night last. The chair was occupied by Mr. J. W. Clark, the vice-chair being filled by Mr. F. Parsons. After the usual toasts,

Mr. Nettleship proposed the toast of the evening, "Success to the Chemists' Assistants and Apprentices' Association." He was pleased to think that the young men of this town had formed themselves into a Society for the advancement of their knowledge in chemistry and pharmacy. Thirty or forty years ago, persons engaged in those pursuits had to rely mainly upon their own resources to attain a certain degree of learning, but at the present time similar societies to theirs were instrumental in enabling young men to successfully pass the examinations of the Pharmaceutical Society. He believed there was no kingdom in the world where chemistry and pharmacy were so satisfactorily carried on as in Great Britain, and expressed his belief that unfounded prejudices which had existed in the public mind respecting chemists' inefficiency in the admixture of medicines would, ere long, cease to exist. He hoped the society would continue to flourish, and requested them, in connection with the toast, to drink to the health of Mr. Young, the President.

Mr. Young, in responding, said few associations could boast of greater success than the one of which they were celebrating the anniversary that night. Since their last annual meeting fourteen or fifteen members of the society had, in different grades, passed examinations of the Pharmaceutical Society.

The Vice-President then gave "Prosperity to the Pharmaceutical Society of Great Britain." He thought they would all admit that they had received great benefit from that Society, and would readily acknowledge the influence it had exercised in promoting the welfare of the chemists and druggists throughout the United Kingdom.

Mr. Clark responded. He said he considered the Pharmaceutical Society had conferred a vast amount of good upon the chemists and druggists of Great Britain, and thought it highly probable that it would eventually raise their position to one of considerable importance.

Mr. Young then proposed "The Honorary Members," associating with the toast the name of Mr. Clark, their chairman upon that occasion.

In responding, the Chairman remarked that two generations ago there were but three chemists in the town of Leicester, while at the present time their number exceeded forty. He hoped the Association would increase in prosperity and usefulness.

Several other toasts were given and responded to, including "The Committee," "The Chairman," "The President, Mr. Young," and "The Local Secretary of the Pharmaceutical Society, Mr. T. Cooper."

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 11, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PROPOSED POISON REGULATIONS.

We are glad to call attention to the circular just issued to the members of the Pharmaceutical Society by its Council, a copy of which will be found in the minutes published this week*—because it is of great importance that the whole question should be thoroughly ventilated before the Annual Meeting, that the members generally should know what regulations they are asked to enact, and that the Council and its present position on the question should be fairly understood. Much misconception has undoubtedly existed both as to the regulations themselves and as to the motives urging the Council to propose them. Men who take the responsibility of public duties must be content occasionally to bear the shade of displeasure, but we think it natural that the Council should endeavour, as they do in this circular, to cast off the imputation of having, in mere servile deference to the Privy Council, sacrificed the liberty of the body to which they belong. It would be extraordinary that they should do so, seeing their daily avocations are similar to those of chemists generally, and whatever would affect or annoy the one would act in like manner on the other.

CHLORAL HYDRATE.

Dr. Richardson's remarks on the use of chloral hydrate, given on the preceding page, will doubtless be read with great interest, and they are calculated to serve as a wholesome warning against the abuse of this valuable agent.

We may take the opportunity of stating that the low results sometimes obtained in testing chloral hydrate appear to be, in a great measure at least, due to the moist condition of the samples. The hydrate is exceedingly hygroscopic, especially when in the form of amorphous cake, and this circumstance seems to be an additional reason why the hard, rhomboidal crystals should be preferred for dispensing. It appears to be doubtful whether the alcoholate is being, to any large extent, if at all, used in the place of the hydrate.

We have received from Messrs. Schœtensack—too late for insertion—a letter containing the results of an analysis of the chloral hydrate manufactured by Saame, of Göttingen, and a copy of a certificate signed by Professor Wöhler, that the material analysed gave the due yield of chloroform. We have also found this to be the case with specimens of chloral hydrate stated to be of Saame's manufacture, and with samples obtained direct from Messrs. De Haen, through their agents, Domeier and Co. But by exposure to the air and absorption of moisture, there will often be a very large reduction in the amount of chloroform obtained in testing.

Mr. W. Beynon, who for nearly two years has filled the office of Honorary Secretary to the London Chemists' Association, has, much to the regret of the members, sent in his resignation, in consequence of not having sufficient spare time to attend to its duties. Mr. J. H. Jessop has been appointed as his successor.

The death of Dr. Sheridan Muspratt is announced as having taken place on Friday last, at his residence, The Hollies, Stoneycroft, West Derby, after a lingering illness. The deceased gentleman was fifty years of age.

Her Majesty has directed that a pension on the Civil List of £100 per annum should be given to Dr. Stenhouse, "in consideration of his scientific attainments."

It is announced that in connection with the *Milk Journal* a laboratory is to be fitted up and placed under the charge of Mr. J. A. Wanklyn, for the institution of original researches into the best methods of testing milk.

The Liverpool Chemists' Association held its eleventh Conversazione, on Thursday, the 2nd inst., at the Royal Institution, Colquitt Street. It was very numerously attended. In the course of the evening Professor Roscoe delivered a very interesting lecture, illustrated by experiments, on "Solar Chemistry."

We observe that it is stated in the *Canadian Journal of Pharmacy* for January, which we have just received, that the prosecution of the twenty-five Toronto druggists for the illegal sale of poisons* has resulted in a conviction, and a fine of twenty-five dollars each and costs. It is intended to carry the matter before a higher Court.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

February 1st, 1871.

MR. SANDFORD, PRESIDENT, IN THE CHAIR.

MR. HASELDEN, VICE-PRESIDENT.

Present—Messrs. Atherton, Bottle, Bourdas, Carr, Deane, Dymond, Edwards, Evans, Groves, Hills, Savage, Stoddart, Sutton, Williams and Woolley.

The minutes of the last meeting were read and confirmed.

The Lot for the next Council having been taken in the usual manner, the following were declared to go out of office, but are eligible for re-election:—*

ABRAHAM, JOHN, 87, Bold Street, Liverpool.
ATHERTON, JOHN HENRY, Long Row, Nottingham.
BOURDAS, ISAIAH, 7, Pont Street, Belgrave Square, London, S.W.
BROWN, WILLIAM SCOTT, 113, Market Street, Manchester.
CARR, JOHN, 171, High Holborn, London, W.C.
DEANE, HENRY, Clapham Common, Surrey.
DYMOND, GEORGE, 17, Bull Street, Birmingham.
EVANS, HENRY SUGDEN, 60, Bartholomew Close, London, E.C.
HASELDEN, ADOLPHUS F., 18, Conduit Street, Bond Street, London, W.
HILLS, THOMAS HYDE, 338, Oxford Street, London, W.
MACKAY, JOHN, 119, George Street, Edinburgh.
SANDFORD, GEORGE WEBB, 47, Piccadilly, London, W.
WILLIAMS, JOHN, 5, New Cavendish Street, London, W.
WOOLLEY, GEORGE STEPHEN, 69, Market Street, Manchester.

The following Members were declared to remain in office for the ensuing year:—

BOTTLE, ALEXANDER, 37, Townwall Street, Dover.
EDWARDS, GEORGE, Dartford.
GROVES, THOMAS B., Weymouth.
REYNOLDS, RICHARD, 13, Briggate, Leeds.
SAVAGE, WILLIAM DAWSON, 30, Upper Bedford Street, Brighton.
STODDART, WILLIAM WALTER, 9, North Street, Bristol.
SUTTON, FRANCIS, 9, Bank Plain, Norwich.

The Report and recommendations of the Finance Committee were received and adopted.

In pursuance of notice given last month, it was moved by Mr. Haselden, seconded by Mr. Savage, and

Resolved unanimously—That an honorarium of one hundred pounds (one year's salary) be presented to Mr. John Barnard, as a recognition of his services in connection with the Journal during a period of fifteen years.

The Report of the Benevolent Fund Committee was received and adopted, and a grant of £5 was made to a Registered Chemist and Druggist, late of Leicester.

The Report and recommendations of the Library, Museum and Laboratory Committees of the 5th and 31st of January were received and adopted.

In reference to the recommendation of the Library, Museum and Laboratory Committee of December 8th, "That the publication of the proceedings of the Evening Meetings be deferred to the week following that in which the meeting is held," it was

Resolved—That the Report of Evening Meetings be published in the Journal of the following week, so as to allow of sufficient time for correction.

* Bye-laws, sect. 5, clause 3:—"Any person qualified to vote desirous of nominating any Member for election as a Member of the Council or as an Auditor, shall give notice in writing with the name and address of the nominee, and if for the Council, disclosing whether such nominee be or not a Pharmaceutical Chemist, to the Secretary of the Society, on or before the 24th day of March in every year."

LIBRARY, MUSEUM AND LABORATORY AND PROVINCIAL EDUCATION COMMITTEE (acting conjointly).

The Committee reported that certain apparatus belonging to the Society might be lent to Provincial Associations, and a list of such apparatus was presented.

The Committee also presented a Code of Rules to be observed in the loan of such Apparatus, and recommended that it should be published with a list of the Apparatus in the Journal, and printed in a separate form for circulation.

Resolved—That the Report and recommendations of the Committee for the loan of Apparatus be received and adopted.

PROVINCIAL EDUCATION COMMITTEE.

The Committee reported that they had considered the applications of the Leicester Chemists' Assistants and Apprentices' Association and the Sheffield Pharmaceutical and Chemical Association, and recommend that Books, Diagrams, or other educational matter, to the value of £10, be granted to the Leicester Association, such materials to be considered the property of the Society, and to be held under guarantee, in accordance with the Regulations of the Standing Provincial Education Committee, the Leicester Association to furnish a list of the requirements costing the sum proposed.

The Committee also recommend that the Sheffield Association be informed that the Council express their willingness to assist in the collection of a Library, Diagrams, Apparatus, or other material in aid of Pharmaceutical Education, but that they do not recommend at present, in the case of towns possessing the educational advantages of Sheffield, that grants of money be given in aid of Lecture or Students' Fees.

Resolved—That the Report and Recommendations of the Provincial Education Committee be received and adopted.

Resolved—That any Association to whom grants on trust are made by the Pharmaceutical Society shall give as guarantors the names of three resident Pharmaceutical Chemists or members of the Society in business, or such other names as may be satisfactory to the Council.

POISON REGULATIONS.

Further Correspondence with the Privy Council.

[COPY.]

"*Medical Department of the Privy Council Office,*
"*January 17th*, 1871.

"Sir,—I am directed by the Lords of Her Majesty's Council to acknowledge the receipt of your letter of the 26th ult., enclosing a copy of some Regulations agreed to by the Council of the Pharmaceutical Society, and proposed to be submitted to the next Annual Meeting of the Society.

"My Lords, in considering the regulations in regard to the *keeping* of poisons, direct me to say that they are of opinion that some regulations as to the *sale and dispensing* of poisons are absolutely necessary for the public safety, and they therefore hope that your Society will, with the least possible delay, frame regulations on that subject, so that their Lordships may be able to give their consent to a complete body of regulations (such as the statute contemplates) in regard to the keeping, selling and dispensing of poisons.

"I am, Sir,
"Your obedient servant,
"(Signed) JOHN SIMON."

"*Medical Department of the Privy Council Office,*
"*8, Richmond Terrace, Whitehall, S.W.*
"*January* 21, 1871.

"Dear Sir,

"There are some alterations which the medical officer thinks should be made in the proposed regulations as to the *keeping* of poisons, and as it would apparently be well that you should be in possession of his views on these matters before the next meeting of your Council, he would be glad to have an opportunity of conferring with you some day next week, and would suggest Tuesday next, the 24th, at 3 o'clock. Please let me know whether you can come.

"Yours faithfully,
"W. ROTTON.

"The Registrar of the Pharmaceutical Society."

In compliance with this request the Registrar reported that he had, accompanied by the President, attended at the Privy Council Office.

The alterations which Mr. Simon considered necessary in the regulations as to the keeping of poisons were merely verbal, calculated to make their meaning more clear; but he most urgently desired that the regulations as to the dispensing of poisons, which he deemed of vital importance to the public safety, should be restored.

The following is the form in which Mr. Simon thought the regulations should be remodelled:—

Proposed Regulations as to the Keeping and Dispensing of Poisons.

1. In the keeping of poisons each bottle, vessel, box or package containing a poison shall be labelled with the name of the article, and also with some distinctive mark indicating that it is poison.

2. Also in the keeping of poisons, each poison shall be kept on one or other of the following systems, viz.

(*a*) in a bottle or vessel tied over, capped, locked or otherwise secured in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop or dispensary; or

(*b*) in a bottle or vessel readily distinguishable by touch from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop or dispensary; or

(*c*) in a bottle, vessel, box or package kept in a room or cupboard set apart for dangerous articles.

3. All liniments, embrocations, and lotions containing poison shall be sent out in bottles readily distinguishable by touch from ordinary medicine bottles, and there shall also be affixed to each such bottle (in addition to the name of the article, and to any particular instructions for its use) a label giving notice that the contents of the bottle are not to be taken internally.

Resolved—That the proposed Regulations as to the keeping and dispensing of Poisons now presented be received and entered on the minutes.

Moved by Mr. Sutton, seconded by Mr. Woolley,

That the discussion on the second letter of Mr. Simon, and upon the proposed Poison Regulations generally, be postponed to the 1st of March.

For the motion (5)—

Messrs. Atherton, Carr, Savage, Sutton and Woolley.

Against (10)—

Messrs. Bourdas, Deane, Dymond, Edwards, Evans, Groves, Haselden, Hills, Sandford and Williams.

The motion was therefore lost.

Moved by Mr. Dymond, seconded by Mr. Deane,

That though the adoption of the proposed Regulations for the Keeping, Sale, and Dispensing of Poisons rests with the Annual Meeting of the Pharmaceutical Society, yet inasmuch as they will affect a large number of the members to whom it will be impracticable to attend that meeting, and as it is necessary that the subject should, if possible, obtain a final settlement, it is desirable that the Regulations, as now submitted by the Council, be sent to each Member of the Pharmaceutical Society, together with a statement of the reasons which have induced the Council to suggest them.

For the Motion (11)—

Messrs. Bottle, Bourdas, Deane, Dymond, Edwards, Evans, Groves, Haselden, Hills, Sandford and Stoddart.

Against (2)—

Messrs. Sutton and Woolley.

The Motion was therefore carried.

In pursuance of the above resolution, a statement of reasons was submitted to the Council, and a Committee, consisting of the President, Vice-President, Messrs. Deane, Dymond and Edwards, was appointed to revise and issue it.

The Committee subsequently met and instructed the Secretary to send a Copy of the following Circular to each Member of the Society and to each Associate of the Society in business:—

A Statement of the Reasons which have Induced the Council to Suggest Regulations regarding the Keeping, Dispensing and Selling of Poisons.

The Council of the Pharmaceutical Society, feeling it to be of primary importance that the question of the adoption of regulations for the keeping and dispensing of poisons should receive early and definite settlement, earnestly desire to call the serious attention of the members generally to it, with a view to its receiving their final judgment at the ensuing Annual Meeting in May.

The course of legislation on the subject of poisons is one which many members of the Council have, in their official capacity, carefully watched for many years. Prior to the passing of the Pharmacy Act of 1868 attempts had been made in Parliament at various times to enforce regulations for the sale of poisons (of which the Act regulating the sale of arsenic is an illustration), and it is due to the Council of the Pharmaceutical Society to say that, but for their vigilance, measures which would have proved most injurious to the true interests of chemists, and of the public, would in all probability have passed the Houses of Parliament and become law. The desire of the Council has always been, whilst, on the one hand, conscious of the just claims of the public on those who are the responsible dealers in dangerous poisons, on the other hand, to restrict legislation on this subject to those moderate and practical measures which they knew to be in accordance with the exigencies of the trade. They venture to think that their efforts in this direction have not been devoid of success.

The history of the Pharmacy Act of 1868 is well known. When, in 1865, the Council of the Pharmaceutical Society, encouraged by public opinion (but more especially by the opinion of the medical profession), that dispensers of medicine should be an educated class of men, introduced their "Bill to regulate the Qualifications of Chemists and Druggists," it contained no allusion to poisons whatever. There is every reason to believe that Bill would have passed had not a second, emanating from the United Society of Chemists and Druggists, led the Government to infer that we were not agreed as to the best course to pursue. In the Bill of the United Society poison clauses were prominently introduced, and a Committee of the House of Commons reported that it was desirable to legislate on that subject.

The Council, therefore, were compelled to accept the regulation of the sale of poisons as one basis of future legislation, or forego their efforts to extend the Pharmacy Act. They drafted a Bill accordingly, for which they obtained the approval of Government, but, owing to the great pressure of public business, could not get it introduced as a Government measure. Fortunately, Earl Granville took charge of this Bill, passed it readily through the House of Lords, and Mr. Headlam ably stood sponsor for it in the Commons. There, however, a much more severe treatment was in store for it. Propositions were made to render the poison clauses so restrictive that, had they passed into law, the trade of a chemist and druggist would have become almost impossible. These propositions were watched and combated from day to day by the Council, and the Act of 1868 was the result. In that Act great privileges were accorded to, and great confidence reposed in, the Pharmaceutical Society, to which, on the urgent representation of the Council, that the Society itself was the only competent judge of what would be practicable and adapted to the various exigencies of trade in all parts of the kingdom, the Legislature committed the duty of arranging the detailed conditions for keeping, dispensing, and selling poisons.

Hence there was a tacit understanding between the Council and the Government that the Pharmaceutical Council should frame a code of regulations to be approved by the Privy Council. It became the duty of the Society to do that which in its wisdom should be consistent with this understanding,—to frame a series of regulations for the keeping, sale, and dispensing of poisons which should be practicable and easy of application to chemists and druggists, and, at the same time, satisfy the demands of Parliament and the public.

In doing this, the Council felt it would be impossible to prepare regulations which would not interfere, more or less, with the existing arrangements of many chemists. But they thought if regulations could be framed which would be neither onerous nor impracticable, every chemist would feel it his duty to submit to some inconvenience, if necessary, to promote the public safety, for the sake of unanimity, the general good, and the satisfaction of the Government.

In framing resolutions, the Council have been most solicitous not to interfere prematurely with the subject, or to encumber chemists generally with any burdensome restrictions in the conduct of their responsible duties; but at the commencement of 1870 they felt the subject could not be delayed, and at that time proposed a series of regulations for the "keeping, selling, and dispensing of poisons." That scheme was presented to the Annual Meeting in May last. It obtained much attention previously to and at that meeting, and though an amendment was moved directly negativing the proposal, a resolution was unanimously passed in the following terms:—"That the subject be taken into consideration by the incoming Council, and that a further report be made to the next Annual Meeting."

During the interval which has elapsed since that time, the subject has obtained the frequent and anxious attention of the Council. They have carefully observed the current of opinion on the subject amongst the members of the Pharmaceutical Society, as shown in the periodical correspondence upon it, and in the memorials which have been received from various Pharmaceutical Associations in the country. They have also watched the expression of opinion in the press, and have been fully informed of the views entertained by the Privy Council and by members of the Legislature. Considering also the obligations which the passing of the Pharmacy Act of 1868 has imposed upon them, they believe it their duty still to propose the same rules for the *keeping of poisons* (though in a simplified form) which they proposed last year, as those which appear to afford on the whole the most scope and simplicity, and which are best suited to the various necessities of chemists in business. They, however, omitted the third proposed regulation for the "dispensing of poisons,"—not because they considered it inappropriate, but in the endeavour to meet the views of members of the Society by disencumbering the proposed regulations of what seemed to be the least important of them.

Since the meeting of Council at which these amended regulations were agreed upon, the Registrar of the Pharmaceutical Society has received two communications from the Privy Council, of which no member of the Council had any previous cognizance. The first of these expressed a desire to know whether the Pharmaceutical Society intended within any specified time to propose such regulations as Parliament, in the opinion of the Privy Council, required. The reply of the Registrar to this inquiry, enclosing the proposed amended regulations, produced another letter from the Privy Council expressing the opinion that some regulation as to the *sale and dispensing* of poisons, "*such as the State contemplated*," were absolutely necessary for the public safety, as well as those for the *keeping* of poisons. (*Vide* 'Minutes of Council,' February 1st, 1871.)

This letter has induced the Council of the Pharmaceutical Society to reconsider the whole question, and the decision at which they have arrived is that it will be incumbent on them to present to the Annual Meeting in May next for its approval, regulations as to the *dispensing*, as well as *keeping* of poisons.

In this decision the Council have not been unmindful of the objections which have been raised, which, however, have been directed more to the imposition of any regulations at all, than to the impracticability of those particularly which the Council propose. The language in which the regulations are couched is so simple that it would appear almost superfluous to explain further, but the Council have been struck by the erroneous interpretations which have from time to time been given. Notably, it has been stated over and over again, that it would be impossible to keep all poisons in one cupboard. The regulations do not contemplate anything of the sort. A chemist may adopt the separate system for one, or as many poisons as he pleases; he may keep others on the ordinary shelves of the shop, provided either that the bottles or vessels containing them be distinguished by some peculiarity of shape, roughened surface, or leather or other cap. It is admitted that very many, probably most, chemists in Great Britain, already adopt them in some or all of their forms. So far, their importance and value are admitted. It appears to the Council one of the strongest arguments in their favour, that so many actually feel it to be a *duty* as well as a *necessity* to adopt them. Some of the objections raised are such as the Council find it difficult to take cognizance of; but with reference to the obligations which the regulations would impose, they venture to say that no vexatious proceedings will be adopted to inquire into their observance. They believe some practical advantages will follow the adoption of them, in the lessening of anxiety in the conduct of so responsible a business, and in the probable mitigation of penalties in case of accidents. They think it not unreasonable that in private and public dispensaries the same regulations as to the keeping and dispensing of poisons should be enforced, but the necessity of their observance by chemists is not affected thereby, whilst it is well known that the great bulk of poisonous drugs is deposited with, and is used by, the chemist. The Council are not without sympathy with those who feel objections to the imposition of any restrictions, however slight, in the conduct of any portion of their business; but, for the reasons before stated, they believe that the concessions which chemists are now asked to make are such as it would be wise and prudent for them to yield, whilst there is every reason to believe that the regulations now framed will fully satisfy the requirements of the Legislature.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be respectively granted a Diploma stamped with the seal of the Society:—

Diaper, Albert .... Bury St. Edmund's.
Reinhardt, William Tynedale .. Leeds.
Sandiland, Robert Burgess, jun. Bicester.
Sherburn, Thomas .... Harrogate.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be elected Members:—

Butterworth, Albert .... Bradford.
Cross, William Gowen, jun. .. Shrewsbury.
Griffin, Thomas .... Boro' Fen, Peterborough.
Peck, Frederick Hamilton .... London.
Perry, William Henry ...... Birmingham.
Raffle, William .... South Shields.
Reinhardt, William Tynedale... Leeds.
Robinson, James .... Darlington.
Sandiland, Robert Burgess, jun. Bicester.
Scruby, William Yull .... London.
Shaw, Henry Woolhouse .... Doncaster.
Skipper, Edward .... London.

Resolved—That the following Registered Chemists and Druggists be elected Members of this Society:—

Arnold, Spencer .... Tunbridge Wells.
Ellis, William .... Burnham.
Ferneley, Charles .... Worcester.
Lewis, Thomas Hopkin ...... London.
MacGeorge, William .... London.
Pipe, Walter .... London.
Rutter, Edmund Yates .... London.
Tully, John .... East Grinstead.
Watson, Gilbert Pickering .... Norwich.
Williams, William .... Tenby.
Wovenden, Henry .... Sale.

Resolved—That the following, having passed their respective examinations, be elected "Associates in Business":—

MINOR.

Brooks, Frederick .... Hastings.
Budden, William .... Liverpool.
James, John .... Liverpool.
Osborne, James .... Ashbourne.
Part, Edward James .... Greenwich.

MODIFIED.

Cottrill, John White .... London.
Hughes, Jacob .... Llanelly.
Light, John Henry .... Bristol.
Oldham, Gervase .... Macclesfield.
Palethorpe, William .... Bingham.
Parnell, James .... Wiveliscombe.
Preston, Alfred Prince .... Abingdon.
Pughe, Rice Owen .... Pwllheli.
Rainforth, Richard .... Sheffield.
Rogers, Henry Frost .... London.
Smith, Allen .... Sale, nr. Manchester.

Resolved—That the following, having passed their respective examinations, be elected Associates:—

MINOR.

Arundel, Matthew Henry ..... Penge.
Bannard, Henry .... Brackley.
Brown, James .... Bideford.
Coles, Samuel John .... Brentford.
Freeman, Ernest .... Stourbridge.
Galloway, George, jun. ...... Inverness.
Hadley, Thomas .... Hereford.
Jones, Alfred .... Northampton.
Macpherson, Richard .... Greenock.
Overton, Charles Arthur ...... Horncastle.
Sant, George .... Atherstone.
Slater, Jonathan .... Keswick.
Smith, John Francis .... Scarborough.
Strachan, Alexander .... Aberdeen.
Wright, Joseph .... Knutsford.

MODIFIED.

Bowler, William Samuel ...... Ashbourne.
Collett, Charles Benjamin .... London.
Morris, John Cape Bevan .... Brecon.
Moule, William .... Bristol.
Sugden, Joseph William ...... High Harrogate.
Yoxall, Henry .... Belfast.

Resolved—That the following be appointed Local Secretaries to the Society:—

Aberdare ...... T. W. Evans *vice* J. Jones, resigned.
Wakefield .... John Taylor " T. W. Gissing, dead.
Gt. Yarmouth .. John Jas. Owles " W. S. Poll, resigned.

PHARMACEUTICAL MEETING.

Wednesday, February 1st.

MR. G. W. SANDFORD, PRESIDENT, IN THE CHAIR.

The first of two Lectures on the Microscope and its Revelations was delivered by W. B. CARPENTER, M.D., F.R.S., F.G.S., F.L.S., which will be found printed at p. 641. At the close a vote of thanks to the lecturer was passed unanimously.

MEETING AT EDINBURGH.

The Third Meeting of the present Session of the North British Branch of the Pharmaceutical Society was held in St. George's Hall on Friday Evening, 3rd February; Mr. AITKEN, President, in the chair.

Professor ARCHER made the following communication on "Isinglass":—

In commencing this paper I beg it to be understood that in this, and similar efforts, my object is not to produce original matter for the instruction of the senior members of this Association, but to draw the attention of the juniors to those subjects of interest in which their profession abounds, and which simply require to be presented to their notice, to be appreciated as steps in the acquisition of that knowledge which is to become the foundation for their future success in life.

Last winter I called attention to a series of animal substances which hold a very interesting position in the history of pharmacy; but I purposely left out the important subject of my present paper, because it was impossible to do justice to it in the general summary which I then presented to your notice.

Isinglass, under its Greek name, Ichthyocolla (from ἰχθὺς a fish, and κόλλα glue) was known in the time of Dioscorides, who, however, says but little about it. Pliny, who wrote about fifty years later, that is, at the commencement of the Christian era, describes it as the production of a fish *called* ichthyocolla. In this he was doubtless mistaken, and he evidently knew little of its history, for he says, "Ichthyocolla is the name of a fish with a glutinous skin; the glue which is made from it is also known by the same name." He further says, "That of Pontus is highly esteemed, it is white, free from scales, and dissolves with the greatest rapidity." This proves incontestably, first, that the Greeks obtained it from the Black and Caspian Seas, as the Russians do at the present day; and, secondly, that, besides this imported isinglass, the Romans had found that certain fish-skins yielded an inferior but still useful kind of fish-glue.

Isinglass (supposed to be derived from *Hausenblase*, or sturgeon's bladder) is generally understood to be the air-bladders of certain fishes carefully prepared by drying; but it is the gelatine which these organs contain in such abundance and purity which is the valuable part for food purposes; and this is obtainable, though less easily, and of less purity from the skin, the membranes of the stomach and other integuments of the same, and many other kinds of fish. This particular kind of gelatine has two principal uses; first, as an article of food, and secondly, as a means of clarifying various preparations, especially fermented liquors; to these may be added its use as a cementing material, which, however, is not very important.

As an article of food only the finer kinds of Russian isinglass are generally used; these are obtained from various species of the genus *Acipenser* (Family, *Sturionidæ*), viz.:—

Acipenser Huso (Linn.). The Beluga.

A. Guldenstadtii (Brandt and Ratzeburg). The Osseter.

A. Ruthenius (Linn.). The Sterlet.

A. stellatus (Pallas). The Sewruga.

These are all natives of the Caspian and Black Seas, and are chiefly caught in the rivers flowing into these seas, the Volga especially. The more common species of *Acipenser*, *A. sturio*, the sturgeon which is found widely distributed not only in the rivers of Europe but also in those of North America, has not been used for obtaining isinglass, because, I presume, it is never found in great numbers in the European rivers. Professor Owen in 1851 called the attention of the Canadians to the fact that the sturgeon abounds in the large rivers of North America, and suggested the utilization of their isinglass, which has been since collected, although not in very great quantities.

One other fish is known to be taken by the Russian isinglass traders, namely, the *Silurus glanis*, a large fish which is supposed to yield the Samovy isinglass of commerce.

The preparation of isinglass, whether for the purposes of food or otherwise, is the same. I will therefore say a few words upon the process employed by the fishers. The air-bladders, when removed from the fishes, are usually slit open or turned inside out, well washed, and the inner membrane, which has a silvery lustre and greater consistency than the outer one, is stripped off to form the finest qualities, or left on as the case may be. The air-bags are then carefully dried in various ways; thus, by some curers they are slit open and spread out to dry, by others they are stretched between pegs giving the staple form, as seen by these specimens, whilst others fold the opened sheets so as to form these specimens of book-isinglass. The Brazilian and Indian methods, probably from the fact that drying is a much easier process in those warm climates, are of a much more simple character.

Of Brazilian there are two kinds, lump and pipe. The *lump* is the collapsed air-bladder, flattened and dried; the *pipe* kind appears to have been dried with air in it, so as to distend it and allow the inner membrane to dry thoroughly.

There are three kinds of Indian; lump, leaf and pipe.

When isinglass is imported it has to be prepared for use by first softening it by moisture, then rolling it into thin sheets between powerful metal rollers, after which it is cut into fine shreds. Before these mechanical appliances were thought of, it was rudely prepared by cutting it into pieces and then pulling these pieces into small shreds by the fingers, or cutting into thin pieces by knives.

As a clarifying material its use is very extensive amongst brewers; it is also used in clearing some kinds of wine and other liquids, but its exact operation is not quite understood. By some it is believed that as the gelatine dissolves in the liquids to be cleared, it spreads in thin, net-like films, which gradually sink and carry down with them the suspended impurities. Others believe that the thin shreds of the isinglass contain net-like membranes, which as the gelatine dissolves out, are left expanded in the fluid, and, as they sink, carry down the impurities as in the other case. The latter is most likely the mode by which it operates, because it is quite certain that a solution of the pure gelatine of isinglass will not produce the same effect, neither some kinds of fish-sounds, prepared as isinglass, which are from time to time tried for this purpose.

Of the substances allied to isinglass which are found in commerce I may mention the—

Cod-sounds, which are the air-bladders of the cod; they are salted and not usually dried, and are only used for food; they come to us from the cod-fisheries of our own country and Newfoundland.

Fish-maws, which are the stomachs of certain fishes caught on the shores of India and the Indian islands; they are dried and form an important article of commerce to China, Japan and other Eastern countries. We have no reliable information as to the fishes which yield them.

Sharks' fins and skin, in consequence of the large amount of gelatine they contain, also form an important trade with the same nations.

Visiaga, the curious article I now show you, forms one of the greatest delicacies of the Russian *cuisine*. It consists of the long tendons which lie along the vertebral column of the various species of sturgeon, from which it is separated, dried over lines, and tied up in bundles for sale. When used, it is soaked until soft, cut into lengths of about an inch, and made with rice and some condiments into very delicious pies, which, however, from their costliness, are only found at the tables of the wealthy.

On the table I have placed specimens of Indian and Siamese fish-maws, shark's skin and fins, viziaga, and the following kinds of isinglass:—

1. Russian.
   - Beluga Leaf, from *Acipenser Huso*.
   - Astracan Leaf, from ditto.
   - Short Staple, from *A. Guldenstadtii*.
   - Siberian Purse.
   - Samovy Leaf, } from *Silurus glanis*.
   - Samovy Book, }
   - Long Staple.
   - Short Staple.
   - Rolled.
   - Cut.
2. Brazilian.
   - Block or Cake, }
   - Lump, } Probably from *Silurus Parkerii*.
   - Purse, }
   - Tongue or Pipe, }
   - Rolled and Cut.
3. Guiana and West Indian.
   - Gilbacker lump (British Guiana), from *Silurus Parkerii*.
   - Ditto, cut.
   - French Guiana lump, from the *Machoiran*.
   - West Indian lump, from *Silurus felis*.
4. North American.
   - Hudson's Bay Purse.

Canadian Leaf.
New York Ribbon, from the refuse of various species.

5. East Indian. Supposed to be produced by several species of the genus *Polynemus.*

Cake and Purse.
Bombay Purse.
Penang Leaf and Purse.
Manilla.
Madras, from a fish like mullet, put up as "Long Staple."

Large as this series is, it by no means comprises all of the varieties of this interesting material. What I have shown will, however, give you some idea of its importance, and still more of the importance that you, who have daily to do with these things, should make yourselves intimately acquainted with such subjects not merely in their more common features, but in their most minute details,—not only because knowledge gives power, but in your case you will find it will give pecuniary reward also, for we are rapidly coming to the point when want of knowledge will bring want of business, whilst its possession will be certain to secure patronage to the pharmaceutical chemist.

There is one book I must commend to all of you,—I mean Pereira's 'Materia Medica.' It has given me more pleasure than any half-dozen novels I ever read. It has given me immense information, and it has been my great aid to this and other papers. It ought to be the aim of every young pharmaceutist to possess it, and his greatest pleasure to study it; and when such is the case the profession of pharmacy is certain to take its proper place amongst the learned professions of this and other countries.

At the close of the paper a cordial vote of thanks was proposed by the Chairman to Professor Archer, seconded by Mr. Blanshard, and carried with acclamation.

LONDON CHEMISTS' ASSOCIATION.

At the Meeting on Thursday, February 2, Mr. Cox occupied the chair, several ordinary members were elected, and Mr. J. B. Hurst, of Louth, and Mr. W. H. Pullen, of Leamington, were elected corresponding members.

A communication from Mr. Button, of Rangoon, containing notes on "Indian Pharmacy" was read, it was considered desirable to bring the matter forward again for discussion.

Mr. Beynon then read a paper on "The Preservation of Vegetable Substances." He said the preservation of vegetable and animal substances had, of late years, attracted a great deal of attention, more especially the preservation of such as are used for food, which, of all others, are most prone to decomposition. The keeping of vegetable substances was of greater interest to the pharmacist, deriving, as he does, so many of his medicines from the vegetable kingdom; upon the storing of them more care should be bestowed, as many, if not dried or preserved in a proper manner, lost their medicinal properties. Mr. Beynon first spoke of the preservation of the lower orders of plants, as the *Algæ*, *Fungi*, *Lichenes*, and *Filices*, mentioning those which are used as food, and detailing also the best way of making specimens of them for the herbarium; he then proceeded to speak of the preservation of different parts of plants, as their leaves, fruits, seeds, etc., giving the different methods by which ordinary articles of food as corn-seed, potatoes, etc. are kept from deteriorating. The keeping of *Digitalis*, *Conium*, and other medicinal plants, and the preparations made from them also received attention; the bottling of fruits was fully described, and their preparation for the purpose of illustrating structural botany.

After an interesting discussion, a vote of thanks was given to Mr. Beynon for his instructive paper, and much regret was expressed at his resignation of the Secretaryship of the Association, which office he has held for nearly two years.

Mr. Jessop was elected Secretary, *pro tem.*

A hearty vote of thanks to the chairman concluded the business of the evening.

Parliamentary and Law Proceedings.

Alleged Poisoning by a Cough Mixture.

On Monday, January 23rd, Mr. John Dale, chemist and druggist, of Great King Street, Macclesfield, was brought before the Glossop magistrates, charged with the manslaughter of Matilda Rowbotham.

The facts were that the defendant had sold several bottles of "Loxham's Cough Mixture" to the mother of the deceased, who retailed them at her shop. On the previous Thursday Mr. Dale called and saw that the little girl was suffering from hooping cough, and recommended a little of the cough mixture to be mixed with water and given occasionally.

The mother, upon cross-examination, admitted she had not followed Mr. Dale's directions, but had given the whole three spoonfuls between two o'clock in the afternoon and twelve o'clock at night. She further admitted that the child might have got to the medicine in her absence. The child was nine years old.

James Rhodes, M.D., proved having analysed the stomach. The child had died from a narcotic poison. In cross-examination he said that by morphine he meant laudanum; sulphuric acid might produce morphia in its action on laudanum. The directions on the bottle, if followed, would not be dangerous.

For the defence it was urged that all intelligent persons were aware that medicine improperly administered would often prove one of the strongest poisons. One of "Dover's Powders" was useful, two might possibly be injurious. Reference was made to Lord Lyndhurst's judgment in the case of *Reg.* v. *Webb*, where it was clearly laid down that to be manslaughter the medicine must be violent and dangerous, and administered by a person totally ignorant. Another point fatal to the prosecution was, that the mother had not followed the directions of Mr. Dale.

At the conclusion of the evidence, the magistrates decided upon dismissing the charge. As, however, Mr. Dale has been committed for trial upon the coroner's warrant consequent upon an inquest, he will have to appear at the assizes, but it is thought that the grand jury will not find a true bill.—*Macclesfield Courier.*

Poisoning by Home-made Lime-water.

At an inquest held at Birmingham, it was shown that a patient having been directed, among other things, to take a certain amount of lime-water every day, but not being told whether to buy it or make it himself, straightway procured some lime, mixed a lump with water, stirred it and drank the thick mixture. A few hours afterwards acute symptoms of gastritis set in, resulting in death. A verdict was returned by the jury to that effect.

The *Medical Times and Gazette*, in commenting upon this case, says that the lesson to be drawn from it is this, always to take for granted the complete ignorance of patients concerning the nature and properties of drugs, and never recommend them to be their own chemists, but tell them to apply to those whose legitimate business it is to supply them.

Attempted Suicide by Sugar of Lead.

Last week, a well-dressed man, named Thomas Gee, was charged at the Mansion-House with attempting to commit suicide. The prisoner was seen by a police officer on Southwark Bridge, apparently in great distress. While the officer was watching him, prisoner took a small packet from his pocket and put a portion of the contents into his mouth; then, seeing the constable coming towards him he ran away. Upon being caught he said, in answer to a question, that he had swallowed some sugar of lead. He was taken to a private surgery, but refused an emetic, and was then conveyed to St. Bartholomew's Hospital, where one was given him. Evidence was given that he was suffering under a monomania, and he was delivered over to the care of his friends.—*Times.*

Obituary.

At Carlisle, on the 29th of January, aged 70, Mr. James Parker Harrison, the oldest member of the trade in that City, having been in business for forty-seven years. Mr. Harrison became a member of the Pharmaceutical Society in 1842, and acted as Local Secretary until 1864, when the infirmities of age led him to relinquish that office.

MEETINGS FOR THE ENSUING WEEK.

Monday ......*Medical Society*, at 8 P.M.
London Institution, at 4 P.M.—"The First Principles of Biology" (Educational Course). By Prof. Huxley.

Tuesday ......*Royal Institution*, at 3 P.M.—"The Nutrition of Animals." By Professor Foster.
Royal Medical and Chirurgical Society, at 8.30 P.M.
Photographic Society, at 8 P.M.—Annual Meeting.

Wednesday ...*Society of Arts*, at 8 P.M.—"The Commerce of India." By Dadabhai Naoroji.

Thursday......*Royal Society*, at 8.30 P.M.
Royal Institution, at 3 P.M.—"Davy's Discoveries in Chemistry." By Prof. Odling.
London Institution, at 7.30 P.M.—"The Action, Nature and Detection of Poisons." By F. S. Barff.
Linnean Society, at 8 P.M.
Chemical Society, at 8 P.M.

Friday ....*Royal Institution*, at 9 P.M.—"The Wolf-Rock Lighthouse." Mr. Douglass.

The following journals have been received:—The 'British Medical Journal,' Feb. 4; the 'Medical Times and Gazette,' Feb. 4; the 'Lancet,' Feb. 4; the 'Medical Press and Circular,' Feb. 8; 'Nature,' Feb. 2; the 'Chemical News,' Feb. 3; 'Journal of the Society of Arts,' Feb. 2; 'Gardeners' Chronicle,' Feb. 4; the 'Grocer,' Feb. 4; the 'Produce Markets Review,' Feb. 4; the 'English Mechanic,' Feb. 3; the 'Florist and Pomologist' for February; the 'Food Journal' for February; the 'Milk Journal' for February; the 'Journal of the London Institution' for February; the 'Brewers' Guardian' for February; the 'Doctor' for February; Evans, Leschers and Evans' 'Price Current' for February; the 'Liverpool Daily Post,' Feb. 3; 'Bristol Times,' Feb. 4; 'Leicester Chronicle,' Feb. 4.

Dead at his Post.—A sad case was mentioned at the last meeting of the Bethnal Green Board of Guardians. One of the dispensers of the parish, Mr. Evans, while performing the duties now made so perilous by the outbreak of smallpox in the East End, was seized with the malady, and after eighteen days' suffering expired. His wife, worn out by tending him, took the disease, and is now lying ill in a wretched state of destitution. If ever there was a case deserving of commiseration this is one, for the unfortunate Evans died at the post of duty as truly as any soldier. The guardians, much to their credit, have started a subscription for the doubly desolate widow, and have voted her £25 out of the rates, a sum, however, which cannot be paid without permission from the Poor Law Board.—*Eastern Post.*

Notes and Queries.

The Proposed Poison Regulations.

Sir,—As a sequel to a case of incompetent dispensing and consequent poisoning in a medical surgery, perhaps the following will prove that Mr. Bean is not the only medical gentleman who considers that "dispensing is merely mechanical, and that previous education has not much to do with it." Some time ago a shop-boy in my employ requested that he might leave, as Dr. —— had offered him more wages if he would come to him. His request was granted, and shortly after I was informed by my assistant that the boy's mother had called to say she was sorry for taking him away, but Dr. —— thought he would be very useful in his surgery after being eighteen months with a chemist, the boy being the only dispenser in the establishment, according to her statement.

Now, Sir, in the face of such glaring facts of incompetent dispensing in medical surgeries, can it be possible that H.M.'s Privy Council will close its eyes against such a reckless system, the extent and result of which can never be known in this world, and insist upon enacting further legislative measures upon the liberty of a body for whom they have done quite enough, whilst illiterate shop-boys and coachmen are allowed to pass observation and dispense with impunity?

Then again, what is a poison? Nearly all our preparations are poisonous only in overdoses; if so, how is the line to be drawn? Must our cellars be converted into poison stores and our shelves into an array of empty show-bottles? The inevitable consequence would be that our dispensing counters would become daily crowded with an indiscriminate mixture of bottles, etc., owing to the want of an opportunity of returning them to their dismal cells below, and mistakes and confusion would be the order of the day. As regards the subject of inspection mooted by some of your correspondents, what man of education and social standing, with an atom of professional pride, would submit to such humiliation and the stigma of utter incompetency to manage his own affairs?

If we are to be placed on a par with, and subject to the crusade against betting-houses and the notorious houses of the Haymarket, the sooner we abandon our profession the better. To a non-professional looker-on these proceedings would imply that poisoning the public must be a profitable traffic, which required to be put down by force of law. Are we supposed to be so ignorant with regard to our personal interests and welfare that we cannot be entrusted with the arrangements best suited to the requirements of our individual establishments? Are we so callous to the result of careless dispensing that we cannot realize the horrors thereof and the inevitable ruin it may entail upon us? Why this great outcry against poisons at the present moment?—we have killed neither a lord nor a bishop!

The majority of your anonymous advocates—(by the way, why anonymous? Are they ashamed of showing a bold front, and proving that they are none other than dispensing chemists?)—have written their "thema," with a "free accompaniment" which detracts from a beauty it never possessed; and the force of the composition is lost owing to the absence of harmonious facts. For instance, that "accidents have continually happened to human life," etc., are inadmissible false alarms, which cannot be substantiated. Since the Pharmacy Act was passed nearly three years ago, we have never enjoyed greater immunity from fatal mistakes,—a fact that commends itself as the most forcible argument. Why not leave well alone, and allow the Act, after advancing untrammelled so far, to accomplish that for which it was originally intended, namely, to provide dispensers of education with a store of knowledge equal to the requirements of their profession? We have allowed the outward, visible sign to engross our attention too long. If we would but spend the time we waste in studying bottles, labels, etc., in making ourselves better acquainted with the various preparations we use, and never allow them to pass through our hands without proper recognition, poisoning would become a thing of the past, and we should then have accomplished what the storing of poisons can never attain.

London, Jan. 31st, 1871. T. C. Jones.

Sir,—I venture again to make a few remarks on the keeping and storing of poisons. In my former letter, you kindly inserted, I mentioned the fact that in Glasgow nearly two-thirds of our drug retailers are surgeons and doctors, who keep open shop for the retailing and dispensing of poisons. It has been a custom to make the shop a stepping-stone to success in their profession among the poorer classes, who (from economy, I presume) find a boy at a salary of four or five shillings a week sufficiently qualified to dispense, manipulate and take charge of the shop during the greater part of the day, while the employer is visiting. Your article of the present week on dispensing in surgeries, illustrates a case very much to the point. I am convinced if the father of that unfortunate child had not been able to recognize the appearance of narcotism, the medical man would assuredly have taken advantage of the old refuge, "unfavourable symptoms set in," the child buried out of sight, the apprentice would begin anew dispensing his thousand prescriptions until the next 'cute father turned up. Is it not very natural to expect such cases to happen here? I am certain I speak for my brethren that we have no objection to a reasonable arrangement for the storing of poisons, and also that we bear no antipathy to surgeon-druggists. What we want is simply fair-play. I would suggest that all surgeons and doctors who keep open shops should be placed on the same restrictive platform with us, and also that they should be compelled to employ a properly qualified and examined assistant.

M. P. S. (p. 578) observes on my former letter that qualification is no protection to the public. I am astonished he should place so little favour on education, as he must know that the great aim of the Pharmaceutical Society has been the advancement of pharmaceutical knowledge, so that we may be more fully able to guard against mistakes, and that we should be led to feel that our privileges had given us greater responsibility. I hope the Pharmaceutical Society will let no opportunity slip so as to bring all dispensers of medicine into the fold. I think that this should have formed a most important part of the Bill at the outset.

Glasgow, February 4th, 1871. Pharmaceutist.

Sir,—Allow me to commend to the consideration of our worthy Council, *in re* the storing of poison question, the following quotation from the works of Dr. B. Franklin:—

"Perhaps, in general, it would be better if Government meddled no further with trade than to protect it and let it take its course. Most of the statutes or acts, edicts, arrests and placarts of parliaments, princes and states" (and I may add Councils of the Pharmaceutical Society) "for regulating, directing, or restraining of trade, have, we think, been either political blunders or jobs obtained by artful men for private advantage under pretence of public good. When Colbert assembled some of the wise old merchants of France, and desired their advice and opinion how he could best serve and promote commerce, their answer, after consultation, was in three words, *Laisser nous faire*—'Let us alone.' It is said by a very solid writer of the same nation, that he is well advanced in the science of politics who knows the full force of that maxim, *pas trop gouverner*, 'not to govern too much;' which, perhaps, would be of more use when applied to trade than in any other public concern."

I will not, Sir, impair the force of the foregoing quotation by any observation of my own. A Founder.

36, *Sloane Square, S.W., February 6th*, 1871.

Sir,—If the discussion upon the "poisons storing regulations" should not result in the withdrawal of the proposed regulations or in the adoption of some definite policy, it will, at least, have formed a most instructive medium for the expression of trade opinions, embracing as it does so many phases of practical interest to the chemist and druggist. I shall not follow your correspondents through the details of the question, for, opposing the scheme, as I do *in toto*, it will be unnecessary for me to depart from the question as to the expediency of the proposed legislation. After years of persevering agitation, conducted with praiseworthy energy, mainly by our metropolitan brethren (*palmam qui meruit ferat*), the Pharmaceutical Society successfully carried the present Pharmacy Act. The result is that the educational test is compulsory for every future chemist and druggist. The Council of the Pharmaceutical Society, nominally assisted by the Privy Council, frame regulations for conducting the examinations. If the present curriculum has not enough of the practical character in it to give a good trade education whereby the public may be protected, by all means let the Council make it more practical, and members and students will cheerfully assist in carrying out the alterations deemed necessary. But I cannot conceive any managing body or Council, after having successfully pursued a steadily increasing and popular mode of improving the qualification and status of the chemist and druggist, stultifying their previous exertions by wishing to force the adoption of an obnoxious, unnecessary and arbitrary scheme of shop-arrangement for the storing of poisons. Moral, or rather educational, improvement has already answered admirably; why then supplement it by force? The responsibility of the trade being established, why may not their discretionary power be safely trusted? And even in cases where there is an absence of average care and observation, restrictive legislation will not supply the wanting necessities. Again, just as a growing feeling of confidence is springing up in the public mind towards the long-despised chemist and druggist, ought it to be disturbed or checked? for, as regards poisons generally, my opinion is that a great error has been committed in making the word poison so common, that the absurdity of its use in many cases brings it into contempt. The majority of people have no just conception of the varying potency of poisons; and as the yellow primrose was to Wordsworth's idiot hero, so to the public generally is the word poison, whether it be applied to aconite liniment or paregoric elixir.

If the probabilities of the origin of all the railway accidents that have ever occurred, were compelled, by legislative enactment, to be kept constantly before railway officials and means adopted for the prevention of a repetition of one and all of such accidents, and the red danger-signal constantly displayed to show not merely actual danger, but the caution necessary to prevent probable danger, would railway accidents cease? Would not one moiety of the protected public always travel in fear and trembling, seeing death or injury in every crimson flash of the signal; while another moiety would regard the precautions with such contempt as would probably even create a victim to a system which an over-cautious policy had introduced? Let moderation guide the Council. All over-drawn or over-cautious measures are failures. We may easily, like a modern Frankenstein, raise a monster in this word poison which cannot be subdued. And whose soothing eloquence shall restore to a disturbed public that peace of ignorance and confidence which a poison agitation of possible dangers shall have destroyed? Our Council need not fall into any error of this kind; they have abundant means of letting the subject drop. Not the least is, that a Parliament overtaxed with necessary national legislation, will not lament the absence of a measure which would cause their time to be wasted upon unnecessary legislation concerning chemists' shop-fittings.

A Country Pharmaceutical Chemist.

A Reclamation.

Sir,—In your Journal of the 21st inst. there is a letter signed "Fair Play," Brighton, in which my name is introduced in connection with a poisoning case which occurred in an establishment I was formerly managing partner of. I therefore wish to let it be known, through your Journal, as an answer to all communications on the same subject, that I retired from the business some time before the occurrence took place, nor was I in any way connected with it, neither was any one of the name of Oldham a partner in the house.

George Oldham.

1, *Upper Mount Street, Dublin.*

Druggists' Charges.

Sir,—As tending to throw some light upon the present state of trade ethics in our locality, we enclose an advertisement cut from our local papers for the benefit of your readers. It emanates from a "*Pharmaceutical*" Chemist in this city:—

DRUGGISTS AND THEIR CHARGES.—Look at the Extract from the *Lancet* copied into the Local Papers. One man charges 4*s*. for a 6 oz. Bottle of Medicine, another 1*s*. 6*d*. for the same. I charge, on an average only 9*d*. Can it be possible that the public will still submit to such an enormous imposition?

If worth an insertion in the Journal please put it in, and oblige I. and I. W.

Jan. 31*st*, 1871.

Chloric Ether and Chloroform Discovery. Detur Digniori.

Sir,—I think it will interest those who are still desirous to trace the original discovery of chloric ether and chloroform, to say that there is not much in this alleged use of chloric ether by Sir W. Lawrence; the great credit is due to Mr. Waldie, the chemist, as recently shown in a pamphlet by his brother, who was decidedly the person who explained its use, and, in a long acquaintanceship with the late Sir J. Simpson, induced the latter to adopt it long before Sir W. Lawrence. It is most unfair the manner in which that pamphlet has been treated by certain medical journals, as poor Waldie was only a "common chemist," not a baronet.

Dr. Formby, of Liverpool, and the eminent French physician Flourens, both had adopted these agents before any one else, but Waldie was the chemist who supplied Formby, and urged it on Simpson; without Waldie (the brother) we should never have heard perhaps of chloroform as a medicinal agent, for it lay forgotten amongst Liebig's discoveries.

C. K.

P.S. In an American Dispensatory, Wood and Bache's, this curious phrase occurs many years before even Waldie, "in affections characterized by difficult respiration, chloroform may be used by inhalation," but the operation was apparently lost.

M. P. S. complains that many persons have been registered as chemists and druggists who were in business previous to the passing of the Pharmacy Act, 1868, and are quite incompetent to perform the duties of such. This must necessarily be the case, and until the transition stage has passed, such cases as he refers to can only be remedied by reporting them to the Secretary, who will lay the matter before the Council of the Society, and if upon investigation any deception has been practised, the registrar will be ordered to strike them off the register. Our correspondent will notice that several such cases have occurred, and he had better communicate with the Secretary, if he thinks he can make out a clear case against the parties of whom he complains.

The Position of Pharmacists.—A correspondent in Cardiff sends us the card of a neighbour who combines the trades of tailor, draper and stationer with that of chemist and druggist, and inquires whether this is an instance of attempting to elevate the trade. It is unfortunate but, perhaps, unavoidable that in some obscure localities such heterogeneous combinations are matter of necessity to some extent. We hope the advertiser is at any rate qualified to act as a pharmacist, and in that case we do not object to his being also a tailor and draper, if he likes it.—Ed. Ph. J.

J. Wain (Ripley).—You can come up for examination at any time, even before you are apprenticed.

Messrs. Beal and Son.—The advertisement and stamps have been forwarded to the publishers.

"*Austria*" has forgotten to forward his name and address.

"*Young Apprentice.*"—*Dies* is nominative, *die* ablative. Each is correct, according to the ellipsis intended. In the case cited, the latter would be preferable.

NOTICE.

We have this week received several letters enclosing advertisements and stamps. In order to prevent loss of time, we beg to call our correspondents' attention to the notice published every week in this Journal, that communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, Bloomsbury Square; instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, Secretary, 17, Bloomsbury Square, W.C.; advertisements to Messrs. Churchill, New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."

Communications, Letters, etc., have been received from Mr. J. R. Jackson, Mr. J. Barnard, Mr. J. J. Thomas, Mr. H. J. Woolley, Mr. H. Humphrey, Mr. J. T. Sandell, Professor Gamgee, Mr. G. Sant, Mr. J. Agnew, Mr. Miller, Mr. F. Barrett, Mr. R. Corner, Mr. A. Uttley, Mr. H. M. Davies, Manchester Chemists and Druggists' Association, A. M. P., J. T., F. C. S., W. B. S., M. P. S., J. T. B., T. W., W. J., "Veritas," Chemist's Assistant, Student, An Assistant.

BRISTOL PHARMACOLOGY.

BY W. W. STODDART, F.C.S., F.G.S.

(*Continued from page 603.*)

Nat. Order. Cruciferæ.

This Order of plants is a remarkable group, both for chemical and botanical characteristics.

They all contain nitrogen and sulphur in large quantities, and when decaying give off most offensive odours. In certain conditions all form peculiar compounds of sulphocyanic acid with peculiar radicals; nevertheless, none are poisonous, and a great number are used for food.

The floral type is peculiarly cruciform, the calyx having four sepals, and the corolla four petals. With a few exceptions the crucifers produce a bivalved pod or siliqua, which is usually two-celled.

The plants of this Order are easily distinguished by the tetradynamous stamens, or while numbering six, four are long and two short.

Cochlearia Armoracia (Linn.).

This well-known auxiliary to the roast beef of old England is found wild on the banks of the river Avon, between Bristol and Keynsham, and also at Stapleton, near the Frome.

It is distinguished from all the other species of *Cochlearia* by the elongated form and large size of the leaves. As before mentioned, its long tapering root has been mistaken for that of the aconite, but may easily be recognized by its light colour and pungent odour. The fresh root is the only part of the plant used in the B. P., as an ingredient in the Sp. Armor. Co.

What is usually termed the root includes not only the root proper, but also the rhizome or underground stem, for the latter produces buds, and multiplies with great rapidity beneath the surface of the ground.

To the chemist, horseradish is exceedingly interesting, because it contains 4 per cent. of a powerfully pungent oil, which is generally regarded as a salt of the radical allyl (C_3H_5), although Hofmann has stated it to be the salt of another radical, butyl or tetryl (C_4H_9). By most authors, however, the oil of horseradish is considered as the sulphocyanate of allyl (C_3H_5CNS).

It is a very singular fact that the cruciferous plants produce compounds of sulphur and allyl that are so well known in the genus Allium, plants so dissimilar in habit and construction as to be in both exogenous and endogenous divisions of the vegetable kingdom.

In every part of the world the garlic flavour seems to be a favourite. The Israelites of old regretted the loss of their leeks and onions. The Englishman likes the addition of a shallot, mustard, or horseradish to his beefsteak. The Spaniard selects the onion, and the Asiatic assafœtida.

Even the Brazilian has chosen the petiveria and sequieria, both of which have an alliaceous flavour.

The whole of these owe their smell and taste to allyl, which in the onion tribe exists as a sulphide.

For the purpose of experimentally examining the oil of horseradish, the author scraped three ounces of the fresh root, and placed it in a glass retort with three ounces of distilled water; a distillate was obtained, containing about half a drachm of a yellowish oil, which smelt strongly of horseradish, irritated the eyes, and was so extremely pungent that the tongue was nearly blistered. The product was then placed in a small retort with chloride of calcium, and again distilled at a low temperature. About half a drachm of a nearly colourless oil was obtained, perfectly soluble in alcohol. The addition of ammonia immediately threw down crystals of thiosinnamine. So strong was the odour of the oil, that it could be detected all over the house. The oil is heavier than water, thus differing from the oil of garlic, which is lighter, and is not acted upon by alkalies.

Sinapis nigra (Linn.).

This plant occurs very commonly throughout the district on hedgebanks, and waste places. In Bentham's 'English Flora' the mustard plant is described as Brassica, following the classification of Boissier.

Sinapis nigra is distinguished from *S. alba* by being nearly smooth. The pod is without the long flattened beak. It is the most plentiful source of flour of mustard, although both species are used. The seeds of *S. nigra* are much more pungent than those of *S. alba*, and differ entirely in chemical composition.

In manufacturing flour of mustard, the seeds, after being crushed and pounded in mortars, are subjected to several siftings. Four qualities are supplied to the trade, viz. seconds, fine, superfine, and double superfine,—the last being the purest, but seldom kept by the grocer. No article is more adulterated or lowered than flour of mustard, and seldom at the dinner table can this condiment be had with even a moderately pungent taste. Some of the witnesses before the Parliamentary Committee plainly stated that the adulterants used were flour of wheat, turmeric, capsicum, black pepper, potato starch, plaster of Paris, charlock, pea flour, radish, rape, linseed meal and yellow ochre!!! In short, if the microscopist wants a little experience in the detection of adulterants, he cannot do better than get a few samples of so-called mustard.

The most valuable constituents of black mustard seeds are the fixed oil, myrosin, and myronate of potassium.

When subjected to pressure, the seeds yield about 23 per cent. of a yellowish-brown oil, which does not easily turn rancid, and has a sp. gr. ·916. It is soluble in four parts of ether and 1000 parts of alcohol. Generally the oil is obtained from the dressings of the mustard seeds.

The most important product is the essential oil mentioned in the Pharmacopœia, and which, singularly enough, does not exist in the seeds at all, but is produced by the action of water on the myrosin and myronate of potassium.

Myrosin is a nitrogenous ferment, and performs the part in mustard that synaptase does in the almond. It may be easily prepared by exhausting with cold water, evaporating to the consistence of a syrup, and precipitating by alcohol. Like albumen myrosin is coagulable by heat.

Myronate of potassium ($K,C_{10}H_{18}NS_2O_{10}$), when crystallized from water, appears as anhydrous rhombic prisms, but when from alcohol as very beautiful little tufts radiating from the centre. To obtain this salt, the seeds are exhausted with twice their weight of alcohol. The pressed residue is then mixed with three times its weight of cold water, and left for twenty-four hours, pressed and filtered. The aqueous solution must be evaporated nearly to dryness, with the addition of a small portion of barium carbonate, and boiled with a large quantity of alcohol. On distilling off the alcohol the myronate crystallizes. About 90 grains are produced from 2 lbs. of seed. With a little solution of myrosin these crystals yield the oil of mustard, which is the sulphocyanate of allyl.

We may now easily understand the chemical changes that take place when table mustard, or a mustard poultice is prepared. The water dissolves the myrosin, sets it at liberty to act on the myronate of potassium, and from its decomposition is produced the essential oil, acid potassium sulphate, and glucose.

$$\underset{\text{Myronate of Potassium.}}{K,C_{10}H_{18}NS_2O_{10}} = \underset{\text{Ol. Sinapis.}}{C_3H_5CNS} + \underset{\text{Glucose.}}{C_6H_{12}O_6} + \underset{\text{Acid Sulphate of Potassium.}}{KHSO_4}$$

Alcohol, acids, potassium carbonate, or heat prevent this change, so that the popular notion of preparing mustard for the table, or as a poultice, with vinegar or boiling water is a great mistake. Cold water and time for maceration are the true scientific and best method. When making the French preparation with vinegar, the oil must first be developed with cold water, and then the vinegar added, because when the oil *is once formed*, acids do not alter its properties.

The natural connection between the mustards and the garlics has been mentioned, and is easily explained by a chemical experiment, the object of which is to convert the oil of mustard (sulphocyanate of allyl) into oil of garlic (sulphide of allyl). This is accomplished by heating the former to a temperature of 250° for some hours in a sealed tube with dipotassic sulphide (K_2S) :—

$$2\,\underset{\text{Oil of Mustard.}}{(C_3H_5CNS)} + K_2S = \underset{\text{Oil of Garlic.}}{(C_3H_5)_2S} + \underset{\text{Potassic Sulphocyanide.}}{2\,(KCNS)}.$$

The well-known pungent smell of the volatile oil is made use of, to detect the adulteration of oil-cake with mustard-cake, and sold as food for cattle. A little of the suspected cake is stirred with a little lukewarm water, and placed aside for a few hours. If a very small percentage of mustard be used, it will soon become apparent by the peculiar odour of oil of mustard.

Sinapis alba (Linn.).

This species is found in the same locality, and in somewhat greater abundance than that already described, from which it differs by the pinnatifid leaves and bristly pods.

It also differs essentially in its chemical composition. The seeds of the white mustard contain no myronate of potassium, and therefore cannot produce any volatile oil. They, however, contain a larger proportion of the nitrogenous ferment myrosin, which explains the reason why a mixture of black and white seeds produces a better flour for dietetic use than the black alone, viz. by furnishing a more plentiful supply of myrosin for the decomposition of the myronic acid in the black.

Instead of the myronate of potassium, the white mustard-seeds contain a crystallizable compound called sulphocyanate of sinapin. It may be procured by exhausting the seeds, first with ether and then with hot alcohol. The greater part of the alcohol is distilled off, when prismatic crystals separate. Sulphocyanate of sinapin ($C_{16}H_{23}NO_5,CNHS$) is inodorous and bitter. It is coloured yellow by ammonia, strychnine, morphine, quinine and nicotine, but not narcotine or salicine. It is reddened by nitric acid and persalts of iron. This explains the curious circumstance that perchloride of iron reddens an infusion of white but not of black mustard. The slightly pungent taste of white mustard is caused by the action of the myrosin moistened with water upon the sulphocyanide of sinapin, forming an acrid but *not a volatile* principle.

When acted upon by alkalies, the sinapin salt is converted into another base, sincalin ($C_5H_{13}NO$), potassic sinapate, and potassium sulphocyanate.

$$\underset{\text{Sulphocy. Sinapin.}}{C_{16}H_{23}NO_5,CNHS} + 3KHO$$
$$= \underset{\text{Potass. Sinap.}}{C_{11}H_{10}K_2O_5} + \underset{\text{Sincalin.}}{C_5H_{13}NO} + \underset{\text{Pot. Sulphocy.}}{CNKS} + 2H_2O.$$

On pressure, the seeds of the white mustard will yield sometimes as much as 30 per cent. of fixed oil.

The microscopic structure of the mustard-seed is extremely interesting, especially in the case of the white, which is essentially different from the black.

The seeds of both have a husk, built up with three layers of cells, or tunics. The exterior tunic consists of a transparent series of hexagonal cells $\frac{1}{435}$ inch broad and $\frac{1}{330}$ inch long, and united to each other by a corrugated cell-wall. In the centre of each is an aperture surrounded by an elastic spiral fibre, from which a long tube passes from the exterior to the interior. When wetted with water this elastic apparatus springs forward, projecting from the surface like the schoolboy's "Jack in the box," carrying with it the tube, from which flows a mucilaginous fluid. It is distinctly different from the well-known spirals of the *Collomia*, but rather resembles the cushion-springs of the upholsterer, covered with an exceedingly fine membrane. The best method of viewing it under the microscope is by the aid of polarized light and a blue selenite stage. This curious compound cell is totally absent in the black mustard-seeds.

The middle tunic is a single layer of very small cells, averaging only $\frac{1}{3000}$ inch, and filled with the colouring matter. The internal coat of the husk consists of a layer of cells about $\frac{1}{1000}$ inch in diameter, and irregular in shape and size. The seed itself is formed of minute cells, which contain a large quantity of fixed oils.

Neither iodine nor polarized light indicate the presence of starch in any part of the mustard-seeds, so that an admixture of wheat or other flour may be readily detected.

Nat. Order. Linaceæ.

This small Order, although only numbering three genera, and all insignificant in size, yet have played no small part in the history of mankind. All are famous for yielding an abundance of useful products. Only one species is made use of in our materia medica.

Linum usitatissimum (Linn.).

As its specific name denotes, the flax plant is most valuable for many purposes. It has furnished our garments from the earliest period. It is the chief ingredient in our paints, the best application for a burn, and a most excellent food for our cattle when other fodder is scarce. To it the surgeon owes his lint, the printer his paper, the navy its ropes, and the housewife her linen; and, after serving every useful purpose, and passing into the rag-bag, these invaluable fibres go—

> "Into the paper-mill, and from its jaws
> Stainless and smooth emerge. Happy shall be
> Its renovation, if on its fair page
> Wisdom and Truth their hallow'd lineaments
> Trace for posterity. So shall its end
> Be better than its birth."

Indeed, so indispensable has the success of the flax crop been considered, that its failure has been frequently described as a national calamity, and is mentioned by Moses as one of the Egyptian punishments.

Hardly an author can be mentioned who does not in some way or other speak of this lowly plant.

Virgil describes the flax crops, with the other profitable speculations of the husbandman:—

> "Urit enim lini campum seges, urit avenæ.'

Horace tells of the benefit derived from straining his Massican wine through the linen filter:—

> "ut illa
> Integrum perdunt lino vitiata saporem."

The products of this humble plant, familiar as they are to every apprentice, most commonly are allowed to pass by without the slightest thought about their hidden interest. To the student the tow, the linseed oil, the linseed and the linseed meal are among the wonders of nature.

Specimens of the *Linum usitatissimum* may be collected at Henbury, Keynsham, Ashton, and several other places in the neighbourhood of Bristol.

The microscopic structure of the seeds and stem of the flax plant must not be passed over, because its knowledge is very necessary to the analyst, who is often called upon to defeat the schemes of the adulterator of oil cake, linseed meal, or various fabrics.

When the stem of the flax plant is soaked in water the fibres of the inner bark, or liber, may be separated for examination. From these is produced our tow. When a few fibres are examined by the microscope they are seen to consist of long cells of cellulin from $\frac{1}{3000}$ to $\frac{1}{2000}$ inch in diameter. These may be used for experimental observations on the chemical properties of cellulin ($C_{18}H_{30}O_{15}$). When tow is boiled with diluted sulphuric acid, it is partially converted into dextrine and grape sugar:—

$$\underset{\text{Cellulin.}}{C_{18}H_{30}O_{15}} + H_2O = 2(\underset{\text{Dextrin.}}{C_6H_{10}O_5}) + \underset{\text{Grape Sugar.}}{C_6H_{12}O_6}.$$

When acted upon by nitric acid or alkalies, oxalic acid is formed:—

$$\underset{\text{Cellulin.}}{C_{18}H_{30}O_{15}} + O_{27} = 9\,(\underset{\text{Oxalic Acid.}}{C_2H_2O_4}) + 6\,H_2O.$$

When strong nitric and sulphuric acids are mixed with flax fibres, pyroxylin is produced, as in the B. P.:—

$$\underset{\text{Cellulin.}}{C_{18}H_{30}O_{15}} + \underset{\text{Nitric Acid.}}{6\,HNO_3} = \underset{\text{Pyroxylin.}}{C_{18}H_{24}, 6\,NO_2, O_{15}} + 6\,H_2O.$$

The tow that is most generally used is not derived from flax, but hemp, a member of the nettle family. It differs materially in its properties. When examined under a high power the fibres, from $\frac{1}{650}$ to $\frac{1}{500}$ inch in diameter, are seen to be formed of bundles of cells, pointed at each end, closely fitted to each other and cemented together by a peculiar resin. Till prepared by boiling with strong nitro-hydrochloric acid the fibres are opaque, but when cleansed are very beautiful objects for polarized light. Hemp cells show traces of transverse striæ, while those of true flax are longitudinal. Flax is not coloured by nitric acid, while hemp is reddened. When the tow derived from hemp is placed in a solution of chlorinated lime it turns yellow; when well washed with water and immersed in sodic sulphite, the yellow tint is changed into a very beautiful crimson. This is not the case with flax, but is due to the presence of the hemp resin.

When a section of the flax seed (linseed) is placed under the microscope four distinct coats may be seen.

The external layer is composed of hexagonal cells, measuring about $\frac{1}{1200}$ inch. These give the polish and colour to the seeds, and are filled with mucilage; when acted upon by warm water these cells swell and burst. The mucilage is slightly acid, and turns a ray of polarized light to the left; when acted upon by iodine with sulphuric acid, or zincic chloride, it is not coloured, like the mucilage from many other plants. It consists chiefly of Arabic acid ($C_{12}H_{22}O_{11}$), which is soluble in water, and bassorin ($C_{12}H_{20}O_{10}$), which is insoluble unless when mixed with an alkali.

The next coat is a layer of rounded cells about $\frac{1}{1430}$ inch in diameter and filled with granular contents. The third layer is built up with long, narrow cells, about $\frac{1}{3700}$ inch in diameter, crossing each other at right angles, as if for the purpose of making a tough envelope for the seed.

The fourth and internal layer is composed of irregular cells, smaller than the others, and filled with a kind of resin, which readily escapes from the cells when cut.

The seed itself consists of very small cells, averaging $\frac{1}{1250}$ inch, and filled with oil and starch.

The seeds yield about one-fifth their weight of oil, having a sp. gr. ·9395. Pure linseed oil dissolves in five times its weight of alcohol when boiling and forty when cold. It solidifies at —17° C., takes fire with fuming nitric acid, and when heated for some time at a high temperature, becomes converted into a dark sticky mass, which is so viscid that it may be used as birdlime.

Linseed oil is a typical example of what is called a drying oil. By exposure to the atmosphere it suffers oxidation and becomes resinified. Linseed oil probably owes this property to the presence of linolein. When saponified the linolein becomes converted into linoleic acid ($C_{16}H_{28}O_2$). When boiled with lead or manganese a margarate and linoleate of the metal are formed, and the drying quality increased. The residue, after the removal of the oil by pressure, is sold as oil cake, and when ground, as linseed meal. Both these are terribly adulterated with sand, clay, twigs, sawdust and refuse from other seeds, and which can only be detected and exposed by the assistance of a microscope.

(*To be continued.*)

Cowhage.—Mr. J. Weichselbaum, of Savannah, in a communication to the *American Journal of Pharmacy*, says that the irritation of the skin caused by contact with the leguminous pods of *Mucuna pruriens* (Cowhage), may be instantaneously removed by the application of camphor liniment.

DECOMPOSITION OF ACETATE OF MORPHIA IN SOLUTION.*

BY JOHN M. MAISCH.

That aqueous solutions of the salts of most officinal alkaloids cannot be kept for indefinite periods is well known to all pharmacists. Whether distilled water, or boiled and filtered hydrant water—the latter containing but traces of foreign matter—be used for such solutions, whitish floccules usually make their appearance after some time, and gradually assume a soft gelatinous consistence, with the appearance of algaceous growth. In the few instances in which the writer assayed such altered solutions of the sulphates of quinia and of morphia, a diminution of the amount of alkaloid has not been observed, and the appearance of this foreign body was therefore rather attributed to accidental organic impurities in the water, and this belief was strengthened by the fact that the bulk of these flocks varies in solutions made at different times, and after some time apparently does not increase, and that the presence of an excess of sulphuric acid prevents such a formation or at least diminishes its amount.

It is also well known that a neutral solution of acetate of ammonia gradually deposits flocks, and that the liquid then assumes an alkaline reaction. This was first observed by Horst,† who attributes this decomposition of aqueous solutions of acetate and succinate of ammonia to the light, and recommends to keep them in a dark place; if ammonia was replaced by potash or soda, this decomposition did not take place. I am not aware that the amount of ammonia has ever been estimated in the fresh solution and after the decomposition has taken place.

A solution of acetate of morphia is very prone to change; it soon acquires a brown-yellowish colour, and deposits a brown matter. A decomposition was already observed by E. Merck in 1837,‡ when experimenting about the best process for obtaining this salt dry, in a neutral condition; he states that the evaporation of its solution must be hastened at a low temperature by a current of air or other means, since it is decomposed at too slow an evaporation. But the nature of this decomposition is not stated.

Some months ago, Dr. Wm. T. Taylor, of this city, informed me that he prefers to use a solution of this salt for hypodermic injection, and that he had repeatedly observed the separation in the liquid of one or more crystals, after keeping it on hand for some time.§ A careful examination of a crystal proved it to be pure morphia, entirely free from acetic or other acid; with nitric and iodic acids, and with sesquichloride of iron, it showed the reactions characteristic for morphia; it had an alkaline reaction to test papers, and neither acetic, carbonic nor any mineral acid could be discovered by the appropriate tests; heated upon platinum foil it was consumed without leaving any residue.

The liquid had deposited a considerable quantity of a brown matter, and was of a pale brownish colour. It was neutral to test paper, but with pure sesquichloride of iron acquired a reddish tint, which disappeared on the addition of muriatic acid. Acidulated with nitric acid, iodohydrargyrate of potassium occasioned a turbidity. Evidently a minute portion of acetate of morphia remained still in solution.

To the kindness of Dr. Taylor I am indebted for the specimen upon the table, which was originally a solution of 8 grains acetate of morphia in half an ounce of distilled water. By accident, it had been set aside, and was lost sight of for several months. On examining it, the deposit and the change in colour of the solution, mentioned before, were observed, and a single crystal reaching from the surface of the liquid diagonally through the solution to the bottom of the vial on the opposite side.

The gradual decomposition of acetic acid in crude vinegar is well known, and it is possible that the changes noticed above are of the same or a similar nature. At any rate it is very evident that acetic acid, in contact with organic bodies, is very liable to undergo decomposition, and since an organic body in such a condition is apt to predispose others, with which it may be in direct contact, to similar changes, it is a question of great moment whether the addition of acetic acid to our officinal fluid extracts of ergot and of ipecacuanha may not be more detrimental than useful.—*American Journal of Pharmacy.*

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

CRETA PRÆPARATA.—Chalk is a native carbonate of lime found in beds of considerable extent in the south of England. It consists almost exclusively of the remains of microscopic foraminiferous and other shells; it therefore contains numerous chemical impurities, of which the most abundant is silica. Magnesia, alumina, iron and phosphates may also be present. Precipitated chalk, however, possesses a distinctly crystalline structure, and if carefully prepared, is chemically pure.

CUPRI SULPHAS.—[§ $CuSO_4 5H_2O$. May be obtained by heating sulphuric acid and copper together, dissolving the soluble product in hot water, and evaporating the solution until crystallization takes place on cooling.] In this process half of the sulphuric acid is decomposed, with evolution of sulphurous anhydride.

$$Cu + 2H_2SO_4 = CuSO_4 + SO_2 + 2H_2O.$$

A more economical plan, and one commonly adopted, consists in oxidizing the copper by heating it in a reverberatory furnace, before submitting it to the action of the sulphuric acid. The black oxide of copper thus formed dissolves easily without evolution of gas.

$$CuO + H_2SO_4 = CuSO_4 + H_2O.$$

Like many other sulphates, this salt is strongly acid to test paper. Heated to about 390° F. it becomes white and anhydrous; in this state it is employed as a test for water in absolute alcohol. Contact with moisture causes it to reassume a blue colour.

[§ The aqueous solution gives with chloride of barium a white precipitate ($BaSO_4$) insoluble in hydrochloric acid; and a maroon-red precipitate (ferrocyanide of copper ($Cu_2FeC_6N_6$) with yellow prussiate of potash.] Much of the blue vitriol of commerce contains a considerable amount of sulphate of iron; to detect it the test given in the Pharmacopœia may be employed. It is first mixed with chlorine water, to convert the ferrous into ferric salt, and then ammonia is added in excess. If iron is present in any notable quantity, it makes its appearance as a brown precipitate floating in the deep-blue liquid. Minute quantities may, however, easily be overlooked.

Emplastrum Plumbi.—Oxide of lead (litharge) in fine powder is boiled for some hours with olive oil and water, the latter being supplied as it evaporates. The Pharmacopœia gives no directions as to what is to be done with the solution of glycerine, which is mixed up with the plaster at the end of the process; most of it is usually squeezed out and rejected. The reaction which takes place is an interesting one. Olive oil is a mixture of a fluid fat, olein, and a solid, usually called margarine. Since the olein forms the chief bulk of the oil, we will consider the action of the hydrated plumbic oxide upon that only.

$$\underset{\text{Olein or Trioleate of Glyceryl.}}{2(C_3H_5\,3\,C_{18}H_{33}O_2)} \quad + \quad \underset{\text{Hydrated Oxide of Lead.}}{3(PbO, H_2O)}$$

$$= \underset{\text{Glycerine or Hydrate of Glyceryl.}}{2(C_3H_5\,3\,HO)} \quad + \quad \underset{\text{Lead Plaster or Oleate of Lead.}}{3(Pb\,2\,C_{18}H_{33}O_2)}$$

This decomposition it will be seen, notwithstanding the complex character of the radicles involved, is really a very simple one, being a double decomposition analogous to that by which, for instance, ferric hydrate is produced from a ferric salt.

$$\underset{\text{Oleate of Glyceryl.}}{2(Gl'''Ol_3)} \quad + \quad \underset{\text{Hydrate of Lead.}}{3(Pb\,2\,HO)}$$

$$= \underset{\text{Hydrate of Glyceryl.}}{2(Gl'''\,3\,HO)} \quad + \quad \underset{\text{Oleate of Lead.}}{3(PbOl_2).}$$

$$\underset{\text{Ferric Sulphate.}}{Fe_2\,3\,SO_4} \quad + \quad \underset{\text{Hydrate of Sodium.}}{6\,NaHO}$$

$$= \underset{\text{Ferric Hydrate.}}{Fe_2\,6\,HO} \quad + \quad \underset{\text{Sulphate of Sodium.}}{3\,Na_2SO_4.}$$

The process of saponification is similar. A fat boiled with a solution of caustic alkali yields a soap and glycerine.

$$\underset{\text{Olein or Oleate of Glyceryl.}}{Gl'''Ol_3} \quad + \quad \underset{\text{Hydrate of Sodium.}}{3\,NaHO}$$

$$= \underset{\text{Glycerine or Hydrate of Glyceryl.}}{Gl'''\,3\,HO} \quad + \quad \underset{\text{Hard Soap or Oleate of Sodium.}}{3\,NaOl.}$$

Ferri Arsenias.—See *Acidum Arseniosum.*

Ferri Carbonas Saccharata.—[§ Carbonate of iron, $FeCO_3$, mixed with peroxide of iron and sugar.]

Hot solutions of carbonate of ammonia and sulphate of iron are mixed together, and the resulting precipitate after the effervescence is over, is collected and washed with boiling water. The mother liquor having been, as far as possible, squeezed out, it is then mixed with sugar and dried over a water-bath.

The white precipitate which is first formed is probably the ferrous carbonate—

$$(NH_4)_2CO_3 + FeSO_4 = (NH_4)_2SO_4 + FeCO_3;$$

but it very soon becomes green, carbonic acid gas escaping. Its constitution is then probably analogous to that of carbonate of zinc:—

$$3\,FeCO_3 + 2\,H_2O$$
$$\text{becoming } FeCO_3\,2\,[Fe(HO)_2] + 2\,CO_2.$$

Subsequently, upon exposure to the air, oxygen is absorbed, and a brown hydrated ferric oxide is produced. To retard this change as much as possible, it is advisable to employ solutions more concentrated than those ordered by the Pharmacopœia. I have found it a good plan to throw into the hot solution of the carbonate the powdered ferrous sulphate in the solid state, and to keep the mixture nearly boiling for about a quarter of an hour. In this way a very dense precipitate is produced which does not so rapidly undergo oxidation.

The product should be grey, not brown, in colour, and should effervesce when introduced into an acid.

[§ 2 grams dissolved in excess of hydrochloric acid and diluted with water, continue to give a blue precipitate with the red prussiate of potash, until at least 22* cubic centimetres of the volumetric solution of bichromate of potash have been added.]

The action of bichromate of potash on an acid solution of a ferrous salt is shown in the following equation:—

$$6\,FeCl_2 + 14\,HCl + K_2Cr_2O_7$$
$$= 3\,Fe_2Cl_6 + 2\,KCl + Cr_2Cl_6 + 7\,H_2O.$$

Every molecule of red chromate, weighing 295 grams, will convert into a ferric salt six molecules of any ferrous salt; and, at the end of the reaction, the solution will no longer give a blue precipitate with red prussiate of potash. Now, 20,000 c. c. of the volumetric solution contain one molecule of the red chromate. If, therefore, 22 c. c. of solution were used in an experiment, this quantity would indicate the presence of ·7656 gram of ferrous carbonate in the 2 grams of saccharated carbonate. For

$$20{,}000 : 22 :: \overset{\text{6 Molecules of }FeCO_3.}{696} : {\cdot}7656$$

This amount represents 38·28 per cent., which is about the average in good samples. By calculation from the proportions of the ingredients, it should contain 45·5 per cent. of $FeCO_3$.

GINSENG.

BY JOHN R. JACKSON.

The history and uses of the Ginseng of the Chinese are so well known, and are likewise so interesting, that some additional interest may be given to the subject to learn how the trade in this article fluctuates in China. The importations to Canton have of late very much declined, large quantities being now sent to Hongkong, where a process of clarification has been established. The roots are also imported and exported free of duty, while in Canton an import duty is first levied, and in addition to this a coast trade duty, if re-exported to other provinces. Of true Ginseng the produce of *Panax Schinseng*, Nees, three kinds are known in Chinese commerce—Manchurian, Corean, and Japanese. The first of these is the finest, but is scarce, being in fact an Imperial monopoly, so that the very best sorts are not seen in the markets. American Ginseng, *P. quinquefolium*, L., appears still to be taken into China, but it is little appreciated by the Chinese. In America it is not employed as a medicine, and is considered to have no other properties than a simple demulcent.

* The Pharmacopœia number corrected.

LIQUID PEPSIN AND SACCHARATED PEPSIN.

BY E. SCHEFFER.

In my essay upon liquid pepsin (*Amer. Journ. Pharm.*, March, 1870) doubts were expressed about the durability of the preparation during warm weather. Subsequently, as the weather became warmer, I found that a mould was forming in the liquid, the quicker the less perfectly the mucus was separated from it, and also when the bottle containing it was from time to time opened, so that the air could come in contact with it.

To satisfy myself I filtered a fresh prepared liquid repeatedly, until it had become perfectly clear, filled several vials with it, corked them tight and sealed them, with the exception of one which was only covered with paper, and set them aside. When, after about six weeks, I looked at them, I found the vial tied up with paper only, almost entirely filled with a fucoid vegetation, and of the others some had mould on the cork, while a few kept entirely clear and free of mould.

Upon these results I thought it expedient to increase the quantity of glycerin in the preparation to 50 per cent., without changing the proportion of mucous membrane or muriatic acid. The resulting preparation stood the test better during summer, but in a few cases a little mould was also noticed on the cork, although never in the liquid itself. In all cases, however, care must be taken to have the mucus entirely removed from the liquid pepsin, and the sooner it can be and is removed, the better the product will be.

Finding it not as easy to get stomachs in summer as I anticipated, and particularly to get a preparation of pepsin free of acid, as in some cases the physicians wish to have, I endeavoured to make a dry pepsin, which, while available for the dispensing in the form of powder, would serve for the preparation of the liquid pepsin.

Of the different formulas given in divers books treating upon organic and physiological chemistry, I found the one by which the pepsin is precipitated by alcohol the least suitable, as the pepsin obtained in this way had, after being dried, lost its solvent power on albumen.

After having precipitated the pepsin and freed it of water as much as possible, by means of a press, it is mixed in the damp state with a weighed portion of sugar of milk, and rubbed in a mortar until it has become dry. By weighing the mixture again the quantity of exsiccated pepsin is ascertained, and sufficient milk-sugar is added to reduce to such strength, that one grain of the *saccharated pepsin*, as I call it, shall dissolve twelve grains of coagulated albumen. This strength seemed to me the most suitable, as one grain is equal to one teaspoonful of my liquid pepsin, which dose is found by physicians sufficient in most cases.

The pepsin dried without addition of an inert substance could not be dispensed, unless it be in solution, as in that state it cannot be made into powder. When taken out of the press and dried between bibulous paper, it is a very tough substance, resembling parchment paper when dried in thin layers, while in thick pieces it looks more like sole-leather; it has a yellowish or greyish brown colour. In water it swells up considerably, and after some time disintegrates itself to white flakes, which float at first and then settle. Although easily soluble when freshly precipitated, it dissolves, after being dried, very little in cold water, more in water of 80°, but very quickly by addition of a little acid. It is therefore necessary, when saccharated pepsin is prescribed in solution, to add a little acid, hydrochloric or lactic. To make liquid pepsin from the dry saccharated pepsin, I propose the following formula:—

℞ Sacch. Pepsin, 64 grs.
Water, 5 fl. oz.
Hydrochloric Acid, 1 fl. drm.

Shake in a bottle until the milk-sugar and pepsin are completely dissolved, then add glycerin 3 fl. oz. and filter. A colourless liquid is formed, of which 1 fl. oz. dissolves $1\frac{1}{2}$ drms. of coagulated albumen.

As the normal gastric juice of man and animals contains chloride of sodium, I tried to ascertain if the addition of a little table salt to a solution of unmixed pepsin in acidulated water would accelerate the solution of coagulated albumen; the result was, that pepsin with chloride of sodium dissolved albumen much quicker than without it. I therefore mention here that chloride of sodium is added to the saccharated pepsin.

As for the strength of saccharated pepsin, compared with the other dry pepsins in use here, it was found that 1 part of it equalled about $3\frac{1}{2}$ parts of Boudault's, 8 to 9 parts of Grimault's, 12 parts of Hawley's, and at least 40 parts of Houghton's. During a period of from three to four hours, 10 grains of saccharated pepsin in 1 fluid ounce of water, acidulated with 10 drops of muriatic acid, and kept at a temperature of 100° to 105° F., dissolved 120 grains of coagulated albumen. Under identical conditions, 60 grains of Boudault's pepsin* dissolved the same amount; 40 grains of Boudault's pepsin dissolved the same amount; 30 grains of Boudault's pepsin did not quite dissolve it; 60 grains of Grimault's pepsin dissolved but 84 grains; 60 grains of Hawley's pepsin dissolved but 60 grains. With Houghton's pepsin, most of the little cubes into which the coagulated albumen was cut had not even lost their sharp angles and corners.

To substantiate the assertion made in my essay on liquid pepsin (*Amer. Journ. of Pharm.*, March, 1870) that wine of pepsin and all other preparations of pepsin containing alcohol were devoid of digestive power, I made the following experiments:—Two equal quantities of dry pepsin were dissolved in acidulated water, and to one of them, after solution, one-third of alcohol was added. The same amount of coagulated albumen was put into each bottle. By the time that the albumen in the vial without alcohol was entirely dissolved, the albumen in the other one was not acted upon, and the little cubes had retained their shape. Dry pepsin, precipitated with alcohol from its solution, was dissolved in acidulated water and coagulated albumen added to it; a solution of my dry pepsin was likewise made, and the same quantity of albumen added. The pepsin made with alcohol did not seem to act at all on the albumen, which appeared to be exactly the same in shape and bulk as when it was put in, when my pepsin had dissolved the albumen entirely.

It seemed to me of importance to find if pepsin made from calf rennet was identical with that made from the hog. I therefore prepared liquid pepsin from rennet in exactly the same way and the same proportions as from the mucous membrane of the hog's stomach. When compared with liquid pepsin as to its digestive strength, it was found that pork pepsin dissolved about one-third more of coagulated albumen than calf pepsin in the same time. With dry pepsin made from rennet I obtained the same result. By experimenting with lean beef meat the difference was still more in favour of the pork pepsin, as a certain quantity of beef was dissolved by this, while the calf pepsin had loosened the fibres and softened the meat, but the bulk was not appreciably diminished.—*Amer. Journ. Pharm.*

* The Boudault's pepsin I had used for experiments last winter must have been adulterated or spoiled, as I recollect right well that it was a damp, sticky powder of somewhat different colour from the one I used this time; therefore its strength, compared with the liquid pepsin, was found so much less than in the present experiment.

THE MICROSCOPE IN PHARMACY.

Dr. Hale (*American Journal of Microscopy*), in speaking of the value of the microscope to the pharmacist, says that the deterioration to which many drugs are subject by being long kept may, in a great number of instances, be traced to the agency of animalcula. In speaking of fungi he remarks:—

Unless the preserved substance can be kept absolutely free from moisture, its surface, and even its deepest interior, will become infected with fungi that more or less rapidly destroy the integrity of its tissues, until the preparation made therefrom is useless as a medicinal agent. The leaves of *Atropa Belladonna*, the seeds of the *Conium maculatum*, and various other powerful narcotic and poisonous substances are probably rendered inert by the destructive process set up in their interior by fungi which obtain access to them.

These injurious changes are not discoverable to the unaided vision. It is notorious that the most carefully prepared tinctures and extracts of certain drugs are sometimes devoid of medicinal power. It has been supposed that certain volatile constituents escape from the substances from which such tinctures are prepared; but of this we have no certain proof. Why is it that the leaves of *Belladonna* may in some instances be kept for years, and at the end of that period be capable of yielding a reliable preparation, while other specimens, when kept only a few months, are worthless? It must be because of some destructive process going on in the substance, which cannot be discovered with the naked eye.

In some of my experiments with the microscope, I have been able to detect the utter worthlessness of the leaves of *Belladonna* and *Digitalis*. In place of the healthy tissue, a mass of fungi appeared to monopolize the place. A thin section of the root of aconite, placed under a low magnifying power, has revealed the presence of such a quantity of fungi as to render the specimen worthless for the pharmacist. In other cases the substance of the root examined would be found destroyed by some insect, which had left only the *debris* of the tissue it had digested or destroyed in its migrations. The pharmacist should first learn to recognize the natural healthy appearance, under the microscope, of all the vegetable substances he works upon; then he should subject a specimen of every substance he prepares to a careful examination, and if he discovers the presence of vegetable or animal parasites, such substance should be rejected. The world is flooded with inert medicinal preparations. Doubtless many such preparations are made worthless by improper methods of manufacture; but it is my opinion that in many instances their worthlessness is due to the fact that the substances used have been injured by certain agencies which could have been discovered by the intelligent use of the microscope.

THE DOSE OF CHLORAL HYDRATE.

The editor of the *Practitioner* for February makes the following remarks concerning large doses of chloral hydrate:—

Two remarkable instances of very large doses of chloral hydrate being taken with only transient effect have come under our notice within the last two months, and, singularly enough, in the same house. A lady was attacked with acute mania; sleep could only be procured by chloral hydrate and a mixture was provided, of which four tablespoonfuls (containing 30 grains) were to be taken every night. Against the plainest orders, the attendants gave four times this quantity (containing 120 grains) one night. Continuous sleep for twelve hours followed, but no evil effects occurred. Singularly enough, the husband of the lady was attacked with delirium tremens, and took, by mistake, either 150 or 180 grains of chloral hydrate. He slept continuously for about twenty-four hours, and even after this could only very gradually be roused—falling asleep in walking, and even on horseback. But his delirium tremens was cured.

On the other hand, we must never forget that some patients are much more sensitive; as *e.g.* the patient mentioned by Dr. Reynolds in the *Practitioner* some time ago, who nearly died from a dose of 50 grains. It is never safe to commence with doses of more than 30 grains.

SOLUTION OF SANTONINE.

BY JOHN HARLEY, M.D.

In a short article in the *Practitioner* for February, Dr. Harley calls attention to the insolubility of santonine, which considerably impairs its utility as a vermifuge. Water cold or warm takes up the merest trace. Chloroform, absolute alcohol, the strongest acetic acid, turpentine, hot olive oil, and hot glycerine are the only simple fluids that dissolve any appreciable quantity. It separates from the oil and glycerine on cooling; water added to the other solvents produces the same result.

Having investigated the subject, Dr. Harley found, after a good deal of trouble, that a useful solution might be obtained by means of carbonate of soda. The following is the formula:—

℞ Santonini, in pulvere, gr. xij
Sodæ Bicarbonatis gr. xx
Aquæ Destillatæ ℥iij.

Put the soda and water into a flask, keep the fluid near the boiling-point, and add the santonine about two grains at a time until the whole has dissolved. Solution is effected in about half an hour, during which time the water is reduced to ℥ij, or if not, may be reduced to that bulk, when ℥j will contain a full dose—six grains of santonine.

The solution is bright and permanent, strongly alkaline, free from odour and, except that of carbonate of soda, taste. Carefully neutralized with acetic acid, an equally bright and permanent solution is formed. Both may be diluted to any extent with hot or cold water without impairing the solution of the santonine. The whole or nearly the whole of the santonine is precipitated in its original form of colourless rectangular plates, with bevelled edges, immediately by mineral acids, and after some hours by excess of acetic acid.

Mixed with acid urine, sp. g. 1017·5, containing excess of uric acid, and kept for several hours at 100° F., no turbidity is produced, unless in the case of the alkaline solution and an excess of phosphates in the urine, when a slight cloudiness may occur from the separation of the latter. This proves that excess of uric acid fails to cause a deposition of santonine.

In cases where powders are objected to, a pleasant mixture may be made by adding a little syrup and flavouring water to the solution of santonine.

SPIRITUS SALIS DULCIS.

In reply to a correspondent in Newhaven, asking for a formula for *Spiritus Salis Dulcis*, as used many years ago, the editor of the *American Journal of Pharmacy* says:—It is a sweet spirit of (common) salt, just as sweet spirit of nitre is of saltpetre. Each was originally made by distilling the respective salts with sulphuric acid and alcohol. This name was officinal in the Edinburgh Pharmacopœia of 1722, and applied to a spirit of hydrochloric ether obtained by distilling a mixture of one part of muriatic acid and three parts of alcohol, after digesting the mixture for several days, and redistilling the product one or more times, until free from acid. This is probably what was used under that name.

In the Prussian Pharm. of 1847, a sort of spirit of chloric ether, under the name *Spiritus Ætheris Chlorati*, is made by distilling 16 parts of chloride of sodium, 6 parts of binoxide of manganese, 12 parts of sulphuric acid, and 48 parts of stronger alcohol, sp. gr. ·813. The acid and alcohol are to be carefully mixed and poured on the salt and oxide, previously placed in a large retort, and the whole mixed; a well-refrigerated receiver being adapted, forty-two parts of distillate are obtained by means of a sand-bath heat. To free the product from acidity, it is shaken with about half a part of calcined magnesia till neutral and then redistilled. Sp. gr. ·815 to ·820. This product has also been called *Spiritus Salis Dulcis*.

The French use a preparation called *Esprit de Sel dulcifié*, which is a simple mixture of 1 part of muriatic acid and 3 parts of alcohol.—*American Journal of Pharmacy*.

PHARMACEUTICAL INFELICITIES IN ENGLAND.

Under the above title, the following editorial note appears in the Chicago *Pharmacist* for January:—

Our city and country are not the only places where physicians and apothecaries sometimes disagree, as we learn in perusing our foreign exchanges. A bitter wordy strife, instigated by the attacks of the *Lancet*, has been waged for some time between these highly respectable and scientific bodies, and, as usual in such cases, some tender spots have been bared on either side. The physicians are incensed at the extent to which counter-prescribing is carried on by pharmaceutical chemists, and incidentally aver that the charges upon their prescriptions are extortionate.

We must acknowledge that on the first ground the physicians have just cause of complaint. The system of combining the vocations of prescriber and dispenser can scarcely be said to exist in this country. It is condemned by our pharmaceutical associations, and no member can indulge in such a practice without violation of the ethical code.

We regard this as eminently just and proper; and however much our English brethren may exceed us in some respects, they are certainly far behind in this.

The discussion has naturally brought forward some of the shortcomings of certain doctors of fair repute, and it seems that they are fully up to the standard allotted to quackery in our own community. We allude to the practice of certain so-called physicians who, from private motives, well understood by the favoured but equally unscrupulous apothecary, designate preparations by secret names or hieroglyphics, which to the uninitiated are about as intelligible as so much Chinese.

A certain Watson Bradshaw having indited such a prescription, which went astray, a copy of it was sent to the London PHARMACEUTICAL JOURNAL for publication and elucidation. The latter request could not be complied with of course, but its publication called forth a note from the prescriber, correcting the "false Latinities" which the published formula ascribed to him. This the editors allowed to pass unnoticed, whereat the critical Bradshaw waxed wroth, and demanded an apology or satisfaction. The editors kindly granted him the latter by publishing a *facsimile* of the original prescription. The writing is itself a curiosity, and scarcely more intelligible than the ingredients of his prescription. The eminent Bradshaw has now no cause of complaint, since full justice has been rendered him—a justice which he doubtless enjoys, as did a certain Shylock in urging his rapacious claim.

Bleaching Sponges.—Sponges can be bleached by first soaking them in hydrochloric acid, diluted with $1\frac{1}{2}$ parts water, until no more carbonic acid is given off; then wash in pure water, and afterwards leave in a bath composed of 2 lb. hyposulphite of soda, 12 lb. water, and 2 lb. hydrochloric acid. If the sponge be afterwards dipped in glycerine and well pressed, to remove excess of liquid, it remains elastic, and can be used for mattresses, cushions, and general upholstery. Sponge mattresses prepared in this way are now finding great favour. It is, of course, not necessary to bleach the sponge where it is intended to be used for such purposes. —*Journal of Applied Chemistry*.

Pills of Sulphate of Quinine.—In order to ensure the solubility of quinine when made into pills, M. Cazac (*Rev. Méd. de Toulouse*) proposes to mix the sulphate with tartaric acid. This had already been recommended, but the quantity of acid proposed was too large. M. Cazac uses one part of tartaric acid to five of sulphate of quinine, making up the pills with conserve of dog-rose.—*British Medical Journal*.

Parasite on the Lemon.—At a recent meeting of the Scientific Committee of the Royal Horticultural Society, Mr. Alfred Smee exhibited some lemons from Sicily which had been attacked by a species of *coccus*, quite distinct from the well-known coccus of the orange, and apparently an undescribed species. It was stated that nearly the whole of the lemon crop in Sicily is attacked by this parasite, which renders it almost valueless for the English market. Although the juice is not much affected, the skin is completely spoiled, and rendered uncrystallizable. The root appears to be at the same time attacked by a fungus.—*Nature*.

Eucalyptus Leaves.—The Rev. M. J. Berkeley mentions in the *Gardeners' Chronicle*, on the authority of a letter received from Cannes, that Dr. Gimbert has introduced a new method of dressing wounds by using eucalyptus leaves in the place of lint. The leaves, which have a "catty" smell, are merely laid on the wounds. The balsamic nature of them not only cures, but after a few hours all the unpleasant odour of the matter ceases.

Incompatibility of Quinine and Veratrum Viride.—Dr. Bradly, of Marys, Ohio, reports that when a patient is under the influence of *Veratrum viride*, it is highly dangerous to administer quinine. The effects are most alarming, immediate sinking and irregularity of the pulse, which in some instances reaches collapse. He ran great risk of losing three patients before he became aware of the actual cause.—*Medical and Surgical Reporter*.

DRUG MARKET NOTES.

The following are a few of the principal parcels of drugs offered for sale lately:—

Rhubarb, 167 chests; China, 80 cases.
Cantharides, 2 cases.
Nutmeg Oil, 9 cases.
Musk,—Tonquin, 77 caddies; Grain, 4 caddies.
Musk Skins, 1 package.
Squills, 54 bags.
Ergot of Rye, 5 barrels.
Bark,—Calisaya, 94 serons; Soft Columbian, 286 serons; Red, 7 cases; Yellow, 56 serons; Pitayo, 52 bales; Crown, 27 serons.
Castor Oil, 250 cases; Italian, 20 cases.
Jalap, 16 bales.
Honey, Chilian, 89 casks.
Cod-Liver Oil,—Newfoundland, 88 casks; Norwegian, 57 casks.
Patchouli Leaves, 6 bales.
Blackboy Gum, 30 casks.
Japan Wax, 324 boxes.
Orris Root, 1 cask.
Aloes,—Cape, 46 cases; East Indian, 29 cases, 7 boxes.
Cardamoms,—Malabar, 32 cases.
Ipecacuanha, 16 serons and 1 case; Carthagena, 6 barrels.
Chiretta, 75 bales.
Cassia Fistula, 8 cases and 47 bags.
Canella Alba, 15 packages.
Camphor,—China, 115 cases.
Ambergris, 7 tins and $5\frac{1}{2}$ oz.
Turmeric—Madras, 320 bags.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 18, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REGISTER FOR 1871.

THE Register of Chemists and Druggists for the present year having been just issued, we take the opportunity of calling our readers' attention to some points in connection with its compilation.

The Register contains about five hundred new names, most of which are those of persons who have passed the Modified Examination. Although every care has been taken to make the list as perfect and complete as possible, some errors still occur in it, the correction of which must rest with the persons registered or those acquainted with them. Many names are registered at addresses which were correct at the time registration was effected, but of the incorrectness of which at the present time proofs are of frequent occurrence. This defect arises principally from the neglect of registered persons to apprise the Registrar of any change of address. This is the more important from the difficulties that may arise from such neglect. Clause 10 of the Pharmacy Act, 1868, enacts that, "to enable the Registrar duly "to perform the duties imposed upon him, it shall "be lawful for the Registrar to write a letter to any "registered person addressed to him according to his "address on the Register, to inquire whether he has "ceased to carry on business or has changed his residence, such letter to be forwarded by post as a "registered letter, according to the Post Office regulations for the time being, and if no answer shall "be returned to such letter within the period of six "months from the sending of the letter, a second of "similar purport shall be sent in like manner, and "if no answer be given thereto within three months "from the date thereof, it shall be lawful *to erase* "*the name of such person from the Register.*" As by the same Act it is provided that the Register shall be sufficient evidence in all courts of law, and that the absence of the name of any person from such printed Register shall be deemed evidence, until the contrary is proved, that such person is not registered according to the provisions of the Pharmacy Act, and as a copy of the Register is supplied for that purpose to all the principal law courts in the kingdom,—it will be seen how important it is that each person registered should secure the correctness of the entry relating to himself.

Another cause of error is that arising from unreported deaths. Notice of the deaths of registered persons should be given by the Registrars of Deaths in the district in which they occur. The neglect of this duty, however, is very frequent, and the Registrar has to rely upon the local secretaries or private sources for this information.

THE current number of the *Chemist and Druggist* contains a Pharmaceutical Sermon, in which Mr. JOSEPH INCE, taking his text from Ecclesiasticus xxxviii. 1–4, defends himself against the criticism of our contemporary the *British Medical Journal* in reference to the publication of prescriptions with the names of their authors. In quoting the opinion expressed by that journal, we did not presume to offer an opinion as to whether it is right or wrong or necessary to so publish names, for if it be an offence to do so, we must confess to being in some degree *participes criminis*, and we now refer to the matter again chiefly because Mr. INCE appears to imply some censure for having inserted a brief statement of the objection raised by the *British Medical Journal*, though we think he will perceive on reflection that, as a representative of the medical profession, its opinion on the point is entitled not only to consideration, but also to publicity in our columns.

IN the House of Commons, on Monday night, Mr. BRUCE said, in answer to a question put by Lord EUSTACE CECIL, that it was not the intention of the Government to propose legislation concerning the adulteration of food and drugs this session. On Wednesday Mr. MUNTZ gave notice of his intention to bring in a Bill to amend the law for the prevention or adulteration of food and drink and of drugs.

PROFESSOR FRANKLAND has accepted office as President of the Chemical Society for the ensuing session.

AT a preliminary meeting held at King's College, it was decided that a fund should be raised for a memorial to the late Dr. MILLER, who, for thirty years, laboured in connection with the College. It was also resolved that a Committee should be formed for the purpose of obtaining subscriptions and carrying out the necessary measures.

THE Canadian Pharmacy Bill, which, in consequence of the press of business, was "discharged" last session, has been again brought before the Canadian Legislature. It has been read a first and second time, and referred to a select committee. From the discussion which took place at the meeting of the Ontario College of Pharmacy, it would appear that the principal obstacle in the way of the passing of the Bill was a clause proposing regulations concerning the sale of proprietary medicines. This was ordered to be withdrawn. It is curious to notice that the same confusion in the use of the term "patent medicine" exists in Canada as in this country, in its application to secret nostrums, whereas the essence of a patent medicine is, that the formula shall be known and deposited with the proper authorities.

The proposed typographical changes in the *Chicago Pharmacist* have been effected in the first number of the fourth volume, just received. Notwithstanding the increased quantity of matter, the journal, in its new form, has a decidedly handsome appearance.

The *American Journal of Pharmacy* announces that proof sheets of the volume containing the Proceedings of the American Pharmaceutical Association at the Baltimore meeting have been received, and that its publication may be expected very shortly.

The Annual Meeting of the Philadelphia College of Pharmacy is to be held on Monday, March 27.

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

February 10th, 1871.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Edwards, Gale, Garle, Haselden and Ince.

Dr. Greenhow was also present, on behalf of the Privy Council.

MODIFIED EXAMINATION.

Forty-two Candidates presented themselves for examination; the following passed and were registered as

CHEMISTS AND DRUGGISTS.

Banbury, William Walter	Burford.
Batty, Thomas	York.
Brunton, William Walker	London.
Burton, Joseph	Southampton.
Cadby, Samuel Kittle	Margate.
Crisswell, Frederick	Seaforth.
Davies, Samuel	Liverpool.
Evans, Daniel Ogilvie	Halstead.
Field, Henry	Brighton.
Fox, George Clement	London.
Gibson, Reuben Leonard	Loughborough.
Graves, Joseph Waddington	Reading.
James, David Owen	Newport, Pembroke.
Johnson, Arthur	Rotherham.
Kiddle, James	Bristol.
Kimber, James	Stamford-in-the-Vale.
Legg, Matthew Henry	London.
Logan, Francis	Pembroke Dock.
Mason, Thomas	Nottingham.
Mitchell, Charles Edward	Tunbridge Wells.
Palmer, Henry James	Hulme.
Phillips, Thomas Madocks	Haverfordwest.
Roberts, James	New Brighton.
Sirett, Henry	Buckingham.
Smith, Joseph	Kilnhurst.
Smith, Lucius Jeffreston	Wortley, Sheffield.
Strachan, Binny	Wimborne.
Toy, George Bentley	London.
Watts, Walter	Peterborough.

Provincial Transactions.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

A General Meeting of the above Society was held on Wednesday, January 25; the Vice-President, Mr. E. Nuthall, in the chair.

The Chairman said, before proceeding to the business of the meeting, as specified by the public notice, he thought it would be well briefly to review the progress of the Society since their last meeting.

In the first place they had been favoured by Mr. Sutton with two excellent lectures on Chemistry—lectures that, although adapted to the requirements of the juvenile members, had been highly instructive to all, and thoroughly illustrated by most interesting experiments.

For information respecting the library and museum, he would refer them to their treasurer, Mr. Butler, who had been acting as secretary, merely noticing the great obligation that the Society was under to Thomas Hyde Hills, Esq., for supplying them with the nucleus of a library.

With the exception of a fortnight at Christmas, the four weekly classes had been regularly held, and he only regretted that the attendance had not been regular as well, for with the exception of the Latin class, the number of students had fallen off considerably. This was a circumstance greatly to be regretted, not only because it showed an indifference to their own interests, but also to those of the Society, for it could only be discouraging to those who promoted the design and had been taking the duty of conducting the affairs of the Association, to find that their primary object, viz. the diffusion of the knowledge so essential to the *status* of a chemist, was passed over, and almost entirely neglected by the majority of members. He wished that all those who had not passed their examinations would set to work and strive to rival the success of one amongst them, Mr. King, who had just been placed first on the list of those who had that month passed the Preliminary.

Before proceeding to the election of the new councillors, he could not help expressing regret at the great loss they had experienced in the resignation (through change of situation) of two such useful members as Messrs. Lincoln and Perkins. Of the latter, with whose courtesy and constant attention to the affairs of the Society they were all so well acquainted, he could not speak too highly. Besides, he had a further claim upon their thanks, in the fact that he was one of the first to suggest the formation of such an Association.

Mr. Butler rose to propose a vote of thanks to their late Secretary, Mr. Perkins; in so doing, he observed how much he regretted the loss of that gentleman's valuable services, from which the Society had so greatly benefited since its formation. He had himself been called upon to work much with Mr. Perkins in the business of the Society, and had always noticed how heartily he had entered into the various duties incumbent upon him, which, as might be imagined, were not always of a trifling character.

Mr. Martin, in seconding the vote, begged heartily to concur with Mr. Butler's remarks, and hoped that an expression of the feeling of the meeting would be conveyed to Mr. Perkins. The vote was then carried with applause.

Mr. Butler stated that he would communicate the result of the meeting to Mr. Perkins. In reference to the library and museum, the Council had selected a Sub-Committee to make all the necessary arrangements for the carrying out of their original plan, and they hoped shortly to be able to show a beginning in the museum, as the requisite furniture was already ordered. In the collection of specimens all members could, and he trusted would aid; the Museum Committee would be glad to receive any good crystals, or characteristic specimens of organic materia medica. They also desired to show the various adulterants. With regard to the donation they had received from Thomas Hyde Hills, Esq., part of the books purchased with the above donation of £5 would be to hand in a few days, and would then be allowed to circulate. Mr. Hills had also kindly presented to them copies of the portraits of the late Mr. Jacob Bell, Dr. Pereira, and Mr. William Allen. The grant from the Pharmaceutical Society, of which they had already heard was in part disposed of in purchase of those diagrams now of so much service to the botanical class. They intended shortly to expend the remainder in the purchase of chemical diagrams. He had been requested to notice the falling off in the attendance at the various classes. It had caused him much pain and surprise that those for whose benefit they were carried on should not have more earnestly availed themselves of their advantages. It was quite unnecessary to enlarge upon these advantages, under the present system of compulsory examination, but he would remind them that they were throwing cold water on the efforts of those gentlemen who had so kindly given up much of their time, not only for the actual delivery of the lectures, but for their preparation. He trusted that those present would incite the habitual absentees, and that in the future there would be a marked improvement.

The Chairman stated that Mr. Butler had consented to act as Financial Secretary.

Mr. Grimditch was elected Secretary.

The meeting closed with a vote of thanks to the Chairman.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Eleventh *Conversazione* of the Liverpool Chemists' Association was held on Thursday evening, February 3, at the Royal Institution, Colquitt Street, and was very numerously attended. The entire building was thrown open to the company, and the many objects of interest in the collections connected with the institution were supplemented by others lent for exhibition on this occasion by various private gentlemen and public societies.

Mr. Albert H. Samuel, several times during the evening, explained and illustrated experimentally Tyndall's theory of the blue colour of the sky. He prefaced his explanatory remarks by shortly noting the fatal objections to the other theories previously accepted, and then proceeded to explain that all space is filled with an extremely subtle and elastic medium to which the name "ether" is given. He then defined *light* as the result of an infinitely rapid vibratory motion of the molecules of luminous bodies, such as those of the sun. These vibrations give to the ether a wave-like motion, which striking on the retina of the eye produces a certain sensation which we call light. The waves of ether are of different lengths and amplitudes. The greater the amplitude the more intense the light. It is the difference in the length of the waves, which gives us the impression of different colours, *blue* being caused by the shortest waves, and *red* by the longest. The long red waves have also a much greater amplitude or depth than the short blue waves, and are thereby enabled to roll over or pass by small obstacles which would interrupt and throw back the short and shallow blue waves. He then stated that our atmosphere is supposed to be filled with countless millions of excessively minute particles, in a state of suspension, and that the long deep red waves *roll* or *pass over* these small particles, but the short shallow blue waves are stopped by them, and thrown back or scattered into space, to which they communicate the blue appearance which we call sky. He then proceeded to demonstrate this theory by drawing the attention of his audience to a large glass vessel of water in which he had suspended, by means of an alcoholic solution of gum mastic, an infinite number of minute particles of the gum.

On bringing the powerful light of a magnesium lamp to bear on the particles, the water at once assumed the characteristic blue appearance of the sky,—the water representing the ether, and the suspended particles of gum, the infinitely minute particles floating in our atmosphere.

In the course of the evening the company assembled in the Lecture Theatre, to listen to an address by Professor Roscoe, illustrated by experiments on "Solar Chemistry."

Mr. Abraham, who occupied the chair, in introducing the lecturer, reminded the audience that fifty years ago the institution in which they were assembled was opened by William Roscoe, the most distinguished ornament to literature the town had produced. Professor Roscoe, however, might be introduced upon his own merits.

Professor Roscoe, after thanking the meeting for the flattering manner in which it received him, and the President for the kind way in which he spoke of his honoured grandfather, said,—The science of astronomy was most important. The sun had, from the earliest times, attracted attention, and even worship; but very little had been known concerning it until within the last few years. Recently, however, this knowledge had increased. Now we know something, not only of its physical constitution, but of its chemical composition; that the sun contains substances found on the earth; that iron, magnesium, and many other elements are present in the solar atmosphere. When it was remembered that the sun was 91,000,000 miles distant from the earth, it seemed a marvel that such information could be obtained. Light and heat form the only medium of communication between this world and the sun. It was by examining the light emitted by the sun that the composition of the solar mass could be ascertained. White light is a compound, whereas coloured light is a simple phenomenon. If light were of only one colour, or monochromatic, colour would not be seen at all, but would appear as different degrees of shade. With the aid of the spectroscope, the professor illustrated the different characteristics of the solar rays. The glowing vapours of the gases were beautifully shown, also the broken spectrum caused by throwing lithium through the prisms, and the effect of thallium. He next volatilized several metals, such as silver, copper, cadmium, tin and sodium, and showed the lines produced by each, observing that, however distant a light might be, it could be ascertained what metal produced it. He then said that there were blue and orange-coloured stars, showing a different kind of light, and the lines produced by them were different from those produced by the sun; while those produced by the planets and the moon, being from borrowed light, were the same, showing that these stars were self-luminous. Kirchhoff came to the conclusion that metallic vapours existed in the solar atmosphere, and that certain lines in the solar spectrum were due to the presence of metals in it. Since Kirchhoff's discovery, their knowledge of the sun had greatly increased. The lecturer next proceeded to explain a few of the phenomena attending a total eclipse of the sun. He said they were most marvellous and difficult of explanation. By means of diagrams he illustrated the red prominences observed during a total eclipse. The Himalaya expedition in 1860, proved that these protuberances belong to the sun. They consist of glowing masses of hydrogen, many of which are supposed to extend 80,000 or 90,000 miles, and move with wonderful rapidity. Speaking of the corona or white halo of light seen outside the sun during a total eclipse, the irregular form of which extended into space, he said the result of the recent eclipse expedition was, on the whole, satisfactory; for in spite of bad weather, accidents and mishaps, the corona had been run down at last, and it was pretty well known what it was. If, however, the astronomers had been favoured with fine weather an important series of observations would have been made at Syracuse. Some of them went up Mount Etna, and saw nothing. About half an hour before the eclipse a snowstorm set in; half an hour after the eclipse was over the weather was most beautiful, the sun shining forth in all his brilliancy. There was no doubt that the corona did belong to the sun. The light from the corona gave a spectrum containing bright lines, one of which was observed by an American astronomer during the eclipse last year. This line does not coincide with any of those found in the spectra of other known elementary substances. A similar bright line is, however, found in the spectrum of the aurora-borealis. Whether they were connected could not be said at present; that is a point for future observers to clear up. It had been enough for them, during the last eclipse, to fix the corona as an absolute entity, and show that it was not merely something produced in the eyes of the observers by irradiation of any glare, but a portion of the solar body. Professor Roscoe concluded his lecture by thanking his audience for the attention with which they had listened to him, and resumed his seat amid loud applause.

A cordial vote of thanks was presented to the Professor for his lecture.

Later in the evening, Mr. Edward Davies, F.C.S., Vice-President of the Association, gave a short but instructive lecture, with experiments, upon modern explosive compounds, including the different kinds of gunpowder, gun-cotton, nitro-glycerine, dynamite, picrate of potash, percussion shells, time fuses, and percussion fuses.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

An Ordinary Monthly Meeting was held in the Memorial Hall, Albert Square, on Friday afternoon, February 3rd; Mr. G. S. Woolley in the chair.

Messrs. Berry, Eckersley and Warton, all of Oldham, were elected members; and Messrs. Woodcock, Spenceley and Bowsfield, associates.

A donation of three guineas, to form a prize in one of the classes selected by the Council, was announced from a member, Mr. T. G. Gibbons, and a resolution conveying the best thanks of the Association to Mr. Gibbons was carried with acclamation.

Mr. Robert Hampson then read a paper "On the Importance of Some Knowledge of Anatomy and Physiology to the Pharmacist." The following is a brief abstract:—

The pharmacist is expected to be fully alive to the requirements of the physician, and conversant with the *modus operandi* of remedial agents. The production of pharmaceutical preparations suited to the varied manifestations of disease necessitates some knowledge of the construction and functions of the human organism. Such knowledge would greatly tend to impress upon the dispenser the absolute importance of accuracy in compounding medicines, and the danger and disadvantage of using adulterated drugs, or drugs not reaching the official standard of potency. The definition of a poison, and the perils of an excessive dose, and the necessity for the use of all suitable safeguards to prevent error or disastrous misadventure, would assist in putting to flight the mistaken notion, that the rigid machinery of law, its penalties and needless rude encroachments are required to ensure the safety of those who deal with us.

It might be argued by some that this kind of knowledge would extend the practice of prescribing by druggists; he (Mr. Hampson) entertained an opposite opinion, founded on the conviction that this particular information which reveals to us that our bodies are indeed "fearfully and wonderfully made," has a tendency to prevent, rather than foster the rash assumption of duties foreign to our special business.

Mr. Hampson illustrated his subject by some remarks on the minute anatomy of the skin and mucous membrane, and their use in the animal economy, and also on the various methods of introducing medicines into the circulation.

In conclusion he advocated that a short introductory course of lectures, embracing a clear outline of anatomy and physiology be given to pharmaceutical students.

A cordial vote of thanks was passed to Mr. Hampson for his interesting paper.

Some discussion then took place on the latest phase of the poison regulations question, and a resolution proposed by Mr. Siebold and seconded by Mr. Mumbray, was carried, "That the consideration of this subject be referred to the Council of this Association, and that they be requested to take action thereon."

The Secretary called attention to a copy of the Year-Book issued by the Pharmaceutical Conference, which he had placed upon the table, and reminded those present that all apprentices and assistants, as well as men in business, were, on payment of the annual subscription of 5s., eligible for election as members of the Conference, by which they would be entitled to a copy of this valuable work.

A paper on Dispensing, by Mr. Halliday, was announced for the March meeting,

BRISTOL PHARMACEUTICAL ASSOCIATION.

A General Meeting of the Association was held on Friday, February 10th, for the purpose of taking into consideration the subject of the proposed "Regulations for the Storing of Poisons."

The President, Mr. Stoddart, briefly introduced the subject, pointing out that the poison clauses in the Pharmacy Acts were really all that the public and the Government cared about, and that they had shown a remarkable confidence in the pharmaceutical body in trusting to their hands the carrying out of their provisions. He thought the pharmacists were bound in honour to fulfil the implied pledge to adopt some compulsory regulations as to the storing of poisons, and that those suggested by the Council were sufficiently elastic to be easily applied to all kinds of pharmaceutical businesses.

Mr. Giles said he had endeavoured to approach the subject with a perfectly unbiassed mind. He had hitherto identified himself with neither side in this controversy, feeling a good deal disposed to trust the judgment of the Council, and to follow their leading. Looking at the question in the abstract, and having regard to the history of the sad cases of accident that all present would recollect, he thought the public had a distinct right to some security against such accidents beyond those provided by the best professional education; and this view naturally issued in the imposition of compulsory precautionary regulations. Those that had been put forth by the Council, with the concurrence of the Privy Council, he considered, were very sensible and very easy of application, and their adoption would, he was sure, act as a great relief to many an anxious dispenser. Moreover, by thus offering a further pledge of safety to the public, the pharmaceutical body would be adopting the course most calculated gradually to draw the bulk of dispensing into their own hands. Mr. Giles then read a circular he had that day received from Mr. Bremridge, which detailed the history of the Council's action in the matter, and explained its present intentions, and he concluded by declaring that he utterly failed to discover any ground for objection to the course it had taken.

Mr. Boucher (Ferris and Co.) confessed he felt no very great faith in the efficacy of "compulsory regulations," as he thought most establishments already practised such precautions as were best adapted to their own particular circumstances; and looking at the exceeding infrequency of accidents in the houses of pharmacists, he did not think they were required. But as something of the kind appeared to be demanded by a portion of the public, and by the Privy Council, he would by no means oppose them.

Mr. Schacht said he had always noticed that those who had the largest experience in dispensing were amongst the most anxious to avail themseves of all possible precautions, whether mechanical or moral, against accidents. He was desirous to do so also; and, indeed, with Mr. Boucher, believed there were but few pharmacists throughout the country who not only felt as earnestly upon the matter as he did himself, but who would have approved these "regulations" warmly, had they only been presented as "recommendations." He believed that what had produced the show of opposition to them was the fear that, as the existing legal power to enforce their observance was manifestly insufficient, the adoption of them as compulsory would be tantamount to a pledge to support some further legal enactments, which, to be efficacious, must of necessity be inquisitorial. This view had presented itself strongly to his own mind, though he had never before publicly expressed it, and had made him regard the whole business, highly as he approved the substance of the regulations, with a good deal of distrust. He could not endure the notion of inspection, and yet without it he could not see how these "regulations" could be rendered compulsory. There was a sentence in the circular the meeting had just heard read, which he interpreted as a disclaimer on the part of the Council of any intention to push what legal power they possessed to a vexatious issue; he should not, therefore, press upon the Association a resolution he had prepared, requesting definite information from the Council upon this very point; but he thought all the more that "compulpulsory regulations," which were not be enforced, had better be called by their proper name—"recommendations."

After a general discussion of a conversational character, in which the details of the proposed regulations were considered, it appeared to be the feeling of the meeting that it was desirable that the agitation upon the subject of poison regulations should be set at rest, by accepting the proposition of the Council of the Pharmaceutical Society, which appeared to satisfy the requirements of the Privy Council. The following resolution was therefore proposed by Mr. Giles, seconded by Mr. Boucher, and carried without a division:—"That this meeting approves of the regulations proposed by the Council of the Pharmaceutical Society, in concert with the Privy Council, for the keeping and dispensing of poisons, and authorizes the Council of this Association to take measures at their discretion for supporting the action of the Council of the Society at the Annual Meeting in May next."

HULL CHEMISTS' ASSOCIATION.

At the usual monthly meeting of the Hull Chemists' Association, the proposed poison regulations were discussed, when it was unanimously resolved, "That the attempt to enforce uniformity throughout the kingdom in the keeping and storing of poisons by chemists, would, if successful, be likely in the first instance to result in greatly increased risk by disarranging existing plans, without any probable ultimate benefit to either the public or the trade, and such proposed regulations are in the opinion of this meeting unnecessary."

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

At the Meeting of the Chemical Society on the 2nd of February, Professor Frankland, F.R.S., read a paper on "The Development of Fungi in Potable Water." He first alluded to Mr. Heisch's experiments on waters contaminated with sewage matter. The addition of sugar gave rise to a kind of fermentation, and a rich fungoid growth made its appearance. Professor Frankland, in repeating these experiments, has arrived, with one or two exceptions, at the same result. But he also met with some reactions which were at first difficult to explain. On the 26th of November last, he collected at Mr. Hope's irrigation farm at Romford, a sample of effluent water from one of the drain outfalls. This water consisted of Romford sewage, which had percolated through four or five feet of loose gravelly soil to the tile-drains below. It was clear, but still contained much unoxidized sewage, as was shown by the following results, obtained upon analysis:—

100·000 parts contained—

Total solid impurity in solution	85·600
Organic carbon	0·844
Organic nitrogen	0·233
Ammonia	0·040
Nitrogen as nitrates and nitrites	1·143
Total combined nitrogen	1·419
Chlorine	9·300
Temporary hardness	27·950
Permanent "	20·600
Total "	48·550

The proportion of organic carbon was three times, and that of organic nitrogen ten times, as great as that found in unpolluted water, whilst the comparatively large proportion of ammonia showed that the oxidation of organic matter was still incomplete. Nevertheless, this water, mixed with the proper proportion of sugar, and maintained at a temperature of about 70° F., remained perfectly transparent for weeks. The result of the next experiment was still more remarkable. Two samples of the Grand Junction Company's water were mixed with sugar in the usual way. One of them was drawn from a foul, uncovered cistern over and within a water-closet; the other from a clean slate cistern, and filtered through 30 or 40 lbs. of animal charcoal. The water from the foul cistern remained transparent for weeks, whilst that drawn from the clear cistern through animal charcoal soon became turbid, and in three days produced abundant fungoid growths. To test Mr. Heisch's statement that filtration through *well-aired* animal charcoal prevented these growths even in foul water, Professor Frankland passed a rapid current of air through the filter for about fifteen minutes, and left it exposed to air for six hours. The result, however, was the same; Grand Junction water drawn through it immediately after aeration, when mixed with sugar, behaved exactly as before. These experiments seem to indicate that the presence of a phosphate was in some way connected with the production of the fungoid growths and other living organisms, for it is known that water dissolves traces of calcic phosphate from animal charcoal, and this supposition was strengthened when Professor Frankland found that the effluent water from the sewage farm at Romford contained no detectable trace of phosphoric acid, the plants and poor soil of this newly-cultivated farm having, doubtless, removed all phosphates from the percolating sewage. The hypothesis of the dependence of fungoid and other growths upon the presence of phosphates was further supported by the results of the following experiments:—

A sample of the Grand Junction Company's water mixed with sugar remained perfectly clear for twelve days; minute quantities of ammonic nitrate and sodic phosphate were then added; three days later, it swarmed with very active vibrios and cells with bright nuclei; subsequently very luxuriant branched fungoid threads were developed, the mixture emitting a strong ferment odour, which, a few days later, became horribly offensive.

A sample of the Southwark Company's water mixed with sugar remained for nineteen days perfectly clear; small quantities of ammonic nitrate and sodic phosphate were then added. In a few days it was crowded with vibrios and monads: later it was found to contain the characteristic mycelial fibres.

The usual proportion of sugar was added to a sample of water collected at the Cerney Springs near Cirencester; it remained clear for eight days and was then mixed with traces of ammonic nitrate and sodic phosphate; it continued turbid, and soon became filled with swarms of vibrios and fine branching tubular fungoid threads; the water subsequently became brownish and emitted a very offensive odour.

These experiments show that potable waters, which stand the sugar test perfectly, become entirely changed in their behaviour with this test when mixed with traces of ammonic nitrate and sodic phosphate; and the following experiments prove that it is the phosphoric salt which alters their behaviour in this respect:—

A sample of the Lambeth Company's water, mixed with sugar, remained perfectly clear for nineteen days: ammonic nitrate was then added; after the lapse of several weeks the clearness of the sample had not been disturbed.

Canterbury deep well-water, softened by Clark's process, remained perfectly clear during twenty-three days after admixture with sugar; traces of nitrate of ammonia were then added. After the lapse of two months, it was perfectly transparent and unchanged.

Thus it is evident that the addition of minute traces of a phosphate, either as sodic phosphate, white of egg, or animal charcoal, at once determines these fungoid growths in saccharine water, which before exhibited no tendency to develope them.

The next question to be determined was, are the germs of these organisms contained only in the waters which develope fungoid growths, or are they present in the atmosphere? The answer was given by the following experiment:—

Small quantities of potassic chloride, ammonic nitrate, sodic phosphate and sugar were dissolved in distilled water, previously boiled for many hours with caustic soda and potassic permanganate, and afterwards again distilled. Just before solution the solid ingredients were strongly heated in a platinum spoon over the flame of a spirit-lamp; the potassic chloride and sodic phosphate to redness, the ammonic nitrate until a considerable proportion had decomposed into nitrous oxide and water, the sugar until, after melting, it began to turn brown. This solution was placed in a stoppered bottle. After a few days' exposure to a temperature varying between 60° and 70° F., a magnificent mycelium of the characteristic description began to grow, soon followed by several others. The liquid was also crowded with very minute moving organisms, probably monads. A specimen of real sewer fungus was found to be very similar in appearance, but more transparent and somewhat smaller.

It is thus evident that the purest water which can be obtained in contact with the air yields splendid crops of this sewage mycelium, if it be supplied with the necessary soil, and further, that the sugar and salts just named contain all the elements necessary for its development. Phosphorus is essential, for, in a solution made at the same time, exposed to the same conditions and containing the same substances, *minus the sodic phosphate*, no trace of mycelium or of any other organism made its appearance during nine weeks.

The presence of germs in a sample of water is therefore insufficient in itself to produce Mr. Heisch's reaction when sugar is added. A short (probably a momentary) contact with air is sufficient to impregnate any sample of water with the necessary germs, which develope on the addition of sugar only in the presence of a phosphate. The reaction is, in fact, an exceedingly delicate test for phosphoric acid. It would probably defy the powers of the most expert chemist to detect, in two ounces of water, the phosphoric acid introduced by the addition of a single drop of a dilute solution of albumen; yet these atmospheric germs find it out, appropriate it, and by their growth, reveal its presence.

Professor Frankland then described some experiments in which water, sugar, sewage matter and the necessary salts, were kept in dark or obscure places at the temperature of the body. He found that these conditions were favourable for the development of bacteria, vibrios and similar organisms, but unfavourable for fungoid growth.

As the result of his experiments, Professor Frankland has arrived at the following conclusions:—

1. Potable water mixed with sewage, urine, albumen and certain other matters, or brought into contact with animal charcoal, subsequently develope fungoid growths when small quantities of sugar are dissolved in them and they are exposed to a summer temperature.

2. The germs of these organisms are present in the atmosphere, and every water contains them after momentary contact with the air.

3. The development of these germs cannot take place without the presence of phosphoric acid, or a phosphate or phosphorus in some form of combination. Water, however much contaminated, if free from phosphorus, does not produce them. A German philosopher has said "*ohne Phosphor kein Gedanke*." The above experiments warrant the alteration of this dictum to "*ohne Phosphor gar kein Leben*."

ONTARIO COLLEGE OF PHARMACY.

At the Ordinary Monthly Meeting, held on the 13th of January, the Legislative Committee reported that they had interviewed the Hon. Attorney-General and several other members of the Legislature, and that there seemed to be a general opinion in favour of the Bill, with the exception of Clause 27, into which a provision has been introduced for regulating the sale of proprietary medicines that has caused great opposition.

Mr. Elliott thought that a modification of the clause was advisable; yet there ought to be some provision to prevent the putting up of laudanum and other dangerous drugs under other names, and scattering them broadcast over the country. This, he thought, might be done without interfering with the sale of legitimate patent medicines.

Mr. Margach moved an amendment, authorizing the Committee on Legislation to withdraw the clause, as he felt convinced that an attempt to carry it would imperil the Bill itself. It would be better to get the Act first, and, at some future time, a well-digested scheme for protecting the public from dangerous secret remedies might be introduced.

Mr. Miller, in supporting the amendment, said that it was certainly a very arbitrary proceeding to compel every proprietor of a patent medicine to send the formula to the Registrar. He felt sure that it could never be carried out.

The amendment was carried.

During a discussion on the Poison Schedule, which is similar to that in the English Act, Mr. Miller said that paregoric, being an article of such common use, ought to be made an exception to the articles in Class 2.

This suggestion was adopted, and a committee instructed to carry out these alterations when the Bill again came before the Legislature.

MEETINGS FOR THE ENSUING WEEK.

Monday ......*Medical Society*, at 8 p.m.
London Institution, at 4 p.m.—"The First Principles of Biology" (Educational Course). By Prof. Huxley.
Tuesday ......*Royal Institution*, at 3 p.m.—"The Nutrition of Animals." By Professor Foster.
Wednesday ...*Society of Arts*, at 8 p.m.—"Water Meters." By Frederick E. Bodkin.
Thursday......*Royal Society*, at 8.30 p.m.
Royal Institution, at 3 p.m.—"Davy's Discoveries in Chemistry." By Prof. Odling.

THURSDAY......*London Institution*, at 7.30 P.M.—"The Action, Nature and Detection of Poisons." By F. S. Barff.

London Chemists' Association, at 9.30 P.M. "Filtration." By Mr. De Putron.

FRIDAY ....*Royal Institution*, at 9 P.M.—"The Latest Scientific Researches in the Mediterranean and Straits of Gibraltar." By Dr. W. B. Carpenter.

Quekett Club, at 8 P.M.

Parliamentary and Law Proceedings.

OVERDOSE OF CHLORAL HYDRATE.

An inquest has been held at Wrington, Somerset, to inquire into the death of Mr. Edward Ratheram. It appeared from the evidence that the deceased gentleman had been placed under the care of Dr. Barnes, in consequence of his addictedness to opium. Visiting Bristol with the Doctor, he took the opportunity of purchasing secretly an 8-oz. bottle of chloral hydrate. A day or two afterwards he was observed to be under the influence of an opiate. Being questioned, he produced a bottle containing about an ounce of chloral hydrate, largely diluted with water. The bottle was not marked "poison," but a printed label was attached, giving directions for use. In the evening he took his supper in bed, apparently quite well; the next morning he was found lying on the floor. Medical assistance was obtained, but Mr. Ratheram died shortly after. The medical evidence was to the effect that death had been occasioned by an overdose of chloral hydrate, and the jury found accordingly, adding, that they believed it to have been taken in ignorance of its strength, and that in their opinion narcotic poisons, when sold to non-professionals, should be labelled "Poison."—*Saturday Bristol Times.*

Obituary.

DR. F. A. G. MIQUEL.

Intelligence has been received of the death of Dr. F. A. G. Miquel, Professor of Botany in the University of Utrecht, and Director of the Botanic Gardens at Leyden. Professor Miquel has occupied high rank among systematic botanists for many years. His numerous publications have been principally devoted to the elucidation of the plants of the Dutch possessions in the Indian Archipelago and of the flora of Japan and New Holland. Besides these undertakings, for which Professor Miquel possessed special advantages, he produced several monographs of particular families, such as the Figs, Peppers, Cycads, Casuarinas, etc. The work by which he will be best remembered is his 'Annales Musci Botanici Lugduno-Batavi,' in four folio volumes, with splendid illustrations. He was one of the Foreign Members of the Linnean Society of London.

Petroleum Accident.—A Mr. Smith, ironmonger, of Keighley, while engaged lately in filling a thirty-five gallon cask, which had contained petroleum, with olive oil, incautiously placed a lighted lamp upon it. An explosion immediately ensued, which blew out the plate-glass front and some of the windows on the opposite side of the street. Mr. Smith was slightly burned about the face and head.—*Grocer.*

The following journals have been received:—The 'British Medical Journal,' Feb. 11; the 'Medical Times and Gazette,' Feb. 11; the 'Lancet,' Feb. 11; the 'Medical Press and Circular,' Feb. 16; 'Nature,' Feb. 9; the 'Chemical News,' Feb. 10; 'Journal of the Society of Arts,' Feb. 9; 'Gardeners' Chronicle,' Feb. 11; the 'Grocer,' Feb. 11; the 'Chemist and Druggist' for February; the 'American Journal of Pharmacy' for February; the 'New York Druggists' Circular' for February; the 'Chicago Pharmacist' for January; the 'Canadian Pharmaceutical Journal' for January; the 'Journal of Materia Medica' for January.

Notes and Queries.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department*, 17, *Bloomsbury Square, W.C., and not to the Publishers.*

[160.]—LIQUOR QUINIÆ AMMON.—Will any correspondent be kind enough to inform me how liquor quin. ammon. is prepared?—S. C.

[*** The following has already been published in this Journal, 1st ser. Vol. XIII. p. 344:—

℞. Quinæ Disulph. gr. xxxij
Spirit. Tenuior. ℥iiiss
Liquor. Ammoniæ ℥ss.

—ED. PHARM. JOURN.]

[161.]—TINCTURE OF MYRRH AND BORAX.—Can any of your readers tell me what is usually sold under this name? The formula given in Squire's 'Companion' seems to dissolve only a very small proportion of borax. I have tried equal parts of tinct. myrrh. and glycerin. boracis, which make a tolerably clear mixture, but I should be glad to know what others use.—PROVINCIAL.

[*** The following is the formula given by Piesse:—

Spirits of Wine . . .	1 quart.
Borax	1 oz.
Honey	1 oz.
Gum Myrrh	1 oz.
Red Sanders Wood . .	1 oz.

Rub the honey and borax well together in a mortar, then gradually add the spirit—which should not be stronger than ·920, *i. e.* proof spirit—the myrrh and sanders-wood, and macerate fourteen days.—ED. PHARM. JOURN.]

[162.]—ANILINE SULPHATE.—Will any reader oblige me with a formula for the manufacture of aniline sulphate?—J. T. SANDELL.

[163.]—ACIDUM CARBOLICUM AROMAT.—"*Country Druggist*" wishes to know what "acid. carbolic. aromat." is, used for inhaling.

[164.]—THE LOGWOOD BREAD TEST.—I have tested various samples of bread with the "methylated alcoholic infusion of logwood" test given in your Journal, amongst them one called aerated bread, which, on standing, turned of a bluish-green colour. Will any one be kind enough to explain what it is due to? The other samples showed their freedom from alum by turning of a yellowish-straw colour.—FILIUS NEMINIS, *Manchester.*

[165.]—PILL COVERING.—Will any reader kindly inform me the way to send out pills with a "tasteless white covering"?—S. R.

[166.]—BLACK INK.—*J. T. B.* and "*Scribe*" would be glad of a good recipe for black ink which would not corrode steel pens.

[167.]—LEMONADE.—*A. Z.* wishes for a good formula for making lemonade (aerated).

[168.]—FRAGRANT ESSENCE.—*G. H. B.* would be glad if any reader could give a good formula for the above.—GEO. HARVIE.

[169.]—CORN PLASTER.—*M. P. S.* wishes for a formula for Corn Plaster (not containing verdigris) to spread on linen.

[170.]—BALSAM OF LIQUORICE.—Will any reader kindly favour me with a recipe for the above?—Z. Z.

[171.]—BOTANICAL SPECIMENS.—Will any correspondent favour me with the best methods of drying and preserving botanical specimens?—HERBARIUS.

Correspondence.

Poison Regulations.

Sir,—My physical inability during the past three months to attend the meetings of the Council has not diminished my interest in the changing phases of the proposed regulations for keeping and dispensing poisons. The publication in the Pharmaceutical Journal of the 11th inst. of a "statement of reasons which have induced the Council to suggest regulations," bearing the endorsement of eleven members of Council, compels me in this way to record my dissent from those "reasons," a feeling which I cannot doubt is shared by many others of the ten remaining members of the Council.

On general grounds, the "reasons" appear to me as being framed upon a basis, suitable perhaps for the excuse of party measures, but inconsistent with the representative character of the Council. The historical notice of the Pharmacy Bill (No. 1) of 1865 may be satisfactory to those who are responsible for that expensive failure, but the allusion to the United Society of Chemists and Druggists as the cause of its failure is a very doubtful piece of good faith towards a body of men who were thought powerful enough to be parties to a treaty in 1868, and who maintained an unselfish fidelity not yet fully recognized, and certainly not rewarded.

The recommendations of the committee of the House of Commons in 1865 (instigated by the United Society) are taken as the origin of present restrictions on the sale of poisons, reserving the fact recorded by the "reasons" that 'prior to the passing of the Pharmacy Act of 1868 attempts had been made in Parliament at various times to enforce regulations for the sale of poisons." Surely this fact, used in the preceding paragraph as one of the "reasons" for present action, might fairly be supposed to have influenced the promoters of Bill No. 2 in 1865. The opponents of the regulations are perfectly aware of the tendency of modern legislation as relating to the liberty of the subject, it being clear that the tide has turned against that doctrine of *laissez faire*, which somewhat illogically received an impetus from the removal of fiscal burdens upon commerce and manufactures. We all know that such changes of policy tend towards an opposite extreme, and that unreasoning panic constantly follows a state of blind security. In connection with the present phase of advancing civilization, it is proper that the old ducal right, "a man may do as he likes with his own," should give way when that wish is exercised to the damage of his fellow-men. But society must apply its restrictions with some fairness, and show cause for the burdens which it imposes upon any class. The restrictions placed upon the sale of poisons was accepted by our body as a general measure which was not unreasonable But where is the evidence making a case for immediate and the most oppressive form of interference in the keeping of poisons? We all know that in years gone by it was no uncommon thing for tincture of rhubarb and tincture of opium to stand shoulder to shoulder, and that several mistakes happened as a consequence. The Pharmaceutical Society may point to its influence during a quarter of a century as having changed this state of things, and may assert that hardly any mistakes now occur which would be prevented by the proposed regulations.

In the 5th paragraph of the "reasons," it is stated that there was "a *tacit understanding* between the Council and the Government, that the Pharmaceutical Council should frame a code of regulations to be approved by the Privy Council." This is a point of the deepest importance, and I ask my fellow-members to observe it closely. "Tacit understanding" is something to be pondered over. "Secret treaty" is the modern phrase, and we now ask who had any power of making either "tacit understandings," or "secret treaties"? The authors of the "reasons" seem to have undertaken a task which will require them to show more "reasons." If the "understandings" of 1868 were something additional and beyond the Society's Bill, why were they not acknowledged? If "tacit," who were to be kept in the dark except the Society itself, which conferred the only representative powers possessed by its mouthpiece? A little study of the negotiations of 1868, by the dim light vouchsafed to us by those concerned, will show what probably happened. Mr. Simon, the medical officer of the Privy Council, constituted a new power in the State, and found a Bill to regulate pharmacy introduced into Parliament without its promoters having thought of obtaining his sanction. The reasonable character of that Bill, its respect for the recommendations of the Committee of the House of Commons of 1865, and its united support by all chemists, gave it a good prospect of viability. In the nature of things, Mr. Simon desired to impress upon the Bill those finishing touches which would show the hand of a master. Schedule A. was divided into two sections, and opium and its long train of preparations were added. The powers of confirmation previously vested by the Act of 1852 in one of her Majesty's Principal Secretaries of State, were transferred to the Privy Council, whilst clause 26 gave that body the power of removing from the Register any person who was convicted of an offence under the Act. The existence of clause 26 is by no means to be overlooked by those who are now asked to run a thousand new risks of conviction and its consequences. I doubt whether for cruel and irresponsible power, a more obnoxious clause can be found in the legislation of the past ten years. Whether Mr. Simon is likely to use such an arbitrary right is no part of the question whether it ought to exist, or of the much more practical one whether the danger should be widely extended.

During the various modifications of clause 1, as shown by copies of the Bill of different dates, its promoters finally accepted the requirement to "conform to such regulations as to the keeping, dispensing and selling of such poisons, as may from time to time be prescribed by the Pharmaceutical Society with the consent of the Privy Council." Now, this clause, so far as referring to a power of revising Schedule A., "from time to time," was what any sensible man would have anticipated as requisite, whilst the distinctly permissive right to regulate "keeping and dispensing" also appeared to be a proof of not unwise forethought for the future. The pretence which has been made that "may" when in an Act of Parliament means "must," is sufficiently answered by the opinion of the Society's solicitor, distinctly denying the prospect of a threatened mandamus. Were it needful to bring any other argument on this point, we have only to compare the language of the Act when compulsion is directed, thus, clause 9, "The Council shall with all convenient speed, etc., make orders for regulating the Register."

Before leaving this notice of the birth of the Act of 1868, it is proper to reflect upon Mr. Sandford's position. The difficulties in the way of the Bill, consequent upon Mr. Simon's demands, must have caused him great anxiety, and increased those laborious exertions for which the Society has already expressed its gratitude. This was the second time that Mr. Sandford had taken charge of a Pharmacy Bill, and a risk of failure upon this occasion might well appear disheartening, whilst success was an object to satisfy the highest ambition of a pharmacist. Does not this supply the clue to the 'tacit understanding" now vaguely acknowledged. Does not this make it probable that Mr. Sandford has been personally entangled in his relations with Mr. Simon?

But, if answering these probabilities in the affirmative, what is the inference as concerns the Society? Simply that Mr. Sandford is not the free agent that the President of the Pharmaceutical Society ought to be. If the present proposals are the necessary result of any "tacit understanding" made in 1868, the Society will soon express its opinion as to those who were parties to such compact. Any time within the past thirty years, the trade would have been roused from one end of the kingdom to the other, rather than accept Government inspection, with a host of pitfalls such as Schedule A. would bring.

Amongst the "reasons," I find the "expression of opinion in the press" put forward by the Council. This is not the first time that this argument has been used; and, if I am correct, those who have put such an argument in the mouth of the Council, without the justification of facts, owe an explanation, which it will not be very easy to give. The *Lancet* has published two articles, and the *Pall Mall Gazette* one article, favouring the regulations. As these articles were immediately reproduced in the leader column of the Pharmaceutical Journal, and as no others have been seen there, we have only three to deal with. I have the best authority for asserting that these three articles were produced by gentlemen officially connected with the Pharmaceutical Society, and they were re-imported as an evidence of popular feeling!

Leaving the "reasons," after the foregoing explanation of my grounds for dissent, I will merely add a formal protest against the unusual conduct of a majority of the Council in delegating to a committee the revision and issue of such a document, which had not been seen until the Council met.

One view of the issue of the "reasons" is very satisfactory. A majority of the Council, after this lengthy explanation, will hardly repeat the not very flattering resolution lately passed, telling the constituency that it had not understood the question when it previously passed an opinion upon it; moreover, as the Council adopts the post as the proper means of communicating its ideas to its constituents, it may certainly be expected to recognize the same medium for receiving the verdict which it invites. The settlement of the question at the Annual Meeting by the voting-papers of all members, is of the first necessity to the welfare of the Society, and as the regulations would press with most unequal force upon different sections of the country, justice requires that all should have the same opportunity of recording their opinions.

I hold evidence that the promoters of the regulations are totally ignorant whether their adoption would be followed by Government inspection without a fresh Act of Parliament, or whether that would be necessary. They ask the Society to take the first and irrevocable step, and afterwards they will inquire about the second.

Richard Reynolds.

Southport, February 14th, 1871.

Sir,—While we search in vain through the statement recently placed before us for any but the old time-worn and threadbare arguments, one fact stands out with an alarming prominence, little intended by the authors of the paper,—the fact that we are at this moment, so far as the Society at large can be bound by the acts of its representatives, as ready to give way to pressure from above, as to resist it from below, under the irresponsible government of the medical officer to the Privy Council; and we may well inquire, in the light of its immediate change of policy in regard to "the dispensing of poisons," what value can be attached to the promise of the Council, that, in the event of the regulations being passed, "no vexatious proceedings will be adopted to inquire into their observance"? What guarantee have we against another change, equally sudden, should the autocratic Mr. Simon, by another letter, choose to bring the Council to a proper sense of its position? This very promise, indeed, puts the Council on the horns of a dilemma; either the regulations will not be enforced, in which case faith will not be kept with the Government; or if they are, then the Council must be seeking to throw dust in the eyes of its constituents, for no ingenuity can devise a means of enforcement which will not be vexatious!

Hampstead, February 13th, 1871. Charles Eve.

Sir,—Having already written twice upon the subject of poison regulations, I had not intended addressing you again; but am so much taken by surprise at the report of last Council meeting, and the circular resulting from it, that I could not feel justified in allowing the matter to pass over unnoticed.

Is it not remarkable that at the December meeting of Council, when Messrs. Woolley and Brown proposed that the opinion of the members of the trade relative to this question should be asked by circular, a majority of the Council then present objected to the chemists generally being communicated with; and that we now have a circular drawn up by a committee consisting of the very men who opposed this proceeding in December last?

Is it forgotten that Messrs. Woolley and Brown were elected by a larger number of votes than any other members of Council, and that these votes came principally from provincial members—members who felt they ought to be better represented on the Council than had previously been the case—who felt also that their representatives had only asked a bare measure of justice in moving that the chemists throughout the country should be asked to say whether or not they thought these poison regulations desirable? I said it was a measure of bare justice, and I reiterate the statement, because the regulations, if adopted, would affect the arrangements of some thousands of chemists, outside our Society, who, but for this proceeding, would have no opportunity of influencing the legislation under which they would be governed.

Did the Council deem it a duty to represent the interests of our Society only, without regard to the outsiders? Had it been so, Mr. Woolley's query might at least have been sent to the provincial members of the Society, who, though not debarred by bye-laws, are prevented by other circumstances from attending the annual meeting. Or was it thought, notwithstanding all the correspondence which has taken place upon this question, that the country members had given no consideration to, nor felt any interest in it? No! I can come to but one conclusion, that the Council knew and remembered all the circumstances of the case, and, knowing them, did not dare to ask the simple question as put by Mr. Woolley, because they knew that the replies would cut away the ground upon which they intended to carry out their foregone conclusion. And now we receive a circular from them, not asking if further regulations are desirable, and, if so, to what extent that may be the case, or of what nature such regulations should be, but telling us what regulations are to be proposed: making an elaborate statement, calculated—probably intended—to stop further opposition by intimidation, and apparently bribing us into submission to the proposed regulations by the statement that "they venture to say," though they do not give us any reason to believe, "that no vexatious proceedings will be adopted to inquire into their observance."

I believe every man of common sense would rather a law were not made, than that it should be made not to be enforced; and now that we have received from the Council the code of regulations which it proposes to submit to the meeting in May, and the reasons why it is thought we should adopt them, I think we cannot do better than give the reasons why we think such regulations should not be adopted.

Personally, I have given much attention to the matter, and have come to the following conclusions:—

1. That it is not desirable to make any regulations which are not very simple and easily adopted, perfectly definite and free from all ambiguity, practically useful as a protection to dispenser and patient.

It is imperative that any regulations to be adopted must be *simple*, because, if not so, they will not be practically carried out. They must be *definite*, that the chemist may know precisely what is expected of him. They must be *free from ambiguity*, that, in the event of an accident happening, a coroner's jury may have no difficulty in deciding whether or not the regulations have been complied with. They must be *practically useful*, that they may not be submitted to as a hardship, but practised willingly for the sake of the advantage to be derived from them.

2. That if any distinctive mark is adopted to indicate a poison, that mark ought to be definite, and it should not be left to the option of each individual to select his own mark or marks; otherwise there will constantly be room to dispute whether or not a bottle bears a distinctive mark.

3. That it is not desirable to use for the less dangerous poisons (such as tinct. opii ammon., empl. belladonnæ or ung. sabinæ) any danger-signal or label which is intended to act as a caution in the use of the more dangerous poisons (such as morphia, strychnia or hydrocyanic acid).

Turning now to the details of the proposed code, the first regulation is objectionable.

A. Because if a distinctive mark be adopted, it is to apply to all poisons, whether very dangerous or comparatively free from danger.

B. Because, if a number of distinctive marks may be adopted, it is not free from ambiguity upon that point.

C. And because it does not define a distinctive mark or marks which should be used.

It is not desirable to have alternative regulations, because their adoption increases the chance of the danger-signal being entirely overlooked, while increasing the chance of censure from a coroner's jury or the public press, if they see that *some* precautions have not been taken, which, according to the code of regulations *might*, and they will say *ought*, to have been adopted.

And there are many articles in the poison schedule, to the keeping of which it is not desirable that any of the three alternative regulations should be required to apply, such as syrup of poppies, sundry ointments, plasters, etc.

There is only a fraction of one of the regulations which it would be desirable to put in force with regard to all the poisons in the schedule, and that is "that each poison shall be labelled with its name." And no schedule can be a satisfactory basis for regulations which does not enumerate every poison distinctly to which the regulations are to apply. The loose way in which are included "all poisonous vegetable alkaloids," "all metallic cyanides," and "preparations of X

Y. or Z." is sufficient to make the schedule a subject of frequent contention.

It would be much more to the purpose if the same trouble were taken to devise regulations for the sale of vermin-killers, with which accidents frequently occur, instead of regulating the keeping and dispensing of medicines, which have not been a fruitful source of danger. I cannot call to mind a single death within ten years resulting from a mistake on the part of a pharmacist in Newcastle, but we have had two deaths from vermin-killers within the last ten days.

It is almost unnecessary to inquire of what use can it be to put lotions in "danger bottles" when prepared in a pharmacy, and allowing them to be put in "safe bottles" when prepared in a surgery? For a danger bottle to be any use, its use should be general. So long as three-fourths of the dispensing is done in surgeries and public dispensaries, where poison regultions are not respected, it is futile to expect that poison bottles used in the other fourth will gain public respect as a caution.

No one need suppose that the Privy Council or the Legislature would wish to enforce any regulations which were not calculated to be of practical advantage to the public. Nor can it be supposed that they wish to see nominally adopted a code of regulations which are not to be enforced. Our policy, therefore, should be to inform them that our experience has shown us the undesirability of attempting to lay down strict rules.

I trust that at the Annual Meeting the Society will express its conviction that it is not desirable to add any regulations for the keeping, dispensng or selling of poisons, till experience has shown that those already contained in the Act do not afford as much protection against errors on the part of pharmaceutists as the public have a right to expect.

Grey Street, Newcastle. BARNARD S. PROCTOR.

Sir,—I am sorry to see so many unnecessary and really frivolous objections to the proposed regulations for the storing and keeping of poisons, etc. That compulsion is repugnant to the feelings of Englishmen—the scientific especially—I am willing to allow; yet I hardly take this matter in a compulsory light, as the plan emanating from the Council, originates with ourselves.

It is quite clear we are expected to adopt something of the kind, therefore is it not far better to frame our own, rather than have to submit *nolentes volentes* to regulations proposed by those who are entirely ignorant of the working details of our business? The regulations suggested by our Council are comprehensive and practicable, and from the choice they offer, are such as I think no "reasonable" man can object to. I would, however, propose, that instead of using a label, "Not to be taken internally," we should prefer, "For outward use only," because if the word "not" became obliterated or torn off, the effect would be exactly reversed; the word 'poison' could be added if desirable.

I think as a rule we are not sufficiently discreet in the arrangement of our stocks, and although it may seem absurd to be "over-careful," yet it is a pardonable weakness, if such it may be called. Whether the medical profession are required or not to use the same precautions, matters little to us; we have quite enough to do without interfering with them. In my opinion, if we were to act more charitably towards them than we do, there would not be half the rancour existing between us that there now is. I have never found any difficulty in the matter; always striving to do my best to oblige them, I am bound to say, those I know are not behind in endeavouring to assist me. If we are continually trying to find out points that are seemingly objectionable to us, and bandying them about, is it likely, I ask, they will look upon us other than as enemies? whereas we should try and cement more closely the two professions that are so nearly related to each other. Again, we have plenty of topics to discuss, such as education, provincial classes and lectures, provincial unity, earlier closing and less Sunday work,—these affect us far more closely than arguments about surgeons and doctors. Meanwhile, let us calmly consider the "poison regulations," so that after the annual meeting the world may be favoured with a report of business-like and amicable re-union, instead of, as last year, an assemblage of chemists which reminded one very forcibly of a zoological exhibition.

In conclusion, let us bear in mind that the Council is composed of gentlemen representing almost every kind of our business,—that they have studied well to regard our various interests, and that they are requested by the Privy Council to move in this matter; therefore instead of putting difficulties in their way, let us rather assist them cheerfully by accepting what they have taken such pains to offer, and thus show our gratitude and confidence in them.

ALFRED W. SMITH.

93 *and* 94, *High Street, Rye, Sussex.*

Sir,—In digesting many of the plans suggested on the above subject, the most urgent, in my estimation, has been overlooked, viz. the great importance of assistants faithfully carrying out such regulations.

In every case where I have been enabled to get at the truth, the accident has arisen from neglect of this simple duty; it was palpably so in the instance referred to by Mr. Oldham in your last impression. Had the excellent regulations of that well-known establishment been carried out by the assistant, I can affirm from personal knowledge that an accident would have been impossible.

If we are to be under a penalty for non-performance of "proposed regulations," should not the same be equally binding on assistants?

Happily, the careless are not numerous among us. I have pleasure in knowing many who use every care, and do their best to carry out established rules, but not one of us is exempt from coming across a careless one now and again. It is to these my remarks apply.

In regard to the "particular bottle" to be used in dispensing liniments, etc., what is to prevent its being afterwards used for tincture of rhubarb, or more frequently for gin, etc.? In this case it might cause that which we wish to avoid,—forgetting that a second particular bottle containing some deadly poison was placed in the same cupboard,—the contents of one are administered for the other, the fatal mistake is made, and the fond mother, weeping over her lifeless child, tells you she did not read the label because she knew it was in that "particular-shaped bottle." The careful need no caution. In giving a distinctive bottle, you offer an inducement for the careless to become more so.

How often do we hear of "Burnett's fluid" being mistaken for something else? It is in a "particular bottle." Shall we be liable to a penalty for using the "particular bottle" for any other than its legitimate use? If so, pray include publicans, oilmen, and all who may make use of it otherwise.

The label is desirable, and is in daily use in all respectable dispensing establishments without compulsion.

Nothing is poison if administered in proper doses. What A calls poison B does not. It is very essential that we be informed what is considered poison by the Council.

London. THOS. J. W. TIPPING.

Sir,—May I also beg a small space for a few words on the subject of "compulsory legislation for the storing of poisons?" I should like to ask a question or two.

Will it protect the public?

Experience so far does not prove the assumption. Did space allow, I could quote cases where the most stringent regulations utterly collapsed.

Is our experience of what legislation has done for us so agreeable and beneficial that we are anxious to have more of the same sort?

If the proposed regulations pass the annual meeting (in the enforced absence of most country members, who, it seems, will therefore not be allowed to vote), how are they to be compulsory?

Is the present Act compulsory?

I suppose it is considered so. Yet I know a pharmacist who told me he had never yet kept a "poison book," nor did he intend to do so. Of course he is liable to action for damages in case of accident; but so, I suppose, we shall all be even if we comply with the most elaborate code of regulations that can be devised. After fulfilling the letter of the law in that respect, we shall be still subject to all its pains and penalties (that is, in the case of any dispenser or seller of poisons who is thought able to pay).

If it were proposed to draw up a series of regulations, and then acquit a dispenser or retailer of blame because he had fulfilled them, very little opposition would be offered by any who had to submit to them.

Seventeen years' experience in my own case goes to prove that where responsibility is felt by each individual, and no faith placed in either loose caps, stopper guards, or other mechanical safeguards, there are less mistakes (and no fatalities) than in other places where stringent and burdensome regulations are imposed upon the assistants.

I would then say to the Council, advise by all means, but compel by no means. Recollect that you now represent the whole trade (not our Society only), and you are in duty bound to show the Privy Council how unsatisfactory such piecemeal and tinkering legislation as has been indulged in on the subject of "poisons" is and must be, if not to all, at least to a large majority.

Liverpool. ALFRED UTLEY.

Sir,—With regard to the third regulation proposed by the Council, that "all poisons be sent out in bottles, readily distinguishable by touch from ordinary medicine bottles," I think a clause should be inserted making it illegal to sell in poison-bottles anything which has to be taken internally.

Poison bottles are of no use if one sells medicines in them, and the public will bring such bottles for syr. rhei, spt. æth. nitr., etc.

I respectfully suggest the above for the consideration of the Council.

Sheffield. EDWARD BARBER.

Sir,—Respecting the "keeping and dispensing of poisons," I think the chemists, as a body of men, ought not to interfere with the proceedings of the Pharmaceutical Society; but rather support its efforts in trying to promote our interest. The simple regulations set forth by the Council cannot in any way inconvenience us, as such regulations already exist or ought to exist in our establishments; and as for thinking them compulsory, why we had better be compelled (if such is the case) by our own Council, which does so for our best, than by the Medical Council or by others, who would only be too glad to interfere, if but an opportunity be allowed. There is one thing which I hope will be the issue of this subject, viz. that the regulations will apply to the medical men who keep open shop as well as to the chemists, and then I do not see how we can have any objection to them. I made use of the words "own Council," because I feel that the interest and promotion of the profession rests with the Society, with which our children and grandchildren will ultimately have to do in some shape or other, if they mean to follow the profession, therefore we ought to do our best to uphold and support the Society. I have, at present, nothing whatever to do with the Society, but I shall certainly take the first opportunity to send my name in for election, and I would urge upon us all to do the same, that we may all be under the same standard.

730, *Old Kent Road, S.E.* J. S. S.

Sir,—I have read the statement which the Secretary of the Pharmaceutical Society has issued by order of the Council, and have given it my most serious attention; but I am bound to say that I cannot see any sufficient reason why the Council should still persist in proposing regulations regarding the keeping, dispensing and selling of poisons.

With reference to the keeping and dispensing of powerful remedies,—for I prefer this designation,—the chemists' own material interest, saying nothing of those moral considerations which I believe to be the primary object of a vast majority of our members, gives more security than any which legislation can provide.

Then, with regard to the sale of poisons. This question I consider has been most satisfactorily settled by law. The Arsenic Act was very important and proper, having quite a different bearing to the keeping and dispensing of powerful remedies. The public had a right to such restriction, as a means of thwarting criminal intention, and of checking evil-disposed persons in their path, through fear of leaving footprints behind.

After forty years' responsible practice, with its experience, I come to the conclusion that to present to our customers' eyes emblems of death is unwise, but that they should rather be taught that many of our medicines are powerful and important agents in the cure and alleviation of human diseases, requiring the most careful attention, for which we cannot, reasonably speaking, be paid too much.

I have been connected with the Society from its foundation, and feel proud of the position it has attained, and I fervently hope the Council, seeing the pain these poison regulations are occasioning a vast majority of its members, will retrace its steps, and report at the next general meeting "that it is of opinion it is unnecessary to propose any regulations for the storing, keeping and dispensing of poisons, believing that the rapid advancement pharmacy is making in this country will be the best public security."

Kilburn, February 13th, 1871. JOHN BEATON.

Sir,—The explanations which the Council of the Pharmaceutical Society have given of the proposed regulations for the keeping and dispensing of poisons, will do much to make them acceptable to the chemists generally. I, for one, must acknowledge my dulness of intellect in thinking that by adopting any one of the proposed systems, it would apply to all poisons, and not as is now explained by the Council, that some of the poisons could be kept in a closet set apart for dangerous articles, and another portion of them on the shelves amongst the other bottles, provided the bottles or vessels containing poisons are either capped or tied over or rendered readily distinguishable to the touch. The delay of twelve months has not been wasted, but during that time the proposed regulations have been so much improved that they can now be carried out in any shop with very little trouble or expense, and need not interfere with the present arrangement of the bottles. The regulation relating to the dispensing of poisons is very simple. There will be no necessity to have specially-made bottles to send out liniments, lotions and embrocations in. Any bottle will meet the requirements of the regulations, if a piece of glass or sand-paper or other roughened material is pasted on the side or back of the bottle. But to make this clause thoroughly effectual, I think another is rendered necessary, prohibiting the sending out of medicines intended for internal use in the distinctive bottles used for internal remedies. Without some such regulation the distinctive bottle will be used for some internal remedy, and, probably, one day we shall find that the regulation has caused to be done the very thing it was intended to prevent, by the liniment being taken instead of the simple remedy from a family recipe. As I expressed in my letter (which was allowed to appear in the number of the Journal for March last) an opinion that the corrugated bottle was best adapted for general use, I will again point out its easy application to all classes of trade. If an ordinary medicine bottle was taken to a chemist to have a liniment put into it, all that would have to be done would be to stick a piece of roughened paper on its side or back, and it would be converted into a distinctive bottle; then, if a bottle so converted was taken for medicine for internal use, it would only be necessary to scrape off the roughened surface, and it again becomes an ordinary medicine bottle. Many chemists object to being trammelled with regulations whilst the surgeon is free to keep and dispense his poisons as he likes. I believe there is even greater need for the regulations to be applied to the surgery than the shop. But I trust this necessity will soon disappear by the surgeon handing over the dispensing to the chemist. Anyhow, the public will learn that there is greater safety in getting their medicine dispensed where every precaution is taken to prevent accidents than where no system whatever is adopted, and where even most deadly poisons may occasionally be found in bottles without labels of any kind on them.

Rochdale, February 14th, 1871. RALPH ROBINSON.

Sir,—In reading the various letters which have appeared in your Journal on the proposed poison regulations, I have regretted that most of them were not so conciliatory as they might have been, as it is very evident that the Council have simply a sincere desire to promote the general welfare of the trade, and are ready to take into their consideration every reasonable objection which may be pointed out to them. I am opposed to regulations for the storing of poisons, not, however, as it affects dispensing chemists, but on account of the difficulty which some must experience in those parts where they deal largely in poisonous drugs and chemicals for manufacturing, etc., purposes. I have no doubt, however, that the Council will try to meet this difficulty to the best of their ability. If, as Mr. Jones states in his letter, "we never allow preparations to pass through our hands without proper recognition, poisoning would become a thing of the past, and we should then have accomplished what the storing of poisons can never attain."

In conclusion, I would briefly state that what seems the most unpleasant part in this matter of legislation is, that public dispensaries and surgeries, etc. should be exempt from it. I hope in the meantime that the subject will be thoroughly ventilated before the Annual Meeting.

Manchester, February 14th, 1871. E. WALSH.

Sir,—I had hoped, probably with the generality of your readers, that the proposed regulations for the keeping of poisons would have been accepted as sufficient by the Privy Council. Our hope, however, has proved fallacious. The Society is asked to frame regulations also for the dispensing of poisons.

I would, with all due deference, ask the Council of the Pharmaceutical Society as to whether they have not unnecessarily yielded to pressure from her Majesty's Privy Council? To honour the powers that be is perfectly right; but have they ever sought a conference with that body, so that the subject might for once be seen by them from other standpoints than from those of physicians, surgeons and the presumably alarmed and endangered public? In short, have endeavours been made to get the Medical Department to look at the question from the chemist's point of view? I am aware that the President and the Secretary of the Society had an interview with Mr. Simon about three weeks ago, but it was at that gentleman's own request, and respected verbal alterations,—not (apparently) a review of the entire subject. (Pharm. Journ. p. 652–3.)

The proposed regulations for the dispensing of poisons are certainly not very onerous, but the clause "that there shall be affixed to each such bottle (of poisonous lotion, etc.) a label giving notice that the contents of the bottle are not to be taken internally," is not altogether free from objection.

Cases often occur in which, from the absence of directions, the dispenser is at a loss to determine whether the lotion, so-called, is really such, an injection or a mouth-wash. Under such circumstances, the label "for external use only" is evidently inappropriate; "not to be taken internally," would lead many patients to question whether the compound was for internal use at all; while the uneuphonious "not to be drunk," or "not to be swallowed," might induce the opposite error, and cause a lotion to be employed as a gargle. The somewhat vague direction "not to be taken" is the only one universally applicable.

Oxford, February 15th, 1871. John Throssell.

Sir,—Having received the statement of the Council respecting the poison regulations, we think, before we can come to a right decision on the subject, the Council should state—

1st. The name of every drug, chemical, or preparation that they propose to call a poison, and which would be affected by the regulations.

2nd. The machinery by which they propose to enforce them. Vines and Froom.

Sir,—In common with the rest of the trade, I have received from Mr. Bremridge "A statement of the reasons which have induced the Council to suggest regulations regarding the keeping, dispensing and selling of poisons," and I find one sentence which, for unpleasant vagueness, might well compare with the guarantee given by Messrs. Dodson and Fogg (on receiving Mrs. Bardell's undertaking for the costs in *Bardell* v. *Pickwick*) that it was "only a matter of form." The sentence, or rather part of a sentence, to which I allude is this:—"But, with reference to the obligations which the regulations would impose, they venture to say that no vexatious proceedings will be adopted to inquire into their observance."

Now, with all due respect to the Council, can anything be more ambiguous or unsatisfactory than this?

I think few men would be foolish enough in any business negotiation to take such an assertion as a guarantee. Would any one, on giving an acknowledgment for money due, believe his creditor if he told him that "no vexatious proceedings" should result if he did not meet his engagement? To me the two cases appear similar.

If it is necessary for the public safety, etc., that these regulations should become law, is it not also necessary that when law they should be conformed to?

If we assent to the passing of such an Act, we ought to do so with our eyes open to the unpleasant consequences in the way of supervision which might, and in all probability would, result from such a measure, and not allow the bait to be sugared with specious promises which the Council itself, if it had the wish, would not have the power to keep.

Edwin A. Lewis.

3, Mornington Street, Mornington Crescent, N.W., February 15th, 1871.

Sir,—Whilst I must submit to the multitude of not-overwise Councillors, Privy and Pharmaceutical, I cannot but protest against their meddling, irritating restrictions upon chemists, a class of men careful beyond cavil, whilst "Knockemorf" is licensed to kill without let or hindrance. Why are not surgeries to have "poison" bottles and three-cornered dispensing ones? Perhaps our Council will tell me into what shaped glass I am to dispense the following recipe, received to-day:—

R. Tr. Opii ʒj
Zinci Sulph. gr. x
Glycerini ℥ss
Aq. Camph. ad ℥vj. M.

It may be an injection, skin- or head-lotion, or cough mixture. Being sedative and expectorant, am I to be made the scapegoat of an antagonistic surgeon or the tool of any prescribing informer? The word "poison" is become as nought, the public sees and hears so much of it; and so does

Wetherby, February 14th, 1871. Jas. Houlton.

Wholesale Druggists' Assistants' Association.

Sir,—The remarks of Mr. Davies Owen in your Journal of the 14th inst., are so severe upon wholesale assistants that it makes it necessary to place the matter in its right light. The picture of retail assistants advancing and wholesale ones gradually sinking in the social scale, judging from the steps taken by employers to prevent dishonesty, would be a sad one were it correct; but the mere fact of employers combining to form a trade protection society, to prevent robberies and prosecute thieves and receivers of stolen goods, is no imputation upon assistants, as it is well known that porters and others of a similar grade are the parties most liable to the operations of the Society.

The next statement of Mr. Owen's, that the retail trade pass a regular apprenticeship, reside with their employers and have access to various works and journals, while the bulk of the wholesale men have not these opportunities, is also incorrect, inasmuch as they serve a similar apprenticeship (and some of them a more practical one than the present generation have served), and many of them have been assistants a few years in the retail, who have taken situations in the wholesale to perfect themselves in their business.

Another idea, that members of the proposed society should discuss matters of trade interest, would simply amount to wholesale houses having their trade secrets made common property. I think that the kind of society proposed by Mr. Owen is not felt to be a want, or it would have been supported before. Justitia.

London, January 16th, 1870.

J. T. (Lewisham).—The law is vague in regard to the question, but probably it may be regarded as not prohibitory of such prescribing, though in the event of any mischance, the punishment would be more severe than in the case of a duly qualified medical man. As a point of ethics, however, there can be no doubt that counter-prescribing by druggists should at least be restricted within the narrowest limits possible.

"*Tolu.*"—We do not consider the negative result satisfactory evidence, neither are we able to answer the question put.

H. J. Woolley (Islington).—The formula has been given recently. See p. 377 of the present volume, and the correspondence concerning it on pp. 397 and 419.

"*Veritas.*"—The mention of emp. hydrarg. is evidently an error, and, as you suggest, emp. opii should be in its place.

"*A Student*" (Sheffield).—There is no danger.

F. L. Cove.—Probably Piesse's 'Art of Perfumery.'

Messrs. Sawyer and Bird.—The advertisement has been handed to the publisher.

C. J. Bell.—Your letter has been given to the Secretary.

A. P. S., *Amicus* and *A Member* have omitted to forward their names.

We have received a letter from Messrs. Domeier and Co., stating that they only execute for De Haen and Co., or the other houses they represent, such orders as are given by manufacturing chemists and wholesale druggists.

Communications, Letters, etc., have been received from Mr. A. W. Bennett, Mr. T. J. W. Tipping, Mr. J. S. Parker, Mr. W. Hills, Mr. G. Harvie, Mr. J. Ash, Mr. Padwick, Mr. Siebold, Mr. E. Walsh, Mr. Smith, Mr. Gray, Mr. P. L. Simmonds, Mr. C. H. Wood, S. R., "A Country Druggist," "Spes," A. P. S.

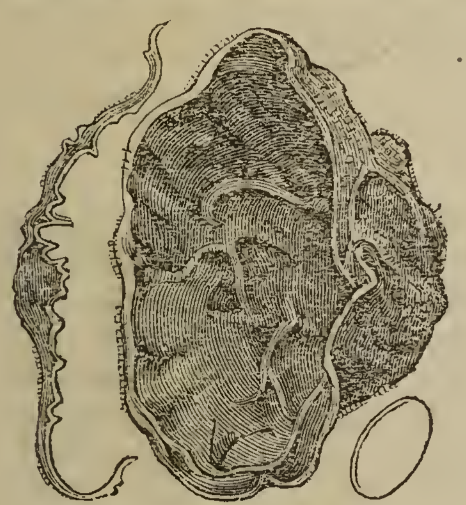
JEW'S EAR.

(*Hirneola Auricula-Judæ.*)

BY M. C. COOKE, M.A.

Notwithstanding Mr. Simmonds's interesting book on that subject, there are still some chapters in the history of the "Curiosities of Food" unwritten, especially those relating to vegetable diet. So peculiar are the tastes of the Chinese, that we are ready to believe it possible for them to relish anything whatever, provided it can be manipulated in any way so as to be capable of mastication. All kinds of gelatinous substances, whether birds' nests, sea slugs, shark fins, seaweeds, and even gelatinous fungi are pressed into the service of the Chinese gastronomist. To the latter belongs the subject of the present notice.

Old Elder stumps in this country are frequently inhabited by a singularly flabby-looking fungus, to which the name of "Jew's-ear" has been given, on account of its fancied resemblance to a human ear. Our figure represents a small specimen, with a section beside it, and one of the elliptical spores.



Hirneola Auricula-Judæ.

This fungus belongs to the *Tremellini*, an order of fungi that are characteristically gelatinous. The scientific name is recorded above. There is but one British species of the genus, and that is widely distributed; it is found again in the United States, and amongst the islands of the South Seas. The fungus itself is thin, concave, flexuous and blackish, folded and veined everywhere, with the under surface velvety, and of a cinereous-olive. When dry it has a horny texture, and shrinks very much, but it will swell out again nearly to its natural size and form if immersed in water, even after the lapse of many years. The size varies from one to three inches in diameter, and sometimes two or three individuals are confluent.

It seems never to have entered into the heads of Englishmen, not even professed mycophagists, that this leathery-looking "Jew's-ear" could be converted into food. There was exhibited in the Indian Department of the Exhibition of 1862 a bottle of dried fungi, sent from China, by way of Singapore, which consisted wholly of this species, identified by us at the time, and as such inserted in the catalogue. By reference also to the catalogue of the French Colonies for the same Exhibition (at p. 109), we find enumerated from Tahiti "Champignons dits oreilles de rats, *Exidia Auricula-Judæ*—Taria eriore." In a note it is stated that this fungus is very common at Tahiti and the neighbouring islands, and is in great esteem in China, to which country it is largely exported. In the fifth volume of Seemann's 'Journal of Botany' (p. 263), is a paragraph stating that Mr. Brander, a well-known merchant, residing at Tahiti, had furnished the following information about an edible fungus, of which quantities were often sent to Sydney; he says, "What is called 'fungus' in our export list, is an article of commerce found in the islands of the South Pacific, principally the Society and Leeward Islands, on decayed trees. The Tahitians call it 'Teria iore' (*i. e.* rat's ear), from a certain resemblance of the shape of the plant to the ear of a rat. The fungus first began to be collected in 1863, and fetches in China, where it is much esteemed and made into soups, from eighteen to twenty cents per pound." In a subsequent number of the same journal (vi. p. 339), this fungus was referred without doubt to the present species.

This was almost all that could be collected of information about the Jew's-ear, until very recently, when we heard of it again in a rather unexpected quarter. From the Reports of the United States Department of Agriculture, we gather that "the *Bulletin* (California) announces the arrival at San Francisco of a brig from Tahiti, with about thirty thousand pounds of fungus gathered on the trees in the southern part of the Society Islands, and packed in bags woven from slips of Booroa bark, the same wood from which the orange crates are made. This fungus is in appearance like very thin and dirty india-rubber, and is to be shipped to China for use in making 'soup' in the Celestial kingdom. The value is about twelve and a half cents per pound at the islands, and about one hundred thousand pounds are produced there annually."*

It is very clear that all these statements refer to the same thing, the *Hirneola Auricula-Judæ*† of Fries, which we allow to ripen, and rot upon Elder stumps and Elms, but which is an article of commerce in the South Seas, and is collected there after the rate of 100,000 lb. a year. The only market for this strange product seems to be China, and the sample sent from thence to the Exhibition of 1862 was in all probability, not indigenous, but derived, in the way of trade, from Tahiti. The observation that it was not collected there till 1863, as mentioned by Mr. Brander, might be an error of date for 1861, or, it might not have been collected as a regular article of commerce until 1863. At any rate, it was most certainly exhibited in London in 1862, from China and Tahiti, as will be seen by reference to the Catalogues of India, and the French Colonies.

At one time this fungus had a reputation for the cure of sore throats, and also as a topical astringent. Its faculty of absorbing and holding water like a sponge has resulted in its use as a medium for applying eyewater to weak or diseased eyes, and similar purposes. Of late years it is seldom, perhaps never, to be met with in the herbalists' shops, and, in England at least, its reputation and "occupation's gone." Old Gerarde writes thus of it, "the fungous excrescence of the Elder, commonly called a Jewes eare, is much used against the inflammations and all other sorenesses of the throat, being boyled in milke, steeped in beere, vinegar, or any other convenient liquor." A rude figure is given under the name of Auricula Judæ, which name is applied to it also by Lobel, but the fungus is not figured by him.

CASTOR-OIL SOAP.

BY F. M. RIMMINGTON.

It is somewhat remarkable that our present English pharmacy has no pure medicinal soap possessing any characteristic property or medicinal activity. The ordinary Castile soap, being that which is commonly used for that ordered by the Pharmacopœia, can scarcely be considered a satisfactory article when we consider its composition and the mode of its manufacture. Having recently had occasion to direct my attention to this subject, it occurred to me that castor-oil offered some advantages, and would yield a soap possessing qualities very desirable in an article which so frequently formed the medium or adjunct for administering other active remedies. On putting this idea into practice, I found that a soap prepared from this oil has rather marked qualities, but my opportunities do not afford me the means of properly testing its medicinal properties. I believe it will be found that it has sufficient aperient power to relax the bowels when taken consecutively for several days, but I believe its greatest value will be found as an adjunct to other aperients. This at least is the result I have arrived at. It is, of course, well known that the purgative principle of castor oil has been ascribed by Soubeiran to the existence of a supposed oleo-resin, and that the ricinoleic acid is extremely acrid. I find when the oil is saponified that this acrid principle is either entirely or partially liberated, and does not continue masked as it is in the oil in its natural state, nor neutralized, as might be expected, by the alkali. It is to this fact, I think, we must look for any active property this soap may possess; and here I must leave the matter for the further investigation of the medical and pharmaceutical professions. The physical properties of the soap are in its favour for use in medicine. It has a clean yellowish-white colour, is free from smell; it soon becomes dry, hard and is easily powdered; it has no tendency to soften or deliquesce on exposure to the air. In proof spirit it makes a perfectly clear and colourless solution, with only little sediment. I shall forward a specimen to the Society for the inspection of those who may feel interested.

MAGNIFICENT FLUORESCENCE OF PEPPERMINT OIL.

BY PROFESSOR FLÜCKIGER.

50 to 70 drops of peppermint oil shaken with one drop of nitric acid, about 1·2 sp. gr., turn faintly yellowish, brownish, and, after an hour or two, exhibit a most beautiful blue-violet, or greenish-blue colour, when examined in transparent light. When observed in reflected light, the liquid is of a copper colour, and not transparent. If the mixture is warmed, the green or blue coloration takes place speedily; it may also be immediately provoked by adding a greater amount of nitric acid, say 1 drop to 10, or 9 drops of the essential oil.

Bisulphide of carbon contributes in no way to improve the test. All the various specimens of peppermint oil at my command show the same behaviour, but the blue or greenish-blue hue exhibits very appreciable differences, which ought to be further examined by chemists possessing authentic specimens of the oil under notice. A very old specimen of an originally excellent English oil, however, was no longer coloured.

The colour which peppermint oil thus acquires is remarkable on account of its persistency, for it lasts a week or two, at least in cold. Yet, unfortunately, it appears not capable of being applied as a true test; an admixture of 5 per cent. of oil of turpentine, for instance, does not at all prevent peppermint oil from assuming the blue or green colour; on the other hand, I have not as yet met with any other oil partaking of the same behaviour; carven, the the more volatile portion of caraway-oil, also acquires a slight similar fluorescence, but by no means comparable to the above-described as regards purity and intensity of colour.

Peppermint oil, which has become coloured in this way, is quickly decolorized if shaken with carbonate of calcium; granulated zinc likewise causes it slowly to turn brownish. Spectroscopic examination of the coloured oil furnishes no phenomena of particular interest. Chromic acid, dissolved in chloroform, does not perform the same reaction as nitric acid.

Berne, January 1871.

CYTISIN.

An article, by Dr. William Marmé, "On the Action and Production of Cytisin," appears in a recent number of the 'Transactions of the Academy of Göttingen.' Cytisin was first separated by the writer, in conjunction with Professor Aug. Husemann, from the unripe pods and ripe seeds of *Cytisus Laburnum*, Linn., as a strongly alkaline vegetable-base, easily crystallizable, and forming single and double salts, readily soluble in water and alcohol, but not in ether. The following observations supplement those already published in the 'Zeitschrift für Chemie,' 8th Jahrg. p. 161, and Husemann's 'Neues Jahrbuch für Pharmacie,' xxxi. pp. 1–21.

1. *Action of Cytisin upon Animals.*—The poisonous action of cytisin, the pure alkali as well as the very easily crystallizable nitric salt, extends to animals of every type. This was established by experiments on animals belonging to the various classes of Protozoa, Cœlenterata, Echinodermata, Vermes, Crustacea, Arachnoidea, Myriapoda, Insecta, Mollusca, Pisces, Amphibia, Reptilia, Aves, and Mammalia. The poisonous action takes effect by application to all parts of the system, except the outer skin. A very small dose is fatal to all the higher animals. For frogs a dose of ·002–·004 gramme was sufficient; for young pigeons ·003 gr.; for owls ·001 gr.; for jays ·0015 gr.; for cats ·03–·05 gr.; for dogs ·06–·1 gr.; for rabbits ·05–·08 gr., and for kids ·3–·4 gr., by subcutaneous application; or by injection, for cats ·015 gr.; for dogs ·025–·05 gr., and for rabbits ·01–·015 gr. of cytisin nitrate. Usually the poison acts in the first place by exciting, the excitation soon passing away, and giving place to a depression or complete paralysis, with a rapidity in proportion to the amount of the dose. The function of the cerebrum is not directly affected; no narcotic action, properly speaking, is exhibited with the lower animals. The spinal cord and the motor nerves are at first excited, a more or less complete paralysis following, which commences in the peripheric ends of the motor nerves. The voluntary muscles may be completely excited

by an induction-current after entire paralysis of their motor nerves, and even when direct mechanical and chemical irritation produces no contraction. The sensible nerves are injured in their action only very late by cytisin. A change in the respiration is, with all the higher animals, one of the first symptoms of poisoning by cytisin. It is at first accelerated, then becomes retarded, and is finally completely suspended by paralysis of the nerves. The vaso-motor system of nerves is excited by cytisin. The ganglionic central-organ, which lies in the heart and occasions its contraction, is at first excited, and then becomes weaker and possibly paralysed. With dogs, cats, and rabbits, and generally also with birds, salivation arises during the poisoning. With birds, and many mammalia, cytisin occasions vomiting by all modes of application. It excites, both after introduction into the stomach and intestines, as well as after subcutaneous application, increased, often powerful, peristaltic action. In no mode of application does cytisin exercise any constant action on the pupil. The temperature of the body is only slightly increased, quite at the commencement of the poisoning, but sinks steadily till death. The elimination of the cytisin introduced into the body takes place especially through the nerves, unless by vomiting. Recovery from poisoning by cytisin can generally be effected when it is possible to maintain the respiration for a sufficient length of time. Death is always the result of asphyxia. The exact chemical proof of poisoning by cytisin is extremely difficult. Comparative experiments with aqueous and alcoholic extracts of the seeds, ripe and unripe pods, flowers, leaves, bark, and roots, prove the poisonous nature of all these parts, and that cytisin is the sole poisonous agent in them.

2. *The Occurrence of Cytisin.*—The supposed laburnin-acid of Mr. Scott Gray, is a mixture of inorganic and organic acids. The poisonous properties observed by him were due to the presence of a small quantity of cytisin, and the alleged narcotic action is altogether erroneous. Cytisin is also present in the black seed-pod. About 500 grammes of the separated pods was found to contain a proportionately large amount of cytisin. The fat oil extracted from the seeds by ether, of a clear yellow colour and agreeable flavour, is not poisonous. Cytisin had been already found by the writer and Professor Husemann in three other species besides *Cytisus Laburnum*, viz. *C. alpinus*, *supinus*, and *elongatus*. During the previous year, the writer had examined, in reference to the presence in them of cytisin, and their poisonous properties, several other species. *C. Weldeni*, *sessilifolius*, *capitatus*, and *hirsutus* gave positive results, both by chemical analysis and experimenting on frogs. With *C. nigricans*, on the other hand, no poisonous substance could be obtained from the pods, seeds, or bark. This circumstance is of special interest, since this species is separated by English botanists, following Grisebach, into a distinct subgenus. Of the three subgenera of Grisebach, *Laburnum*, *Eucytisus*, and *Lembotropis*, the first (including *C. Laburnum*, *fragrans*, and *sessilifolius*) and the second (including *C. capitatus*, *supinus*, *elongatus*, and *hirsutus*) are poisonous; while the third, including *C. nigricans*, appears to be harmless. Dr. Marmé promises a further contribution, with reference to the poisonous effects of cytisin on the human body.

EMULSION OF ALMONDS.

BY H. P. REYNOLDS.

The officinal emulsion of the U. S. P. forms an elegant and suitable vehicle for the administration of many pungent or acrid medicines, but no apothecary cares to spend time for its extempore preparation, and of course it cannot be kept on hand on account of the readiness with which it ferments.

Experimenting recently, by request of a physician, for a satisfactory vehicle for chloral hydrate, I found the emulsion of almonds peculiarly adapted to the purpose, both by reason of its agreeable taste and its thick consistency almost completely obscuring the pungency of the drug. Chloral is now so largely administered in that class of diseases accompanied by an irritated and sensitive condition of the mouth and throat that this seemed a point gained. And it may not be amiss to state here that syrupus acaciæ, slightly flavoured with orange-flower water and essential oil of almonds, is a very agreeable vehicle for the chloral.

Finding I should be called upon to provide the emulsion for this purpose, it became desirable to have it on hand in a convenient and permanent form. I therefore contrived a preparation which I call a "Concentrated Emulsion of Almonds," and which is prepared as follows:—

℞ Sweet Almonds (blanched)
Sugar,
Glycerin ("C. P."), each 1 oz.
Powd. Gum Arabic, 1 drm.
Water, 2 oz.

Rub to a uniform paste, strain through muslin and evaporate by a heat *not exceeding* 150° F., to the consistency of a fresh solid extract. Preserve in widemouth bottles of size for convenient use. It may be flavoured to suit; I have preferred orange-flower water and oil of almonds. When emulsion of almonds is prescribed, it is readily prepared as follows:—

℞ Concentrated Emulsion, 2 drm.
Water, sufficient to make 1 oz. of mixture.
Mix thoroughly.

It immediately assumes the milky hue and consistence of the officinal article, and cannot be distinguished from it, while it keeps without change and without drying. The idea may not be new to all your readers, but certainly is original so far as I am concerned, and I shall be happy if the suggestion proves useful to any of them, as it can hardly fail to do.—*American Journal of Pharmacy.*

DETECTION OF ALCOHOL IN CHLOROFORM AND CHLORAL HYDRATE.

A. Lieben, in the *Annal. der Chem. und Pharm.*, 1870, *Suppl.* Bd. viii. 2, describes a method of dedecting ethyl alcohol by the formation of iodoform. In the simple case when the presence of alcohol in a watery solution has to be determined, the sample is warmed in a test tube, a few drops of an iodinized potassium iodide solution are added, and afterwards a few drops of potassium hydrate solution. If the quantity of alcohol is not too small, a turbidity results by the formation of microscopically small yellow crystals of iodoform.

Hager finds this reaction very accurate, and states that it detects alcohol in liquids containing but $\frac{1}{2000}$ after about one day's standing. The crystals are remarkable and beautiful by the variety of their star-shaped arrangement. Hager suggests the following *modus operandi*:—The reagents used are solution of potassium iodide in 5–6 times its weight of distilled water and over-saturated with free iodine; 2, a solution of potassium hydrate of about 10 per cent. strength. To the liquid to be examined 5-6 drops of the latter solution are added. After warming to about 50° C., so much of the potassium iodide solution is added drop by drop that its colour, after gentle agitation, remains yellowish-brown; then the liquid is carefully discoloured by the addition of a few drops of the potassium hydrate solution. When set aside the iodoform crystals deposit, and are recognized under the microscope.

The process is obvious: it is effected not alone by ethyl alcohol, but by a number of different substances, among which are aldehyde, acetone, gum, sugar, lactic acid, methyl alcohol, propyl alcohol, and many volatile oils. The formation of iodoform does *not* take place with amyl alcohol, ether, ethyl chloride, chloroform, chloral hydrate, glycerin, phenol, and by acetic, benzoic, butyric, citric, formic, oxalic, succinic, valerianic and tartaric acids.

The following test is, according to Hager, superior to any for the detection of alcohol in chloroform and chloral hydrate:—

Chloroform.—To determine the presence of alcohol in chloroform, 2 vols. chloroform are mixed with 5 to 10 vols. of water, of about 50° C. The liquid, after some shaking, is poured on a filter previously completely saturated with water. The filtrate is then examined as described above. After twelve to twenty-four hours' depositing, the sediment is examined under the microscope.

Chloral Hydrate.—Chloral forms with ethyl alcohol chloral alcoholate, corresponding to chloral hydrate in its chemical and physiological properties. Since the equivalent weight of ethyl alcohol is five times greater than that of water, it is of considerable pecuniary advantage to the manufacturer to bring the chloral alcoholate into the market instead of the hydrate; besides, the former crystallizes finer and more solid.

The examination is made with a solution of the sample in distilled water, in the above given mode. When discoloring the iodinized liquid, each drop of the potassium hydrate solution produces turbidity, which, however, disappears on gentle agitation. If the sample contains alcoholate, the liquid remains more or less turbid, or deposits iodoform crystals after a time, although this is partly soluble in the presence of chloral. Of some commercial samples examined by Hager, Schering's chloral hydrate was the only one entirely free from alcoholate. —*Pharm. Centr. H.* 1870, no. 18.

More recently Schering calls attention to some more distinctions between chloral hydrate and chloral alcoholate; when warmed in a test tube in twice their bulk of water, the hydrate, as is known, dissolves readily, but the alcoholate melts without solution, and on cooling congeals under the water. Sulphuric acid, when warmed with chloral hydrate, remains colourless, whilst it turns brown with the alcoholate. When warmed in nitric acid of 1·2 sp. gr., chloral hydrate gives none or but a very slight reaction, whilst with the alcoholate a vehement reaction ensues under evolution of nitrous oxide gas.—*Journ. Pharm. from Pharm. Centr. H.*

THE SO-CALLED "OLIVES" OF SOUTHERN CHINA.

BY H. F. HANCE, PH.D., ETC.

In his excellent "Notes on Chinese Materia Medica," Mr. D. Hanbury refers to certain fruits known to foreigners resident in this country by the name of *Chinese Olives*; and he suggests the desirableness of more precise information being obtained in regard to them. Of those which Mr. Hanbury mentions as sold at Foochow and Shanghae, I have no knowledge at all; and the following observations relate exclusively to the fruit vended everywhere in the south of Kwang-tung province, of which there are two kinds,—the *U-lam*, or Black, and the *Pak-lam* or White Olive,—produced respectively by *Canarium Pimela*, Konig, and *C. album*, Ræuschel.

On these two plants and a third Cochinchinese species, occurring also throughout the Moluccas, Loureiro founded his genus *Pimela*,* which, by the consent of all subsequent botanists, was merged in *Canarium*, until again distinguished by the late Professor Blume, who considered it a "genus optimo jure dignum esse quod restituatur."† The only characters, however, by which it differs from *C. commune* and its allies consist in the thin foliaceous not fleshy cotyledons, and in the insertion of the stamens at the base instead of the margin of the disk; distinctive marks which Dr. Hooker very naturally regards as of merely sectional value.‡

Both the white and black Olives are a good deal grown around Whampoa, whilst I have seen none in the immediate neighbourhood of Canton, or in Hongkong, and their cultivation is therefore apparently local: I can gain no intelligence of their occurrence in a wild state. They are trees from twenty to thirty feet high, with a whitish trunk, and a close round crown of foliage,§ which in hot sunny days exhales a grateful balsamic odour; in which respect, as well as in general aspect, they resemble our common walnut. The two species, though perfectly distinct, are singularly alike, so much so, indeed, that even now, after having made them an object of special study, I am quite unable, in the absence of fruit, to tell one from the other at a few feet distance. Blume gives the following differential characters:—

Canarium Pimela; foliolis 9–11 oblongis acutis inæquilateris glabris, racemis lateralibus simplicibus.

Canarium album; foliolis 11–13 ovato-lanceolatis supra glabris subtus scabris, racemis confertis subterminalibus.

These are, however, never quite accurate, nor by any means sufficient for the discrimination of the two species; and, in their place, I propose the following, drawn up after a careful comparative examination of living specimens of each tree.

Canarium Pimela; petiolo petiolulisque viridibus, foliolis 4–5-jugis cum impari oblongo-lanceolatis 3–6 poll. longis $2\frac{1}{2}$–$3\frac{1}{2}$ poll. latis venulis elevato-reticulatis, racemis plus minus compositis, drupis pedicellis clavato-incrassatis 5–7 lin. longis suffultis fusiformibus utrinque obtusis subtrigonis 20 lin. longis immaturis glauco-viridibus maturis purpureo-nigris lævibus, putamine obtuse fusiformi lævi.‖

Canarium album; petiolo petiolulisque alutaceis, foliolis 5–6-jugis cum impari oblongo-lanceolatis $2\frac{1}{2}$–4 poll. longis 12–16 lin. latis venulis supra non prominulo-reticulatis, racemis simplicibus, drupis sessilibus ovoideis 15 lin. longis immaturis flavido-viridibus maturis sordide flavidis valde rugosis, putamine acute fusiformi ruguloso.

I should remark that, when dried, the leaves of both species have the veinlets prominent, but the network is much closer and finer in those of the white olive.

As regards the mode of using these fruits, the following is the information I have myself gathered, from personal observation and inquiry of the natives:—The white olive is either eaten fresh, in which state its strongly resinous flavour renders it disagreeable to the

* Fl. Cochinch. ed. Willd. vol. ii. p. 494.

† Mus. Bot. Lugd.-Bat. vol. i. p. 220.

‡ Gen. Plant. vol. i. 325. The *flores longe pedicellati*, assigned as a character in this work, do not occur in *C. album*.

§ The name by which these trees are properly known to foreigners, and their dense tufted foliage, recall to mind the Homeric—

῞Ηδε δ' ἐπὶ κρατὸς λιμένος τανύφυλλος Ἐλαίη.
Odyss. xiii. p. 346.

‖ The three very slightly elevated bands, scarcely conspicuous, are represented far too prominently in Konig's figure (Ann. Bot. vol. i. pl. 7, fig. 1. g.).

European palate, or is placed, when quite ripe, in tubs filled with salt, stirred about continually, and, after the lapse of a day taken out and dried. In this state it is hawked about in great abundance, and tastes much as the European olive might be expected to do, if removed from the brine in which it is kept and allowed to dry, with an appreciable *soupçon* of turpentine superadded. I have been told it is regarded as a preventive of sea-sickness. The black olive is never eaten raw, but only after having been steeped for a few moments in boiling water. Thus prepared (and packed in jars, with the addition of a little salt, when desired to be preserved), it is of a fine purplish-red colour, like well-made fresh pickled cabbage, and has some resemblance in taste to freshly pickled mango, a flavour to me not unpleasant, but *de gustibus non est disputandum*. This fruit is held in much higher esteem than the other, and it is usual to keep a strict watch over it as it ripens to prevent depredation. I have seen a man who was found luxuriating in the umbrageous coma of a tree to which he could lay no claim, with a basket full of the fruit in his possession, tied "spread-eagle" fashion to the trunk for nearly a day, the monotony of his durance being varied by periodical flagellations.

Loureiro thus describes the reputed qualities of the two olives:

C. album. Drupæ muria conditæ olivis Europæis similes sunt colore, et quodammodo etiam forma et sapore; sunt autem saluberrimæ, ita ut medici non eas denegent ægrotis, experientia docti digestionem et appetitum cibi promovere.

C. Pimela. Drupæ muria conditæ frequenter apponuntur mensis, non minus sapidæ quam olivæ, sed stomacho graves.

For the following notice of these trees, extracted and translated from a description of the 'Memorabilia of Kwangtung,' published in 1801, I am indebted to my friend Mr. W. F. Mayers, H.M.'s Acting Consul for Che-foo.

"The *Yüeh Chung Kien Wen* states as follows:—Of the *Lan* there are two species, the black and the white. Of both the tree grows high and perfectly straight, usually with the trunk quite devoid of branches except at the summit, where it throws out its crown. There are male and female [trees], the male having flowers [only] and the female fruit. The males are properly called *Lang-kung* [*i. e.* male or 'sir' *Canarium*), and do not produce fruit, but if brought in contact with the female the fruit forms. The fruit resembles that of the *Tsao* (Jujube, or Chinese Date), about an inch or more in length, and is devoid of angles. The earliest growth hangs downward, those grown later point upwards. The fruit is ripe in the eighth or ninth month, when the cultivators mount the tree by means of ladders, and knock the fruit down with sticks. Another way is to make an incision of about an inch [in width] in the trunk, on its east side and to rub in some coarse salt, which causes the fruit on the east side to fall down spontaneously; and similarly on the three remaining sides of the tree. The white *Lan*, if not eaten until after the *Peh Lu* period (8th September), does not cause sickness. Its qualities are heating. When eaten, the tapering points at either end should be removed. On first being chewed, the flavour is bitter and astringent, but after a time the flavour develops itself and turns sweet. The colour is white. When boiled in water at a high temperature the colour changes to a pale green, and its fragrance becomes as that of the *Lan* (*Epidendron ?*), so that it sweetens the breath. Of the black *Lan*, the fruit is larger, and the flesh has greater substance. Its qualities are mild, and its flavour astringent, with a slightly sweet taste. It should be boiled in tepid water until it becomes soft and the purple skin puffs out, when it is fit to eat. If the water be cold, it will emit a gummy exudation; and if too hot, the flesh will harden, so that it is important to use tepid water only. In the southern portion of the Pwan-yü district the black *Lan* is largely grown, and the fruit, after being deprived of its stone, is cooked and preserved with brine as an article of merchandise, which has a sale far and near."

The stones of some species of *Canarium* are beautifully and elaborately carved by the Chinese; and, when set in gold, or separated by gold filigree beads, form exceedingly handsome brooches or bracelets. These are popularly supposed by foreigners, and even by many Chinese, to be cut out of *peach-stones;* though a very cursory inspection will show that this is a fallacy. Amoy is renowned for this kind of work, and, so highly is it esteemed, that some beads I purchased on the spot, to have made into a bracelet, cost me a dollar (4*s.* 3*d.*) each; a very large sum, when the slight remuneration in China for skilled labour and the cost of native living are borne in mind. These stones, so far as I can judge from the sculptured specimens, seem too large to be the produce of *Canarium Pimela.* They may either belong to a distinct species, or to one of those alluded to by Mr. Hanbury, respecting all of which I may, perhaps, hereafter succeed in gaining some reliable information.—*Journal of Botany.*

PREPARATION OF COLOURED CEMENTS THAT WILL HARDEN IN A SHORT TIME.

BY PROFESSOR BOETTGER.

If finely-pulverized chalk is stirred into a solution of soda-water glass of 33° B., until the mixture becomes thick and plastic, a cement is obtained which will harden in between six and eight hours, possessing an extraordinary durability, and alike applicable for domestic and industrial purposes.

If any of the following substances be employed besides chalk, differently-coloured cements of the same general character are obtained.

1. Finely pulverized, or, better still, levigated stibnite (grey antimony or black sulphide of antimony), will produce a dark cement, which, after burnishing with an agate, will present a metallic appearance.
2. Pulverized cast-iron, a grey cement.
3. Zinc dust (so-called zinc grey), an exceedingly hard grey cement, which, after burnishing, will exhibit the white and brilliant appearance of metallic zinc. This cement may be employed to advantage in mending ornaments and vessels of zinc, sticking alike well to metals, stone and wood.
4. Carbonate of copper, a light green cement.
5. Sesquioxide of chromium, a dark green cement.
6. Thenard's blue (cobalt blue), a blue cement.
7. Minium, an orange-coloured cement.
8. Vermilion, a splendid red cement.
9. Carmine red, a violet cement.

—*The New York Druggists' Circular.*

Turpentine as an Antidote to Phosphorus.—Personne's statement that turpentine acts as an antidote to phosphorus, by preventing its oxidation at the expense of the oxygen in the blood, having been called in question by Vigier and Currie, Köhler and Schimpf have repeated Personne's experiments, and report the following results in the *Berliner Med. Wochenschrift*:—(1.) Commercial oil of turpentine is a good antidote to poisoning by phosphorus; there is no fatty degeneration of the tissues, nor is there any free phosphorus in the urine or fæces of animals experimented on. (2.) Phosphorus and turpentine oil form in the stomach a compound resembling spermaceti. In dogs this was found to be readily excreted, or the phosphorus passed away slowly oxidized in the urine.—*Wiener Medizin. Wochenschrift.*

Californian Acorns.—Considerable discussion took place in the *Times* last autumn as to whether acorns were suitable for employment as food for cattle; and the evidence adduced certainly favoured a negative view. Dr. Robert Brown, however, tells us that those produced in California by several species of oak form an important article of food. "The acorns of California are mostly large, and the trees in general produce abundantly, though in some years there is a great scarcity, and much misery ensues among the poorer natives. The acorns are gathered by the squaws, and are preserved in various methods. The most common plan is to build a basket with twigs and rushes in an oak-tree and keep the acorns there. The acorns are prepared for eating by grinding them and boiling them with water into a thick paste, or by baking them into bread. The oven is a hole in the ground about eighteen inches cubic. Red-hot stones are placed in the bottom, a little dry sand or loam is placed over them, and next comes a layer of dry leaves. The dough or paste is poured into the hole until it is two or three inches deep; then comes another layer of leaves, more sand, red-hot stones, and finally dirt. At the end of five or six hours the oven has cooled down, and the bread is taken out, an irregular mass, nearly black in colour, not at all agreeable to the eye or to the palate, and mixed with leaves and dirt."—*Nature.*

Geranium dissectum.—The *Geraniaceæ*, taken as a whole, are by no means noted for their economic properties. In Tasmania, however, a form of the common *Geranium dissectum* having a thick rootstock is employed by the aborigines, who are in the habit of digging up the large, fleshy roots and roasting them for food. About Launceston it is called "native carrot," and is common throughout the colony. The typical form of *G. dissectum* is generally diffused over the temperate regions of the northern hemisphere in the Old World, where it is annual. In the Eastern United States a biennial or annual form, *G. carolinianum*, takes its place, the typical *G. dissectum* being only known as an introduced weed; although connecting-links between the two may readily be detected. West of the Rocky Mountains the stock often appears to be perennial, and it cannot then be distinguished from some of the Australian forms.—*Nature.*

DRUG MARKET NOTES.

The annual official statement of the imports of drugs, etc., is not yet issued by the Board of Trade; but from the commercial returns published of the imports, deliveries and stocks in the docks and various other London warehouses, a fair estimate may be formed of the activity of the trade in the Metropolis of the principal articles.

Aloes.—The imports last year were 3408 cases, 29 kegs and 588 gourds, and there were delivered for home use and export 3092 cases, 83 kegs and 747 gourds. This is about 400 cases and 170 gourds less than in 1869.

Aniseed, Star.—The imports were 195 chests and the deliveries 226 chests, being 250 less than were delivered in the previous year. The stock is small, compared with former years.

Arrowroot.—The imports were 7560 casks and 14,157 boxes and tins, the deliveries 9740 casks and 13,540 boxes and tins, being rather higher than 1869, but about the average of previous years. The stock in the docks, etc., is 10,346 cases and 20,000 boxes and tins, which is rather below the average stock of previous years.

Balsam.—Under this general head the imports of the year are given at 1244 casks, etc.; the deliveries at 1528 and the stock 539 casks.

Bark, Medicinal.—Imports 536 casks and cases and 23,203 serons, etc.; deliveries 430 casks and cases and 18,953 serons, which is about the average of the previous two years; stock 465 casks and 8629 serons, which is double the stock at the close of 1869.

Beeswax and Vegetable Wax.—Imports 594 bales and serons, 2824 casks and cases and 4186 cakes; deliveries 381 bales, 3783 cases and 3881 cakes, which is about the average of the two previous years. The stock is almost much the same as in the close of 1869.

Camphor.—Imports 8371 packages against 15,237 in 1869; deliveries 6432 against 12,037 in 1869; stock also large, 8460 packages.

Cardamoms.—548 chests; deliveries 605; stock 48. All much below the figures of 1869.

Cocculus Indicus.—Imports 1967 bags, etc.; deliveries 1546; stock 2216. There is a large, increasing consumption of this drug, of which in 1866 only 103 chests were taken.

Colombo Root.—Imports 674 packages; deliveries 531; stock 2065 packages.

Cubebs.—Imports 723 bags; deliveries 1075; stock 1806.

Gums.—

Ammoniacum.—Imports 261 packages; deliveries 230; stock 208.

Asafœtida.—Imports 559 packages; deliveries 499; stock 111.

Benjamin.—Imports 1738 packages; deliveries 1445; stock 1641.

Galbanum.—No imports; stock 7 cases.

Gamboge.—Imports 373 packages; deliveries 328; stock 163.

Guaiacum.—Imports 100 packages; deliveries 171; stock 7.

Kino.—Imports 87 packages; deliveries 55; stock 127.

Myrrh, East India.—Imports 376 packages; deliveries 263; stock 247.

Tragacanth.—Imports 164 packages; deliveries 86; stock 146.

Ipecacuanha.—Imports 695 casks and bags; deliveries 609; stock 356.

Jalap.—Imports 740 bales; deliveries 485; stock 447.

Nux Vomica.—Imports 5273 packages; deliveries 4213; stock 3535.

Oil, Castor.—Imports 41 casks, 1212 cases and 35,704 duppers and tins; deliveries 36 casks, 1894 cases and 40,906 duppers and tins; stock on hand 30 casks, 681 cases and 19,484 duppers and tins. The trade in castor oil keeps steady, the annual proportions not varying much.

Oil of Aniseed.—Imports 203 cases; deliveries 382; stock 58 cases.

Oil of Cassia.—Imports 109 cases; deliveries 281; stock 412.

Opium.—Stock 467 chests, etc., which is higher than in any of the previous four years: no particulars of imports or deliveries.

Rhubarb.—Imports 2217 chests; deliveries 2006; stock 1889.

Sarsaparilla.—Imports 2213 bales; deliveries 2150; stock 694 bales.

Senna.—Imports 2209 bales, etc.; deliveries 2275; stock 1090.

Turmeric.—Imports 1771 tons; deliveries 1628; stock 1912 tons.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 25, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

ADULTERATION.

EVER since the time when ACCUM startled the world by the publication of his work entitled 'Death in the Pot,' the subject of adulteration has excited great popular interest, and at times inordinate alarm. Attempts have been made to obtain protection against the practice of adulteration by the formation of supply associations, but these and other less respectable projects arising out of the dread of being poisoned by our daily meat and drink were short-lived and unsuccessful. Few subjects have been more mercilessly encumbered with nonsense and exaggeration in the statements put forward, and it is mainly owing to this circumstance that there has been great difficulty in devising and instituting any thorough and efficient measures for dealing with adulteration. On the other hand, it is with many still a question whether adulteration is really practised at all or to any great extent. In saying this much it is, however, necessary to guard ourselves against the imputation of in any degree apologizing for adulteration, and it is the more necessary to do so since this Journal is the organ of a class of traders to whom the provisions of Adulteration Bills are intended to apply, and for whom we confess to think that there would be less possibility of an admissible excuse being made than for dealers in food or drink.

But at the same time we protest against the absurdities perpetrated by popular writers and by legislators who deal with the subject of adulteration, and we believe it would scarcely be possible to imagine any evidence more strongly in favour of this view than is afforded by the Draft Bill published in another part of this week's Journal. We have not space at present to do more than refer to the strange limitation of the provisions in the Bill to the *admixture* of food, drink and drugs with ingredients other than they profess to be, to the sale of articles containing ingredients injurious to health, and to the case of such adulteration being practised with the knowledge of the seller. The features of the Bill are, we believe, alone sufficient to prove fatal to it, for they leave altogether unprovided for the sale of spurious and counterfeit articles; they would involve the necessity of proving an admixture to be injurious, and they afford an opportunity for all kinds of evasion being practised by unscrupulous persons willing to avail themselves of the plea that they did not know they were selling adulterated articles or that the admixtures would be injurious.

THE PROPOSED POISON REGULATIONS.

THE *British Medical Journal*, in commenting on this subject, remarks that Mr. Simon has "wisely insisted on the introduction of" regulations* as to the kind of bottles to be used for lotions, etc., containing poison; and it then proceeds to censure the action of the Council of the Pharmaceutical Society in a manner which we do not think is merited. But at the same time we think it right to extract the remarks of our contemporary for the purpose of illustrating the views held in certain quarters, and since it is desirable at the present moment that Members of the Society, as well as the trade generally, should have before them all information regarding this question.

"In these regulations Mr. Simon has very wisely insisted on the introduction of the third series. With the perfectly characteristic selfishness which is common to all corporations, the Council of the Pharmaceutical Society had omitted them. They wished to protect the chemist, but were willing to leave the door as widely open as ever to all the calamities which spring from carelessness or ignorance of persons dealing with medicines once dispensed, although well knowing that this is a sadly fertile source of accidental poisoning. Such a course is peculiarly shocking to the conscience; and it is well that the Privy Council retained its power of guarding the public safety, which the Council of the Pharmaceutical Society were perfectly willing to throw overboard, apparently regardless of the sacrifice of life, provided that they could make a show of activity and save their privileges, while they conciliated their constituents. In this their conduct seems to us deserving of very severe and enduring censure. It will be satisfactory to the medical profession and to the public to learn of any mitigating circumstance. These regulations, however, are likely to meet with serious opposition from chemists who wish to pursue their business without regulations, and are unwilling to recognize any moral duty of the many to submit to precautionary measures which the few already voluntarily adopt. We may warn these gentlemen that prolonged opposition will end in more complete restriction. The adoption of such precautions was part of the parliamentary understanding on which they were secured a monopoly of the pharmaceutical trade; and the public safety demands them. The weakness of the Pharmaceutical Society's action in this matter lies in the anomalous and composite character of the Society. It is at once a trade-union society, aiming at the protection of trade interests, and a governmental regulating body, empowered to make binding regulations in the interest of the public; a school at which teaching is carried on for profit, and an examining body which gives diplomas to its own pupils, and enjoys a monopoly of that business in England. This fourfold capacity includes doubly conflicting duties; and it is obviously only by the utmost discretion, and a willingness properly to abandon the exclusive considera-

* See *ante*, p. 563.

tion of trade interests where they conflict with public safety and welfare, that this Society can be allowed to hold in its custody, duties and privileges which have very rarely been consigned to one body. An obstinate resistance to the demands of the Privy Council must lead to the recasting of the pharmaceutical monopoly, under conditions which will ensure that attention to public safety which is at present intrusted to the good sense and good feeling of the members of the Pharmaceutical Society."

CHLORAL HYDRATE.

We have received communications upon this subject from Messrs. Domeier and Co., Messrs. Gehe and Co., Messrs. Schœtensack, Mr. W. S. Squire, and Mr. A. H. Mason, but are unable to insert them this week in consequence of the great pressure upon our space consequent upon the discussion of the Poison Regulations.

THE CHEMISTS' BALL.

We had occasion, in a recent number, to refer to the success of the Chemists' Ball as a social gathering, and we are glad now to be able to report that the financial result has also proved very satisfactory. The Committee, after paying all expenses, have been enabled, from the surplus, to make a donation of Twenty Guineas to the Benevolent Fund, as they did last year. They have, moreover, by a unanimous vote, determined to present a testimonial to Mr. T. Donald Watson, in recognition of his exertions as Secretary to the Ball Committee since the first institution of that successful, and, we hope, now firmly established annual gathering. The testimonial is to be of the value of twenty guineas, and is to be purchased by a Committee of Selection.

The second reading of the Bill to Amend the Law for the Prevention of Adulteration of Food and Drink and of Drugs, which will be found printed at p. 694, is fixed for the 22nd of March.

We have received from the Paris Société d'Acclimatation a circular bearing the signature of Dr. J. Léon Soubeiran, and stating that at a meeting of the Council of that Society, on the 27th January, a resolution was passed to the effect that the names of the sovereigns and princes of the German states engaged in the war with France should be erased from the list of patrons of the Society. This step is stated to have been taken, in consequence of the opinion that the bombardment of Paris has been carried on by the German armies in such a manner as to constitute an act contrary to the law of nations, and the fundamental notions of humanity.

It is announced in *Nature* that the Royal Commission on Scientific Instruction and the Advancement of Science is now in full work, and meeting two or three times a week.

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

February 15th, 1871.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Edwards, Gale, Garle, Hanbury, Haselden, Ince and Southall.

Dr. Greenhow was also present, on behalf of the Privy Council.

Four candidates presented themselves for the Major Examination, and twenty-six for the Minor; the following passed, and were declared to be duly qualified to be registered:—

MAJOR (as Pharmaceutical Chemists).

Appleby, Calvert .... East Retford.
Masson, George .... London.
Storey, Edward Henry ...... London.

MINOR (as Chemists and Druggists).

*Wilson, John Herbert ...... Lee, Kent.
*Savory, Harry Banting...... Painswick.
*Peters, David .... Llandilo.
*Jones, Hugh Ellis .... Swansea.
*Pearce, Frank Tring........ London.
*Dresser, James .... York.
*Hackett, John Henry ...... Lincoln.
*Maddock, William Thomas .. London.
*Iredale, Thomas............ Leeds.
Equal. { *M'Neil, James Norton ...... Macclesfield.
{ *Martin, William Thomas .... Lewes.
*Humphreys, John .... Staines.
Richards, James Griffith .... Newport, Mon.
Margetson, James Francis ... Norwich.
Richardson, Thomas H....... Norwich.
Dowson, Joseph .... London.
Young, John Rymer .... Warrington.
Lord, Frederick .... Boston.
Edey, George .... Rochester.
Crofts, Henry Baptiste ...... Cranbrook.
Watson, Samuel .... Belper.
Connor, Thomas Haigh...... Wakefield.
Thompson, George Alfred.... Tunbridge.

The above names are arranged in order of merit

FIRST OR PRELIMINARY EXAMINATION.

Certificates presented by the undermentioned were accepted in lieu of this Examination:—

Flinders, Matthew Tom ...... London.
Worsley-Benison, Henry Worsley Seymour .... Reading.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The Fourth General Meeting of this Society was held at Britannia Chambers on Friday evening, January 21st; the President, Mr. Atherton, in the chair.

The minutes of the previous meeting were read and confirmed.

Mr. Atherton expressed his hearty thanks for the vote of condolence passed at the previous meeting.

The Hon. Secretary announced that the 'Pharmaceutical Journal' had been received during the month, as also a number of specimens of argal, etc. from Messrs. Matthews, of Bristol, and a vote of thanks was recorded to the respective donors.

The proposed Poison Regulations were then con-

* Passed with Honours.

sidered, and after considerable discussion and the reading of a letter, expressing the opinion of an individual member, the following resolution was passed:—"That this Society views with regret the decision arrived at by the Council of the Pharmaceutical Society, to recommend to the notice of their Annual Meeting the institution of Compulsory Poison Regulations."

The formation of the Museum was then brought forward, and Mr. Atherton agreed to supply specimens of chemicals, and Mr. Rayner the various roots. A fund for the furtherance of the same object was then formed, and contributions to the amount of £3. 5*s*. were promised.

The Annual Supper of this Society was held at the Maypole Hotel on Tuesday evening, the 7th of February; the President, Mr. J. H. Atherton, in the chair, the vice-chair being occupied by Mr. Fitz Hugh, the Vice-President.

After the usual loyal toasts and that of the medical profession, Mr. W. H. Parker expressed the pleasure it gave him to propose "The Pharmaceutical Society and Council." As the governing body of the profession, it commanded their respect, and they would all wish to contribute to its prosperity. They could readily sympathize with the Council in the many difficult matters they were called upon to decide; and, perhaps, never had a more particular subject been brought before them than that of the proposed Compulsory Poison Regulations. It was unnecessary for him to say how much he was opposed to any compulsory measures. A thorough change had been wrought in the constitution of the Council by those regulations, and he thought the new Council must have some very good reasons for now recommending that which many of them formerly objected to. Under any circumstances he objected to the compulsion, but he hoped the discussion by the Council and members at the Annual Meeting would result in the adoption of a thoroughly practical measure, free from anything objectionable to the members generally. There was one other subject which he (Mr. Parker) wished to mention. The income of the Pharmaceutical Society must be something like £7000 or £8000 a year, a considerable portion of which was gathered from the provinces, and he would like to see a portion of this money applied freely to the various provincial associations requiring aid for promoting the educational object for which they were established. As before observed, a large portion had been drawn from the provinces, and he thought it only right that the Pharmaceutical Society, who are unable to educate the number of students at the present time requiring instruction, should make some sort of return in aiding those societies that acted as so many feeders of the parent Society, which eventually reaped a corresponding benefit from their efficiency and extension. Nottingham had the honour of being represented in the person of their worthy President, Mr. Atherton, and he thought they might rely on his efforts to do what he could to promote the welfare of such societies, and in calling upon them to respond to the toast, he begged to couple therewith the name of Mr. Atherton.

Mr. Atherton, in responding, expressed the pleasure he felt in being associated with such a body of men as the present Council; and assured them that whatever might be the differences of opinion on particular questions, they might take it for granted that the truest and best interests of pharmaceutists and chemists generally throughout the country would be safe in such hands. After referring at some length to the questions affecting the welfare of their body, and in special reference to the remarks of Mr. Parker, Mr. Atherton explained the position of the Council in reference to the proposed poison regulations, and deprecated the action of the Privy Council in the matter. Personally he objected to the principle of compulsion, and thought that a code of simple regulations coming as a recommendation from the Council would have answered every purpose, would have been favourably received by the trade and generally adopted. The onus of any one neglecting these or other suitable precautions would be thrown upon the individual, and their responsibility would neither be increased nor diminished if the regulations were to be compulsory. The majority of the Council were in favour of the resolutions being adopted, and their opinions were entitled to respect, but in a matter of such importance, and in the face of so much opposition to any interference with the freedom of the trade, he thought that the Council would do well to take the opinion of the chemists throughout the country before the final decision was taken at the annual meeting in May. Another point for their consideration was the one-sided nature of these proposed regulations. They did not apply to surgeons or dispensaries, but simply to chemists; he would like to know, if chemists were compelled to submit to compulsory regulations, why should not the same principle be applied to all who dealt in and made use of the articles proposed to be scheduled? In conclusion, he thought that if the matter were properly represented to the Privy Council, some other arrangement might be arrived at, more satisfactory to the majority.

The President proposed the toast of the evening, "Success to the Nottingham and Notts Chemists' Association," and referred to the advantages offered to those who choose to avail themselves of the opportunities, and to the moral obligation of all the chemists within the influence of the Society to support it in every possible way, after congratulating the members upon the success which had attended their efforts during the past session, expressed his gratification that the Council of the Pharmaceutical Society had intimated their readiness to assist such Societies by grants of money, books, or apparatus, according to the wants of each case.

The other toasts proposed were, the President, Mr. Atherton; the Vice-President, Mr. Fitzhugh, and Council; the Treasurer, Mr. Rayner; the Hon. Secretary, Mr. Mayfield; the Lecturers to the Society, Mr. Elder and Mr. Mayfield; the Ladies. After having enjoyed a most agreeable evening, the meeting separated.

SHEFFIELD PHARMACEUTICAL AND CHEMISTS' ASSOCIATION.

A Meeting of this Association was held on Wednesday, February 8th, when A. H. Allen, Esq., F.C.S., Chemical Lecturer to the Association, delivered an interesting lecture upon "Our Weights and Measures, with some Proposed Alterations and Improvements."

The President, Mr. Dobb, occupied the chair, and there was a moderate attendance.

The lecturer said that measures of length had first been taken from the various parts of the human body, and we thence had the foot, the cubit, the span, the hand's-breadth, the inch, and the nail; but such standards were highly unsatisfactory, varying as they did in different individuals and nations. Until recently, the English inch was defined to be the length of three barleycorns, taken from the middle of the ear, and placed in contact end to end; now, however, the inch bore a relation to the length of a pendulum vibrating seconds. In establishing a standard of length it was desirable that it should be readily reproducible on an accurate mathematical basis, in the event of all reliable copies being lost or destroyed, and there would be a much better chance of its universal acceptance, if it were not localized. The most philosophical system at present established was that of the French, who took as their standard the length of a line passing through Paris, and extending from the Equator to the Pole, and then dividing this by 10,000,000 they obtained the "metre," equal to about thirty-nine of our inches.

Professor Piazzi Smyth, who had carefully taken the dimensions of the Great Pyramid, had found that the height bore to twice the base the ratio 3·14159, or the same as the diameter of a circle bears to the circumference. The capacity of the stone trough in the interior, usually called the "sarcophagus," was exactly four British quarters of wheat. Its length was *about* 50 English inches, and *exactly* $\frac{1}{10000000}$th of the earth's diameter. The diameter of the earth measured 500,500,000 inches, so that if the inch were increased in length by $\frac{1}{1000}$th part (an amount quite inappreciable) it would be exactly $\frac{1}{50}$th of the length of the sarcophagus, and $\frac{1}{500000000}$th of the diameter of the earth. Such an increase would make a cubic foot of water weigh exactly 1000 ounces, instead of being supposed to do so, as at present. Mr. Allen was firmly impressed with the superiority of a decimal system of weights and measures, but he thought it would be easier and better to "patch" our present system than to adopt the French. The alterations he advocated would not be very extensive, and therefore the more likely to be taken up. He would propose to make the pound avoirdupois (weighing 7000 grains) a *measure* as well as a weight, and it was already used by druggists in the form of the sixteen-ounce bottle. He then proposed a new weight and measure of $\frac{1}{10}$ lb., which was about the capacity of a wineglass, and for which he suggested the name "verre" (the French for glass) or "ver." A weight and measure $\frac{1}{10}$ of this, equal to 70 grains, to be called a "newdrachm" (in one word), and which was sufficiently near in value to the present drachm to be at once substituted in the majority of cases. A weight and measure $\frac{1}{10}$th of this would be equal to 7 grains, and therefore called a "septem."

A gallon of water weighs 10 lb., so, if this were made a weight as well as a measure, no further change in it would be necessary. A weight and measure equal to 10 gallons would weigh 100 lb., and might be called a "hundredweight" and abbreviated as "hwt." The manifest absurdity of calling the present weight of 112 lb. a "hundredweight" would facilitate the change proposed. A weight and measure equal to 20 hwt., and weighing 2000 lb., would replace the present ton of 2240 lb. It might be called a "tone," or, still better, a "newton,"—a name indicating its parentage, and recalling to mind the great discoverer of gravitation. Our system of weights and measure would then stand thus :—

7 Grains	=	1 Septem, S.	=	$\frac{1}{1000}$ lb.
10 Septems	=	1 Newdrachm, Nd.	=	$\frac{1}{100}$ lb.
10 Newdrachms	=	1 Ver, V.	=	$\frac{1}{10}$ lb.
10 Vers	=	1 Pound, lb. or P.	=	1 lb.
10 Pounds	=	1 Gallon, G.	=	10 lb.
10 Gallons	=	1 Hundredweight, Hwt.	=	100 lb.
20 Hundredweights	=	1 Newton, Nt.	=	2000 lb.

Of course the half-gallon bottle, or "Winchester quart," could still be used, and it would be convenient to have a ½-lb. measure of the capacity of an ordinary tumbler (8 oz.), which might be called a "beaker," "rummer," or "tumbler." The smaller weights would scarcely be employed except by chemists and druggists, and could at any time be expressed in decimals of a pound. The change to such a system would take place with infinitely less opposition and dislike than if the French system were adopted.

The proceedings concluded with a cordial vote of thanks to the lecturer.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The Ordinary Weekly Meeting of this Association was held in the Council Room, Mitre Chambers, on Thursday evening, February 9th. The minutes of the previous meeting having been affirmed, a paper was read by Mr. Binns upon 'The Medicinal Use of Vegetables and their Preparations.' The author said that he had lost faith in the present system of administration of vegetables and their preparations as curative agents, on these grounds :—that every plant, or part of a plant, which is medicinally useful, owes its active properties and action on the human frame to one or to several substances formed in, and generally peculiar to that plant, of which they are said to form the active principle; that science is almost dumb as to the mode of formation of those active principles and their ultimate cause; and the results of all published investigation point to their uncertainty in quantity. What is the cause of the medicinal influence of various plants on the human frame? Taking into consideration the undisputed fact, that one species of plant produces a different kind of effect on the human frame from another species, we are led to the conclusion that these effects are due not to any substance or substances which the several species possess in common, such as vegetable fibre, starch, etc., but to some substance which occurs in, and is generally confined to, each individual species. This inference is borne out by the results of chemical investigations into the composition of the matter of plants; thus nux vomica seeds are found to contain a principle to which has been given the name of strychnia; atropia has been found, and found only in the belladonna plant. Now the physical action of these principles has been ascertained by experiment to be mainly and practically the same as that of the plants themselves, and on account of this the name 'active principles' has been assigned to them.

He then gave an account of the growth of a plant, and argued that just as one man cannot, by reason of his very nature, deposit fat or flesh or bone in large quantities, but forms an extra amount of muscle, while another man, fed on the same food, developes bone to an alarming extent, to the consequent diminishment of his muscular fibre,—the same cause operated in the vegetable kingdom, in varying the proportions of body and active principle in each individual plant. Considering the vegetable fibre, etc., to correspond to the bone and flesh of animals and the active principles, etc., to the blood and muscular fibre, facts point to the inference that the proportion between them is regulated by the organic quality or nature of the seed from which the plant sprang. If this be the case, then the weight of a plant has no relation to the amount of active and peculiar principles which it contains. But the British Pharmacopœia assumes virtually that the amount is exactly the same in each of several plants of the same weight.

Mr. Binns then read the following results of various experiments on the composition of the substance of plants :—

Miller's 'Organic Chemistry' tells us that the "composition of opium varies greatly even when it is not adulterated; also, that morphia is its principal sedative constituent, and its salt, the meconate, forms from one-seventh to one-sixteenth of its weight," which certainly leaves a wide margin for variation.

Thomson, in his 'Materia Medica,' states "There is one disadvantage in prescribing opium, that is, we can never rely upon the strength of the specimen." Analyses of various kinds of opium yielded the following results to various operations :—

Sample.	Percentage of Morphia.
Smyrna	About 8.
Egyptian	5.
Algerian	About 6½.
English	Irregular.
French and German	16 to 20.
Indian	3·21–10·5.
Chinese	2·5.

Cinchona barks subjected to analysis with the view of ascertaining the amount of quinine and cinchonine contained, gave the following :—

Sample.	Quinine.	Cinchonine.
Best Calisaya	3·8	
Middle ,,	2·5	
Carthagena	1·04	1·35
Best Red Bark	2·65	1·51

This shows a variation of 50 per cent. of the whole quantity of quinine contained in yellow barks; and that a doctor in ordering tinct. cinchonæ flav., thinking to produce an effect represented by $1\frac{1}{2}$, may be deceived, and obtain instead an effect represented by 1.

Under the head of aconitina Royle states that "both the juice and tincture of aconite are occasionally given without any effect at all; and, on the other hand, several cases of poisoning by small quantities of the tincture have occurred. These different results are probably dependent upon variations in the amount of active principle in the root used. This is the alkaloid aconitina, which is the only preparation of the drug which is constant in strength." Again, in speaking of *conium*, he states that "some preparations of conium contain no conia, either from defective preparation or subsequent change, and this accounts for the discrepant statements concerning the efficacy of conium as a medicine." Ought he not rather to say that the reason lies in the uncertain quantity of conia in the plant?

An analysis of euphorbium, given in Pereira's 'Materia Medica,' shows as a result of one experiment 60·8 per cent. of resin, as of another 43·77. An analysis of croton oil yielded to Brandens 17 per cent. of fixed oil and crotonic acid, to Miers 60 per cent., and Pelletier 50 per cent.

Pereira also states that the red veins of rhubarb are the seat of the astringent properties, and it is undeniable that these vary in quantity.

Foxglove has been the subject of repeated investigations, but until recently with no satisfactory results. From 1000 grs. of the leaves, Henry obtained 140 to 150 grs. of digitaline.

Scammony analysed by Marquart gives the following results:—

Aleppo Scammony, per cent. of Resin.	81·25—32·5
Antioch " " .	18·5 — 8·5
Smyrna " " .	6 —37

The percentage of resin in jalap as found by Marquart varied from 12·08 to 13·33.

Aloes analysed by different persons gave:—

	I.	II.	III.

" Aloesin . .	81·25	52	60

The author considered that all the extracts, tinctures, decoctions, etc., contained in the Pharmacopœia of 1867 were but shams unless it were a known and proved fact that all vegetables, their leaves, roots, barks, etc., contain a constant and fixed percentage of active principles, whereas he thought he had proved the very reverse to be the case. Now, are we going to continue in a blind adherence to a system which, at the least, is open to grave doubts; or shall we discard it? As a remedy for this uncertainty, he recommended that all present should do their best to pave the way towards the use of the active principles from which the drugs derive their healing properties instead of tinctures, etc.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Seventh General Meeting of the Session was held at the Royal Institution, on Thursday evening, the 16th inst.; the President, Mr. John Abraham, in the chair.

Mr. A. W. Wilson and Mr. I. L. Benson were elected members, and Mr. A. Brownrigg was elected an associate.

Several donations to the Library were announced.

Mr. Thomas F. Abraham stated, that in accordance with his promise at the last meeting, he had repeated his experiments upon the crystal hydrate of chloral, supplied by Messrs. Morson and Son, and again obtained from 70 to 72 per cent. of chloroform.* He had also tested it in comparison with the cake chloral hydrate, bearing Liebreich's guarantee, and found no difference whatever; he therefore thought that Mr. Mason's report was incorrect. He had also examined a portion of cake hydrate of chloral, formerly supplied by Messrs. Morson and Son, which also produced from 70 to 72 per cent. of chloroform.

The President said that the publication of the paper read by Mr. Mason on the 22nd December last, had attracted much attention, and it was his opinion that Mr. Mason's statements were inaccurate. The question had been taken up by Dr. Paul, and the results of his experiments showed differences in the character of the chloral in the market of only moderate extent.

Mr. Mason said, that in reading the paper in question, he distinctly stated that sample No. 9 only was an alcoholate of chloral; those samples which did not yield the legitimate percentage of chloroform, *upon his application of the ammonia test*, he considered were hydrated alcoholates, or mixtures of hydrate and alcoholate of chloral. Duplicate samples of the chloral salts which he had experimented upon had been sent for analysis to an arbitrator agreed on by some of those interested; the results of his experiments were to raise the chloroform percentage in some cases, and reduce it in others, but the relative value of the samples, appeared in the same order as arranged by himself.* Referring to Dr. Paul's paper, Mr. Mason said it should be borne in mind that the samples Dr. Paul reported upon were samples supplied from different sources *since* the publication of his paper. The samples he experimented upon were samples met with in the ordinary routine of business, in November and December last. He should be sorry if true and pure articles had been injured by his experiments, and with the assistance of several friends, was doing all he could to endeavour to arrive at the truth, and should he be proved erroneous, he should feel it a duty to state the same for the benefit of all those interested therein.

The President alluded to the death of Dr. Sheridan Muspratt, and regretted that an eminent chemist had been taken from amongst us. He would not attempt to determine his position as a man of science, but he noticed an admirable trait in his character, supplied by the preface to his 'Dictionary of Chemistry,' in his acknowledgment of the valuable assistance rendered to him by a member of the Council of this Association, Mr. Martin Murphy, F.C.S.

Mr. Charles Blood then read the paper for the evening upon the 'Year-Book of Pharmacy, 1871,' in which he gave a *résumé* of each of the principal articles contained in the volume lately issued by the British Pharmaceutical Conference, and urged all those who had not yet joined that Society to do so at once and obtain the book for themselves.

The President said the members would all feel indebted to Mr. Blood for his interesting criticism of the Year-Book; he thought the work would prove a valuable adjunct to progress in pharmaceutical knowledge, and did not doubt that each year the work would be improved.

Mr. Alfred E. Tanner said he had noticed some discrepancies in the formulæ given; for instance, in the formula for Smith's chlorodyne, p. 29, it is printed "Theriacæ ad f℥iv;" this should be ℥v according to formula published by Mr. Smith in the Pharmaceutical Journal, which gives twenty grains of morphia in five fluid ounces.

A vote of thanks was cordially voted to Mr. Blood, who in reply stated that his object had been simply to bring the book before the notice of those who were not members of the Conference, and he trusted all present would be induced to join its ranks.

* Since this meeting, I have *voluntarily* gone into this analysis with Mr. T. F. Abraham, and have much pleasure in confirming his results.—A. H. Mason.

* There is an obvious inconsistency between these two statements.—Ed. Pharm. Journ.

CHESTER CHEMISTS' ASSOCIATION.

At a Meeting of the Chester Chemists' Association' held on Monday last, the proposed regulations for the keeping, dispensing and selling of poisons were discussed, and the following resolution in reference thereto was adopted:—

"That, taking into consideration the public safety, as well as our own protection, the regulations for the storing, dispensing and selling of poisons, recommended by the Council of the Pharmaceutical Society, be adopted by the members of this Association; and that the Secretary be requested to forward a copy of this resolution to the Secretary of the Pharmaceutical Society. This Meeting also begs to recommend that no medicine for internal use shall, under any circumstances, be sent out in poison bottles."

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

After several years' intermission, the Pharmaceutical Meetings in connection with this Institution have been resumed. On the 18th of October last a meeting was held, the object of which was to consider the best mode of conducting the future meetings. The Registrar was authorized to publish notice of meetings in the *Public Ledger;* also to give wide circulation to cards of invitation. A committee, consisting of Israel J. Graham, Professor Maisch and Dr. Pile, was appointed to draw up a plan and submit the same to the next meeting.

At this meeting Professor Maisch exhibited a specimen of the so-called African saffron, obtained from Chicago. Upon examination this proved to be Carthamus, safflower (*C. tinctoria*), much broken and discoloured. Also a sample of gum sennaar, a species of Acacia, at about two-thirds of the price of gum arabic. It comes into commerce *viâ* Trieste, from a port on the Red Sea. Externally it resembles a good quality of true gum arabic, forming a mucilage which is not so bland as that produced from true gum. It may be distinguished from the *Acacia vera* by the following characters:—A mucilage from true gum mixed with Goulard's Extract produces slight opalescence. A mucilage from gum sennaar filters slowly with milkiness; the addition of liquor ammoniæ to the filtrate of true gum produces in twenty-four hours a slight opalescence; added to the filtrate from gum sennaar, a gelatinous mass is formed in the same space of time.

At the Meeting on November 15th, the order of business was as at meetings generally. The Committee appointed at last meeting reported the following suggestions:—

1. As it is of primary importance that a general interest should be felt or created in the attendance of these meetings, the Committee would recommend that an earnest invitation be extended to the members of the College, and all others who may desire to participate in the proceedings; to produce at each of our meetings either written or oral contributions on subjects pertaining to chemistry or pharmacy, or the commercial relation of drugs. Upon the conclusion of such communications, the presiding officer of the meeting to call for any remarks that may be elicited by the subject thus introduced.

2. That there should be appointed annually a Standing Committee, consisting of three members, whose duty it should be to propose subjects for discussion at any of our meetings, whenever there shall be a lack of material voluntarily contributed by members.

3. That a box or other suitable arrangement be provided for the reception of written queries, anonymous or otherwise, which members may desire to propound, relating to any subject connected with the shop or laboratory; which queries may be taken up for discussion either at the meeting in which they are proposed or at a subsequent meeting.

4. That this Committee be requested to obtain, from time to time, the services of any who may favour the meeting with lectures suited to the occasion.

These recommendations were adopted. The Committee appointed for the ensuing year was Charles Bullock, Dr. Pile and Professor Maisch.

Dr. Bridges exhibited a specimen of marked glass cut by a new process, in which sand is blown with great force against the glass, certain portions of which is protected by wire of different shape, or by gauze or lace, the figure of which is left on the smooth glass surface, while the meshes are etched by the attrition of the sand. Wherever the sand strikes, the impression made resembles ground glass. This process will probably supersede ground glass in many of its uses.

Dr. Pile exhibited a sample of insoluble gun cotton, made in the form of gun wad, being very explosive.

Dr. Bridges explained the principle of the spectroscope, its discovery and the wonderful results obtained by its use. Although this species of chemical investigation is but in its infancy, the results so far obtained are marvellous, the minutest quantity of a substance being detected by an undeniable and never-failing colour. After a very interesting exhibition of spectroscopes by the Professor, assisted by Mr. Bullock, the meeting adjourned.

At the Meeting held on December 20th, among other things, Dr. Pile propounded and solved the following problems:—

1. To reduce alcohol of given strength to proof.
2. To reduce alcohol to any required strength.
3. To make any required quantity of either of the above.

Answer to Problem 1.—Ascertain the percentage of the alcohol used, and to every 50 parts, by measure, add water sufficient to make the whole number of parts equal to the percentage. For example, if the alcohol be 85 per cent., then to 50 ounces add water sufficient to make 85 ounces.

Answer to Problem 2.—To as many parts of the given alcohol as are indicated by the percentage required add sufficient water to make the number of parts of the mixture equal to the percentage of the given alcohol. For example, if it is desired to make an alcohol of 30 per cent. from an alcohol of 95 per cent., take 30 parts of the alcohol, add water sufficient to make 95 parts of the mixture.

Note.—In the first example we do not add to the 50 ounces of alcohol 35 ounces of water, but sufficient to make 85 ounces of the mixture. This is owing to the condensation occurring where alcohol and water are mixed.

Answer to Problem 3.—Make the following proposition: As the percentage of the alcohol given is to that of the alcohol required, so is the quantity desired to the quantity of the alcohol to be taken; and to this quantity of alcohol water sufficient must be added to make up the required quantity. For example, suppose 80 ounces of alcohol, of 75 per cent., is desired to be made from 95 per cent. alcohol,—as 95 : 75 : : 80. This gives 63 3-19 ounces of 95 per cent. alcohol to be taken; to this add water sufficient to make 80 ounces.

Alcohol = 89·49 per cent. by volume.
Dilute „ = 46· „ „
Strong „ = 94·65 „ „

Mr. Bullock exhibited a specimen of anhydrous alumina, found in large masses weighing many pounds. Specific gravity, 3·60; next to the diamond, the hardest substance in nature. Surface studded with crystals of sapphire.

Professor Maisch read a paper "On the Precipitation of Quinia by Iodide of Potassium from an Acid Solution." Also a paper entitled "Decomposition of Acetate of Morphia in Solution."*

Professor BRIDGES made some remarks on the vinegar plant.

Professor PARRISH read a paper (illustrated with diagrams) upon "Petroleum, its Mode of Rectification and Refinement, together with its Commercial History," speaking of the immense use during the last few years, almost superseding other illuminating oils of commerce, and exposing some of the immense frauds practised during the coal-oil rage.

Several specimens of petroleum and its derivatives, in their different stages of refinement, were exhibited.

MONTREAL CHEMISTS' ASSOCIATION.

At a late Meeting of the members of the above Association a draft petition, to be presented to the Dean and Faculty of Medicine, relative to the percentage system, was submitted for adoption. The Association finds that the practice which obtains favour with certain members of the medical profession, of sending their prescriptions for mere pecuniary considerations to a particular druggist, is so serious a drawback to the trade and unfair to the public, that it should be represented to the Faculty. The junior members of the Association naturally argue that unless they happen to be so fortunate as to be able to fee some of the leading physicians in order to obtain their influence, their chances of advancement are small.

The report of the Committee on the matter was favourably received, and will be finally discussed at the next meeting.

The above Association is now called "The Pharmaceutical Association of the Province of Quebec," and has received a charter from the Government. The Association has a staff of professors, and classes on botany, chemistry and materia medica, etc.

CHEMICAL SOCIETY.

At the Meeting of the Chemical Society on February 2nd, a discussion took place on Professor Frankland's paper on the "Development of Fungi in Potable Water."

The President, Professor WILLIAMSON, after having expressed the thanks of the Society to Professor Frankland for his communication, asked whether he had taken into account the phosphoric acid present in the sugar.

Professor FRANKLAND said he thought the phosphoric acid would have been excluded by the crystallization of the sugar.

Dr. HEISCH was glad that his statements had been confirmed by Dr. Frankland's experiments, but in two important points the results obtained were diametrically opposed to his own. The first was that water retained organic germs after filtration through animal charcoal. During the last three years he had investigated large quantities of water, and on no single occasion had he found fungoid growth in such water after it had been passed through a charcoal filter. The other point was that while Dr. Frankland had said that the cellular formations obtained from white of egg in sugar solution were very similar to the sewage fungi, he had found them easily distinguishable. The sewage fungus was very small, perfectly spherical, transparent and generally grouped in grape-like bunches. Its development and decay is very rapid. Six hours after the mixture of the sewage matter with the sugar solution the spherical cells will appear; in six hours more they will grow into mycelia, and a short time afterwards the whole vegetation disappears,—the whole growth being accompanied by the odour of butyric acid, which is wanted during the development of fungi from the white of egg. The latter, too, have a different appearance from the sewage fungi.

Mr. BELL remarked that samples of sewage water kept for some time would purify themselves by a process of natural decay. Of seven samples that he had obtained from Dr. Frankland, four, which had been obtained in 1869, did not become turbid when submitted to the sugar test; while three that had been obtained in October and November last became turbid. He had some doubt as to the cause of the turbidity. Shortly after Dr. Heisch read his paper, a sample of water taken from a well in Drury Lane was brought for examination. Some sugar was added to a portion of the water and in about twelve hours the water became turbid. When examined microscopically it was found to be alive with the little creatures he had been in the habit of seeing in vegetable extracts. He at once inferred that these organisms, and not the fungoid development, caused the turbidity. As the result of various experiments with phosphates, he found that when calcic phosphate was present bacteria were largely developed. He had also passed water through animal charcoal, and in every instance bacterian bodies were produced in the water on the addition of sugar. Pure water, into which ignited charcoal had been introduced, might be kept a considerable length of time without developing any organisms on the addition of sugar.

Dr. VOELCKER said, in confirmation of the statement that sewage easily undergoes alteration, that a jar of sewage having been left for some months loosely covered lost nearly all its ammonia, whilst its nitric acid had increased. He also said that iron sponge far surpasses charcoal for filtering purposes; water filtered through it would stand Dr. Heisch's test perfectly. Spongy iron is obtained by calcining with charcoal the residues from burnt copper pyrites.

Mr. WARINGTON said that probably the spongy iron purified the water by removing the phosphates that would be retained by the hydrated ferric oxide with which the sponge is largely crusted. He also called attention to the fact that fresh animal charcoal gives up some of its phosphates to the percolating water, which was not the case with charcoal that had been in use some time. This he thought might help to explain the difference in the results obtained by Dr. Frankland and Dr. Heisch.

Dr. DUPRÉ asked Dr. Frankland whether he had boiled the sugar solutions? He himself had obtained no fungoid vegetation when this had been done.

Dr. FRANKLAND said usually they were not boiled, but that in one experiment the sugar had been burnt to caramel, the water previously heated with caustic soda and potassic permanganate, all the salts added to it being heated to a high temperature, and in that experiment more splendid fungi were obtained than in any other. The discrepancy between his observation as to the efficiency of charcoal, and those of Dr. Heisch, seemed to be explained by Mr. Warington's remark. As to the two kinds of cells, he did not consider them identical, but yet they were similar. He had not paid any attention to the odour of butyric acid during the development of the sewage fungi. In reply to Mr. Bell, he said the samples of effluent water had been examined a day or two after collection. With reference to Dr. Voelcker's remark, he said that the quick disappearance of the ammonia in sewage and sewage water had often been noticed by himself.

MEETINGS FOR THE ENSUING WEEK.

MONDAY ......*Medical Society*, at 8 P.M.
London Institution, at 4 P.M.—"The First Principles of Biology" (Educational Course). By Prof. Huxley.

TUESDAY ......*Royal Institution*, at 3 P.M.—"The Nutrition of Animals." By Professor Foster.

* PHARM. JOURN., 3rd Series, Vol I. p. 661.

WEDNESDAY...*Pharmaceutical Society of Great Britain*, at 8.30 P.M. "The Microscope and its Revelations." By Dr. W. B. Carpenter.
Society of Arts, at 8 P.M.—"The Principles of School Organization and Instruction as Advocated by the Society of Arts." By Rev. W. H. Brookfield, M.A.
Royal Medical and Chirurgical Society, at 8 P.M. Annual Meeting.

THURSDAY......*Royal Society*, at 8.30 P.M.
Royal Institution, at 3 P.M.—"Davy's Discoveries in Chemistry." By Prof. Odling.
Linnean Society, at 8 P.M.
Chemical Society, at 8 P.M.
London Institution, at 7.30 P.M.—"The Action, Nature and Detection of Poisons." By F. S. Barff.

FRIDAY ....*Royal Institution*, at 9 P.M.—"The Latest Scientific Researches in the Mediterranean and Straits of Gibraltar." By Dr. W. B. Carpenter.

Parliamentary and Law Proceedings.

A BILL TO AMEND THE LAW FOR THE PREVENTION OF ADULTERATION OF FOOD AND DRINK AND OF DRUGS.

Whereas the practice of adulterating articles of food and drink and drugs for sale, in fraud of Her Majesty's subjects, and to the great hurt of their health and danger to their lives, requires to be repressed by more effectual laws than those which are now in force for that purpose:

Be it therefore enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. Every person who shall wilfully admix, and every person who shall order any other person or persons to admix, with any article of food or drink, any injurious or poisonous ingredient or material to adulterate the same for sale, and every person who shall wilfully admix, and every person who shall order any other person or persons to admix, any ingredient or material with any drug to adulterate the same for sale, shall for the first offence forfeit and pay a penalty not exceeding £50, together with the costs attending such conviction, and for the second offence shall be guilty of a misdemeanour, and be imprisoned for a period not exceeding six calendar months, with hard labour.

2. Every person who shall sell any article of food or drink with which to the knowledge of such person any ingredient or material injurious to the health of persons eating or drinking such article has been mixed, and every person who shall sell as pure and adulterated any article of food or drink, or any drug which is adulterated or not pure, shall for every such offence, on a summary conviction of the same before two justices of the peace at petty sessions in England, and in Scotland before two justices of the peace in the justices of the peace court, or before the sheriff substitute of the county, or before justices at petty sessions or a divisional justice in Ireland, forfeit and pay a penalty not exceeding £20, together with such costs attending such conviction as to the said justices shall seem reasonable; and if any person so convicted shall afterwards commit the like offence, it shall be lawful for such justices of the peace to cause such offender's name, place of abode, and offence to be published, at the expense of such offender, in such newspaper or in such other manner as to the said justices shall seem desirable.

3. And be it enacted that the Pharmacy Act, 1868, and the Act 23 & 24 Vict. c. 84, for preventing the adulteration of articles of food and drink, shall be deemed to be incorporated in this Act.

4. Any purchaser of any article of food or drink or drugs in any district, county, city, or borough where there is a public analyst appointed shall be entitled, on payment to such analyst of a sum not exceeding 10*s.*, to have any such article analysed, and to receive from such analyst a certificate of the result of his analysis, specifying whether, in his opinion, such article is adulterated, and also whether, if it be an article of food or drink, it is so adulterated as to be injurious to the health of persons eating or drinking the same.

5. Any person who has been convicted of any offence punishable by this Act by any justices may appeal to the next general or quarter sessions of the peace which shall be held for the city, county, town, or place wherein such judgment or conviction shall have been made, or in the case of the conviction having been before a sheriff substitute in Scotland, then the appeal shall be to the sheriff of the county, provided that such person enter into a recognizance within two days next after such conviction, with two sufficient securities, conditioned to try such appeal, and to be forthcoming to abide the judgment and determination of the Court at such general or quarter sessions, or sheriff, and to pay such costs as shall be by such Court awarded; and the justices before whom such conviction shall be had are hereby empowered and required to take such recognizance; and the Court at such general or quarter sessions, or sheriff, are hereby authorized and required to hear and finally determine the matter of every such appeal, and may award such costs to the party appealing or appealed against as they shall think proper.

6. If any such conviction or judgment or order of forfeiture shall happen to be made within six days before any general or quarter sessions of the peace shall be held for the city, county, town, or place wherein such conviction shall have been made, the person who shall think himself aggrieved by any such conviction may, on entering into a recognizance in manner and for the purposes before directed, be at liberty to appeal either to the then next or next following general or quarter sessions of the peace which shall be held for any such city, county, town, or place wherein any such conviction shall have been made, on giving six days' notice to the complainant of his intention to appeal.

7. Any person who shall have been convicted by any justices or sheriff substitute of any offence punishable by this Act, in respect of the selling of any article of food or drink or drugs which shall have been manufactured according to any process patented before the passing of this Act, either by the patentee or owner of the patent, or by any person carrying on his business or otherwise claiming under him during the continuance of such patent, may, instead of appealing to the general or quarter sessions of the peace or sheriff of the county, apply in writing within five days after such conviction to the justices or sheriff substitute, to state and sign a case for the opinion of one of the superior courts of law thereon, in like manner as under the statute of the 20 & 21 years of her Majesty, c. 43, he might have applied to the justices to state and sign a case, and thereupon all such proceedings shall take place upon and in relation to such application, and all such provisions shall be applicable thereto, as would have taken place upon and in relation thereto, and been applicable thereto, under the provisions of the said last-mentioned Act; and in Scotland, for the purposes of such appeal, the justices or sheriff substitute may state and sign a case for the opinion of the Court of Session, in like manner as the justices in England and Ireland may, for the opinion of the superior courts of law under the said Act, and the Court of Session shall have in relation thereto the like powers as the superior courts have under the said Act, and all the other provisions of the said Act shall be applicable to such appeals.

8. In England the provisions in the Nuisances Removal Act for England, 1855, as to procedure, and the provisions of the Act of the 11 & 12 years of the reign of her present Majesty, intituled "An Act to Facilitate the

Performance of the Duties of Justices of the Peace and of Sessions within England and Wales with respect to Summary Convictions and Orders," and in Scotland the ordinary rules regulating the procedure of justices of the peace so far as the same are respectively applicable, shall extend and apply to cases arising under this Act in England or Scotland; and all moneys arising from penalties under this Act in any county, city, district, or borough where there are analysts appointed under this Act shall, when paid or recovered, be paid in England and Ireland to the vestry, district board, commissioners, county treasurer, or town council for such county, city, district, or borough respectively, to be applied for the general purposes of such vestry, district board, commissioners, county, city, or borough respectively, and to the collector of rogue money for each county in Scotland.

9. All proceedings under this Act in Ireland as to compelling the appearance of any such person or of any witness, and as to the hearing and determination of such complaints, and as to the making and executing of such orders, and as to the applications of fines, amerciaments, and forfeited recognizances imposed or levied under this Act at petty sessions, shall be subject in all respects to the provisions of the "Petty Sessions (Ireland) Act, 1851," as the same is amended by the "Petty Sessions Clerk (Ireland) Act, 1858" (when the case shall be heard in any petty sessions district), and to the provisions of the Acts relating to the divisional police offices (when the case shall be heard in the police district of Dublin metropolis), so far as the said provisions shall be consistent with any special provisions of this Act; and when any fine or penalty is imposed at any of the divisional police offices of Dublin metropolis, or by the justices in any corporate town, under the provisions of this Act, such fines and penalties shall be paid over to the same purposes and appropriated and applied in the same manner as is now by law authorized in respect of fines and penalties imposed at such divisional police offices, or by the justices in any such corporate town respectively.

10. In Ireland any person who has been convicted of any offence punishable by this Act may appeal to the next court of quarter sessions to be held in the same division of the county where the order shall be made by any justice or justices in any petty sessions district, or to the recorder at his next sessions where the order shall be made by the divisional justices in the police district of Dublin metropolis, or to the recorder of any corporate or borough town when the order shall be made by any justice or justices in such corporate or borough town (unless when any such sessions shall commence within seven days from the date of any such order, in which case, if the appellant sees fit, the appeal may be made to the next succeeding sessions to be held for such division or town); and it shall be lawful for such court of quarter sessions or recorder, as the case may be, to decide such appeal, if made in such form and manner, and with such notices as are required by the Petty Sessions Acts respectively hereinbefore mentioned as to appeals against orders made by justices at petty sessions; and all the provisions of the said Petty Sessions Acts respectively as to making appeals and as to executing the orders made on appeal, or the original orders where the appeals shall not be duly prosecuted, shall also apply to any appeal or like order to be made under the provisions of this Act.

11. The expense of executing this Act shall be borne, in the city of London and the liberties thereof, out of the consolidated rates raised by the commissioners of sewers of the city of London and the liberties thereof, and in the rest of the metropolis out of any rates or funds applicable to the purposes of the Act for the better local management of the metropolis, and in counties out of the county rate, and in boroughs out of the borough fund, or out of the rogue money in counties in Scotland.

12. Nothing in this Act contained shall be held to affect the power of proceeding by indictment, or to take away any other remedy against any offender under this Act.

A Child Poisoned by Mistake.

The following paragraph appeared under the above heading in the *Manchester Guardian*, Feb. 18th, 1871:—

"Yesterday, the City coroner (Mr. E. Herford) held an inquest touching the death of Florence Adelaide Livesey, 11 months old, daughter of Mr. G. Livesey, engraver, Bradshaw Street, City Road, Hulme. The mother of the child said she had been in the habit of giving the deceased child "infants' preservative," to induce sleep. She kept the bottle beside another containing liniment for a rash on the child's chest. The liniment was got from a chemists' firm named Wild and Fox.* On Wednesday night her husband handed her the liniment bottle instead of the sleeping cordial, and the mistake was not noticed until it was too late to save the child. The liniment bottle was not labelled 'poison.' The jury returned a verdict of 'Accidental Death,' and censured the chemists for not putting a poison label on the bottle."

This was supplemented by the following letter:—

"Poisonous Medicines.

"*To the Editor of the Manchester Guardian.*

"Sir,—As one of the jurymen on the inquest on the child who was poisoned, I beg to correct your report. It was not a chemist, but a medical man, who supplied the liniment to the parents, and who was censured by name by the jury, because that liniment, with which the child was poisoned, was not labelled poison in the way that all chemists would do;—had it been done, the poor child might in all human probability have been now living.—I am, etc. "Thos. Norris.

"100a, Clopton Street, Feb. 20, 1871."

A Druggist Fined for Selling Methylated Spirit without a Licence.

On Monday, at the Huddersfield Police Court, Robert Robinson, Chemist and Druggist, Lockwood, was fined £12. 10*s.* for selling methylated spirit without having a licence. The supervisor of excise, who attended to prosecute, stated that the defendant had been served with ample notice that he was not entitled to sell the spirit without having a licence.—*Leeds Mercury.*

Suicide by Carbolic Acid.

An inquest has been held at Liverpool upon the body of John Perkins, a brushmaker, forty years of age. The deceased had lately been in low spirits and rambled in his talk. On the evening of his death he went to bed after supper. His landlady hearing the sound of a fall in his room, went upstairs and found him lying on the floor in a dying state. There was a very strong smell of carbolic acid. She found a half-pint bottle with a little in it on the table, and a tumbler smelling very strongly of the acid. Medical assistance was called in, but the man was dead when it arrived.

The bottle, which was produced, was labelled "carbolic acid," but not "poison."

Dr. Bligh said that he was of opinion that the deceased died from poisoning by carbolic acid. The small portion left in the bottle was a mixture of carbolic acid, glycerine and water, with impurities.

The jury returned a verdict of "Suicide during temporary insanity."—*Liverpool Courier.*

Suicide by Morphia.

An inquest has been held at the German Hospital concerning the death of Frederick Meyer, aged nineteen.

---

* On referring to the Register, we find that this is a misstatement. Messrs. Wild and Fox are not on the Register of Chemists and Druggists, but are, we presume, the proprietors of an open surgery.—Ed. Pharm. Journ.

A police-officer stated that he found the deceased lying on the grass in a field near the Brampton Road, South Hackney. He then appeared very ill. There was a bottle labelled "Morphia, Poison," close to his right hand. Upon witness lifting him up he said, "My name is Frederick Meyer and I am a German. I have taken poison. I have been two years in England and I am nineteen years old. I am a chemist. I will not tell who my family are." He was removed to the German Hospital, where he died two hours afterwards.

Dr. Blaister said that the deceased had taken 244 grains of morphia. One grain would be sufficient to cause death.

The jury returned a verdict of "Suicide while in a state of temporary insanity."

Obituary.

JAMES SHERIDAN MUSPRATT.

James Sheridan Muspratt, F.R.S.E., whose death we have previously recorded, was born in Dublin in 1821. He early evinced a taste for chemistry, and at thirteen years of age, having travelled through part of France and Germany, he entered the Andersonian University of Glasgow, where, for nine months, he studied in the laboratory of Professor Graham, whom he afterwards followed to London. Before he reached the age of seventeen he was entrusted with the chemical department of a large manufactory in Manchester, and published a paper on chloride of lime, which attracted considerable attention. Proceeding to America, he entered into a trading partnership which was not successful. Afterwards he went to Giessen, where he remained two years under Liebig. He then published a paper upon the sulphites, which appeared in Liebig and Wöhler's 'Annalen,' and shortly after he obtained the degree of Ph.D. In conjunction with Professor Hofmann, he prepared toluidine and nitraniline, two important organic bases. He also edited Plattner's 'Treatise on the Blowpipe.' In 1845 he left Giessen and visited various parts of Germany, in order to become personally acquainted with her distinguished men. In 1847 he returned to Giessen, and spent four months in its laboratory, discovering several remarkable bodies produced from the sulphocyanides of ethyle and methyle. A paper on this subject was printed in Liebig's 'Annalen,' as well as in the Chemical Society's Transactions. In 1848 he produced a paper on the Selenites; in 1849 he published some very interesting remarks in Liebig's 'Annalen,' on the Blowpipe Reactions of Strontia and Baryta. In 1851 appeared his paper on "Carmufellic Acid," a new acid from cloves, published in the proceedings of the Royal Society, and in the 'Philosophical Magazine.' But the most important act of his life was the foundation of a College of Chemistry in Liverpool, students from which are now occupying prominent posts or professorships in various parts of the globe. In 1854 a Glasgow publisher engaged Dr. Muspratt to write a Dictionary of Chemistry, which has commanded a large sale in England, America, Germany and France. He was elected a Fellow of the Royal Societies of Edinburgh and Dublin, and a member of the Société d'Encouragement in France; and the oldest university in America conferred upon him the honorary degree of M.D. He has lately published some treatises on the chalybeate springs of Buxton and other English watering-places.

On his return from Germany in 1848, Dr. Muspratt married Miss Susan Cushman, the celebrated actress, who died in 1859. He was the scientific director of the extensive chemical works at Flint, belonging to Messrs. Muspratt Brothers, of which firm he was a member. He died after a lingering illness, at the comparatively early age of fifty.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department*, 17, *Bloomsbury Square, W.C., and not to the Publishers.*

[146.]—FLAVOURED CASTOR-OIL.—In answer to *W. Smith*, the following amongst other forms, is found to be the best by "*Delta*":—

Heat 5 lb. of finest Italian castor-oil for half an hour over a slow fire till thoroughly liquefied, then beat up the whites of ten eggs and add to the oil, and when well mixed stir in 20 oz. of lump sugar dissolved in 12 oz. of water, and stir again; lastly, add 1 oz. of starch-powder dissolved in 20 oz. of boiling water. The mixture must then be kept stirred briskly with a "whisk" (such as is used in culinary) till quite cold. Lastly, add flavour to taste, and shake in large jar for an hour. Care must be taken that the above quantity at least is used at one time, or the operation will fail.—DELTA.

[155.]—GUM ACROIDES.—Under this name I remember obtaining specimens from the late Mr. Keating, of St. Paul's Churchyard, of one of the *Xanthorrhœa* resins of Australia, which there pass under the name of Black Boy, or Grass-tree resins. The particular species yielding the gum acroides is, I believe, *X. hastilis*. It is darker than gamboge, less uniform in appearance, and not entirely soluble in alcohol. It contains benzoic and cinnamic acids. It has been used medicinally to unite the edges of wounds, and in the form of tincture with opium in dysentery and diarrhœa, and it forms the base of a cement, being much used by the aborigines of Australia to fix their spear-heads. It is also used, I believe, for varnish purposes. Mr. Druce will find further information respecting it in a paper of mine on the gums and resins of commerce read before the Society of Arts in November, 1855, and published *in extenso* in their journal, vol. iv. p. 18. I can also let Mr. Druce have a specimen from my collection as shown in the New South Wales Department of the Paris Exhibition.—P. L. SIMMONDS.

Gum acroides, or acaroides, is a resin obtained from different species of the Liliaceous genus *Xanthorrhœa*, or Grass-trees. *X. hastilis* yields a large quantity. The trees are very common in New Zealand. The resin is also known as "Black-boy gum," "Botany Bay kino," "Grass-tree gum," etc.—J. C.

[171.]—BOTANICAL SPECIMENS.—Good directions how to dry plants as botanical specimens will be found in Oliver's 'Lessons in Elementary Botany,' p. 287. They are, however, too long to be inserted in the PHARM. JOURN.—H.

"*Herbarius*" requires only three mahogany boards, demy size, half a ream of Bentall's paper, and a 56 lb. weight or a press.—WETHERBY.

[172.]—CRYSTAL VARNISH.—"*Pater*" would be glad of a form for crystal varnish for coating negatives to preserve them while printing.

[173.]—UNITED STATES.—Could any reader of the PHARMACEUTICAL JOURNAL give me any information as to whether they have to pass an examination before they can commence business in America or not? If so, where information can be obtained as regards any such examination. —GUILLAUME, A.P.S.

[174.]—GRAIN MUSK.—"*Percontator*" would be glad to receive some information on the method used by the wholesale drug trade to "grain" musk.

[175.]—ESSENCE OF MUSK.—"*Percontator*" would feel greatly obliged for a practical formula for the preparation of a standard essence of musk from the pod musk, *i. e.* the pod and its contents, with a description of the process and solvents employed by manufacturing perfumers in preparing the same.

Poison Regulations.

Sir,—You may imagine that I have watched very closely the correspondence appearing from week to week on the poison regulations, but until the publication in your last issue of a letter from Mr. Reynolds I had determined to take no part therein. That letter however reflects so seriously on the Council (of which he is a member) in their late proceedings, and personally on me as President, that I cannot longer remain silent.

That Mr. Reynolds should deem me unfit to hold the office of President will astonish no one who reads his imputation on the manner in which the duties of the Council have been performed, and his insinuation that a certain deficiency in myself has been the cause of mischief.

My present occupation of the chair was certainly not of my own seeking, and I should have vacated it ere this, had not the agitation on these very regulations assumed such a nature that my withdrawal would have seemed a desertion of duty, and a bequest of trouble to a successor who might have been less acquainted with the difficulties of the question. Had popularity been my sole object, I should wisely have declined to resume the Presidency in June last; my success had then quite "satisfied" my "highest ambition," and the body of the trade had most handsomely, as Mr. Reynolds's letter reminds me, "expressed their gratitude."

But when Mr. Reynolds suggests that my personal entanglement with Mr. Simon has brought the Council into a false position, I feel bound to assure him, and all who may share his opinion, that he is utterly mistaken. If ever there was entanglement between us, it was of an entirely different nature to the one now implied. Of all opponents to the restrictive clauses which the Privy Council sought to import into the Pharmacy Bill, I was (as Mr. Simon has said and would doubtless say again, although we may have forgiven past differences) the most "obstinate."

There is one point of the Act existing as proof of this, which Mr. Reynolds entirely misinterprets—the division of the schedule of poisons into two parts. After our Bill had passed the Lords, it was proposed in the Commons to apply all the formalities of the "Arsenic Act" *to every poison in the schedule.* In a long conference at the Privy Council office between Lord Robert Montagu, Mr. Headlam, Mr. Simon, and myself, I successfully opposed that proposition.

Immediately after, notices of equally objectionable amendments were put on the paper of the House by Mr. Lowe; one of them even went so far as to prohibit the sale of more than one "medicinal dose" of any poison without the order in writing of a legally qualified medical practitioner.

These amendments were discussed in the House, and, resulting therefrom, a conference took place between Lord Elcho, Mr. Lowe, Mr. Simon, Mr. Hills and myself, which ended in the compromise set down in the 17th section; *the division of the schedule into two parts, in order to liberate the articles in more common use from the restrictions applied to those in Part I.;* and the provision that vendors should comply with such regulations as might from time to time be made by the Pharmaceutical Society, etc.

Thus arose the "*tacit understanding*" which Mr. Reynolds now seeks to stigmatise as a "*secret treaty,*" and which may perhaps grow in his imagination, as it is "pondered over," into a "conspiracy;" it is so easy to advance step by step when one is predisposed to go in a certain direction.

The "tacit understanding" is that duty implied in the words of the first section, nothing more. The remedy, on the Society failing in its duty, rests with the House of Commons, which was, and may still be, in the mind to pass a more stringent measure.

And here let me draw attention to Mr. Reynolds's comparison of the style of the 1st and that of the 9th section. I hold the two occasions to be entirely dissimilar: the latter refer to a register which was wanted for immediate use,—indeed the Act could not be started without it,—and the order was that the Council "shall with all convenient speed" proceed to establish it.

As to the first section, the expression is not that the Council "may make regulations," but that all persons registered under the Act shall comply with such regulations as may from time to time be made. This surely implies not simply a power to make, but an expectation that regulations will be made.

Speaking of this "expectation" reminds me of one of the most remarkable passages in Mr. Reynolds's remarkable letter. He there charges some "*gentlemen officially connected with the Pharmaceutical Society*" with suborning evidence to suit the purposes of the Council. I can form no idea of the persons to whom he alludes, and although he talks of having "the best authority" for this assertion, I feel pretty confident he has been "gammoned." The editors of the *Pall Mall* and *Lancet* will probably give us some enlightenment on the point.

I read another article, couched in rather strong terms, in the *British Medical Journal* of last week; perhaps Mr. Reynolds will attribute that to the same source?

Mr. Reynolds chooses to call the Pharmacy Bill of 1865 an "expensive failure." It certainly was not expensive; and, although it failed to pass, it paved the way for the Act of 1868, and I cannot in any way admit that we have shown want of good faith in mentioning the obstruction which certain Chemists and Druggists caused to that Bill, or in our bearing towards them since.

The assertion in the "statement of reasons" that the Bill "No. 2" was the first *Pharmacy* Bill containing Poison clauses is perfectly true. The Society had always previously held, that although the education of the vendors should be an *imperative* condition of any Poison Bill, yet the provisions for their education, and the regulations for the trade in poisons should be contained in two distinct Acts of Parliament.

Mr. Reynolds takes exception to the conduct of the Council in delegating to a committee the "revision and issue of the statement of reasons." I can only tell him the paper so committed was carefully read over and approved by the Council, and the Committee had no power to alter it, beyond making the verbal changes rendered necessary by the discussion of the morning.

And now, Sir, although my letter may already appear too long, I must add a word or two on the "representative" character of our Council. Admitting fully that we are but delegates, I hold that we are *delegated to sit in Council, and there to exercise our judgment; frequently, and in such cases as this especially, to promote action on the part of the Society when that action tends to the common good;* and *that in the matter of these regulations the Society will act for itself, not by its delegates.* It will be a bad day for the Pharmaceutical Society when its Council is deprived of the right of private judgment, and when the members of the Society cease to respect themselves in the persons of their representatives!

Piccadilly, Feb. 21st, 1871. George W. Sandford.

The Journal, the Council and the Poison Regulations.

Sir,—In retiring from the Council a few months ago I hoped to have been able to leave entirely, or at least for a considerable time, the troubled arena of pharmaceutical politics; and were it not for a matter in which the honour and independence of the "Journal" is concerned, I should even now have allowed my views on recent events to have remained unexpressed.

Does the Council need to be reminded that the "Journal" is the property of the Society, and that, so far as they have control over it, such power is only held in trust for the Society? If they recognize this fact, I would ask how they can justify the employment of its official portions for purposes of partisan warfare? I put it thus pointedly, for no one who has closely followed the tone of the leading articles relating to the "Poison Regulations" can fail to see where the Editor ceases to speak for himself, and becomes, under pressure, the mere mouthpiece of a party who chance to be in power.

It happens that a majority of the present Council favour the imposition upon the whole trade of certain "poison regulations," and an attitude of obsequious obedience to the medical officer of the Privy Council; whilst an influential minority, backed by the sense of the members at large, as ascertained at the last Anniversary Meeting, desire independence of action within the limits of distinct (not imaginary) obligations. Now, if the majority of the Council, without any knowledge of the feeling of their constituents, endeavoured only to crush the opinion of the minority by insisting that their particular views should be advocated in a manner not open to those who differ from them, it might be regarded simply as an instance of very bad taste; but to take such action in the face of the decision of a general meeting of the members of the Society (the proprietors of the Journal), is an exhibition of tyranny in the use of temporary power, that needs a worse name than discourtesy.

I possibly feel this the more strongly as I had the misfortune to belong to that minority of the Council who, holding with the late Jacob Bell that "*the only practicable safeguard to the public is the proper qualification of all persons who administer or deal in poisonous substances*," have objected to the imposition of regulations the inconvenience of which to the trade as a compulsory enactment their very authors acknowledge, whilst not even their authors have ventured to predict that any real advantage to the public would follow their adoption. Would it not have been more dignified if the leading articles, instead of reproducing, without contradiction or explanation, paragraphs from other periodicals either false in fact or false in the impression they are intended to convey to the public mind, had been devoted to upholding the position of the Society and vindicating its honour? But the honour of the body is sacrificed, because it suits the purpose of a portion of the Council that the members should be frightened. In Mr. Bell's days chemists looked to the "Journal" for their defence against all outside enemies, and they were never disappointed. It is a painful reflection that now they are compelled to band themselves into associations for defence, not so much against the outside public as against the acts of their own Council.

There were many methods open to the Council of explaining its attitude of antagonism to the ascertained opinon of its constituents, if explanation had been the object sought. Obviously, the right method would have been to have invited the presence of reporters at the Council meetings when these matters were discussed, but it seems that that is much too liberal a measure for the present body. Still there were many others, such as, for instance, the circular which has been recently issued to the members. This particular document may not be very effective—it would be odd indeed if three foolscap pages of weak excuses did not carry their own condemnation, yet it has an interesting phase in the light it sheds on the authorship of at least one of the anonymous letters that have appeared in the Journal—but its issue is no outrage on the independence of the periodical which represents, or ought to represent, the Society at large.

Will you allow me to add a few words touching the proposed regulations? One of your correspondents ridicules the notion of police, or indeed of any inspection of pharmacies, under the impression apparently that "inspection" is a bugbear invented by objectors, and that it is a step which has never been entertained by the official mind. Does he forget that Lord Derby's Bill, which passed the House of Lords, provided for the appointment of examining inspectors; and that in Mr. Walpole's Bill, also a Government measure, the principle of police inspection was a prominent feature? Can anybody suppose the chance of such interference to be less now that we are unfortunately under the guardianship of the Privy Council than when, as heretofore, directly responsible to the Government in the person of the Home Secretary? If there be such an one, let him study the way the Privy Council (or their medical officer) used their newly-found powers when the Bye-laws and the Board of Examiners were matters under consideration. Surely it is humiliation enough that our Council were then compelled to rescind previous resolutions, and to enact laws referring to the internal economy of the Society which they did not approve, in order to save its whole machinery from being brought to a dead-lock by that body. If he wishes to know something of the Privy Council and their ideas of inspection, he might further study with advantage their relation to the medical profession in the matter of the Vaccination Acts; and if he desires to estimate the efficiency of their system as affecting public safety, he may find his data in the weekly mortality rates, or in a recent speech in the House of Commons by the Member for Westminster.

One word more, and I have done, and that on a subject which forbodes ill in its present aspect, namely, the want of unity which seems to exist between "town" and "country" interests, arising chiefly from want of knowledge of the various conditions of business. This was very manifest at the last anniversary meeting, not so much perhaps in respect to the "poison" question as in some others that were then discussed. Apart from principle, and the certainty of a system of inspection to follow, it can make little practical difference to the leading London chemist what regulations are made touching storage. He need hardly keep half the substances known as poisons, and his stock can be renewed at a few minutes' notice from his druggist or manufacturer; but it is a very different thing to men holding a similar position in small or middle-sized towns, and I am assured by some so situated that they find it almost impracticable to carry out faithfully even the regulations already in force under the Act.

The imposition of an irrevocable code of restrictions, whilst the present difference of opinion exists as to their general practicability, would be an act of great injustice; but let the Council of the Society recommend any well-considered scheme for voluntary adoption, and every chemist will give effect to it to the extent of his power. If this course were taken, no Parliament would sanction interference until it could be shown to be inefficient; and until then any compulsory legislation on the part of our own body is premature. Let town and country members pull together heartily, and we need fear little from outside.

Newcastle-on-Tyne, HENRY B. BRADY.
Feb. 20th, 1871.

POISON REGULATIONS.

Sir,—Much has been written in our Journal about the storing and dispensing of poisons; truly, it is a question of great importance to the trade, should the recommendations of Council be adopted, they will entail more and "quite unnecessary" labour. Surely our labours are more than sufficient for our remuneration. I do think the law, as it at present stands, is quite sufficient to guard the public against any mistakes. I should like statistics to be produced for the last twenty years of poisoning and suicides, and I dare be bound that a very small percentage has arisen from the carelessness of chemists.

As to the poison-closet, is it not likely to lead to more accidents, especially where young men are kept; for instance, one is preparing a prescription containing three active poisons, belladonna, aconite and morphia; he goes to this closet and takes out those three bottles, compounds his prescription, and in nine cases out of ten leaves those poisonous bottles on the counter: this might lead to very serious results; whereas, were those bottles on the shelves as at present (of course, marked "poison"), he would take one down, and replace it when done with. Indeed, my opinion is that all the arrangements for storing and dispensing medicines ought to be left entirely in the hands of chemists themselves. Surely, we as a body of responsible agents will and do take every precaution to guard against mistakes.

Chemists in every town ought to petition Parliament not to legislate in this most important matter, till the present law is found to be inadequate. Of course, it is of great importance to us to guard against mistakes, knowing the penalty, the forfeiture of our reputation, and perhaps the ruin of our families. This is more binding than closets or curious capped bottles, etc.

In conclusion, I hope the chemists in every town will bestir themselves and ask their representatives in Parliament to oppose such an absurd system in drug shops as poison-closets. Why, the whole shop might be placed in it, their name being "legion."

Liverpool. PESTLE.

Sir,—It was my intention to have written some strictures upon the "statement" of reasons sent out by the Society, but some of your correspondents—prominently Mr. Reynolds—have so clearly demonstrated its inconsistency, and so exhaustively treated the entire subject, that nothing remains for me but to enter my protest, along with my brother druggists, against any further restrictions being placed upon our trade, but more especially against the position taken by the Pharmaceutical Council in reference to this question. Had there been any real desire to "protect the public," the proposed regulations must necessarily have extended to all places where poisons were stored, and consequently to the dispensaries of public institutions, as well as to the "surgeries" of all medical men. It is by no means difficult to prove that the public safety would have been much better conserved by a strict surveillance of the last-named establishments than by any trade restrictions placed upon chemists and druggists. It is a notorious fact that the dispensing of medical practitioners is often carried on in the most flagrantly careless manner, and, so far as the poor dispenser is concerned, under the greatest possible difficulties. The entire "stock in trade" of a surgeon in what is termed a good practice will often not exceed five pounds sterling, whilst the heterogeneous character of the storing bottles would utterly appal the "public" were it admitted to a private *séance*. The most dangerous drugs or compounds may be seen standing side by side with the most harmless, both of them bearing a dirty paper label, illegibly written, and only distinguishable upon the minutest inspection. The morphia or strychnine will be dispensed by a neophyte in the shape of an errand-boy. Yet, forsooth, these "establishments" are to be exempt from any supervision, whilst the well-conducted and expensively-fitted shop or dispensary of the chemist, where neatness, order, cleanliness, and everything that is calculated to ensure the public against accident is strictly observed, must be periodically invaded by some officious Mr. Bumble. At whose instigation, I wonder, or for whose behoof are those changes to be made? To my mind, it seems something very like an "understanding" somewhere or other, which should be most vigorously protested against by the trade, and that, too, in good time. I should much like to see our Council change their position, and, instead of any "understandings" with the Medical Council, trying only to fulfil their trust by seeking to advance the practice of pharmacy, and to protect the interests of our trade.

CHEMIST.

[*** Whatever may be the proper view to take as to the proposed regulations, we cannot agree with the opinion that they should not be adopted because medical men neglect them. That argument, at least, appears to be fallacious.—ED. PHARM. JOURN.]

Sir,—So many opinions have been expressed in your Journal for and against regulations for the storage and dispensing of poisons that I almost blush to add to the correspondence, but the time seems to have arrived for inquiring, "What is it all about?"

We have had proposals, counter proposals, appeals to common sense, and appeals to the Council of the Pharmaceutical Society. We have "caught the ear" of the Council. A document is forwarded to us, setting forth the absolute necessity of passing poison regulations; and what is more, it assures us that the regulations, only passed, can become a dead letter. Is there any necessity to doubt the word of our Council after such a manifesto? Is it not apparent that the whole affair has been a practical joke, Mr. Simon and our Council shaking their sides with laughter while we have been shaking with apprehension. At least, no other conclusion can be drawn by

M.P.S. BY ELECTION.

Brighton, February 8th, 1871.

Sir,—Are pharmaceutical chemists considered capable of managing their own businesses, and is it intended to exempt "examined members" from the proposed restrictions regarding the storage of poisons (thus placing them on an equal footing with surgeons)? If not, of what earthly use is our Society, and for what purpose has our time and money been spent? I protest against interference on the part of a clique, who always want something to do, feeling convinced if personal considerations fail to ensure carefulness everything else must.

EDWARD BEEKS FORD.

Pontypool, Feb. 20th, 1871.

Sir,—May I ask why chemists and druggists are picked out by Government for surveillance by the Privy Council while oilmen, etc., though selling equally dangerous poisons unlabelled and without a caution, are permitted to go scot free?

GEORGE EADE.

72, *Goswell Road, February 16th*, 1871.

Sir,—Permit me, as an old hand, to suggest to the Council the propriety of sending a printed paper to each chemist in the kingdom, through the respective secretaries, to solicit their ideas relative to the using and storing of poisons; also to ascertain, as far as practicable, the number of deaths known to each, traceable to chemists.

I believe if this was done, the Council and also Government would be satisfied to leave us alone, and not burden us with rules and regulations, which, in the end, would produce more loss of life than there is under the present circumstances.

Cheltenham, February 17th, 1871. JOHN FINCH.

THE APPLICATION OF DISINFECTANTS.

Sir,—A few days since a Darmstadt physician called on me, and said that he had just arrived from Germany, in consequence of his brother having been seized with typhoid fever. The patient, a clerk in a City house, occupied good apartments, and his medical attendant desired that he should not be removed. The inmates objected to having their dwelling rendered uninhabitable by strongly-smelling disinfectants, and insisted on the use of an odourless disinfectant, or the removal of the patient. Under these circumstances I was asked to suggest what might be done. Chlor-alum was placed in cloths and in dishes in the room; it was diffused as a spray, and employed in the chamber utensils. The patient died, and the bedding and other articles were dipped in chlor-alum, then washed out in pure water, and lastly boiled and washed with soap and water.

My reason for publishing these details is to draw attention to the fact that the agents mentioned in your recent article,* with the exception of Condy's fluid, which is firmly believed by some good authorities not to be a fever-poison destroyer, could not have been used, and are often not used, when on sanitary grounds the application of a disinfectant is of paramount importance.

Since you have furnished a statement of the methods adopted in using carbolic acid, chloride of lime, sulphurous acid, and other disinfectants, it may not be uninteresting to your readers to have, in a few words, the rules which may be laid down for the employment of chloride of aluminium and its compounds.

We all know the importance of clearing a sick-room of superabundant furniture and trappings. If to light muslin curtains over the doors, windows and bed, cotton-wool or wadding, treated with chlor-alum, be pinned, antiseptic air-filters of great value are readily improvised.

A slight modification of Dr. Siegle's inhaler, made by Messrs. Krohne and Sesemann, of Duke Street, Manchester Square, affords a means for purifying every particle of air in a chamber by volatilizing a solution of one part of chlor-alum to twenty of water.

In the chamber commode and utensils some chlor-alum solution, or a powder which contains 30 per cent. of chloride of aluminium, will be of the greatest advantage. The late Mr. Francis Taylor, of Romsey, Hampshire, was the first to use chlor-alum powder in earth-closets, and wrote me repeatedly concerning the great efficacy of the material. He had long been seeking an agent for this purpose, and his untimely death prevented the fulfilment of a kind wish he had expressed of paying London a visit, with a view to discuss with me the whole subject of the disinfection of the excreta of the sick, and the application of the earth-closet system.

Dr. Septimus Gibbon was the first to draw attention to the fact that chlor-alum acted under certain circumstances very actively on vegetable fibres, and he was led to doubt its applicability to the disinfection of clothing. I have sought information from Manchester people, and was astonished to find that drying wet clothes before a fire, and many other simple expedients commonly resorted to, rotted the cotton fibre. This rotting is the bane of the bleacher. From the fact that we had used cotton-filters for months without injury to their structure, I was led to try some experiments, and I find chlor-alum the most harmless of disinfectants for clothes and bedding. The following rules must be attended to, viz.:

A solution of 1 part of chlor-alum (which is a 30 per cent. solution of chloride of aluminium) in 20, 30, or even 40 parts of water should be used in which to steep the articles to be disinfected. The longer they steep, the better; but a few minutes of complete submersion suffice. A golden maxim in disinfection is that liquid contact is more effectual for destruction than dry contact between fever germs and the disinfectant. The clothes thus steeped are allowed to drip, or the liquid wrung out of them. They are then placed in pure water, and, having been well steeped, may be placed again in pure water. Warm water washed the chlor-alum out most rapidly. After this, the articles may be boiled and washed as usual. The most delicate fabrics can be treated in this way, and not a particle of contagious matter can escape attack.

Chlor-alum, being odourless and harmless, can be used in the sick-room without danger or inconvenience.

JOHN GAMGEE.

1, *Great Winchester Street Buildings, E.C.*

* See *ante*, page 625.

Poisonous Confectionery.

Sir,—In your Journal of the 14th ult., you report a case in which two tradesmen at Dublin were fined for selling poisonous confectionery. I regret to say this practice is not confined to that city. A short time since I purchased some comfits of a most respectable tradesman in Oxford Street, and my suspicions being aroused by the brilliant colours of some of the sweets, I examined them and found that chromate of lead, vermilion and other metallic poisons had been used in their manufacture.

On complaining to the vendor, he expressed his regret, furnished me with the address of the manufacturers, and said he would at once close his account with them, although he had been a customer for many years.

Wishing to do my utmost to repress an evil so pernicious to the health of children, I addressed to the firm the following letter:—

"*January 26th*, 1871.

"Gentlemen,—I recently purchased some comfits for my children from Mr. —, but having some suspicion of their appearance, I have examined them, and find the colouring-matter to be chromate of lead, vermilion and other metallic ingredients of a poisonous character. On complaining to Mr. —, he has given me your names as the manufacturers. Should you be indifferent of the consequences likely to arise (especially to very young and delicate children) from swallowing such noxious compounds, I would remind you that by using such colouring matters in your manufacture, you render yourselves liable to a penalty. If you refer to the Pharmaceutical Journal of January 14th, you will find the report of a case just decided in Dublin, where two tradesmen were fined for using similar ingredients in confectionery.

"After this intimation I hope you will see the policy, if not influenced by better motives, to at once discontinue this objectionable practice; but should I find at a future examination that these poisonous compounds are still used by you, I shall consider it my duty, in every possible way, to aid in the suppression of an evil, the extent of which we can hardly estimate.

"I am, gentlemen, your obedient servant,
"J. Robbins."

To which I received the accompanying reply:—

"*London, January 27th*, 1871.

"Sir,—In reply to your letter respecting colours used in our trade, we beg to say that the public have it entirely in their own hands; for example, in an article called barley-sugar, there is not a particle of colour in it; how much more wholesome to have that and several others without these glaring colours! which, we are informed MUST contain more or less of some chemical, which, if not prejudicial, at least has a tendency that way. We have our colours from Messrs. ——, who are perfectly aware that any deleterious compound would be injurious to us, if it made children ill (for our trade lies to a great extent amongst the youngsters); we, therefore, always impress upon them to let us have our colours as free from these noxious ingredients as possible.

"If you can suggest to Messrs. —— what to send us (that will answer our purpose), for we are only too anxious ourselves that the articles should not only please, but be beneficial to children's health, though, perhaps, not to their teeth. No one can have eaten many more of these goods than ourselves, and yet our health is in first-rate condition.

"We heartily wish the public would have all white goods, it would be a valuable boon to us, but we fear they will not.

"We are, Sir, yours respectfully,

"Mr. Robbins."

My remonstrance with the vendor may, I think, be considered satisfactory. So much can hardly be said with regard to the manufacturers, who it would appear are determined to supply a demand only maintained by the ignorance of the public.

January 30th, 1871. J. Robbins.

The Microscope and its Revelations.

Sir,—Referring to Dr. Carpenter's able lecture on the above subject, wherein he states, "If any of you are disposed to begin the study of the foraminifera, and will get the sponge merchants to give you the sand that they shake out of their sponges, when these *come over*, you will find an immense variety of foraminifera, which will give you plenty of occupation; and there is nothing more easy to begin upon than this sponge sand."

I beg to inform those readers of your Journal who are interested in this valuable and instructive study that I will give them as much sand as they desire on application, or will send by post on receipt of stamps to pay postage.

It is a matter of considerable pleasure to be able to assist in such a study. Fredk. Hovenden.

93 and 95, City Road, Finsbury Square, E.C.

York Chemists' Association.

Sir,—In reply to the inquiries of your correspondent "Excelsior," of January 28th, 1871, I may inform him that the York Chemists' Association is still in existence, with its President, Secretary and Treasurer and members. Amongst its members are some of the best and ablest Pharmaceutical Chemists of this city, who, from their experience and knowledge, are well able to superintend classes of Materia Medica Chemistry and Botany for the advancement of pharmaceutical education among the assistants and apprentices connected with the trade. It has been said we English live in an age of wind-bags and are all going away into wind and tongue. I am sorry to say that, in my opinion, the York Chemists' Association is no exception to this rule. Nearly two years ago the same question now asked respecting this Association was brought before the members, who, I believe, talked of doing something to advance the education of those under their charge, seeing that the examination had become compulsory; but it ended in talk, for the second winter has nearly gone by and nothing has been done as yet. Circulars were sent out convening a meeting of the Association a short time ago, at which the attendance of the members was particularly requested. Let us hope they are going to bestir themselves.

The York Chemists' Association might be made the means of doing a great amount of good among the young men connected with the trade. I believe they are not far behind other provincial towns in the knowledge they possess of their business, yet there is always something more to learn.

York, February 7th, 1871. An Assistant.

"*Senega*" (Nottingham).—Alkalies, or any substances containing caustic or carbonated alkalies, would be incompatible with chloral hydrate.

"*Dolore*" should apply to the Registrar.

J. W. Lasham.—We should not think you were liable to pay duty for a still which is kept for the purpose of show as you describe.

A. Plummer (Hereford).—We do not know of such a work.

"*Galen.*"—The formula has been recently printed in this Journal, 2nd Series, Vol. XI. p. 663.

A. P. S.—A description of the principal characteristics of the Natural Orders mentioned is required. There is no particular reference to the work mentioned by you.

H. H. Pollard (Ryde).—(1.) The Lectures on Fermentation are concluded. (2.) The name is not on the Register at the address stated.

A. P. S. (Swindon).—The question as it stands is too vague for the Notes and Queries column.

"*Amicus.*"—"*Croco,*" without the accent, is the correct form.

*** Owing to want of space we are unable to answer several inquiries.

CHLORAL HYDRATE AND CHLORAL ALCOHOLATE.

$C_2Cl_3HO, H_2O.—C_2Cl_3HO, C_2H_6O.$

BY DR. F. VERSMANN.

The sale and use of chloral hydrate has of late so largely increased, that it becomes necessary to be quite certain of the quality of the articles, and of the exactness of the method of testing it. In analysing a great many samples, from, I believe, almost every maker, I was naturally led to inquire into the physical properties of the hydrate, and also of the chloral alcoholate which may possibly be met with in the market as a substitute for the former.

Dr. Paul, in his article in this Journal of 4th ult., has drawn attention to the difference in the crystalline forms in which the hydrate is sold; this is, no doubt, owing to the different solvents employed for recrystallization. Thus, a concentrated aqueous solution, placed under the air-pump, gives rhomboid crystals, ether gives small hard crystals, acetone fine needles, warm benzole supersaturated deposits on cooling also fine needles; whereas a solution in benzole, allowed gradually to evaporate, deposits large crystals sometimes ½ in. long. Bisulphide of carbon in same manner yields either fine needles or large crystals. A saturated alcoholic solution gives beautiful long feathery crystals. I obtained some 1½ in. long, which have all the appearance of the alcoholate, and which were found to be so. This is remarkable, and may possibly account for the fact of one sample, obtained as hydrate, being pure alcoholate, as the manufacturer may have recrystallized the impure hydrate from alcohol without being aware of the change produced.

The hydrate is extremely hygroscopic, the more so the smaller the crystals are. 10 grains of fine needles left in an open vessel became quite fluid in a day, whereas the same quantity of hard crystals became only opaque, and again transparent the following day. But in both forms the compound is so volatile at ordinary temperature, that the first had completely evaporated after five days, carrying away with it the moisture absorbed, and the last in eight days.

The hydrate is extremely soluble in water, 100 parts of water dissolve as much as 360 parts of dry crystals; the alcoholate is also soluble in water, but to a much smaller extent, and much slower.

In fact, the two may be readily distinguished in the following manner:—Take a pretty wide beaker-glass, 6 or 8 in. high, full of water, drop a few crystals into it: the hydrate sinks down at once, and is almost dissolved before it reaches the bottom. With the alcoholate the larger crystals only will sink to the bottom, and lie there for several minutes before they gradually and very slowly disappear; but small crystals or fragments of crystals will float on the surface of the water, and as soon as they are attacked by the water, the slight current of the saline solution sinking down occasions sufficient disturbance to apparently impart life to the solid particles, —they begin to spin round and round, and dart from one side of the beaker to the other, until the very last solid particle has disappeared. This is not only a very pretty and amusing sight, but it is really a distinctive mark between the hydrate and the alcoholate. Slightly tepid water makes the action even more violent.

The specific gravities of solutions in water of the two compounds also show a great difference, as will be seen by the following figures:—

Temp. 15·5° C. (60° F.)	Hydrate.	Alcoholate.
20 per cent. solution . . .	1085	1072
15 ,, ,, . . .	1062	1050
10 ,, ,, . . .	1040	1028
5 ,, ,, . . .	1019	1007

The specific gravity of the two substances in the liquid state is another criterion, that of the hydrate being 1610 at 49° C. (120° F.), and of the alcoholate 1143 at 40° C. (104° F.)

I do not attach any value to the boiling-point as a test for purity, and for this reason. Both hydrate and alcoholate at that temperature begin to decompose into chloral and water or alcohol respectively, and it is sometimes extremely difficult to take correct observations. I have had undoubtedly good samples of hydrate commencing to boil only above 100° C., and of alcoholate commencing to boil at 80° C.

So far I have treated the two substances separately, but if the alcoholate really should be introduced as an adulterant, the direct proof of alcohol will become necessary. For this purpose Lieben's method is the best, who converts the alcohol into iodoform, and detects minute quantities.

All the samples I have hitherto had occasion to test were true chloral hydrate, with the exception of one; but they varied very much in the percentage of moisture, and for this reason it is necessary to have a ready and accurate method of determining the percentage of true hydrate in a sample.

We now know only the ammonia test. This method, if properly carried out, is sufficiently exact to decide between hydrate and alcoholate, where the percentage of the resulting chloroform differs as much as 72·2 and 61·76; but it cannot claim analytical accuracy.

The column of ammonium formiate solution always takes up some chloroform, and the chloroform layer is never free from water; chloroform is dissolved while it separates from the ammonia, and its true percentage invariably decreases.

It has also been suggested that during the twelve hours contact of the ammonia and chloroform, the last might be further decomposed into hydrochloric and formic acid; but this I find not to be the case. Experiments made with chloroform and ammonia and with chloroform and pure water gave in both cases a loss of chloroform amounting to 0·2 c. c., the same well-stoppered tubes being used as in the analysis of hydrate, of which always 10 grammes were taken. It is evident, therefore, the decrease in chloroform is not owing to the action of ammonia, but to its solubility in water.

This and the length of time required for the ammonia test are certain drawbacks; and I have tried another plan, which is both more accurate and more expeditious.

I take advantage of the facility with which the chloral hydrate and the chloral alcoholate are decomposed by strong sulphuric acid with separation of chloral, which, in a graduated tube, may be read off and the percentage of hydrate calculated.

I take about equal parts by weight, *i. e.* 10 grammes of the hydrate and from 5 to 6 c. c. of sulphuric acid; the quantity of the acid is of no consequence within certain limits; 5 parts of hydrate and one part of acid do not separate chloral, even when heated. And again, a great excess of acid, such as 5 parts of acid and 1 part of hydrate, does not give a satisfactory result; neither the chloral nor the acid becomes clear, perhaps because of the formation of chloralide.

But as the result of a series of experiments, I find that about equal proportions by weight act very satisfactorily. The acid after combination with the water of the hydrate and the resulting chloral are not so widely different in their specific gravities as to immediately separate; I, therefore, prefer to warm the mixture to expedite the separation.

In a graduated tube provided with a well-ground glass stopper and graduated into 0·1 c. c., I introduce from 5 to 6 c. c. of sulphuric acid, and heat it by placing the tube into a vessel of water of about 60° C. (140° F.); I then add 10 grammes of chloral hydrate, shake well, so as to cover all the hydrate with the acid, and put the tube back into the hot water. The decomposition is instantaneous, and the two liquids separate very distinctly; the chloral floating at the top may be read off as soon as the tube has cooled down to the proper temperature. After an hour or so the two liquids begin to mix again, and in about twelve hours the chloral is changed into metachloral, a substance of exactly the same chemical composition as chloral, but solid and absolutely insoluble in water and alcohol.

I find the previous heating of the acid most convenient, because, just as in the combination of chloral and water very considerable heat is evolved, so in the taking away of the water by sulphuric acid an immense amount of heat is absorbed, and the cold produced is so considerable as to seriously interfere with the separation of the chloral. Determinations with numerous samples, both with the ammonia test and the sulphuric acid test, always gave a somewhat higher result with the last, which is more correct.

For this reason, and also because the whole operation may be completed in a few minutes, I prefer it to the ammonia test. In a subsequent paper I intend publishing the corresponding results of the two methods.

THE DEVELOPMENT OF ERGOT.

BY M. C. COOKE, M.A.

There is probably no article in the whole range of Materia Medica, concerning which more has been written than ergot. This is a very rough guess, and would exclude even the cinchonas from the first place, so that the guess may hardly stand the test. At any rate, a great deal has been written about ergot, much of which is now forgotten. A curious and startling catalogue might be compiled of the titles of books, memoirs and communications on this almost threadbare topic. Yet, in the face of this, we are seated, in a deliberate mood, to add another chapter to the long story of ergot. This chapter is intended to be devoted wholly to one phase of the subject, which is, the "natural history," or plant-development of the fungus.

We will say nothing of the difference of opinion as to the ergot itself being a transformation of the germen, or a parasite of the germen, but start at once with the *Secale cornutum*, as the first stage. In this condition it is called by botanists a *sclerotium*, and this particular one is *Sclerotium clavus*. What is to be understood by a *Sclerotium?* is a very natural question to suggest itself. It will not do to pass it as a generic name, since it has no value as a genus, and even were it not so, the answer would be insufficient. Fungi are known to be developed in the majority of instances, from certain root-like filaments called mycelia. Sometimes these filaments are very much compacted, and in the present, and some allied instances, assume the form of a compact cellular mass called a sclerotium. So that a sclerotium is, in fact, a compact mycelium, a sort of bulbous mycelium, of variable shape. Such is ergot. Whether produced on wheat, rye or the grasses, this sclerotium differs very little in form, being horn-shaped, whilst other kinds of sclerotium are spherical, discoid or irregular.

The earliest condition of this species is manifested by the presence of a thick gummy matter on the spikes of corn or grass, and this contains granules. During the growth of the sclerotium it is invested by a coating described in detail by Professor Quekett, in a memoir devoted by him to this subject. What the relation is between the gummy matter and the sclerotium and its coating is uncertain, unless it be accepted that the sclerotium is developed ultimately from the base of a spermogone, which, in the first instance, exuded spermatia in the aforesaid gummy mass. The coating was considered a distinct fungus, parasitic on the ergot, by Quekett, and called by him *Ergotetia abortifaciens*, whilst Berkeley retained it in *Oidium*, with the same specific name. It is now regarded as the spermatiferous condition of the complete fungus. Quekett described this coating as consisting of minute bodies, which are seen, separated from each other, when they are removed from the ergot, but when viewed in their natural situation they are occasionally united by their extremities forming short moniliform filaments, technically "Sporidia (spermatia) elliptical, moniliform, finally separating, transparent, and containing seldom more than one, two, or three well-defined (greenish) granules."*

Another view taken of the relations of the sclerotium with other fungi is, that the species of *Fusarium*, described by Nees, under the name of *Fusarium heterosporium*, produces, in its supposed spindle-shaped spores, the *spermatia*, and that the simple bodies produced on the sclerotium (the *Ergotetia* of Quekett, and *Oidium* of Berkeley) are the conidia of the fungus ultimately developed from the ergot. Never having had the opportunity of watching the growth of the ergot carefully, we shall not venture an opinion on the identity of all the bodies supposed to be connected with the reproduction of this species, and called by numerous names.

The ultimate stage consists in the growth of little stalked bodies with rounded heads from and upon the sclerotium. If ergot of rye, wheat, etc., be slightly covered with soil in spring (March or April), and kept moderately moist with rain water, in the course of time a crop of these stalked bodies will be produced, but patience is quite necessary, for six months may be required for their growth. These are the *Cordyceps purpurea*, or *Claviceps purpurea*, by which name the whole of the forms of this polymorphous fungus should be called. Hence we have the stroma, or compact mycelium (sclerotium), conidia, spermatia,

* E. J. Quekett, "On Ergot of Rye," etc. Linn. Trans. vol. xviii. p. 453.

and finally the ascophores containing the sporidia, and all appertaining to *Claviceps purpurea*, Tulasne.

The ascophores, or stalked bodies with globose purplish heads, are minute and delicate, several of them being often produced upon the same sclerotium. The globose head is the fruit-bearing portion. Numerous cells, with distinct walls (perithecia) are immersed in the substance of the head. Each of these cells contains a mass of long, narrow, cylindrical, transparent sacs termed asci, which are thickened at their apices. Each ascus enclosed eight hair-like sporidia, flexuous and delicate, slightly attenuated towards each end. This is the final and highest development which the fungus attains. A closely allied species is found on the sclerotium of reeds, and another on the sclerotium of *Eleocharis*,—the latter, as far as we are aware, never having been found, except as a sclerotium, in Britain.

This is a brief and rapid survey of the stages in the history of ergot. It would be an interesting and probably instructive experiment, for those who are only acquainted with *Secale cornutum* as one of the articles of materia medica, just to follow the plan we have indicated, and try the cultivation of the sclerotium. It is possible that the examination of the fresh condition of the *Claviceps*, under the microscope, may reveal a phase of vegetable life before unknown to them. Even as a mere curiosity, and nothing more, the labour is but little that is required to grow the ergot-fungus, and, should this be successful, an effort might be made to develope the kindred species from the ergot which is so common on *Eleocharis*,—the success of the latter effort would add a third species of *Claviceps* to the British list, and this would be some reward for the trouble expended.

THE TESTS FOR CHLORAL HYDRATE.

BY C. H. WOOD, F.C.S.

Having had occasion during the last few months to examine a number of samples of chloral hydrate, I have made a great many trials of the ammonia test described by Mr. Umney. This method possesses the apparent advantage of simplicity; but, to ensure accuracy, several precautions which are somewhat tedious, must be carefully observed. Dr. Paul, in the paper recently published by him, has shown that, unless the mixture be warmed for a considerable time and frequently shaken, a result either too high or too low may be obtained. That exactly confirms my own experience. Moreover, the large quantity of material required for each operation, and the length of time (about 12 hours) which must elapse before the results are obtained, constitute considerable inconveniences. I have therefore had recourse to another method for determining the yield of chloroform, which appears to me to possess several advantages. A hundred grains of the chloral hydrate to be tested are introduced into a 4-oz. flask and dissolved in an ounce of water. Thirty grains of dry hydrate of lime are then added, and a cork, furnished with a long piece of glass tube, is fitted to the mouth of the flask. This tube is bent over just above the cork, so as to slant down and form a condenser. It is surrounded with wet blotting-paper during the experiment. The extremity of the tube is somewhat drawn out, so as to enter a graduated tube, which serves as a receiver. A gentle heat is then applied to the flask and the chloroform slowly distilled over. After a few minutes the heat is increased, so as to keep the mixture boiling, and continued until about 100 grain measures have been collected in the receiver. By this means the steam thoroughly displaces and sweeps over the last traces of chloroform. It is only necessary to read off the volume of the chloroform obtained. Before taking the final reading, it is advisable to keep the tube in a vessel of water exactly at 60° F. A few drops of liq. potassæ poured into the tube destroys the meniscus of the chloroform, and enables the operator to read off very accurately. The whole process does not occupy a quarter of an hour; and, as far as my experience goes, the results obtained are very trustworthy. If a larger quantity of lime be employed than the amount indicated, some inconvenience is experienced from the frothing of the mixture, but this is easily avoided. Milk of lime appears to exercise no sensible action on chloroform. I have made several experiments in which known volumes of chloroform have been taken in the place of the chloral hydrate, and in every case I have obtained the proper amount back within about a single grain measure. The tube which I employ as a receiver was carefully graduated for the purpose. It is about ten inches long and a quarter of an inch in internal diameter. It was graduated by introducing a few drops of liq. potassæ, and then running in pure chloroform at 60° from an accurate burette, marking the tube with a file after every addition of ten grains measurement. Five such marks are all that is required. The space between the fourth and fifth mark may be easily divided afterwards into ten equal parts.

For the recognition of alcoholate in chloral hydrate I have always employed Lieben's test for alcohol, which answers the purpose easily and satisfactorily. It is best applied to the aqueous portion of the distillate accompanying the chloroform. If this supernatant layer be decanted into a test tube and warmed with 2 or 3 grains of iodine and a slight excess of liq. potassæ, a crystalline precipitate of iodoform will gradually form when only minute traces of spirit be present.

As far as my experience goes, the alcoholate is not, if it ever has been, an article of commerce.

For several reasons it is desirable to take the yield of chloroform as a criterion of the quality of chloral; nevertheless it does not appear to me necessary to resort to this quantitative reaction in the ordinary examination of trade samples.

The following simple tests, which are quickly and easily performed, constitute a sufficient guarantee of the purity of commercial chloral hydrate:—

1. A small portion heated on platinum foil should entirely volatilize without leaving any visible residue.

2. Twenty grains dissolved in a drachm of distilled water should form a perfectly bright and clear liquid. A drop of nitrate of silver solution added should produce no turbidity.

3. A drachm introduced into a test-tube furnished with a cork, through which passes a thermometer and

a small outlet tube, should boil, on the application of heat, without the temperature rising above 212°F.

The boiling-point is a very important character of chloral hydrate, and should never be neglected, even when the chloroform test is also employed. It will at once distinguish between the hydrate and alcoholate. Moreover, some samples of hydrate, in which no alcohol can be detected, nevertheless boil at too high a temperature. This is probably due to the presence of some chlorine substitution-products other than chloral. A recent editorial article in this Journal ascribes the low yield of chloroform sometimes obtained, to the moist condition of the samples. No doubt a slight excess of water is frequently present, and forms a very unobjectionable constituent. But while an excess of moisture would diminish the percentage of chloroform, it would not raise the boiling-point above 212° F. It is on this account that I regard the boiling-point as being in some respects a better and simpler test for ordinary use than determining the chloroform.

SPIRITUS AMMONIÆ AROMATICUS, ITS PREPARATION AND COMPOSITION.

BY WILLIAM MARTINDALE, F.C.S.

The attention of the trade having been called to this preparation by a medical contemporary, in an article in which it complains that samples purchased at several chemists, were notably deficient in ammonia and spirit,—by way of testing the correctness of its results, I have been led to perform the following experiments :—

(1.) Having powdered 8 oz. of carbonate of ammonia, dissolve it in 16 oz. of water by means of 4 fluid ounces of strong solution of ammonia, sp. gr. 0·891. This will form a clear solution, but on the addition of 6 pints of rectified spirit, and the essential oils, such a precipitation takes place of ammonia salts that it forms a complete magma of the whole fluid. The product of the Pharmacopœia process would resemble this, if it contained all the ammonia, carbonic acid and spirit ordered to be used. (2.) Let the experiment be repeated, using 2 pints of water in place of 16 oz., making a solution of the carbonate in the water and strong solution of ammonia, as before, first. It will now be found, that on the addition of the spirit, a bright and clear mixture is formed; but when the fluid has been allowed to stand, a quantity of minute acicular prisms, crystals of normal ammonium carbonate (?), will have deposited. And again (3), let the Pharmacopœia quantities be taken, *i.e.* the same as above, but using 3 pints of water. Having dissolved the essential oils in the spirit previous to the addition of the solution of ammonia salts, it will be found that a milky, opaque mixture is formed, due to the separation of the oils,—the spirit not being then strong enough to hold them in solution,—but there will be no crystalline deposit at ordinary temperatures. On proceeding to distil the mixture, in the first portion of the distillate there is always a more or less quantity of crystalline formation noticed in the receiver, but that, as the process is continued, is redissolved. Having obtained the required quantity,—7 pints of distillate,—upon examination of what remains in the still, upwards of two pints of fluid, that will still be found to contain a quantity of ammonia, in fact, an equal volume of it will be found to contain about one-third as much as there is in the distillate. And if, especially on a large scale, the process be not carefully conducted, this liquid, on cooling, may sometimes contain a quantity of mixed salts of ammonia, not held in solution. It is, in fact, found to be impossible to have the distillate to contain more than about 1·7 per cent. of ammonia without its being deficient in carbonic acid. To quote Dr. Divers*:—"By following the directions in the British Pharmacopœia to use, solution of ammonia and commercial carbonate instead of pearlash and sal-ammoniac, the formation of a spirit containing excess of ammonia is favoured, but to only a small extent. The spirit thus obtained is, of course, equally liable, if too strong in alcohol, to decompose into a basic solution and half-acid or acid carbonate, as I ascertained by preparing it." He previously states that it not unfrequently proves to contain much less carbonate than it is intended to contain.

TEST FOR ARSENIC.

A new and very delicate test for arsenic has been discovered by Bettendorff. Its sensibility is so great, that it is said to be capable of detecting one part of arsenic in a million parts of solution, and the presence of antimony does not affect it. In order to apply this test, the arsenious or arsenic liquid is mixed with hydrochloric acid until fumes are apparent; thereupon stannous chloride is added, which produces a basic precipitate, containing the greater part of the arsenic as metal, mixed with stannic oxide.

ARTIFICIAL INDIA-RUBBER.

Prof. Sonnenschein has discovered that an elastic mass resembling caoutchouc may be obtained by combining tungstate of soda with certain organic substances. If tungstic acid or tungstate of soda be added to glue, and afterward muriatic acid, a compound of tungstic acid glue is precipitated which is so elastic at 85–105° F., that it can be drawn out into very thin fibres. On cooling, the mass becomes very solid and brittle. It is proposed to employ this substance in place of the costly albumen for mordanting cotton, especially for aniline colours.

The same material has been used in tanning leather; but this became hard as stone, and consequently unsuitable for ordinary purposes. By adding tungstate of soda and muriatic acid to a solution of gelatine, and heating the precipitate, a substance is obtained which may be used as a putty or cement in many cases.—*Manufacturer's Review.*

USE OF THEINE AS A THERAPEUTIC AGENT.

BY LEWIS THOMPSON, M.R.C.S.

I wish to direct the attention of the medical profession to the use of a valuable agent which has hitherto escaped notice, although its powers are most unquestionable, and its cost price very trivial. The article to which I allude is theine, a substance existing in tea and coffee, and, as I believe, in many other vegetable products. As a medicine, theine is powerfully tonic and stimulant, and appears to possess the tonic virtues of the disulphate of quinia united to the stimulating power of wine, but with this difference, that the stimulus from theine is not followed by depression, as in the case of wine and alcohol.

Theine seems to act chiefly on the great sympathetic

* Divers on the Combinations of Carbonic Anhydride with Ammonia and Water.

or ganglionic system of nerves, and but slightly on the brain. I have used it in doses of from 1 to 5 grains, with very marked advantage in the low stage of typhoid fevers, confluent small-pox, and that form of mortification of the toes which is so singularly fatal to old people. But, in addition to this, different medical friends of mine have found it useful in hemicrania, neuralgia, and what has been called relapsing fever; and in the case of an overdose of opium, it appeared to relieve the narcotic symptoms speedily. With regard to the cost of this medicine, I have discovered that in the ordinary process of roasting coffee the whole of the theine is driven off before the torrification of the coffee is completed, and this theine may be cheaply collected by making the axis of the coffee-roaster tubular. If, instead of a solid axis, we employ at one end of the roaster a tube passing away to the distance of about three feet, the theine is condensed in this tube by the refrigerating power of the atmosphere, and may afterwards be easily dissolved out by a little water, and purified in the manner about to be indicated. As the result of much experience, I have obtained, on an average, 75 grains of theine from the roasting of one pound of raw coffee; and when we reflect that in Great Britain alone there are more than 13,000 tons of coffee roasted annually, we see that about 140 tons of theine are wasted and lost every year by sheer ignorance. It may, perhaps, be thought that the saving of the theine will damage the flavour of the coffee, but from experience I know that it has no such effect; and, in point of fact, it is an advantage to the flavour of the coffee to make both the axes of the roaster tubular, and to cause a gentle current of air to pass through the apparatus during the roasting of the coffee, so as to expel the empyreumatic products as they are formed. I will now relate the fact upon which the purification of theine depends; and when this is once clearly understood, the manufacture of theine from either tea or coffee becomes an extremely simple matter. Theine is absolutely insoluble in a concentrated solution of the carbonate of potash, and thus we may precipitate it from its admixture with sugar, mucilage and vegetable extract. If, then, by means of the subacetate of lead, we have removed from a vegetable infusion the tannin, malic acid, etc., we have only to evaporate the filtered solution to a small bulk, and add to it its own weight of dry carbonate of potash, and the whole of the theine becomes at once insoluble; so that, having collected this insoluble product, and boiled it in rectified spirit of wine, we have a solution of pure theine, which, after distilling off the spirit, furnishes crystals fit for immediate use. In conclusion, I will merely mention a distinctive test for theine, sufficiently delicate to detect the one-thousandth of a grain of that substance. Dissolve the theine in a small quantity of water, and pass through this a stream of euchlorine, then allow the fluid to evaporate at a steam heat; a blood-coloured substance will remain, which, on the application of a few drops of cold water, forms a beautiful scarlet solution like red ink. It is, I apprehend, almost unnecessary for me to say that euchlorine gas is formed by the action of hydrochloric acid upon the chlorate of potash.

I ought, perhaps, to add that theine, collected as a waste product from coffee, and purified by myself, has cost me less than threepence per ounce troy.—*Medical Times and Gazette.*

AMERICAN DRUGS.

BY C. LEWIS DIEHL.

To write an article upon a subject that has not been completely investigated is, perhaps, the most unsatisfactory task imaginable, and this appears to be allotted to me in the present paper. When I accepted query 23, for 1868, I had no idea of the difficulties to be encountered in its proper solution. Apart from those of a purely personal character, I have met with the greatest difficulties in obtaining answers to inquiries from parties who could, if inclined, have given the desired information. Yet some little information has been obtained, which, however meagre, I propose to give in the following.

My sources of information are various. In some few instances I have received responses from those directly or indirectly engaged in the collection of indigenous drugs; but generally I have been obliged to depend upon that obtainable from wholesale dealers, to whom consignments had been made by parties doing business with them.

It is a remarkable fact that our Louisville wholesale druggists depend upon the New York markets for their supplies of indigenous drugs, many of which abound and frequently are collected in our immediate neighbourhood. Our retail dealers are supplied with limited quantities by several gatherers living among the range of hills in the neighbourhood of New Albany, Ind., known as "the Knobs." Formerly there was a lively trade in indigenous drugs in New Albany; but such is not now the case, and the drugs gathered in its neighbourhood find their markets no further than our city. Our immediate neighbourhood, on the Kentucky side, also contributes to our supplies through a few small gatherers, chiefly Germans; but taken altogether, our home supplies far from meet the demand of our retail trade, and generally bring better prices than those obtained from a distance.

The drugs principally collected in our neighbourhood —of which the largest part among the Knobs near New Albany—are: *Podophyllum*, *Leptandra*, *Caulophyllum*, *Lobelia*, *Cimicifuga*, *Gelsemium*, *Ulmus*, *Stillingia*, *Xanthoxylum*, *Phytolacca*, *Asarum canadensis*, *Cornus florida*, *Panax*, *Aralia nudicaulis*, *Aralia racemosa*, *Sambucus*, *Cataria*, *Mentha piperita*, *Hedeoma*, etc., and limited quantities of *Serpentaria*, *Spigelia* and *Senega*. These abound also, and are collected, in the counties of Shelby, Monroe, Brown and Morgan; and one of our principal establishments has lately negotiated for a full line of indigenous drugs from Pembroke, Kentucky.

My information seems to indicate that the mountainous regions of Kentucky, especially Eastern Kentucky, contribute largely to the supplies of our Western dealers in indigenous drugs. From East Tennessee and Western Georgia large quantities may be, and undoubtedly are, obtained. Several years ago I had offers from a party in Chattanooga of quite a line of indigenous drugs. Where they find their market I am unable to say, but incline to the belief that the principal collections reach New York by way of Savannah, Ga. In many of the Southern States this branch of trade appears to attract considerable attention since the war, mainly in mountainous and swampy sections. In the neighbourhood of Walhalla, South Carolina, quite a brisk industry has sprung up, and large shipments are made from there to New York, through the agency of Charleston firms. The drugs collected there may be enumerated in the following:—

Panax, *Senega*, *Cypripedium*, *Liatris spicata*, *Spigelia*, *Sanguinaria*, *Aralia nudicaulis*, *Aralia racemosa*, *Asclepias syriaca*, *Asclepias tuberosa*, *Rumex*, *Podophyllum*, *Hepatica*, *Rhus*, *Rubus villosus*, *Cimicifuga*, *Marrubium*, *Stillingia*, *Spiræa ulmaria*, *Aletris*, *Convallaria Polygonatum*, *Tussilago Farfara*, *Phytolaeca*, *Ulmus*, *Goodyera pubescens*, *Frasera carolinensis*, *Arum*, *Solidago odora*, etc.

Occasionally consignments of *Senega*, *Serpentaria* and *Spigelia* reach our markets from Arkansas direct. Several years ago I purchased several bales of *Senega* and *Spigelia*, consigned to one of our wholesale houses from Ozark, Arkansas. It proved to be a poor investment, as the interior of the bales consisted largely of stems, and had to be garbled. The drug-gatherers of the Southern States being generally small farmers and negroes, make no regular profession of it, and only collect as their time permits; hence the difference in the yield of these drugs between one year and another. They are disposed of by them to the nearest country storekeeper, who on his part consigns them to the wholesale dealer with whom he may happen to do business. I am told by reliable informants that the drugs collected in the Red River districts seldom reach our markets except by way of New Orleans and New York, and that when they do reach us direct, they are generally inferior in quality. One of our principal wholesale drug-houses buys its supplies of indigenous drugs exclusively from a New York firm, and nearly all of the others depend upon the same firm when they cannot obtain bargains nearer home. When first making inquiries regarding the collection of indigenous drugs, I met with the invariable response, "*Inquire in New York.*"

Regarding the method of collecting and preparing the drugs for market, I can give you but little direct information. I have before me a circular addressed to drug-gatherers by one of our principal Western dealers in indigenous drugs, from which I extract the following:—

"Most medicinal roots are perennial (that is, the roots continue more than two years, whether the leaves continue or not), and should be gathered any time between maturity or decay of the leaves or flowers, in the summer or fall, and the vegetating of the succeeding spring. Biennial roots, or those that live but two years (like burdock and yellow dock), should be collected of the growth of one year,—any time between September and the time they commence running up to seed in the following spring.

"Barks should be gathered as soon after they will peel in the spring as possible and all the moss carefully removed. It is usually best to fell the tree and remove the moss while the bark is on the tree.

"Leaves and herbs should be collected just before they mature and before they begin to fade; the stems and stalks rejected, as when dry they are a hard, woody substance, nearly inert.

"Flowers when they first open; and

"Seeds just before they are quite ripe, as they, like leaves and flowers, ripen after being gathered.

"Roots should be thoroughly cleansed from dirt and foreign substances, and if large, like Indian turnip, etc., sliced.

"All the above articles should be dried; the sooner the better. For the first few days it is best to expose them to the sun and air, avoiding any dew or dampness; then spread around on floor and shelves, watching them to see that they do not heat by being piled too thick, till nearly dry. Most roots require from three to six weeks to dry sufficiently to be safe.

"For shipping, it is best to pack them hard in coffee-sacks or large gunnies and burlaps; the next best is good flour-barrels."

These circulars appear to be distributed with great circumspection among herb-gatherers and country stores throughout the Southern and Western States, and in all probability serve as a guide to the gatherers. The few gatherers with whom I have been able to converse personally, proved very slow to give information, but from their conversation I judge that they preserve their collections on the general principles above specified.

It is a matter of sincere regret with me that I have been unable to do more than the foregoing towards the solution of this question; but I feel sufficient interest in it not to let the matter rest where it now stands, and shall do all in my power to give a better answer at the next meeting of the Association.—*Proceedings of the American Pharmaceutical Association*, 1870.

Cure for Corns.—A slice of lemon, secured by a strip of cloth to the part affected, will generally have a beneficial effect.—*New York Druggists' Circular.*

BHANG- AND OPIUM-EATING IN INDIA.*

The saying that every race finds out for itself some stimulant—alcohol for Northern Europe, coffee for Arabia, bhang for India, opium for China—is trite enough and, on the whole, true enough. In India, where the common hemp plant (*Cannabis sativa*) grows freely and acquires properties unknown here, its use as a stimulant and narcotic is of high antiquity. It is prepared in various modes, and is swallowed or smoked—as churrus (the concrete resinous juice of the plant), as gunjah (the dried plant retaining its resinous juice) and as bhang (the larger leaves and capsules without the stalks). So different are the effects of these from those produced by the home-grown plant, that it has been customary to speak of the Indian variety as *Cannabis indica*, as if the species were different; but it is not so. The name "bhang" is also given to a narcotic liquor prepared from the hemp, which in this form is largely consumed. From it is prepared a sweetmeat called *majoom*, which also contains ghee and sugar. The bhang-drinking is had recourse to because alcoholic beverages are forbidden by both the Hindu and Mohammedan religions, and gunjah-smoking is used for a like purpose. Gunjah is never smoked alone, but is kneaded with tobacco in the palm of the hand, and when lighted in the pipe the smoke is inhaled in long whiffs. As usual, under such circumstances, a speedy renewal of the dose is necessary to prevent subsequent depression, and so the hemp-eater, like the opium-eater, soon becomes confirmed in the use, or rather the abuse, of the drug. Whilst it lasts, the intoxication produced by hemp is of a pleasant kind—a feeling of lightness and as if the spirit was no longer connected with the dull body, is common. It was the drug employed by the Old Man of the Mountains to give his followers a foretaste of Paradise, and thus secure their infallible obedience. As his orders usually were for the murder of some offender in cool blood, his followers, in course of time, acquired the name of Haschischi, modified into our modern word assassins.

The effect of the drug on the constitution is marked, but not so great as that of opium. The gunjah-smoker is dry and rickety in his appearance, his eyes sunken, his cheeks flattened, and of a generally faded look. These effects are in a great measure obviated or, at least, mitigated by the use of a diet containing an abundance of fat; but a hemp-eater or smoker is never stout. Dr. Chevers tells us that in practice he has found that an opium-smoker, when sick, must have his dose, or he dies, but that the gunjah-smoker may have his drug cut off with impunity, except in cases where every means of alleviating pain is necessary. In connection with this subject, it may be interesting to note that long ago this substance, in the form of majoom, was used as a kind of anæsthetic, especially in making eunuchs and in circumcision.

One would have expected that, in a country like India, the intoxication produced by the drug would frequently have been seized upon by the criminal classes for the purpose of robbery; but this does not seem to be often the case, although in a former article we pointed out that the drug was occasionally mixed with datura for that purpose. As a result of the prolonged and continuous use of the drug, complete loss of speech is sometimes noted, but is not very common. Much more frequent, as a result of the practice, is the insane condition in which the individual is prompted to acts of savage violence. A few days' quiet generally ends in restoring the mental

---

* 'A Manual of Medical Jurisprudence for India, including the Outline of a History of Crime against the Person in India.' By Norman Chevers, M.D., Surgeon-Major H.M. Bengal Army, Principal of the Calcutta Medical College, Professor of Medicine and Senior Physician in the College Hospital, etc. Calcutta: Thacker, Spink and Co. Pp. 861.

faculties, but many become permanently insane. It is in the intoxication produced by hemp that running a-muck seems most frequent,—not that it follows that hemp is the cause of the violence, but the native, excited by some wrong, real or imaginary, fortifies his determination to be revenged by a dose of gunjah or bhang.

Opium eating and smoking are very prevalent in many parts of India; but the drug does not seem to be very often used as a poison, except in those parts where it is produced in abundance. But it would seem to have been very extensively employed for the destruction of female children. To this end, it was either introduced into the infant's mouth or the mother's nipples were anointed with it; so that it was insensibly taken in with the milk. Drugging older children, by their nurses, to keep them quiet, is common enough, and opium is used for this purpose also. Opium-eating seems to be most prevalent among the Rajpoots; with them, eating opium together is the most sacred pledge of friendship; and upon festivals and high days the chiefs solemnly partake of it in company. The practice was encouraged, because opium was supposed to strengthen their courage in warfare, and to increase their aptitude for business. Finally, it would seem that in certain parts nux vomica is eaten to the extent of as much as twenty grains a day, in the same way as opium, and the hakeems give it to supersede the use of opium.—*Medical Times and Gazette.*

ADULTERATION OF "GOLDEN SYRUP."

A paragraph having gone the rounds of the American papers stating that the substance retailed as golden syrup contains no sugar at all, but that it is produced by the action of strong sulphuric acid upon starch, and mentioning tannic acid as a test to show the difference between it and cane-sugar, Dr. C. E. Chandler has published the following remarks upon the subject in the *American Chemist*:—

Genuine "golden syrup" is the liquor drained from the crystallized sugar of the sugar-house, after all the sugar that can be profitably extracted from raw sugar has been separated. This syrup still contains a considerable quantity of crystallizable sugar, which cannot be profitably extracted, together with uncrystallizable sugar, colouring matter, and the substances which give to syrup its peculiar agreeable flavour, but whose exact nature is not known.

The adulteration complained of is the dilution of this pure sugar-house syrup with syrup made from starch, or the entire substitution of starch syrup for sugar-house syrup. We have no fault to find with this portion of the statement, but the test with tannic acid or strong tea is totally fallacious. It is simply a test for iron, which is much more likely to occur in genuine sugar-house syrup than in the starch syrup complained of. The raw sugar is manufactured in iron vessels; the tanks, pipes, coal-filters, moulds, and often the vacuum-pans in the sugar-house are made of iron, and as the solutions take up small portions of this metal, the syrup often, though not always, contains iron. The refiner is careful to prevent, as far as possible, the introduction of iron into the sugars and syrups, not because it is in any way injurious, but simply because if it occurs in the sugar to any extent, it produces a dark colour when used in tea, which consumers dislike. As syrup is not used in tea, there is no real objection to a small proportion of iron; in fact, as iron is a good tonic, its presence is perhaps desirable. The starch-sugar which we have seen manufactured on a large scale in Europe, would not be as likely to contain iron. This test, therefore, is simply a test for iron, and not a test for adulterated syrup; in fact, guided by this false test, one would be likely to reject pure sugar-house syrup, and select the starch syrup instead.

SYRUPUS CROCI.

Mr. G. W. Kennedy, of Pottsville, Pennsylvania, having been called upon to make considerable quantities of syrup of saffron, gives in the *American Journal of Pharmacy*, as the result of his experience, a formula which, in his opinion, yields a very fine preparation. He says, "As commonly prepared, it is apt to ferment, and become worthless; during the summer months I have found it to ferment with ease. This is entirely obviated by substituting glycerin for sugar. I have some in my store which I made eight months ago, and it is as perfect as when first made. It is known that the medical properties of saffron are due to the volatile oil; and in order to obtain this we must guard against heat in the preparation of the syrup, and make it cold, as when heat is used it drives off part of the volatile oil. The next point is to use something that will dissolve the volatile oil from the saffron, and for that purpose I have used glycerin, and find it to work admirably.

"Take of true Saffron ℥ss
Glycerin ℥ij
Water ℥vj.

"Let the above macerate for seven days, filter into a pint bottle and add water through the filter q. s. to make ℥viij, then add sugar 14 oz. av. and dissolve cold by frequent agitation. The result is a beautiful thick, dark orange-coloured syrup."

SPURIOUS QUININE.

In the last number of the *American Journal of Pharmacy*, Mr. Charles Bullock, of Philadelphia, announced the discovery of an intended fraud in the vending of a spurious preparation. He says that there has lately been offered in the market there what purported to be about five thousand ounces of sulphate of quinine of the manufacture of Pelletier, Delondre et Levaillant, of Paris. The bottles in which it was contained bore the label and the corks the seal of that firm.

An examination of the so-called sulphate of quinine, which was offered at about the market price of quinine, showed that it contained scarcely a trace of quinine, but consisted entirely of muriate of cinchonine mixed with small quantities of the other associated alkaloids of the bark.

The first impression was that old bottles from which the labels had not been removed had been used to perpetrate the fraud; but a more careful examination and comparison with a known genuine package led to the belief that the whole transaction—bottle, label, seal, and circular accompanying each bottle—was a counterfeit.

It is somewhat amusing to read that the original circular issued by the firm, a counterfeit copy of which accompanied each bottle of the spurious quinine, contains a ready method for discovering the fraud, viz. "1 gramme of sulphate of quinine, 4 grammes of ether, and 2 grammes of aq. ammoniæ should form a clear solution."

KAMEELA.

As met with in commerce, kameela is a powder of a dark brick-red colour, having, when recent, a peculiar, heavy odour, increasing on being rubbed between the fingers, but which diminishes with age. In the mouth it is gritty, and has a somewhat acrid taste. When exposed to a temperature of between 200° and 212° F., it undergoes no apparent alteration; when a small portion is dropped into the flame, it flashes up instantaneously. Its best solvents are ether, alcohol and solutions of alkalies, from which it is precipitated by water or acid in the form of a resinous substance. It has been analysed by several chemists, and found to consist of albumen, cellulose, volatile oil, volatile colouring matter, ashes and water; but chiefly of a resinous colouring substance, which constitutes over three-fourths of it. It almost always contains from 6 to 10 per cent. of sand, and 1 to 2 per cent. sesquioxide of iron; more than these amounts of foreign matter depreciates its value. Kameela are the glands that cover the capsules of a small tree or arborescent shrub found in the hilly parts of India, along the base of the Himalaya mountains, and growing from 15 to 30 feet high. Its name is *Mallotus philippinensis*, formerly known as *Rottlera tinctoria*.

The article has been known as a remedy for tapeworm among European and American physicians for only a few years, though long known and employed for this purpose in India. Dr. C. Mackinnon, a surgeon in the English army in India, first made its properties known to the profession, he having been almost invariably successful with it. Other practitioners since have employed it with equal success. In doses of from 2 to 4 drachms it purges, often with griping or nausea and vomiting, and producing from four to ten or fifteen stools. The worm is usually expelled entire, but often without the head, in the third or fourth stool, after 3 drachms of the powder have been administered. A strong alcoholic tincture acts more mildly and with more uniform effects. The dose of the powder for an adult is from $2\frac{1}{2}$ to 3 drachms, given in mucilage, syrup, or other vehicle; of the tincture, made in the proportion of 3 ounces to half a pint of alcohol, half a fluid ounce. The dose to be repeated if necessary.

Tannin will dissolve in water without the help of any agent. A few drops of alcohol, however, generally help to make the fluid clearer. The tannin is not impaired by it.—*Manufacturer and Builder.*

OINTMENT OF MERCURIC NITRATE.

The following remarks upon the preparation of this ointment have been furnished to the *Pharmacist* by Mr. Charles Fredigke, of Chicago:—

Being in need of some of this ointment, I prepared a quantity according to Mr. Rother's formula, which appeared in the *Pharmacist* for July last;* but when effervescence ceased, and the liquid only boiled, even under increased heat (as the formula reads), it turned rapidly to a dark brown colour, and after stiffening, and the addition of the mercurial solution, the ointment appeared of the colour of raw umber. On making a second trial the effervescence was allowed to go on very slowly, confining it to the centre of the liquid till it ceased. It had then a reddish-brown appearance—lemon-yellow at the edge. At this stage it was kept at a temperature between 185° and 190° F., as indicated by a thermometer, and was briskly stirred with a wooden spatula, to ensure the complete liberation of nitrous acid fumes, and the reaction of the acid on the lard. The result was a most excellent ointment, both in colour and consistence.

The patient and scientific research of Mr. Rother upon the reactions occurring in the preparation of this ointment, and the practical results he deduced from them entitle him to the thanks of the pharmaceutical profession at large; for I think that the reduction to a definite result of that which was formerly left to mortifying failures or mere chance, is of importance to every practical member of our profession.

* PHARMACEUTICAL JOURNAL, 3rd series, Vol. I. p. 107.

THE CHEMISTS' DEFENCE ASSOCIATION.

At a Public Meeting held in the Memorial Hall, Albert Square, Manchester, on Wednesday evening, February 22nd, 1871, to consider the proposed compulsory poison regulations, and the advisability of forming an Association of Chemists, for the purpose of resisting their enactment; on the motion of Mr. Jabez Waterhouse, seconded by Mr. Robert Hampson, Mr. W. S. Brown was called to the chair, and the following resolutions were unanimously passed:—

Moved by Mr. Robert Hampson, Manchester; seconded by Mr. Bostock, Ashton-under-Lyne,—

"That in the opinion of this meeting, the action of the majority of the Pharmaceutical Council, in proposing compulsory regulations for the storing and dispensing of poisons, is prejudicial to the true interests of the trade, uncalled for by the public, and ought to be strenuously resisted."

Moved by Mr. Kay, Stockport; seconded by Mr. E. Fisher, Ashton-under-Lyne,—

"That it is the opinion of this meeting, that if the Council of the Pharmaceutical Society really desire to ascertain the opinion of the whole of the members on the proposed compulsory poison regulations, and not merely that of a section who attend the annual meeting in May, they will make arrangements for voting by the use of proxy papers."

Moved by Mr. Jabez Waterhouse, Ashton-under-Lyne; seconded by Mr. Hunt, Manchester,—

"That an Association be formed, to be called 'The Chemists' Defence Association,' having for its objects:—

1st. To organize an opposition, and to adopt all suitable means to prevent a dominant section of the Pharmaceutical Council, influenced by the Medical Department of the Privy Council, from enacting compulsory regulations for the keeping and dispensing of poisons, such being unnecessary in the interests of the public, and from the vagueness of their character, and indefinite scope of application, are certain to prove most vexatious and objectionable to the members of the trade.

"2nd. To protest against the assumption that further regulations for keeping and dispensing poisons are needed to be applied to chemists:—the only true safeguards, viz. improved education, and adequate responsibility, being secured by the provisions of the Pharmacy Act, 1868, which have already produced considerable effects, and will, if allowed fair operation, speedily accomplish all that is required; and the attempt to apply further imperative regulations to chemists, whilst surgeons, veterinary surgeons, hospital dispensaries, etc., are excepted, would expose the public to greater danger from varying customs, than if no such unwise attempt had been made.

"3rd. To influence the forthcoming election of members of the Council, and to secure a more adequate representation of the widely expressed views of the trade on this important question."

Moved by Mr. Councillor Scott, Rochdale; seconded by Mr. Barnaby, Manchester,—

"That an Hon. Secretary, Treasurer, an Executive Committee consisting of twelve members of the Association—four to form a quorum,—and a General Committee with power to add to their number, be appointed."

Moved by Mr. Mumbray; seconded by Mr. T. S. Johnson,—

"That the Hon. Secretary be Mr. Robert Hampson; the Treasurer be Mr. Geo. Woolley; and the Executive Committee be Messrs. W. S. Brown, Benger, Barnaby, Hughes, Halliday, Kay, Reynolds, F.C.S., Robinson, Slugg, F.R.A.S., Jabez Waterhouse, Woolley and Wilkinson.

Moved by Mr. Benger, Manchester; seconded by Alderman Taylor, Rochdale,—

"That the officers be empowered to adopt all suitable means by correspondence, the issue of circulars and other agencies, to organize an effective opposition to the proposed compulsory poison regulations, and that contributions to the funds be solicited; that the Committee be empowered to employ such legal and other paid agency as they may judge necessary, and also to organize branch associations and other means to give effect to their action."

Moved by Mr. Fisher, Ashton-under-Lyne; seconded by Mr. Gill, Pendleton,—

"That every contributor of 2*s*. 6*d*. and upwards be a member of this Association."

The Pharmaceutical Journal.

SATURDAY, MARCH 4, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

CHLORAL HYDRATE.

We have no hesitation in expressing the opinion that in regard to purity, all articles of the *materia medica* should be, like CÆSAR's wife, above suspicion; and holding this opinion, it is with great pleasure we find it to be our duty to vindicate the character of an important therapeutic agent, which has been well described by a leading medical journal as one of the first contributions of pure chemistry to our materia medica. We are the more ready to perform that duty, since the first specific impeachment of the drug was published in the pages of this Journal. Although we have, in consequence, been overwhelmed with reclamations, and are now in a position to say that there was not really any foundation for the alarm and distrust which the statements in that article were calculated to excite, we nevertheless do not think it necessary to offer any apology for having given publicity to the article now referred to, for the simple reasons that we regard it as much a duty to expose the sale of inferior drugs as it is to defend the members of our craft against unfounded imputations, and that the paper was published in good faith, as one bearing on its face evidence of its being important to both pharmacists and medical men, as well as to the general public.

The letter which appears this week from Mr. MASON* sufficiently establishes the fact—already evident otherwise—that his experiments were affected by some source of error that invalidated his results. On general grounds this is satisfactory; and we have now only to express our regret for any temporary inconvenience or prejudice that may have been experienced by individual dealers in chloral hydrate. We have endeavoured in that respect to do all in our power towards correcting the erroneous impression conveyed by the paper immediately the error was pointed out, and we hope in this way to have satisfied all reasonable expectation. But we cannot undertake to occupy our space with the lengthy communications we have received from some sources, and indeed could not do so without affording ground for the charge of inserting trade advertisements out of their proper places. We have therefore made an abstract from the various communications to which we referred last week, and publish them in the correspondence column.* To conclude this matter, we may add here that there is abundant reason to believe that chloral hydrate, as now supplied for medicinal use, is generally of good quality; and that in regard to the chloral alcoholate, we have only met with one sample of it, and do not believe that it is to any extent, if at all, substituted for the hydrate.

* See page 719.

* See page 720.

SPIRITUS AMMONIÆ AROMATICUS.

Our contemporary the *Practitioner*, in further alluding to the subject of the analyses of some samples of the above preparation which were published in its columns and copied into these, is not pleased with our remarks upon them, contained in our issue of the 21st ult. The writer of the article in question states, there "surely can be no excuse whatever for the chemist who sells as sp. ammoniæ co. a preparation which contains only half, or less than a half, the proper quantity of ammonia, and only from three-fourths to four-fifths the proper amount of alcohol." Having had our attention thus pointedly drawn to the subject, we have taken the trouble to go more into detail, and to examine his results carefully. In reply to him we might, in the first place, without being accused of having a disposition to quibble, with justice, object that the samples were, according to his statement, "taken at random from six different chemists' shops,"† as sp. ammoniæ *comp.*, which is not official in the British Pharmacopœia, and was only once so in the London Pharmacopœia—that of 1787. It was then prepared by a different process to the present official one, which ought to contain the ammonia in solution as the normal ammonium carbonate. In the older preparation two drachms of each of the essential oils of lemon and of nutmeg were directed to be mixed—not distilled—with two pints of spirit of ammonia, this latter preparation being prepared by the double decomposition of sal ammoniac and potashes dissolved in proof spirit, and a certain quantity distilled. It would, therefore, contain the ammonia in solution as a mixture of the normal and acid carbonates. Sp. ammoniæ comp. thus made would also contain a less percentage of alcohol than the present spiritus ammoniæ aromaticus. There are pharmacists who keep both the above preparations, and if sp. ammoniæ comp. is prescribed—as it often is—sp. ammoniæ comp. is dispensed. They would no more think of substituting the new for the old preparation than they would pilula ferri carbonatis for pilula ferri composita.

† One of these, where, according to the published analyses, the worst sample was purchased,—that of 44, Southampton Row, Bloomsbury,—is an open surgery. No such name as John F. Staines appears on the Register of Chemists and Druggists at this address; nor yet does it appear on the Medical Register, although the facia states that the proprietor is a surgeon.

In the second place, the writer doubts from his own inquiries, "whether any section of the public has the slightest objection to the official sal volatile." On this point we may inform him that there is a section—we forbear to mention it, further than to state that it is the one which has the most refined taste,—which we know has a great preference for it when flavoured with a substance which is not in the official formula. The following case, which came under our notice some years ago, illustrates how materially the tastes of some persons differ with respect to that preparation. An English family having been travelling in Scotland, on their arrival in the North of England, applied to a pharmacist for a supply of sal volatile,—had he any which he could recommend? Yes; his was So-and-so's make, mentioning a noted Edinburgh house. "Just what we did not want," said the gentleman; "we have been in Scotland during the last month, and have not been able to obtain any but that of Edinburgh make, (that of P. E. contained oil of rosemary,) and my wife does not like it; we felt sure we should be able to obtain some of English manufacture here." No sale was effected. As traders, pharmacists find it necessary to study the tastes of their customers.

Lastly, our contemporary does not publish the details of the analyses. The writer assumes that Spiritus Ammoniæ Aromaticus prepared by the official process would contain all the ammonia directed to be employed in its manufacture, nay—he erroneously assumes even more, as the quantity of ammonia he states it ought to contain should be 2·6 per cent. by weight in volume. By a careful calculation,* we find that supposing the whole of the ammonia (NH_3) ordered in the formula were contained in the seven pints of distillate, which is the resulting yield of the official quantities, it would only contain 2·473 per cent. by weight in any given volume.

The compilers of the 1864 edition of the British Pharmacopœia, who introduced the present process for the manufacture of spiritus ammoniæ aromaticus, tried "to ensure the formation of a neutral carbonate of ammonia"† in solution in that preparation. But this neutral "carbonate is insoluble in alcohol" (absolute), and "an aqueous solution of it is precipitated by alcohol, the precipitate being acid carbonate or intermediate in composition to that and the normal carbonate."‡ If to the aqueous solution rectified spirit be added, as in Mr. Martindale's experiment (2), p. 704, the crystalline formation is most probably the normal carbonate itself.

With these remarks we will leave the matter with the members of the medical profession: we trust that in future, when they censure us for shortcomings, they will clearly establish their case, and hold the balance of justice fairly, so that no trader shall meet with such an unmerited share of obloquy as our contemporary has dealt out.

* See p. 704.

† Dr. Garrod's 'Materia Medica and Therapeutics,' 3rd edit. p. 47.

‡ Divers on the Combinations of Carbonic Anhydride with Ammonia and Water.

THE CALENDAR FOR 1871.

Following closely upon the issue of the Register, referred to last week, the Calendar of the Pharmaceutical Society for the present year is now ready. It contains a list of all persons who are connected with the Society, corrected up to a recent date. It is gratifying to notice the increase in the length of some of these lists, notably in that of the Chemists and Druggists who are Members of the Society, where it amounts to nearly two hundred names beyond last year. There is also a considerable augmentation in the numbers of the Associates, both of those who are and those who are not in business and of the Registered Apprentices.

Besides these lists the Calendar contains the Charter, Bye-laws and Pharmacy Acts, the Regulations of the Board of Examiners, the Examination Papers for the past year, and much useful information concerning the School of Pharmacy at Bloomsbury Square. This is followed by a list of Donors and Subscribers to the Benevolent Fund, giving the number of votes to which each is entitled. In the Appendix are printed remarks on, and extracts from, several Acts of Parliament, Regulations and General Orders, in which Chemists and Druggists may be interested, such as the Medicine Stamp and Licence Acts, the Petroleum Act, the Act to Regulate the Sale of Poisons in Ireland, the Regulations as to Navy Dispensers, etc. Altogether the Calendar will doubtless be very useful to those for whose convenience it is issued by the Council.

OPIUM CULTIVATION.

The question of opium cultivation is just now exciting considerable interest. The reports from different sources (some of which have been printed in this Journal) that it is being attempted on a large scale in many parts of the world, and notably in China, have not only raised the hopes of those by whom it is largely used that the present price may be materially reduced, but they have also awakened the anxiety of statesmen as to the permanence of the revenue at present derived from it in India. We give the gist of some remarks upon the subject from a leading article in the *Times* of Monday last.

As a tax not open to the objection of being levied on an article of prime necessity, the profit made by opium sales is the most defensible form of Indian taxation, though there is more than one other point of view from which it cannot be regarded with satisfaction; but apart from the moral arguments which may be urged against it, Mr. Grant Duff's budget supplies a notable proof of its speculative character. The anticipated surplus of 1870–71 is chiefly due to the fact that "opium has come to the rescue," having realized 1113 instead of 975 rupees per chest.

However grateful we may be for this relief, we cannot forget that opium has before now deserted us with equal fickleness in the hour of need, and that it is, in fact, the most precarious and unstable of all financial resources.

Our contemporary *Nature* states that at Cambridge it is proposed to increase the stipend of the Professor of Chemistry from £300 to £500 per annum. It is also proposed to appoint a Demonstrator of Chemistry at £150 per annum.

The *British Medical Journal*, in a report of a chemical examination of samples of chloral hydrate, expresses disapproval of the practice of stating the dose upon labels attached to chloral hydrate. It says, "In some cases this is done in such a way as to suggest the idea that it is intended for amateurs and as a facility for self-treatment. Considering the possibility that there is, to say the least, of this medicine being misused, and the number of fatal cases which have lately occurred where over-doses of chloral hydrate are suspected of being the cause of death, this is a point on which it is scarcely possible to lay too much stress."

The trustees of the British Museum have appointed Mr. W. Carruthers, F.L.S., F.G.S., to the Keepership of the Botanical Department, recently vacated by the resignation of Mr. J. J. Bennett, F.R.S. Mr. Carruthers, who has been Senior Assistant in the Department several years, is well known to botanists by his contributions towards the study of Fossil Botany.

The method of watering the streets with a solution of the chlorides of sodium, calcium and aluminium, as proposed by Mr. Cooper, appears to have been successfully carried out in Westminster, and is now being adopted in St. Luke's, Finsbury, and several provincial towns.

The following is the list of officers and council of the Royal Microscopical Society for the current year:—President, W. R. Parker, F.R.S.; Vice-Presidents, Charles Brooke, F.R.S., J. E. Gray, F.R.S., J. Millar, F. H. Windham; Treasurer, Richard Mestayer; Secretaries, Henry J. Slack, Jabez Hogg; Council: R. Braithwaite, M.D., John Berney, James Glaisher, F.R.S., W. J. Gray, M.D., Henry Lawson, M.D., Henry Lee, James Murie, M.D., G. W. Royston Pigott, M.D., J. W. Stephenson, Charles Stewart, Charles Tyler, T. C. White; Assistant-Secretary, Walter W. Reeves.

In a communication to the *British Medical Journal*, Dr. Lionel Beale says:—

"You have twice directed attention of your readers to some unphilosophical remarks which the Professor of Natural Philosophy in the Royal Institution of Great Britain, the successor of Faraday, has thought fit to make in a book he has recently published. It may be important the profession should know, and it is desirable the fact should be recorded, that 'tolerance,' and of a particular kind, has been extended both by Dr. Tyndall and Mr. Huxley to one among many who, as the former observes, foolishly (!) try to support or oppose the fiery-cloud-origination hypothesis. Dr. Tyndall says, 'Both Mr. Huxley and myself have long practised, and shall, I trust, continue to practise tolerance' with reference to one conspicuous member 'of the class of microscopists, ignorant alike of philosophy and biology, a Doctor of Medicine, lately Professor in a London College famous for its orthodoxy'! ('Use and Limit of the Imagination in Science,' p. 49.) Let us not attempt to restrict in any way the liberty accorded to 'privileged spirits.' As Dr. Tyndall observes, freedom to them is of paramount importance. They must have liberty to speak openly; and, if they tolerate the 'weaker brethren,' all may be thankful. What would have happened if Dr. Tyndall and Mr. Huxley had not practised tolerance, and what would happen were they not to continue to practise tolerance, with reference to the 'Professor in a London College famous for its orthodoxy'?"

The *Chester Courant* in a recent issue calls attention to the unnecessarily late work which has to be done by druggists, and suggests that, in order to give more time for study to young men preparing for their examinations, the public should endeavour to send all orders during the proper hours of business, and that only exceptionally urgent medicines should be applied for after the shops are closed or on Sunday.

Transactions of the Pharmaceutical Society.

EXAMINATION IN EDINBURGH.

February 21st, 1871.

Present—Messrs. Aitken, Baildon, Brown, Buchanan, Kemp, Mackay and Young.

Twelve candidates were examined,—six for the First or Preliminary Examination, two for the Minor, one for the Major, and three for the Modified; the following passed, and were declared to be duly qualified to be registered:—

FIRST, or PRELIMINARY (as Apprentices or Students).

Brown, Robert .... Leith.
Kemp, John .... Inverness.
Lawler, Hugh .... Edinburgh.
Wood, James .... Edinburgh.

MINOR (as Chemists and Druggists).

Wilson, Thomas Davison ...... Sunderland.
Kemp, John .... Inverness.

These names are arranged in order of merit.

MAJOR (as a Pharmaceutical Chemist).

Strachan, Alexander .... Aberdeen.

MODIFIED (as Chemists and Druggists).

Harcus, John .... North Shields.
Matheson, James .... Dornoch.
Stothard, Thomas .... North Shields.

These names are arranged in order of merit.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS' AND APPRENTICES' ASSOCIATION.

The Half-yearly Meeting of the above Association was held at their Rooms, 4, Halford Street, on Friday, February 3rd, 1871; the President, Mr. Joseph Young, in the chair. After the usual preliminary business of the evening had been transacted, the President called upon Mr. S. H. CADOUX (Hon. Sec.), to read the following Report:—

"The Committee of the above Association, in presenting their Half-yearly Report for the Session ending February 3rd, 1871, have the privilege of stating that the conclusion of this, its Third Session, still finds the Association in a very flourishing condition. Your Committee have met with the most encouraging assistance from the honorary members, the list of which now includes every leading principal in the town. The Committee have also advantageously secured the present rooms, concerning which very general satisfaction has been expressed.

"During the Session forty-nine meetings have been held (exclusive of the usual half-yearly examinations), as follows:—For Botany 7, Arithmetic 9, Latin 9, Materia Medica and Pharmacy 9, and Chemistry 11; the remaining four evenings being occupied by the reading of papers and lectures by as many honorary members. The attendance has been throughout very fair; the Chemistry and Materia Medica classes have secured the largest attendances, Latin and Botany next. Arithmetic having failed to maintain the original interest taken in it, your Committee recommend to the officers of the ensuing Session its discontinuance, thus complying with the suggestion of the Pharmaceutical Committee for Provincial Education.

"During the Session two members have obtained the Major, one member the Minor qualification of the Pharmaceutical Society, and one member has successfully passed the "Modified" Examination: thus in the short space of one year making fifteen pharmaceutical examinations which have been passed by eleven members of the Association, viz.:—2 Major, 4 Minor, 3 Modified, and 6 Preliminary. Such a result for so small an Association the Committee believe to be without a parallel.

"Finally, your Committee express their belief that the Annual Supper (held on the 2nd instant), tends not only to promote the interest of the honorary members of your Association, but is greatly conducive to that good feeling among principals and their assistants which, for the interest of future pharmacy, it is desirable to maintain."

After the reading of the Hon. Treasurer's Report, which showed a balance in hand of £4. 7*s.* 10½*d.*, the meeting proceeded to ballot for the Committee to serve during the ensuing half-year.

The following gentlemen were elected:—Messrs. W. P. Clark (P.C.), *President;* Hy. Cooper (P.C.), *Vice-President;* Jos. Young, (P.C.), *Hon. Treasurer;* T. Wright (A.P.S.), *Hon. Secretary;* S. H. Cadoux, W. E. Hill (A.P.S.), and T. Miller.

A programme of classes, lectures, etc., to be held in connection with the Association during the next half-year has been issued.

SCARBOROUGH CHEMISTS' ASSOCIATION.

A Meeting of the Association was held on Monday, Feb. 20th; the President, Mr. G. PORRETT, in the chair. A majority of the members were present, the special object being to consider the proposed compulsory regulations for storing and dispensing poisons, which were freely discussed, and the following resolution passed:—

"That this Association unanimously and emphatically condemns the action of those of the Pharmaceutical Council who wish to impose on the trade restrictions which are altogether unfair and unnecessary, believing that the tests of competency now required are sufficiently adapted to secure the safety of the public."

It was also resolved, "That concerted action be taken with other Associations to secure the withdrawal or rejection of the proposed obnoxious regulations."

MEETING OF CHEMISTS AT BARNSTAPLE.

At a Meeting of the Chemists of this town it was resolved that the proposed second and third poison regulations are impracticable, delusive and unnecessary, and that the third especially (while an excellent regulation in the dispensing of prescriptions) would totally fail in its object, and could not possibly be adhered to in many poor districts.

As the sale of poisons is now restricted to chemists whose status and education will be continually improving, it was suggested that as personal responsibility will still rest on each individual, the following regulations will be all that can be reasonably required:—

1. In the keeping of poisons each bottle, vessel, box, or package containing a poison shall be labelled with the name of the article, and also with some distinctive mark indicating that it is poison, and shall be kept in a cupboard, drawer, box, or shelf set apart for dangerous articles.
2. All liniments, embrocations and lotions containing poison shall be sent out in bottles with a label on green or red paper, giving notice that the contents of the bottle are not to be taken.

These regulations to be enforced after the 1st of January, 1872.

SUNDERLAND CHEMISTS' ASSOCIATION.

The Monthly Meeting of the above Society was held on Monday evening, Feb. 13th, on which occasion a lecture was delivered on "Heat" by Mr. J. HARRISON, to a numerous audience of members and associates. After the lecture it was announced that Dr. Donkin, lecturer on medical jurisprudence to the University of Durham, had kindly promised to deliver a lecture in May, on "Arsenic;" and with the usual votes of thanks the meeting separated.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The following gentlemen were duly elected to membership at a recent meeting of the Executive Committee:—

Ayre, H. M., Warwick.
Beal, E. J., Ilford.
Borland, J., 7, King Street, Kilmarnock.
Burn, Mr., 138, Coronation Street, Sunderland.
Canning, W., 14, Bath Street, Newgate Street, E.C.
Carran, T., Peel, Isle of Man.
Chapman, Mr., Hendon Road, Sunderland.
Church, Professor A. H., Royal Agricultural College, Cirencester.
Cockeroft, A., Richmond, Yorkshire.
Colchester, William, jun., 2, Crown Street, Hoxton Square, N.
Curtis, H., Lewes.
Daniel, S., 30, Market Place, Reading.
Davenport, J. T., 33, Great Russell Street, W.C.
Davies, T. M., 1, Eversfield Place, St. Leonard's.
Glazier, W. H., 95, Edgware Road, W.
Goodwin, J., Lower Clapton, E.
Gunn, D., 9, Sheldon Street, Bishop's Road, W.
Harvie, G., Helensburgh.

Hay, D., Nelson-in-Marsden, Burnley.
Hunter, H., Layport Street, Alnwick.
Ingham, J., Upper Tooting, S.W.
Johnson, M., Huyton, near Liverpool.
Knowles, W. H. H., Upper Bridge, Holmfirth.
Lake, R., 17, Bloomsbury Square, W.C.
Luff, W., jun., Oxford.
Mason, J. H., Workington.
Metcalfe, W. C., Burneston, Bedale.
Mills, W., Sydney, New South Wales.
Moore, R., Post-Office, Dale Street, Ossett.
Nashill, T., Holmeside, Sunderland.
Owen, R. J., 53, Bath Buildings, St. Mary Charterhouse, E.C.
Parker, J. S., Messrs. Sturton and Sons, Peterborough.
Pennington, T., 14, Bolton Street, Bury, Lancashire.
Phillips, G. W., 43, Leather Lane, E.C.
Pick, R., South Parade, Northallerton.
Potter, H., Sutton, Surrey.
Priestly, J., Beech Street, Sunderland.
Pritchard, J., 67, Chorlton Road, Manchester.
Robinson, J., 2, North Gate, Darlington.
Sargent, D., 222, Albany Road, Camberwell, S.E.
Savory, H. B., Painswick, Gloucestershire.
Skidmore, J., Chilworth Street, Paddington, W.
Smith, W. H., County Hospital, Brighton.
Spence, P., Pendleton Alum Works, Manchester.
Squire, A., 1, Bush Lane, E.C.
Squire, A. P., 1, Bush Lane, E.C.
Steel, F. W., 283, Liverpool Road, Islington, N.
Steward, J., High Street, Brierley Hill.
Sykes, T. H., Lord Street, Southport.
Thompson, H., Moor Street, Sunderland.
Thompson, W., 87, High Street East, Sunderland.
Truman, H. V., Angleside Villas, Streatham, S.W.
Watling, A., 59, Camberwell New Road, S.E.
Weaver, E., 29, Chapel Street, Belgrave Square, S.W.
While, W. J., 45, Westbourne Road, Bayswater, W.
Windsor, G., Torpoint, Devonport.
Wink, J. A., 17, North Bridge, Edinburgh.

Candidates for Membership.—Gentlemen sending in their names to the London Secretary, Professor Attfield, 17, Bloomsbury Square, W.C., and enclosing the subscription, 5*s*., and 7½*d* for postage (in stamps or P.O.O. payable to John Attfield, at the Bloomsbury Office), will receive, by return of post, a copy of the 'Year-Book.' The price of the volume to non-members is 7*s*. 6*d*.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

VACANCY.

The office of Dispenser at the Great Northern Hospital, N. Candidates are requested to send their applications, with copies of testimonials, to Mr. George Reid, Secretary, 40, Great Coram Street, W. C.

MEETINGS FOR THE ENSUING WEEK.

MONDAY ......*Medical Society*, at 8 P.M.
London Institution, at 4 P.M.—"On Astronomy." By Mr. R. Proctor.
TUESDAY ......*Royal Institution*, at 3 P.M.—"The Nutrition of Animals." By Professor Foster.
WEDNESDAY...*Society of Arts*, at 8 P.M.—"The Cultivation and Uses of Sugar Beet in England." By Dr. Augustus Voelcker.
Royal Microscopical Society, at 8 P.M.
THURSDAY......*Royal Society*, at 8.30 P.M.
London Chemists' Association, at 9.30 P.M. "Remarks on Structural Botany." By Mr. J. H. Jessop.
THURSDAY......*Royal Institution*, at 3 P.M.—"Davy's Discoveries in Chemistry." By Prof. Odling.
FRIDAY ....*Quekett Club*, at 8 P.M.
SATURDAY ...*Royal Botanic Society*, at 3.45 P.M.

Parliamentary and Law Proceedings.

SUICIDE BY PRUSSIC ACID.

An inquest has been held at Falmouth to inquire into the death of a young woman named Mary Pitts, who had been found dead in a room where she had been lodging a few days.

Mr. Mitchell, chemist, Market Strand, identified the deceased as having called at his shop to purchase some chloroform for a toothache, after which she wished to be supplied with a small quantity of prussic acid, stating she used it for the purpose of cleaning her jewellery. He informed her of its deadly nature, and she replied that she had no difficulty in obtaining it in London, as she had a brother practising there as a physician. Being thrown off his guard by her manner, he supplied her with half an ounce. Witness produced his register which she had signed, calling herself "Isabella Vaughan," and identified the bottle that had contained the poison as having been supplied by him. The next day she again called and said that while cleaning her jewellery she had accidentally broken the bottle, and he believing her statement, supplied her with another half ounce.

Dr. Guppy said that upon being called in, he found the deceased cold and stiff, and judged she had been dead several hours. He picked up pieces of paper from the floor, which on being placed together formed the label that had been removed from the bottle. In reply to a juror, he said that deceased could not have lived more than two minutes after taking the poison. He thought she was pregnant.

The jury returned a verdict that the deceased died from the effects of poison, but as to the state of her mind at the time there was no evidence to prove.

CASE OF POISONING BY CHLORAL HYDRATE.

In a report of the case of death from an overdose of chloral noticed in the PHARMACEUTICAL JOURNAL, p. 636, furnished to the *British Medical Journal* by Messrs. W. J. Hunt and R. W. Watkins, they state that the deceased first had the prescription (which had been sent to him by a relative) dispensed by a chemist, but afterwards procured from him the chloral alone in ounce-bottles. The chemist, Mr. Tite, thinking he was taking larger doses than was safe, cautioned him as to the use of it, and showed him an article in the PHARMACEUTICAL JOURNAL describing the ill effects of an overdose, loss of power in the lower extremities being the most prominent one. He informed Mr. Tite that on one occasion, after taking three doses in one night, he had felt that effect in the morning, having fallen down twice on getting out of bed. Mr. Tite estimated that on that occasion he had taken seventy-five grains. He subsequently procured a copy of that number of the Journal, and in it there happened to be an advertisement of hydrate of chloral from a wholesale house. This, it would seem, induced him to obtain from that firm a box containing sixteen ounce-bottles of hydrate of chloral, half of which he had expressed his intention of sending to a relation. The housekeeper had often seen him dissolving the chloral in water, in a half-pint bottle (labelled "Chloral Hydrate, 1870"), from which he was in the habit of taking a wineglassful at bedtime; but she did not know the quantity of chloral dissolved each time. She had seen him take a dose from the bottle the night before his death. On January 17th, he had purchased from Mr.

Tite an ounce of chloral; and the supply from London had arrived subsequently to that date. After his death, fifteen of the bottles were found full, and one empty; about two ounces of the solution remaining in the bottle above mentioned, on the table in his bedroom. From this we conclude that, in the ten days between the 17th and 27th of January, he had taken fourteen drachms of chloral—presuming that the solution in the bottle contained an ounce to the half-pint. If, however, it contained half an ounce only, the bottle must have been four times filled; and he had, therefore, taken fifteen drachms in the ten days. He was constantly in the habit of "doctoring himself," and, among other things, frequently took carbonate of soda, as much as eighty grains at one dose—purchasing it from Mr. Tite by the half-pound. His housekeeper was not aware whether he had taken any on the night before his death; and we are, therefore, unable to ascertain whether any decomposition of the chloral had taken place.

Action for Poisoning a Dog.

A case of considerable interest to sportsmen occupied Mr. Baron Cleasby the whole of Monday at the Warwick Assizes. The plaintiff, the Rev. James Finch, curate in charge of Burmanton, near Shipston-on-Stour, Warwickshire, sued the gamekeeper of Mr. Thomas Wright, of Tidmington House, Worcestershire, to recover £50, the value of a favourite Pomeranian dog of the plaintiff's, alleged to have been poisoned by the defendant. The case for the plaintiff was, that the defendant placed strychnine in rabbits' paunches, and left them about the coverts, and that the dog, which the defendant had threatened to destroy, was poisoned by the strychnine. The latter fact was conclusively established by an analysis of the dog's stomach. The jury found a verdict for the plaintiff, with £10 damages.—*Daily News.*

Poisoning of a Child by Caustic.

An inquest has been held in Leeds to inquire into the circumstances attending the death of Frederick William Day, fourteen months old. The child had been taken to Mr. Holmes's surgery, in Beckett Street, in consequence of its having a slight ulceration under its tongue. Mr. Holmes, having instructed his assistant, Mr. Jenkinson, to apply some caustic to the part affected, he took a piece, wrapped it in paper, and, holding it in his right hand, applied it to the ulcerated part of the tongue. Whilst he had his fingers in the child's mouth it suddenly threw back its head, and its gums, coming in contact with the caustic, knocked it out of the operator's fingers, and it slipped down the child's throat, its death following a few hours afterwards. A *post-mortem* examination was made by Mr. Scattergood, who found that the death had been caused by caustic. Evidence was given that caustic was sometimes applied in the way it was in this case, but that it was safer to apply it in a holder. The jury returned a verdict that the child had been accidentally poisoned, but expressed an opinion that the mode employed was not a safe way of applying caustic when it was to be used inside a person's mouth.—*Leeds Mercury.*

[*** It is not stated in the report what caustic was used, but we suppose it to have been nitrate of silver.—Ed. Pharm. Journ.]

Case of Alleged Poisoning.

On Monday, at the Town Hall, Newnham, William Masson, a Licentiate of the College of Physicians of Edinburgh, and Edward Henry Coleman, an apothecary of Mitcheldean, were charged with feloniously killing and slaying Ann Masson, wife of the said William Masson.

In January last an inquest was held at the residence of Dr. Masson, at Mitcheldean, on the body of Mrs. Masson. The husband then stated that his wife had access to his surgery, and took two drachms of laudanum while suffering from neuralgia. He called in an apothecary named Coleman (the other prisoner), who administered hot brandy-and-water. Mrs. Masson fell back in a comatose state and died in forty-three hours afterwards. Suspicions were aroused with regard to the conduct of Masson, and hence the present proceedings.

Mr. Charles Whatmough, a surgeon, was called in to see Mrs. Masson on Saturday night, the 14th of January, and found her in a perfectly helpless state of coma. Dr. Masson said she had taken about two drachms of opium from a bottle in the surgery, having wasted a portion on the counter; that he had prepared an emetic of sulphate of zinc and mustard, which she refused to take; and that she had taken a hot glass of brandy-and-water. Witness gave it as an opinion that, prior to the comatose state, death might have been prevented or retarded by scientific means.

Mr. Fitzherbert Jones, a surgeon, was also called to see deceased a few hours before her death. He knew of no medical authority that recommended hot brandy-and-water for poisoning by opium.

Thomas Buchanan Washbourn, M.D., was of opinion that death might have been prevented or considerably retarded by scientific means. The usual means would have been to administer an emetic or to use the stomach pump, which might certainly have been done with effect before the patient was in a comatose state. The stomach pump might have been used with effect after stupor had commenced. Cold affusions and moving about would retard comatose symptoms. The sleepiness mentioned in the evidence before the coroner by the prisoner Coleman he should have considered as the commencement of stupor. He considered that brandy-and-water would, under such circumstances, lend an additional force to the narcotic influence of the poison. Death would be accelerated according to the quantity of alcohol taken.

Margaret Maclough said that Dr. Masson married her sister, who was then a servant living at Guy's Hospital. Her sister died on Sunday morning, the 17th of January, after drinking laudanum from a bottle. She spoke to the frequency of quarrels between the Doctor and her sister. After her death Dr. Masson told her not to say that her sister had not taken poison purposely, and promised her money and her sister's clothes, cautioning her that if she said anything her sister's body would be cut in pieces and buried in the cross roads. That frightened her so that she did not say anything about it until questioned by a policeman in London. She was quite certain they had quarrelled on the day the poison was taken.

Witnesses were called for the defence, whose evidence contradicted the statement of the girl as to the terms on which the prisoner and deceased lived together.

The Bench eventually committed both prisoners for trial, refusing to accept bail in the case of Dr. Masson.—*Standard.*

Poisoning by Carbolic Acid.

On Monday last, a police officer named Jefford, who has lately been acting as inspector at the Dale Street Police Court, Liverpool, called a man named Thompson, whom he asked to fetch him a pint of beer. Thompson said he had no bottle, and Jefford then took one from a cupboard in the passage and gave it to him. Thompson then brought the beer, and placed the bottle at the back of some boxes which were close to the cupboard from which the bottle was taken. Having done so, he was going along the passage, when he heard Jefford call out that he had taken something wrong, and he was expectorating violently. Thompson hurried back, and found that Jefford had not taken the beer, but that he had begun to drink from a bottle which contained carbolic acid, which had been placed by some one at the top of the boxes. Jefford was at once removed to the Royal Infirmary, where he became insensible, and after lingering five hours died.—*Standard.*

Attempted Suicide by Oxalic Acid.

A young woman was brought up at the Greenwich Police Court on Tuesday, charged with attempting to commit suicide. It appeared she had been found at her master's house, suffering from the effects of having swallowed a quantity of oxalic acid, which she said she had purchased of a neighbouring chemist. She was remanded for a week.

HOUSE OF COMMONS.

Adulteration of Wines.

On Thursday, Feb. 23, Sir J. Lawrence asked the Chancellor of the Exchequer if his attention had been called to a statement that a recent test of sherry wines, described as of superior quality, had shown that they were adulterated with an acid highly injurious to health; whether it was true that the adulteration had been made in the docks, with the knowledge of the officers of Customs; and whether the officers of Customs had received instructions to afford every facility for the adulteration of wines in bond, provided the owners declared such adulteration to be for the purpose of fortifying the wine.

The Chancellor of the Exchequer said that he had made inquiry and had been informed that no adulteration had been carried on with the cognizance or permission of the officers of Customs. Orders were not given to tolerate any adulteration whatever, but that persons having wines in bond should be permitted to fortify those wines, that being absolutely necessary for their preservation. They were also allowed in the event of the wines becoming "cloudy," to use some means of refining them; but the officers are strictly forbidden to allow any adulteration whatever.

Sir J. Lawrence gave notice that he would move for a return of the quantity of Hamburg and other spirits used in the docks for fortifying wines.

Opium Cultivation in India.

Mr. Grant Duff brought forward the Indian Budget on Friday, Feb. 24. In the course of his speech he said concerning the Indian finances, that the one great fact of the year 1870–71, just drawing to a close, was that opium had come to the rescue. When Sir Richard Temple made his statement in April last, nothing could be much more gloomy than the prospect of the opium revenue for the financial year which had just begun. From almost all quarters came prophecies of evil, the prophecies from China being the gloomiest of all. Her Majesty's late representative at Pekin even went to Calcutta to confer with the Governor-General about the increased growth of the poppy in China. Owing to some unknown cause, all these anticipations had been falsified. Sir Richard Temple took the price of the chest of Bengal opium for the year at 975 rupees, whereas the average by the latest advices had been 1113 rupees. In spite, however, of the favourable results of this year, he thought it necessary that the opium revenue should be watched with extreme care. Considering the enormous extent of country, even in Asia alone, where the poppy can be grown with fair success, it was too much to hope that the Indian drug will continue to be so distinctly preferred by those who can buy it as to enable us to lighten by many millions year after year the price which India pays for civilized government; for whatever might be said against the opium revenue, it should not be forgotten that hardly any of it comes out of the pockets of our Indian fellow-subjects, and if it were done away with, India would not be lightened of an impost, but robbed of a splendid estate. He said also that the sudden death of Dr. Anderson had not prevented them continuing the arrangements that gentleman had made for naturalizing the ipecacuanha plant in India.

Mr. Cave said that in Bengal opium was a Government monopoly. Government not only taxed it, but they grew, manufactured and sold it. This opium revenue had an ugly look in more ways than one, for we charged so high for the drug that we had fostered its growth not only in China, where at present it had found no suitable soil, but in Persia, where he understood it was nearly as good as in India, so that we might possibly lose this source of revenue without having the credit of giving it up for conscience' sake.

Mr. W. Fowler maintained the opinion he expressed a year ago about the opium revenue. It had been justly compared to a revenue derived from an enormous distillery carried on at the public expense. Such a thing would not be tolerated for a moment, and yet we talked of the opium revenue as perfectly innocent. In his opinion it was an immoral thing for the Government to have a hand in, and the sooner they got rid of it the better.

Obituary.

COUNT CYPRIAN WOLLOWICZ.

On the 20th of February, Staff Assistant-Surgeon Count Wollowicz died at Netley, after a prolonged illness, in the thirty-second year of his age. The deceased gentleman belonged to a distinguished Polish family, and took an active part in the unsuccessful attempt to re-establish the independence of his native country. Upon the failure of that attempt, he studied medicine at Berlin and Munich, taking in 1862 the degree of Doctor of Medicine at Munich University. After visiting France, Spain and Italy, he eventually came to England, where he became naturalized. In 1867 he entered her Majesty's service as Assistant Staff-Surgeon, having taken the second place among forty-four competitors in the combined Chelsea and Netley examinations. He afterwards served in the Abyssinian campaign, where, it is supposed, he contracted the disease which ultimately proved fatal to him. Upon his return he went again to Netley, where he was associated with Professor Parkes, F.R.S., in a course of experiments on the influence of wine and alcohol on the human body, which formed the subject of two papers read before the Royal Society and abstracts of which have been published in recent numbers of this Journal.

The following journals have been received:—The 'British Medical Journal,' Feb. 25; the 'Medical Times and Gazette,' Feb. 25; the 'Lancet,' Feb. 25; the 'Medical Press and Circular,' March 1; 'Nature,' Feb. 23; the 'Chemical News,' Feb. 24; 'Journal of the Society of Arts,' Feb. 23; 'Gardeners' Chronicle,' Feb. 25; the 'Grocer,' Feb. 25; 'Produce Markets' Review,' Feb. 25; the 'English Mechanic,' Feb. 24; the 'Journal of Applied Science' for March; the 'Doctor' for March; the 'Brewers' Guardian' for March; the 'Educational Times' for March; the 'Falmouth and Penryhn Times;' the 'Chester Chronicle.'

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department, 17, Bloomsbury Square, W.C., and not to the Publishers.*

[151.]—LIME JUICE AND GLYCERINE.—Most preparations bearing the above name are merely emulsions of almond or olive oil, with lime water or saccharated solution of lime, variously perfumed, and with or without the addition of glycerine. A really "elegant" and useful dressing for the hair may be prepared as follows. It certainly has a more just claim to the above title than most lotions.

℞. White Wax ℥ss
Oil of Sweet Almonds ℥viij.

Incorporate by heat of a water-bath, and add gradually S. A.

Glycerine ℥j
Lime or Lemon Juice, or } ℥j
Citric Acid gr. xxxiij }
Water ℥j }
Rectified Spirit of Wine ℥ss
Water ℥ij
Ess. Lemons ʒij
Essential Oil of Almonds gtt. v.

FRED BARRETT.

In reply to *A. C.*, for a recipe for Lime Juice and Glycerine, I think the following will be found a very good one, and will not separate, as the one *F. C. S.* has given:—

℞. Ol. Amygdalæ ℥iss
Ol. Ricini ℥ij
Liq. Calcis ℥iiss
Otto Rosæ q. s.

Shake well.—J. S. PARKER, *Peterborough.*

℞. Ceræ Alb.,
Cetacei, ana ʒij
Ol. Amygd. ℥viij
Succ. Limettæ ℥vj
Glycer. Boracis ℥ij
Ess. Limon. ℥ss
Ess. Bergam. ʒij

Melt the wax and spermaceti, add the oil and perfume, then shake till cold with the lime juice and glycerine previously warmed.—ALFRED UTLEY.

[172.]—CRYSTAL VARNISH FOR NEGATIVES can be made by dissolving 2½ lb. White Shellac, ½ lb. Mastic, and ¼ oz. Camphor, in 1 gall. hot Alcohol, 64 O.P., and filtering. As a practical photographer, I find it does not pay to make in small quantities on account of waste.—ARTHUR ELSDEN.

[176.]—ROSE EMOLLIENT.—*E. H.* would like to be supplied with a recipe for preparing Rose Emollient.

[177.]—SALAD DRESSING.—Will any reader kindly favour me with a good recipe for the above, which will not separate?—MEDICINA.

[178.]—SUGAR OF LEAD.—Will any of our readers let me know the cheapest process for the manufacture of sugar of lead on the large scale?—CHEMICUS.

[179.]—MOSS ROSE PERFUME.—"*Beta*" would be glad if any one would furnish him with a good formula for inexpensive "Moss Rose" perfume.

[180.]—COPYING INK.—*C. W. J.* would be glad if any correspondent would give a good form for copying ink.

[181.]—WHITE SEALING-WAX.—*C. W. J.* also asks for a form for making white sealing-wax for spirit merchants' use.

[182.]—NINE OILS.—"*Rusticus*" wishes for a formula.

THE PROPOSED POISON REGULATIONS.

Sir,—Kindly permit me, as a member of the Pharmaceutical Society,—not as a member of the Council,—and in as few words as possible, to place before the readers of this Journal and the members generally, some remarks relative to the adoption or otherwise at the Annual Meeting of the proposed regulations as to the keeping and dispensing of poisons.

In the first place, the present Council was bound by a resolution passed at the last Annual Meeting, to take the subject into consideration, and make a further report at the next Annual Meeting, so that under any circumstances, at the risk even of opposition from every side, the Council is in a manner compelled to do this, and, as far as I see, cannot do less. Granted that regulations must be submitted, it is still open for any or every member of Council to vote against their adoption, although obliged by the resolution of the last Annual Meeting to bring them forward in some shape or other.

Secondly, I am aware that it would be more than inconvenient to a very large number of gentlemen, both provincial and metropolitan, to leave their businesses, to attend the Annual Meeting in order to vote either for or against regulations.

Lastly, I would suggest to the members generally, who desire to support or oppose the or any regulations, that they should, amongst themselves, make arrangements for sending from every town in the kingdom, as many representatives as possible and convenient, so that the expression of opinion and feeling either for or against shall be such that the Council may be able, with reason and justice, to set before the Privy Council how great and general throughout the trade is the opposition to, or approval of, as the case may be, any interference with the mode in which any one thinks proper to arrange his shop or conduct his business.

I may venture, perhaps, to add that any supposition that there is a desire to inflict either a hardship or an annoyance is doubtless a misconception; whatever the Annual Meeting may decide upon, the Council of the Society, at least, as I understand the matter, is bound to receive.

A. F. HASELDEN.

Sir.—Probably it will be for the benefit of the Society that Mr. Sandford has terminated the attitude of watching to which he alludes, and has descended into the are naof discussion; and it is much fairer that we should meet upon such conditions.

There is internal evidence that a large part of the support given to the regulations has been given by the elected representatives of the Society writing anonymously, and it is impossible to overlook the evil results of this substitute for adequate publicity to the discussions of the Council. If gentlemen successfully oppose the admission of reporters to its meetings, they may be said to write their own condemnation when using the correspondence columns of the Journal for stating their opinions; but, at the least, it would be decorous to do this openly.

I must hold those who exclude reporters from our meetings as being the cause of my having twice to address you. I conceive that the members of the present Council risk being charged with a grave dereliction of duty by permitting the existing rights and privileges of the trade to be grievously shorn whilst in their custody; and, in a discussion of the whole question, it would have been for the general advantage could members of the Council have obtained categorical replies to the closest questions respecting past negotiations with Mr. Simon, etc.

But the opportunity of eliciting such information for public benefit is denied us, and, as a consequence, the present method is the alternative. Our representative duty of vigilance remains the same, and Mr. Sandford must blame himself and those colleagues who join him in excluding reporters, if he dislikes the only method left open for directing attention to points bearing on the whole question.

The position of the Society is unprecedented. Like Paris, it finds that its defences no longer present their front to its enemies, but the official armament is brought to threaten itself. At such a time, I cannot feel justified in a complaisant assumption that the action of a section of my colleagues is necessarily right, and if the negotiations of 1868 are advanced as the groundwork of the present regulations, I claim the right of considering those negotiations, and the situations of their participants, as matters of public interest. The Act of 1868 has been read by pharmacists all over the kingdom, who can find in clause 1 no warrant for the inflexible course insisted upon by Mr. Simon, Mr. Sandford and their supporters, as being without any alternative. If the terms of the asserted contract in clause 1 are considered, one of their essential principles is that the Society is the best judge of what regulations are desirable and proper, and it follows that it should decide this question without external pressure or threats. The objections made to the present proposals are not against their object, but are, firstly, to their construction and details, and, secondly, to the Government inspection and penal consequences which their adoption would entail.

Now, the Society is bound to regard these practical considerations quite as much as the literal interpretation of a dozen permissive words in an Act of Parliament.

The rights of chemists existed before 1868, and were not all bartered away then; whilst it is unquestionable that the evils that would follow the adoption of the present scheme would, from a State point of view, be infinitely worse than those which it sought to remedy.

The grotesque nature of Schedule A when adopted as a basis for storing remedies, and the wild uncertainty existing as to its boundaries, would lead to one of two things, either the cruel penalties of the Act would be inflicted for merely technical breaches of the law, or the regulations would become a dead letter, and disregard of other portions of the Act would be fostered.

There is one passage in the "Statement of Reasons" which perhaps deserves a bad pre-eminence over all others. It is that where the majority leave the policy which the *Chemist and Druggist* describes when it says the Council "has sufficient reason left to know that it may still hope for victory if it can only succeed in frightening its opponents." The appeal to fear is for the moment laid aside, and the already alarmed brother is soothed by this assurance, "*they* (the Council) *venture to say that no vexatious proceedings will be adopted to inquire into their observance.*" Well might Mr. Schacht suggest at a meeting at Bristol that he thought "compulsory regulations, which were not to be enforced, had better be called by their proper names, 'recommendations.'"

Here is a declaration—(is it based on a "tacit understanding between the Council and the Government"?)—solemnly put forward in the name of the Council. I cannot help asking, What does this mean? As eleven gentlemen endorsed the assertion, will not one of them tell us what are the grounds for so remarkable a promise? It is inconsistent with what we thought to be the opinions of some of "the eleven" when studying their anonymously-expressed views, to which I have already alluded.

Under the *nom de plume* hitherto used by a gentleman belonging to "the eleven," I lately read the following:—"*A more weighty objection, and the only weighty one that I can find, is this, that you introduce the thin edge of the wedge, which will lead to inspection and annoyance from public officers.*"

Are not "inspection and annoyance" to be considered *vexations* to a well-regulated mind and shop?

As our representatives give us two divergent statements, which are we to accept?

On the personal relations of the question to Mr. Sandford, I submit that I have not exceeded either right or propriety, and have kept strictly to the matter in hand.

Mr. Sandford's services to the Society have become a part of its history, and I need not here enlarge upon them, but my reply to the suggestion of inability to recognize these, is a reference to a certain meeting at Norwich, which will show who was the mover of the resolution ultimately developed into a lasting testimony of the grateful feelings of our body.

Mr. Sandford's remarks upon the question of leaders in the *Lancet* and *Pall Mall Gazette* are rather Palmerstonian in style, but do not rebut anything that I stated, and as the former of these journals has produced another article on the subject without giving us the threatened information about the earlier ones, I fear our further curiosity will be disappointed.

With reference to the article from the *British Medical Journal*, I have asked a friend to give notice of a motion on the subject at the April Meeting of the Council.

I am sure that many members of the Executive of the British Medical Association would not approve of the language used by their official organ. Whether the mode of advocacy of the Regulations by certain medical journals will make them more palatable to those for whom they have been prepared is somewhat doubtful, but the unblushing effrontery with which these writers ignore any idea of the experiment extending to themselves is quite amusing.

Probably no error ever developed into a system without having, as a basis, some half-truth. So it is in the present case. Give us, by a uniformity of arrangement, any better security against that chance of error which belongs to everything human, and we should all accept it gladly. But it happens that the conditions and consequences attached to the regulations have convinced the judgment of competent and unbiassed persons in every quarter, that the remedy is worse than the disease.

A few persons holding this opinion have been induced to acquiesce in what they take to be the necessity of the case, their judgment yielding to the threats which have been made, whilst in some quarters we have seen extreme sensitiveness, lest it should be supposed that individuals refused to adopt every suggestion that could be made for giving security against error.

More moral courage than this is requisite; and if we are true to ourselves and to our profession, we have nothing to fear.

In past years we have had to tell Parliament that its Poison Bills and Bills for the Prevention of Accidental Poisoning were delusive in their promised security, and impracticable in their working, and having a good conscience, we cared not if ignorant people charged us with indifference.

We are again put through a similar trial of our moral courage, although with aggravated circumstances.

If the opposition to the regulations arose from selfishness and ignorance, should we find the line of demarcation between the *pros* and *cons* such as it is at present?

Let the lists of those who have declared their opinions during the past two years answer this question.

RICHARD REYNOLDS.

Leeds, February 28th, 1871.

Sir,—In the early part of last July (I think) you inserted a letter from me, which was found fault with by one or two of your correspondents, because my name and address did not appear, although, of course, both had been sent to the editor, though not for publication.

"Quot homines, tot sententiæ." The arguments advanced on both sides received my candid consideration. There was, however, just this simple fact, I wrote to condemn systems and practices, and to point out what appeared to me as existing evils; but knowing that these were tolerably widespread, I did not wish to draw attention to any particular place, nor to particular individuals. And as then, so on the present occasion, the observations offered must stand on their own merits. My motives in writing are certainly of an unselfish character.

The following remarks are elicited by a circular received from the Secretary with reference to the storing and dispensing of poisons.

Now, I certainly thought the Council had taken great pains in making these proposed rules as little objectionable as possible, and was greatly surprised to find such an amount of opposition called forth by them. I hope to be pardoned for saying that personally I do not see any reason for this determined antagonism, nor have I been able to perceive much logical force in the arguments made use of to support it.

One of the stereotyped cries seems to be that hospitals and dispensaries required to be placed under regulation as much or more than the establishments of chemists and druggists. Now, were this anything to do with the matter under consideration, I might be able to say something upon the subject, having been several years chief dispenser at one of the London hospitals, besides being engaged at different times both in private and public dispensaries.

However, it seems to me that at present there are two points for deliberation, and two only.

Has the Government any right to impose regulations upon us? Are the regulations proposed, or any regulations, necessary?

The first question I do not feel disposed to argue. But as regards the second, I am disposed to think that some such regulations as those recommended by the Council are necessary, and that it is to our own interest to adopt such. They can (if carried out in a right spirit) be so arranged as to adapt themselves to the varied requirements of either large or small establishments, and the country will, sooner or later, demand some such concessions at our hands.

Few who know anything of trade arrangements generally will dispute the fact that practices such as the following are rather the rule than the exception:—Bottles and packages containing poisons, interspersed among others containing innocuous substances and non-poisonous preparations, and without any mark of distinction, beyond the ordinary label, to point out the dangerous contents. And whilst, on the one hand, the occurrence of comparatively so small a number of fatal accidents from misadventure may be taken to indicate the general care and attention paid to our duties, a careful inquiry into the causes of these fatal cases when they do occur generally points, on the other hand, to some little laxity in the arrangement or storing of goods, or to the want of some striking distinction in the bottles in which poisonous applications and non-poisonous medicines have been sent out.

Reflecting upon this sort of thing, I some time since adopted a plan almost identical with that proposed by the Council, and the arrangement has certainly added much to my comfort and peace of mind, for just before doing this a mistake occurred in my own shop (from want of this), which would, in all probability, have proved a fatal one had not the suspicions of the patient been aroused by noticing some difference in the medicine.

I am quite as great an advocate for sending out liniments, lotions, etc. in poison-bottles; and this, not only because I believe it may be often a means of preventing persons from getting hold of the wrong bottle, but because in two or three cases of fatal poisoning well known to me, the accident has arisen through the bottle being sent for a repetition of medicine, and instead of this a poisonous lotion had been dispensed.

It is true that persons will bring these bottles for sweet nitre, castor oil, etc., but we never find they object to exchange them for others, and we are rather the gainers than otherwise by so doing. Of course, if we be expected when a customer comes for two-pennyworth of laudanum and opodeldoc to give a poison-bottle in place of any old dirty bottle they may bring, we should be rather losers by the transactions. It will require some little consideration how to meet such cases. Probably a small strip of glass paper gummed to the bottle would answer all requirements.

There seems to be no difficulty in understanding the meaning wished to be conveyed by the Council in the following:—"But with reference to the obligations which the regulations would impose, they venture to say that no vexatious proceedings will be adopted to inquire into their observance." Of course, should any accident occur, it would most likely go much harder with those who shall not have complied with the regulations, and very justly so.

It is much to be desired that, instead of the Council meeting with vexatious opposition, they may have the support of the trade generally; for, although it may be true that no amount of regulations will altogether prevent accidents happening, still they must have a tendency in that direction, and the public will, I am sure, rightly value this guarantee from us that nothing is left undone by the trade that may conduce to their safety. And I most earnestly hope the Council will not by any pressure sought to be brought to bear upon them shrink from doing what they have, I think, wisely concluded to be their duty.

One who has known the Drug Trade more than Thirty Years.

Sir,—Your numerous correspondents show that the poison question is a very vexatious one. It appears to me that every M.P.S. has some good arrangement of his own, and no other will suit him as well as the one he adopts for his own establishment. This is the case with me: my plan is to keep acid. hydrocyanic., etc., in a distinct place, and for the ordinary shop bottles containing per. ant. tart., tr. camp. co., tr. nucis vomicæ, etc., I use, in addition to the ordinary label, one of Silverlock's registered labels, and this simple plan is in all points better for my purpose than any I have seen recommended. It is very plain any uniform system will disturb every plan now adopted, and be very likely to produce that confusion and those mistakes sought to be avoided. In reference to dispensing bottles containing outward applications, the application of sand-paper appears to me the best plan, if any is necessary, as the sign can be removed in case the bottle be used for anything else. The proposed particular-shaped bottle may be used for anything, and create rather than prevent accidents. It will be a great annoyance to have one's premises open to inspection, and this, I am sure, every member of the trade ought to protest against.

February 26th, 1871. M. P. S.

Sir,—That Mr. Brady, Mr. Reynolds and others are opposed to the poison regulations may be taken as sufficient evidence of the reasonableness of the opposition, and ought, I think, to make every one interested in the question pause before exchanging the liberty he now possesses of conducting his business in the way most agreeable to himself for a system by which he will be bound to conform to certain fixed rules.

The main argument of those who advocate the change is, that unless we acquiesce now, we shall, by-and-by, be compelled to submit to a more irksome code.

Such an argument is most humiliating, and is suited to any obstinate or tyrannical official who cares only for the carrying out of some pet scheme.

If on the merits of the question we believe the regulations unnecessary, let it be so avowed, and steps taken, as on former occasions, to resist any Government interference.

That part of the scheme which has reference to the storing or keeping of poisons I consider the most objectionable, inasmuch as it partakes in so great a degree of an inquisitorial character.

We do not admit that the public suffers by the existing method of keeping poisons. What, then, has the public, or Government on the part of the public, to do with our mode of keeping them? It may have a right to say how, or on what conditions, it will receive them, or under what restrictions they shall be circulated, but as to the keeping of poisons I submit that no case has been made out which would justify so objectionable an interference.

Bishopwearmouth, Sunderland. John R. Thompson.
February 27th, 1871.

Sir,—In view of the approaching Annual Meeting of our Society, when, if the logomachy be eager,—

"Collecti flores tunicis
Cecidere remissis."

—it should also be dignified and moderate; and having given a careful and dispassionate consideration to the Council's "statement," I think that reticence or neutrality would be untimely.

It is an axiom in military science, that no fortress is stronger than its weakest point. Now the "statement" possesses one feature of weakness. The resolution authorizing its issue had not an unanimous adoption; hence its intrinsic importance and influence are materially diminished.

Touching the proposed regulation,—any code would necessitate for its effectuation, a multitude of contributive and subsidiary conditions; which, while recognizing professional status and requirement, should not unduly interfere with or impede trade interests and convenience. The new Pharmacy Act, by raising the standard of qualification, insured to the public a security that no mere classified inventory of poison-bottles would have effected. For, without this pharmaceutical curriculum,

"'Tis still to be
Senseless to feel and with seal'd eyes to see."

Notwithstanding, no well-affected chemist will ignore those precautions which prudence and discretion dictate as proper and desirable safeguards.

Leeds, February 28th, 1871. Clement Pierson.

Sir,—Surely the Council of the Pharmaceutical Society cannot be so ill advised as to persist in their attempt to force the obnoxious poison regulations on the trade, now rendered doubly offensive by the addition of a clause to regulate the dispensing of poisons. The opposition already manifested does not, I believe, represent one-tenth of that which exists. Many, like myself, have been waiting in the hope of seeing some formal announcement that the Council had reconsidered their decision, and withdrawn the project. I would warn every chemist and druggist, ere it is too late, not to come under the rule of Mr. Simon and his medical colleagues. If they want to know how it will fare with them should such an unfortunate event ever happen, they have only to look at the tyrannical and despotic manner in which Mr. Simon rules over boards of guardians in the matter of the Compulsory Vaccination Acts. All their individuality of action is gone, and they are mere tools in his hands. *Ab uno disce omnes.*

As to the remarks of the *British Medical Journal*, quoted on page 687 of your last number, they are so insulting to us as a body that I think the Council ought immediately to publish an indignant remonstrance, and let the accredited organs of the medical profession know, in unmistakable terms, that we neither covet their praises nor fear their censure.

Harrow Road, W., Feb. 28th, 1871. WM. YOUNG.

Sir,—In your editorial footnote appended to my letter of last week, you exercise a freedom of inference which I venture to assert is not warranted by any of my remarks. I never said the regulations "should not be adopted, because medical men neglected them," and no part of my letter will bear any such construction. What I said, and what I now reiterate, is, that the proposed regulations evince a disregard for the public safety, and that the position of our Council, in reference to them, shows a want of good faith towards the trade and its interests.

The position I take is that, so far as chemists are concerned, these regulations are not required, inasmuch as every precaution is already adopted; and that to disturb the systematic arrangements now in use, and which are especially adapted to the requirements of each individual establishment, will be fraught with stupendous difficulties to the trade, and positive danger to the public. On the other hand, the so-called surgeries of medical men are, as a rule, so ill fitted, so ill kept, and so scantily-provided with anything like safeguards against accidents, that coercion might very advantageously be applied to them in the interests of society. How very absurd, then, or even something worse, must appear the attempt to legislate for the former whilst overlooking the latter! Chemists will do well to remember that the whole scope and tendency of the "poison clauses" of the last Pharmacy Act have not been towards the preventing of poisoning, but was directed mainly against counter-prescribing. They will also do well to remember who were the instigators of these clauses.

CHEMIST.

[*** Our correspondent errs in supposing we attributed to him any enunciation of the argument we spoke of as fallacious. But since two-thirds of his letter was devoted to comments on the need for poison regulations in surgeries, and on the injustice of surgeries being exempted from the application of the proposed regulations, it seemed to us a fitting opportunity to refer to these opinions as being—whether right or wrong—altogether foreign to the discussion of the present pharmaceutical question, for we believe that will be an advantage if the discussion be kept within its proper limits.—ED. PHARM. JOURN.]

Sir,—Though much has been said about voting-papers in the matter of the new poison regulations, I have not heard anything of our power of voting by "proxy," a form of which I here enclose, and which, it appears to me, should give me that proper and legal influence on the decision of the meeting which is my right; because, though I intend to be at the Annual Meeting, yet it may be so full that I cannot get in; and when I get there, if there is anything like a repetition of the uproar which we had last year, it will be a disgrace to us as debaters.

Now, what could be more simple than one page of the PHARMACEUTICAL JOURNAL filled with a form of proxy, which Journal, being posted, as it is, to all members, each one would be at liberty to stamp with a 1*d*. Inland Revenue (a receipt stamp), name his proxy, and return it to the Secretary at a cost of 1½*d*.? So that there could be a full debate, and a clear expression of the feeling of the members; and if the votes were registered according to the number of proxies, a peaceable and gentlemanly solution of the difficulty could be arrived at, which would not put the country members to the great expense and trouble of a journey to town.

A resolution in accordance with this plan was passed last night at the General Meeting of Chemists in Manchester; and if you would be good enough to print along with this a form of proxy suitable for the case, a full and timely consideration can be taken of its utility.

7, *Lower Hillgate, Stockport,* THOMAS KAY.
February 23rd, 1871.

[*** Voting in the manner suggested by our correspondent would be invalid, since the Charter of Incorporation specified, "That at all general meetings and meetings of the Council, the majority of the Members present having a right to vote thereat respectively, shall decide upon the matters propounded to such meetings, the person presiding therein having, in case of an equality of numbers, a second or casting vote."—ED. PHARM. JOURN.]

HYDRATE OF CHLORAL.

Sir,—Since the publication of the paper upon chloral, etc., in your issue of the 7th ultimo, I have found some of the data there given to be inaccurate; I therefore wish to made this statement public in justice to all of those interested.

My analyses were conducted in good faith; but at that time, as at present, the mode of testing hydrate of chloral was only imperfectly understood; therefore, I was liable to inaccuracies which I have since discovered by repeated experiments upon some of the identical samples.

In using the ammonia test, I would suggest that half the quantity of hydrate of chloral (viz. 250 grains) be treated exactly as prescribed by Mr. Umney; immediately the ammonia is added, well secure the aperture of the tube, agitate the liquid freely and immerse the tube in warm water (the temperature not to exceed 100° F.); when quite cold, read the chloroform layer; in this way coinciding results may be obtained.

My paper upon this subject has called attention to a most important question; already some makers have been improving their manufacture, and I do not doubt great good will accrue to all from ventilation of the subject.

I wish to thank those who have so kindly assisted my endeavour to arrive at truth in this matter.

ALFRED H. MASON.
Liverpool, February 22nd, 1871.

Sir,—Mr. Mason hints that in several of the samples referred to in his paper, alcoholate was substituted for hydrate of chloral; yet this can hardly be correct, for while he states that alcoholate is soluble in cold chloroform, he admits that all those samples were insoluble in that menstruum. What, then, is this body possessing such a definite composition as always to yield identical analytical results? Clearly not hydrate of chloral, for it only yields 57 per cent. of chloroform, and as clearly not alcoholate, because it is insoluble in cold chloroform. I hope that Mr. Mason is following up his inquiries, and that we shall shortly learn the true nature of this hitherto unknown compound.*

The subject was evidently of so much interest that I have been induced to make some experiments on my own account, the results of which I propose to lay before your readers. After making several trials, I have come to the conclusion that caustic potash is, on the whole, more trustworthy as a means of separating the chloroform than caustic ammonia. It does not require the application of heat, and I have, at all events, been able to obtain more constant results in this way. Thinking that the sample obtained by Mr. Mason from my firm might possibly have been exceptional, I have examined samples taken out of five different batches; they were all in cake (the only form in which I have yet made hydrate of chloral) and perfectly dry. I may mention here that I have frequently seen it stated that hydrate of chloral is deliquescent, and this statement is repeated in an editorial article in the PHARM. JOURN. of February 11. According to my experience, pure hydrate of chloral is not in any way deliquescent. I have frequently found that the hydrate made at our works has become damp, and even run to a liquid after long exposure, but I have rejected it as an impure article when it

* Mr. Mason's letter will probably be the best answer to this question.—ED. PHARM. JOURN.

possesses this property; and I have generally found that redistillation of a deliquescent article (rejecting the last portions that come over) produces a perfectly non-deliquescent cake. I have not as yet been able to determine the precise cause of this deliquescence, but I consider it to be due to some impurity of a higher boiling-point than the pure hydrate. At any rate I have always found that the last portions which come over are the most prone to absorb moisture.

The following table will speak for itself:—

Theoretical quantity of chloroform from pure hydrate chloral, 72·20 *per cent.*

Theoretical quantity of chloroform from pure alcoholate chloral, 61·75 *per cent.*

		Boiling point.	Chloroform present.
Dunn, Squire and Co. . . .	A cake .	97°	70·5
" " " . . .	B " .	97°	69·5
" " " . . .	C " .	96°	71·5
" " " . . .	D " .	97°	71·0
" " " . . .	E " .	97°	70·5
Von Martius and Mendelsohn	crystal .	97°	71·0
" "	powder .	96°	71·5
" "	cake . .	97°	70·5
De Haen	cake . .	97°	70·0
Saame	" . .	96°	70.5

I gather from these results that there is little or no practical difference in quality of the principal makes of hydrate of chloral, and that the alarm caused by Mr. Mason's paper is entirely unfounded.

That Mr. Mason conducted his experiments with care I can well believe, but if so, there must have been some error. As he does not describe his method in detail, I am unable to criticize it; but it is at least remarkable that it gave perfectly satisfactory results in the case of the so-called guaranteed article which he has taken under his protection, while it failed altogether when applied to the other makes. As he has raised the question of the fraudulent substitution of alcoholate for hydrate, I thought it worth while to inquire how far such a case was probable. I have therefore prepared some considerable quantity of the alcoholate as an experiment, and I find that it is somewhat more costly to make than the hydrate. The process employed for preparing hydrate of chloral must effectually remove every trace of alcohol from it; and even if this were not necessarily the case, the interest of the manufacturer would lead him to supply the hydrate rather than the alcoholate.

W. Stevens Squire, Ph.D.

Langthorne Chemical Works, Stratford, Feb. 14th, 1871.

In further reference to this subject, Messrs. Domeier and Co. desire to state that the sample, No. 8, examined by Mr. Mason, as representing the manufacture of Messrs. De Haen, has been found on re-examination to yield 64·37 per cent. of chloroform, whereas Mr. Mason's original result indicated a yield of only 55·6. They add that the result of this discussion clearly shows that the manufacture of Messrs. De Haen is really what it is represented to be, pure hydrate of chloral, and they express their gratitude to Mr. Mason for having assisted to establish this fact.

Messrs. Schœtensack desire to state that the chloral hydrate manufactured by Saame, of Göttingen, has been examined for them by Mr. K. Müller, who objects to the ammonia test, and adopted in preference treatment with solution of caustic potash (without heat). In this way he has found the chloral hydrate made by Saame to yield 71·4 to 71·9 per cent. of chloroform. These results, as we have already stated, have been certified by Professor Wöhler.

Messrs. Gehe and Co., of Dresden, object to Mr. Mason's result (No. 9) as not possessing any value until he has shown from what stock, and in what manner the sample in question was obtained.

Irish Pharmacy.

Sir,—Some time ago you called attention to the change proposed to be effected in the law regulating pharmacy in Ireland, and invited correspondents interested in the matter to express their opinions thereon. As an Irish apothecary who confines himself, like many others, exclusively to the business of the pharmaceutical chemist, I wish as briefly as possible to express my opinion of the proposed change. As you state in your article of January 28th, "a chemist and druggist is allowed to vend drugs to any extent, but is absolutely prohibited, under fear of a heavy penalty, from making up a single prescription." This has been the law for nearly a century; and I met the difficulty at once, in common with many others, by becoming an apothecary before commencing business. Some gentlemen who had been in business for years, I have known to attend their classes and obtain the necessary qualification.

I believe that the apothecaries would have no objection whatever to admit the pharmaceutical chemists (by examination) to all the privileges, as regards pharmacy, which they themselves enjoy, and I would wish to see a pharmaceutical society for Ireland; but I decidedly do object to any alteration in the law by which an inferior class of men would be permitted to dispense medicine in this country. The druggists at present in existence have no right to complain; they entered the trade with all the advantages and disadvantages it at present possesses, and they cannot reasonably expect to be placed on a footing with men who have spent much time and money in procuring the necessary qualification.

The medical men in Ireland have gradually given up compounding their own prescriptions, owing in a great measure to the efficiency of the apothecaries; but I believe that the inevitable result of a radical change, by which druggists, under a modified examination, might be admitted to perform the duties of dispensers, would be to force the profession to compound their own prescriptions, lest they might be taken by their patients to incompetent persons.

In England all your recent endeavours have been to raise the status of the druggist, and I have gladly seen the different steps taken by the Pharmaceutical Society in this direction, but I would earnestly deprecate the retrograde movement contemplated in this country.

The great difference between the two countries is, that while in England any person so disposed could sell drugs and compound medicines, in Ireland, while any incompetent person might do the former he could not do the latter. This, I think, most persons will admit to be an advantage to the people of this country.

In conclusion, I would wish to see a Bill passed by which the Irish apothecary, or pharmaceutical chemist if you will, should—without studying medicine or surgery—be compelled to be thoroughly well educated in botany, chemistry, materia medica and all things relating to his business. To this, I think, no English chemist or Irish druggist ought to object.

Aliquis.

E. Raynor (Durham).—*Modified Examination.*—Candidates will be required to read autograph prescriptions, translate them into English, render a correct translation of the directions for use, and detect unusual doses. To weigh, measure, and compound medicines, write the directions in suitable language, finish and properly direct each package. To recognize the Pharmacopœia chemicals in frequent demand, and specimens of roots, barks, leaves, fruits, resins, and gums in ordinary use; the following plants, either in a fresh or dried state, or from plates:—belladonna, stramonium, hyoscyamus, conium, aconitum, digitalis, and sabina; also to estimate the quality of each specimen submitted and its freedom from adulteration. To recognize the preparations of the Pharmacopœia which are not of a definite chemical nature, such as extracts, tinctures, and powders, and give the proportions of the more active ingredients.

[*** Capability of passing this examination would probably be acquired better and more readily by cultivating the ordinary faculties of observation than by any kind of books. For that the every-day experience of a well-regulated pharmacy ought to afford ample opportunity.—Ed. Pharm. Journ.]

Lux.—Yes.

W. Lea (Dorchester).—Recipes for making Brilliantine will be found on p. 437.

W. W. (Exeter).—Passing the Minor Examination is sufficient qualification for entering business on your own account as a Chemist and Druggist, but not as a Pharmaceutical Chemist.

Communications, Letters, etc., have been received from Mr. J. Ince, Mr. W. Southall, Mr. C. A. Staples, Mr. J. Noad, Mr. W. Hills, Mr. W. Hartley, Mr. J. Birt, Mr. C. Ekin, Mr. C. Pierson, G. W., F. O., H. R. H., W. H. P., E. W., "A Medical Assistant," "Conservo," "Iodi," "Old Student," "Farina," "Sincarf."

THE MICROSCOPE AND ITS REVELATIONS.*

BY W. B. CARPENTER, M.D., F.R.S., F.G.S., F.L.S.

When I last had the pleasure of addressing you, I directed your attention to some of those lowest and simplest forms of Animal life which have of late years been very much the subject of observation amongst Naturalists, and the study of which has added, I think I may say, a great deal to the science of General Physiology, because it has led us to perceive that some of the most important functions of life in the higher animals are really performed by the protoplasmic substance which enters very largely into the composition of their bodies, and which, as it were, prepares the material that is turned to higher account in the more complicated structure of those organisms that we are accustomed to call superior. Let me dwell for a moment on what we mean by superior and inferior organisms. By superior we mean those in which there is the greatest division of labour, in which the work is most highly specialized, in which there is a particular apparatus for each function, and in which that apparatus is carried to its highest degree of perfection. Why do we call the hand a superior instrument to the corresponding extremity of any of the lower animals, even the most highly organized apes? Because it is much more highly specialized. We do not use it for support or progression; it is entirely used with us for prehension, for laying hold of things. We can oppose the thumb to every individual finger, but an ape cannot; he can only take hold with his whole hand, and he uses his anterior as well as his posterior extremities for support and progression. That is one instance of what we mean by specialization. I showed you on the last occasion that a simple particle of animal jelly lays hold of food by drawing it in to itself without a mouth, and extemporizes, so to speak, a stomach; that without any proper mouth, and without any proper stomach, it performs the function of digestion; that the material imbedded in it is dissolved by its means, and converted into the same protoplasm; that it has also in itself the power of motion; and again, that if it has any power of feeling, this must be diffused throughout the same protoplasm. But this protoplasm in us is simply the preparative material for all that wonderful mechanism which, with us, as in all higher animals, is made subservient to those much more highly specialized and complicated functions which man is capable of performing, and which all minister in the end to the maintenance of his conscious life, his intellectual power, his moral feeling and so on.

This evening it is my purpose to carry you into a slightly different field—into that domain of life in which we have active motion, and in which we have again the curious phenomena of motion in plants;—to carry you, in fact, into the domain which has been the field of great perplexity to naturalists, but which is gradually becoming, by the careful study which has been bestowed upon it, more and better understood.

When I began to devote myself to the application of the microscope to the study of the lower forms of plants and animals, it was believed, with very few exceptions, that everything which has motion must be an Animal. An old observer, Vaucher, of Geneva, had directed attention to the fact that little particles issue from some of those green threads that you see in running streams, the *Confervæ*, which particles, he said, were animals in a very early stage of existence, and that they then returned again to the form of plants. He said they were animals, because they had the power of motion. He watched them very carefully with the imperfect instrument he had, and he found that the motion gradually subsided; they settled down, and then began to develope into undoubted plants. Here is a diagram of one of the plants which Vaucher observed; it is known as *Vaucheria clavata*,—the club-shaped *Vaucheria*,—from the tendency of its ends to swell into these club-shaped masses. It is just one of those green, thread-like plants that you will see in running streams, very often attached, for instance, to the stones where water is running over a mill-dam. When it is in its ordinary growing condition it is simply a filament; but when it is going to put forth one of those curious buds, so to speak, it swells into a knob, and there is an accumulation of green matter in the extremity. This separates itself from the green matter in the tube, and by-and-by it is seen that this green knob has a distinct envelope of a greater thickness than the proper wall of the tube. Then the covering bursts, and from the interior of the tube there issues forth this body, which is known by the name of the *zoospore*. The term spore is given to the reproductive particles of the lower plants as distinguished from the seeds of the higher. The seeds, you know, contain with the germ or embryo a store of nourishment, laid up either in the cotyledons when fleshy, as in the pea or bean, or in the albumen when the seed is albuminous, as in wheat and many other plants. In either case that store is applied to the nutrition of the embryo before it is sufficiently developed to obtain its own nourishment, to get its own bread, as it were. Now, in the cryptogamic tribes generally we find that these minute particles are launched forth upon the world with a power of getting their own bread at a much earlier period, and therefore there is not in them the same store of nourishment that is supplied to the higher plants. The word *spore* is applied to things really very different, of which I shall give you an illustration by-and-by. You are not to suppose that the spore always represents the seed of the higher plants. In this case the spore is a sort of little bud, and it is called a zoospore, from the fact of its having a power of motion very much like animal motion,—*zoon* meaning animal, and zoospore, a spore endowed with power of motion like an animal. This little bud, with a rather thick casing, issues forth from the end of the tube, which bursts and gives it out. Then it takes a spherical form, and then, after a little time, it is seen to be in active motion, and this active motion is given to it by the vibration of a fringe of minute hair-like processes, which are termed *cilia*. These are the active agents of movement in the lower plants, in the lower animals, and in various parts of our own bodies. (For instance, the whole surface of the respiratory tract, as it is called, all the mucous membrane of the air-passages down to the air-cells of the lungs, is covered with these cilia.) By the action of these cilia forming this fringe, this little particle is carried about in the water, and thus the large number that issue from the various filaments of the plant are dispersed, and carried to new localities. After a

* Lecture delivered at the Evening Meeting of the Pharmaceutical Society of Great Britain, March 1, 1871. See *ante*, p. 641.

time the ciliary motion ceases, and then the bud settles down, and begins to extend itself into filaments, and thus becomes a plant like that from which it proceeded.

This is not the result of a true generative process, as the seed is; it is more like a bud. There are various plants that throw off buds by the process that we call *gemmation;* and this is a process of gemmation or budding, not a process of true sexual generation. The *Vaucheria* was observed in the last century by Vaucher, and he ascribed this power of motion to animal life, and considered that here was a curious passage from vegetable to animal, and then back again from animal to vegetable. That, however, we now understand not to be the case. This ciliary motion is not a phenomenon at all peculiar to animals: there is no question that a very large number of bodies that have been described as animalcules are truly plants, and the tendency now is continually to carry into the Vegetable kingdom additional tribes of these bodies that have been called animalcules, rather than to extend the Animal kingdom to comprehend those new and varied forms that are continually being discovered.

You may ask me what is the difference between an Animal and a Plant, and we may well stop a moment to notice what I believe to be the true physiological distinction between them; namely, that the Animal is essentially dependent upon previous plant life for its nutrition, having no power of living upon the elementary substances contained in the air, the water, or the soil. It has no power to combine these with itself, but is dependent entirely on organic compounds which have been previously prepared and combined by the plant. On the other hand, that the Plant has the power, especially, and indeed almost solely, under the influence of light, of decomposing the carbonic acid of the air, of uniting the carbon which it obtains from the air with the oxygen and hydrogen of water, and also of decomposing the ammonia of the air and of the soil (for the air always contains a small quantity of ammonia), and of uniting the nitrogen of that ammonia with the oxygen, hydrogen and carbon that it obtains from the air and water, to form nitrogenous compounds. Thus the plant is continually manufacturing, so to speak, these compounds, and the animal is continually destroying them, and returning them to the inorganic kingdom, because the whole life of the animal is one of decomposition. The animal is constantly giving back to the mineral kingdom—in the carbonic acid of respiration, and in the production of urea and similar compounds in the urine, which decompose into carbonate of ammonia—the very same component elements which it has obtained from the vegetable kingdom, and which the vegetable has taken from the mineral. This is represented here in a circular diagram, where you see the Vegetable kingdom drawing its materials from the Mineral kingdom, combining them into organic compounds, and then imparting them to the Animal kingdom, which in its turn from the decompositions which are always going on in its body, returns them to the Mineral kingdom. That is the physiological distinction, and that, I believe, is the only one on which we can rest with any degree of satisfaction; and even this does not always hold good, for there is one very limited tribe of plants, which a chemist would say ought really to be placed in the animal kingdom, and yet the resemblance to undoubted vegetables is so close that it would be a breach of all natural arrangement to separate them. I allude to the group of Fungi. None of you would feel that there was a fitness in describing a mushroom as an animal, and yet as regards nutrition it is an animal. The group of *fungi* is a group living upon organic compounds previously prepared, and light is not essential to them; many thrive best in darkness. In fact, in the common mushroom it is only the fructification, the upward extension of a growth that is taking place under ground, that appears above the soil. The real nutritive life in the mushroom is performed beneath the ground; what it pushes up is simply the fructification. In the early stage of the mushroom—what is known as the mushroom spawn, when it is laid down to produce the mushroom—the growth of what is called a *byssus*, a long filamentous growth, takes place best in darkness. In old cellars where wine has been laid down a long time, there is often a most extraordinary fungous growth; and underneath paving-stones, again, there is often a fungous growth, which has been known to lift up the stones; and all that takes place in darkness. There is no question that fungi as a rule thrive best in darkness up to the time when they put forth their fructification, and that they appropriate, and have a most peculiar power of appropriating, decomposing organic matter, supplied either by the vegetable or the animal kingdom. You all know the appearance of the growth of mould, which often takes place on preserves, on chemical preparations, extracts, and so forth; and the mould that produces the blueness of Stilton cheese. All these cases show you the readiness with which mould developes itself on substances which are either decaying or ready to decay. And this mould, produced from germs of fungi sown as it were upon such substances, helps their decay. This is a very important and very interesting point, upon which I wish to fix your attention for a few minutes, viz. this peculiar habit of the fungi, and the changes to which it leads. We have heard a great deal lately about disease germs, but I venture to say that Professor Tyndall's lecture, although extremely interesting, and although presenting to the eye, and, so to speak, demonstrating their presence by the beam of electric light which he was able to send through an atmosphere containing such germs, really added nothing to the knowledge previously possessed by naturalists, because we all knew perfectly well that the air is loaded with these germs of fungi. If you take a puff-ball and press it between your finger and thumb, you will see the fine dust that issues forth, and which is carried by the winds into every quarter; for a puff-ball consists of a number of germs or sporules which is really scarcely capable of being expressed in figures. If we measure these, and then consider the size of the whole mass of a large puff-ball, with reference to the size of any one of these minute particles, we can form an approximate calculation of the number of particles contained in it, and it is something almost inconceivable by any effort of our imagination, and almost incapable of being expressed in figures, like the great distances of the stars. Thus you see that these particles must be continually being diffused through the atmosphere in every direction. That is only one case out of multitudes.

Now, with regard to the demonstration of this universal diffusion, many years ago a friend of mine in Bristol made the following experiment, which I mentioned to Dr. Tyndall, and which he was very glad to hear of, as it offered a complete demonstration, by a different process, of the facts which he was wishing to prove. The gentleman I refer to, Dr. Brittan, at a time when cholera was prevalent, employed a man to blow with a pair of bellows for several hours in a room in a low dirty neighbourhood. The bellows were connected with a siphon, and the bend of the siphon was immersed in a freezing mixture. The air had moisture in it, which was condensed as it passed through the cold tube, and carried down with it the floating particles contained in the air. Dr. Brittan sent me a specimen of this to examine, and the fluid was quite brown with the quantity of sporules of fungi which it contained. Yet this was simply the natural moisture of the air condensed. To give another illustration. About the same time my friend Mr. John Marshall was led to pay a great deal of attention to the prevalence of smut and rust in wheat. It was a year after a very bad season, when there had been a great deal of unhealthiness in the wheat grains, and there was a large quantity of bad bread sold, especially among the poorer classes. It was at a time when there was an epidemic of cholera, and there was a notion that this disease was due to the presence of these germs of fungi. Mr. Marshall formed the idea that the presence of these germs in the evacuations was simply due to the patients having eaten bad bread, and he examined through the microscope a great many specimens of this inferior bread. He found that all the inferior bakers were selling bread that contained a quantity of these sporules of fungi. Then he got a number of samples of flour, and found that whilst the inferior flour contained an enormous quantity, even the best flour, with a very few exceptions, contained some. Then he traced it further back to the wheat grains. He got a number of samples from different dealers, and found that almost every grain had entangled amongst the hairs at the point of the grain two or three or more sporules of fungi. That shows the universality of their diffusion, and it added great strength to an opinion I had been previously led to entertain, that the prevalence of these diseases in particular years depends upon the general unhealthy condition of the grain, predisposing it to decomposition; and that the sporules alighting upon a healthy surface will not grow, whilst again, alighting upon a grain already unhealthy, the fluids of which are prone to decomposition, the sporules find an appropriate bed, and begin to vegetate, and then their increase spoils the whole grain very rapidly. Take again the case of a disease that many of you have heard a great deal about—diphtheria. One of the first signs of diphtheria is almost invariably the presence of the diphtheritic crust, as it is called, upon the fauces; and that diphtheritic crust, when examined with the microscope, is found to be almost entirely a fungous growth. But I do not believe at all that the fungous growth is the origin or essence of the disease. It is simply this, that there is a peculiar unhealthy secretion thrown out, which becomes the *nidus*, the bed for the development of these fungous germs, which are constantly floating about. In the same way with the vine disease and the potato disease. I do not believe in either case that the fungus is the first cause of the disease, but that in both instances it is a predisposition to an unhealthy condition of the plant, in consequence of bad cultivation, forcing cultivation especially, which gives to the fungus its power of development. This peculiar power that fungi have of decomposing organic substances is again manifested in the phenomena of ordinary fermentation. Ordinary yeast, which is a substance familiar to you all, is a mass of vegetation. This discovery was made about twenty-five years ago, I think; and I had the pleasure of being the first to satisfy Professor Liebig, (who was at that time in England, and who scouted the idea that fungi had anything to do with vegetation,) that these were unquestionably organic bodies, and thus led him to be more tolerant in his views and in his expressions with regard to those who maintained, as is now universally admitted, that it is the presence of these fungi, and their peculiar power of inducing decomposition, which is really the cause of fermentation. If you can shut out these fungi, for example, in the treatment of an abscess communicating with the air, or of a compound fracture, (and this is one of the greatest improvements of modern surgery,)—if you can shut out these, by the use of carbolic acid or other means; if you can filter the air of these germs of fungi, and protect the cavity of the abscess or the compound fracture, like an entirely internal cavity, instead of allowing it to communicate with the air,—you then promote very considerably indeed the patient's welfare, and give him a very much better chance of recovery. You thus see how one thing leads on to another, and how important improvements in medical practice arise out of a knowledge of the conditions of these low forms of vegetation.

Yeast is composed of a mass of cells which, during the process of fermentation, grow from single cells, putting out little buds, until a single cell grows to four, five or six. By the time that they have formed these little groups of five or six cells, the fermentation has advanced sufficiently far, and it is stopped; but, if it were allowed to go on, it would then put forth a fructification, and become a regular well-known form of fungus, very much like that which you find in old vinegar. Again: there are other forms of fungi which grow in the silkworm, and constitute one form of silkworm disease, which has been extremely fatal in silk-growing countries; in fact, it is said that it has produced losses to the extent of thirty or forty millions sterling, and yet all this arises from a minute fungus, which is developed in the interior of the body of the animal.

I have dwelt upon this subject of the peculiarity of Fungi in relation to the general doctrine of the distinction between animal and vegetable life, because it is a subject of great interest at the present time, and has an important relation to those duties of medical men with which you are likely to become very familiar.

I return now to the point from which we started, the active motion that we find in many of the lower Plants. This motion you may see extremely well if you happen to be anywhere on the seacoast, and take up what you find growing there on the shore, those long, green seaweeds called *Ulvæ;* some of them narrowed very much like blades of grass, and some having large, extended surfaces. In the summer time you will be almost sure to find some of these white at the ends and over a very considerable portion of the edge, perhaps for a third of its length. That white portion is the part of the frond which has discharged its zoospores. All that white portion was once green. The green cells were then filled with green matter congregated into little masses, and by the rupture of the cell they escaped in the form of zoospores. If you take a piece of this sea-weed, and put just the edge where the green and white join under the microscope, you will see the spectacle that astonished me some thirty years ago, when I believe no one else in this country had observed it. An eminent Swedish naturalist had observed it, but I believe I was the first to see that very wonderful spectacle in England. It was really like a swarm of bees,—the multitude of these minute particles that had issued forth in active motion from the cells, and were issuing forth, for I saw them actually coming out from the cells just on the border of the white or empty portion. That is one of the most familiar phenomena that may be observed on the seacoast, and there are many fresh-water *Confervæ* which show you precisely the same.

This motion, then, is a very common phenomenon amongst the lower Plants; and when we once come to appreciate that, we see that it is really the key to the interpretation of a great many other phenomena which had been previously wrongly viewed. For instance, I have here a representation of a favourite object with microscopists, which was called, long after I began the study, the globe animalcule, or *Volvox globata.* They are some of the most beautiful things that can be seen under the microscope, and consist of globular bodies, rolling on and on, turning on their axes, swimming through the water, and studded all over with beautiful little green points; and they very commonly have in their interior other green globular masses. It may surprise you to be told that this is unquestionably a Plant. We can now trace those as the highest, the most specialized forms of a tribe of plants which shows itself in various grades of simplicity, from the single little green cells with one or two vibrating filaments, by the agitation of which it moves, up to a form as complicated as the one here represented. Here are diagrams of some of the less complicated forms, but you will easily see that they differ only in form and not in essential organization, because it is the single cell and its vibrating filament which is the essence of the whole thing in every case. We find that these spheres in the interior are younger bodies of the same kind. One of these little cells buds by the process of cell-multiplication, and forms a little group or cluster; that group becomes a larger mass, and that mass, still with the cells closely packed together, forms a sphere which may often be seen revolving in the interior of the parent sphere. This, again, is not a process of sexual generation, but of gemmation. There is a distinct process of sexual generation, into which time does not permit of my entering to-night. The parent sphere bursts and sets free the contained globes; and each of these is changed, by the formation of a sort of glassy, transparent sphere, which developes itself between the separate green cells, from a green opaque sphere into a large transparent sphere. Here are representations of a number of different forms of this low tribe of plants, all distinguished by their red or green colour. You may ask how do we know that they are plants? We find that they decompose carbonic acid under the influence of sunlight. The great distinction which separates them from the Animalcules which they much resemble, is that all true Animalcules feed upon other animalcules or upon plants. By this distinction we can draw the line pretty sharply except in such perplexing cases as that of the fungi, which seem to unite the attributes of both kingdoms.

To give you an illustration of the dependence of one kingdom upon the other, I may mention a circumstance that happened to myself some twenty-five years ago. I was then living in the neighbourhood of Stoke Newington, and attached to the house in which I was residing there was a cistern that I could look in upon from my staircase window; it was quite open at the top and was filled with rain water. This cistern had become foul from leaves dropping into it, and early in the summer it had been cleaned out. A short time afterwards it was filled by a heavy thunderstorm, and in a few days, going up and down stairs, I noticed that it had a green scum upon the surface, and that this green scum came to the surface when the sun was shining upon it, but that at other times it was not to be seen. On examining some of this, I found it to consist of minute separate cells, with a couple of little tails, so to speak, which were long *cilia*, and these were in active motion. Now at that time the doctrine of Ehrenberg had undisputed sway, and not one of us young naturalists would venture to question the dicta of so great a man. I myself, however, in my own mind had come to entertain a very strong opinion, indeed, that these must be Plants, notwithstanding their active motion. And a very curious circumstance followed, which illustrated the relation of the Vegetable to the Animal kingdom remarkably well. There soon appeared in the cistern a quantity of Wheel Animalcules, creatures of extremely high organization in comparison with some of the lower forms. They fed most greedily upon these little plants; and it was, in fact, a great amusement to myself and friends to take out a few of these wheel animalcules, keep them in pure water for a day or two, to starve them, and then to put in a drop of water from the scum of the cistern loaded with these green cells. The eagerness with which they gulped it down was something only to be paralleled in recent times by the eagerness of the starving population of Paris when food was supplied to them. Here then you see, first the Inorganic material,—the water,—contained in a clean cistern, filled up at once by a sudden shower; from the oxygen and hydrogen of the water, and from the carbonic acid of the air, and from the minute quantity of nitrogen contained in the ammonia which is always found in rain water, the plant manufactured its materials, so to speak. The germ of the Plant, conveyed no doubt by the wind, or brought down by the rain, manufactured the materials, and developed into this enormous mass of vegetation. When that mass of vegetation had been produced, then the Wheel Animalcules, also brought by the wind,—for they are capable of being dried up completely, not only the eggs but the wheel animalcules themselves being capable of surviving the most complete desiccation,—dropped into the cistern, and found such a copious store of food and also of warmth, that they developed themselves very rapidly, and both by gemmation and by the production of eggs would multiply at an extraordinary rate. After a time, in fact, they seem to have killed out the plants upon which they lived, for I found that both plants and animalcules underwent a rapid diminution, so that in about a month afterwards they were scarcely to be found.

Before leaving this last tribe of plants I would mention to you that we now include in that group of lowest plants, the Protophytes, those very beautiful forms which are known as the *Diatomaceæ*. These diatoms are distinguished as having a siliceous envelope; they form, cell by cell, a deposit of silex, which often has markings of the most extraordinary beauty; and the variety of these diatoms, and the extraordinary beauty and delicacy of their organization, make them favourite objects of study with microscopists. Then again, there is one point in their structure which has been of very great value to microscopists, viz. that they furnish some of our very best test objects. Now the finding of a really good test object is a matter of very great importance in the breeding, if I may use the expression, of the best object-glasses; for our manufacturers set themselves to the improvement of object-glasses, just as breeders do to the improvement of racehorses or prize oxen or pigs. Their object is to produce the best glasses, just as a man tries to fatten a prize ox in the shortest possible space of time. The manufacturers of microscopes set themselves to make lenses that shall show certain test diatoms either better than any other lenses or with a lower magnifying power. Now, there is one thing that I must put you on your guard against, and that is the tendency to producing diatom-resolvers, so to speak,—lenses that shall best resolve diatoms; but this deteriorates to a certain degree from the production of lenses that are most useful in actual physiological research. This is a doctrine I have been preaching for many years, and I now find it is generally accepted,—that the lenses which are best for resolving diatoms in virtue of their wide angle of aperture are not, generally speaking, the best for ordinary physiological work. Therefore, if you are going in for a microscope and for getting the higher class of lenses, you should always consider what you want; if you are going to study these diatoms, then you must get lenses of particular qualities, just as if you want to hunt or ride races you must have horses that are of different qualities from those you would use as ordinary carriage horses. This is a point not sufficiently understood, and there is a great tendency amongst our makers to meet the wishes of those who desire these special lenses to resolve special diatoms, and to work them up so as to get out of a particular power results that really ought not to be expected from it. Every power, in my opinion, has its own particular attributes, and to attempt to make a lower power do the work of a higher is a great mistake. Every power should be adapted to do the best work of its kind, to do in the best manner the work for which it is properly suited. That will be found to be the case with well-corrected lenses of comparatively small angle of aperture. I mean small in comparison with the very wide angles that are now sought in powers from a quarter of an inch upwards.—I make these remarks because I really hope and believe that some of you will make the microscope an object of interest in that kind of recreation which we all of us require after the fatigues of business; and, as I said in the last lecture, I cannot imagine anything more grateful to the mind, and really more interesting to those who will acquire the knowledge requisite to give it that interest. These lenses of a moderate angle of aperture may be obtained at very much lower cost than these special lenses that are manufactured with the express view of resolving diatoms.—I have placed several specimens of these extremely beautiful forms under the microscope upstairs. I will allude to them more particularly presently, but I may say there is no doubt whatever they are plants. They have all the attributes of plants, for if we just take away this curious siliceous envelope, we have simply a vegetable cell.

There is one very curious and interesting thing about them, namely, the fact of their conjugation. This was discovered by my friend Mr. Thwaites, whom I have the pleasure of reckoning one of my own early pupils, and who is now curator of the Botanic Gardens in Ceylon. It was very much in consequence of my recommendation that he devoted himself with a microscope that we should scarcely look at, so poor was it, certainly inferior to one which you can now get for £3 or £4, to the study of the lower tribes of plants in the neighbourhood of Bristol. He was rewarded by the discovery of this very curious phenomenon, which is termed conjugation. I will show you what this means in some other tribes of plants. There is one of these filamentous *Confervæ*. Two filaments of this, lying side by side, put out little projections, these unite together, and the green matter passes entirely from the cells of one tube into those of the other, and then, after a time, it all aggregates together and forms this green mass which is liberated at last by the bursting of the cell that encloses it. These, I believe, are true sexual products, and this conjugation I regard as the lowest form of a true generative process, the reunion of the contents of two cells. Here there is very little difference between the male and the female. You can scarcely see which is the male and which is the female. Sometimes the process takes place in a little bridge between the two; each discharges its contents into the little bridge, and there does not seem to be any definite difference between the one and the other. But then, on going a little higher, we find that what is discharged from the cell that empties itself completely is not mere simple green matter, but is composed of little minute filaments, similar to the spermatozoa of animals. These little green filaments are called antherozoids, and they take the place and perform the function of the pollen liberated from the anthers of flowering plants. They are called antherozoids, because they are so much like the spermatozoa of animals, -zoid being the termination expressing likeness to an animal. That mode of conjugation leads us towards the true sexuality of the higher *Cryptogamia;* but the conjugation of Diatoms is essentially similar to that of the conjugating *Confervæ*. The variety in the forms of diatoms is very great, but their conjugation is always the result of the meeting or reunion of two cells; and sometimes the contents of one are entirely discharged into the other, and sometimes the contents of both cells are discharged and mix with each other, and then a new envelope forms around it. That discovery was a most important one in fixing our ideas as to the real character of these bodies, by showing that they were as truly Vegetable as these filamentous *Confervæ*, about the vegetable nature of which there is no question whatever.

Now I will take you to a higher form of vegetation, the Ferns, to show you what has been the remarkable result of microscopic study in throwing an entirely new light upon the sexuality of the *Cryptogamia*. You all know that from the time of Linnæus the sexuality of flowering plants has been admitted, and that the pollen performs the function of the male, and that the apparatus containing the ovules is essentially the female part of the organization. But as to the *Cryptogamia*, the lower tribe of plants, including ferns, mosses, seaweeds, and so on, there was no knowledge at the time of Linnæus what their true generative process was. It was perfectly well known that they had a fructification. I suppose most of you know by ordinary observation those long stalks of the mosses that grow upon walls. For instance, in the autumn you will see these mosses bearing long stalks with beautiful little urns at the top, and these urns contain a number of little bodies, which are known as the sporules of the moss. So, again, you are acquainted, no doubt, with the so-called fructification at the back of a fern-leaf, consisting of spots or ridges of a brown, or in their early stage yellow hue. They are made up of minute spherical, or pear-shaped bodies, composed of two halves, that are carried apart when they burst by the elastic ring that extends them, and they thus set free the little sporules that they contain. If you take a fern-leaf in fructification, put it upon a piece of white paper, and leave it for a day or two, you will find the paper covered with an excessively fine brown dust. If you examine this with a microscope, you will find that it is composed of very minute particles, rounded or angular, which are known as sporules, and every one of these may produce a new fern. But, although all this was known, it was not known how these sporules originated, or whether there was anything in the ferns or mosses at all comparable to the sexual processes of the higher plants. That discovery was made by Suminski, a Polish count, about twenty-five years ago, although it had been partly made before. That was the origin of all our improved knowledge of the *Cryptogamia;* and I will now show you what is the real generative process in the ferns. That spore is a bud. The whole of this apparatus that we call the fructification of a fern is a process for producing *gemmæ*, or buds; and the real sexual generation takes place in a very early stage of the growth and development of these *gemmæ*. If you sow some of these sporules upon a bed of damp earth in a hothouse, where the surface of the garden pot is always kept moist by the dampness of the atmosphere, and at the same time properly warm, you will find after a time that the surface of the mould is covered with very minute green particles; and if, when they be grown a little larger, you take them up, and submit them to the microscope, you will find that they are little, flat, leafy bodies, with rootlets passing down into the soil. If you have not access to a greenhouse or hothouse, there is another very simple mode by which you may perform this very interesting experiment. If you take a bit of porous sandstone, put it in a saucer of water, and sow the sporules of fern upon it, and then cover it over with a bell-glass and keep it in a warm place,—for nothing is needed but water and air to supply the materials for the development of these little bodies,—they will grow into the minute leafy expansions represented on this diagram. When these are carefully examined in the microscope, it is found that there are two kinds of bodies in them, quite distinct from the ordinary cells. One kind consists of little chimney-like bodies, at the bottom of each of which is a green cell; and if we look down at the tube from above we see it is bounded by four cells. In other parts we see little rounded or globular groups of cells, every one of which contains, coiled up within it, a little spiral filament, which is set free by the bursting of the cell, and then it is exactly like the spermatozoon of a mammal. Every one of these clusters sets free a number of these antherozoids, which move about on the leafy expansion until they make their way into the aperture of one of these chimney-like bodies, and, reaching the bottom, they come in contact with the green cell, and dissolve away, as it were, upon it. Their substance becomes incorporated with the substance of the green cell, which at that time has no definite cell membrane; but after this incorporation has taken place the cell is invested with a membrane, and becomes the true primordial cell of a new fern, which is progressively developed from it. That is the process which takes place in these little minute green leafy bodies that had previously escaped notice almost entirely. Here are representations of the various stages through which it passes, and the leafy expansion to which I have already directed your attention has exactly the function of the cotyledons in a common plant; it absorbs nutriment, and supplies it to the young embryo, until it has developed a rootlet capable of penetrating the soil, and a young leaf extended to the air.

You see, then, what a curious history is here opened to us by this minute examination; and the same history has been traced out in the Mosses, and in the tribe of plants humbler than the mosses, the Liverworts. The same again in the seaweeds, the common *Fucus vesiculosus*, so plentiful on our coasts. The green and yellow swellings found upon these contain cells which again contain these antherozoids, and other cells that contain the primordial embryo cells; and there is in all a true sexual reproduction. There is some uncertainty about the Lichens and Fungi, but there can be no reasonable doubt that the same process does take place in some stage or other of their growth, as it has been traced in all other *Cryptogamia*.

These are a few scattered notes of some of the phenomena of the humbler kind of vegetation, which I thought it would be most interesting to you to be made acquainted with; and I will conclude with noticing one or two forms of Animal life. It is impossible for me to go into the general subject of Animalcules in this lecture, because our time is already expired, and I wish you to have an opportunity of examining for yourselves some microscopic objects which I have placed in the library. But I wish to direct your attention, in connection with the last lecture, to one tribe of these lower forms of animal life, the *Polycystina*, which are closely akin to the Foraminifera on which I before spoke to you, but which differ in this respect, that these little masses of animal jelly, which are the constituent parts of these creatures, the *Polycystina*, have the power of secreting silex, just like the Diatoms among plants. All the skeletons of the Foraminifera are composed of carbonate of lime, except where they build themselves up skeletons with sand; but the *Polycystina*, which are generally speaking animals floating on the surface of the sea, form the most beautiful skeletons it is possible to conceive, of silex or flint. There are a great number of these living at the present time on the surface of our seas, and in the Adriatic they seem to be especially abundant; but some of our best illustrations of this group are obtained from fossil deposits, and especially from one in Barbadoes. The island of Barbadoes is chiefly made up of two rocks, one a converted coral, a coral limestone, and the other a sandstone, which is entirely, or almost entirely, composed of these *Poly-*

cystina. To prepare them, all that is necessary is to boil them for a short time in soda to dissolve away the cement, which more easily dissolves than the shells themselves; and then it is found that the whole mass that remains is a mass of extremely beautiful siliceous shells. Upstairs there are placed in the microscope two examples of these, one an ordinary group, which I obtained by the process I have just described, and the other is a selected specimen. You must not suppose that the beautiful circles you see there occur in nature; they are picked out by the delicate fingers of children, and arranged in rows, so as to constitute, so to speak, a show object.—After briefly describing the various specimens arranged in the library under the microscopes, Dr. Carpenter concluded his lecture by expressing a hope that he had succeeded in inoculating some of his hearers at any rate with a taste for what he was confident would prove both an interesting and valuable pursuit, ministering, at the same time, to recreation and mental improvement.

IVA (*ACHILLEA MOSCHATA*).

BY DR. A. V. PLANTA-REICHENAU.

The plant is known in Switzerland as forest lady's herb (*Wildfräulein-Kraut*), and has been used there for centuries as a stomachic, tonic, etc.

The author collected the herb before flowering without the root. It was, in the form of a coarse powder, distilled with steam until volatile oil ceased to come over, and the aqueous decoction evaporated to the consistency of an extract. The herb thus exhausted with water was dried and extracted with alcohol until it ceased to impart to it a bitter taste; most of the alcohol was distilled off.

Iva Oil.—The crude volatile oil is bluish-green, of a peculiar, not disagreeable odour, and a taste reminding of peppermint. It commences to boil at 170° C.; the greatest portion distils between 180° and 210° C.; the distillate between 230° and 260° C. is brown and has the odour of wormwood. A dark brown soft resin is left behind, which is not bitter; insoluble in absolute alcohol, but readily soluble in ether and oil of turpentine. The rectified oil was of a faint yellowish colour, an agreeable refreshing odour, and a warm bitter taste, reminding of peppermint. Its composition is $C_{48}H_{40}O_4$; the author names this ivaol.

Ivaïn.—The dark green alcoholic liquid was precipitated by alcoholic solution of acetate of lead; the filtrate was treated with sulphuretted hydrogen and the filtrate evaporated; the residue was washed with acetic acid until the washings were colourless, afterwards with water, until it floated upon it. It was then repeatedly dissolved in alcohol and evaporated, to remove acetic acid, then treated with animal charcoal and the alcohol evaporated. Ivaïn $= C_{48}H_{42}O_6$ has the consistency of Venice turpentine, is of a yellow colour, insoluble in water, and in alcoholic solution has a persistently bitter taste.

Achilleina.—The aqueous extract was triturated with alcohol until it ceased to become coloured; the alcohol was distilled off and the residue precipitated by water. The precipitate having been washed with water, the aqueous liquid was agitated with plumbic hydrate to remove acids. The filtrate was freed from lead, evaporated and alternately dissolved in absolute alcohol and in water, and evaporated until the achilleina yielded clear solutions with both liquids. Thus prepared, it has an alkaline reaction, is brown red, amorphous, friable, very hygroscopic, readily soluble in water, with more difficulty in absolute alcohol, insoluble in ether; its odour is peculiar, its taste very bitter but not disagreeable. The author isolated also the bitter principle from *Achillea Millefolium*, which had been obtained by Zanoa in a not entirely pure state, and found it to be identical with achilleina. Composition $= C_{40}H_{38}N_2O_{30}$. The salts have not been investigated.

Moschatina.—The precipitate obtained by water, in the concentrated alcoholic residue, was taken up by absolute alcohol, evaporated to dryness and treated with water until the mass became pulverizable under water. It is of an aromatic bitter taste, little hygroscopic, barely soluble in water, fuses under water upon the water-bath, and separates from its solution in hot water in a pulverulent condition. Composition $= C_{42}H_{27}NO_{14}$.

Achilletin.—On boiling achilleina for several days with diluted acids, sugar is formed, together with a volatile aromatic principle and probably ammonia, and a dark-brown powder separates which is not bitter; insoluble in water, sparingly in alcohol, and in this solution has an aromatic taste. Composition $= C_{22}H_{17}NO_8$.

The author also obtained stearic acid on cooling the tincture of iva, concentrated by distillation.

The aqueous solution of the ashes contained very little sulphate of lime and magnesia, but considerable alkalies and chlorine. Nitric acid dissolves from the residue carbonates, much lime, also phosphoric acid and little magnesia. The undissolved portion consisted of charcoal and much silica.—*Annalen der Chemie und Pharmacie, August*, 1870.

BEECH-NUT OIL.

In an article on the products obtained from the common beech (*Fagus sylvatica*), Dr. Wetherbee alludes to the oil obtained from the nuts, and gives the following particulars in regard to it:—At 60 degrees Fahrenheit, it has a specific gravity of 0·9225, and at 29 degrees it becomes solid. One thousand parts of alcohol of 90 per cent. will dissolve four parts of the oil, but it is completely insoluble in water. Its composition is carbon, 79·77; hydrogen, 10·57, and oxygen, 9·12, with a trace of extradine matter, etc., in each one hundred parts. Like other expressed oils, it produces acrolein, or the hydrated oxide of acryl, by destructive distillation at a high temperature. By treatment with nitric acid, it also, like other nut oils, yields elaidin or elaidic acid, in combination oxide of glyceryle, and in about 103 minutes, by this process, in converted into a bluish-green solid. The soap made from this oil is of a dirty grey colour, becoming yellow by exposure to the air, and having a slightly characteristic odour of the oil. It is somewhat greasy and pasty, and for these reasons is less valuable to the soap-maker than many other kinds of vegetable oils, though in France it is extensively used for this purpose. Three pounds of the oil will make five and a quarter pounds of soap, as taken from the frame, which in two or three months, by drying, will lose a considerable portion of its weight.

Beech-nut oil, however, is most valuable for culinary and lighting purposes, for the former of which it is considered very wholesome and palatable, and to a great extent takes the place of butter and lard among the French and German inhabitants of certain districts. It burns well, giving a good light, is free from smoke.

When properly refined it is good for lubricating delicate machinery, such as clocks, etc., and for the preparation of hair-oils, pomatums, liniments, ointments, and for many other purposes it is not inferior to most of the vegetable fatty oils.—*Canadian Pharmaceutical Journal*.

Incompatibility of Digitalis with Sulphate of Quinine.—A physician having ordered a mixture containing the syrup of digitalis of the French Codex and acid sulphate of quinine, observed a precipitate at the bottom of the bottle. Supposing that some mistake had been made, he took it back to the apothecary, when it was found that the ingredients were incompatible with one another, the tannin in the digitalis combining with the quinine and forming an insoluble tannate.—*Journal de Pharmacie et de Chimie*.

REPORT ON COMMERCIAL SPECIMENS OF BISMUTHI SUBNITRAS.

The *Practitioner* for March contains a report of the analyses of six samples of bismuthi subnitras, which yielded the following results:—

No.	Oxide of Bismuth.	Arsenic.	Chlorides.	Sulphates.
	Per cent.			
I.	81·33	None	Traces	Minute traces
II.	78·51	None	None	Traces
III.	79·28	None	Traces	Traces
IV.	82·12	None	Traces	Traces
V.	81·80	None	Strong traces	Slight traces
VI.	82·37	None	Very strong traces	Traces

The amount of oxide of bismuth contained in the pure subnitrate is 76·3 per cent.; but much depends upon the amount of washing and the temperature maintained during precipitation. These may cause the quantity of oxide of bismuth contained in this salt to vary from 76 to 84 per cent. The only impurities detected in the samples examined were traces of chlorides and sulphates and very minute traces of iron. All were specially examined for arsenic, but no trace was found in any of them.

ANNUAL FESTIVAL OF THE GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

On Tuesday Evening, 28th February, the Annual *Soirée* and Musical *Réunion* of the Glasgow Chemists and Druggists' Association was held in the Trades' Hall, Glassford Street. Between five and six hundred persons sat down to tea. Mr. James MacDonald (of the Glasgow Apothecaries' Company) occupied the chair; and among the gentlemen on the platform were Messrs. Aitken and Ainslie, Edinburgh; Drs. T. D. Buchanan, A. M. Robertson, R. Carter Moffat, etc., and Messrs. William Greig, James Taylor, Thomas Davison, A. Kinninmont, T. D. Moffat, J. M. Fairlie, R. T. Dun, D. B. Ker, Robert Brodie, etc. Letters of apology were received from Messrs. Fraser, Brown, Murdoch, Hatrick, Jaap, Currie, Hart, etc.

The Chairman in his opening address expressed the high gratification it gave him to preside over such a brilliant assemblage as that met that night. He had at first some misgivings as to whether he should accept the honour conferred upon him by the Committee in asking him to be their chairman on such an important occasion, and he had done so ultimately on the condition that no speech would be required of him. He could not, however, sit down without saying how pleased he was to know that the trade (he should rather say profession) to which they belonged now occupied such an important position not only in this city but in the kingdom. He was also glad to be able to affirm that the local Association (under whose auspices they were met there that night) had sufficient energy in its Council and Members to make Glasgow one of the first pharmaceutical cities in the country, as it was already one of the first in commerce; but of course energy and perseverance would be almost useless without support and encouragement from one and all connected with the profession. He therefore advised all, the young men in the trade especially, who had not yet joined the Association, to enrol themselves in its ranks as soon as possible, that the labours of the working members to advance the education of the assistants and apprentices may be crowned with success. In further referring to the great good the Society had already done he said he was authorized by the firm with which he was connected to state that it was their intention to hand over to the Council of the Association another £5 (in addition to three guineas already subscribed to the funds of the Society) to be distributed among the members in prizes or in whatever way the Council may decide. After some further remarks about education, poison regulations, and early closing,—concerning which he said he hoped before long to see every doctor's and druggist's shop in the city shutting at 8 o'clock, and a great deal of the Sunday labour curtailed,—Mr. MacDonald concluded a short but pithy address by quoting a piece from 'Horace,' and giving the translation, resuming his seat amid great applause.

An excellent concert was afterwards sustained by Miss Isa Robertson, Mr. Falconer, Mr. Robert Fraser, and a glee party, and several Scotch readings given by Messrs. Wright and Weir.

Short addresses were also given by Messrs. Aitken, Ainslie, and Paterson, and Dr. Moffat, and "Auld Lang Syne" by the audience brought this part of the proceedings to a close.

The Annual Full Dress Assembly was held immediately after the *soirée*, in which upwards of fifty couples took part, and was witnessed by nearly three hundred spectators.

Altogether the Festival was one of the most successful ever held in connection with the Chemists' Association.

DRUG MARKET NOTES.

The following were among the parcels offered for sale in the drug market last week:—

Sarsaparilla,—Honduras, 329 bales; Mexican, 80 bales.
Jamaica Beeswax, 60 barrels.
West India Tamarinds, 41 barrels.
Nux Vomica, 16 pockets and 2 bags.
Senna,—Tinnivelly, 284 bales; Alexandria, 47 bales.
Aloes,—Cape, 118 cases; East India, 10 kegs, 7 cases.
Cardamoms,—10 cases, 21 packages; Malabar, 49 cases.
Blue Galls, 75 sacks.
Castor Oil,—East Indian, 100 cases; Italian, 50 cases.
Bark,—Calisaya, 122 serons; Columbian, 272 serons; Crown, 79 bales; Red, 37 bales; Carthagena, 15 bales; Pitayo, 90 bales; Peruvian, 72 serons.
Indian Bael, 11 barrels.
Gum Sandrac, 33 casks.
Otto Roses, 8 tins.
Ambergris, 8 tins, 50 ounces.
Ergot of Rye, 11 bags, 4 cases.
Cassia Fistula, 92 bales, 35 bags.
Rhatania Root, 35 bales.
Antimony Regulus, 47 blocks.
Kamala, 2 bags.
Matico, 12 bales.
Rhubarb, 136 cases, 31 chests.
Cantharides, 1 case.
Turmeric, Madras, 111 bags and 100 pockets.
Cubebs, 137 bags.
Cajaputa Oil, 101 cases.
Pepper Oil, 1 case.
Macassar Oil, 2 cases.
Citronelle Oil, 78 cases.
Solid Glucose, 18 cases.
Oil Patchouli, 10 cases.
Cascarilla Bark, 360 sacks.

The Pharmaceutical Journal.

SATURDAY, MARCH 11, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

OUR MONTHLY EVENING MEETINGS.

OUR readers will have noticed with pleasure the report, in our issue of the 25th ult., of the proceedings of the Philadelphia College of Pharmacy. After several years' intermission, the pharmaceutical meetings in connection with that celebrated institution have been resumed, and we hope to be able, in due time, to congratulate the College on the success of its fresh endeavours to stimulate research and foster *esprit de corps* amongst its members. Our *confrères* have set about their task in a thoroughly business-like manner, and no apology is needed for introducing here the main features of the scheme by which they hope to render their meetings both profitable and interesting. At the first meeting, on the 18th October, 1870, a committee was appointed to draw up a plan, and at the succeeding meeting in November it reported the following suggestions:—

1. As it is of primary importance that a general interest should be felt or *created* in the attendance of these meetings, the Committee would recommend that an earnest invitation be extended to the members of the College, and all others who may desire to participate in the proceedings, to produce at each of our meetings either written or oral contributions on subjects pertaining to chemistry or pharmacy, or the commercial relation of drugs. Upon the conclusion of such communications, the presiding officer of the meeting to call for any remarks that may be elicited by the subject thus introduced.
2. That there should be appointed annually a Standing Committee, consisting of three members, whose duty it should be to propose subjects for discussion at any of our meetings, whenever there shall be a lack of material voluntarily contributed by members.
3. That a box or other suitable arrangement be provided for the reception of written queries, anonymous or otherwise, which members may desire to propound, relating to any subject connected with the shop or laboratory; which queries may be taken up for discussion either at the meeting in which they are proposed or at a subsequent meeting.
4. That this Committee be requested to obtain, from time to time, the services of any who may favour the meeting with lectures suited to the occasion.

These recommendations were adopted, and Mr. CHARLES BULLOCK, Dr. PILE and Professor MAISCH appointed the Committee for the ensuing year. We reproduce the recommendations *in extenso*, because it seems to us that some such plan is urgently required by our own Society, if the monthly meetings are to be rescued from the miserable condition into which they have sunk of late years.

Notwithstanding the "poisonous" atmosphere just now overhanging, we are congratulating ourselves that, after thirty years of up-hill work, we have grown into the most powerful independent body of pharmaceutists perhaps in the world; and yet of the *few* members who attend our meetings, there is scarcely one but feels humiliated at the want of interest exhibited by councillors, examiners, members, associates and apprentices in a part of our voluntary curriculum which should be a source of profit and delight to old and young.

Our contemporary the *Chemist and Druggist*, ever ready to point out weak points in our official system, has censured us in terms which, though severe, are well merited; and it grieved us not a little to note that Dr. CARPENTER's lectures on the Microscope, recently delivered, were, comparatively speaking, but poorly attended even by associates and students.

These meetings require infused into them the same vitality that now exists in the examining, educational and administrative departments of the Society. But how is this to be accomplished? In our judgment, by following some such plan as is proposed at Philadelphia.

The most important recommendation we take to be the appointment *annually* of a standing committee, whose business and pleasure it should be to cater for their brethren and sustain the high character of the Society and British Pharmacy.

As at present conducted, it seems optional to any person, however ignorant or learned, to extract a roll of manuscript from his coat pocket, and, without any notice or guarantee that it is suitable matter, to read a paper which may occupy one or more pages of this Journal, and which may perhaps deal in generalities on the purity or impurity of the drugs we sell, without embracing a particle of experimental evidence to justify any assumption whatever. It is true the Bye-laws provide "that all communications intended to be made shall be submitted to the President, or, in his absence, to the Vice-President or Chairman of the meeting, for his sanction, and without such sanction no subject shall be introduced;" but in practice it has seldom been enforced, because it was supposed that its observance might increase the difficulties of securing good and suitable communications.

We would suggest, with all respect to the Council, that this Bye-law should be carried out in its integrity; and that, along with the President, a committee of two, *not* holding seats at the Council, should be annually associated, to whom all papers should be forwarded, and by whom they should be read before the meeting, and *approved, abridged or declined* as required. Once secure *good* papers on strictly pharmaceutical subjects, and there will be no lack of listeners.

Perhaps it would be exacting to expect the regular attendance of all the Councillors, members of the Board of Examiners, and the great majority of metropolitan members, many of whom possess a fund of practical knowledge of chemistry and pharmacy which will probably die with them, and the exposition of which would awaken in many a rising pharmacist's breast a feeling of intense gratitude. But we feel that it is incumbent on them to arouse themselves, and remember that there is still ample opportunity for continuing the educational scheme, commenced in 1841, on a higher platform, and that a large number of assistants, well grounded in theoretical knowledge, are still more or less deficient in that sound practical knowledge which has made the world-wide repute of some of our senior members.

Let each of our readers then manfully help the Society in this matter, by active work and frequent attendance, where possible; it is a duty he owes alike to the Society, and, in the elegant language of Mr. Schacht, "to our common Mistress Pharmacy."

SCIENTIFIC HOBBIES.

At the risk of being accused of making a trite observation, we are inclined to repeat at this time what has, in different forms, often been said before, that the man who can lift himself out of the routine and drudgery of his calling, and look upon it as something more than the mere means of obtaining a subsistence, will find that in so doing he makes it much more tolerable. Moreover, he will secure a substantial benefit by his increased skill in his craft. Of no calling is this more true than of pharmacy. He who only sees a cause for annoyance in the unexpected turbidity of a mixture, or the unusual appearance of a drug, knows nothing of the pleasure which is experienced in bringing the results of a favourite study to assist in unravelling the mystery, to say nothing of the additional profit of being able to do so. We need only allude to the articles, by Mr. Stoddart, on Bristol Pharmacology, which are now appearing in the columns of this Journal, as an illustration of the way in which the subjects of daily business may be used for obtaining a considerable amount of healthy recreation.

In the art of pharmacy there is much that is purely scientific, and its followers may well be proud of some who are to be found in their ranks. This is fully recognized in the world of science, which is not at all disposed to look upon as presumption, the ambition of pharmacists to take rank as scientific men, nor like another Jove to resent the encroachment upon its prerogative—

> "Maturate fugam, regique hæc dicite vestro:
> Non illi imperium pelagi, sævumque tridentem,
> Sed mihi sorte datum."

On the contrary, it has shown itself ready to encourage them, and to accord them what honours may fairly be their due.

But many will be ready to say, that there is a long step between scientific studies and the weighing out of pennyworths of carbonate of soda, or perhaps the grinding of paints. This is true; but to such we would recommend the consideration of the remarks of Dr. Carpenter, in the first of the two lectures which have just been delivered by him on the microscope and its revelations. He says, "I hold it "extremely important that every young man should "learn not only how to work, but how to play. I "think that to find a means of constant and attrac-"tive recreation, and especially one which combines "the double character of quiet work at home, and, "on the other hand, gives a zest and interest to a "walk abroad, is to find that which is one of the "very best appliances that any home can have." Or, again, where he speaks of "one of the greatest "comforts to any man of busy life, the comfort of "turning to something which forms a quiet occupa-"tion," as tending more than anything else to distract one from the cares and fatigues of a busy life. This may seem to some far-fetched, but those who have tried it know well that there is a considerable amount of truth in the proverbial paradox, that "a "change of work is as good as a rest."

The particular study advocated by Dr. Carpenter is one in point. Although it might have been expected by a few that the lectures would have had a rather more special bearing upon the application of the microscope to the purposes of pharmacy, still all who heard or have read them must feel convinced that the pharmacist who is a skilled microscopist stands upon a vantage ground when compared with his unskilled brethren. And this is true of almost any study in respect to pharmacy. The man who looks beyond the drudgery is in a fair way to lift himself above it. He will, besides, experience that higher pleasure, so eloquently expressed in the address delivered at the opening of our present session, when it was asked, "Is there so great a dif-"ference between a thing of beauty and a thing of "truth, that one is a joy for ever, and the other "may become a weariness in a paltry lifetime?"

THE MILK JOURNAL.

We have already referred to the establishment of a laboratory in connection with the *Milk Journal*. From the number of that journal which has just issued, it would seem that considerable activity prevails in that quarter, and that a kind of crusade has been entered upon against the dishonest milkman. Country companies which add to their profits by the questionable process of skimming; workhouses supplied with milk consisting half of milk and half water; and a whole multitude of private malefactors (whose names and addresses are not withheld) figure on the black list. Out of 50 dealers in milk, it appears, according to our contemporary, that 13 dealt honestly, 8 doubtfully and 29 dishonestly.

The Philadelphia College of Pharmacy, established in 1821, having now reached its fiftieth anniversary, it was intended to celebrate, on the 23rd ult., its "semi-centennial," by a social *réunion* within its walls of such of its original members as are now living, the former professors, the graduates and members of the college, and the pharmacists throughout the city not connected with the institution. Invitations have also been issued to members of the profession in other cities. The progress of the college during the fifty years of its existence may be inferred from the fact that the number of students in its School of Pharmacy, which in 1821 was thirty, has steadily increased, until this year it amounts to one hundred and ninety-eight. The original college building, having become too contracted for the growing wants, was disposed of and the present substantial building erected, which contains lecture rooms, college hall, library, etc., together with a laboratory fitted up with all the modern appliances for practical instruction in pharmacy and chemistry. One feature of the proposed meeting was to be the exhibition of preparations and apparatus in use fifty years ago, side by side with those of the present day.

The Board of Trustees of the Chicago College of Pharmacy have recently elected Mr. C. C. Tichborne, of Dublin, an honorary member of their College in "consideration and appreciation of his assiduous "and valuable labour to promote the advancement of "scientific pharmacy." This is the second similar recognition that that gentlemen has received from America within the last twelve months.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

March 1st, 1871.

MR. SANDFORD, PRESIDENT, IN THE CHAIR.

MR. HASELDEN, VICE-PRESIDENT.

Present—Messrs. Abraham, Atherton, Bottle, Bourdas, Carr, Dymond, Groves, Hills, Mackay, Savage, Stoddart, Sutton and Williams.

The minutes of the last meeting were read and confirmed.

The following letter was read and ordered to be entered on the minutes:—

"338, *Oxford Street, W.*
"*February 4th*, 1871.

"*To the President and Council of the Pharmaceutical Society.*

"Gentlemen,—I beg to acknowledge the receipt of a cheque for £100, together with a Copy of Resolution voted at your meeting on Wednesday, and beg that you will accept my best thanks for your gift, rendered more gratifying by the kind expressions which accompany it.

"Believe me to remain, gentlemen,
"Yours faithfully and obliged,
"John Barnard."

The Report and Recommendations of the Finance Committee were received and adopted.

The Financial Statement of the North British Branch of the Society for the year 1870 was presented, showing a balance due to Mr. Mackay, the Hon. Sec., of £55. 6*s*. 6*d*.

The several items of the account having been considered and explained by Mr. Mackay, it was

Resolved—That the Treasurer be requested to pay the balance due; and also to advance the further sum of £100 on account of current expenses for the year 1871.

The Auditors' Report on the Financial Statement of the affairs of the Society for the year 1870 was received and adopted.

Resolved—That the Annual General Meeting of the Society be held on Wednesday, the 17th of May next, at noon precisely.

Resolved—That a Conversazione be held on Wednesday, the 17th May, and that the Secretary be instructed to ask for permission to hold it at the South Kensington Museum.*

On the Report and Recommendation of the Benevolent Fund Committee, a grant of £12 was made to a member in Sussex.

The Secretary reported that he had received from the Committee of the Chemists' Ball a subscription of Twenty Guineas to the Benevolent Fund.

Resolved—That the thanks of this Council be given to the Committee of the Chemists' Ball for their subscription of Twenty Guineas.

Applications for grants to the following Provincial Associations were received:—

Ashton and Dukinfield Chemists' Association.
The York Chemists' Association.
The Nottingham and Notts Chemists' Association.

The consideration of these applications was referred to the Provincial Education Committee.

Resolved—That the Conditions under which grants in aid of Pharmaceutical Education in the Provinces are made be committed to the Provincial Education Committee for their revision.

REPORTS OF THE BOARDS OF EXAMINERS.

February, 1871.

England and Wales.

	Candidates examined.	Candidates passed.	Candidates failed.
February 10, Modified	42	29	13

February 21, Major	1	1	0
" " Minor	2	2	0
" " Modified	3	3	0
" " Preliminary	6	4	2
	12	10	2

The Registrar presented a Statement as to Members, Associates, and Apprentices of the Society for the year 1870, details of which will appear in the Annual Report, together with an analysis of the Examinations.

* Since the meeting of Council, the Secretary has applied for and obtained permission to hold the Conversazione at the South Kensington Museum on the above-named date. Arrangements will therefore be made accordingly.

Two Pharmaceutical Chemists having paid their arrears and their subscriptions for the current year, were restored to Membership.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be respectively granted a Diploma stamped with the seal of the Society:—

Appleby, Calvert ....East Retford.
Masson, George ....London.
Storey, Edward Henry ......London.
Strachan, Alexander ....Aberdeen.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be elected Members:—

Appleby, Calvert ....East Retford.
Barnes, Edwin ....Durham.
Brown, Joseph Frederick ....Dover.
Cooper, Henry ....Leicester.
Franklin, Alfred ....Fareham.
Lasham, John William......Romford.
Masson, George ....London.
Rooke, James Henry........London.
Storey, Edward Henry ......London.
Strachan, Alexander ....Aberdeen.
Yates, Samuel Pearce ......London.
Young, Joseph ....Leicester.

Resolved—That the following registered Chemists and Druggists be elected Members of the Society:—

Arrowsmith, Geo. Wm. Thos...Reading.
Bagnall, William Henry......Lancaster.
Bailey, Henry ....Buckhurst Hill.
Crook, Edward ....Windsor.
Edwards, Edward............Lower Clapton, E.
Fairlie, James Mitchell ......Glasgow.
Fenwick, John ....Glasgow.
Gregory, William ....Weymouth.
Hamilton, James ....Glasgow.
Harrower, Peter ....Glasgow.
Harvey, Joseph Smith........Penzance.
Iley, William Henry ....Old Shildon.
McMillan, John ....Glasgow.
Millidge, Thomas Edward ....Tonbridge.
Palmer, George Dudley ......Notting Hill, W.
Rose, Alexander ....Glasgow.
Scott, Walter ....Dublin.
Young, John Clarkson ....Warrington.

Resolved—That the following, having passed their respective examinations, be elected "Associates in Business":—

MINOR.

Iredale, Thomas ....Leeds.
Speakman, Isaac ....Runcorn.

MODIFIED.

Batty, Thomas ....York.
Conway, John Jones ....Flint.
Davies, George ....Reading.
Legg, Matthew Henry ......London.
Moyle, Joseph ....Hammersmith.
Pointon, George ....Birmingham.

Resolved—That the following, having passed their respective examinations, be elected Associates:—

MINOR.

Atkinson, David ....North Shields.
Beard, James Collins ....London.
Butler, William Harsant ....Frome.
Connor, Thomas Haigh ......Wakefield.
Crofts, Henry Baptiste ......Cranbrook.
Davenport, Horace ....London.
Holmes, Charles Joseph ......Kingston.
Humphreys, John ....Staines.
Jones, Hugh Ellis ....Swansea.
Morgan, William John ......Kinver.
Parker, John Samuel ....Peterborough.
Spong, Douglas Morton ......Bedford.
Watmough, George Capes ....Caistor.

MODIFIED.

Brunton, William Walker ....London.
Doughty, Thomas ....London.
Evans, Daniel Ogilvie ....Halstead.
Field, Henry................Brighton.
Foden, Joel ....Altrincham.
Gibson, Reuben Leonard ....Loughborough.
Graves, Joseph W. ....Reading.
Humphry, Horatio ....Southampton.
Mason, Thomas ....Nottingham.
Robinson, Jonathan Scott ....Rhyl.
Savage, James ....Bradford.
Stevens, Edmund Matthew ..London.
Swain, James ....New Wandsworth.
Williams, William Jones ....London.

PHARMACEUTICAL MEETING.

Wednesday, March 1st, 1871.

MR. G. W. SANDFORD, PRESIDENT, IN THE CHAIR.

The second of two Lectures on the Microscope and its Revelations was delivered by W. B. Carpenter, M.D., F.R.S., F.G.S., F.L.S., which will be found printed at page 721.

At the close the Chairman proposed a cordial vote of thanks to Dr. Carpenter for his interesting lecture, which was carried unanimously.

Many of the audience then adjourned to the Library, where a beautiful series of microscopes and microscopical objects had been provided for their inspection by the kindness of the lecturer.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Ninth Meeting of the Session was held in Anderson's University on the 8th of February; Mr. T. Davison, President, in the chair. Mr. William Greig (of the New Apothecaries' Company) and Mr. Robert Stewart were elected members.

The business of the evening was the delivery of a lecture on "Nitrous Oxide," by Dr. R. Carter Moffat, who treated his subject in his usual interesting and instructive manner. In the course of the lecture he took occasion to exhibit and explain the new anæsthetic apparatus, and at the conclusion performed a successful experiment with the gas upon one of the members who volunteered his services. A hearty vote of thanks was afterwards awarded the lecturer.

The Tenth Meeting of the Session was held in Anderson's University on the 22nd of February; the President presiding. Messrs. Charles C. Loftus, Robert Gibson and Andrew Millar were elected members.

After a few introductory remarks by the Chairman, Mr. A. Kinninmont (Local Secretary to the Pharmaceutical Society, and who has been absent from the meetings for some time through indisposition) was called upon, and delivered a brief but practical address to the members generally. He touched first upon the poison regulations, stating that, in his opinion, all compulsory regulations should be opposed, as he always believed that the education of the individual was a sufficient guarantee for the protection of the public. He also referred to the position of the Glasgow chemists should the regulations become law, and stated that he thought one reason why surgeons, etc. who kept open shop were not distinctly included with chemists to be under the same restrictions was, that Glasgow was entirely exceptional in this respect; that in large towns in England there was no such thing as a medical practitioner having a regular drug business. He might have a surgery for dispensing his own prescriptions, but they had no open retail drug shop as in Glasgow; and he said he had had the greatest difficulty, when in England, in making the chemists there understand that a surgeon could drive about in his carriage attending to his practice, and having one, two, or more retail drug shops attended to by druggists' assistants at the same time. He therefore believed that in the Pharmaceutical and Privy Councils especially the position of the Glasgow chemists was not understood, and he thought it would be worth our while to invite some of the members of these bodies to come and see for themselves. He trusted, however, that Glasgow would be well represented at the Annual Meeting of the Council in May next, and that no effort would be lost to have the obnoxious regulations thrown out till, at least, there is more cause for them than at present.

Mr. Kinninmont then explained at length the steps to be taken in gaining admission as members or associates of the Pharmaceutical Society, and urged upon all most strongly to lose no time in having themselves enrolled, and that those who had examinations to pass, should also get them over as soon as possible. He thought it was high time Glasgow was speaking up for representation in the Council; he thought if we put forth a claim for such, we would receive the support of the pharmaceutists of Edinburgh and other provincial towns; but we must also have a strong force of our own to push the claim forward, and that force can only have weight by being members of the Society; he therefore hoped that the Glasgow chemists would not be content with simple registration as chemists and druggists.

Several other members spoke in regard to the poison regulations, and expressing their appreciation of Mr. Kinninmont's remarks.

The Secretary afterwards drew the attention of the members to the fact, that the British Pharmaceutical Conference would meet in Edinburgh next August, showing them the handsome volume issued by the Conference, 'The Year Book of Pharmacy,' which was to be a yearly publication, and which was sent free to every member, on payment of his annual subscription of five shillings. Several orders were afterwards handed in for the 'Year Book,' and six gentlemen (druggists in business before the passing of the Pharmacy Act 1868) gave in their names to be proposed as members of the Pharmaceutical Society.

OLDHAM CHEMISTS AND DRUGGISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The First Annual Meeting of the above Association was held last month, when there was a good attendance. The business of the evening commenced by the reading of the Secretary's Report, which was as follows:—

This being the first Annual Report of this Association, it gives the Committee great pleasure in having to lay before you a favourable and encouraging one of the transactions of this Association.

During the past year the Association has been somewhat prosperous (though we may say it is yet in its infancy), and it is to be hoped that before another year has passed, we may be on a level with many other societies in Great Britain, and that the young men of this town will do their utmost to gain that position, as there is no doubt it all lies with them as to the future success of this Association.

The Latin class that was formed in April last (under the able tutorship of the Rev. A. Peaton) has been very fairly attended, as three-fourths of the members has been the average attendance.

The numerous presentations which the Association has received since its formation have greatly surpassed our utmost expectations, viz.:—

One handsome show-case, containing in ground stoppered bottles seventy specimens of various drugs of the British Pharmacopœia:

One Materia Medica cabinet, adapted for the Major Examination:

Three books, viz. Lescher's 'Elements of Pharmacy,' Fownes' 'Chemistry,' and Royle's 'Materia Medica.' The Pharmaceutical Journal (by the kind permission of the Pharmaceutical Council) has also been sent regularly as published. These have all been thankfully received and duly acknowledged. We have likewise received several donations from various gentlemen in the trade, which have been a great auxiliary, in this our first year's undertaking, of placing a balance in the Treasurer's hand.

We have a bright prospect before us, and we hope the opportunities derived from the Association may not be lacking in their good results, but that our next report may contain some of the names of members of the Association having passed their respective examinations.

The Treasurer's financial statement was then read, showing a balance in hand of 8*s*.

The report having been confirmed, the following officers were elected for the ensuing year:—President: Mr. Taylor. Vice-President: Mr. Radcliffe. Treasurer: Mr. Hurst. Secretary: Mr. Rhodes.

Votes of thanks having been passed to the retiring officers, the business of the meeting was brought to a close.

LEEDS CHEMISTS' ASSOCIATION.

The Monthly Meeting of this Association was held on March 1st, 1871, when the President, Mr. Smeeton, introduced the subject of the proposed poison regulations. He stated that his opinions had not altered since last year, when it was decided to oppose these regulations on the ground that the best security was the better education of chemists, and that he felt as great a repugnance as others to the inspection of an official as to the way in which he conducted his business. He admitted that, in the main, these regulations were not oppressive; and had they been sent down as recommendations, would probably have been adopted, so far as was possible. He deprecated entirely bringing to the consideration of the subject anything like a foregone conclusion, founded upon proceedings taken elsewhere; and strongly urged the consideration of the subject in a calm and unprejudiced manner. He admitted that the Council had not, in the past, shown anxiety to legislate on the poison question, and had repeatedly prevented unwise and hurtful regulations; and he concluded that its present action was owing to pressure from the officer of the Privy Council. He thought that something might yet be drawn up by the Council of the Pharmaceutical Society which would satisfy the Privy Council and be acceptable to the trade; and quoted from Mr. Brady's letter of July, 1864, wherein he said, "The public will have precautions against accidents adopted; let them be of our own choosing, rather than left to the selection of a Parliamentary Committee. Were the Pharmaceutical Society acting officially, as the body governing, not only the interests of its own members, but those also of the nation at large, so far as pharmacy is concerned, to issue a series of simple and reasonable regulations with respect to the storing and dispensing of poisonous substances, it would require no other authority to ensure their general adoption," etc. The general custom of the trade showed that regulations similar to those before them were in use, more or less; and on the assumption that compulsory measures were certain, it was better to choose them rather than have them decided for the trade by those less conversant with the matter. The regulations themselves were next considered. No great objection was taken to Nos. 1 and 2, but Mr. Smeeton thought there were many difficulties in No. 3, which would almost render its working impracticable. He concluded by saying that, though personally he could comply with the requirements, yet he would not like to force such a measure on the trade, except it was done to prevent a severer and more oppressive measure.

Mr. R. Reynolds took the opportunity of again meeting his friends to say a few words on a personal matter. Being unable, since November, to fulfil his representative duties by attending the meetings of the Council of the Pharmaceutical Society, he had consulted his medical attendants, and also private friends, as to the desirability of resigning his seat, but had been dissuaded from such a step; and now he had reason to hope that he could shortly resume these duties. He regretted much the difference of opinion within the trade, due to divergent views on the policy of the proposed poison regulations. It was especially injurious that their energies were thus withdrawn from the subject of improving the local means of education. However, the responsibility of self-government made it impossible to be indifferent on so vital a question; and all must feel that, in approaching it, they owed obligations to their profession and to the labours of those who had defended and consolidated its rights and privileges during a period of thirty years. The present contention was not as to the object, but the means and consequences. He (Mr. Reynolds) had felt it his duty elsewhere to express strongly his views upon the details of the proposed scheme, which had been most ably analysed by Mr. Barnard Proctor, and also to indicate the probable consequence of its acceptance. As to the charge of ignorant selfishness made against the opponents of the regulations by certain medical journals, the members of the Leeds Chemists' Association could afford to disregard them, and to point to their voluntary action during several years as the best confutation of such a slander.

Mr. Thompson remarked that these regulations could only be enforced by penalties and also police supervision, for it was not to be supposed that a new staff of officials would be organized for the purpose; but that the present guardians of the peace would be empowered to see that these laws, like all others, were properly obeyed. Mr. Thompson then moved the first resolution:—

"That this meeting would have received with approbation a well-considered plan for storing powerful remedies, if recommended for voluntary adoption; but is of opinion that the proposed *compulsory* regulations for the storing and dispensing of poisons are ill-judged and unjust to those to whom they would apply, and that they ought to be resisted."

Mr. Edward Brown, in seconding the resolution, remarked that it seemed to him to be an insult to the trade, within twelve months after such an expression of opinion as emanated from the trade last year, that another set of compulsory regulations should be attempted to be enforced.

The resolution was heartily carried.

Mr. Edwin Yewdall then moved, and Mr. Samuel Taylor seconded, the next resolution, which was carried:—

"It is of the greatest importance that at the Annual Meeting of the Pharmaceutical Society, to be held in May next, the vote of every member of the Society respecting the proposed compulsory regulations for the keeping and storing of poisons should be taken through the post by voting-papers, and not merely by a show of hands of those present; and that due regard be given to the expressed opinion of all registered chemists and druggists."

Mr. Edwin Yewdall, after stating that it would be of no avail to organize a Defence Association after we were once really saddled with the compulsory regulations, proposed the third resolution:—

"That this meeting hears with satisfaction of the organization of a Chemists' Defence Association, and approves of its objects."

Mr. Samuel Taylor seconded its adoption, which was unanimously carried.

It was then proposed by Mr. E. Yewdall, seconded by Mr. R. Reynolds, and carried with acclamation:—

"That the thanks of this meeting be presented to the President, Mr. William Smeeton, for his conduct in the chair."

The meeting then concluded, when several present joined the "Chemists' Defence Association."

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

An Ordinary Monthly Meeting was held in the Memorial Hall on Friday evening, March 3rd; the President, Mr. W. S. Brown, in the chair.

The Chairman announced that the consideration of the subject referred to the Council at the last meeting had resulted in the formation of a "Chemists' Defence Association," particulars of which would shortly be in the hands of every chemist in the kingdom.

Mr. W. J. Halliday then read a very interesting paper on "Dispensing," in which he gave a number of valuable practical hints on the subject.

[We propose printing this paper *in extenso* in the next number of this Journal.]

A discussion followed in which many members took part. Opinions were expressed that prescribers should underline any unusually large dose, to indicate to the dispenser that it was not an oversight, and thus relieve him from doubt. That, if any part of the prescription, either the formula or directions, admitted of a double reading, the first dispenser should make a marginal note for the guidance of those who followed him, that uniformity might be secured. That dispensers should accustom themselves to calculate the doses of all active ingredients in a prescription before they commenced dispensing it. That where practicable, the dispensing of powerful medicines should be "checked" by a second person.

"A case containing a great variety of labels for "poisons" and "outward applications" was exhibited by Mr. H. Silverlock, of London.

Proceedings of Scientific Societies.

LONDON CHEMISTS' ASSOCIATION.

The result of the discussions on "Poison Regulations," held at the end of last year, resulted in the following resolution being almost unanimously carried:—

"That the propositions recommended for adoption by the 'Sale and Keeping of Poisons Committee,' and published in the Pharmaceutical Journal of December 17, 1870, be accepted as satisfactory by this Association."

An opinion was generally expressed that the system marked II. is to be preferred; it was considered also that Clause III. in the old propositions, regarding the sale and *dispensing* of medicines, ought not to be omitted from whatever regulations are introduced.

Thursday, Feb. 9, 1871; the President in the chair.

Mr. Pick read a paper on "Belladonna and its Preparations." He gave an interesting history of the plant from the earliest writers, and of its medical value being discovered by Lugus, in the year 1532, and an accurate botanical description, stating that it belonged to the Natural Order *Atropaceæ;* some botanists classified it under *Solaneæ*, but the plants included in this Order (*Atropaceæ*) were separated from *Solanaceæ*, and formed into a distinct class under that name by Miers, the chief distinguishing character being the different æstivation of the corolla. The generic name *Atropa* was taken from Atropa, one of the Fates, who was supposed to cut the thread of life. Its chemical constituents were treated upon at some length, as also its therapeutic properties, which, he said, extended more or less over the whole human body, but more especially the face and head, dilating the pupil of the eye. Its effects on the throat were very marked, it was used successfully in scarlet fever, small doses acting as a preventive. The officinal parts of the plant, both dried and fresh, next received attention, and its cultivation and collection in Britain and Germany. After a few remarks on the extract, tincture, etc., and their preparation, he concluded with the active principle atropia, the sulphate of atropia, and Pseudotoxin.

A long and interesting discussion followed, bearing very much on the uncertainty of the strength of the extract and the advisability of making emp. bellad. from a root extract.

MEETINGS FOR THE ENSUING WEEK.

MONDAY ......*Medical Society*, at 8 P.M.
London Institution, at 4 P.M.—"On Astronomy." By Mr. R. Proctor.

TUESDAY ......*Royal Institution*, at 3 P.M.—"The Nutrition of Animals." By Professor Foster.
Royal Medical and Chirurgical Society, at 8.30 P.M.
Photographic Society, at 8 P.M.

WEDNESDAY...*Society of Arts*, at 8 P.M.—"The Different Methods of Extracting Sugar from Beetroot and Cane." By Mr. F. Kohn.
London Institution, at 6.30 P.M.—Conversazione. "Stained Glass æsthetically considered with reference to Modern Art." By Mr. H. Holiday.

THURSDAY......*Royal Society*, at 8.30 P.M.
Linnean Society, at 8 P.M.
Royal Institution, at 3 P.M.—"Davy's Discoveries in Chemistry." By Prof. Odling.

FRIDAY ....*Royal Institution*, at 9 P.M.—"The Eclipse." By Mr. Lockyer.

Parliamentary and Law Proceedings.

DEATH RESULTING FROM AN EXCESSIVE DOSE OF CHLORAL HYDRATE.

The *Lancet* of the 18th inst. contains a report by Dr. Norris of a case of overdose of chloral hydrate, which appears to be the same as that already recorded in the PHARMACEUTICAL JOURNAL, p. 636. As any additional information as to this now extensively-used drug is of importance, we extract the following particulars:—

The deceased, who appears to have been a victim to dipsomania, when opposed in her desire for stimulants, was very violent. No sedative seemed to produce any effect but chloral hydrate, and for months previous to her decease she was supplied almost every evening with a draught containing from twenty to forty grains. After some time, Dr. Norris was astonished to hear that his patient had been taking, in addition to the draughts supplied by himself, others which she had obtained from a druggist, containing from thirty to thirty-six grains. The following list gives the quantity of chloral hydrate taken by the deceased during the last nine days of her life, the asterisks denoting the draughts supplied by the druggist, of which Dr. Norris had no knowledge until after his patient's decease:—

On the 3rd of January, after 10 oz. of Townsend's sarsaparilla, she had 36 grs. of chloral; on the 4th, 36 grs.*; 5th, 30 grs.; 5th, 36 grs.*; 6th, 30 grs.; 6th, 36 grs.*; 7th, 30 grs.; 7th, 36 grs.*; 8th, 20 grs.; 8th, 40 grs.; 8th, 36 grs.*; 9th, 10 grs.; 9th, 30 grs.; 9th, 36 grs.*; 10th, 10 grs.; 10th, 40 grs.; 10th, 108 grs.*; 11th, 40 grs.; 11th, 72 grs.* Thus making a total of 712 grs. within nine days, the last 260 grains of which had been taken within thirty-five hours.

A hundred and thirty hours after death the stomach and contents, together with portions of the lung, liver, heart, kidney and spleen, were submitted to Mr. Stoddart, of Bristol, for analysis. His report was as follows:—

"The first thing that struck me was the very extraordinary way in which the several portions were preserved. Even now, although more than a week has elapsed since death, yet not the slightest sign of decomposition has taken place, nor any unpleasant odour. This doubtless is the effect of chloroform in the tissues. Part of the gruel-like contents of the stomach was treated with caustic soda, and distilled at 160° F., and the vapour passed through a red-hot glass tube. Chlorine and hydrochloric acid were produced, which reddened litmus paper. Iodide of potassium and starch were coloured blue, and then decolorized. Solution of nitrate of silver threw down the chloride.

"Another portion was placed in a small alembic, with a mixture of potash and soda, and distilled at 160° F. by means of a water-bath, and the head of the exit tube immersed in pure distilled water contained in a small Clark's receiver. In a few minutes small drops of chloroform were slowly deposited at the bottom of the water. These were pure chloroform. The smell of chloroform was perceptible in the alembic the day after. I tested for all the poisons that were probable, but without any success.

"There seems, therefore, no doubt that an excess of chloral must have been taken, and the resultant chloroform was so disseminated through the tissues that they were completely preserved. I should mention that the contents of the stomach had no perceptible smell of chloroform till after the addition of an alkali."

In a subsequent letter, Mr. Stoddart adds:—"I found the most (chloroform) in the liver and contents of the stomach, but could not separate any from the other parts; nor could I from the heart, which seemed to have lost any blood contained in it."

Dr. Norris considers that the mode of death supports the opinion of Dr. B. W. Richardson that, in such cases, dangerous decomposition of the blood may occur before coma is produced, and that the repetition of considerable doses of chloral at short intervals would be followed by the formation of formiate of soda in the blood, by which its coagulating power would be much diminished; and that in such cases the symptoms would be similar to those induced by loss of blood.

POISONING BY CARBOLIC ACID.

An inquest has been held at the Whitechapel District Schools, Forest Gate, touching the death of two children, inmates of the schools. It appears that it was the duty of a nurse to disinfect the lavatory every evening by means of carbolic acid, and then carry what acid remained to the boys' side of the building. On Friday evening, after using the acid as usual, she left the remainder in a vessel in the lavatory. On the following morning the two children came downstairs a little before seven o'clock, and, seeing the vessel in the lavatory, each drank from it, and directly fell down insensible. Medical aid was promptly obtained, but to no purpose. The jury returned a verdict of "Accidental poisoning." —*Standard.*

HOUSE OF COMMONS.

On Monday, March 6, Sir J. LAWRENCE gave notice that on Thursday he should ask the Chancellor of the Exchequer whether the Board of Customs had allowed 15 instead of 10 per cent. of spirits to be mixed with wines in bond for the purpose of fortifying them.

Review.

A MANUAL OF STRUCTURAL BOTANY: for the uses of Classes, Schools, and Private Students. By M. C. COOKE. With upwards of 200 Illustrations, by Ruffle. Third Edition. London: Robert Hardwicke. Price 1s.

We are glad to welcome the appearance of a new edition of this useful little manual; it is too well known to require any lengthened notice. Having originally been prepared for use in classes organized by the Science and Art Department, it has somewhat of a special character, and this has doubtless prevented the author giving full scope to his own ideas of the best mode of teaching structural botany. Though the book has been called a collection of "dry bones," yet it is a most philosophical and well-proportioned skeleton, forming the best arranged note-book with which we are acquainted.

The book is divided into forty sections, corresponding to the number of lessons required by the Department to be given in their classes. Pages 1–19 are taken up with the chemistry of the subject, the nomenclature of which has been brought up to the present day. Four sections are taken up with a description of cellular and vascular tissue, cell development and contents, and of the epidermis and its appendages. Next we have the structure, form, and modifications of roots, and of the ascending axis of exogens, endogens and acrogens, followed by chapters on the structure, parts, form and arrangement of leaves, and their appendages, flowers, ovules, fruits and seeds. These sections are followed by others devoted to the subjects of germination, vital action, the reproduction of algæ, lichens, mosses and ferns, vegetable phenomena, epiphytes and parasites, galls and excrescences. The last section contains very useful hints and models for the botanical description of plants.

As an illustration of the author's manner of dealing with the subject, we will give his chapter on

SUBTERRANEAN STEMS.

"Under the name of subterranean stems we have included also those which are prostrate and not strictly subterranean.

"The majority of forms to be described in this section are properly designated as *roots*.

"It must be remembered that *roots* do not possess scales (modified leaves) or buds (rudimentary leaves) or nodes (whence buds are developed).

"The *Rhizome* (*rhiza*, Gr. a root), or root-stock, is a thick, procumbent stem, partly, and sometimes entirely under the surface of the soil. It develops roots from its underside, and leaves from its upper. Its surface generally bears the scars left by the falling away of old leaves. (Fig. 44.) *Ex.* Iris.

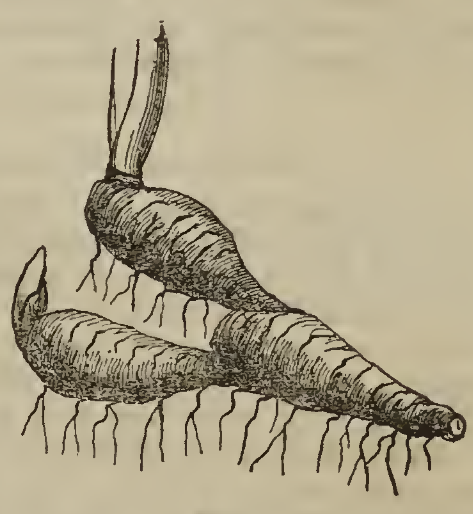

Fig. 44.

"The *Flagellum* (Lat. a young twig), or runner, is a long, slender, procumbent branch, which develops a leaf-bud from its upper surface, and roots from its under, at each node. Each vegetating node becomes a perfect plant (Fig. 45). *Ex.* Strawberry.

Fig. 45.

"The *Soboles* (Lat. a shoot, or young branch) is a creeping underground stem, or branch, which emits roots from its under-surface and leaves from its upper. It thus resembles a rhizome, but is much more slender, and subterranean in its character. (Fig. 46.) *Ex.* Couch grass.

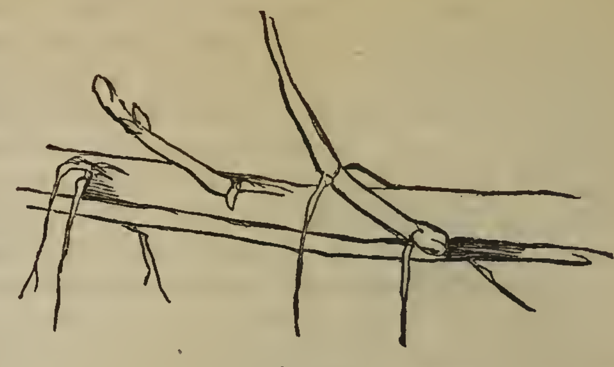

Fig. 46.

"The *Tuber* (Lat. a knob) is a thickened portion of an underground stem or branch, which serves as a depository for starch, and other nutritious secretions for the service of the plant. (Fig. 47). *Ex.* Potato.

Fig. 47.

"A scaly modification of the tuber exists in the species of *Maranta* which yields arrowroot.

"*Bulbs* are scaly modifications of leaf-buds developed upon a flattish disk, from the under surface of which roots are directed downwards. (Fig. 48.) *Ex.* Onion.

Fig. 48.

"The *Pseudo-bulbs* of orchids are thickenings of the base of the stem by the deposit of bassorine; they are produced above the surface, and are of a green colour.

"*Corms* (*kormos*, Gr. a stem) are also expansions of the base of the stem, differing from bulbs in being solid and not scaly, and from pseudo-bulbs in being subterranean, and consequently not green. Corms also contain starch and other nutritious secretions. Some botanists consider them as buds. (Fig. 49.) *Ex.* Meadow saffron.

Fig. 49.

"*Bulbs*, *pseudo-bulbs*, and *corms* are confined to endogenous plants."

For a beginner, the book will prove itself a very valuable aid; for the advanced student, a friendly remembrancer of byegone studies, and in either case a worthy companion to the larger works of Professors Bentley, Balfour, and Henslow, whilst its small size renders it a pocket companion for perusal during those odd fragments of time which play no inconsiderable part in a successful life.

The arrangement, illustrations, and type are good, and we wish the book long-continued success.

Obituary.

We regret to have to announce the death of Mr. JOHN CHAPMAN, Pharmaceutical Chemist, of Tring. The deceased gentleman entered the Pharmaceutical Society in 1853, and has for many years been a very useful member, ready at all times to do all in his power to further the interests of that body and its Benevolent Fund. He died suddenly on the 28th of February last, at the age of sixty.

On February 21st, 1871, Mr. FREDERICK HENRY GARNER, of Aylesbury, aged twenty. Mr. Garner had but recently entered as a student at the School of Pharmacy, Bloomsbury Square.

Notes and Queries.

Sp. Vini Meth. ℥j
Misce secundum artem.—E. H.

The fault of most black ink is too much iron, turning the writing brown from oxidation. To remedy this, acid (generally vinegar or an acid salt, as alum) is added, which corrodes the pens. The iron should only be in sufficient quantity to strike a black colour. The following will be found a convenient and excellent formula:—Boil 1 part of granular powdered galls with 20 parts of distilled water in a glass flask for fifteen or twenty minutes; then add 1 part sulphate of iron, dissolved in 2 parts of distilled water, and 1 part of mucilage of acacia; shake all together. It is ready for immediate use, but improves by keeping. It is better not strained, but poured off as wanted. A few drops of carbolic acid may be added to preserve it, if required to be kept long.—W. B.

[179.].—ESSENCE OF MOSS ROSE.—

℞. Otto Rosæ ʒiss
Ess. Ambergris ℥iiss
„ Moschi ℥j
Sp. Vini Rect. ℥xv
Aq. Rosæ Conc. ℥x
—Alpha.

COLD CREAM.

Take White Wax.
Spermaceti, of each, 1 oz.
Oil of Almonds, ¼ pint.

Melt, pour the mixture into a Wedgewood mortar which has been heated by being immersed in hot water; add gradually—

Rose Water, 4 fl. oz.

and stir until an emulsion is formed, and afterwards until the whole is nearly cold. Put in pots. [It may be perfumed with bergamot or lavender.]

[183.]—TINCTURE OF HOLBECK.—Required a practical formula for tincture of holbeck, with dose.—V.

[184.]—BLACK KID REVIVER.—*E. W.* would esteem it a favour if any reader would oblige him with a recipe for black kid reviver.

[185.]—TACAMAHAC.—Can any reader of the Pharm. Journ. give me any information respecting "Tacamahac," and favour me with a form for a preparation of it used for wounds?—All Saints.

[*** Tacamahac, or tacamahaca, is a resinous substance, obtained from various sources, partially soluble in alcohol, completely so in ether and the fixed oils. It was formerly highly esteemed as an internal remedy, but is now employed medicinally only in ointments and plasters, and that to but a small extent. Its properties are analogous to those of the turpentines. It is sometimes used in incense.—Ed. Pharm. Journ.]

[186.]—BAKING-POWDER. — "*Farina*" would feel obliged to any reader for a form for good baking-powder.

[187.]—LOTION FOR THE SKIN.—Will any correspondent kindly give me a recipe for a good and harmless lotion for roughness of the skin, pimples, etc.?—Alpha.

[188.]—WATERPROOFING.—Will any correspondent kindly give me a recipe for waterproofing?—G. B.

[189.]—ESSENCE OF VANILLA.—*Iodi* wishes to know the usual strength of essence of vanilla sent out by the wholesale houses.

[*** We think our correspondent will find the information he asks for in 'Cooley's 'Dictionary of Practical Receipts.'—Ed. Pharm. Journ.]

Correspondence.

THE PROPOSED POISON REGULATIONS.

Sir,—After the very voluminous correspondence that has for some time filled the columns of the Journal, from writers of every degree of ability and every shade of opinion, I feel it is scarcely possible to bring forward any new idea or any fresh argument on the subject. But as there appears a desire on the part of the Council to learn the general sentiment of the members of the trade, I venture, at the risk of only telling an oft-told tale and repeating what has already been said better by others.

After reading nearly all that has appeared, and reviewing the origin and progress of this vexed question, I confess to feeling some sympathy for the Council, under the very trying circumstances in which they have been placed, and the annoyance they have endured; still this is only matter for sympathy, but the subject is one involving a great public interest, and ought not, therefore, to be disposed of on sentimental grounds.

After all that has been stated on both sides, including "secret treaties" and "tacit understandings," the question resolves itself into one of expediency, and the proposition certainly involves in it police interference prospectively, and pains and penalties for any infringement.

It has been said the regulations are necessary, because a large number of those in business are not properly educated men; by this, I suppose, is meant not systematically educated, which may be admitted; and I would say further that to these the regulations would be a stumbling-block and a rock of offence, making confusion worse confounded. On the other hand, to the properly-trained and systematically-educated man, they are quite unnecessary. His own knowledge and understanding will supply him with regulations that will meet his own requirements far better. Now, the first of these two classes is fast passing away,—a few years and they will be amongst the things that have passed into oblivion.

Is it, therefore, wise or expedient to put upon us a yoke that will gall us in perpetuity, in order to remedy an evil that is only transitory, and will soon come to an end? Pharmacy in England has not yet attained to the dignity of a profession nor the position of an exact science, and until the old leaven has exhausted itself, it will not. An honourable career, I believe, is open to it, but the time has not yet arrived, and it will never do to stifle the new-born life out of it by oppressive legislation.

As regulations recommended for adoption by the Society, there is little doubt but they would be followed by all respectable men, and those who are obstinate enough to refuse, must be left to their own fate. There is, perhaps, one exception will be taken to this, and that is the dispensing clause.

Bradford, March 7th, 1871. F. M. RIMMINGTON.

Sir,—In the last issue of our Journal you make the remark (p. 699) "whatever may be the proper view to take as to the proposed regulations, we cannot agree with the opinion that they should not be adopted because medical men neglect them. That argument, at least, appears to be fallacious."

You, Sir, as representing the majority of the Council, surely do not understand the position of chemists in Scotland. We do not wish to meddle with medical men as such, but when they become druggists by keeping open shop, then we claim to have them under regulations as well as the other portion of shopkeepers, if such regulations are required for the safety of the public.

If you or any of the Council will visit our city—a city of no mean importance—I will show you the actual fact that medical men do become druggists. What do you call a person with the following over his door:—

"Chemist and Druggist," Dr. A. B., Surgeon? or Apothecary Hall, Dr. C. D., Surgeon?

Such is the rule here, not the exception. Their shops, for style and appearance, will bear comparison with any in the kingdom.

There is no fallacy in such hard facts, and I maintain that when a medical man keeps an open shop and retails Holloway's pills and every other quack medicine, he is to all intents and purposes a druggist. Scotland has only one representative at the Council Board; I think now he should be supported by another from Glasgow, that we, north of the Tweed, may not be misunderstood.

If the article reproduced from the *British Medical Journal* without a word of comment against it, is intended to make us comply with the regulations, never was a greater mistake made. It will only arouse within us a firmer determination to reject the regulations, regardless of the threat that "an obstinate resistance to the demands of the Privy Council must lead to the recasting of the Pharmaceutical monopoly."

Let the Privy Council first prove that poison regulations are required for the safety of the public, and next let the *British Medical Journal* prove that "we wish to be protected, and are willing to leave the door as widely open as ever to all the calamities which spring from carelessness or ignorance of persons dealing with medicines," and "are regardless of the sacrifice of life."

If, Sir, we had a monopoly of our business and there were no open surgeries, I wonder how many lives would be sacrificed by our carelessness in dispensing; the cases which have occurred lately certainly prove less lives would be lost.

A member of a late ministry once said the chemists in Scotland were the most intelligent class in the community, and he would oppose their exemption from juries on that ground. If such an opinion is held concerning us, surely we shall be heard in any future legislation concerning our and the public interests. THOMAS DAVISON.

Glasgow, 1st March, 1871.

Sir,—I fully agree with the remarks in the letter of this day's Journal written by Mr. Clement Pierson, of Leeds, relative to the "Poison Regulations;" they are most pertinent to the question at issue. If the status the passing of the New Pharmacy Act has given us will not secure that due and proper precaution so indispensably requisite for the public safety, sure I am that nothing Government can put upon us in the way of coercion will effect that end.

J. BARKER.

37, *Market Hill, Sudbury, March 4th,* 1871.

Sir,—"A house divided against itself cannot stand," and if we members persist in dividing ourselves into two camps, how is our Society to prosper, and in what light shall we appear in the eyes of the Privy Council?

Let us first agree among ourselves as to the best methods of conducting our own affairs, and then we shall command the respect of Government and be trusted with the responsibility of making any regulations where the public well-being is concerned.

All well-wishers of the Pharmaceutical Society must regret the wide controversy on the proposed "poison regulations," and I have looked in vain, hoping for some abler pen than mine to propose some middle course in which the extremes might shake hands and unitedly appear in a strong position before the Government, who will certainly take action in this matter if we do not, or succeed in showing good cause to the contrary. The whole case seems to resolve itself into the fact, that, at the time the Pharmacy Bill of 1868 was planned, certain regulations were deemed necessary for the safety of the public in the matter of storing and retailing poisons, and the said regulations were very much left to the arrangement of the Council of the Pharmaceutical Society.

Nearly three years having elapsed, the Privy Council look for a fulfilment of the then implied conditions from the Council of our Society.

Now the reply of the Council appears to me to be palpable, viz.:—

The wise and careful provisions of the Pharmacy Act of 1868, as a whole, for the protection of the public and further regulation of the dispensing of poisons in question, have worked so efficiently and been so faithfully observed by the Pharmaceutical body, that the necessity for any more stringent imposition of any particular clause of that Act than is now generally observed, would be superfluous, for each individual member has voluntarily undertaken, and has carried out such precautions and regulations as his own particular case seemed especially to demand; so that now, to introduce further alteration would destroy, in many cases, great aids to security which at present exist, without increasing such security as is aimed at in a general way.

The Council of the Pharmaceutical Society would, therefore, submit to the Honourable Privy Council, with the unanimous opinion of the whole Pharmaceutical body in general meeting assembled, that the regulations, now in general use, are efficient, and any further regulations for the proposed purpose would not have any tendency to promote the welfare of her Majesty's subjects.

The proof of this position is the fact, that accidents to the public arising from the improper storing and retailing of poisons by Pharmaceutical Chemists and Registered Chemists and Druggists, are now almost unknown, and that the danger is therefore already reduced to the lowest point attainable by any regulations.

Hampstead, March 7th, 1871. WALTER BIGGS.

Sir,—Education is, we are told by those opposed to this proposal, the one safeguard against poison accidents, apparently forgetting that a careless man, although he may have received the best of educations, would remain careless. We do not expect universal education to make policemen magistrates, and judges useless members of society. Daily experience, unfortunately, shows that the worst criminals are too frequently well educated; failure in one case is good reason for doubt in another.

But are we, as a body, educated? The Pharmacy Act, it is true, will in future compel all who enter business on their own account to pass two examinations, but there are many engaged in pharmacy who will never become the owners of a business; consequently, we have no guarantee for their intelligence. Out of London I only know one establishment in which no apprentices are employed; in the majority there are no assistants, and in these, as a rule, the principal is seldom present, consequently, all the work is done by the apprentices, and I know many of them when their indentures or agreements are signed are quite ignorant of Latin. I know pharmaceutical chemists who receive as apprentices lads whose knowledge of English consists of not more than six words. Surely it cannot be said that in those cases education is a sufficient precaution. The Act has nothing in it to prevent a continuance of this state of things.

When I find your correspondents, one after another and week after week, asserting that every shop has now some regulation or another in use, I begin to doubt my own eyes and memory. I have, during my little experience of the trade, been engaged in some six or seven different situations, including a surgery and a workhouse infirmary, but have never known regulations or precautions whatever. I know where drawers were labelled in alphabetical order,—acacia, alumen, arsenic, etc., next one another in a row; bottles were arranged so that one shelf should hold white powders, another dark ones, thus arsenic and calcined magnesia (in one case the heavy), cantharides and powdered cubebs, etc., were next-door neighbours, liquids in the same order; these arrangements remain the same to-day. There are several on the Register who are well known to consider the pharmacy branch of their trade as of far less importance than the wine, spirit, beer and porter branch, and in their shops everything is made to give place to the drinkables, the young men having to leave bottles of mixtures partly prepared, to serve glasses of grog, etc.

My experience (for I write what I know to be true) thus tells me that regulations for the keeping of poisons are necessary, because of the want of education and the general neglect of any precautions.

The fact that frequent recommendations and fearfully narrow escapes have failed to convince many of the necessity of adopting any precautions is, I think, sufficient to prove that nothing short of stern compulsion will secure the general adoption of any rules that may be proposed.

Many object to the proposed regulations because they would include all the articles named in Schedule "A." Section 1 of Act declares the word "poison" to mean the whole of those articles. Any regulations which may be proposed for the "keeping of poisons," must, therefore (unless we have a new Act), apply to the whole list.

I hope the Council will persevere and succeed.

March 7th, 1871. D. W. JOHN.

Sir,—I am one of those who think that compulsory regulations as to the safe *keeping* of poisons are quite unnecessary. Many abler pens than mine have written on that point, therefore I will say nothing. But I wish to ask a question or two relative to the third clause in the proposed regulations, which says, "All liniments, embrocations and lotions containing poison, shall be sent out in bottles readily distinguishable by touch from ordinary medicine bottles."

Will a particular-shaped bottle be required, or can a piece of sand-paper be affixed to any ordinary bottle?

Is the rule to apply to the *sale* of laudanum, and such articles, or only to the dispensing of prescriptions?

If it only applies to dispensing, I think it is quite unnecessary, for as far as my experience goes,—and I have seen a good deal of dispensing,—it is already carried out in dispensing establishments, medicines for external and internal use being put in different shaped bottles. If it is intended to apply to the sale of such articles as laudanum, I venture to say it will be impossible to carry it out in many shops. In the neighbourhood in which I live the sale of laudanum and opium is of hourly occurrence, and we could not *give* a poison bottle when a customer came for a pennyworth or a halfpennyworth of it; and I am certain, in the majority of instances, the customer would not *buy* one.

Even supposing all the poisons mentioned in the schedule were sent out in poison-bottles, people could not be prevented using the bottles for other purposes when they had got them. Many people would take a fancy to the bottles, and make use of them for gin, vinegar, hair oil, etc., and *would* use them in spite of any Act of Parliament, even if you could get Parliament to pass such an Act, which is very improbable, and then what security would there be in "poison" bottles?

If laudanum has to be sent out in poison bottles, how is opium to be sent out? The sale of it is quite common in many districts, and it is usually sold in paper or pill-boxes; and it would be absurd to place such restrictions on laudanum and leave opium alone. Perhaps a particular shaped box would be required, or one covered with sand-paper.

Again, what is the use of applying such regulations to the poisons in the schedule when oil of vitriol, spirit of salt, aquafortis and a host of other dangerous things, can be sold by any person, in any quantity, without any restriction whatever?

Perhaps some supporter of the regulations will answer the above questions. ASSOCIATE IN BUSINESS.

Sir,—I think, before voting for or against the Poison Bill, we ought to know what is a poison. What is more absurd than to tell the public that camphorated chloroform, paregoric, syrup of poppies, cough lozenges, morphia lozenges, etc., are poisons according to the Pharmacy Act? The line must be re-drawn, and it must include all trades and professions, whether wholesale or retail.

When the word poison has been decided or clearly defined, then the feeling of the trade ought to be taken before the Society does anything in the matter.

What does the Society tell the public?

"That all chemists shall be examined, to show that they are educated and qualified to dispense medicines, etc., and that they are the only persons to sell poisons (under certain restrictions). They shall label the said poisons distinctly. The said label shall have the name and address of the seller on it." In the next place, if the Society does not protect the chemists in their legitimate business, why take their fees and yearly subscriptions? It is only fair that the chemists should have something in return for their money.

What chemist, with regard to his own safety, does not keep all virulent poisons away from other drugs, and have them distinctly labelled, not only while in stock, but when sent out, either as a prescription or recipe, and use blue bottles for lotions and poisonous applications?

If chemists are qualified by their examination, why impose these restrictions, which are not imposed on the grocer, oilman or drysalter, who sell more poisons than all the chemists in London?

Cases of accidental poisoning by chemists are very rare, in fact, scarcely known, considering the number of prescriptions they dispense. As a rule poisoning is attempted, or occurs through the poison having been sold by mistake by those who are not able to distinguish arsenic from carbonate of soda, much less give an antidote in case of emergency.

Lastly, as there is no law to compel a pharmaceutical chemist or chemist and druggist to be members of the Society, I hear that several of my friends intend to discontinue their subscriptions unless the Society looks better after their interests as the Society are compelled by law to place all pharmaceutical chemists, chemists and druggists, and associates on the Register, which Register shall be admitted in all courts of law.

An Associate of '53 by Examination.

A "*City Pharmacist*" writes to protest against submitting to an innovation "useless, foreign and tyrannical," to express his "confidence in Messrs. Brown, Bottle, Savage and Woolley," and to suggest that "the opinion of every chemist be taken by vote." In such case he believes the majority would pronounce against any "further interference" with the trade.

Sir,—To-day a gentleman handed me a prescription as follows:—

℞. Tr. Gentian. Co. f℥iiiss
Acid. Hydrochlor. Dil.
„ Nitric. dil. aa f℥ii.
M. ft. Guttæ.

Inquiring my charge for the same, on my replying 2*s.* 6*d.*, he withdrew the prescription from my hand, saying, "the charges in this town were exorbitant and out of all proportion; the mixture only contained gentian and hydrochloric acid, which would not cost more here than at Tunbridge Wells and other places, where he had paid 1*s.* 6*d.* for it."

I politely hinted that I thought such a charge would not be made at Tunbridge Wells, but he assured me the prescription had been dispensed there several times at that price.

Now I do think at the present time, when we are about taking upon ourselves increased duties as a protection to the public, such miserable charges should be abandoned, for surely no one conversant with our business will contend that 1*s.* 6*d.* is a sufficient remuneration for the above prescription; and any man charging this price does not act fairly either to himself or his brother chemists.

I should like to add a few words respecting the proposed regulations for keeping and dispensing poisons. I have read a great deal the last few weeks about the supposed hardships and annoyances to which the trade will be subjected, in case the proposed regulations become law. Now I feel sure a candid consideration of what they entail, when carried into practice, would strip them of half their terrors.

All will admit that at the present time more precautions are taken against accidents in the better-class dispensing businesses than in mixed country businesses; and although this partly arises from the supposed greater difficulty in carrying them out in the latter cases, I feel persuaded the will to do, together with a little ingenuity in the doing, would overcome all obstacles, and I speak with a practical knowledge of that class of business.

Could not the casks in the warehouse containing arsenic, sheep dipping, etc., be provided with lids and secured by a padlock? Also the acid. hydrocyan., the various alkaloids and their solutions, and the more potent poisons, be consigned to a cupboard, the key of which should be in charge of the principal, and only opened in his presence, or by his permission, instead of, as is too often the case at present, these things standing side by side with innocent preparations, probably on a shelf at the back of other bottles, with every chance of a mistake being made by a young apprentice. Then again, the laudanum bottle may be transferred from its vicinity to the Tr. Rhei to some corner, besides being rendered distinctive by a strip of sand paper or leather cap. Surely such precautions as these are not very onerous, and their observance must impress the mind of the apprentice with an idea of the potency of the articles he is using. If therefore it be once admitted that these regulations will be found practicable, I think we may dismiss any fears as to vexatious proceedings likely to be adopted to inquire into their observance, for the law has no terrors to those who carry out its provisions.

It has been strongly insisted upon by some that there is more need of these restrictions being placed upon public and private dispensaries than upon us; now this I fully endorse, but surely we should be able, with a much better grace, to ask that they should be extended to meet these cases, when we could point to our own observance of them. A few accidents like the one at Manchester, reported in a recent journal, would then add considerably to the force of our argument. I much regret to see so much personal ill-feeling imported into the discussion, as it only tends to make it more difficult to come to an agreement. I would like to see those who are in favour of the regulations speak out, and so strengthen the hands of the Council, who I am sure have only the interests of the trade at heart, and more especially as the same restrictions will fall upon them as upon us. I would also suggest that local secretaries should call together the members of the trade in their districts, to talk over the subject in a friendly way, which would do much, I believe, to smooth many difficulties, and would certainly tend to promote a better feeling between chemists in the same town, and allay much of the present trade jealousy.

W. H. P.

A Child Poisoned by Mistake at Manchester.

Sir,—In justice to Mr. Wild allow me to state that he (Mr. Wild) has for some time retired from practice, and consequently he was not "the man censured by the jury." The practice belongs entirely to Dr. Fox, who works excessively hard, and, to my thinking, should not have been rated for the pardonable omission of his dispenser. I know the class of patients Dr. Fox has to deal with, and I must say I never met with a more careless set in the course of my existence. The surgery is not an open one.

Herts, February 25th. A Medical Assistant.

"*Chemicus*" and *H. R. H.* are referred to the rule as to anonymous communications.

"*Boetis.*"—Dr. Hassall's is the famous work on food adulteration, but we do not recommend it.

J. S. R.—The substance of your letter has already appeared in this Journal more than once.

M. P. S.—It would be legal if the proprietor of the business be a Registered Chemist and Druggist within the meaning of the Pharmacy Act.

W. F. C.—See the letter on this subject from the Medical Officer of the Privy Council, Pharm. Journ. 2nd ser. Vol. X. p. 567.

W. J.—Pharm. Journ. 1st ser. Vol. II. p. 649; Vol. IX. p. 511.

A Member.—No.

"*Podophyllin.*"—We cannot assist our correspondent.

W. Rogers (Maidstone).—As a memorial addressed to the Council, the document of which copy is forwarded cannot be published before it appears in the proceedings of the Council meeting.

T. Padwick.—Oleate of soda.

F. O.—We cannot undertake to teach our correspondents the first principles of chemistry and mathematics, and would recommend the careful study of an elementary work on either subject.

"*Spes.*"—We think if our correspondent would carefully study the relative value of grammes and cubic centimetres, as compared with grains and grain-measures, the apparent discrepancy in the Pharmacopœia would be clear to him.

"*Rumex.*"—Epsom salt and salt of lemons are the correct terms.

G. W.—You will find a formula for syr. ferri bromidi in Pharm. Journ. 2nd ser. Vol. XI. p. 744, and one for vinum pepsinæ, 1st ser. Vol. XVIII. p. 197, or 2nd ser. Vol. VI. p. 192.

W. P.—You will find what you require in Ure's 'Dictionary of the Arts,' under the head "Silvering."

H. D.—(1.) For liniments it is; but not for any preparation for internal use by man or beast. (2.) You should give notice to the Registrar to make the alteration in the Register, for which no fee is charged.

J. P.—We should think Bonjean's preparation,—an infusion made with water and evaporated to a soft extract.

The following journals have been received:—The 'British Medical Journal,' March 4; the 'Medical Times and Gazette,' March 4; the 'Lancet,' March 4; the 'Medical Press and Circular,' March 8; 'Nature,' March 2; the 'Chemical News,' March 3; 'Journal of the Society of Arts,' March 2; 'Gardeners' Chronicle,' March 4; the 'Grocer,' March 4; 'Produce Markets' Review,' March 4; the 'English Mechanic,' March 3; Messrs. Longman's 'Notes on Books' for February; the 'New Lebanon Journal of Materia Medica' for February; the 'Food Journal' for March; the 'Brewers' Guardian' for March.

Communications, Letters, etc., have been received from Mr. C. Pierson, Mr. D. Hanbury, Mr. J. A. Forster, Mr. P. L. Simmonds, Mr. A. H. Mason, Mr. G. Edward, Mr. D. O. Evans, Mr. W. G. Scruby, Mr. A. W. Gerrard, Mr. A. Girdler, W. F. C., A. B. N., E. Y., J. C. B. M., T. D. M., "All Saints," "Alpha," "One in a Fix," "Quercus."

DISPENSING.*

BY W. J. HALLIDAY.

There are in Lancashire many large and important towns where little or no dispensing is done by the druggist, the medical practitioners dispensing their own medicines, and also such prescriptions of consulting physicians or surgeons as may come into their hands. The latter practice is very objectionable, and it is time the Pharmaceutical Council should use its influence to alter the system. Under these circumstances, how is an apprentice to learn dispensing? After he has fulfilled his term, and obtained a situation as assistant, he finds he has to commence learning what he should have had the opportunity of being taught during his apprenticeship.

Mr. Ince's remarks, made nearly twenty years ago, are applicable to the present time:—"The young beginner was apprenticed to a chemist because his parents thought it *such a nice clean business;* contrarywise, the tyro found himself immediately smothered up to his eyes in white, red and blue paint, not unlike the clown at Astley's, happy to present himself to society not too redolent of varnish, and, having escaped the oil-can on the one side and the blacklead on the other, allow a comprehensive apron to cover all deficiencies for seven long years. He then comes to London."

At the Pharmaceutical Conference held at Liverpool last year, the President stated "that the education of the present day was too superficial, the simple fact being that pupils neglected to learn how to spell. In the Crimean war many dispensers were thrown out because of their inability to spell even one-syllable words. Few persons who had not given special attention to this subject would credit the extent of the evil. He had examined a class of five boys supposed to be prepared for the preliminary examination, and, upon dictating a sentence of words of one syllable, none of the boys made less than three mistakes in the spelling."

Take an example of such an assistant in a new situation, where a prescription is given into his hands to dispense by an impatient customer. Say—

Mellis ℥j
Potass. Chlor. ʒj
Acid. Hydrochl. Dil. ʒij
Inf. Rosæ ad ℥viij.

The probability is he will overlook the infusion, and commence operations by weighing and measuring the other ingredients, and then, inquiring for the concentrated infusion, when told it is the custom to prepare fresh infusions, he is somewhat nonplussed; and if the customer is waiting, and of an irascible turn of mind, he will not find it a very agreeable duty to have to explain the cause of delay. And now for the infusion. If he has had no experience in preparing it, he will probably throw in the petals without separation; and when the medicine is prepared, in what style will he write and affix the label? for often much depends on the external neatness of a bottle of medicine.

I remember a case in point. A lady had a prescription dispensed, not at her regular chemist's, but at a first-class London house. In a short time she returned with the bottle, saying she had been accustomedto having her medicines delivered with clean labels.

Take another example, a young man who has had five years' experience in a house where dispensing is part of the ordinary daily business. He would read through the prescription carefully and intelligently, notice the infusion, tell the customer at once how long it would require for preparation. After making the infusion, he would copy the prescription, write the label, etc., and have all in trim for finishing off when the infusion was ready. The former instance is not unusual; and I believe pharmacists, as a rule, prefer assistants from parts of the country where at least a moderate share of dispensing is done.

In the towns referred to, the druggists make better way in the world and secure the reward of their labour earlier than those whose business is principally dispensing; their returns are much larger, and the variety and extent of stock kept would astonish a West-End chemist who has had no experience in country trade.

Since the passing of the Pharmacy Act, it is imperative that every young man must pass two examinations before commencing business. It has been proposed that the Preliminary should be passed before the youth is articled, which is a very good suggestion. In the second, or Minor examination, there is a pharmacy bench, where each candidate is examined practically in dispensing; and to pass he should be well up in that department, which is of the utmost importance for the future welfare of pharmacists. I would, therefore, suggest to this Society the advantage of having a dispensing-counter, where associates might obtain a knowledge of dispensing. There need be little expense about the medicines or apparatus required. A knowledge of Continental pharmacy might be obtained in this manner.

I will very briefly call your attention to a few instances of dispensing, commencing with mixtures. A slight difference in colour is often immediately noticed by the patient, and requires an explanation. To prevent this, it is very needful to have everything scrupulously clean about a dispensing-counter. A good flow of water is generally more useful than a fluffy towel in cleaning a measure or mortar, and it is my rule, where practicable, to rinse a bottle before dispensing a mixture. It is well known that gallic acid and water should be a colourless mixture, but by carelessness in the use of scales, measure or mortar not properly cleaned, it may become coloured; and one containing iron may be spoiled if any tincture containing tannin comes into contact.

Where practicable, perfect solution of soluble salts should be made, for even in the simplest form of mixture containing potass. bicarb., syr. aurantii et aquæ, I have seen the bottle wrapped up for delivery with the potash undissolved and the syrup unmixed.

The other day, I dispensed a mixture containing

Potass. Bromid. ʒvj
Tinct. Aurant. ℥iij.

When the medicine required to be repeated, half of the bromide remained in the bottle.

In mixtures containing potassæ bicarb. and acid. citric. or other effervescing salts, the effervescence should be effected first before the tinctures or syrups are added, and in as little water as possible to form the solution; if so, the saturation is completed more rapidly than by adding all the water, besides pre-

* Read at a meeting of the Manchester Chemists and Druggists' Association, March 3, 1871.

venting an explosion from excess of carbonic acid when the cork is drawn.

The dispensing of pills is not very popular, yet their use is extending; not so much in the old way of an aperient to accompany a mixture, but in usurping the place of mixtures altogether. A few pills sometimes contain several alkaloids requiring great care in manipulation, and, like all other pills, should be of uniform size and shape. In dispensing pills containing extract. nucis vomicæ, strychnia or other powerful ingredients, an excellent plan is to add a few grains of sugar of milk to pulverize the extract, or subdivide the alkaloid before mixing with the excipient, by which means more equal division of the active ingredient is obtained. When pills are repeated, they should be dispensed the same size as before, the 'q. s.' required should be noted for reference. Minute pills, containing one-eighth or one-fourth of a grain of alkaloid might be increased with advantage to a standard size of one grain by the addition of sugar of milk.

Powders should be weighed, and not guessed by what has been termed the rule of thumb.

Liniments and lotions require no special notice; but in dispensing liniment. chlorof. or camphoræ it is needful to have dry bottles, as the least addition of spirit or water prevents a bright liniment.

Most of the formulæ in the B. P. are prepared to a definite quantity of twenty ounces, but in the preparation of linim. camph. comp. the old formula has been copied. Thus,—

Camphoræ ℥ijss
Ol. Lavand. ʒj
Liq. Ammon. Fort. ℥v
Spt. Vini ℥xv,

forming liniment. ℥xxijss, as camphor in solution, equals its weight.

℞ Hydrarg. Perchloridi gr. ij
Hydrarg. Subchloridi gr. xx
Aquæ Calcis ℥ij.

A lotion prepared from this prescription may be dispensed of two colours. If the calomel is mixed first, and a solution of sublimate, often kept for convenience, added last, a black deposit—black oxide of mercury—is formed; but if the sublimate is dissolved in the lime water, and the calomel added afterwards, the red oxide is deposited.

Ointments are often prepared on a slab; in most cases a mortar answers better. I passed through Clerkenwell some years ago, and observed an abortive attempt made to prepare about 2 lb. of ung. sulph. co. on a slab, the hellebore and sulphur were in distinct lumps, and the lard frigid. How much more satisfactory had the powders been mixed in a mortar, and melted lard added!

An ointment from this formula is more frequently dispensed by mixing; but a better plan is to melt the lard, add the oil, and when nearly cold stir in the precipitate:—

Hyd. Nit. Ox. Lev. ℈ij
Adipis,
Ol. Amygd. aa. ℥j.

Expressed oil of mace and other fatty substances mix much better with lotions if previously melted than if rubbed cold.

Ung. potassii iodidi, ung. hydrarg. perchloridi are best prepared if the salts are dissolved in a little water in a test-tube, and ung. camphoræ can be prepared perfectly smooth if the camphor is dissolved by a gentle heat in the lard.

I should like to caution young men against commencing business too early in life. They had much better gain experience in London, or some other large town, and, if possible, obtain a knowledge of Continental pharmacy in France or Germany; and a term of engagement in the marble palaces called drug stores in the great continent of America might not prove useless.

SPIRITUS AMMONIÆ AROMATICUS.

BY JOHN T. MILLER.

In the last number but one of the Journal there is an article on spiritus ammoniæ aromaticus, in which it is stated that this preparation "ought to contain the ammonia in solution as the normal ammonium carbonate." That the authors of the official process entertained the same notion may be inferred from the construction of the formula.

Some time back, I noticed while distilling this spirit that ebullition was preceded by considerable effervescence. This fact led me to examine the composition of the distillate, which proved to be, as I had suspected, strongly basic,—a result which subsequent experience showed to be invariable. Indeed, so large is the excess of base in sp. ammon. aromat. B. P., that we shall not be far wrong in regarding it as a solution of

$$2NH_4HO + (NH_4)_2CO_3.$$

Variations in the composition of the product, but not, probably, to any great amount, may be expected to attend different conditions of manufacture.

The statement of Dr. Divers, that by following the directions in the British Pharmacopœia, "the formation of a spirit containing excess of ammonia is favoured but to only a *small* extent," falls so short of the mark, that I can hardly imagine it to be founded on actual analysis.

The writer in the Journal goes on to remark that in the older preparation—sp. ammoniæ *comp.*—the essential oils were mixed with spirit of ammonia, "this latter preparation being prepared by the double decomposition of sal ammoniac and potashes dissolved in proof spirit, and a certain quantity distilled. It would, therefore, contain the ammonia in solution as a mixture of the normal and acid carbonate."

I venture to say, however, that this argument is fallacious, and that the spirit in question contains *basic* ammonium carbonate.

I would refer those interested in the matter to a paper of mine in the number of the Journal for January, 1867.

Dangerous Drugs.—Women will meddle with dangerous drugs, notwithstanding the fatal consequences that have so often resulted from their recklessness. Because a child was cross, a Liverpool midwife, named Margaret Cunningham, gave it five drops of laudanum, which effectually stopped its cries, for the infant died. It is a pity women like Cunningham cannot find some better mode of quieting children than poisoning them. At an inquest the jury returned a verdict that the deceased had died from an overdose of laudanum "unskilfully administered," and the coroner cautioned the woman.—*Liverpool Courier.*

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Ferri et Ammoniæ Citras.—Solution of persulphate of iron is precipitated by pouring it into an excess of solution of ammonia—

$$Fe_2 3SO_4 + 6NH_4HO = Fe_2 6HO + 3(NH_4)_2SO_4.$$

The ferric hydrate thus thrown down is collected on a calico filter, and washed with distilled water until the filtered liquid gives no indication of sulphate of ammonium when tested by solution of chloride of barium. The hydrated oxide of iron is then dissolved in a solution of citric acid, and ammonia added in slight excess. The filtered liquid, evaporated by a very gentle heat to a syrupy consistence, and spread thinly on plates, forms scales which should readily shake off on drying.

There are several little points in this process which are deserving of attention, as students often fail to obtain a satisfactory product. In the first place it is essential to pour the solution of iron into the solution of ammonia, not *vice versâ*. The object of this device is that the ferric sulphate, by coming into the presence of considerable excess of ammonia, may really undergo the decomposition expressed in the equation above; that is, that it may be transformed into pure ferric hydrate. If the ammonia is poured into the solution of iron, the ferric sulphate undergoes a decomposition which is incomplete, for the precipitate contains a very appreciable quantity of sulphate, carried down in the form of an insoluble oxysulphate of iron. The composition of the precipitate is, of course, very variable, but the general nature of the change is shown by this equation—

$$Fe_2 3SO_4 + 4NH_4HO = Fe_2SO_4 4HO + 2(NH_4)_2SO_4.$$

Hydrate of iron mixed with such impurity, when dissolved in citric acid and ammonia, furnishes a granular semi-crystalline product, not the usual brilliant scales. The proportion of citric acid must also be adhered to, or the solution, on evaporation, will often become turbid and yield a compound only partially soluble in water.

Several combinations of citric and tartaric acid with peroxide of iron have been employed for a long time in medicine. They are, however, inferior to the ammonio-citrate in richness and brilliancy of colour, and in solubility. Nevertheless, it is obviously improper to substitute this, or any other salt, when ferri citras or ferri tartras is ordered in a prescription. Any little difficulty in effecting solution, if it should occur (which is, however, unlikely), may be got over as recommended by a correspondent of this Journal ("Notes and Queries," p. 437), by warming the salt with distilled water in a test-tube.

[§ Heated with solution of potash, it evolves ammonia and deposits peroxide of iron. The alkaline solution from which the iron has separated does not, when slightly supersaturated with acetic acid, give any crystalline deposit. When incinerated with exposure to air, it leaves not less than 27 per cent. of peroxide of iron, which is not alkaline to litmus.] The former of these tests serves to detect the fraud when tartaric has been substituted for citric acid, and the latter shows that the preparation contains no potash.

Ferri et Quiniæ Citras.—Solution of persulphate of iron is precipitated by excess of solution of ammonia, and the washed precipitate is dissolved in solution of citric acid, employing the same precautions as in making ferri et ammoniæ citras. Similarly, sulphate of quinine, previously dissolved in a little dilute sulphuric acid, is mixed with solution of ammonia in excess, and the precipitated hydrate of quinine collected and washed. It is then dissolved in the solution of citrate of iron already prepared. A little ammonia is then added to the solution, not, however, sufficient to precipitate the quinine, but leaving the solution slightly acid. Finally, the liquid is evaporated down to a consistence suitable for scaling on plates.

[§ Thin scales, of a greenish golden-yellow colour, somewhat deliquescent and entirely soluble in cold water. The solution is very slightly acid, and is precipitated reddish-brown by solution of soda (a mixture of the hydrates of iron and quinine), white by solution of ammonia (hydrate of quinine), blue by the yellow and red prussiates of potash, and greyish-black by tannic acid.]

This compound contains both ferrous and ferric salt, since it gives a deep blue precipitate with red as well as with yellow prussiate of potash. Part of the citric acid, in fact, reduces some of the iron to the ferrous state, becoming itself converted into a mixture of acids which have not been closely examined. Without this reduction the scales are not of the usual greenish-golden colour. The addition of a very small quantity of potash is said to favour it, though this is not recognized by the Pharmacopœia, and is precluded by the test there given. [§ When burned with exposure to air, it leaves a residue which, when moistened with water, is not alkaline to test-paper.] It should contain 16 per cent. of quinia, unmixed with cinchonia and quinidia. [§ 50 grains, dissolved in a fluid ounce of water and treated with a slight excess of ammonia, give a white precipitate, which, when collected on a filter and dried, weighs 8 grains. The precipitate is almost entirely soluble in pure ether, and, when burned, leaves but a minute residue.] This quantitative test as indicated in the Pharmacopœia is defective, because it does not give sufficient detail. No mention is made of washing the precipitate, nor of the temperature at which it should be dried. Both these points should be clearly defined, or very untrustworthy results will be arrived at. The temperature at which hydrate of quinine gives up the whole of its combined water, and becomes anhydrous, $C_{20}H_{24}N_2O_2$, is about 260° F.; the precipitate should be dried at this temperature.

From recent analyses of the commercial salt supplied by different makers, it appears that the amount of quinia introduced varies very considerably, in some cases not exceeding one-fourth of the official proportion. As stated already, great injustice may be done in such analyses unless conducted with due precautions.

Ferri Iodidum,—[§ Iodide of Iron, FeI_2, with about 18 per cent. of water of crystallization and a little oxide of iron.]

Iron wire, iodine and distilled water are digested together till the colour of the iodine has disappeared; the solution is then filtered into a clean iron dish, and rapidly evaporated till a drop removed on the end of an iron wire solidifies on cooling. It is then poured out upon a porcelain dish, and, when solid, broken up and put into a bottle.

Ferrous iodide forms a greenish solution, which gives the usual reaction of ferrous salts with red prussiate of potash, resulting in the formation of a deep blue precipitate.

$$3\,\dot{Fe}I_2 + K_6Fe_2Cy_{12} = 6\,KI + Fe''_3Fe_2Cy_{12}.$$

Iodide of iron is a deliquescent substance and soon absorbs oxygen from the air, giving a brown mixture of iodine and a ferric hydrate-iodide, which is insoluble in water. In this state, particularly if it shows signs of containing uncombined iodine, it is unfit for use in medicine, but should be digested with water and iron wire, and when the brown colour of the liquid has disappeared, filtered, and once more evaporated to dryness.

The syrup is an important preparation. In making it, it is essential to follow closely the instructions of the Pharmacopœia and to employ the *purest* sugar.

BISMUTHI SUBCARBONAS.

BY T. P. BLUNT.

It may not be generally known that the commercial "subcarbonate of bismuth" (Bismuthi Carb. P. B.) contains an appreciable quantity of silver, in the form of chloride.

I have been in the habit for some time of preparing liq. bismuthi by the solution of the above salt in nitric acid, and though samples from various sources have been used, there has always appeared a heavy and very finely divided sediment, which passed with readiness through a filter, and could only be removed by subsidence and decantation; as this proved a source of some annoyance, I determined to ascertain the nature of the insoluble matter, when it was found as above stated, to consist of chloride of silver.

The amount was ascertained as follows:—

1000 grains of the subcarbonate of bismuth were dissolved in nitric acid, the sediment allowed to subside, and the supernatant fluid decanted off as closely as possible, the residue was washed with nitric acid by decantation, and a large excess of strong ammonia was then gradually added, the precipitated oxide of bismuth was thrown on a filter and repeatedly washed with ammonia water.

To the filtrate a slight excess of nitric acid was added, the precipitate collected on a filter in the usual way, dried, ignited in a porcelain capsule, treated with nitro-hydrochloric acid, and again gently ignited; it weighed 1·3 grains, representing 0·98 grain metallic silver, or about 0·1 per cent. This proportion is obviously of no importance from a therapeutic point of view; it might, however, be worth while for large makers to separate it in the course of manufacture, as might readily be done by some such process as that given above, without any loss of bismuth.

THE PRECIPITATION OF QUINIA BY IODIDE OF POTASSIUM FROM ACID SOLUTIONS.*

BY J. M. MAISCH.

Some time ago the following prescription was received:—

℞ Quiniæ Sulphatis gr. xv
Potassi Iodidi ʒi
Tinct. Ferri Chloridi ʒi
Aquæ ℥iv
Syrupi Zingib. ℥i.
M.

The quinia salt was dissolved in the tincture of iron, the potassium iodide in the water, and the solutions mixed; a brown precipitate was at once formed. The quinia salt was now dissolved in the water with the addition of a little dilute sulphuric acid, the iodide added, and after solution had taken place, the tincture of iron; the same result was produced.

It was now supposed that the iodide might contain some iodate, that on the addition of an acid, iodine was liberated, which, with the excess of iodide, would form biniodide of potassium, and that the precipitation occurred in consequence of the presence of this compound. But when the solution of the iodide (Atkinson and Biggar's) was acidulated with muriatic acid, a reddish colour was not produced, nor would starch paste brought in contact with the liquid acquire a blue colour; iodic acid was therefore not present.

Righini stated (*Journal de Chim. Méd.* vol. xiii. p. 116) that bisulphate of quinia produces with iodide of potassium a red pulverulent precipitate.

A considerable quantity of iodide of potassium was dissolved in a solution of one part of sulphate of quinia in twenty of water, the solution of the latter salt having been effected with just enough dilute sulphuric acid. A white precipitate was the result, doubtless owing to the presence of some quinidia in the quinia salt; for a solution of one part of quinia sulphate in forty of water, effected with a sufficient quantity of sulphuric acid, remained clear on the addition of iodide of potassium in substance. When a considerable excess of pure sulphuric or muriatic acid was used for dissolving the quinia, the addition of solution of potassium iodide occasioned no turbidity or sediment; therefore the observation of Righini is not correct as far as it relates to neutral potassium iodide.

A solution of sulphate of quinia (1·40) with just sufficient acid was prepared, iodide of potassium added, and then solution of citrate of iron; a white turbidity with the gradual production of a bright red precipitate was the result.

The same quinia solution was made, except that a considerable excess of dilute sulphuric acid was used; after the solution of iodide of potassium had been effected, every drop of the solution of iron citrate occasioned a brownish-white precipitate, which rapidly changed through various shades into deep brown. If the order of mixing was reversed, the potassium iodide yielded with dilute sulphuric acid a colourless solution, which became turbid and turned brown with the iron citrate, and now yielded with

---

* Read before the Philadelphia College of Pharmacy, at the Pharmaceutical Meeting, Dec. 20, 1870.

solution of quinia a darker coloured precipitate, changing more readily.

If an aqueous solution, or the tincture of sesquichloride of iron, diluted with water so that the iron colour can scarcely be perceived, is mixed with solution of potassium iodide, an iodine colour is at once produced, doubtless owing to the formation of ferric iodide: $Fe_2Cl_8+3KI=Fe_2I_3+3KCl$. But since in a mixture of solutions of different salts the acid and bases interchange in part, provided an insoluble compound be not formed, a mixture of the two solutions must contain Fe_2Cl_3, Fe_2I_3, KI and KCl; the third equivalent of iodine in Fe_2I_3 being but loosely combined, we have in the above mixture practically KI_2, and obtain with it in quinia solutions the same precipitate which we observe on the addition of Lugol's solution.

The appearance of the red or brown precipitate which, according to Righini, contains quinia, hydriodic acid and iodine, depends therefore on the presence of KI_2, or if KI be used, on the presence of some other compound producing the former.

The precipitate obtained in putting up the above prescription, after having been well washed with water, forms a brown powder having a slight odour of iodine, which is slowly evolved. When the precipitate is treated with ammonia, it changes to a dull cinnabar colour; dissolved in acids, it yields a copious precipitate with iodohydrargyrate of potassium. Heated upon platinum foil, it decomposes, leaving a bulky charcoal, which is burned with difficulty without leaving any residue behind. The precipitate therefore contains, beside the elements of quinia, only iodine.—*American Journal of Pharmacy.*

THE BOTANICAL STUDENT'S DREAM.

"Ridentem dicere verum
Quid vetat?"

It was the middle of February, and I hoped to pass the Minor Examination in May. I had devoted my winter evenings to botany, and was endeavouring to create out of Bentley and my own inner consciousness a correct idea of a plant. It was my off-duty night, and, after a good spell of reading, I found that my notions, instead of clearing up, became more and more confused and complicated. Suddenly it came into my head that I was a primordial utricle, and how to get out of my cell, notwithstanding its walls were but cellulose, was more than I could accomplish. But no, that was not it; a painful sensation across the chest made it evident that I was a cell myself, and that the hour-glass constrictive, preparatory to a division into two cells, was taking place. Though painful, this did not otherwise distress me, when I heard a rushing noise—(was it a cytoblast?)—and, presto! the perfect image of my thoughts,—my ideal plant was full in view before me. Alas! what a Frankenstein had I brought to life, or to death in life! No old oak wild and gnarled, worn with the storms of five hundred winters, ever looked so weird and ghostly to the belated traveller as he passed it in the thickening twilight as did my unfortunate creation. Its arms were stretched out as if to seize upon its author, but the cell division being now completed, I slid easily out of the way. I saw what a frightful abortion I had produced. Was it an exogen with the wrong side out, or an endogen with the wrong side in? The fibro-vascular bundles were rattling loose like old bones, and the bark of the trunk, where there was any, was altogether unlike bark. Surely the liber must have got outside the epidermis, owing to its being made out of a book. The petioles were at the wrong ends of the leaves, and the peduncles had no work to do. The lacteals were leaky, and my nose assured me they were distilling assafœtida; but if so, why were they in the stem? The conversion of the elements of leaves into flowers was going on badly; some had got as far as stamens, and were intended to be hypogynous when the ovary arrived. The process had followed the too frequent example of higher organizations, and become a case of cryptogamy. There were old carpels hanging about, which ought to have dehisced long ago,—septicidally probably, suicidally most likely. The seeds were all loose, so I supposed the dissepiments did not fit, or the placentation was not correct. There were spines in abundance,—naturally enough in this case, for the development of the leaf-buds had proceeded upon false principles. Involucres, bracts, spathes and glumes were stuck about here and there, looking as out of place as bills upon a lamp post.

One thought pleased me at last—the roots were hidden out of sight. Consequently, whether they were true roots or adventitious I did not care; whether rachis or underground stem, whether bulb, corm or tuber, it mattered not; and, as long as my own medulla was safe, it was a toss up whether there should be any in the root or not.

To complete my confusion, I now saw approach the venerable but slightly aquiline form of the examiner in botany, and on his coming the miserable spectre I had raised fell to pieces like a disarticulated skeleton. He saw my embarrassment, and, picking up one of the fragments, asked me, in a gentle voice, "What is *prosenchyma?*" I hesitated. I, who had been using it—alas! too freely, from a book mind, as I afterwards remembered. I was brimful of hard and uncomfortable words as good companions to each other as teasel heads or thorn-apples, which nevertheless kept shifting about as in a kaleidoscope; but this one *would not* come into the field of view. I answered at a venture, "*Protoplasm.*" He gave me just one look, stern but full of pity, and the expected collapse took place.

It might have been a few minutes or a few hours afterwards that I saw a graceful maiden, with a golden glory round her head, walking towards me. "Youthful student," she said, "I know your troubles, and am come to help you. My name is Clytie. The sun whom I follow has risen, and I will take you to the fields where grow the anemones and primroses and the yellow daffodils. We will follow his course till night, and before he sets, you will learn more of the glories of flower-land than books will ever teach you." So we went forth with the sun, and picked the earliest blossoms wet with dew. As he got high others unfolded, and the green leaves overhead and the grass below, the leafy hedgerows and mossy banks, all had something to tell and something that could be remembered. And the bees entered the flowers, to show us where were the nectaries, and got covered with pollen-grains, till they were as dusty as millers. We saw, too, the colchicum leaves, like bundles of spearheads, in the meadows; and the feathery hemlock, with its livid stems, lurking by the hedges; the viscid henbane on the chalky upland; the dark green belladonna; the dandelion, despised among herbs yet honoured pharmaceutically, its seed-heads a botanical study; the tall foxglove, with its cups for the fairy folk; and the malefern, with its crown of unfolding fronds, a model of graceful beauty; and the sycamore seeds springing up in the shade where grass did not grow, taught the secret of cotyledons, and other lessons were quickly learned. And the odours were crushed out under-foot,—the allium, fine but somewhat high; the wild thyme, fresh and sweet; whilst the scent of the anthoxanthum, sweetest in death, was borne far away down the wind. And so, as the sun westered, the world of flowers had acquired a new meaning; and my spoils grew heavy, and—but the fate that befalls walking philosophers and star-gazers in general befell me. Whether it was a stump or a bramble I do not know, but my forehead came into sharp contact with—the ground, I was about to say; but no, it was the corner of that 'Bentley' lying on the table. And so I awoke.

Moral.

If you want to learn botany, do not begin by studying an advanced work on the subject, and by cramming yourself with names and details that, if you have a good memory, may enable you to pass your examination, but which, unless you have struck the keynote of your work, will very probably be soon afterwards forgotten, or reduced to the state of jumble portrayed above.

Instead of this, provide yourself with a pocket lens and a sharp penknife; take an early walk into the country, and bring back a few common flowers, pulling them up by the roots. A buttercup will do excellently well to begin with, as it is a representative of the first Natural Order, and is a good plant to work upon. Examine it carefully by the aid of a simple elementary work, such as Oliver's 'Lessons in Botany,'—a cheap book,—and by the time you have got through a few common plants and a few chapters of your book, you will begin to take an interest in your subject, and will be glad to turn to the pages of 'Bentley' for further and necessary knowledge, —a book which, if taken up first-hand is "worse than Greek" to many. By pursuing this course, you will be learning at the same time both systematic and structural botany,* and, as far as the mere examination goes, you will gladden the heart of your examiner by showing him that you practically understand your subject, and that, even if your knowledge be limited, it is sound. Beyond this, however, and what is of far more importance, you will obtain some real insight into botany, which will not be merely ornamental, but will be of direct personal utility as long as you follow the pharmaceutical profession.

WILLIAM SOUTHALL.

* To any one desiring to pursue English botany further, I should recommend Bentham's 'Handbook of the British Flora.' There are pharmacists among us, men of our own order, who are specially qualified to write an introductory treatise on botany more immediately applicable to the wants of pharmaceutical students. Oliver's instructions are too limited in their range; his work might be amplified to great advantage in our particular direction. Whoever (and names rise instinctively to the mind) deigned to contribute such a manual would confer an incalculable benefit on many a perplexed student, and effectually prepare him for the full enjoyment of more advanced abstract compendiums.

REPORT ON THE CULTIVATION OF CINCHONA AT DARJEELING FOR THE HALF-YEAR ENDING SEPTEMBER 30, 1870.

FROM C. B. CLARKE, ESQ., M.A.,

Officiating Superintendent, Botanic Garden, and in charge of Cinchona Cultivation in Bengal, to the Officiating Secretary to the Government of Bengal, General Department.

The season has been unusually wet, the rainfall having already (25th October) amounted at the inspection bungalow to 200 inches, whereas the total fall for the year averages 180 inches only. The health of the plantations of *C. succirubra* and *C. calisaya* has remained good, and their growth satisfactory, though somewhat less than that of the preceding year. But *C. officinalis* has suffered more than during previous rainy seasons, and all hope must be abandoned that this species can be grown to an economic profit at Rungbee.

Taking the plantation called the 5th in the tabular report, which represents best the present centre of the plantations, it will appear that the average growth of the measured plants of *C. calisaya* for the half-year has been 36 inches, and that of *C. succirubra* 22 inches. The latter, from accidental circumstances in choice of the plants measured, is too low, and does not represent fairly the growth of plants of that age in that part of the plantation. The best plants of *C. succirubra* and *C. calisaya* have, within three years of planting out, surpassed 20 feet in height. No measurement is given of *C. officinalis;* it may be said generally of the older plants that some 40 per cent. perished during the last six months, and that those which survived did not grow. The number of plants of *C. officinalis* has been by estimation reduced from 930,704 on 31st of March, 1870, to 440,000 on 30th of September, 1870, but it would be best, in any calculations regarding these plantations, to write off these 440,000 at once; for, though some of them may survive for years, there is no probability that any profitable result will ever be derived from them.

Throughout the *C. officinalis* plantation, below 4500 feet level, *C. succirubra* was planted in 1869 in order to utilize the area, kept clean at considerable expense. These young *C. succirubra* promise exceedingly well.

The 164,615 plants of *C. succirubra* planted out during the early part of the six months under report were required to fill up the 1000 acres of that species as designed by Dr. T. Anderson. The 33,101 plants of *C. officinalis* were put out at a higher level (5000 feet) than before as an experiment.

By far the greater portion of the coolie labour is spent in scouring the young plantations during the rains. In order to ensure a sufficient supply of labour at this period, it is necessary (as in the surrounding tea plantations) to maintain the coolies during the year, so that during the cold weather it has been difficult to devise sufficient employment for them. The cold weather is the best time for planting out; and in accordance with Dr. T. Anderson's advice, it is proposed, during the ensuing cold season, to employ them in planting out *C. succirubra* in a rough way on some portions of the reserve, which are at too high a level for *C. calisaya* to thrive upon. And it is for this purpose that a considerable quantity of *C. succirubra* seed has been raised, put down at 500,000 (including some stock raised by cuttings).

C. calisaya has set its seed very favourably during the last two months. This seed should ripen in the course of next spring: and it is hoped that in future the quantity of seed produced will be sufficient to enable the extension of *C. calisaya* in any quantity that may be thought desirable.

Rungbee, near Darjeeling,
October 25th, 1870.

NOTE ON AROMATIC SULPHURIC ACID (U.S.).

BY JOHN W. EHRMAN.

Every dispenser is acquainted with the objections which may be brought up to the present officinal formula for aromatic sulphuric acid. As the committee on revision of the pharmacopœia is now in session, it is to be hoped that the formula under consideration may be modified, and with it several others of a like nature.

The aromatic sulphuric acid is used most extensively as a solvent for sulphate of quinia, in prescription, usually with watery or syrupy vehicles. When prescribed alone for the medicinal effects of the acid, it is not unfrequently diluted in order to modify its taste, and, avoiding the use of drops, to render its administration more convenient.

Now, when the elixir of vitriol is associated in this manner with watery fluids, the colouring and extractive matter becoming insoluble in the menstruum, precipitates, and the result is a muddy mixture instead of the clear solution we should otherwise obtain. But the elixir of vitriol, even undiluted, is constantly undergoing change, with the continual deposition of a bulky precipitate, so that it can be dispensed in a bright condition only by frequent filtration. This, of course is exceedingly annoying, and it is a reproach to the progress of pharmacy that the formula has been so long retained without material change. The old method of preparing it by exhausting the powders with the mixed alcohol and acid is preferable to that now employed, as it gives a preparation less prone to deposit by standing. The other objections, however, apply to this with equal force; for the ingredients afford to the menstruum principles which must of necessity separate upon dilution.

In revising this formula we should keep in view the fact that the resulting preparation should be miscible with water without precipitation, hence aromatics of an oleo-resinous nature cannot be used.

The following formula we have used for some time, and have found entirely satisfactory:—

Take of Sulphuric Acid, 3 troy oz.
Fluid Extract of Orange Peel, 1 fl. oz.
Red Rose Leaves, 2 drchs.
Boiling Water, 1 fl. oz.
Alcohol, a sufficient quantity.

Add the acid gradually to half a pint of alcohol, and pour the boiling water upon the rose leaves; when both liquids have become cool unite them, add the fluid extract and sufficient alcohol to make up the measure of eighteen fluid ounces. Mix thoroughly and filter.

Elixir of vitriol, thus prepared, has a pleasant aromatic odour and flavour, and the beautiful red colour of the rose leaves, heightened by the presence of the acid. It is miscible with water without turbidity, and a specimen, after long keeping, has deposited but a trace of sediment.—*The Chicago Pharmacist.*

WEST INDIAN MEDICINAL PLANTS.

Many plants not ordinarily recognized possess almost magical powers in the relief and cure of diseases, and are worth further investigation, and many that were only a few years ago considered of no value, are again brought into use in the West Indies. I will here allude to but two. The little herb (*Verbena officinalis*) generally known in the Bahamas by the name of blue flower, is acknowledged to possess some medicinal qualities.

The Spanish name yerba sacra, holy herb, is assumed in consequence of its acknowledged and undeniable virtues; it has been in use in the West Indies as a remedy from time immemorial.

The vervain possesses diaphoretic, diuretic, laxative, anthelmintic, and antiseptic powers. For children it is one of the best preventives against worms. By making a decoction or infusion of the leaves once or twice a week, and giving this instead of their ordinary drink for breakfast, it will keep the bowels regular, the skin free and moist, and they will not then be so frequently troubled with those obnoxious companions. If this plan were generally adopted, we should hear less of children dying suddenly or being attacked with convulsions.

The expressed juice of the whole plant also serves as a gentle purgative, by taking a tablespoonful for an adult every hour till it operates. Externally applied, the juice is found to be of no little value in healing fresh cuts and wounds, where no proud flesh exists. But it developes its qualities in a most marvellous manner in the cure of fevers, especially those of the putrid kind, such as yellow fever, black vomit, etc., cleansing and purifying the system so completely and in such a short time, and in many instances where all other remedies have failed to perform a cure, as would astonish the most sceptical and unbelieving.

Dr. A. Jackson, a physician of Nassau, Bahamas, states that he has used it extensively in his practice for many years and with success. He cites numbers of cases, and one of putrid fever was cured in eight days, the principal ingredient being *Verbena*. Mr. Kenneth Matheson, British Vice-Consul at Bolivia, in a letter to the Governor of the Bahamas, dated April, 1853, states that the plant was proved to be "a cure for yellow fever and black vomit, and that it was successfully used in restoring to perfect health many persons afflicted with that disease who had been declared by several medical practitioners to be in a hopeless state. The medical men likewise have adopted the same remedy with perfect success." He then continues to say, "that in Jamaica it was also proved to be a remedy of great value in this disease, having been tried and found as successful."

Another plant, called locally the Bitter Bush (*Eupatorium sp.*), is stated in Jamaica to be a remedy for cholera.

The class of plants arranged under the head "*Eupatorium*" is as varied and extensive as the surface over which they are scattered,—species of it being found in every climate and situation throughout the known world. Whether they all possess similar principles is a question to be decided only by time and inquiry. There are many species described as indigenous to Jamaica and the other West India Islands, namely:—

Eupatorium parviflorum; diffusum; macrophyllum; villosum; nervosum; cordifolium; montanum; rigidum; macranthum; Dalea; trifidum; conyzoides; atriplicifolium; repandum; sinuatum; obtusifolium; cotinifolium; triplinerve; ivæfolium; stœchadifolium; myosotifolium; spicatum; furcatum; cubense; sophiæfolium.

Of these, only three have been as yet applied as a remedy in cholera. Two, which appear to be *E. nervosum* and *E. villosum* in St. Catherine's and the neighbouring parishes, and *E. rigidum* on the north side of the island.

In collecting the plant, the best mode of proceeding is to gather it after the dew has disappeared; and as soon as a sufficient quantity has been collected and brought in, and whilst fresh, cut the small branches, with the leaves on, in lengths of 8 or 10 inches,—put them in straight lengths, then tie them up in bundles of half a pound and pack them close in a clean box. When the bush is allowed to remain for a few hours the leaves become dry and crumble into dust when handled. The name of Bitter Bush is applied indiscriminately in St. Catherine's and some other parishes in Jamaica to several species of *Eupatorium*, and in St. Ann's and other parts Christmas Bush is in like manner applied to tho same plant.

These several species of *Eupatorium*, variously called Bitter Bush and Christmas Bush, have been used in all stages of cholera with invariable success.

The *Eupatorium* leaves none of those dangerous permanent unpleasant symptoms produced by opium, lead, zinc, calomel, or by the saline treatment alone. Suppression of urine never occurs, but, on the contrary, when that painful and dangerous symptom takes place after the use of other remedies, a dose or two of the decoction immediately relieves the patient. It is a remedy at every man's door in the tropics, and requires no other preparation than is necessary to make any other bush tea. Boil two drachms of the bush in a pint of water into a strong decoction, let it get quite cold, and, in case of cholera, give a small teacupful (two or three ounces) every half-hour until the symptoms are checked; then extend the time (according to the severity of the symptoms) to every hour or second hour until the symptoms are entirely abated.

In simple diarrhœa give the same quantity every hour or second hour, according to severity of the attack,—but seldom more than one or at most two doses are required.

It is, perhaps, as well to give a caution against the use of the decoction as a preventive. The *Eupatorium* is a remedy in the existing disease, but the use of it as a preventive will be more injurious than otherwise.

P. L. S.

Death from Vaccination.—In Liverpool a death has followed as the result of vaccination. It appeared that the deceased had vaccinated himself from the arm of a friend, who was a chemist and druggist, and died about ten days afterwards of pyæmia. Medical evidence was given to the effect that the deceased was in a very unfit state for vaccination, as he was suffering from diabetes.

THE DIFFERENCE BETWEEN SPECIES AND RACE.

In the review of a work by M. Quatrefages, entitled, 'Charles Darwin et ses Précurseurs Français,' which recently appeared in the *Gardeners' Chronicle*, a *résumé* is given of the arguments of that celebrated naturalist, from which we abstract the following particulars.

As the result of an examination of the doctrine of Darwin, M. Quatrefages considers that it resolves itself into a simple and clear notion, which may be represented in the following formula:—All the actual and present animal and vegetable species descend by way of successive transformations from three or four original types, and probably from one solitary primitive archetype. Thus explained, he thinks Darwinism has in it nothing very new, and that the admirers of Darwin have not done justice to those who have preceded him in this path of speculation, such as De Maillet, Robinet, Buffon, Geoffroy and Isidore Saint-Hilaire, Bory de Saint Vincent, and M. Naudin.

The "general exposition of Darwinism" which follows is probably more in accord with the real views of Darwin, especially in reference to the doctrine of natural selection, than the writings of professed admirers and champions of the school.

M. Quatrefages is at issue with Mr. Darwin on the subject of the transmutation of species, whilst he believes in their variability. All Nature manifests correlation, and all the extinct species of animals range themselves side by side, or in the vicinity of species at present existing. To find place for all the fossil animals yet discovered, it has not been necessary to create one single additional class. The extinct and the living species appear as the integral parts of one system of creation. The embryonic structure of animals tends to the same conclusion. The second part of the book deals with the nature of the proofs invoked. The author finds that in all the writers quoted personal conviction takes the place of logical argument. Modern science requires more than this, and only accepts as proofs well-defined facts, and such as have been subjected to vigorous criticism. M. Quatrefages contends that the notions of Darwinism are opposed to the observed and ascertained laws of creation, and to the facts brought to our view by Paleontology, and says that Lamarck, in setting out from an assumption of spontaneous generation has, at all events, a logical basis on which to rest his theory; but Darwin, in refusing this doctrine, and in leaving out of sight the origin of his primordial being, is obliged to admit that some unknown cause has played the part of a creative power on this globe, and that only for once, during a limited time, and in only one manner. To produce for once an archetype, and to remain inoperative for ever after, is contrary to all human experience and belief.

M. Quatrefages afterwards enters upon the questions of species and races of hybridation and cross-breeding (*métissage*). He says the two first terms are often confounded. He quotes Isidore Saint-Hilaire, who, after a learned examination of the opinions of the most eminent botanists and geologists, says:—"Such is species and such is race, not only for the schools into which naturalists are divided, but for all. The gravity of their differences respecting the origin and the anterior phases of the existence of species does not hinder them from proceeding to the distinction and determination of species and race in the same way. So long as the question is only concerning the actual state of organized beings, all naturalists think the same, or at least act as if they thought the same."

M. Quatrefages thinks these words exactly define the question. "They teach us that schools exist only when we take a position outside of time and place accessible to observation, and that they are effaced as soon as we enter on reality. In the presence of what is, it is no longer possible to argue about what might be." Our author cites the definitions of between twenty and thirty leading naturalists, from the times of Ray to the present, and finds that "when they would define species they have all been constrained to include in their formulas the two ideas of resemblance and of descent." Vogt first comprehended in his definition of species the notion of the phenomenon of *généagenesis;* more recent works, and especially those of Darwin, have shown the great importance of *polymorphism.*

This is illustrated by the changes undergone in a cycle of generations of a *Medusa,* through the whole of which it remains fundamentally the same. Similar facts leading to the same result have been traced out in the vegetable kingdom.

"The species," then, according to M. Quatrefages, "is the collective amount of individuals more or less resembling each other, which are descended, or can be looked upon as descended, from one primitive pair by an uninterrupted and natural succession of families.

"The variety is an individual, or a collection of individuals, belonging to the same sexual generation, which is distinguished from other representatives of the same species by one or more exceptional characteristics.

"The race is the totality of individuals belonging to a single species having received, and transmitting by way of generation, the characters of a primitive variety.

"Thus the species is the point of departure. In the midst of the individuals which compose the species appears the variety, and when the characters of the variety become hereditary they form a race. These are the relations which for all naturalists reign between these three terms, and which it is necessary to have constantly before the mind in the study of the questions which occupy us."

Hence it follows that the notion of resemblance, which is very much attenuated in the species, becomes of absolute importance in the race.

The union of individuals of different species is very rarely productive. It is quite otherwise with the union of individuals of the same species but of different races.

M. Quatrefages considers both Lamarck and Darwin confound the ideas of species and of race. He says that Darwin, in order to sustain his theory, should have proved that crossing between races is not always possible; and that crossing between species can give rise to hybrid races. This he is so far from being able to do, that his works are a storehouse of observations tending to prove the direct contrary.

The power which man possesses of creating and modifying races both in the animal and vegetable world, is very great. Beginning with the egg, he can, by the simple application of heat in different ways, evolve abnormal productions, and by altering the surrounding circumstances of life, and by carefully crossing only with those possessing like peculiarities, he can produce races so unlike the species that they would certainly be set down, at first sight, as altogether different species. Thus, from one species of pigeon (as Mr. Darwin believes) he has succeeded in raising 150 races, but they are all, nevertheless, one species, and propagate freely among themselves. The dog, also, in like manner, has varied under his hand into 180 races, and it is familiar to every one how wonderful the triumph of human art has been in the vegetable kingdom. But man has never yet succeeded in producing one species, self-maintaining, capable of continued fertility within itself, and unfruitful in crossing with other species.

The advocates of Darwinism say that, if man can do so much, Nature, having all time at her disposal, can do much more, and M. Quatrefages admits that the argument is plausible, but denies its correctness. He shows that man can do many things which Nature cannot, and that in the natural state of things we do not find such phenomena as occur under the hand of man. In fact, if there is anything which must strike an observer in the organized world it is the order and the constancy which we see reigning for ages. The cause of all this is simple and unique. If the unions between wild species were in all senses and indefinitely fruitful, as they are among our doves and in our stables, what would happen? The barriers between species, between genera, would be taken away. Crossing would take place in all directions; everywhere would appear intermediate types, everywhere the actual distinctions would gradually become effaced and disappear. It is impossible to imagine where the confusion would stay its course. It would become a chaos of misformed creatures, such as the Babylonians dreamt of, and such as Lucretius described.

The same observations apply to past geological ages as well as to the present. All things being alike in other respects, fossil species are as well defined and as distinct as those of the present era.

Everything leads us to the conclusion that the laws of the organic world have not changed since the beginning. To admit the contrary is to oppose to all that we know concerning the present and the past of our globe, the possible, the unknown, or, in other words, hypothesis, having for its foundation our very ignorance.

On this account M. Quatrefages declines to believe in the origin of species by gradual transformation, and, in the name of science, feels compelled to combat Darwinism as much as the hypothesis of Lamarck.

GLYCYRRHIZIN.*

BY JOSEPH M. HIRSH.

The mode of preparing glycyrrhizin, mentioned in the last Dispensatory, of precipitating the same from a cold infusion, I found highly impracticable, on account of the slight solubility of the same in cold water. Berzelius's method of preparing it from sulphate of glycyrrhizin gave but a dark-coloured product, difficult to purify, while Vogel's method of preparing a plumbate of glycyrrhizin, and subsequent decomposition with hydric sulphuret, is rather laborious. The best practical process appeared to be the preparation from an infusion made with *boiling* water of acetate of glycyrrhizin, which upon evaporation to dryness is dissolved in alcohol, when the acetic acid is neutralized with soda, the new salt crystallizing out, while the glycyrrhizin remains in solution. Another method, giving good results, I found to be the preparation of an alcoholic extract by percolation, which I heated to the boiling-point, filtered off from the product produced, when I evaporated nearly to dryness, redissolved in alcohol, from which solution it remained behind almost pure upon evaporation.

Experimenting with this product in regard to its relation to masking bitterness, I found one part to cover up the bitter taste of four parts of Epsom salts, a slight addition of the latter being plainly perceptible, although by no means as disagreeable as when tasted alone. Of an alcoholic extract of coffee, an amount representing twenty parts of coffee, lost its bitter taste upon the addition of the glycyrrhizin. A number of other experiments of similar kind were made, but your reporter respectfully expresses his doubts about the *mathematical* reliability of results, arrived at by taste alone, and confines, therefore, his remarks to the *modus operandi* of the glycyrrhizin.

Taste being an effect upon the nerves of sensation (of taste), the change of taste can be produced either by a chemical change of a substance, or by a peculiar local affection of the nerves of taste. The first case, as might have been anticipated, with Epsom salts, does not occur, the glycyrrhizin not affecting the sulphate of magnesia in any way.

The second supposition then lay near, namely, that the nerves were rendered insensible to the bitter taste. This might be done by an organic change of nerve matter, or by the interposition of a foreign body between the nerves and the bitter substance. To ascertain the former lay beyond the facility of your reporter, and I made, therefore, the best of the last supposition, which seems to give a true solution of the problem. When glycyrrhizin or liquorice dissolves upon the tongue, the latter soon becomes furred, coated, this coat being a coagulum of the albumen of the saliva with the glycyrrhizin. A few tests convinced me that even a weak solution of albumen coagulates readily with glycyrrhizin, and I took the artificial coating of the nerves produced by the albuminous coagulum of glycyrrhizin to be the true cause of its masking bitterness. If this was true, other substances, which readily coagulate albumen, should produce the same result.

With this idea I tried a solution of carbolic acid with various bitter substances, and in each case the bitterness was annihilated if the quantity of carbolic solution was sufficient. But while glycyrrhizin and its compounds are sweet, this is not the case with carbolic acid, the taste of which replaced that of the bitter substance with which it was mixed, this taste being in itself not agreeable. To remedy this evil, carbolate of glycerin was tried with marked success. Epsom salts, coffee, absinthe, etc., lost their bitter taste when mixed with a sufficiency of carbolic glycerin.—*Proc. Amer. Pharm. Assoc.*, 1870.

* Paper read at the Meeting of the American Pharmaceutical Association in answer to the query, "What is the easiest and most practicable method of isolating glycyrrhizin; to what extent does it possess the power of masking bitterness; and what is its mode of action?"

NEW METHOD OF DISTINGUISHING VEGETABLE FIBRES.

Dr. Isidor Walz gives, in the *Manufacturer's Review*, a summary of M. Vetillard's method of distinguishing the fibres of linen, hemp, cotton, jute, China grass, New Zealand flax, which is of such easy execution that we print the whole of it.

If a woven or spun fibre is to be examined, it must first be disintegrated into the single fibres, and any colour or finish must be removed as completely as possible. Vertical and longitudinal microscopic sections are next made. These are rendered transparent by glycerine or chloride of calcium, and treated with tincture of iodine, made by simply dissolving iodine in a solution of iodide of potassium. The excess of this tincture is removed, a drop of dilute sulphuric acid added, and the sections examined by the aid of the microscope.

Linen Fibre.—Bundles of smaller fibres, with a fine canal in the centre, long, uniformly thick, and pointed at the ends. Longitudinal section: the fibres are coloured blue, the canal yellow. Cross section: regular polygons, loosely connected, coloured blue; centres yellow.

Hemp.—Fibres aggravated; each fibre covered with a thin skin, coloured yellow. They are thick and less uniform than the linen fibres. The ends are thick, and of the shape of spatulas, and become blue or greenish-blue with iodine. Cross section: irregular polygons, firmly connected; rim yellow, the mass blue, the centre colourless.

Cotton.—Longitudinal section: single fibres, spirally wound on their own axis, with a central canal and broad ends; coloured blue by iodine. The cross sections are rounded in the shape of kidneys and coloured blue, with yellow spots interspersed.

China Grass.—Longitudinal section: fibres separated lengthwise, of varying thickness. The interior canal is often filled with a yellow granular substance, which is coloured brown by iodine. The fibre is turned blue by iodine. Cross section: irregular, with re-entrant angles, and little cohesion. The fibres are stouter than all other fibres, and are turned blue by iodine.

Jute.—Fibres strongly coherent, the ends undulating, and difficult to separate. Central canal wide, empty, and gently rounded at the ends; coloured yellow. Cross section: polygons strongly coherent and regular, much like those of hemp, but the central opening is larger; coloured yellow, darker at the rim.

New Zealand Flax.—Bundles of cells of the leaves, easily separated with a needle into stiff little fibres, provided with a canal of uniform width. The sides are rolled inwards; coloured yellow. The cross section resembles that of jute, but the corners of the polygons are rounded off. They are coloured yellow by iodine tincture.—*Journal of Applied Chemistry.*

MEETING IN NEWCASTLE-ON-TYNE.

A Meeting of chemists and druggists was held in the lecture-room of the College of Medicine, Newcastle, on March 13th, to consider the poison regulations as proposed by the Council of the Pharmaceutical Society, and other business. Mr. J. W. Swan, having been called to the chair, opened the proceedings by saying it would be desirable to discuss, in a conversational manner, the merits of the proposed regulations before passing any formal resolution upon the subject. He remarked that if the regulations were adopted, and we were to practise a minimum of what would then be required, the requirement would be that all vessels containing poison should be distinguished in some exceedingly slight manner from those which contained non-poisonous substances. One great objection to a compulsory measure was, that the enforced precaution to be general must of necessity be slight, probably much less stringent than the precautionary measures which would otherwise have been voluntarily adopted. As to special forms of poison bottles, as a particular pattern was not, and cannot be, universally adopted, the connection between a particular form of bottle and its contents, being invariably of a poisonous nature, could not by any possibility take hold of the public mind. Such bottles would, by the public, be put to all the natural uses of bottles in general, and at last be used quite indiscriminately. It appeared to him they had two or three courses to pursue in the matter. One was not to do anything at all; another was to support the Council in carrying out these compulsory regulations. Another course was to recommend some modification of the regulations; but if they wished to be left to themselves in the management of poisons, to use their own judgment, then the obvious course for them to pursue was to oppose the new regulations.

Mr. Brady explained the present position of the question as between the Privy Council, the Council of the Society and the members; and reviewed some of the reasons which might be given against the enactment of the regulations brought forward by the Council, condemning any increase to the present compulsory code as probably entirely unnecessary and certainly premature.

Mr. R. H. Brockett supported the remarks of the previous speakers; and after some further observations from the meeting, which expressed itself as being strongly opposed to the regulations, he moved the following resolution, which was seconded by Mr. Glover and carried unanimously:—

"Considering the great diversity of arrangements necessary in different pharmaceutical establishments, this meeting thinks it impracticable to draw up any code of regulations for the keeping of poisons which it would be desirable to enforce alike in all."

The Chairman said he did not see the necessity for compulsory regulations, for practically no serious danger to the public at present existed.

Various gentlemen present having expressed their conviction that the number of cases of poisoning which were sought to be prevented by the proposed regulations was very small, and likely to become gradually less under the operation of the Pharmacy Act, and that any compulsory derangement of existing precautions would result in a present, if not a permanent, increase of danger. Mr. R. Elliott moved—

"That it is not desirable to attempt any additions to the compulsory regulations for the keeping and selling of poisons already contained in the Pharmacy Act, till experience has shown that the latter do not afford all reasonable protection against errors on the part of pharmacists."

The resolution, having been seconded by Mr. Wilkinson, was carried unanimously.

Mr. B. S. Proctor said that remarks having fallen from Mr. Brady and other gentlemen that it might be desirable for the Council to submit a code of regulations which they could recommend for voluntary adoption wherever practicable, he would suggest that the addition of a label stating the dose was the most desirable addition to the name of the article, as a means of promoting an intelligent caution in the handling of dangerous drugs. He said he had taken so prominent a part in the discussion of the question in the Journal, that he would not now move any resolution upon the subject; his desire being rather to elicit the expression of opinion from others than to advocate his own. He had already advocated this proposition, and now would only add that he considered it eminently useful, practical and simple, and calculated to encourage a thoughtful attention to the labels; in this respect contrasting with many distinctive marks or stoppers which had been proposed, which he thought likely to encourage the habit of knowing the bottle by its stopper or its general appearance, thus withdrawing part of the attention which should be concentrated upon the label. If the meeting agreed with him in this respect, he would be glad to see a resolution proposed embodying the suggestion.

A general conversation ensued, after which it was moved by Mr. T. E. Watson, seconded by Mr. J. C. Ritson, and carried unanimously,—

"That the following be suggested to the Council of the Pharmaceutical Society as a suitable basis for regulations to be recommended for voluntary adoption:—

"*In the keeping of Poisons.*

"1. That all poisons should be labelled with their name.

"2. That poisons which are used internally should also bear a label stating their usual adult dose.

"3. That poisons which are not used internally should bear a label with the words 'not for internal use.'

"*In the sale of Poisons.*

"4. That the above regulations should be observed in cases of ordinary sale, though not necessarily in dispensing."

Mr. Greenwell, M.P.S., moved and Mr. Alfred Brady, M.P.S., seconded the following resolution—

"That in the opinion of this meeting reporters should be admitted to the meetings of the Council of the Pharmaceutical Society, with the view of affording to the members of the Society fuller information respecting the management of its affairs."

The Chairman remarked that though the whole body of chemists and druggists, now being in some measure under the control of the Pharmaceutical Society, had a right to criticize its management, he was glad to see that this resolution was moved and seconded by members of the Society.

The Chairman said a meeting which had been so unanimous in its resolutions could not close more appropriately than by all the gentlemen present contributing to defray the expenses incurred by those who had taken the trouble of drawing attention to the important question they had just been discussing.

In response to this invitation fourteen gentlemen subscribed to the defence fund and towards the expenses of the meeting.

On the motion of Mr. Glover, a vote of thanks to the Chairman was carried by acclamation.

The Pharmaceutical Journal.

SATURDAY, MARCH 18, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

BUSINESS.

BUSINESS has been defined as "the art of transferring money from other people's pockets to one's own," and in these days of "free" trade there is much reason for regarding the definition as very generally apt and truthful; but it is at the same time obvious that the principle it involves necessitates some limitation in the exercise of the art. Without attempting to define precisely the limits of legitimacy, it is easy to perceive in certain forms of business various degrees of shadiness that show they are very near those limits, if they are not outside them.

We have been led to these remarks by two circumstances that have quite recently come under our notice. The first is a very singular advertisement appearing in some of the daily papers headed "extraction of silver from sea-water," and announcing that the advertiser requires twenty subscribers of £10 each, to enable him to carry out his invention for that purpose. In return he proposes to give each subscriber "a free licence to use his patent for forty years or life," and for an additional £25 to provide him with an instrument "of limited dimensions," to which silver is to adhere on passing it through the sea-water. It is added that an ordinary seaman can work the apparatus without being able in any way to deceive the proprietor, also that "not more than one subscription will be given to one person, and not more than twenty will be taken."

We are unable to say what has been the result of this remarkable "silver-extracting enterprise," and therefore we can only leave our readers to speculate on this point as they may feel inclined.

The other illustration of modern business to which we have referred, is afforded by our contemporary the *Chemist and Druggist*. It will be remembered that in January last an editorial article appeared in that journal on the vexed subject of poison regulations, which we do not hesitate to say excited considerable astonishment, and in certain quarters the most poignant horror. For our own part we must confess to having been amazed to see our contemporary assuring its esteemed friends that although feeling its position acutely there was no help for it—that although believing from its antecedents that its place is most properly in opposition, and while trying always to be on the right side, it could, in the matter of Poison Regulations, only advocate the same views as those enunciated by the majority of the Council, and denounce the opposition to them as weak, the sentiment on which it was based as an error, the objections as illogical, irrelevant or absurd.

We have never yet been able to decide, in our own mind, how far Christmas festivities were to be held responsible for that article; but in any case the succeeding number bore evidence that he had seen the error of his way—the process of conversion had evidently set in, and awakening penitence was indicated by an article ridiculing the circular issued by the Council of the Pharmaceutical Society. This month, to judge from the symptoms manifested, we may assume that a "state of grace" has been attained, and we cannot illustrate this better than by the following juxtaposition of an extract from the article of January with one from a circular just issued by our contemporary:—

January 14th.	*March.*
"To state the case thus—and we have endeavoured to state it fairly—seems to us sufficient to prove the weakness of the opposition. The sentiment on which the resistance is based, which is a conception that the Council is arrogating to itself tyrannical powers, is simply an error. The Council suggest these regulations, and asks the trade—shall they be enacted or not? Granting that, neither the second, third, nor fourth objection which we have mentioned is logical; that the best druggists already adopt some such plan, surely argues its wisdom; whether the risk of accidental poisoning by the druggists would be diminished *at all* is the point, not whether it would be removed altogether; and the final argument that doctors would not be subject to these regulations, is unanswerable, purely for the reason that it is quite beside the question."	"We say that the Council of the Pharmaceutical Society, by its action in this matter, has shown itself unworthy to occupy the position which has been delegated to it, because unable to appreciate the broad view of the responsibilities and duties which now belong to that position, and which could not be attached to it when the Council was merely the governing body of a private society."

But it will be asked, what has this to do with the subject of this article? To answer this question, we must refer to another document issued by our contemporary, together with the circular above mentioned,—not generally, however, but only to a select portion of the trade,—the non-subscribers to the *Chemist and Druggist*. In this supplementary manifesto the virtues of our contemporary are modestly narrated, and a cordial invitation given to come within the fold.

Light now falls on the affair. Since January, our contemporary had not only been converted, but, looking down from a dangerous eminence,—like that whence Count BISMARCK was lately represented as pointing to kingdoms and principalities,—had perceived that among the thirteen thousand registered Chemists and Druggists of Great Britain, there was outside the circle of its subscribers a margin in which a stroke of business might, perhaps, be done by means of the poison regulations.

The whole transaction may be depicted by a slightly-altered rendering of a verse from a familiar pre-TUPPERIAN source of infantile morals :—

How doth the little *C. and D.*
On poisons seek for voters;
And scatter stamps through all the trade,
In hopes of further orders!

THE ONTARIO PHARMACY BILL.

ON Monday, February 6, the Bill for regulating the practice of Pharmacy in the province of Ontario was read a third time in the Legislative Assembly and passed. According to our latest advices, it was only awaiting the signature of the Lieutenant-Governor to become law.

The Bill met with considerable opposition during its passage through Committee, and clause 4 was struck out; but it was restored in the full house, after the Committee had made their report.

The following is a *résumé* of the Bill :—

Clause 1 declares that after the 1st July, 1871, it shall be unlawful for any person to keep open shop for compounding medicines or retailing poisons, or selling any of the articles named in a schedule attached to the Act; or to assume the title "chemist and druggist," "druggist," "pharmacist," "apothecary," "dispensing chemist or druggist," unless such person be registered under the Act or has taken out a certificate under the 21st section, which provides that parties registered shall receive a certificate stating the time during which they may carry on business. This term extends from year to year, and the certificate must be procured annually from the Registrar.

The second and third clauses have reference to the articles which are to be deemed poisons within the meaning of the Act. We intend to give these particulars next week.

The fourth clause relates to the formation of the Ontario College of Pharmacy. Persons engaged in business, as principals or assistants, at the time of the passing of the Act, or who have carried on the business for three years, or who have served an apprenticeship of three years and acted as assistants one year, are, upon payment of a fee of four dollars, to be enrolled as members. Clerks, assistants and apprentices lacking the above qualifications, or not wishing to become full members, may upon the payment of a fee of two dollars be enrolled as associates. An associate may subsequently become a member by passing such examination as may be prescribed by the Council.

The sixth clause constitutes the College of Pharmacy a body politic and corporate. A provisional Council and Registrar are appointed to hold office until the first election in October, who have the power to grant certificates of competency to conduct the business of a chemist and druggist, and to be registered under the Act. The election of the first Council is to take place in October next, and the persons qualified to vote at that election are those who at the time of the passing of the Act were actually engaged in business. Subsequent elections are to take place in July of each year, and the persons qualified to vote at such elections are to be the members of the College.

The Council are to hold two sittings every year for the purpose of granting certificates of competency. Persons desirous of being examined have to give notice to the Registrar, and pay a fee of four dollars. Persons passing the examination satisfactorily to the majority of the examiners are to be entered upon the roll of Registered Chemists and Druggists, and become members of the College. The examination may be conducted by the Council or by examiners appointed by them. The Council have the power to prescribe the subjects upon which candidates are to be examined.

The fifteenth clause directs that the Registrar is to keep a correct list of persons registered under the Act, and publish annually a list of persons qualified to keep open shop as pharmaceutical chemists.

The seventeenth defines the qualifications which are to entitle a person to be registered as a pharmaceutical chemist. These are identical with those necessary for membership, and an annual subscription of four dollars. Non-payment of the subscription is followed by the withdrawal of all privileges.

According to clause 20, the title of "Pharmaceutical Chemist" may not be assumed by any other than those registered under the Act, and none but such persons or their servants are authorized to dispense the prescriptions of medical practitioners. The certificates of qualification are to be displayed conspicuously in the places of business.

The rights and privileges at present enjoyed by physicians and surgeons are reserved by the Act, and it provides that any physician or surgeon may be registered as a Pharmaceutical Chemist without undergoing any examination.

ACCORDING to the financial statement made to the Indian Legislative Council at Calcutta last week by Sir RICHARD TEMPLE, the revenue to be derived from opium in the ensuing year is estimated at £8,000,000.

THE Medical Act (1858) Amendment Bill, No. 1, brought in by Dr. LUSH, and No. 2, brought in by Dr. BRADY, have been read a first time in the House of Commons. Their second reading is set down for June 14.

Transactions of the Pharmaceutical Society.

BOTANICAL PRIZE FOR 1872.

A Silver Council Medal is offered for the best Herbarium, collected in any part of the United Kingdom between the first day of May, 1871, and the first day of June, 1872; and should there be more than one collection possessing such an amount of merit as to entitle the collector to reward, a second prize, consisting of a Bronze Medal, and also Certificates of Honour and Merit, will be given at the discretion of the Council. In the event of none of the collections possessing such an amount of merit as to warrant the Council in awarding Medals or Certificates, none will be given.

The collections to consist of Flowering plants and Ferns, arranged according to the Natural System of De Candolle, or any other natural method in common use, and to be accompanied by lists, arranged according to the same method, with the species numbered.

The collector to follow some work on British Botany (such as that of Babington, Hooker, or Bentham), and to state the work which he adopts. The name of each plant, its habitat, and the date of collection, to be stated on the paper on which it is preserved.

Each collection to be accompanied by a note, containing a declaration, signed by the collector, and certified by his employer, or a Pharmaceutical Chemist to whom the collector is known, to the following effect:—The plants which accompany this note were collected by myself, between the first day of May, 1871, and the first day of June, 1872, and were named and arranged without any assistance but that derived from books.

In estimating the merits of the collections, not only will the number of species be taken into account, but also their rarity or otherwise, and the manner in which they are preserved; and should a specimen be wrongly named, it will be erased from the list.

The collections to be forwarded to the Secretary of the Society, 17, Bloomsbury Square, on or before the first day of July, 1872, indorsed "Herbarium for Competition for the Botanical Prizes." After the announcement of the award, they will be retained one month, under the care of the Curator of the Museum, for the inspection of persons connected with the Society, and then returned to the collectors, if required.

No candidate will be allowed to compete, unless he be an Associate, Registered Apprentice, or a Student of the Society, or if his age exceed twenty-one years.

FREE ADMISSIONS TO THE ROYAL BOTANIC SOCIETY'S GARDENS, REGENT'S PARK.

The following pupils of the class of Botany and Materia Medica, in the Pharmaceutical Society, after examination by Professor Bentley, have had free admission given to them, at his request, by the Secretary of the Royal Botanic Society:—

Mr. Chas. Alexander Blake.	Mr. F. W. Kendle.
,, Wm. Milner Burgess.	,, W. T. Maddock.
,, Henry Churchill.	,, Charles A. Overton.
,, Walter Cole.	,, Charles Pretty.
,, Herbert E. Constance.	,, Harry Savory.
,, Horace Davenport.	,, Charles T. Ward.
,, Chas. Joseph Holmes.	,, Herbert Charles Webb.
,, N. W. Holmes.	,, Wm. Henry White.
,, G. B. Howarth	,, Alexander Wood.
,, Thomas Iredale.	,, Harold Woolley.

The above names are arranged in alphabetical order.

These orders will admit to the Gardens upon ordinary days in the months of March, April, August and September, from 9 A.M. till 1 P.M.; and in May, June and July, from 7 A.M. till 1 P.M. Such admissions, therefore, give every facility to those who possess them of making themselves practically acquainted with plants.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The Fifth General Meeting of the Society was held at Britannia Chambers, on Friday evening, 24th ult.; the President, Mr. ATHERTON, in the chair.

The meeting was well attended by the members and Associates.

The minutes of the previous meeting were read and confirmed.

The SECRETARY announced that the PHARMACEUTICAL JOURNAL had been received regularly during the month, as also a number of old works on pharmacy and allied subjects, from Dr. Wright, and, through the kindness of T. Hydo Hills, Esq., portraits respectively of the late Dr. Pereira, Mr. Jacob Bell and Mr. W. Allen. A cordial vote of thanks was accorded to the several donors. A variety of interesting objects were exhibited and explained; conspicuous amongst which was Siebold's collection of dried plants.

The PRESIDENT then called upon Mr. Elder, M.B., for his promised paper on "Our Foods."

Mr. ELDER responded, and explained in a very lucid manner the physiological action of our foods, commencing with the action of the salivary glands and the nature of the changes which take place in the mouth with the consequent production of ptialine; he next proceeded to divide the foods into four classes,—albuminous, oleaginous, saccharine and mineral,—following with the composition of each class, their respective utility and the amount of carbon and nitrogen by which their value as heat or flesh-producers is estimated; the importance of the mineral constituents for the proper formation of blood, and the effect produced upon the blood when not taken in proper quantities.

A vote of thanks to Mr. Elder for his interesting paper was unanimously carried.

Mr. W. H. PARKER brought forward the objects of the Defence Association just established in Manchester, and expressed his approval of their proceedings.

Mr. ATHERTON also was in favour of the defence, considering as he did that the regulations about to be brought forward in May are objectionable; that pharmacists already do their best for the public safety, and, therefore, he thought compulsory measures quite unnecessary, as by that means the liberty of the subject would be interfered with, and the status of the chemist detracted from or lowered thereby. Admitting that accidents had happened, he was convinced that the frequency had been much diminished since the improvement in the education of the chemist. He also mentioned the fact that in Glasgow and many other Scotch towns, the number of open surgeries and chemists' establishments was about equal; the former would be exempt from the regulations, and he wished to know if the proprietors of these surgeries were better acquainted with the art of pharmacy than ourselves, and, if not, why the exemption? He considered this fact a weak point in the regulations, but a strong one for the defence.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Eighth General Meeting was held at the Royal Institution, on Thursday evening, the 2nd instant; EDWARD DAVIES, Esq., F.C.S. (Vice-President), in the chair.

Mr. Alfred Coughtrey was elected a member.

A short discussion took place upon the "Proposed Poison Regulations," and it was moved by Mr. REDFORD, and seconded by Mr. SHAW, "That the Secretary be instructed to call a meeting of the chemists and druggists of Liverpool, to consider the proposed compulsory regulations for the keeping, storing and dispensing of poisons."

The paper for the evening was read by Mr. W. Keith, upon "Permanent Photographic Printing."

After describing the autotype, Woodbury-type and heliotype processes, Mr. Keith showed practically the development of the picture in the carbon process by the use of hot water only. The paper was illustrated by specimens of various processes, as well as the instruments used. He drew particular attention to the heliotype process of Messrs. Edwards and Kidd as being the latest, and supplying a want long felt of a means of applying photography to book illustration, the pictures which he exhibited having been printed in printing-ink at an ordinary press, with a margin so as to obviate the necessity of mounting, and ready to bind up with printed matter.

A discussion followed, in which the Chairman, Messrs. Hallawell, Houghton and Bird took part; and, upon the motion of the Chairman, seconded by Mr. Redford, an unanimous vote of thanks was passed to Mr. Keith for his very interesting and instructive paper.

SUNDERLAND CHEMISTS' ASSOCIATION.

The Monthly Meeting was held on Tuesday, March 7th; Mr. H. Thompson in the chair.

Mr. Sharpe introduced a motion on prices. He compared the chemists of the present day unfavourably with those of older times in the profits they obtained on their articles, and moved that a committee be formed to draw out a list of prices on the basis of that so successfully carried out in Edinburgh and other places.

Mr. Sidgwick referred to the cost of education and apprenticeship, and drew attention to the manner in which dispensary prescriptions were carried about the town until some chemist was found who would dispense them for less money than the others.

Mr. J. Harrison admitted that Mr. Sharpe had shown that an evil does exist, but contended that he had not suggested an effectual remedy; that the Society had neither the right nor the power to impose conditions on those who were outside its pale, and that it was useless attempting to enforce uniformity in practice until there was unity in principle.

Mr. Robinson thought Mr. Sharpe's plan quite practicable, if there were as much good feeling among the chemists and druggists as among the solicitors, who, by the moral power of their Law Society, were able to prevent any individual member from injuring the others by undercharging.

Mr. Nicholson agreed with Mr. Sharp's proposal in principle, but was doubtful as to their power to carry it out in a town like Sunderland, where the dispensing and higher branches of a chemist's business formed so small, and the mixed retail so large a proportion of their returns. The success of a plan in Edinburgh was no evidence that it was adapted to Sunderland, where the conditions were so essentially different.

Mr. Sharp replied, and proposed that a Committee be appointed to adopt some feasible arrangement on the subject, which proposition was carried by a large majority.

Mr. Harrison gave notice that, at the Annual Meeting, in April, he would propose:—(1.) That the ordinary meetings of this Society be held on Tuesday evenings instead of Mondays. (2.) That a petition be forwarded to the Annual Meeting of the Pharmaceutical Society on the subject of the Juries Act. (3.) That a petition be also forwarded against the poisons regulations.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The usual Monthly Lecture in connection with this Association was delivered at the Music Hall, on Wednesday evening last, by H. C. Sorby, Esq., F.R.S.—subject, "Blow-pipe Chemistry." Mr. G. B. Cocking, Vice-President, occupied the chair. Mr. Sowerby commenced his lecture by explaining the methods adopted to obtain blow-pipe beads enclosing various crystals, which, independent of their connection with chemistry and mineralogy, were of extreme beauty merely as microscopical objects. His own method differed materially from those described by Emerson, Rose, Ross, and other authors, he using borax as the solvent, and, if requisite, adding various reagents, so as to produce, as it were, precipitates of characteristic crystalline form. By this means transparent, glass-like beads were obtained, containing perfect crystals of the substances added. The beautiful forms in which the following and other chemical substances crystallized were described, viz. borate of magnesia, first as thin prisms, then, by the deposit of smaller crystals, giving rise to objects very much like a handle with a brush at each end; borate of zirconia, as small prisms with a simple cross at each end afterwards becoming more complicated; molybdate of zirconia, which are so delicate that their own weight would probably break them, if in an aqueous solution, but being supported in solid borax, like insects enclosed in amber, they are secure from all injury, and become extremely elegant and beautiful objects; tungstate of lime, molybdate of strontia, phosphate of lime or soda, titanic, columbic, and molybdic acids, etc. The method of preparing and mounting these objects for permanent use was explained; this being to enclose them in a cell with Canada balsam, by which means the moisture of the atmosphere which causes the borax to become hydrated and opaque was excluded, the alteration then taking place so slowly that the lecturer had not remarked any change after a period of six months. The full beauty of these specimens can only be seen with a binocular microscope; and few objects are better fitted to show the advantage of that kind of instrument, for the crystals then stand out in perfect relief, and are seen to be equally complicated in all directions, though not in each case alike, as those formed on the surface of the bead differ very materially from those in the interior, and in both positions, though the type is constant, the forms vary very considerably. As illustrating the scientific value of microscopic blow-pipe chemistry, Mr. Sorby related the following fact:—Mr. Maskelyne, of the British Museum, had obtained from a new rare mineral in a meteorite a very small quantity of a substance which much resembled the earth zirconia. If it had been so, the fact would have been very interesting, since hitherto there has been no evidence of the occurrence of that substance beyond our own globe. The amount of material was, however, too small to enable Mr. Maskelyne to decide the question by the usual methods of chemistry; he therefore placed about one-half of the entire quantity in the hands of Mr. Sorby, and, though this was no more than 1-100th of a grain, he succeeded in proving that it was titanic acid, a substance which had previously been detected in meteorites and not zirconia.

GLASGOW CHEMISTS' AND DRUGGISTS' ASSOCIATION.

The Eleventh Meeting of the Session was held in Anderson's University, 204, George Street, on the 8th instant; Mr. T. Davison, President, presiding.

Messrs. A. Jamieson and Robert Walker were elected members.

After the regular preliminary business, Mr. Clark, who was introduced by the Chairman, delivered a paper on "Botanizing, or some hints in the Collecting of Botanical Specimens."

Mr. Clark said he found his subject was naturally divided into two parts, namely, "Collecting" and "Drying," and as his remarks on the former required the full time allowed for the reading of his paper, he would reserve the latter part till some future night. He then described the first steps the botanist required to take in beginning the collection of plants, and explained the use of the necessary apparatus, viz. the digger, vasculum, and pocket-glass, and after mentioning the proper time for collecting plants in fit condition for the botanist's purpose, and giving some hints on the selection of plants for beginners, he described the different parts of a flower as calyx, corolla, stamens, and pistil; and in referring to the fruit, begged to explain what was a popular error, viz., that the soft part of such fruits as the strawberry, apple, orange, etc., was not in reality fruit, but merely a soft covering or protector of the fruit proper. He then referred to the uses of botany in the arts and medicine, and made particular reference to the value of a thorough understanding of its principles to the chemist, and that these principles could only be well grounded in the earlier years of one's apprenticeship; he also referred to the selecting of poisonous from non-poisonous plants, showing how a traveller who had a knowledge of botany could not be at a loss for food, in an emergency. He then drew attention to the specific and generic names of plants, recommending the 'Clydesdale Flora,' by Professor Hennedy, as the best text-book for this district, and mentioning some spots in the neighbourhood well adapted for the study of the science. Mr. Clark's paper was listened to with marked attention, and was rendered all the more interesting by being illustrated with diagrams and natural flowers.

The Report of the Soirée Committee was then brought forward by the Secretary, showing a balance of cash of £1. 6*s*. 6*d*., and, on the motion of the President, this sum was ordered to be added to the funds of the Association.

Mr. Paterson, in proposing a vote of thanks to the Committee, referred to the promise made by Mr. Macdonald to give a donation of other £5 to the Society, and also read a communication he had had from Messrs. Evans, Sons, and Co., Liverpool, authorizing him to present to the Association one of their five guinea cabinets of Materia Medica.

On the motion of the President, seconded by Mr. Paterson, the Secretary was instructed to convey to these gentlemen the best thanks of the Association for their handsome donations, which was agreed to by acclamation.

An address by Dr. Black was announced for next meeting.

HALIFAX CHEMISTS AND DRUGGISTS' ASSOCIATION.

Mr. Stott, President, in the chair.

The business of the meeting commenced with the presentation of prizes to the successful students in the botany class. All the pupils being present, Mr. Stott addressed them, saying it had fallen to his lot to present these first prizes of the Association, and the pleasure he had in doing so, though great, would have been far greater if he could have congratulated them on the result of the examination. He found, however, that the most successful had reached little more than half the number of marks attainable. He pointed out the importance of these local classes, and thought they would become more numerous, as the number of young men who presented themselves at Bloomsbury Square for the purpose of study kept steadily increasing. He bade the students go on in their career, and take advantage of every opportunity to increase their store of knowledge, till they were able and competent to fulfil the duties of their future calling.

Mr. Shaw thought the President had been rather too hard upon the class. Having gone over the same ground as the students, he could make great allowance for their comparatively slight success. Botany was not such an interesting science as some others, and, unless there was a special liking, and an intuitive reception of its laws and principles, he could quite understand it might prove a little dry and tedious at the commencement. The neighbourhood, too, was not the best for botanizing. Some twenty miles off was a better ground, where they might collect many specimens, and, with Bentham for reference, would find employment for many evenings of study. He pointed out to them the scholarships in connection with Bloomsbury Square, and hoped the seeds now being sown would in time bear fruit.

After a few words from Mr. Farr,

Mr. Hebden stated that it was the intention of the Association to commence a class for materia medica, and that an examination would be held, and prizes offered, as well as in Latin and chemistry.

The President then drew the attention of the meeting to the proposed regulations of the Council with respect to poisons, and whilst for his own part he could not support them, he should be glad to hear the views of the members generally.

Mr. Dyer, believing there was no halfway of meeting the Council on this question, had come to the conclusion that they should be opposed, and was glad that Manchester had moved in the matter, and the Defence Committee, he thought, should be supported. He could not but feel it to be an insult, and degrading to a chemist, to have these regulations forced upon him, and his shop to be inspected by a surgeon.

Mr. Shaw could not support them. From the tone of the medical journals, he thought he could perceive a strong *animus* against our body at large, and an evident desire to fetter us with restrictions, whilst their own surgeries should be exempt. The Privy Council, in conjunction with the Pharmaceutical Council, having the power of increasing the schedule of poisons, might prove a serious source of annoyance under the proposed regulations. From the ignorance displayed by those in authority with respect to the poison schedules in the Act of 1868, he dreaded being placed any further under their jurisdiction.

Mr. Hebden would have been glad if the members would have approached this question with an earnest desire to improve the regulations, rather than throwing them overboard altogether. A mild inspection, in his idea, was not so frightful as had been stated. He thought, in the long-run, it would even prove beneficial in many respects. He felt sure, if rejected, stronger and firmer ones would be brought forward, perhaps in the midst of a panic on the part of the public, when reason would be lost sight of, and we should be compelled to accept such as the Privy Council demanded.

After a few words from Mr. Farr against the proposition, and Mr. Wood supporting the views of Mr. Hebden,

Mr. Brook agreed with Mr. Shaw, that the Medical Council had a great deal to do with it; in fact, he looked upon it as an attempt on the part of that body to create a vast monopoly of their interests. Inspection by surgeons first, then they would try to put down counter-prescribing. See what a power for annoyance would be created and placed in their hands by inspection, and couple that with the 26th clause of the Act of 1868. He advocated a strenuous opposition to the regulations.

Mr. J. B. Brierly and Mr. Jessop strongly condemned them as insulting and degrading.

The following resolution was carried unanimously:—

"That, in the opinion of this meeting, the proposition of the Council for compulsory regulations in the dispensing and storage of poisons is uncalled for by the public, inimical to the true interests of the trade, and ought to be most strenuously opposed and resisted."

Proceedings of Scientific Societies.

LONDON CHEMISTS' ASSOCIATION.

At the Meeting on Thursday, February 23rd, 1871; Mr. Peal in the chair,

Mr. De Putron read a paper on "Filtration." Commencing with the important filtration of water, he described several modes and mediums. He considered animal charcoal to be the best and cheapest of all for household purposes, but it was not a sufficient purifier for medical or chemical use, as it did not entirely remove lead and lime. Silicated carbon was a valuable improvement. Speaking of the indispensable paper filter, he said care should be taken to fold it with a sharp end, as the flow of liquid from an acute point was much more rapid than from an obtuse angle. Bibulous paper first became charged with the fluid, it was then forced through by the pressure of the remainder, therefore as the capillary passages are more open when the paper is dry, the first of the liquid passes through quickly, but was not so bright as when the pores of the paper had closed, so it should be refiltered. To keep a continual flow, and to prevent the paper giving way, a good plan was to throw in some small pieces of blotting-paper, tow, or any similar light substance, so as to separate the viscid sediment; the funnel should be kept quite full. If percolators were properly packed, it was not necessary to filter the tinctures.

He noticed an excellent filter funnel made by Messrs. Bailey, of Salford, which was so constructed that the liquid passed through a layer of sand at the top of the neck; also one invented by Mr. Schacht, upon the principle of causing a vacuum, and employing the consequent pressure of atmosphere for forcing the liquid through the filtering medium. After describing the best methods of filtering and clarifying several pharmaceutical preparations, he concluded with that of oils.

MEETINGS FOR THE ENSUING WEEK.

Monday ......*Medical Society*, at 8 p.m.
London Institution, at 4 p.m.—"On Astronomy." By Mr. R. Proctor.

Tuesday ......*Royal Institution*, at 3 p.m.—"The Nutrition of Animals." By Professor Foster.

Wednesday... *Society of Arts*, at 8 p.m.—"Drill, the Complement of the present School Teaching." By Major-General Eardley Wilmot.

Thursday ......*Royal Society*, at 8.30 p.m.
Royal Institution, at 3 p.m.—"Davy's Discoveries in Chemistry." By Prof. Odling.
London Chemists' Association, at 9.30.—"Phosphoric Acid." By Mr. G. Brownen.

Friday ....*Royal Institution*, at 9 p.m.—"The Eclipse." By Mr. Lockyer.
Quekett Club, at 8 p.m.

Saturday ...*Royal Botanic Society*, at 3.45 p.m.

Parliamentary and Law Proceedings.

Charge of Poisoning.

At the Leicester Police Court, on Thursday, March 9, a case of poisoning of a very unusual character was investigated. Two young Jews, named Heyman Balsam and Simon Ettel, were charged with having, on the 18th of February, administered poison to three young girls, named Amelia Westbury, Mary Jane Faulkes and Sarah Bale. According to the evidence it appeared that the prisoners and the girls worked together for a tailor. On the 18th of February the prisoners, who were about to leave their employer, asked all the girls working in the room to go to a public-house and have some ale at their expense. The girls, to the number of fourteen, went with the prisoners. They had one gallon of ale, and when that was drunk Balsam called for another half gallon and a clean glass. These having been brought, the prisoners turned their backs to the girls for a short time, Ettel holding the glass. When they turned round again, Balsam filled the glass with ale, and handed it to the girl Westbury, saying, "Drink our healths, and you'll remember us leaving you as long as you live." She drank, and was setting the glass down when Balsam told her to pass it on. Both the other girls then drank, and they all three immediately became very ill. Medical assistance was obtained and an emetic given, and they were afterwards conveyed to the infirmary. A portion of the vomit was sent to Professor Attfield for analysis.

Professor Attfield said that he had received a six-ounce bottle, sealed and tied down. He examined the contents of the bottle, according to his instructions, for opium and nux vomica. He found no opium, and but a slight trace of strychnine. He examined the remainder for cantharides, but found none. He afterwards received another bottle, with instructions to search for aconite, which he did, and found distinct evidence of its presence. The prisoners were committed for trial at the assizes.—*Leicester Advertiser.*

Poisoning by Laudanum.

An inquest was held recently at Leicester upon the body of a young woman named Wykes. It appeared that as the deceased, who was a servant, did not come down at her usual time in the morning, the door of her room was forced open, when she was found lying dead on the floor. A small empty bottle was on the window sill, which was labelled "Laudanum, Poison." Deceased had been in the habit of using laudanum for the toothache. There had been some little unpleasantness between deceased and her employers, and it is probable that she expected to lose her situation.

Mr. Bowman, surgeon, who had been called in, said he had no doubt that the death was caused by an overdose of laudanum. The bottle was a half-ounce one, and if half full and the laudanum good, it would be sufficient to destroy life in a person unused to taking it.

Mr. Berridge, druggist, said he knew deceased by her coming to his shop. She had been in the habit of coming there occasionally to obtain a pennyworth of laudanum for the toothache and neuralgia. The last time was about three weeks previously, when she had a pennyworth of laudanum. The bottle produced had his label on it, and was the one she was in the habit of bringing. A pennyworth of laudanum would about half fill the bottle.

The jury returned a verdict "That deceased died from taking laudanum, but that there is not sufficient evidence to show what her state of mind was at the time."—*Leicester Advertiser.*

Obituary.

Died, on the 2nd of March, in his forty-sixth year, after a short illness, Dr. J. B. Henkel, Professor of Pharmacy in the University of Tübingen. Dr. Henkel was author of *Handbuch der Pharmacognosie*, Tübingen, 1867, and of an illustrated work on Pharmaceutical Botany (Tübingen, 1862), as well as of many separate papers on pharmacological subjects.

On the 10th March, at Hull, after a long and painful illness, Mr. Thomas Toogood, Chemist and Druggist, aged 65 years. Mr. Toogood held the office of alderman until a few weeks since, and was for many years a member of the Hull corporation.

On March 12th, 1871, after a few days' illness, Mr. John Tuck, 114, St. Aldate's, Oxford. The deceased gentleman was a zealous worker in the cause of pharmacy, and did everything in his power to forward the interest of the Society. He became a life member in 1863, and was but recently appointed Local Secretary for Oxford. Mr. Tuck was also Local Secretary for the British Pharmaceutical Conference.

[82.]—COLOURS FOR CARBOYS.—May I be permitted to place on record my experience in the use of the formula given for the above in the Number for Dec. 24th, in the hope that it may be useful to others?

The red, made strictly as directed by Mr. Hearder, gave a very satisfactory result (at the time), but a month's exposure in the window brought about rapid fading, and rendered necessary the substitution of another colour.

The blue, made also according to Mr. Hearder's formula, was very intense, so much so that about half the contents of the carboy had to be replaced by distilled water.

It proved, however, even more evanescent than the red; numerous flocks being soon deposited at the bottom, leaving the upper part of the liquid almost colourless.

I have substituted a formula from Beasley, and would only note that the quantity of nitrate of copper there ordered is largely in excess of that actually required. I speak advisedly when I say that one-tenth of the given weight would still err on the side of superfluity.

Without wishing to seem ungracious to the contributors of formulæ, would it not be well that some trial should be made of their working before publication, or that the user should be warned of his entrance upon wholly untrodden fields?

J. F. Brown.

[177.]—SALAD DRESSING.—In reply to "*Medicina*,"

Yolk of Eggs two
Table Salt $\frac{1}{4}$ oz.
Salad Oil 4 oz.
Mustard $\frac{1}{2}$ oz.
Best Vinegar 6 oz.
Isinglass 1 dram
Soluble—Cayenne 10 grains.

The Proposed Poison Regulations.

Sir,—Forty years ago, I have myself sent out pound parcels of arsenic and cream of tartar, of "ox-vomit," white hellebore, linseed meal and rottenstone in the same butter-basket, with frequently no other than a written label, and sometimes, I fear, if in a hurry, not even that. I did it because it was the custom; because I was told to do so; and because I knew no better. It will be supposed, therefore, that I am not individually hostile to poison regulations. But have we made no advance since 1831? One would think, to judge by the stir made about poison legislation, that we had not; that things continued now as they were then.

I think a line between public and private acts may be sufficiently easily drawn. I think the public have no right to interfere with a man who only plays in private with edge tools for his own amusement and at his own risk; but if he throws them about to the manifest danger of others, he should be restrained from doing so; *i.e.* I think the public have no business to determine for me in what manner I shall keep the articles I deal in, while I acknowledge that it has every right to prevent my scattering them abroad to its own great danger and probable detriment. I object on principle to all excise or police interference whatever with me in the management of my private affairs. I consider a line of argument, based upon hopes or promises of leniency in carrying out a law, a line to be ashamed of taking one's stand upon. And I claim that my house, and shop too, be what unhappily an Englishman's house too often is *not*, my "castle." If a cry of murder alarms, a charge of cruelty be made, or reasonable suspicion of gross immorality, of knowingly secreting from justice vicious characters, stolen goods, or highly explosive compounds exist, storm it, and, if proved, sack it, if you will; but otherwise I hold that the said public, and its myrmidons of the law, have no right to enter but by my permission. And I hold, also, that laws should be impartial, and aim at the public good solely and exclusively. Therefore, if you exempt one man from all control over his mode of conducting a confessedly dangerous trade, solely because he is enabled—cheaply enough perhaps—to add surgeon or physician to his name, and fine another for the very same act, you are not impartial, you do not legislate for the public benefit solely, nor even chiefly,—for you make the knowing better than others the excuse for recklessness, whilst supposed ignorance aggravates the offence,—but for that of certain individuals, or to gratify the *animus* of a certain class. It is palpably most unjust that A. B. and C. D., both in the same street, both dealing openly in hair-oil, red precipitate, laudanum, quack medicines and vermin-killers should have a difference made between them, the one having his trade hampered with restrictions which are acknowledged to be unnecessary, by the very fact that it is not sought to apply them to the other. I say, too, that both public dispensaries of every kind, and those of private surgeons, should alike come under the same surveillance. And if the medical profession deny this, they transparently betray that they seek not legislation solely for the public good, but for the sake either of some special benefit to themselves or the gratification of some party spleen, though I by no means assert that, as a body, they do either. Still, this is a crucial test.

Having said thus much in opposition to the principle of such legislation, I will now add that I most cordially approve of the terms of all the proposed regulations, provided they come forth with no stronger enforcement than the recommendation of the Council of our Society. This ought to be enough, and it would be enough with all the well-disposed among its members, who most likely—indeed, it seems to be admitted on all hands that they do so—adopt them already. To the evil-disposed, such legislation is rather a gain than otherwise in the long-run. By the exercise of his wits he soon learns to evade the penalties of a new Act, and the honourably-minded man neither will nor can compete with him in doing so. It should be borne in mind that legislation for repression is not legislation for elevation. No one pretends that the pharmaceutical body will be cleansed, raised or "educated" by such proposed enactments; and it seems to me that the Council propose to cast a stigma upon themselves and upon those whom they represent, which at present only here and there an isolated individual besides is found rabid enough to do.

THOMAS LOWE.

Breckfield Road North, Liverpool,
March 11th, 1871.

Sir,—As a member and well-wisher of the Pharmaceutical Society, I cannot help sympathizing with, and feeling every confidence in, the Council in their desire to bring in the proposed Bill; but at the same time it appears to me, since examinations are compulsory, and education has ever been recognized as a public safeguard against cases of poisoning, the proposed compulsory regulations are quite unnecessary, and would rather impress the public mind with doubt as to our capability of managing our businesses, and lead them to ignore the fact of educational status, instead of increasing their confidence that every member of the trade would make such precautionary arrangements as his class of business, shop and warehouse accommodation and staff would suggest. It is not so much to the "regulations" themselves that I object, as to the fact of making them compulsory,—from what I can learn, those or similar arrangements being at present adopted in almost every dispensing establishment.

Further, these "regulations" would be incomplete unless, they applied to all other dispensaries besides those of chemists, such as surgeons', apothecaries', hospitals', and infirmaries', which need reform much more than our own.

With regard to the regulations themselves. To the first clause I cannot raise the slightest objection, as it is just what is at present almost universally adopted. To the second clause my objection is the classification of "poisons," as some persons would include henbane, digitalis, colchicum, etc., under this head, while others would not; if the list of "poisons" contained in the former Act is to include all that are to come under the new one, such outside drugs and preparations must be considered as non-poisonous, and consequently require no precautions as to storage and dispensing. I cannot see why "white" and "red precipitate," "oil of vitriol," "spirit of salts," "sugar of lead," and many other (I will call them) commercial articles, as also many essential oils, which have caused more accidents than those which come under the list, should be excluded. With regard to (B) of clause 2, using a bottle or vessel such as described would make the dispenser a mere machine; and then would arise the difficulty of distinguishing between various poisons, corrosive sublimate being distinguished while calomel would not,—thus depending on the sense of touch, rather than that of sight. This plan alone would, I believe, cause more errors than already occur. (C) of clause 2 greatly meets the requirements, provided all poisons (I mean such as are not in the last Act) were so included, which would be a matter of some difficulty, considering their number. Clause 3 is such as might be adopted with much advantage and security. On the whole I consider the already existing arrangements most satisfactory, and that chemists themselves are the best persons to regulate the keeping and dispensing poisons according to their own judgment, and as best suited to their individual requirements.

Finding that it has been the desire of the Council to ascertain each member's individual opinion is my apology for troubling you on this occasion.

JOHN H. LAKE.

41, *High Street, Exeter,*
March 13th, 1871.

Sir,—In the Journal of the 11th ult., I expressed my opinion that there was no necessity for restrictive legislation upon the matter of poisons. With your permission, I will make a few other remarks.

The errors of judgment made by the Council are now beginning to bear fruit, more particularly that very foolish one whereby they refused to take the sense of the trade throughout the country upon this subject. Upon a question of this importance, whereby the liberty of the trade is so much threatened, it must have occurred to the Council that a strong current of opinion would manifest itself in opposition to the scheme they suggested. The Council might have placed before Mr. Simon a protest numerously signed by the trade against any further pharmaceutical legislation, especially of a restrictive character; and also a statement, that any interference with the individual freedom and responsibility of the chemist and druggist would be encountered with the unanimous opposition of the trade. It is more than probable that the question would then have dropped, and with it would also have died the no little ill-feeling that has arisen.

In the statement of reasons issued by the Council is mentioned "the great privileges accorded to, and confidence reposed in the Pharmaceutical Society; to which, on the urgent representation of the Council, that the Society itself was the only judge of what would be practicable and adapted to the exigencies of trade in all parts of the kingdom," etc. Are we to deduce from the above that the Council desire that the majority of the 2000 members of the Pharmaceutical Society who elected them should arrogate to themselves so immense a superiority over their 10,000 brethren who have been contemptuously called "outsiders"? If so, the language is certainly worthy of the notorious Mr. Chollop, who, speaking of his brother Yankees, said, "We are the intellect and virtue of the airth, the cream of human natur', and the flower of moral force."

Does it not occur to the Council that strength has been given them, and consolidation to the whole of the trade, by the ready adhesion of these "outsiders" to the government of a Council which they do not elect? Has it never occurred to the Council that in event of any further parliamentary pharmacy the 10,000 "outsiders" may have accorded to them a voice in the pharmaceutical franchise? In these days of reform, Parliament would scarcely refuse so reasonable a request, and the status of the select few who now have the management might be somewhat altered.

After carefully considering the transactions of the Council upon this question, my opinion is that, notwithstanding their specious statement of reasons, they could have shelved the subject had they wished to do so. The eloquence of our President, which could dissuade even the sturdy Mr. Lowe from pressing his objectionable amendments, might, combined with the support of the trade, have convinced Mr. Simon that the Pharmacy Act had provided all that was necessary for the public safety.

The energetic proprietors of a popular contemporary have now also taken the question in hand. Let us hope that their efforts, and those of the Council, will not cause us to say, in the language of the lamented Artemus, "We are governed too much."

A COUNTRY PHARMACEUTICAL CHEMIST.

Sir,—After so recently troubling you with my views upon the "poison regulations," I should not again have thrust myself into the arena of conflict, had it not been for the appearance of Mr. D. W. John's letter in your last impression.

My object on the present occasion, is to endeavour to draw the earnest attention of all parties to that letter; and at the same time to say that I can, from personal experience and ample information, fully endorse every statement made therein as to the existing condition of things in not a few establishments, and I am fully persuaded the picture he has drawn is not too highly coloured.

I also agree with him as to the educational bearing. Education will not always make a man careful, nor will it *per se* prevent misadventure.

In two or three of the most distressing cases of accidental poisoning which have occurred within my memory, no attempt was made to explain the disasters by the want of proper educational acquirements, for the contrary was well known to be the truth of the case.

Then again, as Mr. John truly observes, in the majority of businesses it is absolutely necessary that there shall be apprentices and young assistants employed, and it seems to me that the "poison regulations" may be a safeguard. That they can be "a delusion and a snare," or the means of "making confusion worse confounded," is I believe perfectly absurd to imagine.

Quoting from Mr. John's letter, I say, "The fact that frequent recommendations and fearfully narrow escapes have failed to convince many of the necessity of adopting any precautions is, I think, sufficient to prove that nothing short of stern compulsion will secure the general adoption of any rules that may be proposed."

And for the same reasons it appears to me quite a farce to ask men who will take no pains for the establishment of proper arrangements, whether or not they object to being made to do so by compulsory regulations.

One thing, however, seems imperative, and that is, that if medical men will keep open shops for the sale of drugs, they should be liable to similar coercive regulations. Certainly, the public safety seems to require it quite as much in the one case as in the other.

ONE WHO HAS KNOWN THE DRUG TRADE MORE THAN THIRTY YEARS.

Sir,—Having carefully and regularly perused the very voluminous correspondence regarding the poison regulation question appearing in your valuable journal from week to week, it has occurred to me as somewhat strange that we have been favoured with so few editorial remarks on this very important subject, the more so from the fact of the Journal being the property of the Society, under whose auspices the regulations emanate.

I am certain that such would have been gratefully received, and might have tended to soothe the fears of those who consider they are about to be bridled with something of a very stringent nature, and put aright the vaunters of such frivolous excuses as we have seen in those pages since the regulations were mooted,—such as infringement of trade rights, compulsory education, on toxicological etiquette, etc.,—from members of the trade throughout the country.

There is one particular point about which I would like to clearly understand, viz. do the Pharmaceutical Council intend using their influence with the Medical Department of the Privy Council to extend the poison regulations to those who, under present circumstances, will be exempt by virtue of being under the wing of the medical profession? Surely, if the public safety demand a greater safeguard than exists at present from us, as examined druggists, the Privy Council cannot possibly object to a measure to include medical men, whose shops for the retailing of everything constituting the business of a chemist and druggist are in many cases their chief source of income,—as is the case in this city, where there are three retail shopkeeping surgeons to every druggist.

And I tell you, Sir, that on those grounds particularly, the regulations will be strongly opposed from this district.

In the Chemists and Druggists' Association of this city, of which I have the honour to be a member, there has scarcely been a single murmur against the poison regulations as issued by the Pharmaceutical Council, except that they are not universally adapted for the object in view.

A REGISTERED ASSISTANT.

Glasgow, March 7th, 1871.

[*** Our correspondent is referred to leaders at pp. 92 and 489 of the present volume, also to the statement of reasons issued by the Council.—ED. PHARM. JOURN.]

THE 'CHEMIST AND DRUGGIST' AND THE POISONS REGULATIONS.

Sir,—I enclose you a circular I received this morning. I can scarcely express the astonishment I felt when I read its purport. And so we are to have a Red Republic in pharmacy, I thought! Sir, I trust the pharmacists of this country will repudiate this scandalous and barefaced intermeddling busybodyism. What right has the *Chemist and Druggist* to call for a plebiscite of the trade? But I suppose it is a good stroke of business; and smells strongly of the shop—shoppy.

F. M. RIMMINGTON.

DISPENSING REFORM AND POISON RESTRICTIONS.

Sir,—I must say wonders never cease. It certainly is astonishing the amount of wisdom put forth and maintained by the promoters of Pharmacy Acts and amendments. If these people think they are going to elevate the trade by making stringent and oppressive laws, with respect to the selling, keeping and storing of poisons, the names of which are given in the schedules (each reformer having his pet scheme as to the kind of poison, the locality and the kind of bottle and label), they are much mistaken. Any man who has his reason would, for his own sake, take the amount of precaution necessary in these things. But if a man is careless, no Act of Parliament will make him careful; it may punish him when he has made a mistake. And, again, these reformers must know, if they are or have been at all connected with the trade, that the sale of most of the poisons mentioned in the schedules is very small, and the amount of profit so small that it would not pay for the least possible alteration, *i. e.* distinguishing bottles, cupboards, partitions, etc.

I think we, who have spent our time and money in passing the examination, should have a little more justice done us by these reformers. Would it not be far better for them to try to enlighten the conscience of those men who charge for dispensing the following prescription for pills at one shilling per dozen:—

℞. Pepsin. Porci gr. vj
Ferri Redact. gr. j
Sol. Æther. Phosphori ♏ij
Pulv. Rhei gr. j
Pulv. Capsici gr. j
Mucilaginis q. s. fiat pilula.

The twelve pills would contain 72 grains of pig-pepsin. What profit would there be for the dispenser who faithfully prepares these pills at a shilling per dozen? At the same establishment the charge for eight-ounce mixtures, one tablespoonful doses, is the enormous sum of eightpence; and also one shilling was charged for the following:—

℞. Chlorodyne, C. B.'s, ʒiij
Aq. ad ℥viij
St. ℥j, omni nocte.

This has been done by one who has been in business, I believe, over forty years, in one of the best situations in a large manufacturing town,—one who stands amongst the "founders," a "member" of the "Society" and the "Conference," and a local secretary. Such line of conduct might have been passed over had he been "hard-pushed," or a young man just "commencing." But it is far from it. I should blush to give the name of the town in which I reside, though it might be said to be justice to the trade to do so. I refrain for pity's sake.

Now, with respect to the poison question. I will give you a rule which, if observed, is the only way to prevent poisoning by accident. 1st. Have every bottle or parcel distinctly labelled. 2nd. That the bottle or parcel contain the article indicated by the label. 3rd. In dispensing, keep the mind upon the work; look at and read every label before taking out the stopper; examine every weight before putting it into the scale pan; and in measuring, let nothing else but the quantity and article occupy your mind. 4th. Do everything by system. 5th. Do nothing by "use." 6th. Use best articles, and charge according to the class of customer. If first-class, charge accordingly. If you have mostly poor people, adapt your charges to their circumstances; but never charge less than cost price, for that is dishonest to yourself and fellow-dispenser. If your customer is too poor to pay you, give him a bottle or two of medicine, for if he cannot pay for his medicine he will not be able to pay the doctor. But, instead of the poor, it is those that are able to pay who, in an extra prescription, are charged under cost price, in order to "catch," or are afraid lest it should give an offence.

I think it would be much better for our pharmacy reformers to look at these rules with their minds unprejudiced. They would find it much better than their distinguishing bottles, separate cupboards and partitions scheme.

Now a word of common sense to our Council and pharmacy reformers. We are in the trade, and have a right to live by it. I would say, then,—Do not oppress the trade with a lot of measures unnecessary and unprofitable. Do all you can to protect our interests, and to obtain for us the sole right to deal in drugs, and to sell castor oil, salts, senna, and all those things which are the chief source of revenue to us. Do all you can to keep the sale of such articles from those who do them for a grocer's profit, for it is well known we cannot live upon $2\frac{1}{2}$ per cent. on our small returns; we should not have the pleasure of paying much income-tax. Try to do something to regulate the present system of so-called "wholesale druggists" in large towns. Many inquiries are made, What do you charge for so much of so-and-so? When the price is mentioned, their reply is, "Oh! we pay so much at the wholesale druggists." Attention is required to this far more than to poisons.

A PHARMACEUTICAL CHEMIST BY EXAMINATION.

Dispensing Prices.

Sir,—If it will not be encroaching on your valuable space with what, I am sorry to say, has become a thing of frequent occurrence, I should like to add another example of that pernicious and despicable system of undercharging.

A few days since, a person, whose outward appearance certainly bespoke respectability, brought the following prescription, and desired to know what we should charge for dispensing it:—

℞. Quiniæ Sulph. ℈j
Acid. Nit. Dil. ʒij
Acid. Hydrochlor. Dil. ʒj
Sp. Æth. Chlor. ʒj
Aquæ Dest. ad ℥xij.
M. ft. mist. Sumat coch. amp. ij bis dic.

2*s.* 3*d.*, including bottle, was the price mentioned, which was, if anything, insufficient, considering the amount of quinine, besides the fact of there being sufficient to last the patient six days. She then said that she never paid more than 1*s.* 8*d.* for it, and had had it for that amount at a chemist's in the north-west of London, at the same time stressing the fact that his establishment was on a large scale. On referring to the Register, I find that he is a Pharmaceutical Chemist by Examination, and also a member of the Society, and his shop is in one of the most fashionable districts of London. It seems to me that notwithstanding all our boasted education and strenuous measures to improve the trade, the modern chemists forget the proverb "Live and let live," and try as far as possible to injure themselves and the trade in general.

Grumbler.

Sir,—The following prescriptions were brought to me some time since to be dispensed:—

℞. Quin. Disulph. ʒij
Sp. Æth. Chlor. Destil. ʒij
Tinct. Ferri Sesquichlor. ʒiij
Mist. Camph. ad ℥vj
Ft. mist. Capiat coch. ampli bis terve die.

Aug. 7th, 1866. T. W. G.

When I told the person what I thought a reasonable charge was, I was indeed almost insulted, for I was told that at every place in London where it had been dispensed they had only charged 1*s.* 6*d.* Can anybody tell me what was used instead?

℞. Codeiæ gr. j⅔
Ext. Nucis Vom. gr. j
Ext. Calumbæ gr. ij.
Ft. pil. et rep. ad xxiv, cap. ij ter dic.

This, I was told, was charged the usual price for two dozen pills, viz. 1*s.* Codeia cost 26*s.* per oz.; what could have been used in this case? These pills have been taken regularly since the beginning of March last year until the end of July. Is not the dose of nux vomica rather strong?

Video.

Pharmacy in Ireland.

Sir,—I have read with great pleasure the letter of your correspondent "Aliquis" on the above subject, and I believe his opinions to be those of the majority of the respectable apothecaries in this country.

I hope that the few letters which have so far been published will show the leaders of the "Pharmaceutical Society" the real position of the druggists of Ireland, which (judging from some of the articles which have appeared in the Journal) I think they have unfortunately misunderstood, considering them analogous to the chemists and druggists of England and Scotland.

I may here say that the reason why the druggists have not expressed their opinions in the Journal, as invited, is that they scarcely ever see it, the matter therein contained being entirely foreign to their line of business.

With regard to the complaint that the apothecaries have an undue monopoly, it would be a very similar case if, in seventy years' time, the grocers of England were to complain that while they (the grocers) were allowed to sell drugs, such as castor oil, etc., they were not allowed to compound medicines under a heavy penalty. Of course the answer would be that the privilege was theirs on passing the necessary examination; and this is the case with regard to the Irish druggists, with this exception, that in England the examination is confined to subjects necessary for the proper discharging of their duties as dispensing chemists, while in Ireland unfortunately it is not so; and this, together with the assimilation of the laws which govern the two countries, would seem to be the principal advantages gained by making a change in the present system; for, so long as a sufficient number of gentlemen think their remuneration as apothecaries a sufficient reward for the high education required of them, I do not see any other ground on which to complain of their monopolizing the dispensing part of the profession. Of course, if they abused that monopoly by charging exorbitant prices, etc. there would be more ground for complaint; but this is not the case.

In conclusion, I think the Pharmaceutical Society might with advantage frame a Bill similar to the one proposed by the Apothecaries' Hall, omitting the Modified Examination for druggists, which was necessary in England to protect existing interests, but is not so in Ireland. Such a Bill will be far less likely to meet with opposition from the apothecaries, in the face of which it is scarcely possible that any measure on the subject could become law.

Oswald A. Reade,
Belfast. *Local Secretary.*

Exemption from Serving on Juries.

Sir,—As according to the present Act of Parliament pharmaceutical chemists only are exempted from serving on juries, and as the same duties and obligations devolve on chemists and druggists, I think it only just that the same privilege should be extended to the whole of the trade.

Such a measure would tend to remove any existing jealousies between the two departments, and they would be enabled to act more in concert for the general welfare.

A short Act could easily be introduced to Parliament for the purpose.

7, *Wheeler Street, Birmingham,* James A. Foster.
2nd March, 1871.

Louisa Plumbley.—We are of opinion that clause 16 of the Pharmacy Act, 1868, which creates exceptions, must be strictly construed in favour of the public, so that the widow of a deceased chemist and druggist will not stand in any more favoured position than any descendant, ancestor, or collateral relative of a deceased chemist and druggist would stand in. In short, that no relative of a chemist and druggist can claim any special exemption in right of the relationship, and the only persons who can claim the special exemption are those who stand in the position of trust as defined in the statute.

W. Hartley.—No.

"*Tonic*" (Watford).—You will find the information you require concerning quinine wine given in a letter printed on p. 519 of the present volume.

"*Omega*" will find the formula for Dr. Coffin's composition powder on p. 457 of the present volume.

C. E. W.—The formula for Easton's syrup has been already given in the present volume, p. 377. See also the correspondence respecting it on pp. 397 and 419.

T. W. (Scarborough).—We are informed that the third edition of Attfield's 'Chemistry' is now being printed, but that it is intended chiefly for American circulation, being adapted to the United States' Pharmacopœia.

"*Aroma.*"—The 'Journal of the Society of Arts' is published by Messrs. Bell and Daldy, York Street, Covent Garden.

⁂ We are compelled to defer the publication of several letters until next week.

The following journals have been received:—The 'British Medical Journal,' March 11; the 'Medical Times and Gazette,' March 11; the 'Lancet,' March 11; the 'Medical Press and Circular,' March 16; 'Nature,' March 9; the 'Chemical News,' March 10; 'Journal of the Society of Arts,' March 9; 'Gardeners' Chronicle,' March 11; the 'Grocer,' March 11; 'Produce Markets Review,' March 11; the 'English Mechanic,' March 10; the 'Chemist and Druggist' for March; the 'New York Druggists' Circular' for February.

Communications, Letters, etc., have been received from Mr. T. P. Blunt, Mr. T. A. Reeve, Mr. J. Barker, Mr. F. B. Benger, Mr. D. H. Warwick, Mr. M. C. Cooke, Mr. F. Coles, Mr. S. Dean, Mr. Cohen, Mr. D. Anderson, Mr. W. Lee, Dr. Steele, Mr. W. W. Stoddart, "Alpha," "Nil sine Labore," "Vincit Amor Patriæ," "Senega," "Apprentice," C. W., A. O. Z., T. E. R., J. H.

SYRUP OF PHOSPHATE OF IRON

AND OTHER SYRUPS CONTAINING PHOSPHORIC ACID.

BY MICHAEL CARTEIGHE.

Of the numerous preparations of iron at the disposal of the practitioner few have in late years acquired more favour than the syrup of the phosphate. First introduced to the notice of the profession by Mr. Greenish* in a form more or less opaque, it was not until about ten years ago that it came into very general use. About this time Gale and Schweitzer each read a paper† at one of the evening meetings of the Pharmaceutical Society, detailing processes for the preparation of this syrup in a form which should remain perfectly bright and free from deposit. Gale's process was introduced into the British Pharmacopœia of 1867, and since the publication of that volume the demand for this medicine has vastly increased. Its tendency to darken in colour after having been kept for some time was soon noticed, and Umney‡ made some experiments with the view of preventing or retarding this change, but the results were not practically satisfactory. T. B. Groves§ afterwards examined a very old specimen in his possession, and determined the chemical composition of the precipitate, which is formed on long standing. He describes this precipitate as being essentially a compound of iron with phosphoric acid, corresponding to the octocalcic phosphate of Warington. The dark colour he thinks due to the production of caramel by the action of the phosphoric acid and iron salt upon the sugar. He also prepared several specimens with a stronger acid, made by himself from amorphous phosphorus, and found that these kept somewhat better than when made according to the B. P.

The necessity of keeping the syrup recently prepared induced me to try a few experiments with a stronger acid, and to devise a shorter process than that of the B. P. This has doubtless already suggested itself to, and been practically tested by, other chemists, but, so far as I am aware, it has not hitherto been published. It is as follows:—

SYRUP OF PHOSPHATE OF IRON.

Phosphate of Iron	96 grs.
Water	9 fl. drms.
Syrupy Phosphoric Acid, sp. gr. 1·500	7 fl. drms.
Syrup	10 fl. oz.

Rub the phosphate of iron with the water in a glass mortar, add the phosphoric acid and filter the mixture into the syrup.

As thus prepared, it contains the same proportion of iron, about 2 minims less of the dilute acid (25 instead of 27), and rather more sugar than when prepared according to the Pharmacopœia.

The phosphate of iron is made by the B. P. process, and dried at a temperature not exceeding 100° F. The specimens I have found in the ordinary course of trade are not readily soluble in the acid. This want of solubility is, I believe, due to the length of time they have been kept before sale.

* Pharm. Journ. Vol. X. p. 534.
† Pharm. Journ. 2nd series, Vol. I. p. 497.
‡ Pharm. Journ. 2nd series, Vol. VIII. p. 129.
§ Pharm. Journ. Vol. XI. p. 138.

I have obtained the best results with phosphate only a few days old, and find it advantageous to make as much as is required frequently.

Syrupy phosphoric acid of sp. gr. 1·500 may now be obtained of any manufacturing chemist, and according to Dr. Watts's table,* contains about 50 per cent. of P_2O_5. It is made by the action of nitric acid on phosphorus, the excess of acid being driven off in a platinum vessel.

Manganese is sometimes prescribed with or without iron, and according to Pereira, the former is a useful adjunct to ferruginous preparations, and occasionally a desirable substitute for them.

SYRUP OF PHOSPHATE OF MANGANESE

May be prepared in a similar manner with the following ingredients:—

Phosphate of Manganese	96 grs.
Water	9 fl. drms.
Syrupy Phosphoric Acid, sp. gr. 1·500	7 fl. drms.
Syrup	10 fl. oz.

Strength—1 *grain phosphate of manganese and acid equal to about* 25 *minims of the dilute phosphoric acid in each fluid drachm.*

The phosphate of manganese is made in the same manner as the phosphate of iron, substituting sulphate of manganese for the ferrous sulphate.

SYRUP OF PHOSPHATE OF IRON WITH MANGANESE.

Phosphate of Iron	72 grs.
Phosphate of Manganese	48 grs.
Water	8 fl. drms.
Syrupy Phosphoric Acid	8 fl. drms.
Syrup	10 fl. oz.

Rub the powders with the water, add the acid and filter into the syrup.

Each fluid drachm contains ¾*-grain phosphate of iron,* ½*-grain phosphate of manganese and acid equal to about* 30 *minims of the dilute phosphoric acid, B.P.*

The tendency of modern practitioners of medicine to encourage the exhibition of substances which may assist in the formation of bone, etc., has led to the introduction of the—

SYRUP OF PHOSPHATE OF IRON AND LIME.

Take of Phosphate of Iron	96 grs.
Phosphate of Lime	192 grs.
Water	8 fl. drms.
Syrupy Phosphoric Acid, sp. gr. 1·500	8 fl. drms.
Syrup	10 fl. oz.

Mix the powders with the water in a glass mortar, add the acid and filter into the syrup.

Each fluid drachm contains 1 *grain of phosphate of iron,* 2 *grains of phosphate of lime, and an amount of acid equal to about* 30 *minims of the dilute phosphoric acid, B. P.*

The phosphate of lime is made by precipitation from solutions of chloride of calcium and phosphate of soda, and dried at 100° F., and should not be kept too long before use. That made from *bone ash*, as the Pharmacopœia directs, is much less readily soluble.

The following formulæ may be useful as an appendix:

* Pharm. Journ. 2nd series, Vol. VII. p. 191.

SYRUP OF PHOSPHATE OF ZINC.

Phosphate of Zinc	192 grs.
Water	11 fl. drms.
Syrupy Phosphoric Acid, sp. gr. 1·500	5 fl. drms.
Syrup	10 fl. oz.

Rub the phosphate with the water, add the acid and filter into the syrup.

Each fluid drachm contains 2 *grains of zinc phosphate and about* 18 *minims of dilute phosphoric acid.*

SYRUP OF PHOSPHATE OF QUININE.

Take of Phosphate of Quinia*	96 grs.
Water	$13\frac{1}{2}$ fl. drms.
Syrupy Phosphoric Acid, sp. gr. 1·500	$2\frac{1}{2}$ fl. drms.
Syrup	10 fl. oz.

Mix the acid with the water, add the quinia and filter into the syrup.

Each fluid drachm contains 1 *grain of phosphate of quinine and acid equal to about* 10 *minims of the dilute phosphoric acid.*

SYRUP OF PHOSPHATE OF IRON WITH QUININE.

Take of Phosphate of Iron	192 grs.
Phosphate of Quinia*	96 grs.
Water	7 fl. drms.
Syrupy Phosphoric Acid, sp. gr. 1·500	9 fl. drms.
Syrup	10 fl. oz.

Rub the powders with the water, add the acid and filter into the syrup.

Each fluid drachm contains 2 *grains of phosphate of iron and* 1 *grain of phosphate of quinine.*

SYRUP OF PHOSPHATE OF IRON, QUININE AND STRYCHNINE.

Easton's Syrup.

Take of Phosphate of Iron	192 grs.
Phosphate of Quinia*	96 grs.
Strychnia (in crystals) . . .	3 grs.
Water	7 fl. drms.
Syrupy Phosphoric Acid, sp. gr. 1·500.	9 fl. drms.
Syrup	10 fl. oz.

Rub the phosphate of iron with 5 drachms of the water in a glass mortar, dissolve the strychnia and quinia in the acid, previously mixed with the remaining 2 drachms of water; mix and filter into the syrup.

Each fluid drachm contains 2 *grains of phosphate of iron,* 1 *grain of phosphate of quinine and* $\frac{1}{32}$*nd part of a grain of strychnine.*

SYRUP OF PHOSPHATE OF IRON AND STRYCHNINE

May be prepared in the same manner as the last, omitting the phosphate of quinine.

I am conscious of the objections which may be urged against the prescribing of these *compound* preparations, but in the face of the constant and increasing demand for many, it appears to me futile to attempt to discourage them by declining to publish formulæ. Such a course tends to perplex both the medical profession and pharmacists and to the introduction of quasi-secret remedies of unknown, and possibly of uncertain, strength.

172, *New Bond Street, W.*

* The same weight of quinia, prepared by precipitating an acidulated solution of the *disulphate* by solution of ammonia, collecting, washing and drying at 100° F., may be used, in the absence of the phosphate.

NOTE ON OPIUM CULTURE.

BY GEORGE W. KENNEDY.

In a letter to the editor of the *American Journal of Pharmacy*, the author informs him that he has procured poppy seed from abroad, and supplied it to a friend in Illinois, with the view of trying an experiment in opium culture. The seeds were planted in rows two and a half feet apart, in well-manured, rather dry soil and in moist soil. The seed sown in the wet soil failed. The plants received good garden culture, and attained a height of three feet. After the petals had fallen, and the capsule attained some size, horizontal incisions were made around the capsules in the afternoon, and the exudation removed in the morning and dried in the sun. Some of the capsules failed to yield any juice, owing to the wound being too deep, and the juice passing into the cavity of the capsule. The yield of opium was small, many of the plants being imperfect. Mr. Kennedy made a partial examination of it, and detected meconic acid; and when treated by Mohr's process, with subsequent crystallization of the precipitate from alcohol, yielded 8·75 per cent. of morphia crystals, which gave the proper reactions with nitric acid and chloride of iron.

Mr. Kennedy hopes to make a more successful experiment next year.

SULPHO-CARBOLATE OF ZINC.

In a letter to the editor of the *American Journal of Pharmacy*, Dr. A. B. Lyons, of Detroit, recommends the following process for the preparation of sulpho-carbolate of zinc as simple, economical and satisfactory:—A crude sulpho-carbolic acid is first prepared in the usual way, by heating together sulphuric and carbolic acids—seventeen parts of the former to sixteen of the latter. This is diluted with ten times its volume of water, and saturated with carbonate of lead. Into the filtered solution of sulpho-carbolate of lead is introduced a quantity of pure granulated zinc, equal in weight to the carbolic acid employed. At the end of twenty-four hours the solution will usually be found free from lead, giving no precipitate with sulphuric acid or potassium iodide. When quite freed from lead, as indicated by these tests, the solution is decanted, heated to boiling, filtered and evaporated to a small bulk to crystallize; or the evaporation is carried to complete dryness, the salt being obtained in the granular form. The salt procured in this way is of necessity free from sulphate, and yields fine large colourless crystals, without any empyreumatic odour.

BORAX.

The *New York Druggists' Circular* states that it may not be generally known how very valuable borax is in various purposes of household use. We find it the very best cockroach exterminator yet discovered. One half-pound, costing but fifty cents, has completely cleared a large house formerly swarming with them, so that the appearance of one in a month is quite a novelty. The various exterminating powders puffed and advertised have been found not fully effective, tending rather to make the roaches crazy than to kill them. There is something peculiar, either in the smell or touch of borax, which is certain death to them. They will flee in terror from it, and never appear again where it has once been placed. It is also a great advantage that borax is perfectly harmless to human beings; hence no danger from poisoning. It is also valuable for laundry purposes. The washerwomen of Holland and Belgium, so proverbially clean, and who get their linen so beautifully white, use refined borax as washing-powder instead of soda, in the proportion of a large handful of borax powder to ten gallons of water. They save soap nearly one-half. All the large washing establishments adopt the same mode. For laces, cambrics, etc., an extra quantity of the powder is used; and for crinolines (requiring to be made stiff) a stronger solution is necessary. Borax, being a neutral salt, does not in the slightest degree injure the texture of linen. Its effect is to soften the hardest water, and therefore it should be kept on the toilet table. As a way of cleaning the hair, nothing is better than a solution of borax in water.

SOLVENT POWERS OF GLYCERINE.

The following table of the solubilities of various chemicals in one hundred parts of glycerine is given by Klever (*Pharm. Zeitsch. f. Russ.*):—

Arsenious Acid	20
Arsenic Acid	20
Benzoic Acid	10
Boracic Acid	10
Oxalic Acid	15
Tannic Acid	50
Alum	40
Carbonate of Ammonia	20
Muriate of Ammonia	20
Tartarated Antimony	5·50
Atropia	3
Sulphate of Atropia	33
Chloride of Barium	10
Brucia	2·25
Sulphide of Calcium	5
Cinchonia	0·50
Sulphate of Cinchonia	6·70
Acetate of Copper	10
Sulphate of Copper	30
Tartarated Iron	8
Lactate of Iron	16
Sulphate of Iron	25
Perchloride of Mercury	7·50
Cyanide of Mercury	27
Iodine	1·90
Morphia	0·45
Acetate of Morphia	20
Muriate of Morphia	20
Phosphorus	0·20
Acetate of Lead	20
Arseniate of Potash	50
Chlorate of Potash	3·50
Bromide of Potassium	25
Cyanide of Potassium	32
Iodide of Potassium	40
Quinia	0·50
Tannate of Quinia	0·25
Arseniate of Soda	50
Bicarbonate of Soda	8
Borate of Soda	60
Carbonate of Soda	98
Chlorate of Soda	20
Sulphur	0·10
Strychnia	0·25
Nitrate of Strychnia	4
Sulphate of Strychnia	22·50
Urea	50
Veratria	1
Chloride of Zinc	50
Iodide of Zinc	40
Sulphate of Zinc	35

Burns and Scalds.—Dr. S. B. Judkin, in a communication to the *Journal of Materia Medica*, says that he has successfully treated many cases of burns and scalds by dissolving white-lead in linseed-oil to the consistency of milk, and applying it over the entire burn or scald every five minutes with a soft feather. He has used it a great many times during fifteen years of practice, and found it to give relief sooner, and to be more permanent in its effects, than any other preparation.

THE PROPOSED POISON REGULATIONS.

MEETING OF CHEMISTS IN NOTTINGHAM.

A General Meeting of the Chemists of the town and district, was held in the rooms of the Nottingham and Notts Chemists' Association, on Friday, the 10th of March; Mr. J. H. Atherton, the President of the society, in the chair.

The meeting was well attended and unanimous in its expression.

The following resolutions were adopted:—

Proposed by Mr. W. H. Parker, seconded by Mr. T. B. Fletcher,—

"That in the opinion of this Meeting, the proposed institution of compulsory regulations for the keeping and dispensing of poisons is unwise, and an unnecessary interference with the freedom and independence of the trade."

Proposed by Mr. Fitz-Hugh, seconded by Mr. Mayfield,—

"That the importance of the proposed measure demands that the opinion of members of the Pharmaceutical Society should be taken, before the Annual Meeting in May. This Meeting would urge the Council to issue with the voting-papers a form, to be filled up by each member, requesting his opinion, 'Ay' or 'No,' on the subject, in order to ascertain definitely the views of the trade."

Proposed by Mr. Blankney, Arnold, seconded by Mr. F. White,—

"That this Meeting approves of the objects of the Defence Association, and hereby agrees to support its efforts."

Proposed by Mr. Oakland, seconded by Mr. Lewis,—

"That the resolutions arrived at by this Meeting be printed and circulated throughout the town and neighbourhood."

MEETING OF CHEMISTS AND DRUGGISTS AT HULL.

On Wednesday evening, the 15th inst., a large and influential Meeting of Chemists and Druggists of Hull and neighbourhood was held at the Cross Keys Hotel, Market Place, to take into consideration the proposed poison regulations. On the motion of Mr. Gales, seconded by Mr. Smith, the President of the Hull Chemists' Association (Mr. Baynes) was called upon to preside.

The Chairman in opening the proceedings said they were called together, as they were doubtless well aware, for a most important purpose, the consideration of a question which was of vital importance to the trade generally. The Hull Chemists' Association had previously taken action and placed on record their opinion on the matter. It had, however, been thought fit, under the present circumstances of the case, to call a meeting of the trade; and as some persons must take the initiative, he and the Secretary (Mr. Bell) had chosen to do so. The meeting was one of the entire trade, and every gentleman would be at liberty to express his opinions on the proposed regulations. He trusted the gentlemen would speak with calmness, good temper and with as much brevity as was consistent with what the speaker desired to say. The poison regulations, unless their enactment was defeated, were about to be made the means of placing the chemists under very stringent regulations, which were not intended to apply to any other class of dealers in medicines. The action which their committee had previously taken was, he was informed, to the utter condemnation of the scheme proposed by the Council, and he had very little doubt the result of their present meeting would show that they rightly judged the general feeling of the trade. Certain resolutions had been prepared for the meeting, but they had only been drawn for the purpose of facilitating business, and would be open for discussion. A memorial would be read, but the meeting would be at liberty to mar or amend it as they thought fit. Personally he had no very strong objections to the poison regulations, so long as he was allowed to do as he liked about them, but he should strongly object to their being forced on him by law. At present he was allowed, and did make such arrangements as he thought would conduce to the safety of his customers, and he had no doubt every other chemist in the district did the same. With regard to the suggestion of Dr. Simon as to angular bottles, it was merely one of his crotchets. Some gentlemen had an idea that they could prevent cases of poisoning; he thought the chemists might congratulate themselves that of late years the cases of poisoning had been very few. Some of the cases occurred where rules as stringent as those to be imposed had been in operation. The Chairman concluded by referring to the memorial, which he read, and expressing his belief that nearly the whole of the seventy or eighty chemists in the town would sign it. The memorial is as follows:—"The undersigned chemists and druggists of Hull having had their attention drawn to the proposed poison regulations which the Council intend bringing before the Annual Meeting of the Pharmaceutical Society in May next, with a view to their adoption, hereby desire to record their dissent from the said propositions, and respectfully urge upon the Council the danger and impolicy of partial legislation on the subject of poisons; and your memorialists further desire to impress on the Council in the strongest manner that, in their opinion, no regulations can be deemed satisfactory to the trade which do not apply alike to surgeons, veterinary surgeons, hospitals and dispensaries (by whom, by far, the greater portion of medicine is supplied), as well as to chemists. The third regulation is very objectionable, and has a direct tendency to favour the conclusion that any medicine not in a "danger bottle" is necessarily harmless, and it would probably lead to serious accidents. It is very questionable, in the opinion of your memorialists, whether any regulations, capable of universal application, can be devised which are likely to press with such constant force on the minds of chemists and druggists as that of the tremendous responsibility now existing."

Mr. A. Pickering then moved the following resolution:—"That this meeting, whilst fully recognizing the duty of every pharmaceutical chemist and chemist and druggist to take all due precautions against mistakes and accidents, and securing the safety of the public when dealing with poisons or dangerous articles, does not consider the enforced adoption of the proposed regulations for keeping and dispensing poisons to be either necessary or desirable; and that a memorial be prepared and presented to the Council, objecting to the proposed poison regulations." He observed that, in the first place, he considered the regulations proposed by the Pharmaceutical Society were absurd; in the second place, impracticable; in the next place, an unnecessary interference with business; and, lastly, they were regulations that could not be carried out. All chemists and druggists knew the injurious effect which a case of poisoning had upon a person's business, and he believed the great majority of chemists used every ordinary care to prevent accidents. During an experience extending over twenty years, he had never had a single case of poisoning or anything approaching to a serious mistake, in his shop. The ordinary precautions which most chemists exercised were used, viz. labelling poisons and articles for external application as such. He was persuaded that no regulations could be made which would prevent persons from committing suicide who had once allowed such an idea to obtain possession of their minds. With regard to the dispensing of poisons, generally speaking, the principal of a business kept a very strict eye upon everything poisonous; and he was not aware that any alteration in the shape of bottles, or the assignment of a particular place in the shop for them, would have any influence at all in the prevention of accidents. The idea of keeping all poisons under lock and key was quite incompatible with trade. Barrels of arsenic, casks of sheep-dipping, and other articles largely used, could not be so stored. He really did not see how any regulations could be so universally applicable as to prevent accidents of the nature in question. He considered the best means to prevent accidents was to have those connected with them possessing a sufficient knowledge of the properties of the articles dealt in. If left in the hands of those educated for the business, he had very little doubt but that all ordinary care would be exercised, and as few accidents take place as was within the bounds of possibility.

Mr. C. B. Bell seconded the resolution, and, in doing so, trusted the meeting would pardon him if he made any mistake, for he should endeavour to be as brief as possible. At the last Annual Meeting, held in May, they would remember that these poison regulations came on for discussion, and that, after a very stormy meeting, they were voted against; and a resolution was passed that the incoming Council should consider them during the ensuing year, and report on them to the next Annual Meeting. Last December a letter from Mr. Simon, calling the attention of the Council to them, was brought forward. On the 1st of February they came on for discussion again, when ten of the Council voted in favour of the compulsory poison regulations, and four against them. A resolution was moved, "That the sense of the members of the Pharmaceutical Society should be taken on the regulations," but that proposal was outvoted. Personally he had strong objections to the regulations; and he agreed with Mr. Pickering that, though many of them might endeavour to carry them out, it was incompatible to do so entirely. He considered that, if passed, the regulations would act very injuriously on their trade. Take, for instance, the town of Glasgow. If the regulations became law, they would press heavily on sixty pharmaceutical chemists and chemists and druggists, but they would not touch the hundred and twenty physicians, etc. keeping open chemists' shops. That was a piece of inconsistency in legislating which ought not to exist. At the last Annual Meeting a beautiful elegy was preached by one of the Council, who asked them to put themselves out of the pale of the Society for a short time, and inquire of themselves what their feelings would be if they had a friend or dear child poisoned by mistake; he asked what must have been the feelings of that poor chemist in Lancashire, who, a few weeks ago, lost his child by poison administered through the mistake of a surgeon's dispenser? That was another reason why they should oppose the proposed regulations. He had the honour of voting against them last year, and he trusted every member would endeavour to be present and oppose them next May.

At the suggestion of one of the gentlemen present, Mr. Bell read the proposed regulations.

Mr. Gales observed that they all agreed that the regulations, if passed, would be a grievance inflicted upon the trade; they all felt they had grounds for complaint against those parties who were introducing the regulations, and endeavouring to make them law. In remedying any grievance, or in counteracting the effect of any mis-legislation, it was necessary, in the first place, to draw a correct diagnosis, and to ascertain the cause from whence the evil sprang; he took it that it arose from the chemists and druggists of Great Britain having incautiously committed the governing power to the Pharmaceutical Society. His views had been before the trade from the commencement of the agitation of the rights of chemists and druggists. Those gentlemen who possessed copies of the *Chemist and Druggist* would be able to place their fingers on articles he had written in that periodical, in which he had deprecated the continuance of the governing power in the hands of any section so small as the Pharmaceutical Society. He did not find fault with them availing themselves of the privilege; they were in perfect order, they having a right by law, as the governing body, to pursue what course they thought proper. The chemists and druggists had pledged themselves to abide by any regulations which the Pharmaceutical Society should pass, therefore it was not so much against the Pharmaceutical Society as against themselves they ought to complain, in having put confidence in man. They had an opportunity some years ago, when the Bill was before the House, of resisting it, and they had the power in their own hands. As non-pharmaceutical chemists, as they were often called, although many of them understood pharmacy and practised it as much as some, the present was only the first instalment arising from such a course of procedure. He would object to memorializing the Pharmaceutical Society, as they had taken no notice of the registered chemists; they were governed without being consulted, they were not represented on the Council, although they had a claim to have seven out of twenty-one, and he questioned whether there was one registered chemist on the Council. It was contrary to British liberty and to British legislation that men who were not represented should be legislated for, without being consulted in the slightest degree, and asked to submit to any law they wished to make. He objected to the resolution proposed, as their remedy was in the House of Commons; he should propose that a memorial against the regulations be drawn up and sent to the Privy Council.

Mr. Akester seconded the amendment.

The Chairman said he did not see how they could approach the House of Commons on the subject; no doubt the Medical Council had moved in the matter through Mr. Simon, and it was with the Council of the Pharmaceutical Society we had to remonstrate, but he did not care what course was adopted so long as the proposals were upset.

The amendment was then put, and only three hands held up for it, it was declared lost. The original motion was then put and carried.

Mr. Myers proposed "That whilst chemists generally would doubtless welcome, and, as far as possible, adopt any suggestions tending to lessen the risk of accident, this meeting is of opinion it is practically impossible to lay down any rigid rule applicable to all establishments alike, with respect to the keeping, selling and dispensing of poisons, and the enactment of such a law would seriously trammel and increase the responsibility of chemists and druggists without leading to greater safety on the part of the public."

Mr. Hollingsworth seconded the resolution, which was earnestly supported by Mr. A. Smith and carried.

Mr. Smith moved "That this meeting considers it would be an act of great injustice and severity to the chemists and druggists of England and Scotland should the proposed regulations be enforced upon them, whilst surgeons, veterinary surgeons, and dispensaries are exempted, and would expose the public to greater danger from varying customs, than if no such unwise attempt been made." This was seconded by Mr. Barlow, supported by Mr. Gales, and carried unanimously.

Mr. Earle proposed the following resolution: "That this meeting deeply regrets that the Council of the Pharmaceutical Society had not decided to take the sense of the trade prior to the Annual Meeting, as suggested by Messrs. Woolley and Brown," which was seconded by Mr. Akester, and carried unanimously.

Mr. Staning moved "That assistance be given to the Defence Association by subscribing to its funds," which was seconded by Mr. Smith.

Mr. Gales objected to the subscriptions being sent to the Association at Manchester, and moved an amendment, that they be sent to the United Society of Chemists and Druggists, which, not finding a seconder, the original motion was put and carried.

A hearty vote of thanks to the Chairman closed the meeting.

MEETING IN LIVERPOOL.

A Meeting of the Chemists and Druggists of Liverpool was held at the Royal Institution on Thursday evening, the 16th instant,—

"To consider the proposed compulsory regulations for the keeping, storing and dispensing of poisons."

It was moved by Mr. Abraham, and seconded by Mr. Alfred E. Tanner, that Mr. Edward Davies, F.C.S., take the chair.

The Chairman said he had been invited to preside, not being affected in any way by the question for discussion, and, therefore, unbiassed in his opinions. The meeting, though called by the Council of the Chemists' Association, was not connected therewith, but the resolution would be the voice of the chemists and druggists of Liverpool.

The Secretary read the circular convening the meeting; the proposed compulsory poison regulations; and several letters of apology from those not able to attend, each of which expressed strong protests against legislative interference.

Mr. Redford said that he had taken the course which had resulted in the present meeting being convened from a sense of duty, but he thought it must be a matter of deep regret to all who sympathized with him that they should be compelled to take up a position of seeming opposition to the Council of the Pharmaceutical Society, and to the proposed "poison regulations." He thought this was a false and painful position to be placed in, and he shrank from the unpleasant but pretty certain fate of being misunderstood by the Society, by the public and the Legislature. He therefore felt it necessary to protest against inferences that might possibly be drawn by any parties, that in wishing to make a stand against aggression upon the rights and liberties of the trade, he and those who felt with him were actuated by any feelings of hostility to the Pharmaceutical Society, or were opposed to the voluntary adoption of wise poison regulations. It would be gratuitous to commend the Society, and idle to attack it, as the legal guardian of our trade qualifications, whose *imprimatur* was indispensable to the status of all who should enter the profession. But an attitude of defence now was justifiable, and, he maintained, must be assumed. It was said that ten thousand of the trade were "outsiders," and were unrepresented, and so without voice in the Society's counsels. This large body of Englishmen had feelings, opinions and rights which, if hurt, ignored, or invaded must drive them into a position of defence. The qualifications of the Council for framing "poison regulations," and the weight of their recommendation, were probably indisputable. Perhaps the "regulations" were unexceptionable; without conceding that, however, he thought that was not the question now. He would not dissuade any man from adopting safeguards which commended themselves to that man's judgment, but he contended strongly for freedom. "Let our judgments," he said, "be free and unfettered; throw on us all the responsibility you can heap, and compel us to pass crucial educational tests of the severest examinations of any college in Christendom, but spare us the ignominy of being compelled in addition to adopt artificial material expedients to obtain an imaginary immunity from accidents, which it has been one great aim of our education to secure, and which that education is the only good and safe means of securing."

He said he believed that, as a body, the chemists and druggists of the country did not need this compulsory measure, and that it was impossible to prove the preamble of such an enactment, because, when the vast amount of dispensing done was taken into consideration, the ratio of accidents was infinitesimal. He thought, further, that it would be unconstitutional and essentially tyrannical for the few individuals constituting the Annual Meeting of the Society to coerce and injure, as virtually they would have the power to do, the whole trade; that the policy of compulsion was unworthy of the Society, after the recent legislation on the subject of poisons and educational tests, such a policy being retrograde, tacitly discrediting education, and provocative of ill-feeling, opposition and perhaps schism, and would, if persisted in, result in imperfect and disappointing results. Looking ahead, he must warn them of what they might fairly infer from this attempt in the shape of consequences,—inspection with all its repugnance,—and after that, perhaps, under pressure from the medical officer of the Privy Council, curtailment of other rights.

The absurd exemption from the coercive operation of the proposed "regulations" of doctors' shops and dispensaries was then referred to, and the confusion likely so to arise was pointed out. The formation of a Defence Association he thought most opportune, and deserving of general support, as well as the issue of non-official voting-papers to the whole trade from the *Chemist and Druggist* office, by which he hoped all would express their opinion. He begged to move the following resolution:—

"This meeting, having fully taken into consideration the proposed *compulsory* regulations for the keeping and dispensing of "poisons," strongly protests against such regulations being passed at the Annual Meeting of the Pharmaceutical Society to be held in May next, and further hopes that the members present at the said Annual Meeting will unanimously reject the same."

Mr. Shaw, in seconding the resolution, observed that its construction implied that the meeting had well considered the proposed regulations, otherwise he should have been tempted to dispense with any further argument *pro* or *con.*, seeing that the subject had already been debated almost to the death during the past year. He then briefly alluded to the Pharmacy Bills introduced into Parliament during the last five or six years, calling special attention to the fact of the absence of any stated or implied interference with chemists and druggists in the keeping and dispensing of poisons in the drafts of the Bills submitted to the country in 1867 and 1868, and published in the Pharmaceutical Journal in May, 1867, and in the March and June numbers, 1868. He strongly insisted that there was no evidence before the country at the present time proving the necessity for *legal enforcement* of such regulations, and pointed out the circumstances attending the introduction of the Arsenic Act, the Adulteration of Food and Drink Act, the Petroleum and Nitro-glycerine Acts, in justification of their enactment. Education and a guaranteed competency by means of an examination, combined with personal responsibility, had always been considered the most effective protection against accidents by poisoning; and he considered that such compulsory regulations in the present and prospectively more improved state of education amongst chemists and druggists, were totally uncalled for. He next alluded to the fact that such proposed legislation, applying only to chemists and druggists, was partial, invidious and must prove mischievous by entirely exempting surgeons, apothecaries and veterinary surgeons from its operation, whether occupying private surgeries or keeping open retail shops, as was done in many parts of the country, especially in Glasgow. The public dispensaries were also to be exempted from the observance of the regulations, notwithstanding that upwards of 200,000 packages and bottles of medicine were sent out by the Liverpool dispensaries alone, to the lowest class of the population, during the past year. It had been said that the adoption of the regulations would throw the whole of the dispensing into the hands of chemists. He did not believe that, but thought that, if the surgeons and others were included, it would more probably have that effect. One of the proposed regulations was intended to "educate" the public by means of the sense of touch, as to when a bottle contained poison and when it did not; and he thought that confusion and danger were sure to be the consequence, especially bearing in mind the exemptions already alluded to. Some of the words used in the clauses of the proposed regulations were very ambiguous and indefinite, a circumstance much to be deprecated in any Act of Parliament, more especially where consequences of the most serious character were involved. For instance, the word "poison," of course, embraced all the substances named or implied in Schedule (A), as arsenic, belladonna, strychnia, paregoric and ferrocyanide of potassium, though the latter, according to Fownes, "has no poisonous properties." But the term "poison," in the keeping and dispensing of poisons, could not possibly be restricted to the articles embraced in Schedule (A). The term "ordinary articles" was intended to represent such articles as acetic, citric and tartaric acids, cream of tartar, sugar of milk, magnesia, subchloride of mercury, etc. etc.; but it must not be forgotten that it also included carbolic acid, the corrosive acids, sugar of lead, barytic and cupreous salts, biniodide of mercury,—some of these being most virulent poisons, but not legally requiring any particular regulations as to keeping and dispensing them. The word "dangerous" he looked upon as indefinite and objectionable, from the fact that the Pharmacy Act did not comprehend and define what articles were dangerous, and the Council, with ingenious reticence, did not condescend to point them out. Allusion was then made to the late Jacob Bell, Esq., who commanded the highest respect for his sound business sense, and whose opinion on all matters relating to pharmacy was highly valued. In the year 1857 Mr. Bell said, "The provisions regarding the sale of medicines in square bottles of a particular coloured glass, with the word 'poison' moulded on them, was one of those visionary ideas it was curious to see in print; and he had published the Bill entire" (Sale of Poisons, etc., Bill of that year) "in last month's Journal, as it would be a literary curiosity to be referred to in future." Also, "that no Act of Parliament could make them more careful than they were obliged to be for their own reputation." Mr. Shaw then remarked there was one member of the Council who at present enjoyed a prominent and deservedly popular position in the Society,—he alluded to Mr. Ince; and that gentleman had just communicated his views on this vexed question, and he would beg to read a short letter written to the editor, and inserted in the *Chemist and Druggist*, published the day before.

Mr. Abraham at this point rose and objected to Mr. Shaw reading Mr. Ince's letter, without he also read Mr. Groves' on the other side of the question.

Mr. Shaw said he had not the least objection to Mr. Abraham reading Mr. Groves' letter, if he thought it desirable to do so; but he would content himself by reading that from Mr. Ince.

Suggestions were then made that the pith of Mr. Ince's letter might be given, to which Mr. Shaw replied that the letter was pithy from beginning to end, and that, if he gave the pith, he must give the whole; however, as the time was limited, he contented himself with reading the latter portion of it, and concluded by seconding the resolution.

Mr. Abraham said that he agreed with many of the statements of the preceding speakers, and he had intended to call attention to the fact that the proposition for these regulations was not to be found in any Bill at the time of its introduction by the Council of the Pharmaceutical Society. He himself had no confidence in such provisions in a compulsory sense, and he was not aware that any other member of the Council had. The provisions of the Act were introduced during the passage of the Bill through Parliament, and the discussion upon them would be found in the PHARM. JOURN. 1868–9, pp. 58 *et seq.* It would there be found that the struggle was, not as to the question whether compulsory regulations were to be made,—upon which point both parties in the State appeared to be agreed,—but as to the question who should make them. The present Chancellor of the Exchequer (Mr. Lowe) and the present Home Secretary (Mr. Bruce) were of opinion that the Privy Council should be empowered to make them, but Mr. Headlam said that the noble Duke at the head of the Privy Council (the Duke of Marlborough) had introduced the words "Pharmaceutical Society, with the consent of the Privy Council," as the proper persons, and he supported that view. So also did Lord Robert Montagu and others; Mr. Alderman Lusk saying "that he had no fear of the Pharmaceutical Society not doing their duty." The Act passed, and the Privy Council, possessing a co-ordinate authority, called on the Pharmaceutical Society to make the regulations contemplated by it. Mr. Abraham quoted the speech of the late President of the Pharmaceutical Society, Mr. Sugden Evans, in introducing the recommendations of the Council at the last Annual Meeting, to show that the Council did so as a duty imposed on the Society by Parliament, and not *ex proprio motu.* The meeting referred the propositions back, with instructions to make a further report. Accordingly, the Council having again considered the subject, its propositions will come before the general meeting of the members on the 17th of next month, in Bloomsbury Square. By that meeting, and not by the Council, the matter will be determined, and the question was, what duty, good faith and prudence required them to do. No power existed to take any authoritative vote, except from the members then present. It was not to be assumed, however, that they could have all their own way, and that the matter would end there. He had shown them that both parties in Parliament required regulations to be made, and the Privy Council had, in the letter of January 17th, expressed the opinion that some such regulations were absolutely necessary for the public safety. These being the facts, what would follow the rejection of all regulations? Was it not almost certain that Government would seek new powers, and that another hand than their own would frame the regulations, and seeing how unwilling the Pharmaceutical Society were to adopt them, that their adoption would be enforced by inspection? And who would the inspectors be? The Privy Council was empowered to appoint a visitor to watch the examinations of the Society, and had appointed not a pharmacien, but a medical man. He believed that if all regulations were rejected by the Pharmaceutical Society, the result would be that they would be forced upon them, and that a medical man would be authorized to come behind every one of their counters. On the other hand, what was it they were afraid of? He could not conceive any difficulty in observing the regulations. He observed them himself, but if it could be shown that in any shop in the kingdom they could not be easily observed, they ought not to pass without amendment; and he did think that the regulation with respect to dispensing required amendment. No power but Parliament could authorize inspectors to visit them; if they acted in harmony with the Privy Council, he believed that no attempt would be made to do anything of the sort, but if they set at defiance the expressed wishes of Parliament and of the Privy Council, he had already intimated what he thought would follow. If he thought that there was the least prospect of their being able to influence the Privy Council he would be glad to join in representing the objections which were so strongly entertained.

Mr. CHARLES SYMES, Ph.D., moved an amendment. He said,—Last year I voted against them as a compulsory measure. As being new and untried, we could not tell how they would work; now we have had opportunity for a twelvemonth's trial, and no one who has adopted them unbiassed can say they are impracticable; indeed, it is admitted by all that they are good, but should emanate as a recommendation from the Council and be left for voluntary adoption. For twelve months they have been precisely in this position; and now let me ask, have one-half of the chemists throughout the country given them a trial? Nay, I venture to say, not 50 per cent. have ever read them carefully through, or thought about them other than as an oppressive measure, which, if passed into law, would rob them of their liberty. What then becomes of the voluntary system? Many improvements have been suggested, but all fall short of effectiveness and simplicity compared with the original regulations; to get at any proper idea of the remedy we must first ascertain the cause. You speak of education as the only remedy (no one is a stronger advocate for education than myself); but let me ask you, gentlemen, do not educated men make mistakes? The true cause of 90 per cent. of the accidents (so called) is not ignorance but preoccupation of the mind; the persons who commit them are thinking of something else; and anything which brings a man back to a remembrance of what he is doing must be, to a great extent, an important and effectual remedy. But, gentlemen, this is a question in which principle and honour are involved; it is a fact which it is impossible for any candid man, who would take the trouble to inquire into the matter to deny, that it was part and parcel of our arrangement with the Government at the passing of the Act, that some compulsory regulations should be adopted. We have made a bargain (a bad one, if you like to think it so) as binding as any between man and man; let us then in all fairness as honourable and honest men carry it out. Some jealousy exists on account of the exemption of dispensing medical men. I should be very sorry to associate the dispensing of the surgery with that of the pharmacy; the public know something of the difference even now; but the fact of this law not applying to the surgery, and that medicines and lotions were sent from it in similar bottles, would only serve to make more vivid that line of demarcation which already faintly exists in the public mind and would be of considerable benefit to us. Mr. Symes then moved the following amendment:—"That this meeting approves of the proposed poison regulations as suggested by the Pharmaceutical Council."

Mr. WRIGHT said that for the sake of seeing how many would support it, he would second the amendment, though he should vote against it.

Mr. SUMNER said that whenever this question had been discussed, it was always necessary to fall back upon education, and that was the only safeguard. He did not for one moment suppose that the Government would pass any law making such regulations compulsory; they had altered their opinions since last session, and he thought they would settle this matter much in the same way as they had the control of the railways, and conclude that no man was more competent to take charge of his poisons than the qualified pharmacist himself. It appeared to him that the Pharmaceutical Council thought it better to teach the hand, and leave the head to Act of Parliament for protection, in case of a mistake being made.

The resolution was supported by Messrs. Ball, Jones, Holt, Wright, and was carried by a large majority.

Three votes only were accorded for the amendment.

The SECRETARY was requested to send a copy of the resolution to the President of the Pharmaceutical Society, to be read at the Annual Meeting in May next.

Mr. HAMPSON, of Manchester, who attended as a delegate from the "Chemists' Defence Association," being called upon, urged the importance of united action; invited those present to join the association, and several members were enrolled.

A vote of thanks was unanimously passed to the Chairman and the proceedings terminated.

MEETING OF CHEMISTS AND DRUGGISTS IN LONDON.

A Meeting of Chemists and Druggists, which had been convened by a circular, for the purpose of discussing the proposed Poison Regulations in anticipation of the Annual Meeting of the Pharmaceutical Society, and considering what steps were desirable in reference to them, was held on Monday last, March 20, at the Freemasons' Tavern, Great Queen Street.

On the proposition of Mr. Vizer, seconded by Mr. Bland, the chair was taken by Mr. S. C. Betty.

The Chairman, having read the circular calling the meeting, said the object of the meeting was to consider the compulsory regulations submitted by and through the Pharmaceutical Council, and to determine what action should be taken in reference to them. On previous occasions it had been the salutary custom of the pharmaceutical body to pay all deference to, and acquiesce in any proposals or resolutions emanating from its Council, which had thus been practically acknowledged to be not simply a body of delegates, but of gentlemen elected to sit in council, and to initiate those measures which their professional experience dictated as requisite for promoting the good-working of pharmaceutical institutions; but these sympathizing and co-acting conditions were liable to become developed into mistrust and opposition by what was open to the suspicion of being a foreign element in their governing body. In such a case, questions would arise of vital importance to the well-being of pharmacists, forcing themselves upon their most serious consideration,—such an occasion he believed was the present one. And whilst giving all credit to the Pharmaceutical Council for a desire to do what it considered a duty urged upon it, perhaps by a feeling of conviction, certainly by a chivalrous sentiment of plighted honour, they were fain to raise a wider issue, and now when the Council challenged a verdict, to argue this question, not in the light of a compact to which they were no parties, but as one between chemists and druggists, on whom these compulsory regulations would fall, and the public in whose interests they were proposed. The resolutions offered for acceptance would, from their nature, elicit such practical arguments and illustrations as a knowledge of every-day business would suggest. He would anticipate them but briefly. They might labour at the onset under the disadvantage of appearing to advocate a narrow or a selfish policy. The exhaustive debate that must ensue on this question, would, he doubted not, entirely dispel such a notion. Every speaker would be able to state that he now adopts some plan in the storing of poisons, which, being voluntary, must, in his case, be practical and effective. An argument had been deduced from this practice. It was said that a custom so prevalent must have some merit to recommend it; it was instigated by a motive to do what is morally right, and we cannot logically object to a law that only puts such a moral obligation in a substantive form. But they pleaded to be as diligent in the discharge of their public duties as is any other body in the State; that penal laws should be enacted to meet conditions of a proved necessity; above all, that unless they are consonant with the public feeling of what is right and just, by being indiscriminate in their operation, such laws degenerate into *dilettante* legislation; and, in view of attempts at such legislation, it was their duty to defend, as best they could, the interests and social rights of the trade. Their successors would otherwise censure those who consented to or promoted the Pharmacy Act of 1868, justly upbraiding them that they left this sting coiled up in the provisions of the Bill. At the time of the passing of the Act, chemists and druggists thought, after the numerous hostile motions (and some had no other object than to render its operation impossible, and thus strangle the Bill) had been defeated by formal voting at the time they were proposed, that all the contemplated statute-safeguards which could, consistently with the scope of the Bill, be imposed upon us, had been exhausted: otherwise attempts would have been directed to obtain some mitigation of those cumulative penalties that would attach to other and undefined regulations. They believed the essence and the intention of the Pharmacy Act to be educational; they did not assert that accidents could be wholly avoided solely by a previous technical education, but they did assert that the thorough theoretical and practical training now demanded, begot an intimate acquaintance with the nature of their trade articles, and enabled them, so far as human foresight and intelligence permit, to be the guardians of the public safety. The present law permitted the shirking of no obligation attached to their calling. They invited all aid in recommendations which they might systematize, and they were confident that the discussion and decision of this question would prove how little the Pharmaceutical Society was unmindful of its duty to public demands or to the great body of chemists and druggists.

The first resolution was proposed by Mr. Collins, seconded by Mr. Urwick, "That in the opinion of this meeting the advanced educational qualification of chemists and druggists as provided by the Pharmacy Act of 1868, together with their personal and legal responsibilities, render any 'compulsory' regulations for the storing and dispensing of poisons unnecessary and undesirable and, as a protection to the public, illusory. And this meeting affirms that, whilst it would regard any well-digested 'recommendations' upon the subject with attention and respect, it pledges itself to oppose most strenuously the proposed 'compulsory' regulations of the Pharmaceutical Council."

Mr. J. R. Collins, in presenting the resolution for acceptance, said that it had been most carefully drafted so as to embody objections to compulsory poison regulations which must be patent to all who are engaged in the trade. Time was when the qualifications of chemists and druggists might with justice be challenged; when many, if not most, of those calling themselves chemists knew but little of chemistry, or of the nature and properties of the drugs they were daily compounding. Among such a class of men "regulations" might have been useful; but for thirty years many present, and many now no more, had laboured to improve the technical education of their brethren, till at length, in 1868, what had been voluntary effort was rendered compulsory by the Pharmacy Act, which provided that no person should, for the future, carry on the business of a chemist and druggist without having given evidence of fitness to the satisfaction of competent examiners. Surely this was the best kind of protection, both for themselves and those who employed them. For ill-informed men mechanical contrivances might be necessary, but scarcely for the educated and well-informed. Mind must be superior to matter; and sand-paper, angular bottles, fluted or plain, could not compare as a protection to educated intelligence. To enact that poisons of all kinds should be sent out in particular bottles must end in confusion, as no legislation could prevent these poison bottles from being used for different purposes. The resolution affirmed compulsory regulations to be unnecessary; upon those who affirmed the contrary must the burden of proof rest. Was the Council prepared to say they were necessary? Did not its "Reasons" rather show that it was impelled to take action by the provisions of some "secret treaty" of which they knew nothing, and therefore could not be bound by? They were free to repudiate conditions which had not been communicated to them. The assumption that Clause 1 of the Pharmacy Act committed them to accept compulsory regulations for the "keeping, dispensing and selling poisons" was a delusion; it merely enacted that, should the Pharmaceutical Society think such regulations necessary, the Privy Council was authorized to render such regulations compulsory and legally binding upon all concerned. From the nature of their business they were habitually careful, and needed neither whip nor spur to keep them straight; the liability to compensate the victims of carelessness was a terrible reality, which was always staring them in the face. It was marvellous how seldom mistakes occurred among them, showing how close was the supervision exercised in their vocation. He thought the Council guilty of a moral cowardice in countenancing for a moment the idea that any other safeguard for the public was necessary; and, how much soever they might regret it, they must endeavour to make such an impression upon the Council by the rustication of the advocates of compulsion as would place that body more *en rapport* with the sentiments and interests of its constituents than it appeared to be at present. It was most insulting to them, as educated men, to be told that they could not be trusted to manage the details of their business, and that, in the interests of society, they must be bound by a chain of regulations enforced by penalties; that they should be subjected to inspection, whilst apothecaries, who probably supplied three-fourths of the compounded medicines consumed by the public, were to be let alone, presumably as being more trustworthy than themselves. He emphatically protested against such assertions or assumptions, and without egotism claimed for himself and his craft that they were second to none in the practice of their art. They did not profess to be physiologists, anatomists, or physicians, but as pharmacists they would yield precedence to none. He trusted he had succeeded in establishing the propositions laid down in the resolution; and if so, he would ask most earnestly those present to give effect to their approval by attending the Annual Meeting in May, recording their votes in favour of the foes to compulsion, and most resolutely negativing root and branch the compulsory regulations which were sought to be imposed on them. There were ten thousand chemists and druggists who would be equally affected with themselves by these regulations, but —not possessing the franchise—were unable to protect themselves as they were. As the mover of the resolution in 1868 which reconciled the differences between pharmaceutical chemists and chemists and druggists, and resulted in the Pharmacy Act, he felt specially bound to regard the position of those who had no votes; those who elect the Council should consider themselves as exercising an important trust, and vote only for those candidates who on this question represented their views, and if both town and country were united, they would not fail to set this vexatious question at rest once and for all.

Mr. Urwick, in seconding the resolution, said the regulations were uncalled for, and had never been suggested as necessary. If what Mr. Reynolds had stated was true that some of the articles on the subject were written by members of the Pharmaceutical Council, such conduct was disreputable. Chemists and druggists were qualified by education to conduct their own businesses without the interference of Downing Street. Every person had his own way of conducting his business, and what was safe for one might be unsafe for another. He considered that self-interest was the strongest possible motive for carefulness. The Council in their "Reasons" said that similar precautions to those recommended were probably adopted already, and it was asked why should they be objected to? But he would ask if such were the case, where was the necessity for interference? As to the statement that if adopted they would not be enforced, that was mere child's play. He considered that as a body, they were bound to set their faces against compulsory regulations.

Mr. Page supported the resolution.

Mr. Bland, speaking of the use of particular-shaped bottles, said there was no connection between the shape of such bottles and their contents. They were already used by perfumers and others, and he considered it would be impossible to educate the public to their use.

Mr. Fitch said that a customer coming for a small quantity of laudanum to a chemist and druggist, and being told that he must pay for a poison-bottle, would go to the apothecary where he could get it without such restriction. It had been said that the Pharmacy Act would give them a monopoly of the sale of poisons, but it had not been put in force. He knew of a barber's shop where a large quantity of cantharides was displayed in the window and marked for sale at 6*d.* per ounce.

Mr. Lewis said that he had recently purchased for 2*d.* at an oilshop, an ounce of oxalic acid, which was sold without name or label.

Mr. Vizer wished it to be distinctly understood that the meeting had not been called to load the Council with abuse, but calmly to discuss this very important question. As in days gone by the members of the Society by examination had voluntarily expressed their willingness to give up privileges, which had cost time and money, for the benefit of the trade at large; so now they desired to raise their voices to protect the privileges which they enjoyed for the benefit of future generations. The first words uttered by the President at the last Annual Meeting were to this effect:—"That the avowed objects of the founders of the Society were the amelioration of the condition, and the elevation of the character, of those professing pharmacy; and the means suggested for carrying out these objects were, first, to unite the whole of the chemists and druggists into one body; and, secondly, to organize a system of education, and claim for the qualifications thus obtained certain privileges." It seemed to him another clause might have been well added, viz. having brought the whole body of chemists and druggists under their paternal wing, to strip them of every vestige of self-respect and moral responsibility, and to convert them into mere machines driven by "official" power. They were told by the Council that if they would acquiesce in these regulations "no vexatious proceedings would be adopted to inquire into their observance." If ever a Council betrayed weakness, it had been exhibited in such puerile utterances as these, —to tell us with one breath the resolutions must be absolutely compulsory, and with the next that although compulsory, nobody would desire to ascertain how far they were really carried out. What was that but to hamper and increase risk of accident to those desirous of obeying and faithfully carrying out the law; whilst those who disregarded all precautions now (if such there be) would snap their fingers at these most compulsory regulations, and would go about their daily business unfettered, and far less liable to accident than the man whose mind was full of rules and laws to be observed at his peril? For his own part, if these regulations were forced upon them, he would hold up both hands for their being carried out under the strictest surveillance. The sale of poisons by grocers and oilmen was but an illustration of the point; the first clause of the Act restricted sale of such articles to chemists. Why was it, then, they found them sold without let or hindrance by grocers, but that the Pharmacy Act was not enforced? He considered it the absolute duty of the Pharmaceutical Society to use means for preventing this disregard to law. They were told that should they meet with an accident, the law would regard them tenderly, whilst the utmost rigour of the law would fall upon the disobedient; he presumed, the law considered we paid annually dearly enough by the constant extra anxiety. Again, they were told the public was clamorous for protection. This he distinctly denied as an untruth; that certain medical journals had contained unwarrantable articles he would admit, and considered it most unjust that the Pharmaceutical Journal should reprint such without one word of comment in defence of their interest, but further than the columns of such not one word was heard; and, after an experience of over twenty years, he could positively assert he had hardly once been seriously asked by the public what precautions he used to protect them from danger Mr. Vizer then referred to the answer of Jacob Bell to

Parliamentary Committee, "That he would never put up a fence unless it were strong enough to bear leaning against;" and a remark of Mr. Squire, that it was transferring a man's brains from his head to his fingers. He also alluded to a letter from Mr. Ince in the *Chemist and Druggist*, where it was said,—

"That any pressure from without should admire "and seek to bind on others mechanical substitutes "for intelligence excites no surprise; but that educated "men should endeavour to be chained up as dan-"gerous individuals, and should provide their own "fetters, seems an attitude at once humiliating and "unaccountable."

In the event of the regulations being made compulsory at the Annual Meeting, Mr. Ince suggested the proposal of the following resolution:—

"That our educational system be discontinued, hav-"ing proved ineffective either as regards the training "of pharmacists or the consequent safety of the pub-"lic, and that the commanding premises situate in "Bloomsbury Square be put up to auction."

He concluded by stating that common sense asserted the supremacy of a properly-educated mind stored with real solid acquaintance with the nature and properties of the substances with which it deals, over any mere mechanical arrangements that could by any possibility be devised; and he believed that had the Council met the very first suggestion of Dr. Simon with a straightforward explanation of facts, showing the improving educational status of the chemist, and the increasing desire and willingness on their part to adopt any practical suggestion, the rarity of accidents, and the natural repugnance with which such regulations were viewed by an intelligent body of men, whose qualification their own diploma certified,—had they thus acted the present meeting had never been needed.

The resolution was then put and carried unanimously.

The second resolution was proposed by Mr. Quiller, seconded by Mr. Wade, "That an Association be formed, to be called 'The Metropolitan Chemists' Defence Association,' instituted to protect the London trade from 'compulsory regulations for storing and dispensing of poisons;' and to co-operate with Provincial Associations formed for the same purpose."

Mr. Quiller believed that both the Privy Council and the Pharmaceutical Council meant to do good. But poisoning had not increased lately, and during the last ten years had been extremely rare. Neither was there any popular feeling on the question. He found by reference to the Calendar that already they were subject to eight Acts, and these were enough without any fresh enactments. He referred to a case recently reported in the Pharmaceutical Journal, which he thought would not have occurred previous to the passing of the Pharmacy Act, as no chemist would have ventured to supply so large a quantity of prussic acid to a stranger. But now he had only to produce his book and show that he had complied with the law. The organization proposed was not meant to be a permanent one. He for one would not lend his influence to assist in opposing the Pharmaceutical Society. He had a great respect for it and the Council, and he believed that to them they were much indebted for the position they now enjoyed. But it was simply meant to keep a watch upon this present subject, and he thought they might do good service by uniting together to secure the election of good representative men to sit on the Council.

Mr. Wade, in seconding the resolution, referred to the feeling manifested last year at the Annual Meeting against any such regulations, the wishes of which meeting he said the Council had not carried out. Never was there so strong opinion in the trade upon any question as upon this one throughout the country. Manchester, Norwich, Maidstone, Newcastle, and other places were organizing opposition, and London ought not to be behind. It was not intended to throw any slight upon the Pharmaceutical Society, but to secure the placing of such men upon the Council as would put on one side for ever all such restrictions upon their business.

The resolution was carried unanimously.

The third resolution was proposed by Mr. Patterson, seconded by Mr. D'Aubney, and carried unanimously, "That an Honorary Secretary and Treasurer, an Executive Committee consisting of twelve members of the Association—four to form a quorum,—and a general Committee, with power to add to their number, be appointed."

The fourth resolution was proposed by Mr. Bland, seconded by Mr. King, and carried unanimously, "That Mr. Vizer be appointed Hon. Secretary, Mr. S. C. Betty, Treasurer, and the following gentlemen members of the Executive Committee, Messrs. J. R. Collins, John Wade, W. W. Urwick, J. Beddard, Henry King, J. Bland, W. H. Froom, Geo. Pattison, Thos. D'Aubney, J. Owen, S. Greenish, and C. R. Quiller."

The fifth resolution was proposed by Mr. Lynch, seconded by Mr. Cawdell, and carried unanimously, "That every subscriber of 2*s.* 6*d.* and upwards be a member of this Association.

The sixth resolution was proposed by Mr. Vizer, seconded by Mr. Bland, and carried unanimously, "That the Executive Committee be requested to make choice of such gentlemen as they may consider would represent the correct feeling of the trade and its general requirements. And this meeting pledges itself to support their candidature at the forthcoming election for the Pharmaceutical Council."

Mr. Vizer stated it was very important at all times in electing a new Council to bear in mind that a considerable number of the gentlemen should be resident in London. Through a strange coincidence, the result of the ballot, by which seven old members are annually chosen to remain, had this time not left one London member; and as the greater part of the real business of the Society was conducted at the Committee meetings which met frequently, it was of the utmost consequence that a sufficient number should be elected who were within easy access of Bloomsbury Square. He hoped therefore that members of the Society would not omit to support the gentlemen whose election would be advocated by this Association in concert with Provincial Associations; the list would comprise a due proportion of London and country representatives.

A gentleman present rose and asked why the papers issued by the proprietors of the *Chemist and Druggist*, asking for the opinion of the recipients as to the proposed poison regulations, had been sent to medical men? He thought that it was a question that concerned chemists and druggists alone.

The Chairman said he was authorized to state that such was not the case. The issue had been confined to persons on the Register of Chemists and Druggists.

The gentleman replied that he knew of instances in which they had been received by medical men.

At the close of the meeting, several gentlemen came forward and paid in contributions towards the funds of the proposed organization.

The Bunya-Bunya (*Araucaria Bidwilli*), a native of the northern district of New South Wales, is of considerable interest, as being the only hereditary personal property possessed by the natives, who greedily devour the fruit, either raw, or roasted and made into cakes. This fruit is only plentiful every third year; and at the proper season the aborigines assemble in considerable numbers for the purpose of obtaining it. Each tribe has its own set of trees, and each family its particular individuals among them; and these are handed down from generation to generation. The right of ownership is almost universally respected; but occasional depredations occur, when a fight ensues, the sympathies of the bystanders going with the lawful proprietor.—*Nature.*

The Pharmaceutical Journal.

SATURDAY, MARCH 25, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PROPOSED POISON REGULATIONS.

THE foregoing pages of our present number, together with some reports published in previous numbers, will afford sufficient evidence of a very general response to the circular of the Council calling the serious attention of the members to this question as one demanding early and definite settlement. The Pharmaceutical *vox populi* is at length making itself heard, and we may gather from the resolutions passed at the various meetings, that British pharmacists are to a large extent resolved to oppose the application of compulsory regulations. We consider it unnecessary to enter upon any discussion of the reasons which have been advanced either for this opposition, or in favour of the proposed regulations being adopted, for the arguments, on both sides, have been worn threadbare, and they may be fully studied in our correspondence columns.

But we would especially urge upon our readers the desirability of putting an end to the state of disquiet prevailing in regard to the matter of poison regulations, inasmuch as we consider it is a state fraught with possible danger to the best interests of the craft, one already showing signs of incipient disunion and anarchy.

As regards the action of those concerned, it seems to us the case is very simple, and that much of the argument we have heard is superfluous. The Pharmaceutical Society, having been by law constituted the body to prescribe regulations, with the consent of the Privy Council, it is obviously the duty of its members individually to exercise, at the coming meeting, the power they have of deciding the question, in accordance with the provisions of the Charter. To fail in doing this would, we consider, indicate an inadequate appreciation of the privileges belonging to members of the Society. In like manner we cannot attach much weight to the complaint that a large portion of the trade may be legislated for, and subjected to compulsory regulations by, a body consisting only of a much smaller number, for this complaint is urged with an assumption that the Pharmaceutical Society, as a body, is in favour of the proposed regulations, or that its members will neglect to exercise their power of self-government; while, at the same time, it is still more seriously invalidated by the circumstance that those who complain thus fail to avail themselves of that power to influence the action of the governing body which is open to all registered chemists and druggists. Such reticence, in either case, might well be construed as indicative of indifference to the general interests of the trade, or even as a practical disbelief in the objections to any measure complained of.

We feel the more called upon to dwell on this point since there is one feature of the meetings that have been held which we look upon with much satisfaction, as showing that progress has been made towards the establishment of a creditable *esprit de corps* among all classes of pharmacists. We refer to the almost unanimous expression of respect for the Pharmaceutical Society and for its Council, and to the candid recognition of its good intent and of the service which it has rendered to the trade generally.

Although these meetings have represented a certain degree of antagonism, it has not been of an unwholesome nature, and we have had no exhibitions of stump oratory or abuse, neither has there been any opportunity afforded for parasitic attempts to make trade grievances or difference of opinion amongst members of the trade a battening ground for the promotion of sordid individual interests.

We trust that the good feeling thus manifested will become even still more apparent, and that, by the time when the Annual Meeting takes place, all who take a hearty interest in the question now so prominent, will have resolved to avoid the reproach of unseemly contention—that in place of joining with the medical journals in censure of our Society and its Council, they will devise means of supporting the view they take to be the right one, by a peaceful exercise of their privileges in a way calculated to command respect as well as the confidence of the public in the propriety of British pharmacists being, as a body, entrusted to provide for its safety in regard to the sale, storing and dispensing of poisons or medicines of dangerous potency.

DISPENSING.

WE have much pleasure in drawing the attention of our readers to the remarks upon dispensing, by Mr. W. J. HALLIDAY, in our issue of last week. Our younger friends in particular may peruse some of them with profit, especially those parts drawing their notice to care in dispensing, cleanliness in the matter of labels, bottles, etc., the weighing of powders, and the best mode of proceeding in mixing ointments, essential oils, etc.; but there is a great deal more to be learnt, as the paper explains, than mere manipulation, although dispensing has occasionally been spoken of as a mere mechanical operation. Mr. HALLIDAY points very clearly to the fact that the art of dispensing prescriptions is not born with a youth, and that there is no royal road thereto; on the contrary, that it requires much care, tuition, practice, and discrimination,—that not only the desire, but also the actual opportunity, of practising and perfecting it are necessary. We go further than this, in thinking that, to make a thoroughly good dispenser, it is necessary that he should have some opportunity of seeing, not only how dispensing is practised in different localities, but also the systems adopted at different establishments in the same locality; and here Mr. Halliday's caution to young men not to commence business too soon comes in with good force. But even this is not all, for the mode of prescribing, and the remedies employed, are constantly varying; the formulæ of prescriptions used a quarter of a century ago are nearly obsolete now, and so a similar change may follow in another quarter. Thus, he who was a pupil years ago, finds himself a pupil once more with regard to the material upon which he operates. It is not our intention to specify now these particular substances or forms of medicines; sufficient has been stated to show the kind of training a good dispenser requires, and the material of which he should be made. However, it is not to be expected we can all be A 1 dispensers, neither is it needful that it should be so. But it is desirable that the time should come when all dispensing should be performed by those educated and trained for the purpose; and whether the prescriptions in particular towns or districts be few or many, or not even one a week, taking an extreme case, it is still desirable that the one should be dispensed with as much care —for it may be a most important one—as though there were from ten to twenty per diem. This is only one part of the duties of a pharmaceutist, to this only at present do we desire to point our observations.

We have reserved for the last that portion of our correspondent's communication which is surrounded with the greatest amount of difficulty. Thus far we have sailed with him in still waters. The difficulty is this: how are our apprentices to learn the art and practice of dispensing in those places where there is none to be done, or rather where it is monopolized by the apothecary? Well, we confess this is a very difficult question—almost a poser. Our correspondent offered two suggestions: one, that the Pharmaceutical Society should use its influence to alter the system of dispensing by apothecaries, or, in other words, to obtain the dispensing in its entirety for the chemists. Now, without desiring to throw one drop of cold water upon this suggestion, we think he can scarcely recognize the full difficulty of the task. We conceive that to accomplish this the apothecary must be somewhat raised in his position, so as to be able to live without dispensing, and the public convenience also consulted; in some places, especially poor ones, the inhabitants with large families can hardly do without the apothecary and his annual, ofttimes small and sometimes unpaid account. Our correspondent's second suggestion is that the Manchester Chemists and Druggists' Association should establish a dispensing counter where associates might obtain the required knowledge. We think such a course would not be necessary in London, as pupils attending Bloomsbury Square have already many advantages, and London is, *per se*, the very place where junior assistants of every standard may, if so disposed, find situations to suit them. Help, when required, should be given, and we think freely given, where it can be done advantageously and fairly. We are now entering upon more delicate ground still. The pharmaceutist who takes an apprentice should have within his reach the means of teaching him the business, not the preliminary education,—he should have gained that at school,—but the actual business. There are many things to be taught besides dispensing, and at a very small outlay. Upon a future occasion our attention may be turned in the direction of those other points, and not dispensing. Upon this but a few words more. We have, in our experience, known small establishments where the dispensing formed but a minute portion of the business, and where the opportunities of acquiring practical dispensing knowledge were very limited. The following plan was adopted:—Pharmacopœia pill-masses were dispensed, and the ingredients mixed in small quantities, as if from a prescription, divided, put up and directed in due course, though never sent out; imaginary mixtures and lotions after the same process; plasters were spread upon brown paper, and without shapes. When cold, the plaster was recovered, and worked over and over again, until the tyro could spread a good plaster, with a steady hand and straight eye, without a shape. An intelligent industrious youth with practical business habits, will make himself a good dispenser, but he must be content to become so by degrees. We prefer, as we believe many others do, a *well-trained* country youth, pliable and not wedded to preconceived ideas. Such a junior will, with perseverance and good guidance, make a first-rate assistant, not merely able to dispense, but also to attend to his employer's interests in every department of the *shop* or pharmacy.

PHARMACEUTICAL LEGISLATION IN AMERICA.

In continuation of our *résumé* of the Ontario Pharmacy Bill, we now give the substance of the two clauses relating to the sale of poisons. In a schedule attached to the Act, these are divided into two classes. The first class is subject to precisely the same regulations as apply to the sale of poisons contained in part 1 of Schedule A of the English Pharmacy Act. This class includes hydrocyanic acid, aconite and compounds thereof, tartrate of antimony, arsenic and compounds thereof, corrosive sublimate, digitaline, ergot, Indian hemp, morphia and its salts and solutions, strychnine and nux vomica, savin and preparations, veratria, and oil of cedar. The second class includes those articles which can be sold without restriction by registered druggists, but cannot be sold by any other. They are oxalic acid, belladonna and compounds thereof, Calabar beans, cantharides, chloroform and ether, conium and preparations thereof, croton oil and seeds, cyanide of potassium, euphorbium, elaterium, Goulard's extract, hyoscyamus and preparations, hellebore, iodine, opium and its preparations (not including paregoric), podophyllin, iodide and bromide of potassium, St. Ignatius's bean, santonine, scammony, stramonium and preparations, valerian, verdigris, sulphate of zinc, acetate of lead, and pink root. The Council of the Ontario College of Pharmacy is empowered to add to the number of the above poisons, and from time to time to declare, by resolution, that any other article ought to be deemed a poison within the meaning of the Act. Such resolution, subject to the approval of the Lieutenant-Governor, to take effect one month after it shall have been advertised, together with the Lieutenant-Governor's approval, in the *Ontario Gazette.*

Compounds mentioned in the British Pharmacopœia are to be dispensed according to the formula directed in the latest edition of that work, unless the College of Physicians and Surgeons shall select another standard, or distinct instructions are given to the contrary.

A clause allowing chemists and druggists to sell wines and spirits, and another exempting them from penalties for selling adulterated drugs were struck out while the Bill was in committee.

In various parts of the United States, there is considerable agitation just now in reference to the enactment of laws regulating the practice of pharmacy and the sale of poisons.

We read in a New York contemporary, under the heading "The Murdering Drug Clerks," that a Bill has been introduced into the Legislature for the purpose of shielding the "public from the ignorant drug "clerks, who manage from time to time to kill some "miserable patient of a neighbouring physician by "mistaking a poisonous drug for a gentle physic "powder." The Bill refers only to New York city, and directs the mayor and commonalty to appoint two skilled pharmaceutists, two practical druggists and two regular physicians as an examining board for the examination and licensing of all persons now or hereafter to be employed by any druggist or keeper of drug stores. It enacts that, thirty days after the organization of such board, it shall be illegal to employ any person as a clerk in a drug store who has not passed an examination and received a certificate of competency. It is also made illegal for any other than a prescription-clerk to make up prescriptions. The penalties proposed for the infringement of the provisions of this Bill are a fine of not less than five hundred dollars, or six months' imprisonment, or both, at the discretion of the Court. This Bill, which we are told will undoubtedly become law, does not appear to deal with the qualification of principals, but only of the persons employed by them.

In New Jersey a Bill has been brought forward, which has met with strong opposition on the part of some physicians, from its requiring all to pass an examination who shall hereafter open apothecaries' stores; the physicians claiming that they should be exempt and at liberty to open as many stores as they please.

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

March 15th and 17th, 1871.

Present (15th)—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Edwards, Gale, Garle, Hanbury, Haselden, Ince and Southall.

Dr. Greenhow was also present, on behalf of the Privy Council.

(17th)—Messrs. Allchin, Bird, Cracknell, Davenport, Deane, Edwards, Gale, Garle, Hanbury, Haselden and Ince.

Five candidates presented themselves for the Major Examination and thirty-four for the Minor; the following twenty-four passed, and were declared to be duly qualified to be registered:—

MAJOR (as a Pharmaceutical Chemist).

Scott, Walter ....Elgin.

MINOR (as Chemists and Druggists).

	*Howorth, George Buxton	Chertsey.
	*Hulme, Richard Gleave	Hammersmith.
	*Ground, William Davie	Grantham.
	*Clarke, George Ernest..........	Stowmarket.
	*Hetherington, Martin Luther ..	Highbury.
	Holmes, Nathaniel Wheatcroft ..	Grantham.
	Jaques, William	Beverley.
	Maddison, Henry Gildon	London.
	Hill, William	Louth.
Equal.	Bothamley, Richard Broughton ..	Guildford.
Equal.	Wrighton, Charles Edward	Birmingham.
	Woolley, Harold	Manchester.
	Miller, Nathaniel.............	Preston.
	Guy, Frederick................	Louth.
Equal.	Bird, Matthew Mitchell	Lynn.
Equal.	Constance, Herbert Edward	London.
	Earee, Edwin Thomas..........	Staines.
	White, William Henry	London.
Equal.	Jasper, Frederick William	Penzance.
Equal.	Wilkins, George..............	Stratford-on-Avon.
	Farrow, Charles Henry	Diss.
	Churchman, James	London.
	Pound, Henry William	London.

The above names are arranged in order of merit.

FIRST, OR PRELIMINARY EXAMINATION.

Certificates presented by the undermentioned were accepted in lieu of this Examination:—

Beall, Samuel Smart ....Cambridge.
Evans, Thomas ....Salford.
Harrington, Arthur Lewis ......Rochford.
Kingzett, Nathan Izod ....Birmingham.

* Passed with Honours.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

A General Meeting of the Association was held on Friday, March 10th; Mr. Stoddart, President in the chair.

The minutes of the previous meeting were read and confirmed.

The President exhibited and handed to the Honorary Secretary for present custody, the Book of Prescriptions, collected by Joseph Ince, Esq., and presented by that gentleman to the Bristol Pharmaceutical Association; and a resolution was immediately adopted requesting the Honorary Secretary to acknowledge its receipt and to convey the best thanks of the Association to Mr. Ince for his handsome and valuable gift.

The subject of the death of the late Dr. Symonds was introduced by Mr. Giles, and the following resolution was unanimously adopted, the members and associates all rising in token of their assent to the expressions of respect it contained. Resolved,—

"That the Bristol Pharmaceutical Association desires to express its sense of the public loss occasioned by the death of the late Dr. Symonds, and particularly to acknowledge the respect and reverence in which his memory is held by the pharmacists of the city in which his long and distinguished professional career was pursued."

It was also resolved,—

"That the Hon. Sec. be requested to communicate the preceding resolution to John Addington Symonds, Esq., accompanied by an expression of respectful sympathy in the personal affliction which has fallen upon himself and his family."

A lecture was then delivered by Mr. Wm. Lant Carpenter, Esq., B.Sc., upon "Respiration Chemically and Physiologically considered." At its conclusion, a cordial vote of thanks to the lecturer was carried by acclamation.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

An unusally well-attended Meeting was held in the Council Room, Mitre Chambers, on Thursday evening, March 16th, to discuss the "poison regulations" question.

The President, who was in the chair, after making a few preliminary remarks, called upon the Secretary (Mr. B. H. Cowgill) to read a short paper he had prepared upon this important subject. He showed at some length how disadvantageous, to by far the greater number of chemists, any such compulsory regulations for the keeping and dispensing of poisons, as those recommended by Mr. Simon, would necessarily become. He did not think that however severe the regulations might be made, they would in any way diminish the number of accidents which occur under the present system; that number being so very small in proportion to the prescriptions dispensed and the amount of business done with those dangerous drugs, the "poisons." He was of opinion that the great responsibility necessarily felt by each individual chemist, and the great precautions taken, as a rule, in the keeping and dispensing of poisons, was of far greater importance and much more weight than anything which would be embodied in any "compulsory measures."

Mr. Clark said he should like to be informed what was the good of all future chemists being obliged to educate themselves to pass examinations, which examinations are considered to be the test as to their capability of becoming chemists, if such regulations as those previously mentioned are to be imposed upon them.

The Secretary was also supported in his views by Mr. Harrison, Mr. Lane, Mr. Yeats and others.

The following resolutions were then put to the meeting and passed unanimously:—

First resolution, moved by Mr. Midgley, seconded by Mr. Yeats.

"That this meeting is of opinion that any compulsory regulations for the keeping and dispensing of poisons are entirely unnecessary, either as a safeguard for the chemist or in the interests of the public."

Second resolution, moved by Mr. Lane, seconded by Mr. Clark.

"That this meeting is of opinion that the standard of efficiency required by the Pharmacy Act, 1868, is a sufficient guarantee as to the fitness of a chemist in the keeping and dispensing of any poisonous drugs required in the transaction of his business.

Third resolution, moved by Mr. Harrison, seconded by Mr. Allcock.

"That this meeting is of opinion that, should any such regulations be enforced, they would be most offensive and objectionable to members of the trade generally."

Fourth resolution, moved by Mr. Lane, seconded by Mr. Midgley.

"That a special fund be raised in connection with this Association, to be called the Defence Fund,—the proceeds of which, after paying any incidental expenses, shall be handed over to the Chemists and Druggists' Defence Association to aid them in their object."

The Secretary proposed, which met with the entire approval of the meeting, "That the above resolutions be formed into a petition and signed by the chemists' assistants of Manchester as an expression of their views upon this subject; that Mr. W. S. Brown be invited to present the same at the Council Meeting of the Pharmaceutical Society."

The proceedings then terminated.

Proceedings of Scientific Societies.

QUEKETT MICROSCOPICAL CLUB.

The Annual Conversazione of this Club took place at University College, on Friday evening, and was very largely attended, as it usually is. The objects provided by the club for the entertainment of its guests, comprised all the optical novelties of the year, and the members as well as the leading opticians did all in their power to exhibit objects worthy of the position the Club claims in the encouragement of microscopical science. Photography was on this, as at the last Annual Soirée, well represented. A large and interesting series of photographs of Indian temples and scenery was kindly lent by the India Office, also frames of photographs were lent by Mr. J. Van Voorst, Mr. John Foster, Mr. E. Kiddle and Mr. A. Shapcott. Mr. Apps exhibited, at frequent intervals, the marvellous electrical effects produced by means of his well-known induction coil.

In the midst of so many attractions it is difficult to single out for especial mention any one feature of interest, but that which seemed possessed, at this time, of surpassing interest was an exhibition on the screen by the oxy-hydrogen light of a series of transparent photographs illustrative of the scenery of the late lamentable Franco-Prussian War, contributed by the London Stereoscopic Company, with an explanatory lecture by Mr. James Martin, and which commanded crowded audiences all the evening.

Obituary.

We regret to have to record the death of Mr. Robert Westwood, of 16, Newgate Street, London, aged seventy-three. Mr. Westwood was one of the founders of the Society, and for the last seven years has been annually elected one of the auditors.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

APPOINTMENT.

Mr. Robert R. Welborn, Associate of the Pharmaceutical Society, to the office of Dispenser at the Dispensary of the St. George's Union, Mount Street. There were six candidates, amongst whom was a medical officer of the Leeds Dispensary.

VACANCIES.

The office of Dispenser at the Leicester Provident Dispensary. For particulars, see advertisement in last week's Journal.

Compounders of Medicines required for the Convict Service. For particulars, see Advertising Sheet, p. 18.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, March 27. — *Medical Society*, at 8 P.M.
London Institution, at 4 P.M.—"On Astronomy." By Mr. R. Proctor.

TUESDAY, March 28. — *Royal Institution*, at 3 P.M.—"The Nutrition of Animals." By Professor Foster.
Royal Medical and Chirurgical Society, at 8.30 P.M.

WEDNESDAY, March 29. — *Society of Arts*, at 8 P.M.—"Woman's Work, with Special Reference to Industrial Employments." By Miss Emily Faithfull.

THURSDAY, March 30. — *Royal Society*, at 8.30 P.M.
Royal Institution, at 3 P.M.—"Davy's Discoveries in Chemistry." By Prof. Odling.
London Institution, at 7.30 P.M.—"Economic Botany." By Professor Bentley.

FRIDAY, March 31. — *Royal Institution*, at 9 P.M.—"Solar Myths." By Professor Max Müller.

Parliamentary and Law Proceedings.

POISONING BY PRUSSIC ACID.

On Thursday, February 9th, Dr. Lankester held an adjourned inquiry into the death of Mr. Lorenzo Adolphus Staunton, who was discovered, on the morning of his intended marriage, dead from the effects of poison. The deceased was bookkeeper at a mercantile house in Great St. Helen's, and on the evening previous to his death was in good health and in high spirits about his marriage, which was to be celebrated next day. In the morning, breakfast was taken up to his bedroom, according to custom, by the servant, who noticed a bottle beside the bed, since found to contain prussic acid. Shortly afterwards, a jeweller called with some ornaments ordered by the deceased for his bride, and when the servant went upstairs to inform him she discovered that he was dead. The *post-mortem* examination made by Dr. Vans Christian Clarke proved that the cause of death was prussic acid. It was also shown that deceased suffered from a cough, for which he was in the habit of taking diluted prussic acid and ammonia in seltzer water, and also that he was suffering from consumption. The contents of the stomach were analysed by Professor E. Rogers, who stated that it contained prussic acid, and that there was enough to cause death. A letter written by deceased to his mother on the morning of his death, spoke of his joyous anticipation of wedded life. It was also shown that deceased was in the receipt of nearly £400 a year. The jury found that death was caused by an overdose of prussic acid taken by deceased for medicinal purposes, and arose from misadventure.—*Times.*

ATTEMPTED SUICIDE BY CARBOLIC ACID.

At Westminster, on Monday last, Maria Norman, aged fifty, was charged with attempting to commit suicide by taking a large quantity of carbolic acid. It appeared that the prisoner was found on the previous Tuesday insensible. She was conveyed to Westminster Hospital, where she said she had taken some carbolic acid.

Mr. F. Wallace, the house physician at Westminster Hospital, said there were severe excoriations in the mouth, lips and throat of the defendant, produced by carbolic acid. He could not tell how much had been taken, or how much would destroy life, as there was only one instance of suicide by this acid, and that in a lunatic asylum.* He administered olive oil as an aperient and to produce reaction. Carbolic acid was an irritant, not a narcotic, and he had great difficulty to prevent the closing of the windpipe, as it produced great irritation of the mucous membrane. The prisoner had suffered from bronchitis since, but was now out of danger.

The prisoner was remanded for a week.—*Times.*

A CHEMIST FINED FOR SELLING A TOOTH-POWDER WITHOUT A LICENCE.

At Richmond, on Wednesday, the 8th inst., Mr. Lloyd, chemist, was summoned by the Excise authorities, under 42 Geo. III. c. 56, for selling patent medicines without a licence. The defendant admitted the sale, but submitted that the article (a box of "Rowland's Odonto") was not a patent medicine within the meaning of the Act, but a tooth-powder. He was further summoned under 24 & 25 Vict. c. 91, for selling methylated spirits without a licence. He contended that he had a right to sell methylated spirits for mixing with varnish, or for similar purposes. The Bench held that all tooth-powders came within the meaning of the Act as patent medicines, and they fined the defendant in the mitigated penalty of £17. 10*s.*—*Medical Times and Gazette.*

HOUSE OF COMMONS.

WINES IN BOND.—*March 16th.*—Sir J. Lawrence asked the Chancellor of the Exchequer whether the Board of Customs had been authorized to sanction the admixture with wines in bond of tannin, ether and other chemical preparations, provided the owners declared that such a mixture was necessary for fining and flavouring the wines.

The Chancellor of the Exchequer said there was no such authority.

THE METRIC SYSTEM.—*March 21st.*—Mr. J. B. Smith obtained leave to bring in a Bill to establish the metric system of weights and measures. The second reading was fixed for the 18th of April.

ADULTERATION OF FOOD, ETC., BILL.—*March 22nd.*—This Bill was read a second time, with the understanding, suggested by Mr. Muntz, that the discussion upon it should be taken on the motion for going into Committee. That stage was fixed for the 18th of April.

The following journals have been received:—The 'British Medical Journal,' March 18; the 'Medical Times and Gazette,' March 18; the 'Lancet,' March 18; the 'Medical Press and Circular,' March 23; 'Nature,' March 16; the 'Chemical News,' March 17; 'Journal of the Society of Arts,' March 16; 'Gardeners' Chronicle,' March 18; the 'Grocer,' March 18; 'Produce Markets Review,' March 18; the 'English Mechanic,' March 17; the 'American Chemist' for March; the 'Chicago Pharmacist' for February; the 'American Journal of Pharmacy' for March; the 'New York Druggists' Circular' for March; the 'Doctor' for March; the 'Brewer's Guardian,' March 15; the 'Journal of the Royal Institution;' the 'Photographic Journal' for March; Draft of a proposed Law for Regulating the Practice of Pharmacy and the Sale of Poisons in the State of Illinois, from Mr. Ebert; the 'Portsmouth Times,' March 18; the 'Newcastle Evening Telegraph,' March 20.

* See, however, another case, reported *ante*, p. 508.

Correspondence.

The Proposed Poison Regulations.

Sir,—It will be a matter much to be deplored if the negligence of a careless few should necessitate the infliction on the careful many of the observance of possibly irksome abstract rules, which, so far from being in their case a *desideratum*, may prove in many instances a positive detriment. No doubt in hundreds and thousands of well-regulated establishments throughout the kingdom the rules that therein obtain—though possibly varying considerably, being adapted to the special requirements of each—are in practice far superior to any fixed rules the Council of the Pharmaceutical Society can frame for the observance of all.

I believe that no code of rules will ever prove a perfect, or, indeed, any material safeguard. Improved education, and firmness in coroners' and common juries, in declaring every man tried by them, in cases of gross carelessness, guilty of manslaughter, are likely to prove infinitely greater safeguards. The laxity of juries in cases such as I refer to, is a great scandal, and fraught with ill consequences. Some few years since a druggist's assistant, while engaged in dispensing a 6-oz. mixture, one of the ingredients of which was Scheele's acid, was called upon to supply an ounce of castor oil in a 6-oz. bottle brought by the customer. He weighed the oil into the bottle into which he had put the *quantum* of prussic acid. The result was that the patient got no acid in his medicine, and the customer who swallowed the oil was killed. And what was the further result? Was the assistant sentenced to six or twelve months' imprisonment, as he ought to have been? Not a bit of it. The trial in some of its incidents resembled that celebrated one of *Bardell* v. *Pickwick*, and proved that fiction to be no exaggeration of actual fact. The counsel for the prisoner deeply sympathized with his "unfortunate" client, who, according to him, ought never to have been placed at that bar; but in his place ought to have stood his employer, who stored prussic acid in such a manner as to render such an accident possible. Having elicited the fact that the castor-oil bottle stood upon a shelf within two yards of the poison (he took no heed of the further fact that the prussic acid was kept in a locked cupboard), he denounced the reckless conduct of the employer in no measured terms, whom, when in the witness-box, he browbeat in a most brutal manner; but he thereby succeeded in securing the acquittal of his client. A slight additional result of his forensic eloquence—to him, doubtless, of no import whatever—was the commercial ruin of the truly unfortunate employer.

It is obvious that the regulations proposed by the Council could not prevent such an accident as the above. What could? Simply sufficient education on the part of the dispenser. Education enough to teach him that the prussic acid was the last instead of the first ingredient that should have been put into the mixture, and sufficient conscientiousness to observe the obligation.

Assuming it to be true that, unless the Council do something in the matter, more rigorous measures will be insisted on by the Medical Department of the Privy Council, the question comes what is best to be done? And when it has been made patent that some druggists are so scandalously reckless, as to keep cyanide of potassium in gallon stone jars, without any label at all being on them; and while, as I happen to know, another is anxious to get into business for himself, who actually is ignorant that muriatic acid is synonymous with hydrochloric acid, one can hardly deny that there is necessity for something to be done. Are the regulations proposed by the Council unexceptionable or desirable? Assuredly not.

Accidents having occurred from the reckless administering of medicines to patients during the night, perhaps in the dark, or when "a light" was burning which only made "darkness visible," it was a sensible suggestion to send out lotions and embrocations, especially when accompanied by draughts or mixtures, in bottles as dissimilar in shape and to the touch, to the bottles which contained the latter as possible. But, unless it is intended to legislate for blind dispensers or for dispensing to be carried on in the dark, I think it would be an absurdity to insist on druggists dispensing any medicines from such bottles, however advisable it may be to dispense some of them into such.

The very regulation must be framed on the belief or supposition that druggists do not infrequently substitute, by mistake, the contents of one bottle for another, when dealing with more or less potent articles, kept in bottles similar to those in which they may keep morphia, ant. pot. tart., strychnine, veratria, etc. And if, unfortunately, this be the case, how much more frequently must it occur with non-poisonous articles, especially liquids,—say, tinct. sennæ for tinct. rhei, tinct. aconiti for tinct. arnicæ, tinct. capsici for tinct. cantharidis, vin. colchici for vin. ipecac., etc.! If such blunders do now occur, they would be likely to be increased fourfold, by a certain number of articles being kept in bottles, "readily distinguishable by touch," by inducing a laxity and carelessness with all others, which otherwise would not be likely to obtain.

The blind and purblind should have no place behind a druggist's counter; all persons there should be especially enjoined to make the utmost use of their eyes,—that those members should not only inform the brain of what is required, but that the brain should, through their medium, direct the hands.

The whole of regulations 2, (A) and (B) as well as (C), would be likely to tend to more blunders than they would prevent. If a goodly number of bottles are to be treated as proposed, they would frequently, especially in establishments where much business is done, be left "untied over," or "uncapped," or "unlocked," or left out of "the cupboard."

Allow me to suggest a much more simple, and likely to prove a more efficacious code of regulations. I would premise that all bottles and even drawers, should as a rule, be kept in alphabetical order. Exceptions, the tinct. opii to be kept in a cupboard with bottles totally dissimilar in size and appearance, or on a shelf with colourless liquids, as spirits or waters, or with dry articles, or with articles for outward application only.

The liq. plumbi bottle not to be placed on the same shelf with liq. plumbi dil. Arsenic, if kept in a drawer, not to be allowed loose in it, but either tied up in paper and labelled, or in a labelled bottle in the drawer, and no other article to be kept in such drawer. If kept in a bottle, not to be allowed to stand on the ordinary shelves, but kept in a cupboard or locker, with bottles and substances totally dissimilar. That strychnia, veratria and atropia be kept in a locked cupboard out of the shop, and set apart for dangerous articles. That certain articles—to be enumerated—be distinctly labelled "Poison," the least potent of them with a black printed label, the more potent with a red printed label, and the most potent ones with a red printed label, with the addition of a death's head and cross bones.

If such simple rules as these I indicate had been universally adopted, I believe scarcely any, if any, of the sad accidents occurring by substituting one article for another would have occurred. "Some distinctive mark indicating that it is poison" is very vague, and scarcely less absurd than the proposition of one of your correspondents who proposed to stick a triangle on poisons, the apex to be up or down (I forget which, and so would many if the proposal were in operation), according to their greater or less potency.

Southampton, 14th March, 1871. Rob. Chipperfield.

Sir,—I have hesitated to add to the extended correspondence with reference to the proposed regulations for keeping and dispensing poisons, but, feeling that it is decidedly unwise to make them compulsory, I am induced to trouble you with this note. Unanimity should be secured if possible. I am sorry to see so much divergence of opinion on this subject, and can only attribute it to want of clear understanding of the necessities of the case. The interests of both sides are really the same, and both, doubtless, are only seeking the best interests of all. I am sure all who are fit to be in the business recognize the absolute need of careful regulations in their establishments. In fact, most of your correspondents seem to think that the proposed regulations are in general use. I hope some united plan of action may be arrived at, and should be glad to see such regulations as may be deemed really necessary issued as recommendations only, backed by all the weight of experience. I feel sure that there would be no further need to attempt compulsion. If, however, there should be any obvious and extensive neglect of wise precaution, then in two or three years the subject can be dealt with.

as may then appear best. Owing principally to the wise action of the Pharmaceutical Society, the condition of things is vastly improved, and progress is by no means stayed. The Council of the Pharmaceutical Society, elected by the free votes of members, are fully qualified to regulate all matters connected with the business, without any interference by outsiders, medical or other.

Education and self-interest are, in my opinion, quite sufficient to lead to the adoption of wise recommendations. But if laws are to be made, they should be absolute, and must affect all alike. It is worse than useless to make laws with no provision for carrying them out. I have been much surprised to see it stated that allusion to dispensaries, etc. is not appropriate here. I presume the safety of the public is the object to be secured. Assuredly, then, wherever poisons are kept and dispensed, the same laws should apply. I was surprised at the character of the remarks quoted from the *British Medical Journal.* There is such an imputation of unworthy motives, and use of threatening language, as is quite unworthy of any honourable journal.

I append my name, as I think it best that the names of your correspondents should be given.

Pendleton, March 15th, 1871. SAMUEL GILL.

Sir,—I believe that poison regulations are certain to be enforced upon us, and that the regulations proposed by the Pharmaceutical Council are such as should be adopted in every well-conducted pharmacy. I do not believe that the better education of chemists is the best security against mistakes: note the strychnine poisoning case at Liverpool and the cyanide of potassium case at Dublin. There was no want of education in either establishment,—might there not have been better regulations?

I hope the Council will succeed in making their proposed regulations compulsory. I am satisfied chemists would feel more secure against the carelessness which it cannot be doubted exists, more or less, where apprentices are employed.

March 16th, 1871. WM. HOUGHTON.

Sir,—I am induced to take up my pen, and reply to the letter signed W. H. P. in your last week's Journal, inasmuch as he makes a statement that might be challenged by hundreds of chemists in the provincial towns. He writes, "All will admit that at the present time more precautions are taken against accidents in the better-class, dispensing businesses." Now I for one do not admit it; and in looking over the record of disasters, *i. e.* mistakes which have occurred during the last twenty years, the greater number will be found to have taken place in the so-called better dispensing businesses, and not in the unfortunate mixed country businesses, where we should be willing to accept 1*s*. 6*d*. for the drops as recipe with which his letter is headed. If we all could find a better-class dispensing business, and get 2*s*. 6*d*. for ℥iij of tr. gent. co., we might then try our hand at country legislation, and suggest a plan for ending the great poison-storing question, especially if a cupboard three feet square would contain all the poisons we required in stock. It is simply nonsense to talk about consigning poisonous acids and alkaloids to a cupboard; and, presuming arsenic would come within this catetory, what kind of a cupboard would be required where half a ton is kept in stock, and must the master always remain at home to unlock this treasury of death? The thing is simply preposterous. Why all this ado about the storing of poisons? Has the business care and vigilance so depreciated, or has the number of poison cases so increased as to call for this change? Why not include guns, pistols, and rope? For there are more deaths from their abuse than all the poisons put together. The sooner this outcry is hushed, and the Council at some different work, the better. We may, I think, safely leave the matter in the hands of individual chemists, for the law and self-interest guard the matter sufficiently.

I am free to confess that I am exceedingly jealous of the Pharmaceutical Council, and it seems clear that unless they are resisted they will throw their silken web around the hundreds of unsuspecting country chemists, and finally bind them hand and foot. Country chemists who are not favoured with better-class dispensing businesses had better look out ere it be too late, and the Council had better look more to the interests of the general trade than try and toady favour with the Privy Council.

Sleaford, March 16th, 1871. GEO. WESTON.

Sir,—Having taken as much interest in trade matters for years past as most of my fraternity, and perhaps more on the poison question, I may venture to express my opinions upon the reasons why the Council have been induced to suggest regulations concerning the keeping and dispensing of poisons after giving them my earnest consideration.

I am quite willing to admit that, by the decision of the members at the last Annual Meeting, the Council was bound to consider the subject, but their decision should have been arrived at by ascertaining the sentiments of those who had sent them to the Board to represent their requirements. The "Reasons" reveal many things not creditable to a body representative of chemists and druggists.

When we read that in 1865, "the Council, encouraged by public opinion (but more especially by the opinion of the medical profession)", it sounds reasonable, as the Council at that time was a select few, representing a small section of the trade intimately associated with the medical profession; but in 1871 the Council, being no longer only the executive of a society, but the governing head and constituted protector of all registered chemists, should receive its encouragement, not from the public, not from the medical authorities, but from its own constituents. When will the Council comprehend that its duties are no longer to legislate so that the Society may be enriched and exalted, but to secure the advancement and benefit of every chemist on the register?

In writing history, even of trade progress, it is well to be accurate; and I endorse Mr. Reynolds's remark, that allusion to the United Society was uncalled for. Before the Bill of the Pharmaceutical Society was made known, that of the United Society had been suggested by our energetic Manchester brethren; and it was the existence of that Bill, even more than the opinion of the medical profession, which compelled the Council to legislate. The promoters of the United Society's Bill have no desire to shirk the responsibility of having defeated the Pharmaceutists' Bill, but rather to take credit for comprehending that Government would not sanction any Pharmacy Act which did not include a Poison Bill also.

Experience at that time had not taught the Council that, although in league with the medical authorities, the outsiders were too strong for it; but this it discovered in the end, and was compelled to accept the tactics of its opponents; and yet it has already forgotten that salutary lesson, and is again attempting to yoke all members of the trade to its restrictions, when all they ask is to be left alone. When defeated it talked of uniting the whole trade, and so accepted the policy of its opponents, by whose efforts we became a corporate body. Yet, no sooner was that happy result of their combination achieved, than, forgetful of its obligations, it returns to its former policy, is influenced by the opinion of the medical profession, and makes tacit understandings with Government medical officers, without considering how far its constituents desire it. It is with much regret that those who laboured hard and long in opposition to the old Council see the reformed government acting in such a manner as to create fresh factions, and give encouragement to agitators and the formation of new societies, when there was an opportunity to cement the whole trade under a liberal and consistent government.

If proper representative men were chosen, we should not behold the lamentable spectacle of a Society divided against itself, but, by judicious conduct, they might bring the whole of the trade to their support.

We want on the Council men who will take a broad and liberal view of all sections,—men, not influenced by the medical profession, but having a clear understanding of what a shop in the country is like as well as a pharmacy in town; who know that the regulations suited for the one would be totally inapplicable to the other, and that—even if suitable to both—interference of any kind would be intolerable.

It is easy enough to classify all under the head of chemist and druggist, but what a diversity of character there is among them! The pharmaceutist in a rich neighbourhood; the prescribing chemist in a poor district; the retail druggist in a mixed locality; large sellers of chemicals; those who include seeds, oils, confectionery, etc.,—all are chemists, but the regulations suitable to one would be utterly impracticable to all the others; and yet we are threatened with compulsory rules for one and all! There is but one remedy. The question at the Annual Meeting must be handed over to the new

Council, and the Society will have the opportunity of placing on the Council fourteen men who will determine not to have our liberties infringed.

March 18th, 1871. JOHN WADE.

Sir,—The question of the proposed new regulations as to poisons has been well discussed in the Journal, but as I felt it my duty strongly to oppose all coercive measures at the meeting of Liverpool chemists on the 16th inst., as one of the founders of the Pharmaceutical Society I wish to give a few reasons for thus differing from the Council.

Firstly.—The Pharmaceutical Society was formed expressly to oppose all compulsory legislation from without. At its formation it completely succeeded in defeating very similar oppressive measures to those now threatened, and up to the passing of the Poisons Bill it effectually protected the trade from this class of legislation. The Poisons Bill was thrust upon it by the non-pharmaceutists, backed by the Government, and now there is strong evidence that the Council is about to leave dependence upon its first principles, viz. improved education and status, with self-control and government, and to adopt or accept a course of obnoxious interference and control, which, however mild at first, will certainly prepare the way for future tyrannical interference, until all self-government is destroyed, and the calling is degraded.

Secondly.—The mechanical arrangement of bottles, and all similar distinctions, as every chemist must know, will utterly fail to add any efficient protection against accidental errors. Before the end of a busy day, or even during a few hours of active and pressing business, any possible arrangement of bottles, caps, or cupboards will be utterly broken into and destroyed, and all safeguards from such a system will entirely break down. Even the poison bottle, when once in the hands of the public, will be used freely for all purposes; servants, nurses, and juniors will be quite accustomed to drink the contents of such bottles, and the poison bottle which came in a few days ago from the chemist with deadly contents will be as much, if not more, likely to be taken in mistake for the vinegar or linseed tea, simply because the shape of the bottles rather than the labels is to be trusted to.

Thirdly.—If some slight protection can be proved to be thus afforded, even this does not justify the infliction of a degrading and insulting system of legislation which will expose chemists, above all other class of men, to pains, penalties and oppression, and make it impossible to conduct the business lawfully. My own business is not so difficult as many, but I have found it impossible in every instance of urgency fully to carry out the present Poison Bill, and the poison book is most obnoxious to many customers; but should any chemist, in any hasty or forgetful moment, send out an article which, from the carelessness of the public, afterwards causes the death of a valuable life, the outraged feelings against him for any trivial omission will know no bounds, and the whole trade may prepare for still further oppressive laws.

Lastly.—Such legislation is un-English, and belongs only to despotic governments. If the Pharmaceutical Council cannot or will not any longer protect us, the chemists of the United Kingdom must and will rise up, and tell the Privy Council and the House of Commons that we are doing all we can to protect life and health, but we will not be hampered and degraded by oppressive enactments. If this is done, there is no fear whatever that the House of Commons will ever attempt such tyranny, while the House of Lords has already decided that the chemist himself must know better how to arrange his bottles than they can tell him.

As one of the founders of the Society I beg a small space in the Journal.

Oxton, 20th March, 1871. JOSEPH BALL.

Sir,—Minute legislation is always burdensome and vexatious, and often futile. We have an illustration of this in the late Cab Act. I was astonished when a cabman placed in my hands a small pamphlet containing a number of regulations he was to observe in his daily avocation. On my remarking the perplexing complexity of these regulations, and asking him what he intended doing, his reply was characteristic, "Take no notice and go on as usual." I fear if pharmaceutical legislation becomes microscopical, we shall have, in sheer self-defence, to "take no notice and go on as usual." It is hard enough to have to carry in our memory the Pharmacopœia without having a cabinet lawyer in addition.

We were told, before the passing of the Poison Act, that our business would be increased at least one-third, but I think the majority of us, if candid, would confess that the reverse is the case. We are now told, if we will suffer a strait-waistcoat to be placed on our internal arrangements and movements, it will not be so in reality. For my part, I believe it will be as stringent as the enforcement of the Poison Act, and ten times more worrying. All legislation ought to be based on broad principles, not minute and tiresome regulations. Whatever regulations are made ought to be within the easy obedience of struggling tradesmen as well as the fops of pharmacy. Take the poison cupboard recommended in the *Lancet*. Many of us could not find room for such an apparatus in our shops if we wished, and the expense of it to some of us would be irksome, nay, impossible. Such complicated gear is likely, by constant working, to get out of order, and while it is being repaired, where are the poisons to be placed? A cupboard is at all times stuffy and inconvenient. Poisons are far better on a shelf by themselves, where they can be plainly seen. As the labelling every poisonous article sold "poison," is considered sufficient for the public safety, surely the same regulation ought to be sufficient for our safety in selling and dispensing. In legislating for us, our legislators must remember we are thinkers and not *automata*.

Bottles of a peculiar form or colour for poisons would be troublesome to the pharmacopolist and burdensome to the public. The word "poison" on any bottle, whatever its shape or colour, ought to be a sufficient safeguard.

I fear this pother about poisons, if carried too far, will lead to a reaction. Wealthy chemists will be having two shops, the poison shop and the safe shop. All diseases, doubtless, can be cured without the use of any poison, and the public will naturally ask, "Why should we take a poison to kill a disease, and thus run the risk of being killed ourselves?"

Were a surgeon to announce that he cured disease without any poison, I have no doubt he would soon obtain a large practice, for the public are becoming uneasy at having to take medicine which requires such careful manipulation, and may, through misadventure, give them their death-blow.

March 21st, 1871. E. K. C.

Sir,—If asked to vote on the poison question, I really could not do so, I should be obliged to remain neutral; such is the position, I am sure, of hundreds besides myself.

If the question were merely the introduction of measures, voluntary or not, conducive to safety, there would be no difficulty in deciding what to do.

The proposed regulations, in themselves, are not so much objected to, from what I can make out of the correspondence on the matter and the opinion of numerous pharmacists (employers and assistants) as to the consequences which would result from their adoption.

The Council of the Pharmaceutical Society should, I think, take chemists generally more into its confidence, and tell them more about the matter than it has. Is it afraid of, or does it despise, the opinions of the many thousands not connected with the Society?

As all chemists really now constitute one body, the body as a whole should be consulted; if it is, all will be knit together in one bond of fellowship, and forgetting bygones, all will work together for good and be one united society.

What will the adoption of the regulations lead to? seems to be the question: to the appointment of inspectors to see that they are carried out, is the reply that comes from most. The Council has not enlightened us on this point. We must not take a leap in the dark. If there are to be inspectors, who will they be? A decided objection is made to the inspecting business, but I do not stick at this myself. Who will the inspectors be? Will the Council appoint them? Many, I dare say, would not object much to have their arrangements overlooked by a brother pharmacist, who, knowing more about the profession or trade, would of course be the best judge of matters and understand any difficulty that may arise; but if medical men are to be the inspectors, I would most decidedly oppose, in every way, the adoption of the regulations at the very outset.

Another objection is that the regulations at present are not intended to apply to other than pharmaceutical and registered chemists. You, Sir, have said that this is no argument against their adoption, and the *Chemist and Druggist* has said that if chemists (proper) adopt them, medical shopkeepers will be left out in the cold. But a friend reminds me that the public may take this sense of the matter: Oh, you see that these men are not to be trusted; the Government is even obliged to make laws to compel them to conduct their business with more care. Go to So-and-so, who is considered properly qualified and competent to prepare medicines without being so looked after. We are told that probably Government will see that the regulations are enforced in all shops or dispensaries, by whoever kept, but of this we wish to be assured.

I have remarked that the Council has not taken care to consult the opinions of the whole body as it should. Although I do not question the result of the Annual Meeting in May next, yet it will be a farce if the voice of the meeting, which is to be held in the small theatre of the Society, is taken as representing that of many thousands who cannot possibly be present at it. The Council should, if it wishes to better the unfortunate position it is in, retrieve its character and fulfil the bright hopes formed of it at the commencement of its term of office, engage a larger room for the meeting, and invite all chemists, whether connected with the Society or not, to attend and express their opinions. This is the more necessary as the Council itself is divided in opinion, and from the fact that two eminent pharmacists, who have just retired from it, express themselves so unequivocally against the adoption of any regulations whatever. The Council would thus in a great measure relieve themselves of the heavy responsibility of allowing regulations to become law without consulting the wishes of chemists generally.

You will gather, Sir, from some of my preceding remarks that I do not object to the regulations themselves, and I would remind those that do, and argue that few mistakes occur, to remember that there are hundreds committed of which we hear nothing. The object of regulations is not only the prevention of fatal mistakes, but the prevention of mistakes of any kind as far as is possible. I am convinced that many are made (it may be by ignorant pharmacists, and there will be none, of course, in a few years) which could be prevented by a few simple rules.

Many already, since the agitation on the subject, have "set their house in order." Laws are not made for good men; regulations are not for those who adopt precautions, but for those who have none and who almost criminally despise all law and order.

With regard to the compulsory adoption of regulations, and the perhaps consequent necessity of seeing that they are enforced, I beg to suggest the following feasible plan, which I have brought forward elsewhere, and which, if carried out, would answer every purpose, and almost do away with the necessity of framing any special regulations:—"To each district let a pharmacist (not a resident in the district) be appointed, who shall inspect the arrangements of every pharmacy in it, and who shall, if he considers that arrangements conducive to safety are carried out, give a certificate signifying that such is the case."

This I firmly believe would satisfy all,—the Privy Council and its medical officer and the public, whose attention has unfortunately been drawn to the matter. Mr. Reynolds' assertion has not been refuted yet.

"When a new pharmacy is opened, the Pharmaceutical Society to be communicated with, and some one appointed to see that suitable arrangements have been made."

Such inspection, or certificate, might last for all time; convenient and proper arrangements once made are not likely to be done away with. But if an inspection took place at stated intervals, say once in five or ten years, no conscientious man, I think, would take it either as a hardship or a troublesome interference.

Should you deem this letter worthy of insertion in the Journal, I may be bold enough to address another to you upon other features in the poison question. E. B.

Sir,—As regulations for the keeping and dispensing of substances, so-called poison, if enforced, must be as simple as possible to ensure their general adoption, let me suggest for consideration whether the following will not meet the case. Let there be no restriction as to shape of bottles, sandpapering, colour of labels or poison closet; but strictly enforce that all vessels containing dangerous remedies be distinguished by a round label (on any ground, gold, or painted any colour, as may suit the taste of the chemist), with "for internal or external use" so expressed above the name; and if for internal use, the minimum and maximum dose expressed below. These labels to be in use for stand vessels.

For dispensing in bulk, the same form of label to be sent out with the necessary directions, and if required, "Poison—care," be printed on the labels in addition to the directions for use.

In the hope that some conclusion may be come to, satisfactory to all parties, I remain, A Founder.

36, *Sloane Square, S.W., March 20th*, 1871.

1. For Outward Application only.
2. Not to be taken Internally.
3. Not for Internal Use.

Sir,—As I expect at our Annual Meeting a precautionary label will be recommended for general adoption for all liniments, etc. containing poison, I beg to state that I consider No. 1 of the above by far the best. Outward remedies are often but partly used, the remainder put aside for another time, and if the word *not* become defaced, the label might lead to the mischief it was intended to avert; but no such result could possibly attend No. 1, which I have used for years and which answers remarkably well.

Thomas Kent.

226, *Blackfriars Road, London, S.E.*
March 21st, 1871.

Poison Bands *v.* Poison Bottles.

Sir,—Of the three clauses (Pharm. Journ., Feb. 11th, 1871, page 653) that are proposed to regulate the safe keeping and dispensing of poisons, the last seems to create by far the greatest opposition.

Every experienced pharmacist knows that neither tri-, quadr-, nor pentangular bottles, blue, "actinic" nor any other coloured glass, rough, smooth nor parti-coloured labels, are of the slightest use in dispensing unless uniformly adopted by each and every member of the whole trade; and consequently no suggestion can ever find favour with all classes, unless it is inexpensive as well as intelligible.

Of the "thousand and one" suggestions that have been made to effect the above purpose, I do not remember one that bears favourable comparison with the simple and inexpensive plan originated by Mr. Jos. Goddard, of this town, viz. that a solution of red sealing-wax in methylated spirit (=the red varnish of the electrician) be painted round the neck and over the stopper's head of the shop or dispensing bottle containing any poison; and for dispensing "external applications" a band of blue paper (about one-third the height of the bottle) be pasted round its lower part, on which band the following label (in black letters on a red ground) should be printed or gummed:—

The Blue paper on this Bottle
is to show that its contents are
NOT TO BE TAKEN.

Specimens of Mr. Goddard's suggestion have for some years been exhibited in the poison bottle section of the Society's Museum.

It is not every one that can find the room, if they can the means, to add a series of poison bottles to the arrangements of the shop; but what druggist is there, worthy the name, who has not an abundance of seidlitz paper in his drawer?

The method suggested in no wise interferes with the usual position of the direction label, nor with the dispatch of business, since it only requires the demand to raise a host of neatly-printed "poison-bands," ready cut and gummed if required. The present difficulty also with which we have to contend, viz. the use of poison bottles by the public for improper purposes, would be avoided, a wash being all that is necessary to convert the dangerous into the usual white or flint-glass bottle.

Finally, this suggestion has the twofold advantage of being, not only "distinguishable to the touch," but appeals at the same time to the sight of the patient, who, with these precautions before him, if he still persists in drinking his liniment, and rubbing in the mixture, stands in need to have his cranium "examined by two duly qualified medical men."

16, *Gallowtree Gate, Leicester*, Jos. Young, P.C.
March 14th, 1871.

Clause 16, Pharmacy Act 1868.

Sir,—If your interpretation, as I understand it, of clause 16 of the Pharmacy Act of 1868 is correct, viz., that neither the widow nor any other unqualified person can legally continue the business of a deceased chemist (even if managed by a properly qualified man) except as a trustee, in which case it can only be for a limited period, I would ask why the Pharmaceutical Council takes no action in the case of co-operative stores retailing and dispensing poisons, where neither trusteeship nor any other qualification obtains?

The case may be put thus, either co-operative stores are illegally constituted, or they are not. If they are, then the Council is bound to prevent any violation of the Pharmacy Act; but if they are not, then the Pharmacy Act is a mere sham, and not worth the paper on which it is printed, since any man or woman, or any association of them, or any relative of a deceased chemist, can keep "open shop for the retailing and dispensing poisons," exactly as the co-operative stores are now doing, *i. e.*, by employing, as dispenser, a registered chemist and druggist.

It seems to me that clauses 1 and 15, taken in conjunction with clause 16, are quite sufficient to prevent any irregular associations from practically evading the law, and I think the Council ought to put in force the powers intrusted to them to this end, or give some valid and sufficient reason for permitting what appears to be, not only a gross violation of the spirit and letter of the Pharmacy Act, but also very damaging to the interests of legally qualified men.

There can be no doubt but that these societies are, in fact, "open shops kept," by certain persons *not on the register*, for the "retailing, dispensing and compounding of poisons," in defiance of the 1st clause of the Act of 1868.

Torquay, March 21st, 1871. EDWARD SMITH.

Dispensing in Surgeries.

Sir,—The instance quoted by Mr. T. C. Jones (in last month's Journal), of a medical man inducing a boy, by the offer of higher salary, to leave his employer is not a solitary one. I experienced the same treatment myself a few months since.

In my case the inexperienced boy was not to take charge of a surgery merely. The medical gentleman (although the place was well supplied with druggists) was starting a regular drug-shop, for the sale and dispensing of the medicines. He has a large out-door practice, and during his necessary absence on his professional rounds this mere boy (who had been with me some twelve months, running messages and occasionally entrusted with the sale of hair oil, logwood and some of the rough drugs) is left in charge of the establishment, and, assisted by a youth of even less experience, compounds the patients' prescriptions, sells patent medicines, and dispenses drugs and poisons to the villagers.

Of course, when a surgeon or doctor keeps open shop his patients have no alternative, but must get their medicines compounded there, be the assistant competent or incompetent. Should a serious mistake ever happen, it will be very difficult to prove that it was not "unfavourable symptoms set in." How different would be the position of the regular druggist under similar circumstances!

Cases of the above kind show the absurdity of imposing restrictions ("for the safety of the public") on a portion of the drug sellers only.

A COUNTRY DRUGGIST.

Bathgate, N.B., February 15th, 1871.

An Advertisement.

Sir,—The fate of a house divided against itself would certainly fall on chemists, if many of them could advertise as follows:—

EASY INSTRUCTIONS FORWARDED TO PREPARE AN ESSENCE OF SARSAPARILLA for 1*s.* pint, equal to that sold at 4*s.* 6*d.* or more. Infallible restorer of Broken-down Health and Blood Purifier. Free for 14 stamps.—REGISTERED CHEMIST.

The Council, I presume, has no power to interfere in such a case, but it is as well the profession should be made aware of this peculiar phase of self-destruction. AVALON.

Adulteration of Food, etc., Bill.

Sir,—As the Bill on the adulteration of food and drugs may probably be passed, it will be advisable that the answers to the following questions be well known:—

Who are eligible for election as analysts?

What person or persons have the power of appointing the analyst?

Are the existing analysts known as the "county" analysts to have the work in this Bill?

May not the examined pharmaceutists compete for the appointment under the Act?

OLD STUDENT.

The Case of Poisoning at Falmouth.

Sir,—In your report of "Suicide by Prussic Acid," in Journal No. 36, date March 4th, Mr. Mitchell is stated to have produced his register signed "Isabella Vaughan (*alias* Mary Pitts)" as the purchaser of the poison. It is not stated who witnessed her signature. Had the Pharmacy Act been complied with in the production of the witness, would the fatal results have followed? Or was the purchaser known to the vendor?

March 8th, 1871. J. BARKER.

Dispensing.

Sir,—I was much pleased to read the paper on "Dispensing" in your last number, and I hope that the subject will often be brought into the columns of your valuable Journal. It is a most important and essential qualification of every young man who is connected with pharmacy. But it does not seem to meet with the attention its importance demands, especially in the matter of apprentices. A great many, after spending a term of several years with a chemist, seem to know comparatively nothing of the practical part of dispensing, and generally have to gain their knowledge in that department from experience in after situations, when they are supposed to be practically acquainted with all the branches of their business. When I left my first master, and went to a situation where dispensing formed a large part of the work, I was at a loss in many respects; and I may say, without exaggeration, that I learnt more practical lessons that would stand by me in after life during my first six months there than I did the whole of my previous term. And this is not a solitary case, but many such could be found daily, and shows a want of attention in this respect on the part of the masters. But it should be a duty incumbent on every master to qualify his apprentice as much for practical dispensing as for the ordinary routine of a chemist's business; and I hope we shall often have a paper or a few suggestions from those who are competent to give them, and they will, I am sure, prove of great benefit, especially to your youthful readers and subscribers.

Allow me, Sir, in conclusion, to say a few words on the almost worn-out "poison" topic. I believe that, to a great extent, the restrictions which many wish to put upon us are unnecessary and superfluous. After the examinations which persons are obliged to pass before they can enter into business, which must ensure a practical knowledge of all articles they have to deal with, every man would take what precautions he thought necessary for preserving his own reputation and the safety of the public. Notwithstanding the stringent rules already adopted, you can scarcely take up a paper but you read some case of poisoning or of suicide. And is the fault the chemists and druggists'? Decidedly not; and nothing that the law can do will effectually remove it. If a man or woman has really made up his or her mind to get a poisonous article they will do so, no matter what burden is laid upon the chemist, and nothing in the shape of coercion or law will do anything to mitigate the evil. It lies with those who wish to procure it; and as long, Sir, as there are people who contemplate self-destruction, or the destruction of others, so long will the evil last.

GEORGE G. JEFFRIES.

51, *Old Market Street, Bristol, March 21st*, 1871.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. J. Doubell, Mr. J. L. Roberts, Mr. W. B. Orton, Mr. W. W. Stoddart, Mr. C. B. Allen, Mr. C. R. C. Titchborne, Mr. E. Fox, W. H. H., G. W.

WATER ANALYSIS.

THE ESTIMATION OF ORGANIC MATTER AND NITRATES IN POTABLE WATERS.*

BY CHARLES EKIN, F.C.S.,

PRESIDENT OF THE BATH CHEMISTS' ASSOCIATION.

Whilst referring for details to the several memoirs that treat of the subject, I propose to pass briefly in review the various methods now or lately in use for the estimation of organic matter in potable waters, and then to make a few remarks on the value to be attached to the presence of nitric acid.

The old process of incineration, so far as the loss of weight bears any proportion to the amount of organic matter, is now universally discarded, and no doubt rightly so, at the same time one is much helped in forming a judgment of the wholesomeness of a water by heating to redness the residue obtained by evaporation. If it blackens or has a decided empyreumatic odour, there cannot be much doubt as to its character.

The permanganate test, though not by any means to be relied upon by itself, sometimes gives valuable confirmatory evidence. The deoxidation may, however, be due to the presence of a proto-salt of iron or of alkaline nitrites. If the latter, the bleaching takes place in a very few seconds, and it can consequently be at once distinguished and measured separately from the reducing effect occasioned by organic matter, which is always gradual. I find iron to be frequently present in waters which have passed through iron mains, and when we consider also how widely-distributed this metal is, it is manifest that we must be very careful to ascertain its absence before we attribute any bleaching of the permanganate to organic matter. All the strata, and therefore the springs in and about Bath, contain very appreciable quantities of iron; and where this is the case, the permanganate test is almost useless. Yet, notwithstanding this, Dr. Letheby, relying upon this method alone, undertakes to speak authoritatively upon the purity of waters, as in the case of the samples sent up to him by the Bath Corporation a year or two ago.

Frankland and Armstrong's method—although in the hands of such excellent chemists as themselves it may yield good results—is altogether too elaborate and troublesome to come much into use, especially as the alternative process of Wanklyn offers so many advantages. The details of this latter process, which is now generally acknowledged to be the best yet devised, has been so thoroughly explained in Wanklyn and Chapman's little treatise that I need not take up your time by dwelling on it here. Having had a tolerably extensive experience in working it, I can thoroughly indorse all that has been said in its favour as an *improvement* upon the older methods; but I hope the day is not far distant when this even will be replaced by a process yet more satisfactory.

Where sewage is present in a water, it is invariably accompanied by an abnormal quantity of chlorine, but the reverse by no means holds good. I find that the quantity of soluble chlorides varies so much in different strata, that the estimation of chlorine is quite useless as a comparative test between different waters; but it is certainly valuable when it is wished to examine the same water at different times. Thus, the Birmingham water last autumn was regarded with more than suspicion when it was found that the chlorine had increased in it from 1·41 parts in 100,000, in May, to 7·44 parts in 100,000, in August.

Last autumn, too, the Bristol supply, generally so good, was found to be offensive, and to contain a good deal of ammonia, and Mr. Stoddart was requested to investigate the cause. Finding that the quantity of chlorine in the water had not increased above its normal rate, he was enabled at once to say that there was no contamination by sewage; and it was then found that, owing to the lowness of the water, and the exceptional summer, there was present in the reservoir a large accumulation of decomposing diatoms, which had, no doubt, given rise to the impurity.

Of the fermentation test by means of sugar I have had no experience, but I am not sanguine that it will be found of much practical use.

The oxygen of atmospheric air is soluble in water in the proportion of one part to two of nitrogen; and if a less proportion than this is found, it may fairly be concluded that it has been used up in oxidating sewage or other organic matter present in the water.

The estimation of the proportion of oxygen to nitrogen, in conjunction with Wanklyn's plan, seldom leaves any doubt as to the character of a water.

It has always been supposed that, with the exception of the small proportion of nitric acid present in rain water, the nitric acid to be found in spring- and well-waters is to be referred to the oxidation of sewage in some shape or other, but I have ascertained that this is by no means the case. In a paper read before the Chemical Society last month, I showed that the result of several analyses of rocks and fossils collected in this neighbourhood was to prove that they all contained nitric acid in greater or less quantity. Thus, grey chalk marl contained 1·1 part of combined nitrogen in 1,000,000; Bath oolite, 1·3 parts; fossils from the greensand, 2·23 parts; fossils from the lias, 3·6 parts; fossils from the fuller's earth nearly 3 parts, and inferior oolite rock, which is almost entirely made of fossils, 7·6 parts.

Although it is surprising that such soluble salts as nitrates, which probably resulted from the oxidation of organic beings that existed countless ages ago, should still be found in the different strata, it is not entirely without parallel. In one of the very first formations in which evidence of organic life is found, namely, in the Caithness Flags, Sir Roderick Murchison says that the bitumen found there is undoubtedly due to the numerous fishes of the period, and this bitumen, when analysed by Dr. Hofmann, yielded 30 per cent. of organic matter and ammonia. We find, too, from Watts's 'Dictionary of Chemistry,' that such substances as fossil teeth still contain a large proportion of their original organic matter.

Thus Rhinoceros teeth contained .	23·03 per cent.
Elephas primigenius . . .	15·6 ,,
Cave Bear	23·45 ,,
Fish, Acrodus	2·17 ,,
Fish from the Chalk . . .	·54 ,,

If then organic matter even can exist as such, through indefinite time, we shall cease to wonder that salts, the result of the oxidation of organic matter, should also be found.

* This paper was read at a meeting of the Bath Chemists' Association, February 3rd.

The springs rising at the junction of the Great Oolite with the fuller's earth at the north-east side of Hampton Down, contain as much as ·65 grain nitric acid per gallon, and yet the land is never manured, a few sheep only grazing on it, and there is not a house or any drainage near it.

Again, the Monkswood spring, about four miles from Bath, which is going to form part of our new supply, contains as much as 1·28 grains per gallon, but if you will carefully go over the ground for a mile or two all round as I have done (and the spring, from its splendid volume and picturesque surroundings, will well repay a visit), you will fail to find any sufficient source of contamination. The spring, like all those that have percolated through the inferior Oolite, contains more nitrates than those which rise above that stratum, and this is easily to be accounted for, from the stratum being so very fossiliferous.

According to the reports of the Registrar-General, in the *Times*, Professor Frankland regards the amount of nitrates in a water as necessarily the result of the oxidation of sewage matter; and from the nitrates present he actually calculates how great "the previous sewage contamination" has been.

We have seen, however, that nitrates may be present in a water in very appreciable quantities without there having been any sewage contamination at all, and consequently the term "previous sewage contamination" is, to say the least, very misleading.

THE CULTIVATION OF OPIUM IN CHINA.

BY JOHN R. JACKSON, A.L.S.,

CURATOR OF THE MUSEUM, KEW.

It is interesting to note to what extent the cultivation of the poppy for the production of opium varies in different districts of China. From time to time its growth has been forbidden by proclamations from the Emperor, the penalty for growing it being death. Small quantities have been nevertheless constantly grown; for instance, ten years ago all the opium that was produced in Szechuen was grown in small patches of gardens, ostensibly for the amusement of the owners, but specially for the value of the crop. It is a fact that, though the proclamation is still in effect, the executive authorities have found it necessary to take no official cognizance of the existence of the plants; and it is significant of the impotence or the venality of the Chinese authorities, or the discord between the imperial and provincial governments, that the white poppy fields may be seen on the most conspicuous places on the great river route while the cultivation of it is nominally punishable with death. That the cultivation of opium in China is actually increasing cannot be denied, though it is still, in some districts, planted with great secrecy; small patches of land under its cultivation being hidden by fields of tall millet, and when so situated are quite safe from any interference from revenue officers.

Notwithstanding the increase in the production of Chinese opium, and the consequent decrease during the past year or two of the importation into China of the Indian drug, the question still remains whether the native will drive the Indian produce out of the market, or depress the latter so much as to seriously affect its importation and price. In point of strength or flavour the Indian is far superior to the Chinese, the latter averaging 40 per cent. less in price. It is its cheapness that is one of its chief recommendations in the Chinese market, and, being purchased at such a reduced price, it is often mixed with the Indian drug.

With regard to the conditions under which Indian opium now enters the Chinese market, the following notes contained in a recent report on the subject will better explain them than any words of our own:—

"Malwa opium is cultivated by native growers in the province of Malwa and the adjacent and central provinces of India,—the land upon which the crops are grown paying to the Government the customary ground-rent. The farmers, upon gathering in their crops, offer the juice of the poppy daily upon the nearest country markets, and it is there purchased by other natives (who may be denominated packers), who, in their turn, pack the drug in balls, and thus prepare it for transmission to Bombay. These packers then sell the opium, thus prepared, to other native merchants, who purchase it especially for sale upon the market of Bombay, where exporting and foreign merchants buy it for shipment to China, etc. The importing Bombay merchant, before attempting to take the drug to Bombay from the hand of the packer, has first to procure a pass from the Government treasury, costing 600 rupees per chest, which pass frees the opium from further taxation *in transitu*, certifying that the drug has paid its duty. Upon reaching the market in Bombay, as aforesaid, it is purchased by the exporting merchants, who, before operating, naturally base their calculations on the China demand and quotations; and thus the market in Bombay, and necessarily throughout the producing districts, is governed by the market of China. The quantity placed under cultivation by the growers is also almost entirely dependent upon the demand, both of the present as well as of the preceding season; and thus the crops usually range from 35,000 to 50,000 chests per annum. No opium is allowed by the English Government to be reimported into India. It may be as well here to state that, during the past three or four years, the demand for China having decreased, the cultivation in India has been lessened in like degree.

"Of the Bengal drug there are two descriptions,—one, called Patna (produced in the province of Behar), and the other Benares, from the province of that name, where it is grown. Both descriptions are cultivated entirely by the Government itself, which employs men for the special purpose of cultivating the poppy, collecting the juice, inspecting and packing it into balls. The drug is supposed to cost the Government, laid down in Calcutta, 400 rupees per chest. On arrival of the drug into the Government godowns at Calcutta, it is sold by public auction, in lots of five chests, to the highest bidder. On the fall of the hammer, the buyer has always the option of there and then securing as many succeeding lots as he wishes at the same rate as the lot he has just bought. The purchaser of any parcels has to pay, on the fall of the hammer, bargain money at the rate of Rs. 50.100 per chest, and the balance of purchase money within a fortnight. It is not compulsory, however, to take immediate delivery of the opium, as the Government allow it to remain, free of warehouse charge, for an indefinite period.

"These auctions take place once every month, a limit of 400 rupees per chest being placed on the drug; therefore, all it realizes over and above this price goes towards increasing the revenue, and is a profit to the Government. The crop is apportioned in equal quantities to each month for public competition, and its extent is, in a great measure, regulated by the demand, as in the case of Malwa. No private individuals are allowed to store opium in these godowns; all so found is looked upon as smuggled, and confiscated. When a buyer wishes to export his purchases, they are shipped for him by the Government agent, and delivery cannot be taken in Calcutta."

About fifty years ago, when Patna opium had been introduced and had made some way in Szechuen and the neighbouring provinces, it fetched double its weight in silver, and the people smoked it cut in slices and rolled up in paper like a cigar. At the present time there seems little doubt but that its consumption is increasing rapidly, more especially among the labouring classes. It is said that already eight men out of every ten smoke it, and quite one-half of the women. Irrespective of the moral bearings of the subject, there can be no doubt that if a general and open system of poppy cultivation were allowed in China, it would become a highly remunerative branch of agriculture.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Ferri Oxidum Magneticum.—[§ Magnetic oxide of iron, Fe_3O_4, combined with about 20 per cent. of water of hydration and containing some peroxide of iron.]

Sulphate of iron is dissolved in water and mixed with solution of persulphate of iron [free from nitric acid] and the mixture is precipitated, boiling, by solution of soda. The precipitate, at first brown, becomes black on standing, and is collected, washed thoroughly and dried at a gentle heat.

The iron salts must be employed in such proportion as to contain one atom of iron in the ferrous state, and two atoms in the ferric state. Thus, if solution of persulphate of iron be not ready, a quantity of sulphate may be divided into three equal parts, and two of them boiled with sufficient sulphuric and nitric acids to convert them into ferric salt. Excess of nitric acid must be driven off by evaporation.

The reaction is as follows:—

$$\left.\begin{matrix} FeSO_4 + 2NaHO \\ Fe_23SO_4 + 6NaHO \end{matrix}\right\} = \left\{\begin{matrix} Fe2HO + Na_2SO_4 \\ Fe_26HO + 3Na_2SO_4 \end{matrix}\right.$$
$$= Fe_3O_4 + 4H_2O + 4Na_2SO_4.$$

This compound may be regarded as a kind of salt in which the iron fulfils both the basylous and acidulous function $Fe''(Fe'''_2O_4)$. This view of its constitution is countenanced by the fact that ferric hydrate acts towards metallic iron as an acid; freshly prepared and boiled with iron filings, it evolves hydrogen and gives rise to the production of magnetic oxide:—

Ferrous oxide	FeO
Ferric oxide	Fe_2O_3
Ferrous ferrite	Fe_3O_4

Magnetic oxide of iron is an important and abundant ore of iron; it forms the *loadstone.*

The magnetic oxide of iron, dissolved in acids, forms solutions which give the reactions both of a ferrous and of a ferric salt. Thus a dark blue precipitate forms with yellow as well as with the red prussiate of potash. The latter is Turnbull's blue (see Ferri Iodidum); the former is Prussian blue, a ferric ferrocyanide:—

$$2(Fe_2Cl_6) + 3(K_4FeCy_6)$$
$$= 12KCl + Fe_4(FeCy_6)_3.$$

[§ Two grams dissolved in hydrochloric acid continue to give a blue precipitate with the red prussiate of potash until 8·3 c. c. of the volumetric solution of bichromate of potash have been added.] This amount corresponds to very nearly 9, or more precisely 8·965 per cent., of ferrous oxide. The calculation is precisely similar to that explained under ferri carb. sacch.:—

$$20000 : 8{\cdot}3 :: \overset{6FeO.}{=432} : {\cdot}1793$$
$$\text{and } 2 : 100 :: {\cdot}1793 : 8{\cdot}965.$$

PHARMACY IN PARIS DURING THE INSURRECTION.

The advantages possessed by iron revolving shutters have generally been admitted, but few, I think, ever found them more useful than did the shopkeepers and pharmacists in the neighbourhood of the Place Vendôme on Wednesday last. Since the horrors of the siege, Paris had been gradually sliding into the old grooves; strangers reappeared, letters and telegrams seemed no longer a strange and new pleasure, and commerce had reinstated herself. It was unfortunately but the lull before the storm. Three days before, the Place Vendôme had been occupied by the insurgent battalions of the National Guard, the pretending friends of order, who, at the approach of a peaceful unarmed deputation headed by the journalist Henri de Pène, discharged more than 500 shots into the crowd, killing over twenty and wounding about sixty persons. In an instant the pavement was red with blood, and the dead and dying were carried into the neighbouring pharmacies, to receive what attentions could be given to them, awaiting the arrival of the surgeons. Ambulance stretchers were soon procured, and mournful processions, headed by men bearing large white flags with the Geneva cross, traversed the streets of Paris, exciting the hate and loathing with which all orderly citizens regard the resumption of a new reign of terror at the hands of the Belleville insurgents. All business, excepting the mournful duty of stanching death-wounds, is over for the present in this usually gay quarter of Paris. Half-a-dozen blood-stained mattresses piled in a corner of nearly every pharmacy tell their own sad tale, and the once white marble floors are variegated and slippery as the pavement of the Piazza San Marco, at Venice, on a rainy day. All the shops are closed, and peremptory commands to shut all windows fronting the street are issued in loud tones, accompanied by menaces from loaded chassepots. In comparison with this, the siege was quite enviable; then, at all events, shops were open, and one could walk about the central parts of the city in perfect safety.

And then a certain amount of business was done,—business of the pathetic kind. Wives, sisters and sweethearts came and bought pocket pharmacies, little stocks of lint and plaster, perchloride of iron, etc. for their dear friends about to start for the fields of battle. Many a tear was shed over the purchase, many a wish uttered that those dear to them should never require the sad appliances of modern civilization to heal the wounds caused by the destructive engines of modern barbarity. Alas! how many hopes have been scattered to the wind! How many pale, weeping figures, clothed in black, are daily to be seen carrying in pious hands wreaths of "immortelles," to deck the rude crosses that lie thick at Montretout and for miles around. The past was dreadful enough, gilded over by a coating of patriotism; the present is doubly fearful,—brother against brother, and no canopy of glory, but one reeking shroud of vengeance, hatred and bloodshed.

The siege, by provoking the appetite, instigated curious researches among the edibles generally found in pharmacies. As long as a few tins of concentrated milk remained, we fared luxuriously on arrowroot puddings and oatmeal gruel; in fact, a tolerable pharmaceutical dinner, save the monotony, was daily procurable, and consisted of a soup of Liebig's extract, thickened with tapioca or pearl-barley. A *hors d'œuvre* of anchovy-paste or olives; then a *pièce de résistance*, such as curried horseflesh, or a cat's thigh strong with garlic, a salad of mustard and young flax, which we grew in boxes in the cellars, a dessert of Jordan almonds and conserve of hips, and a strong cup of coffee with which to wash all down. When the bread became almost uneatable, Hard's food was brought into requisition,—the dough was cleanly made in a large pestle and mortar, with a due proportion of bicarbonate of soda and hydrochloric acid, and baked into light little loaves, or rather cakes, of surpassing delicacy of flavour. Our distaste for horseflesh induced us to invent sundry *bouquets*, the success of which was so great in imparting a really pleasant flavour to the insipid meat, that I am sure no *cordon bleu* should ignore their utility. The favourite consisted of a clove of garlic and a pinch of peppercorns, corianders, cloves, parsley-seed, dried thyme and ginger, bruised together and tied in a piece of muslin.

The only article for which an extraordinary demand existed was extract of meat. Tonics were much taken, and resulted in several new specialities, rather more ingenious than tasty, such as a combined essence of calisaya and Liebig prepared with Cognac!

HERMODACTYLS.

BY M. C. COOKE, M.A.

It might be supposed that all had been written and said about hermodactyls that could be said, and that the subject had been settled for ever. Such was my own impression until lately, when the notion entered my head that the microscope might reveal something more, and this appeal to the microscope has unsettled the question again. Hermodactyls are eminently starchy products, and, should it be found that there is any peculiarity about the starch granule sufficiently positive to throw doubt upon the generally accepted notions regarding hermodactyls, then it needs no apology to reopen the subject.

The conclusion which seems to be accepted is, that hermodactyls consist of the corms of one or more species of *Colchicum*, one of them being *Colchicum variegatum*. On referring to Pereira we find two kinds of hermodactyls described from specimens communicated by the late Dr. Royle, one of these being the tasteless hermodactyl and the other the bitter hermodactyl. The opinion which seems to have prevailed has been that these are only forms or conditions of the same drug; and that they are two quite distinct sorts of hermodactyls produced by very different plants has never been supposed. That such, however, really is the case is the object of this communication.

In order that the subject may be fairly before us, we give the characters from Pereira:—

1. "TASTELESS HERMODACTYL; *Soorinjan Sheeran* (*i. e.* sweet sorinjan), Royle.—In their general form these cormi resemble those of *Colchicum autumnale.* They are flattened, cordate, hollowed out or grooved on one side, convex on the other. At their lower part (forming the base of the heart) is a mark or disk for the insertion of the root fibres. Their size varies; the specimens I have examined were from $\frac{3}{4}$ to $1\frac{1}{2}$ inches in length or height, 1 to $1\frac{1}{2}$ inches in breadth, and about $\frac{1}{2}$ an inch in depth. They have been deprived of their coats, are externally dirty yellow or brownish, internally white, easily broken, farinaceous, opaque, odourless, tasteless or nearly so, and worm-eaten. They agree precisely with hermodactyls furnished me by Professor Guibourt. They are readily distinguished from the cormi of *Colchicum autumnale* by the following characters, which are correctly stated by Geoffroy:—They are not rugose, are white internally, are moderately hard, easily broken, and form a whitish powder; whereas the dried cormi of *Colchicum autumnale* are rugose, softer, and have a reddish or greyish tint both internally and externally."

This is an accurate description of the tasteless hermodactyls, the starch granules of which are very much like, almost identical with, those of *Colchicum autumnale;* that is, the granules are compound, either binate or trinate, two or three granules being fused together into one mass of an elliptical or triangular, and rarely when four are united, into a quadrangular form. It is not at all uncommon to find mixed up with these corms in the bazaars of India Singhara nuts (*Trapa bispinosa*), which are very similar in size and form, but more distinctly triangular. The starch of these is simple, with a distinct crack or fissure in the centre.

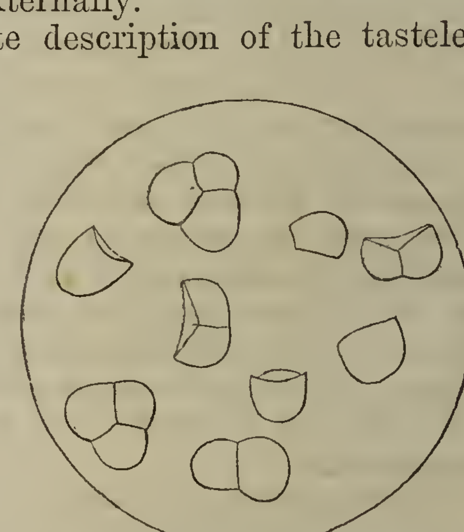

Fig. 1.—Starch-granules of the Tasteless Hermodactyls.

2. "BITTER HERMODACTYLS; *Soorinjan tulkh* (*i. e.* bitter sorinjan), Royle.—The cormi of this variety are distinguished from the preceding by their bitter

taste, their smaller size, and by having externally a striped or reticulated appearance. Their colour for the most part is darker; in some specimens it is blackish. One cormus is ovate cordate; 1 inch in height or length, ¾ of an inch broad, and about ¼ of an inch thick, grooved or hollowed on one side, convex on the other; of a brownish yellow colour, semi-transparent, has a horny appearance, and is marked by longitudinal stripes, indicating a laminated structure. A second is opaque, amylaceous, reticulated externally, white internally, less flattened, and of a remarkable shape, the concave or hollow side of the cormus being continued half an inch below the mark for the attachment of the root fibres. The other cormi are of the size and shape of a large orange-pip, but flattened or grooved on one side; some of them are worm-eaten, and one is blackish-brown externally."

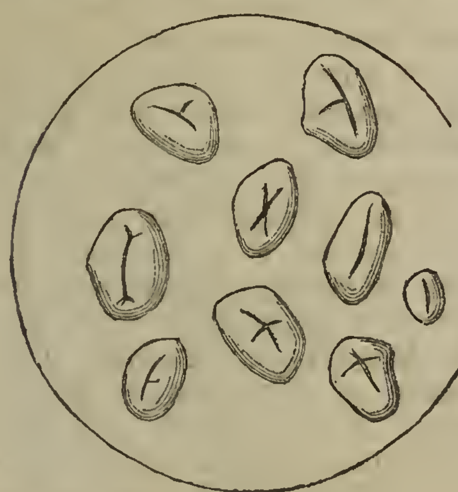

Fig. 2.—Starch-granules of *Trapa bispinosa.*

Whatever these specimens may have been, the description does not agree with the Soorinjan tulkh received from Bombay: the corms are larger than those of Soorinjan shereen, are split, and laid open, yellowish, more horny, quite bitter to the taste, and the starch is simple, elliptical or oblong, sometimes ovate, and nearly of the same size as the granules of *Trapa bispinosa*, but there is no indication of hilum, crack, or fissure of any kind. The starch does not therefore bear the slightest resemblance to that of *Colchicum autumnale*, or that of the tasteless hermodactyls, so that, although I have not the slightest doubt that the tasteless hermodactyls are correctly referred to a species of *Colchicum*, and probably *Colchicum variegatum*, I do not believe that the Soorinjan tulkh of the bazaars of Bombay are the produce of a species of *Colchicum* at all. It is clear that they are entirely distinct from Soorinjan shereen.

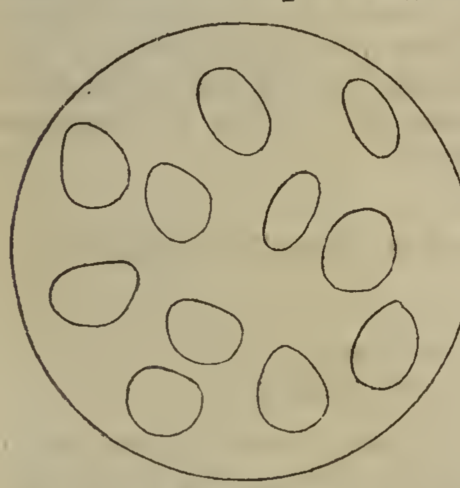

Fig. 3.—Starch-granules of the Bitter Hermodactyls.

I have no doubt whatever that there are two definite vegetable products known in India under the name of hermodactyls, and that they are the produce of very different plants and should be treated as distinct drugs. The character of the starch is quite sufficient to justify this conclusion. At present I am without any evidence as to the place of production, or the plant which yields the Soorinjan tulkh, but it is probably the most active drug of the two, since the tasteless hermodactyls seem to be about as starchy, tasteless, and inert, as fragments of dried potato. From the figures above given it will be observed that the starch of the bitter hermodactyls is nearly of the same size as in the Singhara nuts, but without the characteristic fissure; and that the starch of the tasteless hermodactyls is nearly identical with that of *Colchicum autumnale*. These facts, revealed by the microscope, again partly revive the question, "What are hermodactyls?" or, at least, if we assume that the source of tasteless hermodactyls is settled, the inquiry assumes the more definite shape, "What is the source of bitter hermodactyls?"

THE DIGESTIVE POWER OF COMMERCIAL PEPSINS.

BY J. S. HAWLEY, M.D.

The following remarks upon an article entitled "Liquid Pepsin and Saccharated Pepsin," which has been reprinted in this Journal* from the *American Journal of Pharmacy*, appear in the March number of that journal:—

In a recent number of your journal an article appeared by E. Scheffer, of Louisville, Ky., which not only impeaches my veracity, but is likely to do me serious harm pecuniarily.

This article contains an account of an experiment to test the digestive power of several varieties of pepsin, among others one made by the author of the article and one made by myself.

Of Mr. Scheffer's pepsin I have no knowledge, and am not disposed at present to question his statements concerning it. But in respect to the other varieties, I have made frequent tests of their strength, some of which I have published. To vindicate the truth of my statements I have performed a digestive test, following the method pursued by Mr. Scheffer, and will thank you to do me the justice to give it a place in your journal. In doing this, I wish it to be understood that no unfavourable reflections are intended towards Mr. Scheffer. On the contrary, his article bears intrinsic evidence of candour and scientific accuracy. It is my belief that he unfortunately procured a damaged sample of my pepsin, as he admits he did of Boudault's on a former occasion.

My only object in this communication is to set myself right before the professions of medicine and pharmacy.

In this test the same varieties of pepsin are used, and the same method pursued, as by Mr. Scheffer, except drying the residue, which has been done to secure greater accuracy of result.

In each of four suitable bottles were placed sixty grains of coagulated albumen (white of egg), one fluid ounce of water, five drops of muriatic acid, and five grains of Boudault's, Grimault's, Houghton's, and Hawley's pepsin respectively.

These were kept in the same water-bath, at a temperature of 98° to 102° F., and frequently agitated during the space of four hours. At the end of this time the undigested portions were removed and drained of moisture.

The following appearances were presented by the residua respectively:—

That digested in Houghton's pepsin appeared unaltered in form, colour and quantity, and soon became dry as before digestion.

That digested in Grimault's had lost something of its opacity, the angles were rounded, the quantity sensibly diminished, and presented an appearance of increased softness and moisture.

That digested in Boudault's possessed a slightly translucent appearance, the angles of the remaining pieces entirely destroyed and the quantity decidedly diminished, wet and inclined to remain so.

That digested in Hawley's pepsin had become nearly translucent and amorphous, the quantity much more diminished than the last and very wet, evidently considerable peptone adhering to the undigested portion.

These residua, together with sixty grains of coagulated albumen, which had been subjected to no diges-

* Pharm. Journ. *ante*, p. 666.

tion, were placed separately upon clean earthen plates and desiccated to dryness.

This desiccation was employed to avoid the difference of weight due to the difference of capacity for retaining water possessed by substances in different stages of digestion.

After complete desiccation, the residua weighed as follows:—

The albumen which had undergone no digestion weighed	$7\frac{1}{2}$ grs.
That digested in Houghton's	$7\frac{1}{2}$ "
" Grimault's	5 "
" Boudault's	2 "
" Hawley's	1 "

Now, since it appears that one grain of dry is equal to eight grains of fresh coagulated albumen, it follows that—

Houghton's pepsin is entirely negative or digested nothing.	
Grimault's digested	20 grs.
Boudault's "	44 "
Hawley's "	52 "
One grain of Grimault's pepsin digested	4 grs.
" Boudault's "	$8\frac{4}{5}$ "
" Hawley's "	$10\frac{2}{5}$ "
Grimault's digested of the albumen	$\frac{24}{60}$ "
Boudault's "	$\frac{44}{60}$ "
Hawley's "	$\frac{52}{60}$ "

This last comparison between Boudault's and Hawley's pepsin agrees, within a very small fraction, with my digestive test upon fresh beef, made more than a year ago, and published in my circular. This circumstance is somewhat corroborative of the correctness of both tests.

PHARMACEUTIC NOTES.

BY C. LEWIS DIEHL.

Blue Pill is one of the simple preparations of our Pharmacopœia that is seldom prepared by the apothecary; in fact, its preparation is the exception and its purchase appears to be the rule. There are numerous reasons why it is not generally prepared by dispensers, first and foremost among which may be mentioned the labour attending the extinguishment of mercury. Quite a number of processes for facilitating this have been from time to time recommended, but none seemed to me so simple as one recommended some time ago by a writer in one of our pharmaceutic journals, which consists in agitating the mercury with a small proportion of tincture of tolu, and then incorporating it with the proper ingredients. Another reason appears to be that blue-mass, when made strictly according to the Pharmacopœia, soon becomes hard and unmanageable. Manufacturers, taking advantage of this, aim to produce a blue-mass which, while corresponding in mercurial strength to the officinal article, will retain its plastic condition, and thus they create a demand for their particular manufacture.

While engaged in the manufacture of blue-mass on a considerable scale, I soon found it necessary to change the ingredients in order to obtain a more plastic mass, and succeeded very well, with but one objection, namely, that the mass was liable to become somewhat tough, and consequently more or less difficult to roll out. In other respects the mass left nothing to be desired. By experiments lately made, I believe to have overcome this difficulty; but I cannot say as yet that my experiments with tincture of tolu warrant the assertion that it affords a rapid and convenient medium for extinguishing mercury, without the application of more manual labour than is likely to be bestowed upon the object.

When one ounce of mercury is briskly agitated with half a fluid drachm of tincture of tolu, contained in a two-ounce vial, it soon becomes divided into globules, and in perhaps one or two minutes these globules will be scarcely visible, as such, to the naked eye. Occasional brisk agitation for twenty to thirty minutes, however, is necessary to so far extinguish the mercury as to render globules invisible through a lens of moderate power. After the mercury is so far extinguished, it would appear an easy matter to mix it with syrup, honey or any other desirable fluid that, in the manufacture of blue-mass on a large scale, is employed as an extinguishing medium; but this I have found not to be the case, for when the mixture is stirred into the remaining ingredients for blue-mass, globules of mercury abundantly form, and delay the completion of the process considerably. This is probably owing to the action of the syrup or honey, etc. upon the tolu coatings of the minutely-divided mercury, by which a portion of mercurial surface becomes exposed, and unites with another in a similar condition.

However, something is gained by the use of tincture of tolu, for I have prepared blue-mass in less than an hour,—twenty to thirty minutes of which being consumed in briskly rubbing the mixture to entirely remove globular mercury.

If it were practicable to keep blue-mass in the form of three-grain pills, as provided by the formula of our Pharmacopœia, there would be no necessity for a change in its ingredients. This not being the case, the formula should be so altered as to ensure a mass that will keep its soft consistence for a reasonable period. It may be contended that the ingredients entering its composition are necessary to its remedial properties, for some authorities maintain that blue-mass owes its virtues to the metal in an oxidized condition, and the question may then arise, "*Do the ingredients of the officinal blue-mass specifically tend to promote this oxidation?*" It is reasonable to suppose that such is not the case, for otherwise much of the blue-mass of commerce, in every other respect properly prepared, would be found ineffective. I venture to doubt that either powdered liquorice root or the components of confection of rose are essential to the effectiveness of blue-mass, and propose for its preparation the following formula:—

Take of Mercury,
Finely-powdered Marshmallow root, each 1 troy oz.
Syrup,
Glycerine, each 240 grs.
Tincture of Tolu, 30 minims.

Introduce the mercury into a two-ounce vial containing the tincture of tolu, and agitate briskly, at short intervals, for thirty minutes, or until the mercury shall have become entirely extinguished; then weigh the syrup and glycerine into the vial, agitate briskly, and immediately incorporate with the powdered marshmallow, rubbing the mass until any globules of mercury formed shall have entirely disappeared.

Blue-mass is formed in this manner with less labour, in a shorter time, and of a better consistence, than by any other process known to me. While the mass is decidedly firm, it will remain plastic for a long time, and can be rolled into pills that will keep their shape perfectly. After the addition of the liquid mixture to the powdered marshmallow, the mass retains a very soft consistence for a considerable time, requiring less laborious mixing than when confection of rose is used.

Regarding the use of tincture of tolu in the formation of blue-mass no decided opinion is offered, as I am still engaged with experiments, and hope in the next issue of the *Pharmacist* to present some more satisfactory results.

In connection with this subject, I would offer a few hints regarding other pill-masses that may be familiar to some but new to others.

Quinia pills are dispensed by me preferably, by forming the mass with the aid of glycerine, and rolling the pills in sifted arrowroot. A beautiful white pill is formed, which, by fastidious persons, is preferred to pills rolled in liquorice powder or lycopodium. Some authors object to the use of *glycerine*, on account of technical difficulties, but I have always found it the most convenient excipient for general pill-making, having seldom to resort to any other. Then its tendency to prevent the pills from becoming hard will fully compensate any additional labour that may now and then attend its use.

Several of our physicians prescribe sulph. quinia with tartaric acid, according to a formula published some years ago. Quinia pills so formed may possess some advantage over the simple quinine pills, being probably more readily dissolved and assimilated. The following is the formula:—

Take of Sulphate of Quinia, 30 grs.
Tartaric Acid, 4 grs.
Water, 1 drop.
Mix, and make pills of the required quantity.

The single drop of water is sufficient to form 30 grs. of quinia into a plastic mass, which must, however, be rolled into pills rapidly, else it becomes hard and more water is required.

These pills, like the preceding, should preferably be rolled in sifted arrowroot; in fact, all pills composed of colourless substances should be rolled in this powder, as it, apart from other considerations, necessitates the utmost cleanliness.

Carbolic acid in pills is occasionally prescribed. I have never met with any particular formula, and suggest the following as convenient and satisfactory:—

Take of Carbolic Acid, 1 part
Powdered Elm Bark, 3 parts
Gum Arabic, 1 part
Tragacanth Paste, a sufficiency.
Mix, and make pills of the required size, which may be coated with tolu or silver leaf.

Muriate of Ammonia, when required in form of pills, demands very careful handling, on account of its ready solubility. By adding about ten per cent. of powdered gum arabic, and sufficient tragacanth paste to simply moisten, pills are readily formed by the aid of glycerine.

Ammonio-ferric Alum is sometimes required in the form of pills. A handsome pill is produced by adding about one-eighth part of powd. gum arabic, and making the mass with glycerine, being careful to avoid an excess.—*The Chicago Pharmacist.*

QUINIA, AND SOME ANALOGOUS SUBSTANCES IN PRESCRIPTIONS AS TONICS AND EFFICACIOUS ANTIPERIODICS.

BY J. B. R. PURNELL, M.D.

The object of what follows (a part of which has before appeared in the *Medical and Surgical Reporter*, Oct. 1869) is not to allude to medicine of agreeable taste any more than to speak of certain combinations as more efficacious antiperiodics than quinia sulphate alone. Nevertheless, a knowledge of means of disguising any disagreeable taste—whenever this is possible without damage to remedial power—is and ought to be admitted as important, a palatable remedy being essential in a great many cases to comfort, in not a few to a cure. And, having noticed several accounts of formulæ intended to conceal the bitterness of quinia, I am induced to make some statements—conclusions which I think can be relied upon, being arrived at by some years of observation and many experiments made with care.

Ext. glycyrrhizæ alone (better with a little tannic acid) answers a good purpose with many patients, but a large proportion is usually required (5 grs. may be used for each grain of quinia sulphate or 2 grs. of cinchonia sulphate), and I find the taste of the extract is more often objected to than that of some other things that may be used; hence the importance of a knowledge, if possible, of a variety of substances to be employed to destroy the bitterness.

Tannic acid used in large proportion with quinia sulphate—less for cinchonia sulphate or the alkaloid quinia—conceals the bitterness, and the fact may be well known to the profession generally, or the majority; but it is probably not generally known that a slightly bitter taste of tannate of quinia—more properly a minute portion of precipitated quinine—will be perceived, though not until about half a minute after swallowing the mixture. The same is perceived, to some extent, in the case of any other combination by which the bitterness of quinia or cinchonia is disguised, but is probably more distinct with the tannic acid mixture; to prevent this it is only neces sary to rinse the mouth with water, or with cold tea, which is better.

In the first place, however, it is important to know whether the medical properties of a remedy are at all impaired by the substance used to disguise its taste; and there is evidence that there are many practitioners who would be unwilling to depend upon quinia sulphate combined with tannic acid in large proportion as an antiperiodic.

Quinia in the form of tannate in solution (or rather, in mixture) I have used for several years (in over a thousand cases), and believe it to be in no case less, oftentimes more, efficient as an antiperiodic than sulphate of quinia alone.

Without the aid of any other substance 8 grains of tannic acid will be required to entirely cover the taste of 10 grains of quinia sulphate; it is better, however, to use less, and in combination with aromatics unless an astringent be indicated. But the roughness of tannic acid is unpleasant to many persons. To prevent this, add sugar in abundance and a little aromatic. But if sick stomach should be present much sugar cannot be retained or will be refused (true at least in the majority of cases), and this will be a trouble; and if to the same person the taste of tannic acid should be very unpleasant, there will be another trouble, and the difficulty will be increased. Now in this case, as well as the case of a patient who for any other reason objects both to sweet medicine and tannic acid, if, while employing but little sugar, we use rather less tannic acid and a large instead of a small quantity of aromatic, and dilute the dose sufficiently—though unnecessary to dilute very largely—we shall generally succeed. Though in regard to quinia sulphate directly, a small quantity of aromatic, however used, can accomplish nothing, and the effect of a large quantity, when employed alone, is too trivial to make it useful, the same (large quantity) will nevertheless assist much in disguising it, provided a certain proportion of tannic acid be present.

Some persons who sweeten quinine, expecting by this means to somewhat diminish the bitter taste, only add to the trouble, for the bitterness is increased by the addition of sugar without any other substance, or at least is not lessened in the slightest degree, and is caused to be perceived for a much longer time for the reason probably that it imparts an adhesive property to the solution which, consequently, remains longer on the organs of taste and penetrates.

Cinchona, though containing the alkaloids and not usually requiring tannic acid—a fact readily accounted for from the presence of cincho-tannic acid—will be sufficiently disguised by the use of sugar, cinnamon and orange. Tr. cinchonæ comp., already containing aurantii cort., will require only sugar and cinnamon. For tr. gentianæ comp. tannic acid and sugar may be used, though the addition of syr. sarsaparilla comp. or ext. sars. fl. co. will greatly improve it, or either of the last two named with an aromatic alone can be employed. A palatable and efficient elixir of cinchona may be found in

Parrish's 'Pharmacy.' The following recipes will be adequate to the end proposed:—

℞. Tr. Cinchonæ Comp. f ʒv
Tr. Calumbæ f ʒij
Spt. Lavandulæ Comp.
Tr. Cinnamomi, *aa* f ʒj
Syr. Aurantii f ℥ss
Ext. Glycyrrhizæ ʒss. M.

℞. Tr. Gentianæ Comp.
Tr. Cinchonæ Comp. *aa* f ℥ss
Ac. Tannici gr. ij.
Syr. Sarsaparillæ Co. f ℥i. M.

℞. Tr. Cinchon. Co. f ℥ss
Ferri et Potass. Tart. ʒj
Spt. Cinnamomi f ʒss.
Curaçao f ʒij
Sacch. Alb. ʒij
Aquæ f ℥iij. M.

The fer. et potass. tart. here serves a twofold purpose, since it helps materially to conceal the bitterness. The following formulæ will generally prove efficacious as tonics or antiperiodics, and not unpalatable to the majority of persons, and may be varied somewhat according to the case and the taste of the patient.

℞. Quiniæ Sulphatis gr. xv
Cinchoniæ ,, gr. x
Acidi Tannici gr. x
Syrupi
Syr. Aurantii Cort. *aa* f ʒvj
Ol. Aurantii
Ol. Sassafras, *aa* gtt. iij
Aquæ Cinnamomi f ℥ij Misce.

℞. Quiniæ Sulph. gr. xv
Cinchoniæ ,, gr. viij
Ac. Tannici gr. v
Ext. Sarsapar. Fl. Co. f ʒiij
Syr. Sarsapar. Co. f ℥iss.
Aquæ f ℥i. M.

℞. Quiniæ Sulph. gr. xx
Liq. Potassæ Arsenitis m. xx
Acidi Tannici gr. xij
Syr. Aurantii Cort. f ʒvi
Aq. Menth. Pip. f ℥iij.
M. S. f ʒj ter die. As an antiperiodic f ℥ss–f ℥ij.

℞. Quiniæ Sulph. gr. xx
Cinchoniæ Sulph. gr. xv.
Ac. Tannici gr. vi
Syr. Sarsapar. Comp. f ℥iiiss
Ol. Anisi m. vi
Tr. Cinnamomi f ʒiij.
M. S. f ʒj ter die. As an antiperiodic f ʒss–i.

To prevent the slightly bitter taste which begins to be perceived about half a minute after swallowing the dose, rinse the mouth with water, or with cold tea, which is better.

Coffee (if a good article) in strong decoction, or prepared by displacement or in powder, while it adds to the antiperiodic effect, disguises the taste of a large proportion of the sulphates of quinia and cinchonia and like bitters, as well as some other remedies, not impairing the medical properties, and though not new it seems not to be generally known. It is, perhaps, generally known to have been much used to conceal the taste of senna and magnesia sulphate, and in regard to quinia, Waring mentions the fact on page 229, 'Practical Therapeutics.' He says, "Coffee is of importance as a means of disguising the taste of nauseous medicines, particularly quinine, senna and epsom salts." It is to be remembered, however, that a weak preparation will not do.

℞. Coffee ½ teacupful, Water Oiss.

Use no milk with it unless a very small quantity only is desired to flavour; with or without sugar according to taste.

In relation to this subject there is an important fact to be borne in mind. The quinia or cinchonia sulphate should be put in the coffee in form of powder. If dissolved first with an acid, a decided bitterness will be perceived. So, in the case of anything employed to conceal the taste of quinia sulphate and like bitters, use the bitter in powder, avoiding an acid or (with a few exceptions) any perfect solution.

Cocoa or chocolate, if the quinia sulphate is not in large proportion, conceals the taste to a great extent, provided it be used of a sufficient strength, as in the solid or semi-fluid state. For cinchonia sulphate it will do better, since the taste of this substance is not so difficult to cover.

A decoction—five minutes boiling—of a certain strength (a weak preparation will not answer) of a mixture of green and black teas (I have not succeeded so well with either alone, yet there can be no reason why one will not do), after standing with the leaves for eight hours, disguises the taste of quinia and cinchonia sulphates, though not in so large proportion as coffee. For this purpose:

THE FOOD PRODUCTS OF ST. PETERSBURG.

In a Report on the Food Products of St. Petersburg to the Lords of the Committee of Council on Education, Mr. Andrew Murray has given some very interesting information, the result of inquiries having special relation to the Food Department of the South Kensington Museum and its requirements.

At the Industrial or Agronomic Museum in St. Petersburg he found some curious specimens of what may be called abnormal food, only eaten on occasions of great scarcity, as lichens and sawdust cakes from the north, and different kinds of clay from central Russia; but the normal food was not represented. M. de Solsky, the gentleman in charge of the museum, was engaged in making a collection, and not only gave Mr. Murray every assistance in his power, but insisted on being himself allowed to supply a set of specimens gratuitously to the South Kensington Museum.

The breads resolve themselves practically into different modifications of three chief kinds: tschernoi-chleb, black bread, made of rye; kalatsch, white bread, made of wheat, of which the best kind comes from Moscow; and saika, white bread enriched with raisins or other accessories, equivalent to our buns or Scotch "cookies."

Ices are made in great perfection in St. Petersburg. Those met with in London are all in common use there. In addition, there are some others. One, a very good kind, is made from, or flavoured by, the hazel nut. Another, still better, is a water ice, made from the fruit of the "clucva" or cranberry (gathered after the berry has been touched by frost), sweetened and slightly flavoured by vanilla. In Russia this is much used for invalids, and Mr. Murray thinks it worthy of introduction into this country, or, if already in use, of being more generally known and adopted, not only for the sick-room, where its refreshing coolness and slightly subacid flavour are inexpressibly grateful to the fevered palate, but simply and selfishly for the gastronome. The cranberry is also put to another use in Russia. During the summer months a great traffic in beverages is carried on in the principal streets. Boys with large glass ewers, holding about half a gallon of some coloured liquid, haunt the corners of streets or porticos of buildings. The most common is a rose-coloured drink, which owes its colour and its virtue to the clucva. The other drinks are lemonades and similar concoctions.

St. Petersburg is well supplied with fresh vegetables.

The great vegetable staple of the country, however, is the cabbage, which grows in great perfection, fine, large, solid, white and crisp. It supplies a chief portion of the subsistence of the people all the year round. At the beginning of winter every family lays in a store. At that time the plants are cut down, and chopped up or shred into thin slices. These being packed in barrels with vinegar and salt, a kind of fermentation takes place, the cabbage becoming a kind of sour crout. This is made with meat into a cabbage broth called "shtshi," which is the most characteristic national dish in Russia, and forms the daily food of the mass of the people. Meat is about half the price in St. Petersburg that it is in England, and much more freely used. For 40 kopecks (about 1*s*.) Mr. Murray had a plate of shtshi, with three large pieces of meat in it, sufficient for any average Englishman to have made a copious dinner from. The shtshi is of various degrees of excellence. When the fermentation goes too far, it becomes rather "high;" this, however, is considered a blemish. It also is made to assume various shapes, such as green pea and similar soups, but the subacid flavour is always more or less pronounced. As the shtshi is generally composed of very strong rich bouillon, with only a moderate amount of cabbage, the effect is agreeable. A small dish of sour cream, beautifully white and thick, is placed on the table, in order that the guest may suit the acidity to his taste. Another little dish is sometimes placed alongside the sour cream, and used as a substitute for bread. It consists of a small plateful of fried or roasted groats, which are eaten with a spoon alternately with the shtshi. Garlic is used, if at all, in moderation, and its flavour is not allowed to obtrude itself.

Fungi constitute another food-product which figures largely in the consumption of the upper classes of St. Petersburg. All the chief species used in this country also occur in greater abundance in Russia, and are greatly prized there. The true mushroom (*Agaricus campestris*), the morel and the *Agaricus deliciosus*, are the most generally used, but a great many others are freely eaten.

Leaving the vegetables, and turning to the products which vegetarians look upon as a transition between them and flesh, milk and its phases, it appears that the preparations of milk and curd are more various than in this country. In cheese Russia is making great progress. A kind is now made so like gruyère that it is impossible to distinguish it from it, and it is sold as gruyère. A second variety in the same direction, called meschtschersky, is not unfrequently passed off under the same name. Sour cream is a favourite accessory to many dishes. Its use with shtshi has already been alluded to. It is used with pork as we use apple sauce, and the Germans sour crout.

Mr. Murray found the pork to be very free from trichinæ, a result which he attributes to the precautions taken by the Government to prevent the spread or introduction of diseased meat. The mutton in Russia is much inferior to our own, as it is in all the plains of the North of Europe. The beef and veal appear to be of medium quality.

We can but hurriedly notice the fishes used as food in Russia. The principal of these is the sterlet, a small species of sturgeon, tasting something like an eel, and esteemed a great delicacy. It is taken in immense numbers near the mouth of the Volga at certain seasons of the year. There is also the sturgeon, from which is prepared caviare, pronounced by experts to be the greatest delicacy in existence. This only applies to it in its fresh state, when its green pellets of roe, as large as swan shot, are seen floating in a rich gelatinous menstruum, which disappears in the dried or preserved state. Another fish, called the "schnepel," is cured and smoked, and tastes something between a fresh salmon trout and a kippered herring. Mr. Murray discusses at some length the possibility of naturalizing these and other fishes in the British waters.

Lastly, the drinks of Russia are treated of. The water of St. Petersburg is said not to be altogether wholesome, at least to those unaccustomed to it. New-comers who use it freely usually suffer from diarrhœa. It does not always affect strangers immediately, six months elapsing sometimes before the effects show themselves; these gradually wear off as the stranger becomes acclimatized.

Coffee is generally prepared by the ladies of the household and not trusted to the servants. The material is the same as elsewhere and the product is of good quality.

The tea is very different from that used in England. The strong black high-flavoured Congou, from the south of China, which is most generally drunk here, is almost unknown in Russia. When by accident a Russian has it, such as by present from an English friend, he does not know how to use it; so that the Englishman who wants what he would call a good cup of tea in Russia, must take his tea with him and make it himself. The kind used is the light delicate-flavoured tea from the north of China. However strong the infusion might be made, it would be impossible to make from it one as dark and black as ours. At the strongest theirs never seems to get beyond a light amber colour. A cup of tea of the colour of senna or coffee would revolt them. Hence, when they have English Congou they regulate the strength of the infusion by the colour they are accustomed to see in their own, a standard which, to speak mildly, does not produce strong tea. But their tea has merits not possessed by ours. Coming from the colder districts and more mountainous regions of northern China, it has not the strong aroma of that from the less elevated and hotter slopes of the south, but it has in its place a peculiar delicacy and refinement of flavour. Mr. Murray is inclined to think that this tea must differ also in chemical properties and physiological effects, as the last meal of the Russian is generally a cup of tea, a custom that could hardly be carried out with impunity if our variety were used.

Of the native fermented drinks, there is first a poor beer called "guass," manufactured from the remains of rye used in making bread; it has a muddy appearance and very much the taste and strength of what is known to housewives as "treacle beer." Hydromel is a fermented mixture of honey and water. It is an undecided suppose flat and ungingered ginger beer might be. beverage of a mild character, not unlike what one might

Vodka is a kind of whisky or spirit of wine distilled from rye and usually much diluted. The word is also employed in a general sense. To take a vodka means also to take a dram, and is applied to all kinds of liqueurs. The practice of the Russian is to take a vodka before dinner, and by way of a whet a mouthful or two of caviare and bread, or sardines, or something of that sort. These materials are provided for the guests to avail themselves of before sitting down to dinner; a custom not without its ludicrous side, as we are told that before now strangers have mistaken the "whet" for the dinner and acted accordingly.

With regard to the wines, it is well known that the Crimea, Bessarabia and the Caucasus are becoming great wine countries. Great care has been taken to procure the best vines from France and Germany, and skilled labour has been introduced to instruct the natives in the manufacture. But the result at first was not encouraging. The vines lost their special qualities by the transfer; the grapes had not the same taste, and, as might be expected, the wine was not the same either. By perseverance and continued experiment, a process of selection and elimination being adopted, it was found that, although they could not obtain the old well-known wines, they could produce some well worth drinking, and the wines of these countries are gradually acquiring a character of their own.

TINCTURE OF NUX VOMICA (U.S.).

BY J. B. MOORE.

The tough and corneous character of nux vomica, and the obstacle this offers to the solution of its active constituents, render it one of the most difficult substances in the materia medica to exhaust with a limited quantity of menstruum. It is, therefore, important that the greatest care be exercised in the preparation of the tincture and all the pharmaceutical preparations of the drug.

The U. S. Pharmacopœia directs *fine* powder, No. 60, to be employed in making the tincture, and gives the following directions for its preparation:—"Mix the powder with a pint of alcohol, and digest for twenty-four hours, in a close vessel, with a gentle heat; then transfer the mixture to a cylindrical percolator, and gradually pour alcohol upon it until two pints of tincture are obtained."

Having, in common with many of my brethren in the profession, had frequent difficulty in thoroughly exhausting the drug and obtaining a satisfactory preparation when complying with the above directions, I was induced about two years ago to institute a series of experiments, with the view of so amending the officinal formula and process, that a more uniform and reliable tincture might be made; and, after many experiments with various modes of manipulation, and with powders of different degrees of fineness, I became convinced that a finer powder than is directed in the officinal formula was necessary to ensure the perfect exhaustion of the drug, and that some change in the process was also required. As the result of my efforts, I offer the following modification of the officinal process, as affording the most satisfactory results:—

℞ Pulv. Nux Vomica, No. 80, ℥viij troy
Alcohol a sufficient quantity.

Mix the powder with $1\frac{1}{2}$ pint of alcohol, and digest for twenty-four hours, in a close vessel, at a temperature of 120°, with occasional agitation; then strain through muslin with strong expression, and rub the residue through a No. 20 sieve; then pack it firmly in a glass cylindrical percolator, and gradually pour upon it the expressed liquid, and, when it has all been absorbed, continue the percolation with alcohol until 2 pints of tincture are obtained.

Instead of digesting the drug with only a pint of alcohol, as directed by the Pharmacopœia, I use a pint and a half, as it is desirable to secure the solvent action of as much of the menstruum as is possible during the digestion.

I also direct the mixture to be expressed at the completion of the digestion, as the residue can then be properly packed for percolation. This is of paramount importance to the success of the operation, and is much better than pouring the mixture into the percolator and allowing it to settle and adjust itself, as in the officinal formula, because in doing so the homogeneous condition of the mass is disturbed by the partial separation of the finer and coarser particles.

The residuum should be packed so firmly in the percolator that, when percolation commences, the tincture will not pass at a faster rate than from five to eight drops per minute.

If the above directions are carefully complied with, a good and reliable preparation will result. When the process is completed, the dregs in the percolator will be found to be tasteless, or nearly so.

The almost insuperable difficulties attending the reduction of nux vomica to a very fine powder, with the facilities afforded by any ordinary retail drug store, forbid the idea of any pharmacist attempting to powder the drug for himself; consequently, nearly all are compelled to rely upon the wholesale market for their supply. Therefore, I think that our wholesale druggists should keep constantly on hand nux vomica in *very fine* powder. I presume it is quite a difficult matter to reduce it to so fine a state of division, even by the aid of the appliances of the best arranged drug-powdering establishments; yet, by proper treatment, it can be done.

At the time I was engaged with my experiments I found it impossible to obtain any powdered nux vomica in this market that even came up to the requirements of the Pharmacopœia; and to procure the very fine (No. 80) powder I desired, I was obliged to send to Dr. Squibb, in Brooklyn.

There was but one or two of our wholesale drug houses that had any powder finer than from No. 30 to No. 40. Now, as pharmacists have to depend almost exclusively upon the commercial powder to prepare their tincture from, this would seem to indicate that it is nearly all made from powder entirely too coarse, and must necessarily often be of very deficient strength. To this cause may be attributed the frequent failure of physicians in deriving the desired therapeutic effects from the administration of the tincture. It is not uncommon to hear medical men remark that they have lost confidence in the virtues of tincture of nux vomica, and many have ceased to employ it in their practice. But I believe that if it be carefully and properly prepared, it is as efficient and reliable a preparation of the drug as any that is made.—*Amer. Journ. Pharm.*

Will Snake-Poison Kill a Snake?—Dr. Fayrer, in India, has been experimenting to correct the popular error that a snake cannot kill a snake. He took a young and very lively cobra, fourteen inches long, and which was bitten in the muscular part of the body by a krait forty-eight inches long. The krait had not bitten for some days before. From a detailed report by Dr. Fayrer, it appears that the cobra was bitten at 12.50 P.M. At 1 P.M. it was very sluggish, at 1.3 P.M. so sluggish that it moved with difficulty, could be easily handled, and made no effort at resistance. At 1.20 it was apparently dying, and its movements were scarcely perceptible, and at 1.22 it died, thirty-two minutes after the attack. Dr. Fayrer has found that the water-snakes of India are deadly poisonous. In the Bay of Bengal they swarm, and it is noted as ominous that lately it was proposed to erect a sea-bathing establishment for Calcutta at Barwar, under the assurance that there were no sharks. It is remarked that sharks need not be noticed when a bather may have deadly water-snakes swimming after him.—*Nature.*

Tuba Roots.—The roots of a plant known in Borneo by the name of Tuba or Tooba, are reported to be much valued in that country for destroying vermin on plants or animals. They are thrown into water and allowed to stand a short time, after which the plants or animals are washed with the water. Europeans who have used it say that its effects are sure and instant, and that while fatal to insect life, it does not in the least degree injure the plants or animals to which it is applied. The roots are used when fresh, and evidently lose their properties by drying, as a decoction which had been prepared from some roots received in the dry state has been applied to some plants infested with vermin without the slightest effect. The roots are also constantly used by the natives for poisoning fish in streams and pools. The plant is said to be leguminous.—*The Gardeners' Chronicle.*

Test for Silver-Plating.—In the January number of *Polytechnisches Journal von Dingler* is a simple process by Professor Bœttger for testing the genuineness of silver-plating on metals, which may be of value to many. The metallic surface is carefully cleaned, and a drop of a cold saturated solution of bichromate of potash in nitric acid is placed upon it, and immediately washed off with cold water. If the surface is silver, a blood-red spot of chromate of silver is formed, whereas on German silver or Britannia metal the stain is brown or black.—*Athenæum.*

The Pharmaceutical Journal.

SATURDAY, APRIL 1, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

MR. MUNTZ'S ADULTERATION BILL.

MR. MUNTZ's Adulteration Bill has now been read a second time, and the discussion on its merits is to take place when the Bill goes into Committee. The provisions of the Bill are probably known to our readers, as it was published in a recent number of this Journal. It will be remembered that Mr. MUNTZ intends to deal with the adulteration of food, drink and drugs, and proposes to incorporate in his Bill the Adulteration Act of 1860, and those portions of the Pharmacy Act of 1868 which deal with the adulteration of drugs. The question of the adulteration of food and drink will, doubtless, be discussed in the columns of other periodicals directly interested in the subject; we, therefore, intend to remark more particularly on the regulations for suppressing the sophistication of drugs and the nature of the penalties to be enforced for infringements of the law.

In the Bill are recognized two classes of offenders, namely, those who wilfully admix or who cause to be admixed any ingredient or material with any drug to adulterate the same for sale, and those who sell any drug which is adulterated or not pure. The first class of offenders are for a first offence liable to a penalty not exceeding £50, and for a second to be imprisoned for not more than six months with hard labour. The penalty for a first offence in the second class is a fine not exceeding £20, and for a second offence, in addition to the fine, the justices may cause the offender's name, address and offence to be published in the newspapers.

The provisions of this Bill are certainly not founded on simple justice, for while the adulterator or seller of food or drink cannot be convicted, unless it be proved that he is aware of the adulteration, the vendor of drugs has no such leniency extended to him, as in his case the onus of proof that he had no knowledge of the adulteration rests not with the plaintiff but with the defendant. Why there should be this difference is not for us to say, and probably the framers of the Bill could not give a very satisfactory reply to the question, but we think no distinction ought to be made between such offences, as they are all equally bad, and consequently deserve a like punishment.

It is hoped that when the clauses in the Bill are discussed, attention will be drawn to the fact that by far the greater portion of the drugs used in this country are imported, and that to check adulteration at its source, it is certainly the duty of the promoters of the Bill to take steps to prohibit the importation of all adulterated drugs, and thus give facilities to those dealing in drugs to comply with the law. We hope that this will be insisted on by those anxious to deal justice all round, and it is the more necessary that this all-important thing should be done, because very many druggists have neither the appliances nor the skill to test the genuineness of the drugs they purchase. It will, doubtless, be said that the examination of drugs on importation would cause a great deal of labour and much inconvenience; we are aware it would, but in America the machinery has been devised for such a purpose, and, doubtless, such a thing could be performed equally well in this country. However, of this we are certain, that if adulterated drugs are allowed to be imported without hindrance, and Mr. MUNTZ's Bill becomes law, it will require only a few convictions either to make the law a dead-letter, or to cause the chemists and druggists of the United Kingdom to take a proper view of their position, when their numbers and influence will certainly cause the legislature to pay respect to and redress their grievances.

We are by no means advocates of adulteration, but would gladly do all in our power to assist in its suppression; at the same time it is our duty to point out one of the gravest defects of the Adulteration Bill now before the House of Commons, and we are sure that if this defect be not remedied the Bill will in practice be found unworkable.

PHARMACEUTICAL LEGISLATION IN ILLINOIS.

AMONG the proposals for legislation affecting the practice of pharmacy on the American continent now under discussion is one that has been prepared by the pharmacists of Chicago. The Board of Health of that city having made an attempt to limit the sale of poisons and regulate the dispensing of medicines, failed from not having the necessary powers. Consequently the draft of a proposed law for regulating the practice of pharmacy and the sale of poisons in the State of Illinois has been drawn up, and is now before the State Legislature for adoption. Its principal provisions are—

That on and after the 1st of August, 1871, it shall be unlawful for any but a registered pharmacist or a registered assistant in his employ, or an aid or apprentice under the immediate supervision of a registered pharmacist or assistant, to retail, compound or dispense medicines or poisons.

The persons entitled to registration under the Bill would be (1) "graduates in pharmacy," who have had four years' experience in a store where the prescriptions of medical practitioners are compounded and possess satisfactory credentials of their attainments from a regularly incorporated college or school of pharmacy; (2) "practising pharmacists," who at or prior to the passing of the Act have kept or continue to keep open stores for the dispensing of prescriptions and the sale of drugs and medicines; (3) "practising assistants in pharmacy," of not less than eighteen years of age, who at or prior to the passing of the Act shall have been employed in the compounding of prescriptions of medical practitioners, and who shall furnish satisfactory evidence of their attainments and competency to the Board of Pharmacy. Afterwards none are to be deemed qualified for registration under the Act but "graduates in pharmacy" and persons who have had four years' experience in a store where prescriptions were compounded, and shall pass an examination before the Board of Pharmacy.

The Board of Pharmacy is to consist of three pharmacists, chosen by the Governor of the State from twelve gentlemen to be nominated by the incorporated colleges of pharmacy in Illinois. This Board is to appoint two examiners in each town when necessary, for the purpose of examining candidates for registration as assistant pharmacists. Certain fees are to be paid, and any balance remaining after the expenses of carrying out the Act is to be paid in equal amounts to the library fund of the colleges of pharmacy in the State.

A registrar is to be appointed, who is to prepare annually a list of persons entitled to be registered, a copy of which he is to send free to every registered pharmacist in the State. A registered pharmacist, upon changing his place of business, is to forward a notice of the same, together with a fee of one dollar, to the Board, that the necessary alteration may be made. Once a year every pharmacist is to notify whether he still practises pharmacy at his registered place of business, and to send a fee of one dollar, that his name may be inserted in the register for the ensuing year. The names of persons who do not comply with this regulation, are, after one letter of inquiry from the Registrar, to be omitted from the register.

There are three schedules of poisons attached to the Act, which are as follows:—

Schedule A.—Aconite and its preparations; arsenic and its preparations; corrosive sublimate; cyanide of potassium; hydrocyanic acid; nux vomica and its preparations; opium and its preparations,—excepting paregoric and all preparations containing two grains or less of opium in one ounce; strychnia and all poisonous vegetable alkaloids and their salts; essential oil of bitter almonds, of pennyroyal, of savine, of tansy, and of rue.

Schedule B.—Oxalic acid; sugar of lead; sulphate of zinc; white precipitate; red precipitate; tartar emetic.

Schedule C.—Belladonna and its preparations; cantharides and the tincture; chloroform; cotton root and its preparations; croton oil; digitalis and its preparations; ergot and its preparations; henbane and its preparations; chloral (hydrate); poison hemlock or conium; all mineral acids.

A penalty of fifty dollars is to be inflicted upon unregistered persons keeping open shop for retailing or dispensing medicines or poisons, but provision is made that in rural districts retail dealers may be licensed by the Board to sell the usual medicines and the poisons included in Schedules B and C. Neither of the poisons in the three schedules is to be sold to any person who appears unduly excited or intoxicated; or to a child of less than twelve years of age, or until inquiry has been made of the purpose for which it is required. Poisons in Schedules A and B are to be labelled with the name of the article, the word "poison," and the name and address of the seller. Besides this, an entry is to be made in a book of the sale of poisons in Schedule A, stating the date, name and address of purchaser, name and quantity of article and the purpose for which it is stated to be required.

The dispensing of physicians' prescriptions is exempted from the provisions relating to the sale of poison. It is, however, provided that all prescriptions shall be numbered and filed, and preserved for at least five years; but a copy is to be furnished if demanded by the writer or the purchaser, for which no fee is to be charged.

Another Bill has been framed in Illinois, in reference to the vending of proprietary medicines, requiring that a statement of the ingredients of all such preparations should be filed in the office of the clerk of each county in which they are sold. The *Pharmacist*, referring to this Bill, expresses an opinion that it would not be enforced if passed, and that it would be better to require the formula to be plainly printed upon each bottle or package offered for sale, and to provide a severe punishment for those who do not prepare their nostrums in strict accordance with the printed formula.

In a letter to the *Lancet*, Mr. M. C. Furnell, F.R.C.S., Professor of Physiology at the Madras Medical College, and formerly a student in the Laboratory of the Pharmaceutical Society, has made another contribution to the history of anæsthetics. He says that in 1847, he, being then a pupil at St. Bartholomew's, was trying the effects of sulphuric ether, when he was led by accident to try chloric ether, and found its effect in producing insensibility to be the same, while it was free from the disagreeable taste of sulphuric ether. At Mr. Jacob Bell's recommendation he brought it under the notice of Mr. Holmes Coote, who was then Mr. Lawrence's assistant; and upon Mr. Furnell's assurance that he had tried it on himself, and that it was perfectly safe, it was administered to a patient who was to be operated on that very day. Its success was so decided that Mr. Lawrence subsequently administered it to a lady who could not take sulphuric ether.

We wish to remind our readers that the evening meeting of the Pharmaceutical Society for April will be held on Wednesday next. The papers to be read are, "Alterations in the Pharmacopœia Nomenclature," by Professor Attfield; "Note on Vinum Ferri," by Professor Attfield; and "A Concentrated Form of Mistura Ferri Composita," by Mr. C. A. Staples. The chair will be taken at half-past eight precisely.

General Sir E. Sabine having expressed his intention of resigning the office of President of the Royal Society at the next Annual Meeting, the Council have selected Mr. George Biddell Airy, the Astronomer-Royal, for nomination to the office. Mr. Airy has expressed his willingness to accept office.

The first Report of the Royal Commission was issued on Wednesday. It recommends the consolidation of the School of Mines and the College of Chemistry as a Science School, to be governed by a Council of Professors. It is proposed that mathematics be added to the courses of instruction, and laboratories and assistance for giving practical instructions in physics, chemistry and biology be provided. The Commission recommends that the Science School should be accommodated in the buildings, now nearly completed, at South Kensington, for the projected School of Naval Architecture and Science.

At the semi-centennial meeting of the Philadelphia College of Pharmacy a gold watch was presented to Mr. Procter, the retiring editor of the *American Journal of Pharmacy*, by the members, as a token of their appreciation of the services rendered by him to Pharmacy during his twenty-five years' editorship of that Journal.

According to the *Worcestershire Chronicle*, it having been found by a Board of Guardians that the wine ordered for the patients did not reach them, a resolution was passed to mix an ounce of bark with each gallon of port wine intended for the patients, in the hope that it would thus be rendered unpalatable.

We learn from our contemporary *Nature*, that Mr. Herbert M'Leod, of the College of Chemistry, has been appointed Professor of Chemistry and Experimental Physics at the Indian Engineering College.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Ninth General Meeting of the present Session was held at the Royal Institution, on Thursday evening, March 16th; the President, Mr. John Abraham, in the chair.

The President handed to the Honorary Secretary a Book of MS. Prescriptions, collected and arranged by Joseph Ince, Esq., F.L.S., etc., of London, and presented by him to the library of the Liverpool Chemists' Association. He said the Association would feel much indebted to Mr. Ince for his valuable present, which he trusted students in pharmacy would take advantage of. He also suggested that it would be of service to employers, to test assistants before engaging them. The Council were desirous that the members should have optunity to avail themselves of the benefit to be derived from the collection; and, in order to accomplish this, they had adopted a resolution, which he called upon the Secretary to read:—

"That application for the book be made to the Librarian *in writing*, that no Member or Associate be allowed to keep it longer than three days without being liable to a fine of twopence per day. The written application to be given up when the book is returned."

The President also handed to the Secretary a copy of Bentley's 'Manual of Botany,' 2nd edition, 1870, which the author had requested him to present to the Association.

The Secretary announced donations of the *New York Druggists' Circular*, the Pharmaceutical Journal, etc., to the Library; and a specimen of fresh nutmeg fruit, with leaves, etc., to the Museum, from Mr. Richard Evans.

Unanimous votes of thanks were accorded to the donors for their valuable contributions.

The paper for the evening was read by Mr. James Blair, on "The Chemistry of Calico Printing," No. I. The author very ably showed the various processes from the first stages, describing in detail the chemical composition and combinations of the aniline salts, etc., used to produce the various colours.

The paper was practically illustrated with numerous drawings and photographs of the machinery employed; specimens of cloth, showing the various stages of bleaching and printing, from the raw or grey cloth to the finished pattern of many colours and intricate design.

A short discussion followed, and upon the motion of Mr. Davies, supported by Mr. Garnett and the President, a vote of thanks was accorded to Mr. Blair, for his valuable paper.

BRADFORD CHEMISTS' ASSOCIATION.

At a General Meeting of this Society, held on Friday, the 24th inst.; Mr. Rimmington, President, in the chair, the following resolution was moved by Mr. Joseph Hicks, seconded by Mr. G. H. Whitehouse and unanimously adopted, after a free discussion of the proposed regulations for storing and dispensing of poisons, and ordered to be forwarded to the Council of the Pharmaceutical Society:—

"That this meeting, while wishing to give every reasonable support to the Council of the Pharmaceutical Society in its efforts to promote the interests and the progress of pharmacy, views with regret the decision of the Council to again submit the regulations for storing and dispensing of poisons to the Annual Meeting in May, believing that the education now required now of all who enter the business is the best guarantee of safety to the public."

In acknowledgment of the handsome volume of autograph prescriptions recently received from the parent Society, the following resolution was moved by Mr. J. Hicks, seconded by Mr. F. Bell, and unanimously adopted:—

"That the best thanks of the meeting be conveyed to the Council of the Pharmaceutical Society, for the presentation of the Book of Autograph Prescriptions."

A similar resolution to the last was also adopted, and ordered to be forwarded to Mr. Ince, for his kindness in compiling the collection.

Mr. H. G. Rogerson was elected to fill the vacancy in the Council.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

At the Meeting of this Society on March 2, a paper was read on "The Distillation and Boiling-point of Glycerine," by Mr. Thomas Bolus.

It is well known that when glycerine, subjected to the ordinary atmospheric pressure, is heated so much as to cause ebullition, it is more or less rapidly decomposed by repeated distillations. This decomposition may be, however, entirely prevented by a reduction of the pressure in the apparatus employed to 12·50 mm. The boiling-point of glycerine was determined by effecting the distillation in a long-necked flask, having a supplementary neck attached at right angles to the principal one. In the principal neck, the thermometer was fixed by the aid of a caoutchouc cork, while the smaller neck was connected in a similar manner with a two-necked receiver. The glycerine, together with a few fragments of tobacco-pipe (this latter being required to prevent the bumping which would otherwise occur), being placed in the retort-flask, the receiver was connected with a Sprengel's mercurial pump and a manometer, the caoutchouc joints being made air-tight with glycerine in the usual way. Unless the glycerine distilled had been dehydrated by previous distillation in a vacuum, the first portion of the distillate consisted principally of water; afterwards, when the glycerine in a pure state came over, the temperature indicated by the thermometer was 179·5° C. At this time the pressure on the liquid was 12·5 mm., a pressure nearly corresponding to the tension of aqueous vapour at the temperature of the receiver. A determination of the carbon and hydrogen in the glycerine distilled as above was made; the oxidant employed being copper oxide, followed by oxygen gas (I.), 0·4281 grm. CO_2 and 0·3439 grm. H_2O.

	Theory.		Found. I.
C_3	36	39·1	38·9
H_8	8	8·7	8·9
O_3	48	52·2	
	92	100·0	

Under a pressure of 50 mm., glycerine distils without change at about 210° C. Glycerine, dehydrated by distillation, absorbs water from the atmosphere to the extent of about 50 per cent. of its weight. The amount absorbed is, as might be expected, very variable.

On March 16, Mr. C. Houghton Gill read some notes "On the Examination of Glucose-containing Sugars." Those engaged in the examination of low sugars and molasses have frequently had to complain of obtaining quite unintelligible results. It is well known that the solution of the sugary body is decolorized and clarified by the addition of basic lead acetate before submitting it to optical examination; but Mr. Gill finds that the power of invert sugar to rotate a ray of polarized light is so greatly altered by the presence of this reagent, that the results obtained by the so-called polarization of syrups containing much invert sugar are worthless when the clarification has been effected in the ordinary way. The alteration of rotatory power of pure invert sugar by basic lead acetate is shown by the following experiments:—

15 c.c. of a solution of invert sugar made up to 50 c.c. by water, observed with a Soliel's saccharometer* in tube of 20, read −28·25 at 24° C.

15 c.c. of a solution of invert sugar with water and 2 c.c. of saturated solution of basic lead acetate, observed with a Soliel's saccharometer in tube of 20, read −24·7 at 24° C.

15 c.c. of a solution of basic acetate solution alone, observed with a Soliel's saccharometer in tube of 20, read +57 at 25° C.

These results have been confirmed by many other observations.

The alteration producing this reversal of rotatory power takes place only on the *levulose* of the liquid; the *dextrose* suffers no change of optical properties.

A solution of pure *dextrose* prepared from invert sugar, and reading 60·3, made up to 2 vols. by strong solution of basic lead acetate, read 30·5.

A solution of nearly pure levulose prepared by Dubrunfaut's method, and reading −44 at 20° C., made up to 2 vols. by solution of basic lead acetate, read +6 at 20° C.

The alteration of the rotatory power of levulose is not permanent. On removal of the lead, or on acidifying the liquid, the original rotatory power is restored. The alteration is not due to the alkalinity of the lead solution as regards alkalinity alone, for weak soda or ammonia produce no such change till they begin to decompose and destroy the sugar. It is probable that a soluble lead compound of levulose possessed of dextro-rotatory power is formed.

Now, when a sugar solution containing invert sugar is clarified by basic lead acetate, the invert sugar loses, in part or in whole, its levo-rotatory power, and the first direct reading is too high. When the liquid is acidified and inverted by heat, the original invert sugar has its true levo-rotatory power restored and added to that of the invert sugar proceeding from the cane-sugar, thus producing a greater "difference" in the readings than that due to the cane-sugar alone, and consequently leading to too high a result.

The remedy for this difficulty is to remove the lead and acidify the liquid before making the first reading. For this purpose Mr. Gill uses a strong solution of sulphuric dioxide, which possesses the advantages of removing the lead and bleaching the liquid at the same time, while it is incapable of inverting cane-sugar in the cold even in twenty-four hours. The decolorizing effect is so great that even the worst treacles give liquids of a pale straw colour when thus treated, and, moreover, "inversion" can afterwards be performed without any fear of spoiling the colour, whereas by the ordinary method the liquid frequently becomes too red to allow of optical examination.

Another error also arises from the use of the lead-salt as a clarifier for those sugar solutions in which glucose is to be estimated by the use of Fehling's copper solution. The presence of lead here leads to a result much too low, since it also becomes partly reduced, and thereby necessitates the use of a greater volume of the saccharine solution which is called on to reduce lead as well as the known amount of copper. Sulphuric dioxide serves to remove the lead, while excess of the reagent exerts no other action on the copper solution than that of facilitating the subsidence of the cuprous oxide.

As illustrating the extent of the error which may be introduced by the presence of lead, the following experiment, selected from many others, may be taken (solutions of invert sugar of the same strength used in each case):—

Volume required to precipitate cuprous oxide from 10 c.c. of Fehling's liquid—

(1.) Free from foreign bodies, 10 c.c.

(2.) Containing 10 per cent. of its volume of solution of basic lead acetate, 17 c.c.

PHILADELPHIA COLLEGE OF PHARMACY.

At the Meeting held January 17th, Dr. Pile continued his problems on alcoholic menstrua, for ascertaining the strength of and preparing alcohols of different percentage from a definite strength alcohol.

1. To reduce alcohol to any desired strength.

* The readings of this instrument × $\frac{25·8}{100}$ = angular degrees.

2. To make a definite quantity of any desired strength from a stronger alcohol.

3. To make a mixture of any desired strength by mixing a stronger and a weaker alcohol.

4. To make a definite quantity of any desired strength by mixing a stronger and weaker alcohol.

Answer to Problem 1.—Multiply the quantity of the alcohol (either in fluid ounces or in gallons) by its percentage strength (Tralle's alcoholometer) and divide by the required per cent.: the quotient gives the quantity to which the alcohol must be diluted.

Answer to Problem 2.—Multiply the required amount by the required per cent., and divide by the per cent. of the given alcohol; the quotient gives the quantity to which the alcohol must be made up by the addition of water.

Answer to Problem 3.—Subtract the percentage of the weaker alcohol from the required per cent., the difference indicates the quantity of the stronger alcohol to be used. Next, subtract the required per cent. from that of the stronger alcohol: the result indicates the quantity of the weaker alcohol to be used. Mix the two results together, and as the contraction will be more or less, add sufficient water to make the mixture equal to the quantity of the two liquids before mixing. For example, it is desired to prepare an alcohol of 60 per cent. by mixing an alcohol of 90 per cent. and one of 40 per cent.

$$60\left\{\begin{array}{l}40=20 \text{ of the 90 per cent. alcohol.}\\ 90=30 \quad ,, \quad 40 \quad ,, \quad ,,\end{array}\right.$$

Add water sufficient to make 50 parts.

Answer to Problem 4.—Ascertain the quantity of each alcohol to be mixed (by Prob. 3). The proportion which the required amount bears to the quantity thus shown will indicate the relative proportion of each alcohol to be used. Thus, if 30 parts were required to be made from the two liquids given in the previous example, as 30 is to 3-5ths of the mixture, then 3-5ths of each alcohol must be taken, or 12 parts of the 90 per cent. alcohol and 18 parts of the 40 per cent. alcohol, adding sufficient water to make 30 parts.

These rules comprise most cases which are likely to occur in preparing solutions of alcohol in water, and are interesting problems in pharmaceutical arithmetic.

Dr. Pile described a package of saffron coming under his notice in which covering nearly half an inch of the entire surface was a mass of small worms; in the centre was a mass (about a quarter of the whole) of small specks, which proved upon examination to be excrement of the worms.

Professor Maisch spoke of a sample of adulterated saffron with about 10 per cent. of carbonate of lime fixed to the saffron with some saccharine matter. A sample was also observed in Switzerland containing 3 or 4 per cent. of the same adulteration. Mr. Hanbury, of London, about the same time examined a specimen containing 15 or 16 per cent. of the same material fixed to the stigmas. These specimens had no suspicious appearance until placed under the lens of an ordinary magnifying glass, when the fraud was easily detected. By throwing the suspected samples into water, the carbonate of lime will fall to the bottom of the vessel, while the saffron will float. Prof. Maisch also spoke of a sample, of frequent adulteration,—carthamus and calendula having been dyed with a solution of true saffron. This sample also contained a large quantity of the styles of crocus.

Mr. M'Boring spoke of the difficulty of filtering a tincture of senega after having been evaporated preparatory to making compound syrup of squill, owing to the large quantity of pectin contained in the senega. The question was asked, whether bicarbonate of potash interfered with the tartar emetic.

Prof. Maisch replied that he did not think there was any change in tartar emetic, the bicarbonate only neutralizing any excess of acid that may exist in the preparation.

Dr. Pile inquired for a practical test for glycerine, one that may be employed without delay and with little preparation, one to be proof against the ordinary and most common adulterations.

Mr. Remington, who has been making some experiments in this direction, gave as his experience, after the examination of several (eight or ten) specimens of the most prominent makers, that a glycerine which is not discoloured by nitrate of silver in solution was generally pure; the nitrate will in five minutes show a discolorization should impurity exist. He considers that sulphuric acid is not thoroughly reliable; there is a possibility that the bottle in which it is kept contained straw, cork, or some organic matter, upon which the acid would immediately act, and possibly condemn a pure glycerine in this way. Trommer's test may also be applied to glycerine, and is entirely reliable in determining the presence of sugar.

Mr. Shoemaker produced a circular on "Ætherlidon Chloral," used in Berlin as a substitute for chloroform, without unpleasant result.

Prof. Maisch gave the results of his experiments with hydrate of chloral of different makes generally known as German. The experiments were made with a view to overcome, if possible, the disagreeable pungency found on opening almost every vial of this salt. The pungency is probably due to an excess of hydrochloric acid. Attempts were made to neutralize this with carbonate of ammonia. This seemed to overcome the unpleasantness for a short time; when, however, the bottle was again unstoppered the hydrate chloral possessed the same qualities.

A sample of crystallized hydrate of chloral was exhibited. This preparation is more permanent and may be crystallized from bisulphide of carbon. The chloral fuses by heating the bisulphide to about 60° or 65°. On cooling, the entire solution is filled with crystals. The following process was detailed:—Take a half-gallon retort, with capacious neck; into this place 1 lb. bisulphide of carbon and 5 oz. of commercial hydrate of chloral; stop the neck of retort with a small piece of cotton, to prevent waste of bisulphide; place the bulb of retort in hot water; the chloral will first fuse; agitate the retort until entirely dissolved; set aside to crystallize; by keeping the neck of retort cool during process the vapour of the bisulphide when condensed will flow back into retort; by careful use the bisulphide will serve for several operations. Allow the crystalline mass to remain several hours in retort, when, with a glass rod, the crystals can be removed, dried, and are ready for use. The solution drawn off still contains chloral, which will in time crystallize. The crystals are long, needle-shaped, sometimes reaching 2 or 3 inches in length. In this form chloral is possessed of little or no pungency, and is far preferable for dispensing purposes. By placing aqua ammoniæ near chloral as met with in commerce, dense white clouds are formed, indicative of hydrochloric acid.

At the Meeting held February 21st, 1871, a communication from Mr. Charles Bullock was read, as follows:—

"A disaster, occasioned by the breaking of large show-bottles from freezing, during the late cold weather, led to experiments to determine the congealing-point of mixtures of glycerine with water, with results as follows. Common glycerine, sp. gr. 1·250=29° B., was used:—

½ pint glycerine in	1 gall.	of water	congeals at		.	30° F.
1 ,, ,,	1	,,	,,	,,	.	24° F.
1½ ,, ,,	1	,,	,,	,,	.	18° F.
2 ,, ,,	1	,,	,,	,,	.	10° F.
3 ,, ,,	1	,,	,,	remains fluid at		3° F.

Prof. Maisch spoke of a combination of oil of wintergreen and sesquichloride of iron as forming a very beautiful colouring material for show-bottles. Prof. Procter thought this combination was not permanent enough, as it soon lost its brilliancy by exposure to the sunlight.

Prof. Procter mentioned an article, by Mr. Wharton, of Nashville, Tenn., recommending the use of carbonate of magnesia in making syrup of senega and comp. syrup of squills. The magnesia is used similarly to the process for the officinal waters, and is said to entirely overcome the objectional cloudiness generally found in this preparation, forming, probably, a pectate of magnesia.

Mr. England said he had no difficulty in making a clear preparation, by percolating the senega with diluted alcohol first, then using water, evaporating the watery solution, mixing with the tincture first obtained, boiling, evaporating and allowing to settle, filtering and adding the sugar.

Mr. M'Intyre had used glycerine and carbonate of magnesia; the glycerine to prevent the extract formed by evaporating from becoming too hard and unmanageable. This preparation was pronounced to be very satisfactory.

Prof. Procter spoke of the original formulæ for comp. syrup of squills, as invented by Dr. Cox, which consisted of a watery extract evaporated to syrupy consistence and combined with honey.

Mr. Gailard had used with success carbonate of magnesia in the preparation of tinct. nux vomica, which obviates any cloudiness from fixed oil.

Prof. Maisch made some further remarks upon the crystallization of chloral hydrate from bisulphide of carbon. Not being able to entirely free the crystals from the unpleasant taste and smell of the solvent, alcohol was experimented with. One half-pint was used, and dissolved 17½ ounces of chloral as fast as it was added, the mixture measuring 18 fluid ounces. Prof. Maisch could not report finally on this process until the next meeting. Chloral does not evaporate as fast as is generally supposed.

Mr. Shinn exhibited two lemons which had been wrapped in tinfoil since November. On examination one of them had undergone partial decomposition, while the other remained fresh, having the characteristic odour. They could be bought when plentiful at 15 c. a dozen, and kept in this way for a great length of time.*

Prof. Maisch exhibited some seeds of strychnos, with structure similar to that of nux vomica, which came as ballast from the East Indies, and were bought by a New York drug house. It was supposed to be from the *Strychnos Tieuté;* the fruit of which was about the size of a cherry, having six large seeds. No experiments were made towards obtaining strychnia from this species.

Mr. England suggested a plan for preparing fluid extract of vanilla, by using powdered quartz in connection with sugar. This was thrown into a bottle closely corked and boiled. By this means the aroma of the vanilla is retained, and the bean entirely exhausted.

Prof. Procter spoke of purifying residuary alcohol, and the difficulty in overcoming the odour of some substances—buchu, or cubebs, for instance. He mixed alcohol recovered from many different preparations, added 20 grs. permanganate of potash per gallon in ℥ij of water, and after a day's contact distilled; he could not destroy odour of buchu.

Prof. Maisch exhibited a specimen of cherry grown as an ornamental tree in some Southern cities, but native of West Indian Islands and Panama. This plant has a very strong odour of hydrocyanic acid. The leaves have the margin entire, which was rare in the cherry family. He said it was the *Prunus* or *Cerasus occidentalis.* It could be used in making cherry-laurel water, and for preparing an oil similar to oil of sweet almonds, which is almost entirely derived from peach kernels.

Some remarks were made on a recent law-suit concerning a lot of adulterated assafœtida, which was purchased by a wholesale house. Upon being examined it was found to be largely adulterated with gypsum. From this fact the parties refused to take it. The law was resorted to, and after a thorough examination it was found to contain in some specimens as high as 60 per cent. of sulphate of lime; the case containing the best article, when examined, proved to be composed of 27 per cent. of the same material. The case was decided for the defendants, the jury pronouncing the assafœtida unmerchantable.

Prof. Maisch exhibited a specimen of Tampico jalap, which comes into this market very rarely,—then only as a materia medica specimen.

Mr. England recommended the use of butter in making citrine ointment, being careful to free the butter from salt.

* This is E. Baudriment's method; see *ante*, p. 4.

MEETINGS FOR THE ENSUING WEEK.

Monday April 3. ......*Medical Society,* at 8 p.m.
London Institution, at 4 p.m.—"On Astronomy." By Mr. R. Proctor.

Wednesday April 5. ...*Pharmaceutical Society of Great Britain,* at 8.30 p.m.—"Alterations in Pharmacopœia Nomenclature necessitated by the Advancement of Chemistry." By Prof. Attfield.—"Note on Vinum Ferri." By Prof. Attfield.—"A Concentrated Form of Mistura Ferri Composita." By Mr. C. A. Staples.

Thursday April 6. ......*Linnean Society,* at 8 p.m.
Chemical Society, at 8 p.m.—"On 'Burnt Iron' and 'Burnt Steel.'" By W. Mattieu Williams.—"On the Formation of Sulpho-acids." By H. E. Armstrong.
London Institution, at 7.30 p.m.—"Economic Botany." By Professor Bentley.

Saturday ...*Royal Botanic Society,* at 3.45 p.m.

Parliamentary and Law Proceedings.

A BILL TO ESTABLISH THE METRIC SYSTEM OF WEIGHTS AND MEASURES.

Whereas it is desirable that the weights and measures of the United Kingdom should be decimalized, and made to correspond with those of other countries.

And whereas the use of metric weights and measures is now legal, but no provision has been made for procuring the standards of said metric weights and measures, and for verifying and stamping those in use under the said Act.

Be it enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons in this present Parliament assembled, and by the authority of the same, as follows:—

1. From and after the expiration of —— years after the passing of this Act, the length of the metre to be prepared under the authority of the Privy Council for Trade, verified by comparison with the original standard in Paris, having the words and figures "Standard Metre, 1871," engraved upon it, and kept in the custody of the Warden of the Standards, shall be and is hereby declared to be the unit or only standard measure of lineal extension, wherefrom or whereby all other measures of extension whatsoever, whether the same be lineal, superficial or of capacity, shall be derived, computed and ascertained, and all such measures shall be taken in decimal multiples or decimal parts of their respective units.

2. The unit of the measure of surface shall be the square of ten metres, which shall be and is hereby denominated the "are."

3. The unit of the measure of capacity, as well for liquids as for dry goods, shall be the cube of a tenth of the metre, and the same shall be and is hereby denominated the "litre."

4. The unit of weight shall be and is hereby denominated the "gram." A thousand grams shall be and is hereby denominated the "kilogram." A standard of the

kilogram shall be prepared under the authority of the Privy Council for Trade, verified by comparison with the original standards in Paris, and have the words "Standard Kilogram, 1871," engraved upon it, and the same shall be kept in the custody of the Warden of the Standards.

5. For the more convenient use of metric weights and measures, it shall be lawful to take the double and the half of all the said units, and their decimal multiples and decimal parts.

6. The said weights and measures hereby established shall be and are hereby denominated the standard metric weights and measures, as shown in the table hereto annexed.

7. Copies and models of the same standard metre and kilogram shall be sent to the Lords Mayors of London and Dublin, to the Lord Provost of Edinburgh, and to all counties, shires, stewartries, ridings, divisions, cities, towns, liberties and places in which by law copies and models of the standard imperial weights and measures are required to be kept, and to such other places and persons as the President of the Committee of the Privy Council for Trade may from time to time direct.

8. All judges, magistrates and other person or persons who now are or shall hereafter be authorized by law to order or provide copies of the present imperial standard weights and measures shall at all times hereafter have like power and authority in every respect to order or provide copies of the standard metric weights and measures, and to charge the expenses thereof upon the fund or funds, money or moneys, that would have been liable in case it had been copies of imperial weights and measures that had been ordered or provided.

9. All and every the provisions and provision which are by law in force with respect to the inspection, verification, reverification, stamping, counterfeiting and modes of conviction, with the penalty or penalties relating thereto, of the present imperial standard weights and measures, shall apply to and be in force with regard to the standard metric weights and measures in every respect as if the said standard metric weights and measures were comprised in and designated by the imperial weights and measures in the Acts relating to such inspection, verification, reverification, stamping, counterfeiting and modes of conviction, and the penalty or penalties relating thereto as aforesaid.

10. From and after the expiration of —— years from the passing of this Act, the imperial and all local or customary weights and measures shall be abolished, and every person who shall sell by any denomination of weights and measures other than those of the standard metric weights and measures, or such decimal multiples or decimal parts thereof as are authorized by this Act, shall, on conviction, be liable to a penalty not exceeding the sum of 40*s*. for every such sale.

11. From and after the expiration of —— years after the passing of this Act, if any person or persons shall print, or if the clerk of any market or other person shall make any return, price list, price current, or any journal or other paper containing price list or price current in which the denomination of weights and measures quoted or referred to shall denote or imply a greater or less weight or measure than is denoted or implied by the same denomination of the metric weights and measures under and according to the provisions of this Act, such person or persons or clerk of the market shall forfeit and pay any sum not exceeding 10*s*. for every copy of every such return, price list, price current, journal, or other paper which he or they shall publish.

12. As soon as conveniently may be after the passing of this Act, accurate tables shall be prepared and published, under the authority of the Committee of Privy Council for Trade, showing the proportions between the imperial weights and measures heretofore in use and the standard metric weights and measures hereby established, with such other conversions of weights and measures as the said Committee of the Privy Council for Trade may deem necessary, and after the publication of such tables all future payments to be made shall be regulated according to such tables.

13. And whereas the weights and measures by which the rates and duties of the customs and excise and other her Majesty's revenue have been heretofore collected are different from the metric weights and measures directed by this Act to be used: It is hereby enacted, that so soon as conveniently may be after the passing of this Act, accurate tables shall be prepared and published under the direction of the said Committee of the Privy Council for Trade, in order that the several rates and duties of customs and excise and other her Majesty's revenue may be adjusted and made payable according to the respective quantities of the standard metric weights and measures directed by this Act to be used, and that on the expiration of —— years after the passing of this Act the several rates and duties thereafter to be collected by any of the officers of her Majesty's customs or excise or other her Majesty's revenues shall be collected and taken according to the calculations in the tables to be prepared as aforesaid.

14. From and after the passing of this Act, and until the use of the metric weights and measures shall be made compulsory, the said metric weights and measures shall be deemed and taken to be legal weights and measures, and as such may be used for all purposes whatsoever.

15. As soon as conveniently may be after the passing of this Act, the metric standards to be provided under this Act shall be placed in the custody of the Warden of the Standards, and the Committee of the Privy Council for Trade shall cause the metric weights and measures in use under the present Act to be verified and stamped in the same manner as the imperial weights and measures are now required to be.

16. From and after the passing of this Act the "Metric Weights and Measures Act, 1864," shall be and is hereby repealed.

TABLE OF STANDARD METRIC WEIGHTS AND MEASURES.

Measures of Length.

Systematic Names.	Metres.	Value.
Myriametre . .	10,000	Ten thousand metres.
Kilometre . .	1,000	One thousand metres.
Hectometre . .	100	One hundred metres.
Dekametre . .	10	Ten metres.
Metre	1	Unit of measure of length.
Decimetre . .	·1	The tenth of a metre.
Centimetre . .	·01	The hundredth of a metre.
Millimetre . .	·001	The thousandth of a metre.

Measure of Surface.

	Square Metres.	
Hectare . . .	10,000	One hundred ares, ten thousand square metres.
Are	100	Unit of measure of surface.
Centiare . . .	1	One hundredth of the are.

Measure of Capacity.

	Cubic Decimetres.	
Kilolitre . . .	1,000	One thousand litres.
Hectolitre . .	100	One hundred litres.
Dekalitre . .	10	Ten litres.
Litre	1	Unit of measure of capacity.
Decilitre . . .	·1	The tenth of a litre.
Centilitre . .	·01	The hundredth of a litre.

Measure of Weight.

	Grams.	
Millier or ton .	1,000,000	One thousand kilograms, the weight of the cubic metre of water and of the ton.
Quintal . . .	100,000	One hundred kilograms.
Myriagram . .	10,000	Ten kilograms.
Kilogram . .	1,000	One thousand grams.
Hectogram . .	100	One hundred grams.
Dekagram . .	10	Ten grams.
Gram	1	Unit of weight.
Decigram . .	·1	The tenth of a gram.
Centigram . .	·01	The hundredth of a gram.
Milligram . .	·001	The thousandth of a gram.

Adulterated Tea.

At the Shropshire Quarter Sessions, the report presented by the analyst committee stated that a number of samples of tea, etc. had been submitted to Dr. Johnson and Mr. Blunt for analysis. The former reported that he had analysed fifteen samples of tea and seven of flour; and the latter twelve samples of tea. In four samples of tea a few grains of iron were detected by the use of the magnet, but in such insignificant quantities as not to call for proceedings against the vendors. The remaining samples of tea were of a fair average character. In seven samples of flour which had been analysed no adulteration was found.—*Grocer.*

Death from an Overdose of Laudanum.

At Salford, an inquest has been held upon a child seventeen days old. On Sunday the child became unwell, and continued so until the next day, when its mother administered three drops of laudanum. For a time it appeared benefited, but subsequently relapsed, and died the same night. Verdict, "Died from the effects of an overdose of opium."—*Medical Times.*

Deaths from Overdose of Chloral Hydrate.

An adjourned inquest was held last week to inquire into the death of Mr. Raphael Mendola, surgeon, of Victoria Park. After hearing the evidence of Dr. Letheby, who had analysed the contents of the stomach, the jury returned a verdict "That death had resulted from a dose of chloral, but that there was no evidence to show under what circumstances it was taken."

Shortly after the inquest, a letter was addressed to the newspapers by the solicitors to the deceased gentleman's family, stating that they had discovered that Mr. Mendola had recently purchased an ounce of chloral hydrate from the wholesale druggists with whom he generally dealt, stating that he intended to use it to relieve paroxysms of pain from which he occasionally suffered. It appeared from the *post-mortem* examination that the deceased was suffering from fatty degeneration of the heart.

Another inquest was held on Monday, at the Middlesex Hospital, upon the body of Mr. Edwin Charles Smallman, M.R.C.S. For some time past deceased had been in the habit of taking morphia to induce sleep. On Friday morning he was discovered dead in his bed. By the bedside was a bottle which had contained chloral hydrate. The *post-mortem* examination showed that the deceased had been in a very bad state of health, and that his death resulted from an overdose of chloral, taken while in a state of great weakness, probably for the purpose of obtaining sleep, and relieving pain. The jury returned a verdict of "Death from natural causes."

Suicide by Oxalic Acid.

On Friday, March 24th, an inquest was held on the body of John Lovelace. It appeared that the deceased had been taken into custody on a charge of attempting to murder his wife. When apprehended, a paper and white powder were noticed lying on the floor. Soon after being taken to the station he began to vomit. A doctor was sent for, but before he arrived the man was dead.

Professor Attfield said that he had made an examination of the contents of the stomach, and that there was enough oxalic acid in the stomach to account for death.

The son of the deceased said his father was a shoemaker, and used oxalic acid in his business.

The jury returned a verdict of "Suicide while in an unsound state of mind."—*Times.*

Standards of Weights and Measures.

(*From the London Gazette, March* 28, 1871.)

The following imperial measures of capacity, which have been constructed and duly verified and authenticated in the Standards Department of the Board of Trade, and their capacity accurately determined in relation to the imperial standard measure of capacity established under the provisions of section 6 of the Act 5 George IV., cap. 74, have been declared to be legal secondary standards of capacity, in pursuance of sections 6 and 8 of the Standards of Weights, Measures, and Coinage Act, 1866, viz.:—

Imperial Standard Measures of Capacity.

Liquid Measure.—The quarter-gill, equal to 1-128th gallon.

Bottle Measures.—The bottle, equal to 1-6th gallon; the half-bottle, equal to 1-12th gallon.

Fluid Ounce Measures.—Measures containing respectively the following weight of distilled water, at the temperature of 62 deg. Fahrenheit's thermometer, weighed in air at the temperature of 62 deg. of Fahrenheit's thermometer, the barometer being at 30 inches, viz.:—Four avoirdupois ounces, two avoirdupois ounces, one avoirdupois ounce, half an avoirdupois ounce. Note.—The following ounce measures are already legalized as imperial standard measures of capacity, viz.:—Quart, equal to 40 fluid ounces; pint, equal to 20 fluid ounces; half-pint, equal to 10 fluid ounces; gill, equal to 5 fluid ounces; half-gill, equal to $2\frac{1}{2}$ fluid ounces; quarter-gill, equal to $1\frac{1}{4}$ fluid ounces.

Liquid Measures of Grain Weights of Distilled Water.—Measures containing respectively the following weight in grains of distilled water, at the temperature of 62 deg. of Fahrenheit's thermometer, weighed in air at the temperature of 62 deg. of Fahrenheit's thermometer, the barometer being at 30 inches, viz.:—7000, 4000, 2000 1000 grains; 500, 300, 200, 100 grains; 50, 30, 20, 10 grains; 5, 3, 2, 1 grain.

BOOK RECEIVED.

Handbuch der Pharmakognosie und Pharmakologie für Aerzte, Studirende der Medicin und Pharmacie, Apotheker und Droguisten. By Prof. Dr. Archimedes von Schwarzkopf, Teacher of Pharmacognosy, National Economy and Commercial Science at the University of Basle and Director of the Germano-Swiss Commercial School. Part I. Leipzig und Heidelberg: C. F. Winter'sche Verlags-handlung. 1871.

The following journals have been received:—The 'British Medical Journal,' March 25; the 'Medical Times and Gazette,' March 25; the 'Lancet,' March 25; the 'Medical Press and Circular,' March 30; 'Nature,' March 23; the 'Chemical News,' March 24; 'Journal of the Society of Arts,' March 23; 'Gardeners' Chronicle,' March 25; the 'Grocer,' March 25; 'Produce Markets Review,' March 25; the 'English Mechanic,' March 24; the 'Journal of the Royal Institution.'

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department*, 17, *Bloomsbury Square, W.C., and not to the Publishers.*

[64.]—COLD CREAM.

℞. Cetacei,
Ceræ Alb., āā ℥ss
Ol. Amygd. D. ℥iv
Otto Rosæ gtt. xx.
M. Geo. B. Gudgen, *Kimbolton.*

[166.]—BLACK INK.

℞. Gallæ Aleppo Cont. ½ lb.
Ligni Hæmatoxyli 2 oz.
Gum. Acaciæ 3 oz.
Ferri Sulph. 4 oz.
Alum. Sulph. 1½ drm.
Cupri Sulph. 1½ drm.
Aquæ Moll. 1 gall.

And a small quantity of muriate of soda dried, and a few drops of creasote.

This is a good ink. It must be done by cold digestion, as heat takes out the starch from the galls, which increases the tendency to mouldiness; and I always dry the sulphate of iron.—J. H.

[183.]—HOLBECK TINCTURE.

℞. Tr. Rhei Co. ℥iij
Tr. Cardam. Co. ℥j
Tr. Opii ℥ss
Sp. Vini Rect. ℥iss
Aquæ Puræ ℥ij.

This is a Leeds form, taking its name, from some peculiarity unknown to me, from a place called Holbeck, near Leeds. It is a stimulant and partly antispasmodic; the dose should be regulated by the quantity of tr. opii it contains.—J. H.

[186.]—BAKING-POWDER.—"*Farina*" will find the following a good formula:—

℞. Sodæ Bicarb. ℥xvj
Pulv. Acid. Tart. ℥xiv
„ Magnes. Carbon. ℥vj
„ Farinæ ℥xij
M. Rub through a sieve.—Harry.

"*Senega*" sends the following excellent receipt:—

℞. Pulv. Acid. Tart. 8 oz.
Pulv. Sodæ Bicarb. 9 oz.
Rice Flour 10 oz.
M. A teaspoonful to every pound of flour.

℞. Sodæ Bicarb. 1 lb.
Farinæ 1 lb.
Pulv. Alum ¾ lb.
Magnes. Carb. ½ oz.

Dry in oven separately. Magnesia may be put on the flour. If Scotch farina can be got, it is better than English ordinary farina. Mix.

P.S.—Acid. tart. may be used, if preferred; but the writer has found quite as ready a sale for it with pulv. alum.—J. H.

[188.]—WATERPROOFING.—

Bisulph. Carbon. ℥ij
Gutta Percha ℥ss
G. Asphalt. ℥ij
(Brown Amber) ℥ss
Ol. Lini ℥xij.
Misce.

Dissolve the gutta percha in the bisulph. carbon., the asphalt and amber in the oil, and mix well.—D. L. Jones.

[198.]—COD-LIVER OIL.—Can any of your readers give a short descriptive process of the manufacture of cod-liver oil at Newfoundland?—Alpha.

[*** Papers on this subject have already been published in the Pharmaceutical Journal: by Professor Soubeiran, 2nd Ser., Vol. VIII. p. 39; and by Mr. Howden, 2nd Ser., Vol. VI. p. 191, and Vol. IX. p. 312. Information as to the different methods of preparation will be found also in Cooley's Encyclopædia.—Ed. Pharm. Journ.]

[199.]—GAS BLADDERS. — Will any correspondent kindly furnish me with a method for keeping bladders in a soft pliable condition, suitablo for experimenting with gases?—Nil sine Labore.

[200.]—LEMONADE.—Will any reader oblige me with a good receipe for making lemonade *without a machine?*—Harry.

[201.]—SOLID YEAST.—"*Aroma*" wishes to be furnished with the formula for solid yeast given in the transactions of the Royal Scottish Society of Arts.

[202.]—SYRUP OF SANTONINE.—*J. E. B. M.* wishes for a form for making syrup of santonine.

[*** Our correspondent will find the information he requires in the abstract from Dr. Harley's paper on Santonin, *ante*, p. 667.—Ed. Pharm. Journ.]

[203.]—MILK OF MAGNESIA.—Will any reader favour me with a receipe for the preparation sold under this name?—Vincit Amor Patriæ.

[204.]—LINIMENTUM RUBRUM.—Can any of our dispensers give me a formulary for this article, used sometimes in prescriptions?—Vincit Amor Patriæ.

[205.]—COD-LIVER OIL AND QUININE.—Can any correspondent kindly oblige me through the medium of your paper with a formula for an elegant preparation of cod-liver oil and quinine or cod-liver oil, quinine and iron?—T. E. R.

[*** Some information on this subject will be found in the Pharmaceutical Journal, 1st Ser., Vol. XV. p. 475, and Vol. XVII. p. 36.—Ed. Pharm. Journ.]

[206.]—PEPSINE WINE.—Will any reader kindly furnish me with a good formula for making pepsine wine?—James Doubell.

[207.]—SOAP POWDER.—I shall feel obliged by being supplied with a receipe for soap powder, suitable as a toilet soap.—D. S. Anderson.

[208.]—ALUMINIUM.—Wanted, the address of a worker in this metal; or where shreds or shavings of same may be cheaply procured.—P. C.

[209.]—CORN SOLVENT.—*T.* would feel obliged by being informed of a good solvent for soft and hard corns.

[210.]—COD-LIVER OIL JELLY.—"*Senega*" would feel obliged if any correspondent would send him a formula for cod-liver oil jelly.

[211.]—HORTICULTURAL INK.—Can any of your correspondents give me a good receipt for making horticultural ink? Beasley has been tried.—A. P. S.

[212.]—WOOD STAIN.—"*Pyroligneous*" wishes for a good receipe to stain wood oak-colour.

[213.]—LIQ. AMMONIÆ VALERIANATIS.—Can any of your readers give me a formula for liq. ammoniæ valerianatis?—A. B.

[214.]—SOLUTION OF ATROPIA.—*Associate P. S.* (Exeter) wishes to be informed how eight grains of atropia can be held in solution in aq. destil. ℥j without the addition of spirit or acid. sulph. dil.? To be used for complaints of the eye.

[*** According to Klever's table, published in last week's Journal, p. 763, it might be effected by glycerine or a mixture of glycerine and water.—Ed. Pharm. Journ.]

Erratum.—On p. 737, No. [159], "Aniseed Cordial," *for* Sp. Vin. Rect. ʒviij, *read* Sp. Vin. Rect. ℥viij.

Correspondence.

OUR MONTHLY EVENING MEETINGS.

In the number of this Journal issued March 11th, I read with attention a leader bearing the above title. As a constant attendant and sometimes contributor, I have taken considerable interest in these meetings. Amongst other contributions of mine in the Journal, I find three upon this particular subject, the first dated August 10th, 1857, when I endeavoured to stir up the members, etc. to more energy and better attendances. It appeared to me at that time that the chief reasons which deterred many from contributing, especially the young, were diffidence, the dread of criticism,—it has been sometimes, I have felt, over-sharp,—and the difficulty of finding something new; but I believe I cleared away these seeming impediments.

It is clear, nevertheless, from past experience, that if we are to have papers and good attendances some system must be established for securing them; and it appears to me that the plan of an annually-selected committee for the express purpose, as recommended in the said leader, would be a good one.

Old contributors require whipping up, young ones a little encouragement. *Embryo* authors are naturally timid, and, like exotic plants, want nursing and gentle forcing.

Our Society does not, I feel sure, stand alone in the matter of occasionally flat and uninteresting evenings, and, without descending to particulars, many circumstances during the two past sessions have in some measure tended to the present state of our monthly evening meetings. In the future may there be much improvement!

There is a difficulty; how it is to be got over has to a great extent been suggested.

I intrude again, in order that the matter may be kept prominently before the members, associates, etc. generally and the in-coming Council especially, so that the seed now sown may not be unproductive for lack of encouragement and culture.

18, *Conduit Street*, A. F. HASELDEN, V.P.
March 27*th*, 1871.

A MEDLEY.

Sir,—Si mihi licet "desipere in loco" hoc, I will send you a medley this time, which may serve to relieve the dryness of the present "legal" discussion.

Can any of your readers or yourself tell me why some tinct. cinnam. co., which has been made a long time, has deposited all its colouring matter in the form of a loose brown powder at the bottom, and not upon the sides of the bottle at all? I did not make it, but, knowing who did, I have no reason to believe it otherwise than strictly P. L.

I once removed my bergamotte bottle (containing a very fine sample, I thought) from the shade to a position where the sun during part of the day shone directly upon it. It assumed in a comparatively short time, as seen through a thick incrustation on the sides of the bottle, the appearance of weak muddy coffee, and its fragrance was decidedly impaired. Having previously enjoyed a due north aspect without a ray of sunshine, I was not prepared for this, and cannot account for it. Thinking the sample might be in fault in some way, I placed a second lot of "super." at 18*s*. in the same situation, but soon found it changing, and removed it.

But the following is my greatest puzzle:—Considerably more than two years ago, a painter employed in my house, but not needing for his work with me any such colour, borrowed my gum-brush. It was lost for about a week, but turned up again, stained of a most intense crimson. If this man did not so stain it, I cannot conceive who or what did. It was rinsed out in boiling water, and restored to its former use. Since that time it has been constantly used for the one purpose, repeatedly and well rinsed in hot water as well as the pot, and the gum—tragacanth—renewed on an average once a fortnight perhaps; notwithstanding which, to this day it continues to impart a decidedly pink tinge to every successive lot of mucilage. At first, of course the colour gradually imparted was deep, but I thought I should wear it out, and curiosity impelled me to continue to use it, as it now does to ask, what can the dye be? Any one can see the brush in use.

Any one may also see the following order, distinctly and very fairly written, with two errors of spelling,—transparently such,—only:—

"The high dried up azh poweder,"

as it is in my possession. My customer—for I supplied him with threepennyworth of the article wanted—was a poor Irishman, who had evidently got some better-educated friend to write down the name, probably from his own dictation.

This may exercise the ingenuity of some of our younger friends, and the following will make them laugh:—

A respectably-dressed child, of seven or eight years old, came one day into my shop, and asked for "A pennyworth of Uncle William's pills." I told her I had not the pleasure of knowing her uncle, and dismissed her; but before she got out of the door she returned, saying, "Mother said, Aunty Billy's, but I thought it couldn't be right."

Lastly. As my contribution to the question of dispensing charges, I give this, which happened some years ago. A lady, named Watkin, came to my shop, saying she had heard a good report of me, and intended to bestow her patronage, giving me at the same time a prescription for a single powder of three ingredients, hydr. c. creta and p. rhei, being two of them to make up. I dispensed it, copied and registered her prescription, and sent both, with envelope, etc., by her order, to her residence, charging 3*d*. The next day Miss W. called, and in perfectly grammatical and perhaps elegant (?) language abused me for imposing upon her, asserting that as "I only sent a little paltry boy a few yards, I must have uncommon assurance to charge her 3*d*. for one powder, when Messrs. — and — had sent their man with it more than half a mile for a charge of 2*d*." I never saw her again. I desire to add that I treated the story with contempt at the time, and never believed it.

Within the last eighteen months a 4-ounce bottle was brought to me to be filled with laudanum for a shilling, as the party—tenanting a £40 house at least—"used a great deal of it." I simply refused without stating my price, and, not hearing again from the party, must needs suppose they get it somewhere at or near that price.

Breckfield Road North, Liverpool, THOMAS LOWE.
March 20*th*, 1871.

Suicides by Carbolic Acid.—It is suggested to a correspondent who has sent us a cutting from a newspaper on this subject that 'suicide' and 'fatal accident' are not synonymous terms.

W. Lea will find recipes for Brilliantine on p. 437 in the present volume.

W. B. Orton and *J. L. Roberts*.—As the advertiser did not ask for a chemists' assistant to perform the duties in question, we do not see that there is any ground for complaint.

G. W. (Horncastle).—A pocket lens may be obtained from any optician.

"*Herbarius*."—Cooke's 'Manual of Botanic Terms,' published by Hardwicke, Piccadilly, would meet your requirements and give you the other information you ask for.

F. R. W.—No licence would be required to make orange wine if used for vin. quinæ by the pharmacist who makes it. The orange wine, however, cannot be made and sold as such.

W. B. B., a Junior.—Pil. saponis co. was certainly intended, and not a pill containing two grains of opium.

A. W. V. has omitted to send his name and address.

J. Brough.—See "Colours for Carboys," *ante*, p. 516. We cannot give recipes for sauces; try Cooley, Beasley, or the 'Dictionary of Daily Wants.'

J. S. Harvey.—Ol. laurocerasi is very rarely met with, and is very poisonous, containing 5 per cent. of hydrocyanic acid. It would be an expensive remedy. Try infus. quassiæ.

E. K. Campbell.—We are not aware of the existence of "scientific poisoners," and therefore cannot give you any information as to the poisonous gases they may be in the habit of using.

J. Lewis (Swansea).—The loss amounts to about 23 per cent. by volume.

THE CHEMICAL NOMENCLATURE OF THE PHARMACOPŒIA,

WITH SUGGESTIONS FOR ITS REVISION.*

BY PROFESSOR ATTFIELD.

The vocabulary of technical terms, or nomenclature, of a pharmacopœia is chemical, botanical, zoological and galenical. In the following paper chemical nomenclature is alone considered.

Introductory remarks.—The chemical nomenclature of the current Pharmacopœias is mainly scientific, founded on theory, and therefore liable to change. Its one great fault, in relation to medicine and pharmacy, is mutability. A fault, and a great fault, because the life and health of people are largely dependent on the perfect understanding which should always subsist between physician and pharmacist respecting names of medicines which the former prescribes and the latter prepares. But it is a fault which cannot altogether be avoided. For a name is seldom given haphazard; it is commonly designed to express our ideas regarding a thing or substance, and as those ideas are developed and extended, our point of view or theory respecting them necessarily changes; the old name is no longer consistent with our knowledge, and must therefore be also changed. Moreover, there is a limit to the power of language, and desirable as may be a system of names for remedial agents which shall be fixed, abiding, permanent, the production of such a system in the present state of knowledge is altogether impossible. What, then, are pharmacists, medical practitioners and others to do when chemical names they have accepted on authority are, by the same authority, modified or abandoned? Within the last few years the views hitherto prevailing of the constitution of matter have undergone radical alteration, being no longer consistent with ascertained truths, and the nomenclature or language embodying those views has, of course, shared the fate of the theories. Under these circumstances, by what principles are we to be guided in adopting for medicine, pharmacy and the Pharmacopœia, such names as, on the one hand, shall be perfectly explicit, readily understood, unambiguous; and, on the other, consistent, or at least harmonious with prevailing chemical theories as expressed in the educational literature of the science? For not only is it to be remembered that changes must be expected in pharmacopœial names because we have already adopted and employ a nomenclature which, in the nature of things, is liable to change; but we must bear in mind that the successors to men now in practice are learning chemistry by aid of the new hypotheses, and their progress is impeded by old forms of language and by the erroneous notions which that language imparts. This state of things cannot continue; the march of science has ever been aided, never hindered by medicine or pharmacy. But what position are we to take in respect to this subject? The question is one that demands careful attention. I have endeavoured to answer it myself, and now venture to give to others the train of thought I have followed, and the conclusions at which I have arrived.

Outline of the paper.—I intend, firstly, to outline the history and present position of the chemical names already employed in Pharmacopœias, especially the British, and to glance at the causes of the recent revolution in chemical nomenclature; and to do so, not by way of aiding the followers of medicine to criticize matters purely chemical, but to enable them to arrive at sound conclusions respecting the application of modern chemical nomenclature to pharmacy. I shall then shortly allude to chemical notation, which is inseparably connected with my subject; mention disadvantages attending alterations in chemical names; state the functions and positive or negative qualities which names should possess; give a complete list of current pharmacopœial names, with the names now proposed, and their scientific synonyms; and finally refer to names requiring special or exceptional treatment.

History and present position of the chemical names of the Pharmacopœia.—The system of nomenclature hitherto accepted from chemists by pharmacists, practitioners in medicine and the public, that which is employed in European and American pharmacopœias, was mainly devised by Lavoisier, eighty-four years ago. The fundamental principle on which it was founded was, that the name of a salt should express its composition. The many animal and vegetable substances discovered since that time (notably alkaloids and neutral crystalline principles) are designated, perhaps fortunately, by unsystematic names, names which, at all events, are not liable to change, and which may therefore be omitted from consideration in this paper. The great majority of chemical substances employed in pharmacy are such mineral salts as were known to Lavoisier, and their names were given by him on the assumption that they contained, on the one hand, an undecomposable body, generally a metal, common to a whole class of salts (the compounds of *copper*, for example), and on the other, a body, or a group of elements, also common to a number of salts (*sulphates*, for example). Soda, potash, lime, baryta, magnesia and alumina were then considered to be elements; hence, as I shall further show presently, such names as carbonate of soda, nitrate of potash and sulphate of baryta were perfectly consistent with those of carbonate of iron, nitrate of mercury, sulphate of copper. During the twenty years succeeding 1787, Lavoisier's views of the constitution of salts and the language or nomenclature in which those views found expression, were generally accepted throughout Europe. Green vitriol, blue vitriol, Glauber's salt and gypsum, for example, were considered to contain, on the one hand, the "elements" iron, copper, soda, and lime respectively, and, on the other, a group of elements common to each of the four compounds; the four different elements were indicated in the spoken and written nomenclature of the compounds by their four names, 'iron, copper, soda, lime,' while the one group and its presence in each of the four compounds was indicated in the spoken and written nomenclature of the compounds by the word 'sulphate'; sulphate of iron, sulphate of copper, sulphate of soda, sulphate of lime. This change from such trivial names as green vitriol, blue vitriol, Glauber's salt and gypsum to the systematic chemical names sulphate of iron, sulphate of copper, sulphate of soda, sulphate of lime, seems to have been effected without much opposition. At that time comparatively few persons were interested in, or affected by the matter, and radical changes of this kind are made with less difficulty by the few than

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, April 5, 1871.

the many. Afterwards it was felt that the multiplication of chemical substances by discovery rendered adherence to a trivial and arbitrary nomenclature impossible, and the adoption of Lavoisier's scientific plan imperative. Lavoisier got the world out of a difficulty, not placed it in one, when he introduced the principle of scientific nomenclature.

Up to 1807 no necessity arose for interfering with the nomenclature of Lavoisier; but in that and the following year Davy made his brilliant researches on the alkalies and alkaline earths, discovered that potash, soda, baryta, strontia and lime were not elements, as previously had been supposed, but that the true basylous radicals of the so-called compounds of potash, soda, baryta, strontia and lime were metals—to which were given the names potassium, sodium, barium, strontium and calcium. Thenceforward the old names potash, soda, baryta, strontia, lime, were used to designate the oxides of the new metals. Then at once there arose a dilemma in regard to nomenclature. The names of all the salts of Davy's metals were no longer consistent with the names of the salts of all other metals. While on the one hand the names 'sulphate of copper' and 'sulphate of iron' distinctly expressed the compounds formed by the union of metallic 'copper' or metallic 'iron' with a common acidulous group of elements, represented by the word 'sulphate,' the names 'sulphate of soda' and 'sulphate of lime' as distinctly expressed compounds formed by the union of oxide of sodium and oxide of calcium with a common acidulous radical still indicated by the word 'sulphate,' but not having the same composition as (having less oxygen than) the similar acidulous radical united with the copper and the iron. It was felt that either such words as sulphate, nitrate and carbonate must each have two significations, and the salts of the alkalies and alkaline earths be considered as compounds of oxides of metals, and all other salts (sulphate of iron, etc.) as compounds of metals, or such words (sulphate, nitrate, carbonate, etc.) must have a common (though an altered) signification, and all oxygen salts be considered as compounds of oxides of metals. Davy, supported afterwards by Dulong, Clark, Graham, Liebig and Daniell, suggested that *all* metallic salts were composed of metal alone on the basylous side, and a distinct radical on the acidulous side. Unfortunately, however, accurate knowledge of constitution was included in this idea; even definite names being proposed for the said acidulous radicals. Thus blue vitriol was termed oxysulphionide of copper (Daniell), sulphatoxide of copper (Graham) and sulphanide of copper (Otto). Many other objections to the theory arose, and hence salts came to be regarded as compounds of oxides of metals with certain acidulous radicals (now known as anhydrides). But the followers of applied chemistry never took kindly to the nomenclature; such names as sulphate of oxide of iron, nitrate of oxide of silver, acetate of oxide of lead, got shortened to sulphate of iron, nitrate of silver, acetate of lead; a matter of no great moment to any one who had become a chemist, but of considerable importance to every one learning to be a chemist. The names acetate of lead, iodide of lead, etc., logically planted in the mind the impression that the compounds were formed of lead with the radical of acetates and lead with the radical of iodides,—a natural idea, which had to be unlearned, and by considerable effort of memory a mere conventional one put in its place, namely, that certain acidulous radicals (iodine, sulphur, etc.) combined with metals, while certain others (anhydrides, formerly called acids) with oxides of metals. Again, that a yellow granular precipitate, caused by the addition of perchloride of platinum to a liquid sometimes indicated potassium and sometimes potash, or that a certain black coloration sometimes indicated lead and sometimes oxide of lead, were illogical statements against which the mind naturally rebelled. It is true an explanation was afforded of such anomalies by the assumption that even haloid salts (such as iodide of potassium) on dissolving in water became true salts of oxides of metals (hydriodate of potash); but weighty arguments were adducible against this hypothesis. In short, no theory of the constitution of salts was offered, or has yet been offered, which satisfactorily explains and harmonizes all known facts respecting salts. Hence, when a very few years ago chemists were led by irresistible arguments and stubborn facts to double many of the old atomic weights, an opportunity of abandoning existing constitutional theories then presented itself, and was by common consent accepted. The exertions of Dumas, Laurent and Gerhardt bore fruit. The dualistic idea of salts being formed of an acidulous radical with the oxide of a metal, and the not less binary notion of their being composed of a distinct acidulous radical united with a metal, were renounced, and hypothesis altogether rejected, or, at all events, restricted to the idea of *oneness*. These views were, of course, accompanied by a commensurate alteration in chemical notation and nomenclature. Blue vitriol no longer being considered to be the sulphate of the oxide of copper, as shown in the formula $Cu\,O, S\,O_3$, nor even to have the binary constitution implied in the formula $Cu, S\,O_4$, but to be a structure *per se*, or, at least, one whose detail of constitution was unknown,—it became necessary to devise for it and all such salts, a notation and nomenclature which should be consistent with the unitary idea. Strictly speaking, this was impossible. The relationship, nay, the absolute identity of the constituent radicals in whole classes of salts demanded fair representation in notation and nomenclature, a result fatal to pure unitary ideas. Thus, the unquestioned relationship of the cupreous compounds to each other demanded the employment of the word 'copper' in their names and the symbol Cu in their formulæ; while the unquestioned relationship of salts containing the elements which occur in the non-cupreous portion of blue vitriol demanded the employment of the word "sulphate" in their names and the symbols $S\,O_4$ in their formulæ, and with the employment of such names and such formulæ the binary idea is difficult to repress. At the same time all are agreed that the unqualified assumption of knowledge of chemical constitution involved in the old binary theories is wrong, hence professedly binary systems of notation and nomenclature must be relinquished; the names sulphate of oxide of copper, with its formula $Cu\,O, S\,O_3$, and sulphate of oxide of magnesium (or sulphate of magnesia), with its formula $Mg\,O, S\,O_3$, must be given up for sulphate of copper $Cu\,S\,O_4$ (or copper sulphate or cupric sulphate), and sulphate of magnesium $Mg\,S\,O_4$ (or magnesium sulphate). Such names and formulæ sufficiently exhibit unquestioned relationships, while they include the least possible amount of theory.

Chemical Notation.—I would offer a few additional sentences respecting chemical notation. All teachers of chemistry, including the authors of nearly every modern manual, with remarkable unanimity have relinquished the old system of notation, that which was exclusively employed in the British Pharmacopœia of 1864, and have, to a greater or less extent, adopted the new. In the present (1867) Pharmacopœia the new notation is represented by formulæ printed in Egyptian type (**KNO_3**), the old by formulæ in Roman (KO,NO_5); a course suggested by the unsettled condition of the subject at the time this Pharmacopœia was published. It is to be expected that the next British Pharmacopœia—still "representing accurately, yet with caution, the advancement made in chemistry and pharmacy" (*vide* Preface), and reflecting the settled practice of scientific chemists—will employ the usual chemical symbols as expressive of the new atomic weights ($O = 16$) to the exclusion of the old ($O = 8$), and will altogether discard the hypothesis of the constitution of salts involved in such formulæ as KO,NO_5, or (accepting the new atomic weights) K_2O,N_2O_5, using only the less theoretical formulæ (*e.g.* KNO_3) which are now employed by the majority of teachers. The following formulæ will further illustrate what has just been stated:—

Old and New Chemical Formulæ.

	Old atomic weights and dualistic hypothesis.	Old atomic weights and binary hypothesis.	New atomic weights with dualistic hypothesis.	New atomic weights with binary hypothesis.	New atomic weights with unitary hypothesis.
Nitre	KO,NO_5	K,NO_6	K_2O,N_2O_5	K,NO_3	KNO_3
Pearlash (anhydrous) . . .	KO,CO_2	K,CO_3	K_2O,CO_2	K_2,CO_3	K_2CO_3
Epsom salt (anhydrous) . .	MgO,SO_3	Mg,SO_4	MgO,SO_3	Mg,SO_4	$MgSO_4$
Corrosive sublimate	$HgCl$	$HgCl$	$HgCl_2$	$HgCl_2$	$HgCl_2$

Old atomic weights . . . . K, 39; Mg, 12; Hg, 100; N, 14; O, 8; C, 6; S, 16; Cl, 35·5.
New atomic weights . . . . K, 39; Mg, 24; Hg, 200; N, 14; O, 16; C, 12; S, 32; Cl, 35·5.

Little more need be said in favour of the exclusive employment of modern chemical notation in future British Pharmacopœias. Arguments for or against the atomic and other theories and hypotheses concerning the constitution of salts on which this notation is based would be out of place in this paper. The old system is given up by chemists; the new is already officially recognized by the Council under whose authority the Pharmacopœia is issued, and by the various examining Boards,* and is adopted in educational works on chemistry.

These are sufficient reasons for justifying us in the expectation of seeing the new notation, if any, alone employed in the third British Pharmacopœia. This much on chemical notation it was desirable to state; for it is inseparably connected with the chemical nomenclature of a Pharmacopœia. Indeed, notation and nomenclature should obviously harmonize, seeing that they are simply different methods of expressing the thoughts and wants of everybody respecting chemical substances. Formulæ are more comprehensive than names, and convey to the mind far more information, but they are intelligible only to the educated chemist. Names comprise less knowledge, but are more or less understood by all and suffice for general purposes. To formulæ, however, we look to ascertain the views of chemists concerning the constitution of chemical compounds, and it is on these views that chemical nomenclature is founded.

Disadvantages attending alterations in Nomenclature.—Thus far have I endeavoured to outline the progress of chemistry in those directions which affect chemical nomenclature, those which suggest modification in the chemical names of pharmacopœial substances. Such names as nitrate of potash and sulphate of magnesia are unwarrantably theoretic and not now current in chemical literature. How can these and similar names be modified, and to what extent must modification be carried? Before answering the question and proposing a modified system of nomenclature, I would allude to (*a*) the alteration of chemical names as involving disadvantages, and (*b*) the properties of names. The disadvantages are obvious, unquestionable, and to be avoided whenever practicable. Scientific chemists, those with whom originate new discoveries of specific and generic truths, meet with these difficulties to a very small extent. Modification and extension of mental views respecting the constitution of chemical compounds are necessarily accompanied by modification and extension of the language in which those views are expressed; hence alterations in chemical nomenclature are naturally met with in the original memoirs recording new discoveries. Indeed, altered nomenclature is advantageous, rather than the opposite, while confined to the literature of original research, for it assists the mind in comprehending new truths. But such restriction is only possible for a time. Each additional discovery, whether relating to old substances or new, gives additional impetus to the ever-advancing waves of knowledge until the old landmarks have to be removed or relinquished, and reconstruction becomes inevitable. Here commence difficulties; for while alteration in language is easy and convenient to followers of pure science, because a natural consequence of altered mental views, it is excessively troublesome and inconvenient to the followers of applied science, who have to entertain the alterations first and the reasons afterwards.

More than this, most serious consequences have sometimes resulted to patients from one medicine

* Extracts from Letters to the Author.

Royal College of Physicians, London. "I am instructed to say that the Examiners here accept either notation. While themselves adopting the new, they are unwilling to jeopardize the chances of those who have been educated and accustomed to the old."—Henry Moody, Secretary.

Royal College of Surgeons, London. "Only in the Preliminary Examination is chemistry included. The new system of notation is adopted by the Examiners."—Edward Trimmer, Secretary.

The Society for Apothecaries, London. "Candidates are allowed to use the old or the new notation, according as they have been instructed."—R. H. Robertson, Secretary.

The Pharmaceutical Society of Great Britain. "The *new* notation is recognized by the Board, but candidates having an imperfect knowledge of this system are not rejected if they possess a sufficient acquaintance with the *old* notation."—Elias Bremridge, Secretary.

being substituted for another, solely through variation in nomenclature. But I need say nothing further on this head; it has already been adverted to at the commencement of this paper, and has been fully and ably treated, either specially or incidentally, by the following writers on pharmacopœial nomenclature:—

PHARMACEUTICAL JOURNAL: Jacob Bell, Dr. Paris, Dr. Pereira, Vol. II., 1st Ser., pp. 369–374; Mr. E. Thompson, Vol. VIII., 1st. Ser., p. 3; Mr. A. F. Haselden, Vol. I., 2nd Ser., p. 112; "C. W. M." and the well-known initials "C. W. Q.," Vol. III., 2nd Ser., p. 335; Professor Redwood, Vol. VI., 2nd Ser., p. 566; in Vol. VII., 2nd Ser., "On the Vegetable Drugs," by Mr. Daniel Hanbury, p. 96; Mr. Henry Deane, p. 101; Mr. Proctor, p. 381; Mr. T. Lowe, p. 409; Mr. J. C. Brough, Vol. VIII., 2nd Ser., p. 214; Mr. J. C. Wilson, Vol. IX., 2nd Ser., p. 363.

Properties of Names.—The names of pharmacopœial chemicals should fulfil certain functions or possess definite qualities, positive or negative, namely,—

1. The name should, as far as possible and practicable, indicate composition. This Lavoisierian principle is, as I have already shown, one of necessity as well as expediency.

2. One name should be associated with only one substance; but the converse I would by no means urge, namely, that one substance should be known by only one name, synonyms being useful both from a theoretical and a practical point of view.

3. A name, even if fallen out of use, should not be transferred to a substance having properties different from the original substance.

4. The name of an official chemical substance, that is, a name officially recognized in national pharmacopœias, should possess the minimum of instability. This quality is most important. Verbal changes of almost any kind are unpopular; changes in chemical nomenclature have done much to retard the progress of chemistry amongst the people; but changes in the names of pharmacopœial chemicals are objectionable in the interests of medical practitioners, their patients and pharmacists.

The free employment of Latin and Greek numerals in a chemical name was strongly advocated by the late Professor Miller. But though highly useful in general chemical literature for indicating details of composition, the principle is too dependent on hypothesis respecting atomic values and weights, and too susceptible of disturbance caused by new discoveries to possess the element of permanence; hence it must be avoided in pharmaceutical chemistry.

5. A pharmacopœial name should admit of being either easily spoken or written, both in the full and in the contracted form, in modern languages and in Latin.

6. When close resemblance between two salts is indicated by identity in all but one of the syllables of their names, that syllable should be at the commencement of the names and not at the end, where it would be liable to be omitted by a prescriber. Indeed, such variations are often indicated with most usefulness by a separate word altogether, confusion and even mischief being thereby avoided. Thus, for calomel and corrosive sublimate the names *subchloride of mercury* and *perchloride of mercury* are greatly to be preferred to *mercurous chloride* and *mercuric chloride;* for a physician, in writing a prescription, would contract the former to *hydr. subchlor.* and *hydr. perchlor.*, which are still sufficiently distinctive, while the others would *both* be liable to be contracted to *hyd. chlor.*, and a patient perhaps be killed by corrosive sublimate instead of cured by calomel. So *green iodide of mercury* and *red iodide of mercury* are better than *mercurous iodide* and *mercuric iodide*, or *green sulphate of iron* and *persulphate of iron* to *ferrous sulphate* and *ferric sulphate;* any greater precision that may be desired being given by chemical formulæ.

7. A name should not be changed for mere purpose of euphony, real or fancied; thus, chlorhydric for hydrochloric.

8. Names of pharmacopœial chemicals should be consistent with each other.

9. The chemical names employed in pharmacy should be consistent with those used in other branches of applied chemistry, and with the language of scientific chemistry and general chemical literature. I say consistent, certainly not identical. *For I believe the time has come when, by making a few slight alterations in the terminations of a few of our chemical names, we shall have a system of pharmaceutical nomenclature which, while perfectly harmonious with, is quite independent of, scientific chemical nomenclature, and which therefore contains greater elements of permanence than any yet adopted.* These alterations, be it noted, are in the terminations of the names only; hence the contracted names almost universally used by physicians and pharmacists would in no way be interfered with,—an argument which, if somewhat left-handed, must be admitted to be one of great strength.

(*To be continued.*)

A DISINFECTING APPARATUS.

BY A. W. GERRARD.

This little machine is intended to supersede the clumsy and inconvenient method recently proposed for the elimination of carbolic acid vapour and sulphurous acid gas, by means of heated fire-shovels, warming-pans, saucepans, etc. Its parts consist of

the body, which is about the size of a quart measure, its sides being fine wire gauze; it has likewise a lid of the same material. In the interior is a spirit-lamp, and two tin pans, one for the reception of sulphur, the other for carbolic acid.

The method of using it with sulphur is to place one of the pans, containing some of that article, upon the rests provided for it, and ignite; the fumes will readily diffuse themselves. The combustion of this substance is accelerated if the spirit-lamp or a night-light is burnt beneath it.

Carbolic acid can be used in the same manner as sulphur, but either the lamp or a night-light must be burnt; it is best applied in the undiluted form.

The advantages of this apparatus are, that it does away with the necessity of sprinkling, and causes a more general diffusion of vapour, thus attacking the floating germs and purifying the atmosphere. It can be placed between bedding with perfect safety, and there is no occasion for the patient's removal while this is being done. It is well suited for deodorizing rooms, closets, hospitals, vehicles, and all purposes for which disinfection is required, being clean, simple, and efficient in its action.

Another use to which it may be applied is that of a child's food warmer. If a night-light be lit and placed in the interior, a tea-saucer or other vessel containing the food, placed over it, will keep warm until the light has burnt out.

MORPHIOMETRIC METHODS COMPARED.

BY WILLIAM PROCTER, JUN.

The question, "What is the best process for assaying opium to determine its morphia strength, suited for adoption into the United States Pharmacopœia?" was accepted by the writer at the Chicago meeting.

Reflection on the query suggests that it is not so much what is the best analytical process, as to decide what process is best suited for practical use by druggists and pharmaceutists in determining the morphia value of opium for the purposes of the Pharmacopœia. Those who take the view that the process should embody the nicest and most refined manipulations of the analytical laboratory, may not accept this view; but when it is understood that a large majority of the persons needing its use are not analytical chemists, it is believed that simplicity, united to a fair degree of accuracy, is more available than extreme accuracy, beyond the reach of most apothecaries, applied in a complex process.

So many able chemists have published processes, some of which are well known in connection with their names,—as Staples' process, Mohr's, Guillermond's, etc.,—that the ground would appear to be well examined. The process of Staples is that of the United States Pharmacopœia. Its point is in the employment of alcohol to retain the colouring matter in solution during the precipitation of the morphia, and in mixing the ammoniacal precipitant also with alcohol. The process of Mohr avails itself of the selective power of boiling lime-water to reject narcotina and retain morphia in solution. Both of these processes extract the opium with cold water. Guillermond's process employs alcohol of 71 per cent. to extract the opium, which is then precipitated by ammonia. The precipitate, as in Staples' process, contains narcotina.

One difficulty in extracting the portion of opium soluble in water is the caoutchoucoid matter which tends to resist its solvent action. The idea of employing benzine, or light coal oil, to remove this as well as the free narcotina, has been suggested by Albert E. Ebert for another purpose, and has been used by Dr. Flückiger in his examination of opium. It is believed that the preliminary use of this solvent in opium assays may be usefully adopted.

Believing that the best way to arrive at a solution of the query was to try several processes with the same solution of opium, a sample of nearly dry opium, weighing 300 grains, was triturated to coarse powder, and then rubbed with repeated portions of water until finely divided, and macerated in six times its weight of water for twelve hours, then percolated on a filter until the washings were nearly colourless. The united liquids (amounting to 4500 grains) were divided into three equal portions, each representing 100 grains of opium.

No. 1.—The solution was evaporated with moderate heat to half a fluid ounce, mixed with an equal bulk of alcohol (sp. gr. 835), filtered through a small filter, and the latter washed with a little diluted alcohol. 50 minims of solution of ammonia (sp. gr. 960) was mixed with 2 fluid drachms of alcohol. One-half of this was added to the alcoholic solution of opium with agitation, and allowed to stand six hours, when the remainder of the ammonia was mixed in, and the vessel permitted to rest for twenty-four hours. The crystalline matter deposited on the interior of the vial being detached, the contents were at intervals poured on a small tared filter, and the crude morphia washed, first with diluted alcohol and then with water, dried at 120°, and weighed. The product was 9·75 grains. This was treated several times with boiling non-alcoholic ether, and the ethereal solution, evaporated in a small tared capsule, gave 0·31 grain of crystalline prisms, equivalent to 0·31 per cent. of narcotina, and 9·44 per cent. of morphia in the opium examined.

No. 2.—This portion was treated with solution of subacetate of lead till it ceased to be precipitated, the precipitate separated on a filter and well washed, the filtrate treated with diluted sulphuric acid by drops to separate the excess of lead as sulphate, and filtered. The clear solution by moderate heat is reduced to half a fluid ounce, mixed with its bulk of alcohol, filtered, and the filtrate mixed with 50 grains of solution of ammonia containing alcohol, in two portions added half an hour apart, and allowed to stand twenty-four hours. The morphia was deposited in large distinct crystals, very few of which were attached to the interior of the vessel. They were collected on a filter, washed with diluted alcohol and water, dried, and weighed 8·75 grains. This, repeatedly boiled in ether and the ethereal liquids evaporated, afforded but a trace of crystalline matter, too small to weigh and yet distinctly visible in minute prisms.

No. 3.—This was mixed with 60 grains of lime, previously hydrated and boiled for fifteen minutes, the decoction filtered hot from the dregs, and these well washed with hot water. The filtrate, slightly acidulated with muriatic acid, was evaporated to half a fluid ounce, mixed with its bulk of alcohol and filtered; an excess of alcoholic ammonia was added and mixed, and the vessel set aside for twenty-four hours. The coloured crystalline powder and the portion attached as a crust to the interior were carefully collected on a filter, washed, dried and weighed, affording 10 grains of impure morphia, more coloured than either of the other results.

The use of alcohol in this process is intended to retain the colouring matter, yet did not succeed in producing a light-coloured morphia.

The last result, according to Mohr, should contain no narcotina, yet, when boiled to exhaustion in ether deprived of alcohol, the ethereal liquid afforded 0·75 grain of narcotina, making the result of morphia 9·25 per cent., and narcotina 0·75 per cent.

It will appear, by a comparison of these results, that the Staples' process, whilst less complicated than either of the others, yields a purer product than the Mohr process, and a slightly larger yield of morphia; whilst the process No. 2, which is suggested by the writer, affords the purest and best crystallized morphia, but is more complicated than either of the others. Hence it is the first, or Staples' process that is to be preferred, modified by treating the powdered opium with warm benzine as a preliminary operation. The final success is greatly aided by conducting the evaporation of the liquor at a moderate temperature, which renders the product less contaminated with colouring matter. By reducing the bulk before precipitation to the extent noted above, the precipitation of the morphia is facilitated, whilst the crystals are equally light-coloured. By using benzine beforehand, the extraction of the opium will be more thoroughly accomplished.—*Amer. Journ. Pharm., from the Proc. Amer. Pharm. Assoc.* 1870.

THE HONEY TRADE OF THE UNITED STATES, DOMESTIC AND FOREIGN.

BY B. F. STACY, CHARLESTOWN, MASS.

This article, which twenty-five years ago formed quite an insignificant article of trade in this country, is rapidly increasing year after year in domestic production; whilst the amount imported is growing smaller. While less is used for pharmaceutical purposes, it nevertheless is rapidly increasing in domestic use. It is also used largely by confectioners, and is an ingredient of many of the fancy beers which have recently become in vogue. Some dealers maintain that the honey which is the product of a cold climate is vastly superior to that of warmer latitudes, which seems almost a contradiction to nature, as Southern lands teem with flowers far excelling as a base of supplies to the bees. One sample that the writer saw from Canada excelled all others in whiteness, clearness and density. Samples from New York, Minnesota, Vermont and New Hampshire ranked next in order. The only way to obtain pure honey is to buy it in the comb, as nearly all the strained honey sold in the market bears unmistakable evidence of adulteration; this is, however, so well known and so easily discovered that it is unnecessary for me to dwell on it, and as the adulteration is mostly sugar and occasionally a little starch, to give it a whitish appearance, it is at least *harmless;* would that all the adulterations now in use were equally so. Out of ten samples purchased of different dealers, eight of them gave plain evidence of having been tampered with, the remaining two being samples from Cuba, right from the custom-house.

"In 1860 the total product of honey of the United States, reported, was 23,366,357 lb." "New York stood at the head of the list, with 2,369,751 lb., followed in order by North Carolina, 2,055,969 lb.; Kentucky, 1,768,692 lb.; Missouri, 1,585,983 lb.; Tennessee, 1,519,390 lb.; Ohio, 1,459,601 lb.; Virginia, 1,431,591 lb.; Pennsylvania, 1,402,128 lb.; Illinois, 1,346,803 lb.; and Indiana, 1,224,489 lb.; all other States falling below 1,000,000 lb." "Since the census of 1860 the statistics obtained have been partial and fragmentary; the statistics of Massachusetts for 1865 showed an increase of 26 per cent., and that of Iowa for same year an increase of 22 per cent. over the figures of 1860." "In the winter of 1868–69 the Department of Agriculture sent out circulars to known apiarians in most of the States, and received returns from 489 counties in 32 states. The aggregate number of hives reported was 722,385." "Estimating for counties not reporting, and and making due allowance for the fact that many of the counties reporting were giving special attention to bee culture, 2,000,000 of hives were deemed as low a figure as the returns would warrant. Allowing 15lb. of surplus honey to the hive (about two-thirds of the average reported), the total product in 1868 would be 30,000,000 pounds, which at an average valuation of 22½ cents per pound, would give $6,750,000." "In 1868 the quantity of honey imported was 212,176 gallons; value, $117,172; of which 90,452 gallons, value $50,569, were re-exported. A very small quantity of domestic honey was exported the same year. These figures show conclusively that an immense trade in honey has been built up in this country and is constantly increasing, which will eventually supersede all necessity of the importation of any from the West Indies." A small township in Minnesota reports 262 hives; from these hives 2826 pounds of surplus honey was taken in the season of 1869. When we consider that the cost of production is merely nominal, it will be seen that it pays to keep bees.

The writer respectfully acknowledges his indebtedness to the Commission of Agriculture for the statistical information.—*American Journal of Pharmacy, from the Proceedings of the American Pharmaceutical Association,* 1870.

NOTE ON CONFECTION OF SENNA.

BY JOHN W. EHRMAN.

This preparation, when properly made, is an excellent laxative—for habitual constipation superior, perhaps, to any other remedy. It is not in such general use among physicians or the public as it is entitled to, and this probably arises from the fact that much of the confection of senna of the market has little or no resemblance to the officinal article, and is comparatively worthless. Pharmaceutically considered the officinal process yields a result which is unobjectionable, save in two particulars; first, the presence of the powders of senna and coriander (and especially of the latter, which is most difficult to prepare) imparts a degree of "grittiness" which is disagreeable to the patient, giving the impression that "dirt" is present; secondly, the consistence of the confection when evaporated to the specified weight, varies as prepared from different specimens of drugs, and is sometimes too thin, when the mass is apt to go into fermentation. Fortunately, these defects may be easily remedied. In our opinion, the purging cassia, considering that it is so difficult to obtain, might well be omitted and substituted by an additional quantity of senna, particularly as there can be no advantage in multiplying the number of substances having similar therapeutical properties, in this or other preparations. We have used the modified formula given below (the coriander also being omitted and substituted by ginger), which is free from the objections we have mentioned. It is much more agreeable to take than the officinal confection, and is equally efficient:—

Take of Tamarinds	20	parts.
Figs, bruised	20	„
Prunes, sliced	15	„
Fluid Extract of Senna	10	„
„ „ Ginger	1	„
Sugar	30	„
Water, a sufficient quantity.		

Digest in a close vessel, by means of a water bath, the tamarinds, figs and prunes in ten parts of water for three hours; separate the coarser portions with the hands, and press the pulpy mass by rubbing, first through a coarse sieve, and then through a very fine one. Mix the residue with four parts of water, and, having digested the mixture for a short time, treat it as before, and add the product to the pulpy liquid first obtained, evaporate to a syrupy consistence over a water bath, add the sugar and continue the heat for twenty minutes, or until the sugar is dissolved; then remove from the bath, add the fluid extracts of senna and ginger, and mix thoroughly.—*The Chicago (U.S.) Pharmacist.*

SUMBULUS MOSCHATUS.

Inspector Lungershausen, of Moscow, reports in No. 27 of *Wochenschr. f. Gärtnerei und Pflanzenkunde*, that the hitherto unknown plant yielding musk, or sumbul root, is now in bloom in the botanical garden at Moscow. When the Russians occupied Bucharia, the plant was discovered and several roots were sent to Moscow, of which but one arrived in good condition. This new umbelliferous plant it was hoped would produce fruit and thus be propagated in Europe. The root has been used in Russia with considerable success in Asiatic cholera.

Professor C. Koch regards the plant as a very interesting one, on account of the strong musk odour of its root, and because the musk deer lives in the same regions. The root has been known for about thirty-five years, without, however, sustaining the high reputation it has gained in Russia, so that it belongs already to the obsolete remedies. It is now mainly employed in perfumery in place of the high-priced musk. There may, possibly, be two musk roots, both indigenous to Central Asia, one being exported through Russia, the other from the East Indies.

The musk root contains about 9 per cent. of a soft oleoresin, obtainable by ether, which in contact with water has the odour of musk. It contains a peculiar acid, sumbulic acid, which appears to differ from angelic acid and from umbelliferone. It has been long known that the root belongs to an umbelliferous plant; flowers and fruits have sometimes been found with it. The latter differing from those of other *Umbelliferæ*, were made the type of a new genus, and the plant was named *Sumbulus moschatus.*—*Hager's Ph. Centralhalle*, 1870, Nos. 39, 367, 368.

CHINESE PRODUCTS.

In the Reports of her Majesty's Consuls in China, for 1869–1870, there are some interesting particulars respecting the production of several substances which are of interest to the drug trade.

First in interest among these stands opium. The increasing consumption of this drug is now largely met by native cultivation. The native opium is not in favour with those who have acquired a taste for the foreign drug; but it is thought that the adulteration practised in the preparation of the Indian opium for smoking, may tend eventually to make the cheap native article more popular. This adulteration is said to consist of the admixture of various kinds of vegetables, ground nuts, and sometimes even human hair. It is probable, however, that the Indian opium, from its superior qualities, will always hold its own at the point now reached as an article of luxury against the native grown. There seems little doubt that the actual consumption of opium in China is increasing; the Consul at Kiu-kiang reports that "the number of dens for the accommodation of opium smokers has considerably increased within the past few years;" while the Consul at Foo-chow-foo reports that "opium smoking is still the fashion of the elegant and wealthy classes of society in China, no matter in what rank; it is the pastime of the literary man and the mandarin, as well as of the merchant."

The following information concerning the cultivation of opium in the province of Sze-chuen, the result of personal observation and inquiries made on the spot, is given in the report of the delegates of the Shanghae Chamber of Commerce on the trade of the Upper Yang-tze:—

"Cultivation of opium is very profitable, and is, consequently, increasing everywhere. The climate of Szechuen is warm and the season early, so that at least two crops, and probably three, are taken off the ground annually. Where the poppy is grown it is the first crop of the year, and only occupies the ground three months, competing with wheat or beans or some of the other cereal crops which come to maturity in the spring. The seed is sown in the first moon, say February. It is in flower during April, and the juice is nearly all gathered by about the middle of May, when the stalks are taken up for burning. Before this, the succeeding crop has generally been sown, if it is a dry crop, such as Indian corn, tobacco or corn, and the green leaves of the young crop appear as soon as the dry stalks of the poppy are cleared away. Rice may also be seen growing on the field where the poppy has been, as the means of damming up and irrigating the arable patches on the hillsides on which the poppy grows are always at hand, and the time of sowing the rice was found to correspond exactly with the time when the opium fields had been cleared. Very little labour seems to be needed in the cultivation of the poppy, and the gathering of the juice may be the work of the children of the family. The incision in the pod is made in the morning, and in the evening the juice that has oozed out is scraped off into a cup, when it gradually becomes black, and a few days' exposure to the sun renders it dry enough to be packed. The poppy seed is used for food."

For commercial purposes three kinds of opium are particularly worthy of notice, although as far as soil and climate are concerned there seems scarcely any limit to its cultivation. These are the growths of Szechuen (called Chuen-tu), Yunnan (called Nan-tu), and Kweichow (called (Kweichow-tu).

The quality and strength of the Szechuen opium varies according to the district. Fungtoo opium is said to yield 75 per cent. of extract; Foo, 70 per cent; Kai, 80 per cent., but these are vague native estimates. The opium ordinarily produced in Eastern Szechuen is from a large variety of poppy with white petals; but at Patung-hien it is obtained from a smaller kind with pink-tipped white petals, and is dearer than the other. Pink flowers are common amongst the white, and there are, doubtless, many slight differences in the quality of the drug which smokers recognize.

Yunnan is said to produce more opium than Szechuen. This opium, called Nan-tu, yields 80 per cent. of extract, is of finer quality and possesses better medicinal qualities than the Szechuen, and is longer in consuming. It is imported in large quantities into Szechuen, where it is used by wealthy people.

The Kweichow opium resembles the Szechuen. It was formerly largely imported in the latter province; but since the cultivation of the opium has extended there, the demand has fallen off.

Rhubarb is collected and sold in the Kwan-hien district. The price is about 40 taels per picul. (The tael is equal to about 6*s.*; the picul 133⅓ lb.) The finest quality is the produce of Szechuen. A distinction has usually been made between the Szechuen and the Shansi rhubarb, but it is doubtful whether it be a real one. The shipment to London during 1869 amounted to 1290 piculs, against 1910 piculs of the previous year.

Safflower, or Hung-hwa, is another valuable product of Szechuen. The best kind is called Kwa-tsze-hwa. The flowers are rolled together and cut in slices about a mace in weight, which are formed into square blocks. The second quality is called Ko-tsze-hung-hwa, and is made from the heart of the flower dried. An inferior description grows in Honan. A small trial shipment has been made to Marseilles, but the result is not known.

White wax, insect wax or pela, is also produced in Szechuen in large quantities. The insect which makes the wax is found in Yunnan on a tree, which is merely designated the Chung-shu, or insect tree. On this tree the insect forms a case containing hundreds of eggs, which is removed in the fourth moon and placed on the la-shu (wax-tree) in Szechuen. The insects come out of the case and commence secreting the wax round themselves, which operation is finished by the seventh moon, when the insect dies and the wax is collected. It bears a high market value, and is prepared at a trifling cost. The journey into Yunnan to procure the insect includes all that can be called expense or labour in the production. The insect does the rest, and the proprietors have to do little more than take the wax off the tree when it is ready; yet 500,000 taels would probably be a small estimate of the value of this wax exported annually from Szechuen. It is found also in Yunnan and Kweichow, but probably the Szechuen product is the best in quality, as it certainly is the most abundant.

The quantity of cassia has increased year by year since 1864, when the shipment was 13,800 piculs against 40,600 piculs in 1869. The export of musk, too, during 1869, was slightly in excess of that of 1868. On the contrary, the shipments of gall-nuts in 1869, amounted to not quite half the quantity of the previous years.

Sulphur is produced in considerable quantities in the hills near Yun-yang-hien, and a small quantity in Kweichow. Kweichow is also rich in mines of lead, copper, and especially of quicksilver, which latter were being worked with great advantage previously to the late rebellions, but have not since been resumed.

Tung oil is one of the largest products of Szechuen. The tung-shu tree grows everywhere throughout the province, preferring steep places with patches of good soil. The export of this article from Hankow by vessels under foreign flags was, in 1868, 174,000 piculs. Other oils are produced, as tsai-yew (cabbage or rape oil), chema-yew (tilseed oil), hwa-yew (ground-nut oil) and cha-yew (tea oil), but these are unimportant as articles of commerce.

LIME-JUICE AND PEPSINE.*

Besides pepsine and pancreatine, now much used as aids to digestion, there are certain food solvents equally worthy of attention, which have hitherto been somewhat neglected. The gastric juice, besides certain saline matters, contains a free acid and the organic substance called pepsine, both of which are secreted by a healthy stomach during a meal, and are essentially necessary for its digestion. While pepsine always constitutes the fermentive principle, the acid of the gastric fluid varies,—hydrochloric, phosphoric, lactic and acetic acids having been found therein. The gastric juice is in itself antiseptic, and this antiseptic virtue appears to depend greatly upon the acid portion. A few grains of pepsine moistened with water and submitted to a temperature of 100°, will in a short time ferment and emit a strong, almost urinous, odour. But if a few drops of hydrochloric, phosphoric or acetic acid be previously added, no such smell will be perceived. The solvent effect of certain acids upon albuminoids may be shown by coarsely bruising a small portion of meat and adding sufficient water to cover it, acidulated with either of the above-mentioned acids,—hydrochloric acid especially. If the mixture be then digested at the heat of the stomach for three or four hours, it will be found that although not reduced to such a homogeneous as it would have been by pepsina porci, nevertheless the solvent action of the acid is manifest.

In order to test the comparative digestive powers of hydrochloric acid and pepsine, Eberle suspended a solid piece of meat in a solution of each. He found that, in a few hours, the piece of meat in the pepsine solution had wholly disappeared, but the piece in the acid solution remained. Although this experiment proves that pepsine constitutes the digestive principle of the gastric juice, it does not prove that the acid is not a food solvent. Pepsine dissolves by virtue of its fermentive action. There is evidently an attracting affinity between the ferment and the albuminoid resembling chemical affinity, inasmuch as a new compound is the result. The acid, possessing no such affinity, acting on such a complex texture as a piece of meat, and that in a state of rest, could not be expected more than partially to exert its solvent action under circumstances so unfavourable to its action. But if the changes that food undergoes previous to and on entering the stomach—by mastication and by the powerful muscular action of the stomach—be taken into consideration, it will be readily perceived that it is here that the acid of the gastric juice, if it act at all as a food solvent, would be found to exercise its power. This may explain the *modus operandi* of lime-juice and other acids in curing or preventing scurvy. All the acids that have been discovered in the gastric juice are, without exception, antiscorbutics.

Dr. Farr considers that indigestion also may arise almost or quite as frequently from a want of acid as from a deficiency of pepsine in the gastric juice. He has noticed many times that where pepsine alone has failed to relieve dyspepsia, the exhibition of one of the non-astringent acids has been successful. Believing that the prophylactic virtue of lime-juice and other acids depended upon their direct action as food solvents, it occurred to him that an excellent artificial gastric juice might be made by allowing lime-juice to represent the acid portion. Accordingly he had a mixture of lime-juice and pepsine prepared, which he reports that he and many of his medical friends have used successfully in cases of dyspepsia. He says that lime-juice with either pepsine or pancreatine makes a very elegant preparation, is very convenient for prescribing, and may be made to keep almost any length of time without deterioration.

* Abstracted from a paper on "Food Solvents," by Dr. Archer Farr, published in the *Medical Times and Gazette*, March 18th, 1871.

Note on Milk-Ash.—Mr. J. A. Wanklyn writes as follows:—The statement current in the text-books that caseine is kept in solution in milk by means of alkali, with which it forms a kind of salt, cannot be correct, inasmuch as I find, on examining the ash left on incinerating milk, that there is no appreciable quantity either of alkali or of alkaline carbonate. The experiment was made on two specimens of milk, one from Hertfordshire, and the other from Essex. I evaporated down ten grammes of milk in a small platinum dish, incinerated the residue, and then moistened the ash with water, added drops of very dilute standard sulphuric acid, and observed the reaction on litmus-paper. After the addition of 0·5 cubic centimetre of standard acid, the action on litmus-paper is not alkaline; and on the addition of 1 c.c. the reaction is distinctly acid. 0·5 c.c. corresponded to $2\frac{1}{2}$ milligr. H_2SO_4. Milk-ash, if it contain any alkali at all, does not contain so much as 2 per cent. of carbonate of soda, and the ratio of alkali to caseine cannot be so large as 2 to 400.—*British Medical Journal*.

Prevention of "Pitting" in Small-pox.—The *Melia Azadirachta*, L., an Indian plant, is used by the natives to cover the bodies of patients recovering from small-pox, as it is supposed to prevent the mark from becoming permanent. Dr. Wight says of this tree that "the leaves beaten into a pulp and externally applied act like a charm in removing the most intractable form of psora and other pustular eruptions."—*Nature*.

THE PROPOSED POISON REGULATIONS.

MEETING OF CHEMISTS AND DRUGGISTS AT SHEFFIELD.

On Thursday evening, March 30th, a Meeting of Chemists and Druggists was held at the rooms of the Pharmaceutical and Chemical Association, to consider the regulations which have been proposed for adoption by the Pharmaceutical Council as to the storing, dispensing and sale of poisons.

Mr. J. T. Dobb, the President of the Association, occupied the chair, and stated that if the regulations were passed at the meeting of the Pharmaceutical Society in May, they would be sent to the Privy Council and would very soon afterwards become law. Many chemists and druggists thought the regulations were too stringent, that they would interfere with their privileges, that chemists and druggists were sufficiently well educated and qualified to dispense poisons, and that special legislation for them was not required. The subject was a most important one, and the meeting had been called in order to obtain an expression of opinion from the chemists and druggists of the town.

Mr. Wilson moved, "That this meeting regards the proposed compulsory regulations for the storing and dispensing of poisons as an unwarrantable interference with the freedom and independence of the trade, uncalled for by the public and without leading to their greater safety; and further, this meeting desires to impress upon the Council of the Pharmaceutical Society the serious personal and legal responsibility already resting upon chemists and druggists, which naturally makes them adopt the most careful precautionary measures to prevent accidents; and as every business is so varied and peculiar in its character and circumstances, each principal should remain at liberty to make such arrangements as will best suit his own case to secure safety, and therefore the proposed legislation upon the subject would be unwise, inconvenient and unnecessary; and this meeting, while recognizing with respect the Pharmaceutical Council, pledges itself to oppose energetically the proposed compulsory poison regulations."

This was seconded by Mr. Stevenson.

Mr. Preston objected to the proposed regulations, but at the same time thought some regulations were needed, and that certain regulations might be suggested which every member of the trade could agree with. He objected to the clause in the resolution—"and, therefore, any definite legislation upon the subject would be unwise, inconvenient and unnecessary"—and moved, as an amendment, the proposition with the clause omitted.

This was seconded.

Mr. Radley was opposed to the regulations, and suggested that the Pharmaceutical Society should send to every member of the trade recommendations as to poisons which they might adopt or not, as they thought fit.

This was objected to by Mr. Hudson, who considered that if they laid themselves open to receiving recommendations, the Privy Council would think the regulations were necessary.

Mr. Cubley spoke in favour of the resolution, and expressed his opinion that if the regulations were enforced, innumerable accidents with poisons would arise within twelve months after their coming into operation.

After some further discussion, at the suggestion of Mr. Cocking, Mr. Wilson consented to alter his resolution so that the words "the proposed legislation" were inserted instead of the words "any definite legislation."

Mr. Preston then withdrew his amendment, and the resolution as amended was carried unanimously.

Mr. Radley proposed, "That in the opinion of this meeting the best means to prevent accidents in the storing, dispensing and selling of poisons is the improved education of the chemists and druggists, secured by the Pharmacy Act, 1868, which will accomplish all that is required for the protection and safety of the public."

Mr. Ward seconded the motion, and after some discussion it was adopted unanimously.

Mr. Cocking moved and Mr. Preston seconded, "That partial legislation on the subject of poisons is impolitic and unjust, and that any regulations which do not apply equally to surgeons, apothecaries, veterinary surgeons, hospitals and dispensaries cannot be deemed satisfactory to this meeting."

The motion met with cordial approval; and in the course of a brief discussion upon it the Chairman expressed his opinion that some surgeons required to be looked after more than chemists and druggists, as they allowed their medicines to be dispensed by the boys who looked after their horse and carriage, who cleaned their boots, and who filled up the remainder of their time by making themselves useful about the house. The motion was unanimously adopted, as was another to the effect that the resolutions be forwarded to the Pharmaceutical Council.

A cordial vote of thanks to the Chairman concluded the proceedings.

MEETING OF CHEMISTS AND DRUGGISTS AT BIRMINGHAM.

A Meeting, convened by the Midland Counties Chemists' Association, was held, March 31st, in the Committee Room of the Temperance Hall, Temple Street, to consider the proposed new regulations with respect to the sale of poisons. The chair was taken by Mr. Arblaster, President, and there were present Messrs. Palmer, Dymond, Crookes, Miller, Sanderson, Brown, Price, Grieves, Lucas and others.

In commencing the proceedings, the Chairman said the question was one of great importance to all of them. It would be in the recollection of most present that at the meeting of the Pharmaceutical Society in May last the proposed poison regulations were the great subject of discussion. The regulations which were then submitted were negatived after very considerable discussion; but a resolution was passed in the following terms:—"That the subject be taken into consideration by the incoming Council; and that a further report be made to the next Annual Meeting." From that time—from May last till the present time—he believed the subject had continually engaged the attention of the Pharmaceutical Society, and they had again proposed regulations somewhat similar in character to those of last year; but they had tacked on a clause relating to the dispensing of liniments, embrocations and lotions in particular-shaped bottles. With that exception, the regulations were the same as before. They now stood as follows:—

"1. In the keeping of poisons, each bottle, vessel, box or package containing a poison shall be labelled with the name of the article, and also with some distinctive mark indicating that it is poison. 2. Also in the keeping of poisons, each poison shall be kept on one or other of the following systems, viz. (*a*) in a bottle or vessel tied over, capped, locked or otherwise secured in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop or dispensary; or (*b*) in a bottle or vessel readily distinguishable by touch from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop or dispensary; or (*c*) in a bottle, vessel, box or package kept in a room or cupboard set apart for dangerous articles. 3. All liniments, embrocations and lotions containing poison shall be sent out in bottles readily distinguishable by touch from ordinary medicine bottles, and there shall also be affixed to each such bottle (in addition to the name of the article, and to any particular instructions for its use) a label, giving notice that the contents of the bottle are not to be taken internally."

The arguments which had been used against the proposed regulations were many. Some said that a higher state of education would be a better safeguard. But they had continually seen that mistakes had occurred among the best educated and in the best regulated establishments, and he did not think they must look to a higher educational standard for the sole means of preventing those mistakes. Besides which, some years must necessarily elapse before that high standard of education could make itself felt among the thousands of chemists in the country. Another objection was that the surgeons and medical practitioners generally, including veterinary surgeons, were not subjected to the same regulations as were proposed by the Pharmaceutical Society; but this, he thought, was not worthy of consideration, for he was of opinion that if the sale of poisons became the subject of legislative interference, no person, surgeon or otherwise, would be allowed to retail poisons without placing himself under the regulations. Again, objections had been made to the mode of storing poisons; but this might be obviated by the adoption of a particular description of bottles, and taking care that those bottles were properly labelled and placed in a particular spot. If such things as the alkaloids, strychnine, morphia, etc. were put into a cupboard, apart from the general run of medicines, it would be the means of preventing many of the mistakes which had occurred. Looking at the correspondence which had taken place between Dr. Simon and the Pharmaceutical Society, it seemed to him that something must be done. Dr. Simon wrote to the Registrar of the Pharmaceutical Society to the following effect:—

"My Lords believe it to have been the opinion of Parliament that proper regulations in this matter are required for the protection of the public, and as more than two years have elapsed since the passing of the Act without the Pharmaceutical Society having proposed any such regulations, my Lords think it right to inquire whether the Pharmaceutical Society intends, within any time you can specify, to propose such regulations to their Lordships. They direct me, therefore, to request that you will have the goodness to give me, at your earliest convenience, the information required by their Lordships."

If that was so, if something must be done, they had far better do what they could to regulate themselves, rather than have regulations forced upon them by the Government. He had drawn up, and would submit for the consideration of the meeting, the following resolution:—

"That from the correspondence between Dr. Simon and the Council of the Pharmaceutical Society, it appears that her Majesty's Privy Council insists on regulations being framed for the vending and dispensing of poisons; and it is the opinion of this meeting that the regulations proposed (with the exception of the third) by the Pharmaceutical Society are such as will be the least objectionable to chemists, and at the same time satisfy the requirements of the Privy Council."

Several gentlemen present expressed an opinion that the regulations would be found to work very harshly upon the trade, and suggested many minor difficulties which would present themselves, especially in the poorer districts.

Mr. Dymond said he was glad of the present meeting, because he valued a free expression of opinion on a question of such importance as this. He had read with interest the reports of the various meetings which had been held throughout the country, and had been impressed, with what seemed to him, an absence of such an impartial view of the subject as would enable chemists justly to appreciate the difficulties of the question. No doubt chemists, like many other classes of the community, were mainly influenced by what was convenient to themselves in the conduct of their affairs. This was not unnatural, but they ought at the same time not to ignore what was passing, or had passed, outside their own circle. The Pharmaceutical Council, upon whom had devolved the duty of suggesting these regulations, contained men of long experience and high standing in the trade. They had, with special opportunities, watched the progress of Pharmacy Acts and legislation on poisons, and had laboured in their behalf for many years. These men knew intimately what the determination of the Government was, that it absolutely demanded regulations to be observed by chemists in the use of poisons. They saw that the press demanded it (and Mr. Reynolds was quite mistaken when he declared that only two papers had spoken on the subject), and they knew that the public approved it. These various considerations must be allowed weight in considering the question. Regulations of some kind would, no doubt, have been contained in the last Pharmacy Act had not the Privy Council, on the urgent recommendation of the Pharmaceutical Council, that *they* were the best judges of what was possible and practicable to chemists, surrendered to them the duty of framing regulations. The Pharmaceutical Council, therefore, were bound by the highest considerations of honour to suggest such regulations as they conscientiously believed to be just, as well as of value to the trade. Very little objection, indeed, had been made to the regulations themselves. It appeared that most chemists adopted them in one or more ways. What the chemists objected to was compulsion and interference. He believed the fear of interference was groundless. But subjection to law was not an evil. The whole of our liberties were based upon the restraints of law, which prevented one man from injuring another. It was illegal for one person to injure another with smoke or an offensive smell; but these were imaginary nuisances compared with that of one man poisoning another, or even with the possibility of doing so with an unprotected array of poisons. The present fact, however, before them was this,—the Government were determined that chemists should observe some regulations in the keeping and dispensing of poisons. They had now the opportunity of regulating themselves. Would they accept this golden chance, or by waiting a little longer have to submit to Government regulations with results which no one could anticipate?

The resolution was seconded by Mr. J. Lucas, who said he could see no hardship in having to comply with the regulations. For himself he did not think they were necessary; but if regulations were to be framed, he believed that those proposed were as easy as any that could be devised for the general good. There was much misconception abroad as to the sale of poisons, some persons still believing that the sale of paregoric and pennyworths of laudanum and the like, must be in particular poison-bottles, and not in bottles or vessels that their customers might bring for the articles.

No other resolution being proposed, it was submitted to the meeting, and declared to be carried by a majority of eight votes to four votes.

Some of the dissentients said that the resolution would not express the general feeling of the trade in Birmingham.

The Chairman said he had advertised the meeting in the daily newspapers, and had sent out 120 post cards of invitation. Those who were absent could not find fault, and he thought they would be right in assuming that many of them were satisfied with the regulations.

The proceedings terminated with a vote of thanks to the Chairman.

The Pharmaceutical Journal.

SATURDAY, APRIL 8, 1871.

THE LAST STEP IN POISON REGULATION.

BETWEEN the Scylla and Charybdis of displeasing the governing body of our Society and of becoming obnoxious to the reproach that we do not purvey information with such promptitude as befits this age of progress, we are irresistibly impelled to commit what may be deemed a breach of the regulations with which we ought to comply. But as the occasion is one that we may fairly term exceptional, we trust that the balance of opinion will be in favour of our disobedience,—since the majority of our members, as well as the great body of the trade, must be anxious to hear of anything taking place in reference to a question that interests them so profoundly as that of poison regulations.

We understand that in the Council Meeting of last Wednesday, Mr. SUTTON's motion that the sense of the members be taken on the question at issue, was followed up by an amendment, proposed by Mr. DYMOND, to the effect that the Council perceiving the opinion entertained by members of the Society to be so decidedly antagonistic to the application of compulsory regulations, should, therefore, suggest the issue of the proposed regulations simply as recommended by the Society. This amendment was put to the vote and carried with only one dissentient vote—that of the PRESIDENT.

We may at least congratulate our readers that the question which has for months agitated our Society and the entire trade is thus finally disposed of. There is no longer any ground for hostility. We trust that we may also, by anticipation, congratulate them on the removal of all reason for future antagonism between town and country, and on the possibility of provincial and metropolitan energies being hereafter united to promote the general interest of pharmacy rather than directed to hostile efforts.

We have now learnt to appreciate the power of the country members, and may therefore take this opportunity to urge upon them not to neglect its exercise in all matters which affect the advancement of the trade.

And though last, not least, we would most sincerely express our regret that the attainment of the result we now record involves a loss which it may be long before the Society can make good—we refer to the resignation of the Presidency by Mr. SANDFORD, which followed immediately on the carrying of Mr. DYMOND's amendment. Mr. SANDFORD's labours for the good of pharmacy are far too well known and appreciated by the trade to need any reiteration here, and we feel confident that few will hear of his resignation without profound regret that his strong sense of duty has rendered it impossible for him to be any longer the leader and representative of British pharmacists.

MEDICAL DRUGGISTS.

WE commend to the consideration of our medical contemporaries the state of things described in Dr. CAMPBELL BLACK's paper* as existing in Glasgow, more especially since the reverse of the picture was not long since prominently dwelt upon in the columns of the *Lancet* in a manner which, we think, was wanting in fairness to the general body of pharmacists.

Having but recently expressed our opinions on "the relations of pharmacy to medical practice,"† we will not again enter upon the arguments which we then adduced in answer to the complaints of our contemporary on the subject of counter-prescribing by druggists. We are no advocates of the practice, but while we know that under some conditions it would be studiously avoided, we cannot shut our eyes to the fact that under other conditions, probably of most frequent occurrence, it is unavoidable and, if only for that reason, not properly a ground for reproach by medical practitioners. Indeed, we believe that all reasonable men, whether medical or pharmaceutical, would agree in the opinion that no precise rule can be laid down in this matter as to what is proper and what improper, but that under the guidance of mutual respect and consideration between medical men and pharmacists, the individual judgment of those concerned is the best means of preventing any interference with the proper functions of either class.

The circumstances described by Dr. CAMPBELL BLACK, however, are of such a nature as not to be regulated by any such principle of action. The keeping of open surgeries—as they are called—or, in plainer terms, druggists' shops, by medical men is an open invasion of the pharmacist's business, not a mere shifting of the demarcation between that business and the sphere of the medical men, determined by local conditions. We would willingly entertain the idea that the practice described by Dr. BLACK was confined to Glasgow; but though we know this is not the case, we trust that city is unequalled in regard to the extent of the evil.

* See p. 812. † See p. 410.

MEDICINAL PLANTS.

There are but few plants with which we are acquainted that have not, at some time in the course of their history, had a reputed value for the cure of some complaint or disease. This is notably the case in India and other parts of the tropics. If good for no other purpose, they are invariably said to cure snake-bites. The reason why so many Indian plants of reputed medicinal value are not used in this country is, we suspect, not so much on account of the want of a proper trial of their properties, as to the fact of our having already articles with similar properties of recognized and proved value. Considering the number of members of the medical profession now scattered over India, we might reasonably suppose that as good a test of the properties of medicinal plants can be made there as in England.

Occasionally, however, new medicinal agents are brought to this country from various parts of the world,—one of the most recent of these introductions which has come to our notice being a packet of sticks of irregular length, each about three-quarters of an inch in diameter, with a thick whitish-grey bark. They are sent under the name of condor or vulture cane, and are said to be a valuable medicine in cases of cancer, in the Republic of Ecuador. The plants, we are told, grow in the province of Loja, but, as nothing but the mere sticks have been received, we are unable to give even a clue to their botanical affinities.

Professor Frankland, in his latest report to the Registrar-General, states that the quality of the Thames water has greatly improved during the past month, but that the best water supplied from that source still contained more than four times as large an amount of organic elements as that present in water obtained from wells sunk into the chalk.

In a letter which we publish elsewhere, Professor Frankland corrects the statement in Mr. Ekin's paper, that he regards the amount of nitrates in water as necessarily the result of the oxidation of sewage matter, and points out that the data given by him as representing antecedent contamination of water are reported under the general heading of "Previous Sewage or Animal Contamination (Estimated)."

As a proof that it is not intended to allow the new law for sustaining the better education of apothecaries in Baltimore to become a dead letter, it is stated that a druggist doing business in the western section of that city has been arraigned upon the charge of prosecuting his business without having undergone the examination prescribed by the Act of last year, and fined fifty dollars and costs.

In reference to the paper on "Sumbulus Moschatus," at page 807, we may remark that a specimen of the plant yielding this drug has, we believe, been received from St. Petersburg, and is now growing at Kew Gardens, but has not yet flowered.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The usual Fortnightly Meeting of this Association was held in Anderson's University, 204, Georges Street, on the 22nd of March; Mr. Thomas Davison, President, in the chair. There was a very large attendance, several medical gentlemen being on the platform: D. Frazer, Esq., P.C., and Messrs. Beattie, Scott, Peacock, Symington and Nelson were elected members. On the motion of Mr. J. Fergus Wilson, seconded by Mr. W. R. Kermath, a large and influential Committee was appointed to endeavour to extend the early closing movement to all branches of the drug trade in Glasgow and neighbourhood.

D. Campbell Black, Esq., M.D., was then introduced, and delivered an address on "The Relations of Prescriber to Dispenser."

Mr. President and Gentlemen,—As a practitioner, a comparative stranger in this city, the request that I should deliver a short address before the members of this Association I received as a compliment. I received it in that spirit, on the reflection that it emanated from a Society representing now a large and intelligent section of the community, and one entitled at the hands of the medical profession to the most courteous consideration. If I ask myself on what grounds I merited this honour, I confess to feeling somewhat puzzled for an explanation, if it be not, perchance, that a report of my pugnacity—which let me do myself the justice to inform you much belies me—has reached you, and that towards the termination of your course of lectures you were solicitous of a little mental relaxtion. Be that as it may, it is nevertheless true that I hold, on some medical questions opinions which some are pleased to term extravagant and Utopian. Whether they are entitled to be so designated it is not for me to say, while I am satisfied that they are the expression of a sincere conviction, and that, as such, I have never exhibited timidity in proclaiming them, but have ever regarded personal consequences as of subsidiary moment. Well, Gentlemen, you have heard that in the culinary achievement of making hare soup, the first part of the process is to catch your hare; and having in an evil hour, perchance for myself, acceded, so to speak, to the flattering dalliance of your secretary, the question of a subject presented itself. In this several things had to be considered. Prominently among these, the limited time at my disposal; and, again, the desirability that I should endeavour to entertain you with a subject mutually familiar. Perhaps you are aware, some of you at least are, that in a paper which I read before the Medico-Chirurgical Society of this city in October last, and for portions of which I had to submit to the usual amount of abuse,—a task which I congratulate myself on having survived,—I animadverted on some of the relations which subsist, in this city, between the dispenser of medicine and the prescriber. The limits of my paper on that occasion permitted but a cursory allusion to this important subject; and it occurred to me that on this occasion which you have done me the honour to place at my disposal, I ought profitably to enlarge on that portion of the subject treated of in my paper on "Medical Reform," and endeavour to show, not that the present relations between prescriber and dispenser are desirable, but that they are extremely unsatisfactory, and that the public benefit, and the dignity of the profession, demand of a large number of my professional brethren concessions which they appear extremely reluctant to make. There was a time in the history of medicine when dispensing was exclusively in the hands of medical practitioners. As medical science extended, and as investigations into physiology and pathology were more assiduously prosecuted for the purpose of unravelling the hidden symteries of disease, and basing its treatment on rational principles—an object at present the most prominent and most praiseworthy of modern medicine,—what might be called the manipulatory portion of our art became discarded by the heads of the profession, and was confined in England and Ireland to the licentiates of the Apothecaries' Company in the respective countries, such licentiates possessing, according to law, certain privileges; while in Scotland the same conditions developed the drug trade, in addition to the shops of medical practitioners. Corresponding to the licence of the Apothecaries' Company in England and Ireland, there was no analogous qualification in Scotland, save, perhaps, that the licence of the Royal College of Surgeons of Edinburgh and of the Glasgow Faculty conferred the right to deal in pharmacy. In the latter country a physician, *i. e.* a graduate of medicine of a university considered it quite honourable and legitimate to keep open shop; while in the former the apothecary was almost exclusively what might be called, with a violation of gender, in these primitive times when ladies attended to their household duties, the handmaid to the physician, or pure surgeon. To indicate how defined the duties of apothecary were even in the sixteenth century the following quaint rules for an apothecary's life and conduct merit quotation:—

"1. Must fyrst serve God, forsee the end, be clenly, pity the poore.

"2. Must not be suborned for money to hurt mankynde.

"3. His place of dwelling and shop to be clenly to please the sences withal.

"4. His garden must be at hand with plenty of herbes, seedes, and rootes.

"5. To sow, set, plant, gather, preserve and keep them in due tyme.

"6. To read Dioscorides, to know ye nature of plants and herbes.

"7. To invent medicines, to choose by colour, taste odour, figure, etc.

"8. To have his mortars, stilles, poltes, filters, glasses, boxes, clene and sweette.

"9. To have charcoles at hand to make decoctions, syrups, etc.

"10. To keep his cleane ware close and cast away the baggage.

"11. To have two places in his shop, one most cleane for the physic, and a baser place for the chirurgerie stuff.

"12. That he neither increase nor diminish the physician's bill, *i. e.* (prescription) and keep it for his own discharge.

"13. That he neither buy nor sell rotten drugges.

"14. That he peruse often his wares, that they corrupt not.

"15. That he put not in *quid pro quo* (*i. e.* use one ingredient in the place of another when dispensing a physician's prescription) without advysement.

"16. That he may open wel a vein for to helpe pleurisy.

"17. That he meddle only in his vocation.

"18. That he delight to reede Nicolaus Myrepsus, Valerius Cordus, etc. etc.

"19. That he do remember his office is only to be ye physician's cooke.

"20. That he use true measure and weight.

"21. To remember his end and the judgment of God; and thus do I commend him to God, if he be not covetous or crafty, setting his own lucre before other men's help, succour and comfort."

The apothecaries to whom these rules were given were merely grocers, who elected to perform the meaner duties of the physician or surgeon. In the fourth year of James I. a charter was obtained that "willed, ordained and granted, that all and singular the freemen of the Mystery of Grocers and Apothecaries of the City of London, should and might be one body, corporate and politic, in deed, fact, and name of the Warden and Commonality of the Mystery of Grocers of the City of London." And in the thirteenth year of the same King and reign these so-called mysteries were disunited, this being the origin of the London Apothecaries' Company. For a considerable time after their formation as a company, the apothecaries were kept closely under the surveillance of the College of Physicians; but as time wore on, they began to assert their independence, and took to prescribing after the fashion of the physicians. This, of course, applies to England, but I refer to the circumstances in order to indicate that originally the Society of Apothecaries was intended to be subservient to the physician and surgeons. In Scotland the conditions to which I have already adverted, developed a large commercial enterprise, independent of the Scotch physicians and surgeons, but possessing no chartered privileges. Public benefit at length demanded—the trade having become such an extensive one—a guarantee of knowledge of the business, and ability to dispense physicians' and surgeons' prescriptions, and through the exertions of the Pharmaceutical Society, an enlightened measure was carried through Parliament in 1868, whereby it is, *inter alia*, provided "That it shall be unlawful for any one to sell, or keep open shop, or to assume the title of 'chemist and druggist' or the like, unless he shall be properly registered under the Act," and in order to obtain proper registration under the Act the passing of a very stringent examination is a necessity. Now, Gentlemen, I look upon the Pharmacy Bill as having entirely superseded the charter of the Apothecaries' Company in England, and as having virtually cut the connection between the practice of medicine and surgery, and pharmacy as a trade in Scotland; and as the result of some attention to the subject, I am firmly persuaded that it is expedient that this separation should exist. I shall not take up your time by animadverting upon the hue-and-cry raised against the Bill by the medical practitioners. You may remember the widespread consternation as to the shutting of their shops. I thought the agitation discreditable to the profession, and I, for one, extremely regret that the Act was not enforced in its primary interpretation. I therefore think the Pharmacy Bill an enlightened measure, for if there is any one belief that I hold stronger than another on medical matters, it is this principle, that no medical practitioner should have a pecuniary interest in the drugging of his patients. This being the case, I maintain that indiscriminate drugging is too much the custom both in England and Scotland (I cannot speak for Ireland); that it does much to subvert a rational faith in medicine, and that, to a great extent, the shop system is chargeable with the offence. In the face of the Pharmacy Bill, and for sundry other reasons which I shall refer to in the sequel, I hold that it is highly discreditable to the city of Glasgow, that out of a total of 190 practising practitioners, not less than 120 should put themselves in open competition with qualified druggists. In the discussion raised upon my paper, read before the Medico-Chirurgical Society, the President of the Faculty contended that I exaggerated and misrepresented the condition of the profession in Glasgow, and by implication admitting the shop system to be inimical to the interests and dignity of the profession, held that there was not now one medical man's shop for eight that previously existed. I now tell you that this is a great mistake, for there never were more doctors' shops in Glasgow than at present.

But, Gentlemen, if I denounce this system of practice I must justify my denunciations of it. For the shop system, so far as several medical men in this city are concerned, I plead the apology of necessity, but this is quite beside the question of principle, and in what respect I plead this necessity I have in my paper on "Medical Reform" endeavoured to point out, and your time will not permit me to enter on this part of the subject on this occasion.

Well, I charge the shop-system with slipshod treatment of disease, indiscriminate drugging, and a downward competition. You may find in some of the surgeries of Glasgow, so-called, of an evening, perchance from a dozen to two dozen people waiting to see the mysterious person ensconced beyond the green door, on which "Consulting Room" shines so prominently. It takes time to arrive at a correct diagnosis, it takes time to prescribe suitably to the disease, and this time being taken, an honest advice should be given, and an honest advice is worth paying for. It is the merest farce in the world, and it is an outrage on medical science, to prescribe for a crowd of an evening, and dole out to a credulous multitude a heterogeneous mixture from this bottle and the other; and I deny that in the majority of cases this system of treatment can be reconciled to any physiological, pathological, or chemical principle. No; the threshold of such establishments is like Pluto's portals—

"Smooth the descent and easy is the way;
But to return (without the bottle) and view the cheerful skies,
In this the task, the mighty labour lies."

No fee being exacted in the back room, "the bottle" is sure to be advised "to be got at the counter." It is what might be called a case of *double do;* the patient endeavours to *do* the doctor, and the doctor in return *does* the patient. This is what is called "the bottle system," and is one for which Glasgow holds conspicuously an unenviable notoriety; and it has ingrained into the minds of so many in the city the belief that medical men should be paid for their medicine, that a medical man without a shop is a *rara avis in terris.* But if he be asked why this system is so much in favour here, the only explanation vouchsafed is, that it will not do to practise otherwise in Glasgow. Well, I have only to remark, that I am not aware of any physiological peculiarity in Glasgow citizens compared with the denizens of Edinburgh or Greenock; in the former of which there are but few doctors' shops, the number not above four, if I am correctly informed, and in the latter only one. I believe these towns have an equal proportion of poor people as we have, and in Greenock especially there are none of those self-seeking excrescences on modern practice—Special Institutions. Yet we never hear complaint that the humbler orders do not receive adequate medical attendance. In a word, medical practice in Greenock is conducted on the purest method—considering the size of the town and the large proportion of the artisan class—perhaps in Scotland.

But further, the shop system encourages a downward competition, and, in consequence, an adulteration of drugs. I am of those who believe that if a thing is worth purchasing it is worth paying for; and if this principle hold good in any commercial transaction, it assuredly obtains in the purchase of medicine. Unfortunately, however, "common sense" is a very *un*common attribute of modern humanity, and ten to one, the chances are, that the man who asserts most strongly in perfect disregard of an ancient virtue, called truth, or who most conforms to the claptraps of a Cheap-John, is the man who will be most generally patronized. If the power of assertion was ever of service, it is eminently in this age; lying, to use a plain term is, *par excellence,* one of the most profitable avocations in these latter days. In an age, therefore, when people do not hesitate to stuff life buoys with other material than cork, and even tamper, according to the sage of Chelsea, with the very composition of bricks, we need not be surprised if what is termed a colocynth pill is *not* a colocynth pill. In the adulteration of medicine the man who is both prescriber and dispenser has an obvious advantage over the simple compounder of medicine; the former, trusting to the beneficence of the *vis medicatrix naturæ,* and having an eye to a plethoric till, often goes on the principle that a rose by any other name will smell as sweet, finds, by experience,—a much abused term by the way,—that it is immaterial whether his compounds are made according to the Pharmacopœia or not. You will not be surprised, therefore, to learn that I know of an instance where a surgeon represented to a pharmaceutical chemist that he must reduce his pills to three-halfpence per dozen, a price at which, I am told, it is perfectly impossible to make up colocynth pills according to the Pharmacopœia, not to speak of the trifling profit which every reasonable person will, as a matter of justice, ungrudgingly allow the compounder. In these cases, I am informed, the scammony is either all or in part left out,—a veritable case, Gentlemen, of the play of 'Hamlet,' with the ghost omitted.

Now, medical science may suffer in this respect, and if I were at a loss to draw an inference, I might contend that practices such as these conspire to make Glasgow practitioners so little known beyond the good old city of Saint Mungo. I am, at all events, informed, on excellent authority, that druggists are worse remunerated here than in any city in the kingdom, and that, as we might consequently expect, we excel likewise in the adulteration of medicines. Not only does medical science suffer in this manner, but the reputation of a gentleman who simply prescribes is imperilled if his prescriptions lucklessly find their way into any such establishment. It is in my recollection that while the Pharmacy Bill was passing through Parliament, one of the grounds of opposition to it was that there was no clause in it rendering the compounding of medicines according to the British Pharmacopœia compulsory; and I remember that on this point the *Lancet* very sensibly suggested that any such procedure was like putting the cart before the horse, for if physicians prescribed according to the British Pharmacopœia, the necessity of compounding medicines according to it would be forced upon druggists; but it is surely breaking faith with us, and is a violation of a public trust reposed in druggists, if physicians so prescribe, and their patients are not supplied with what is so ordered. Now, is it a fact that the existence of medical practitioners' shops to the extent that we have them in this city fosters indiscriminate medication? My experience decidedly confirms this belief. Repeatedly have I witnessed an ominous row of bottles, so significant of wry faces, adorn the mantelpiece of poor patients' houses; and how often is the confiding remark made that Dr. So-and-so is a very fine man,—"a skilly doctor,"—that no one grudged him his fee, but had an awful horror of the bottles! I have elsewhere endeavoured to show that by this system a great injustice is done to the public, and that it is a method of practice the most powerful of any I know in pauperizing people of slender means, and subverting professional integrity and honour. Human nature will be human nature to the end of time; and be a man however estimable and upright in his inclinations, circumstances have a proverbial influence in altering cases; and when a certain amount of money is invested by a medical man in a drug establishment, looking at the question from a commercial point of view, he must to a great extent be influenced by a good return. I hold that this inducement—be it an unconscious bias—is not compatible with the honest practice of the medical profession. This, of course, leads to the incessant changing of bottles, powders, etc. Now one bottle, to-day another, and so on. It is a case of—

"At nine these powders let him take,
At ten the draught, the phial shake:
And you'll remember at eleven
Three of these pills must then be given.
This course you'll carefully pursue,
And give at twelve the bolus too.
If he should wander, in a crack
Clap this broad blister on his back;
And after he has had the blister
Within an hour apply the clyster.
I must be gone; at three or four
I shall return with something more."

To my mind, the man who so acts,—and this is no imaginary picture,—if he be honest, can at least have no well-founded conception either of disease or its appropriate treatment; and the intelligent patient will not fail to discover that his medical attendant is a man fighting an unseen enemy in the dark, or is solicitous of pushing the trade in which he has so immediate an interest, that medical science must suffer. That will be apparent to any one; for how is it possible to deduce any reliable inference from such heterogeneous treatment?

But, Gentlemen, to give you a home thrust now, the complaint is frequently urged against you by my professional brethren, that you encroach on the province of the physician in counter-prescribing, and that opportunities are afforded you of doing so in a peculiarly favourable manner in this city, where a drug shop and a medical man are with the great bulk of the population identical. Let me remind you of the rules of Bullyen above-quoted, "That the apothecary meddle only in his vocation," and "That he do remember that his office is only to be ye physician's cook." You will accede to me the right to contend that if I consider it expedient that we should leave the pharmaceutical department to you, you must meet us in an equally liberal spirit.

And I will say this for the most respectable druggists with whom I have conversed on this subject, that they discourage counter-prescribing, and reprehend its performance in others. To me it is quite clear that it is only by mutual concessions between dispenser and prescriber that their relations can be satisfactorily adjusted. It is thus that we must endeavour to wipe out the stigma against medicine,—that the ancients endeavoured to make it a science and failed; the moderns to make it a trade, and succeeded.

But, Gentlemen, while I am opposed on principle to the shop system, you will not be surprised if I fail to find words to express my indignation at the sale of quack medicines by duly qualified medical practitioners. It appears to me to be a lamentable manifestation of professional degeneracy that so many doctors' shops in this city should display the meretricious tinsel of the impostor; nay, further, that registered practitioners should stoop to the issuing of circulars for the purpose of bringing quack medicines under the notice of the public in conjunction with their names. There has been, and ever will be, a section of the public which *will* be gulled, and that section, I regret to say, not the most illiterate; but, above all others, should we not expect members of the medical profession to spurn the puffing of quack medicines? What can be expected of the public, in the face of such conduct by medical men? I cannot witness without a feeling of profound humiliation such cards as, "For a Cough, try Gibson's Lozenges," exhibited in surgeons' windows, and, with like feeling, "Rooke's Pills" and "Solar Elixir" or "Whelpton's Purifying Pills," pressed into the service of surgeons' shop-window ornamentation. Of a surety Ichabod has been inscribed on the Æsculapian temple in modern times. Let me refer you to the birthplace of our science in the island of Cos, 400 years before the Christian era, for a nobler example. Here Hippocrates, in the grey dawn of history, dedicated his best energies to the cultivation of our science, with that object which, above all others, should be paramount with the honest physician, the amelioration of suffering; and to the immortal honour of our father be it said that, diligent and skilled in his profession, he openly avowed the measures he had taken to cure diseases. And even in the fourteenth century a righteous detestation of imposition manifested itself in such punishment as the following:—It is recorded that one Roger Clerk professed to be learned in the art of medicine, and prescribed for a woman suffering from fever the hanging of a certain document round the neck, containing certain herbs, which he stated were an antidote to the disease under which she suffered. The charm did not work. He was summoned before the Mayor and Aldermen of the Guildhall of London, at the instance of the husband of the patient, to show upon what authority he practised the art of medicine. His own statement was sufficient to convict him of being a rogue and an impostor, and he was forthwith ordered to be placed in the pillory, and therein to be punished for the offence he had committed against society. His progress to the pillory is thus described:—"It was adjudged that the same Roger Clerk should be led through the middle of the city with trumpets and pipes, he riding on a horse without a saddle, and the said parchment and a whetstone for his lies being hung about his neck, a urinal also being hung before him and another behind." Oh for some such punishment in these days of boasted progress! Only I would extend the treatment to all abettors of quackery; and you can fancy, gentlemen, if such treatment were enforced in Glasgow, what an imposing procession would be thus formed.

Time compels me, however, to draw these remarks to a conclusion; but I may observe that I find it far more excusable on the part of the pharmacist to sell quack medicines as a branch of his business. This is a question with him regulated by the law of supply and demand, and one over which the druggist has no control, save at considerable sacrifice, which his refusal to sell patent medicines would entail. The ignorance and gullibility on the part of the public is an antecedent condition, and it is his as a matter of business to meet the demand so created. The case is very different with the medical man, whose duty it ought to be to dispel delusion and error. I am of those who believe that no enlightened Legislature should afford its protection to any secret preparation, and on this point the law of France is worthy of imitation. As there is no law to which exception may not be taken, and no principle which is universally applicable, there may occur certain cases in which it is impossible to practise medicine without dispensing also, as in rural districts and in connection with appointments to large public works. I will go a little further than this: if a medical man chooses to supply medicine to his own patients from his private dwelling, I do not think, looking particularly at the matter, as a step further advanced in the severance of the duties of medical practitioners from that of the pharmacien, that the practice is so objectionable.

Gentlemen, these then constitute some opinions I have long entertained on the relations of prescriber and dispenser, and you will do me the justice to believe that I have come here neither to flatter you nor to traduce my professional brethren; my endeavour has been to follow the sound rule of nothing extenuating, nor setting down aught in malice. I cordially sympathize with you in asking my brethren to move on—to give up merchandise—and I am firmly persuaded that medical science and the public would be the gainers. Perfection, it is true, does not pertain to things terrestrial, but that is no reason why we should not vie one with another in the degree to which our actions should incline towards the most honourable conduct, even at the risk of being classed as I have been among the "fussy grievance-mongers."

I console myself with the reflection that I am actuated by no envy, while it is a well-known truism—

"How rarely, friends, an honest man inherits.
Honours and wealth with all his toils and pains,
It sounds like language from the land of spirits,
If any man obtain that which he merits,
Or any merit that which he obtains."

Gentlemen, I am exceedingly obliged to you for the courteous attention with which you have listened to these my fragmentary observations.

The President, in proposing a vote of thanks to Dr. Black, stated that he could corroborate many of Dr. Black's remarks with reference to both surgeons and druggists keeping very inferior drugs; it was only the other day, he said, that a medical practitioner who held his diploma from the University, called upon him and wanted colocynth pills at 1*s*. per gross; and though he was glad to say such a state of things was gradually dying out, he thought it was a disgrace to the profession that they should encourage such a state of things.

Mr. Kinninmont, in seconding the motion, also referred in humorous terms to the unhappy state of matters between prescriber and dispenser. With regard to counter prescribing by the druggists, he said that respectable chemists were very often placed in an awkward predicament; for, through the great number of surgeon-druggists in the city, the public had got accustomed to look upon the counter as the proper place to get prescribed for in any but serious ailments, and that if a druggist refused to prescribe bilious pills or a calomel powder when asked, the customer would invariably go to the nearest surgery and get supplied there with what he wanted. He also pointed out that people when they asked a druggist's opinion on anything, generally had their mind made up as to what they wanted, and merely wished the druggist to assure them that the medicine they had made up their mind to take was the proper thing.

After some amusing remarks by Dr. Moffat, the vote of thanks was heartily responded to.

The Secretary afterwards, with permission of Messrs. Evans, Sons and Co., Liverpool, presented one of their Five Guinea Cabinets of materia medica to the Association.

The President, in accepting the cabinet in the name of the Association, said he had no doubt the members would all make a good use of it; and those especially who had examinations to pass, would find it of great benefit in assisting them in their studies.

Mr. Paterson seconded the motion, and suggested that a brass plate be engraved with names of donors and date of presentation, to be placed on top of cabinet, so that "he who runs may read."

The suggestion was supported by Mr. M'Millan, and agreed to with acclamation.

A special general meeting of pharmaceutical chemists and chemists and druggists on the "poisons" question was announced for Monday, 3rd April; and a paper on "Volatile Oils" for next ordinary meeting of the society.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Anniversary Meeting, March 30th; Prof. Williamson, F.R.S., President, in the chair.

The President delivered the following address:—

"Gentlemen,—I feel much pleasure in congratulating you on the rapidly increasing prosperity of our Society and the enlargement which has taken place in its sphere of usefulness; for, on the one hand, the number of our Fellows continues to show a most satisfactory increase; and, on the other hand, your Council has made arrangements for carrying out the system of monthly reports which has been for some time in contemplation. It was hoped that the Chemical Society of Paris might, from the first, co-operate with us in the preparation of these monthly reports, but circumstances beyond their control have prevented the sister society from joining us in the beginning of this year. Deeming it undesirable to delay the commencement of the reports, your Council still look forward to the future co-operation of the Paris society in their preparation.

"You are aware that the present available income of the Society was not considered to be sufficient to defray the additional expense of writing and printing these reports, and I have the pleasure of informing you that contributions to the extent of £1175 have been promised by members of your body towards supplying the deficit during the first five years of the appearance of these reports. The British Association has, moreover, granted us the sum of £100 for this year in aid of the undertaking. We hope that in five years the funds of the Society may have sufficiently increased to enable us to pay the whole expense of the reports, and that their publication will be valued by the members of our Society, and promote the advancement of our science, wherever the English language is read. The next number of our Journal, which I hope to see in a few days, will be the first to contain the monthly reports in addition to the original papers contributed to the Society.

"At the last anniversary meeting, we numbered 551 ordinary members and 36 foreign members; 6 of the former have withdrawn from the Society. On the other hand, 42 new members have been elected into the Society. We have lost 5 ordinary members by death, viz. Mr. George Tolley, Dr. W. A. Miller, Dr. Aug. Matthiessen, Dr. J. S. Muspratt and Mr. W. W. Rouch; and it is also my painful duty to record the death of two of our foreign members, viz. Prof. Gustav Magnus and Prof. Weltzien."

After the delivery of the address, the Treasurer read his account of the Society's finances, which shows a balance of more than £1300 at the Society's bankers.

The election of the President, the officers and the other members of Council for the ensuing year was then proceeded with, and the following is the list of the gentlemen elected:—

President: E. Frankland, D.C.L., F.R.S.

Vice-Presidents, who have filled the office of President: Sir B. C. Brodie, F.R.S.; Warren De la Rue, Ph.D., F.R.S.; A. W. Hofmann, D.C.L., F.R.S.; Lyon Playfair, Ph.D., C.B., F.R.S.; A. W. Williamson, Ph.D., F.R.S.; Col. P. Yorke, F.R.S.

Vice-Presidents: H. Debus, Ph.D., F.R.S.; J. H. Gilbert, Ph.D., F.R.S.; H. M. Noad, Ph.D., F.R.S.; W. Odling, M.B., F.R.S.; T. Redwood, Ph.D.; J. Stenhouse, Ph.D., F.R.S.

Secretaries: A. Vernon Harcourt, M.A., F.R.S.; W. H. Perkin, F.R.S.

Foreign Secretary: H. Müller, Ph.D., F.R.S.

Treasurer: F. A. Abel, F.R.S.

Other Members of the Council: E. Atkinson, Ph.D.; H. Bassett; C. L. Bloxam; A. Dupré, Ph.D.; F. Field, F.R.S; M. Holzmann, Ph.D.; H. M'Leod; E. J. Mills, D.Sc.; H. E. Roscoe, Ph.D., F.R.S.; W. J. Russell, Ph.D.; R. Angus Smith, Ph.D., F.R.S.; A. Voelcker, Ph.D., F.R.S.

The meeting terminated with the customary votes of thanks to the retiring President, the Secretaries, the Treasurer, etc.

MEETINGS FOR THE ENSUING WEEK.

Tuesday April 11.	*Royal Medical and Chirurgical Society*, at 8.30 p.m. *Photographic Society*, at 8 p.m.
Wednesday April 12.	*Society of Arts*, at 8 p.m.—"Boiled Oil and Varnishes." By C. W. Vincent. *Microscopical Society*, at 8 p.m.
Friday April 14.	*Quekett Club*, at 8 p.m.

Obituary.

AUGUSTUS DE MORGAN.

Although not connected with the particular branch of science which is of most interest to the readers of this Journal, the late Professor De Morgan was a man of such eminence, and had secured to himself the admiration and respect of so large a portion of the community, that no apology is needed for giving more than a bare notice of his death.

Augustus De Morgan was born at Madura, in Southern India, in June, 1806, and was the son of a colonel in the Madras army. On the maternal side he traced his descent from the mathematician, James Dodson, F.R.S., many years master in the mathematical school of Christ's Hospital and author of the 'Antilogarithmic Canon,' a circumstance to which he regarded himself as indebted for his particular bent of mind. Sent early to England, in 1823 he went to Cambridge, where he became fourth wrangler in 1827, before he was twenty-one years of age. Conscientious scruples preventing him from subscribing to the necessary tests, he was debarred from the college fellowship to which his high position would have otherwise entitled him. He afterwards entered Lincoln's Inn and commenced the study of law, but he soon left this and devoted himself to his favourite study. In 1828, he became Professor of Mathematics at the London University—now University College,—which office he held, with the exception of the five years from 1831 to 1836, until 1866; when, not approving of the course adopted by the Council in an appointment to one of the professional chairs, he resigned and left the College, of which he had been for nearly forty years one of the most distinguished ornaments.

Professor De Morgan was the author of several well-known treatises on the various branches of mathematics and logic, and a contributor to the *Penny Cyclopædia*, Knight's *British Worthies*, the *Philosophical Magazine*, the *North British Review*, the *Transactions of the Cambridge Philosophical Society*, the *Athenæum*, etc. He was also resorted to for advice by many of the principal life assurance companies.

Professor De Morgan had been ill for a considerable time previous to his death. An attack of paralysis was followed by a disease of the kidneys, and he died on Saturday the 18th of March, at sixty-five years of age.

M. Émile Hepp, the well-known pharmaceutical chemist, of Strasbourg, while labouring to extinguish the fire caused by the German artillery in the civil hospital, on the night of the 25th of August, received an injury which has caused his death, after more than five months' suffering, at the age of fifty-two. The *savants* of Strasbourg assembled around his grave, and several short addresses were pronounced over his remains. M. Hirtz has paid a further tribute to his late colleague by the publication of a careful biography, setting forth Émile Hepp's scientific claims.—*Athenæum.*

The death is announced of Mr. Samuel D. Hendel, a prominent American pharmacist, and member of the firm of Leitch and Hendel, of St. Louis, Missouri. He died suddenly from apoplexy on the 23rd of January, at the age of forty.

Another eminent pharmacist, of the same city, Mr. Eugene L. Massot, died on the 14th of February. At a special meeting of the St. Louis College of Pharmacy, the following resolutions were passed:—

"Whereas, the death of Mr. E. L. Massot having been announced to this college, we feel it our privilege and duty to give some expression to our deep sense of his loss and our affectionate respect for his memory. Therefore, be it

"Resolved—That we bear most willing testimony to his faithfulness and devotion in promoting the interests of this college, he being one of its most thorough friends, who, at all times, spared no trouble and thought no labour too great to advance its interests. The records of this institution recite the confidence placed in him by its members. Filling successively the offices of President and Vice-President, he gave to each position that careful attention so necessary for the successful workings of such an institution as ours is. His blameless and consistent life, his amiable and genial disposition, and his eminently attractive social qualities, rendered his society sought for not only by members of his profession, but by all who came within the sphere of his acquaintance.

"Resolved—That we will attend the funeral and cordially unite in every token of respect to his memory.

"Resolved—That a copy of these resolutions be presented to the family of the deceased, and that the pharmaceutical journals of the country and the city press be requested to publish the same."

The *Chemical News* announces the death of Dr. Charles M. Wetherill, of Bethlehem, Pennsylvania. The deceased gentleman had been a pupil of Liebig, and was esteemed by his American fellow-workers as one of the most active chemists America possessed.

Review.

The New Theory and Practice of Medicine: a Treatise on the Nature, Cause, Cure and Prevention of Disease, with practical illustrations of the medicinal and other uses of Hibbert's Patent Antiseptic Solutions. Published by the Author, W. Hibbert, Cheetham, Manchester. 1870.

At a time when the most accomplished and philosophically-minded physicians are admitting that medicine, as a science, is little more than on the threshold, Mr. W. Hibbert announces his discovery of the true nature and cause of disease in general, and, what is more to the point, the sovereign remedy for its symptoms in particular.

In a preface, the style of which makes us more than dubious whether Mr. Hibbert has received an ordinarily good education, he unfolds what may be regarded as his ideas of "pathology"—ideas, we may confidently assert, considerably in advance of any entertained by the Royal Colleges of Physicians or Surgeons. Dexterously hooking on Professor Lister, of Edinburgh, to his little medical go-cart, he comes to a halt before the British public, and assures them, in genuine showman's language, that the remedy for all their ailments is stowed away in his vehicle, and that they have only to "walk upstairs," and on payment of a small gratuity, obtain the desired relief. Like all others of his class, he is very strong in the kind of phraseology which at once alarms and mystifies the vulgar—"debility," "organic imperfection," "misdirected nervous irritability" (whatever that may mean), "disposition to morbid activity," and so forth—phrases which may signify anything or nothing, but which the empiric is well aware will be interpreted by his appropriate audience on the principle of "omne ignotum pro *horrifico*." It is quite unnecessary to examine Mr. Hibbert's positions in detail. His *ipse dixit* is quite sufficient for us. But before proceeding to burn our Pharmacopœia, throw physic to the dogs, and sign a petition for the ostracism of "duly-qualified" pretenders, we should like him to explain how his antiseptic solution is good at once for diarrhœa and constipation. When he has satisfied us on this point, we shall refrain from inquiring whether or not it is an accidental coincidence that he hails from *Cheet-ham?*

The following journals have been received:—The 'British Medical Journal,' April 1; the 'Medical Times and Gazette,' April 1; the 'Lancet,' April 1; the 'Medical Press and Circular,' April 5; 'Nature,' March 30; the 'Chemical News,' March 31; 'Journal of the Society of Arts,' March 30; 'Gardeners' Chronicle,' April 1; the 'Grocer,' April 1; 'Produce Markets Review,' April 1; the 'English Mechanic,' March 31; the 'Journal of Applied Science' for April; the 'Florist and Pomologist' for April.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department, 17, Bloomsbury Square, W.C., and not to the Publishers.*

[186.]—BAKING POWDER.—
Sodæ Bicarb. 16 oz.
Acid Tart. Exsicc. 8 oz.
Rice Flour, 12 oz.

The acidity naturally present in a mixture of flour and water renders a larger proportion of tartaric unnecessary.—T. S.

[191.]—SOLVENT FOR WHITE SHELLAC.—Perhaps your correspondent is not aware that, unless white shellac is dissolved *within a fortnight of its preparation*, it is not worth 6*d*. per ton; but within that period it is easily soluble in naphtha or finish.—CHARLES B. ALLEN.

[*** White shellac is usually kept in water, by which means its capability of being dissolved is preserved. This property is very soon lost upon exposure to the air.—ED. PHARM. JOURN.]

[192.]—OXYGEN GAS PURE FOR INHALATION.—Take a bottle furnished with a tube and funnel, and put into it a mixture composed of equal parts of lead peroxide and barium peroxide, then add some weak nitric acid: the reaction takes place immediately, the effervescence is performed quietly and the oxygen liberated.—SAMUEL ELIOTT, Jun.

[193.]—LIQUOR OPII SEDATIVUS.—I send the following formula, given by Mr. Cooley:—Dissolve ℥iij of hard extract of opium (prepared by percolation with temperate water) in ℥xxx of boiling distilled water, and adding to the cold and filtered solution ℥vj of rectified spirit, and water to make up exactly Oij.—HERBARIUS.

[205.]—COD-LIVER OIL AND QUININE.—Methods of dissolving quinine and many other alkaloids and metallic oxides in cod-liver and other oils were described by Professor Attfield in the PHARMACEUTICAL JOURNAL, 2nd Ser. Vol. IV. p. 388. Some time afterwards Mr. Daniel Hanbury stated at an evening meeting of the Pharmaceutical Society that he had found the method answer well for cod-liver oil and quinine.—ED. PHARM. JOURN.

[210.]—COD-LIVER OIL JELLY.—The following formula has been published for this preparation:—

℞. Ol. Morrhuæ	75·00	parts.
Sacch. Alb.	14·88	"
Acid. Citric.	0·60	"
Gelatin	2·76	"
Aquæ	6·56	"
Ol. Essent.	0·20	"
	100·00	

[211.]—HORTICULTURAL INK.—I have tried receipt in Beasley, headed "Ink for writing on Steel or Tin Plate or Sheet Zinc," on zinc, and find it answer perfectly if the labels are well cleaned before and baked after writing.—THOMAS STOKOE.

GLYCERINE BALSAM.

This is designed to whiten and soften the skin, remove roughness, chaps, chilblains, and irritations from common causes.

Take White Wax (pure), 1 oz.
Spermaceti, 2 oz.
Oil of Almonds, 9 oz.

Melt together by a moderate heat in a glazed earthenware vessel, and add—

Glycerine (best), 3 oz.
Balsam of Peru, ½ oz.

The mixture is to be stirred until nearly cold, and then poured into pots. [Instead of balsam of Peru, 12 or 15 drops of otto of rose may be employed.]—*Druggists' Circular.*

ALMOND BALLS.

1. Take of Spermaceti, 2 oz.
White Wax (pure), 4 oz.
Oil of Almonds, ½ pint.

Melt them together in an earthenware pot by the heat of a water-bath, and, when the mixture has cooled a little, add—

Essential Oil of Almonds, 1 drm.
Expressed Oil of Mace, 1½ drm.

Stir the mixture constantly until it begins to cool, then pour it into slightly-warmed moulds, which may be ounce gallipots or egg-cups with smooth bottoms. This will form hemispherical cakes.

2. Take of Hard Clarified Suet, 14 oz.
White Wax, 2 oz.

Melt, and add—

Essential Oil of Almonds, 1 drm.
Oil of Cloves (or Pimento), ½ drm.

and proceed as in No. 1. Cheaper and inferior to the first. Rub it into the skin. [They may be coloured by adding the colouring material while the whole is in a fluid state.]—*Druggists' Circular.*

CAMPHOR BALSAM.

1. Take of Spermaceti, 2 oz.
Olive Oil, ½ pint.

Dissolve by a gentle heat, and add—

Camphor (cut small), 1 oz.

Stir the mixture until nearly cold, and then put into short, wide-mouthed bottles, which should be kept well corked.

2. Take of Curd Soap, 1 oz.
Water, 1½ oz.

Dissolve by heat, and stir in of

Camphor, ½ oz.

previously dissolved in

Olive Oil (hot), 3 oz.

When the whole is thoroughly combined and cold, add—

Oil of Origanum, ¼ oz.
Strongest Solution of Ammonia, ½ oz.
Alcohol, 1½ oz.

and proceed as in No. 1. [These are stimulant and anodyne. The first may be used to prevent chapping of the skin, remove chilblains, and to stimulate the growth of the hair. The second is better for frictions in lumbago, rheumatic pains, etc.]—*Druggists' Circular.*

BALSAM OF HONEY.

Take Fine Pale Honey, 4 oz.
Glycerine, 1 oz.

Mix by a gentle heat; when cold add—

Alcohol, 1 oz.
Essence of Ambergris, 6 drops.
Citric Acid, 3 drms.

This is intended to remove discolorations and freckles, as well as to improve the general appearance of the skin.—*Druggists' Circular.*

CALENDULA JELLY.—HOMŒOPATHIC.

Take of Starch in powder, 70 grains.
Glycerine, 1 fluid ounce.

Mix the powdered starch with the glycerine, and gradually heat the mixture to about 240° F., constantly stirring, and when cold add—

Saturated tincture of marigold flowers, 1 fluid drachm.
Tincture of Cochineal,
Oil of Rose, q. s. to colour, and perfume.—*Pharmacist.*

CALENDULA CERATE.

Take of Marigold flowers, bruised, 1 part.
Place into a porcelain dish and add boiling water, 2 parts.
Let it digest for several hours, and add butter, fresh, 6 parts.
Apply heat until all the water is dispersed, and strain through linen cloth with pressure.

Although the above is an authoritative formula for preparing this innocent external remedy, it will not, if prepared by this process, receive the endorsement of the disciples of Hahnemann, with whom it is a prominent remedy "for all the ills that flesh is heir to," for want of the characteristic yellow colour; and as appearances are great aids to strong faith, we will add a formula for a cerate having the requisite colour, and ensuring simplicity and dispatch in its preparation:—

Take of Tincture of Marigold flowers (saturated) 1 part.
Lard (fresh), 8 parts.

Heat on a water-bath until all the spirit is dispersed, and a uniform preparation is obtained.—*Pharmacist.*

SUGARED CALAMUS, OR CANDIED SWEET-FLAG ROOT.

Take of Calamus Root (cut in small pieces), 1 part.
Macerate in 4 parts of water twelve hours.
Add sugar (crushed), 12 parts,

And with constant stirring dry it perfectly, by the aid of a gentle heat.—*Pharmacist.*

SPECIES LAXANTES SAINT-GERMAIN—SAINT-GERMAIN LAXATIVE POWDER.

Take of Senna leaves, previously exhausted with strong Alcohol, and dried, 16 parts.
Elder flowers, 10 parts.
Fennel seed,
Anise seed, of each, 5 parts.

Cut and well bruise them, mix together, and when dispensing add 40 grains of Bitartrate of Potash to each ounce of species. —*Pharmacist.*

CASTILLION'S POWDER.

Take of Tragacanth,
Sago,
Salep,
Sugar, of each, in very fine powder, 4 parts.
Carbonate of Lime (precipitated), 1 part.
Cochineal, q. s. to colour.

Mix them thoroughly, and pass through a fine sieve.—*Pharmacist.*

BLACK CURRANT LOZENGES.

Take of Black Currants, dried, a sufficient quantity; add a small quantity of water, and soften by heating in a water-bath until reduced to a soft, pulpy mass, pass this through a hair sieve, and evaporate to the consistence of a paste.
Take of this Black Currant paste,
White Sugar, in fine powder, of each 1 pound.
Gum Arabic, in fine powder, 2 ounces.
Citric Acid, in fine powder, ½ ounce.

Mix, and make into a mass with Raspberry Syrup, q. s., and divide into lozenges of 10 grains each.—*Pharmacist.*

[215.]—HAIR DYE.—"*Beta*" would be glad if any one will oblige with reliable and not too expensive recipes for black, dark brown, and light brown hair dyes, without using ammoniæ hydrosulph.

[216.]—SHOW COLOURS FOR LAMPS.—Can any of your readers supply me with the formulæ for good red and green show colours for lamps? They must neither fade nor freeze.—C. S.

[217.]—POMADE.—Can any reader oblige me with a form for Sardinian or Zouave pomade for fixing the moustache?—DELTA.

[218.]—INKS FOR DIES.—"*Inquirer*" would be glad to be furnished with recipes for black and coloured inks to use with dies or stamps.

[219.]—DISPENSING.—I received the following prescription to dispense last week:—

℞. Liq. Ammon. Acet. ℥iv
Spt. Camph. ʒss
Aquæ Destill. ℥iiiss.

M. ft. Lotio.

To be applied to the face frequently. Upon adding the spt. camph. to the liq. ammon. acet. and aqua, there was a copious separation of camphor, by the addition of a little tinctura myrrhæ the camphor was taken up and the lotion became turbid.

Can any of your readers inform me if I am justified in either adding the tinctura myrrhæ to, or straining the camphor from, the lotion?—B. H. H.

Correspondence.

PREVIOUS SEWAGE, OR ANIMAL CONTAMINATION IN POTABLE WATERS.

Sir,—In your last number, Mr. Charles Ekin states, in an article on the estimation of nitrates in potable waters, that "according to the reports of the Registrar-General, Professor Frankland regards the amount of nitrates in a water as necessarily the result of the oxidation of sewage matter; and from the nitrates present he actually calculates how great the previous sewage contamination has been.

Permit me to say that I do not entertain, or express in my reports to the Registrar-General or elsewhere, any such view regarding the presence of nitrates in water. Mr. Ekin will find, on referring to my reports to the Registrar-General, that he has misquoted the heading of one of the columns in the analytical table, the words being, "Previous Sewage or Animal Contamination (Estimated)." Even if it be admitted (but the evidence adduced by Mr. Ekin on this point is by no means conclusive) that the nitrates in certain oolitic waters are derived from the oxidation of fossil animal remains, my definition of their origin would still be perfectly accurate.

Royal College of Chemistry, E. FRANKLAND.
March 31*st*, 1871.

STORAGE OF POISONS.

Sir,—In looking over the correspondence in your columns on the storage of poisons regulations, it has struck me that the following would be a good way of putting the whole question.

In the management of our railways, two systems of signalling were, and, I believe, still are, in use,—one a "positive," the other a "negative." Under the former, the way is always considered safe unless a positive signal of danger is raised. Under the latter, the danger-signal is kept raised, and the way considered unsafe until it is lowered.

Now it seems to me that in enforcing the storage of poisons regulations, the Pharmaceutical Council (acting as directors) would be adopting the first of these systems. The officials, *i.e.* the apprentices, assistants and working principals would consider themselves quite safe in discharging their duties, until a danger-signal in the shape of a red triangular label, or "some other distinctive mark" were raised; when they would be expected immediately to pull up and look well that their way was clear before proceeding.

On the other hand, by allowing individual responsibility to rest upon every person in the trade, I consider the second system would be put into operation. The danger-signal would constantly be against us, only to be lowered when we were off duty.

As the railway companies, after putting the positive system to a practical test, have almost unanimously abandoned it in favour of the negative, I think the Pharmaceutical Council would do well to profit by their experience, and not make "physic-taking" a more dangerous experiment than railway travelling.

Leeds, March 29*th*, 1871. S. T.

POISON CUPBOARDS.

Sir,—What sort of cupboard would it take to hold half a ton of arsenic? is a question asked in a recent Journal. Having just planned with a friend something of this description, it may be useful to state what was done. In one of the warehouses is a sort of counter, 8 feet long, some old jars and boxes have to be cleared away from under it, it is then boarded up at each end; about 20 inches of boarding nailed up also at each end in front, and a couple of doors hung in the centre; the doors not locked but fastened with a spring-catch. This will hold a ton of arsenic, if need be; at all events it has room for two casks and a half, containing 7 or 8 cwt. in the whole, and for a box of other poison packages.

A cupboard can easily be made wherever there is a blank wall by putting up a shelf of about 2 feet wide, and then carrying out my plan. For jars, etc. in warehouse, a cupboard is at once had by putting a couple of doors in front of the shelves.

I know some have a very heavy trade in these poisonous articles; the plan I have stated would not be suited so well to meet their wants as the appropriating of an entire room in which all poisons could be kept.

Whatever difference of opinion there may be as to the advisability of compulsory poison regulations, all seem to be agreed as to the propriety of adopting, individually, suitable arrangements for preventing accidents. I am, therefore, induced to trouble you with these remarks.

A COUNTRY CHEMIST.

SYRUP OF PHOSPHATE OF IRON.

Sir,—With reference to the article on syr. ferri phosph. by Mr. Carteighe in this week's Journal, I should like to make a few additional observations.

It appears to me to be not so much a stronger acid in itself which is required, as a freshly prepared (or, perhaps, more strictly speaking I should say, freshly diluted) acid; and I was led to this opinion by noticing, that when the syrup began to deposit very soon after being made, it was just at such times as my stock of dilute acid was getting low, and, consequently, what there was of it was comparatively old. On first noticing this, the thought struck me,—why, this acid has deteriorated from repeatedly using and opening the bottle; but upon second thought, considering the stable nature of this acid, I could not fancy it to be so; and upon testing, it proved not to be, but to be as good as ever, with the simple exception, that I could not get a good syrup with it.

Up to the time of my noticing this I had thought the fault was with the phosphate, and I had tried precipitating from hot and cold, concentrated and dilute solutions, with the acetate of soda, and without it; but all these plans made but a trifling difference in the product. However, after I had such good grounds for believing the acid to be at fault, I made the following trial:—I first diluted a quantity of acid to the proper strength, then with a portion of it made some of the syrup, which I found to keep well, and from time to time, as the acid got older, I made more syrup with portions of the same; and I found that as the age of the acid increased, so the liability of the syrup to spoil increased. Since then I have invariably made the dilute acid when wanted for making the syrup, and I have invariably obtained a satisfactory result; with ordinary precautions it will keep good six months, or even longer. I made a batch in September, 1870, which lasted me until the commencement of the present month, and the last bottle sent out was as good as the first; and I have by me now some dilute acid made last summer, which was used at the time of diluting for making syrup which kept well, and yet that acid will not now hold the phosphate in solution beyond an hour or two, the syrup beginning to turn cloudy almost directly the sugar is dissolved. Beyond this one thing I can find no difference between the old acid and the fresh. Can it be a molecular change? The reaction with all tests is identical, and the neutralizing power with alkalies is the same.

So far, therefore, my experience would go to support the formula proposed by Mr. Carteighe, and I scarcely like to find fault with so accomplished a pharmaceutist; but in one particular it appears to me to be not quite what could be desired. In his formula there is 2 fl. oz. of limpid liquid to be mixed with 10 fl. oz. of syrup; this would make an unusually thin syrup, and might, I think, detract somewhat from its keeping quality. I think the following might be recommended as an amendment, which I have tried and found to answer well:—

Phosphate of iron (freshly precipitated)	96 grs.
Phosphoric acid, sp. gr. 1·5	7 fl. dr.
Sugar	$8\frac{1}{2}$ oz.
Water (q. s. to form 12 fl. oz. syr.)	$5\frac{1}{2}$ fl. oz.

Mix the acid with the water, dissolve the phosphate, then add the sugar, shaking occasionally until dissolved.

ALFRED ROSE.

Maida Hill, W., March 29th, 1871.

PRESERVATION OF SULPHATE OF IRON.

Sir,—I beg to make a correction of a statement promulgated by me, and printed in the PHARMACEUTICAL JOURNAL for May, 1868, on the preservation of sulphate of iron. The method recommended was to place a small quantity of camphor in the vessel containing the sulphate. After having given this plan a fair trial (on a good sample of the sulphate), I was led to the conclusion that it answered the intention perfectly, presuming that the atmospheric oxygen was excluded partially, at least, by means of the vapour of camphor.

More recent experience, however, has shown me that camphor has not the smallest effect in preventing oxidation of badly-made sulphate of iron, *i. e.* when crystallized from a solution containing much free sulphuric acid; while, on the other hand, a well-made salt, with hard, brilliant facets, appears to require nothing beyond a good stoppered bottle and a dry situation to keep it entirely free from oxidation.

GEORGE WELBORN.

OBSCURE PRESCRIPTIONS.

Sir,—As an illustration of one of the numerous phases of a provincial druggist's business, I send the following verbatim copy of a prescription lately brought to a druggist's shop in the county of Lincoln to be compounded. It is probable that no other than an agricultural mind could have conceived such a medley of ingredients, or spelt them in a more intensely rural manner.

2 dr. of fabach.
2 dr. of pilochc.
2 dr. of bittirhapple.
2 dr. of colomet.
10 gr. of gold dust.
2 dr. of mercury.
Sprit of buckthorn sufficient for 60 pills.

31*st March*, 1871. G. W.

ONE OF THE CRAFT.

Sir,—Perhaps the following inscription from a tombstone at Broadwater, near Worthing, might interest some of your readers:—

IN
MEMORY OF
MRS. FRANCIS SMITH,
DRUGGIST,
OF WORTHING,
WHO DIED
JULY 4TH, 1837.
AGED 101 YEARS.

An old customer of Mrs. Smith remembers going into the shop sixty years ago for something for the toothache, when the old lady observed, "Now, my boy, the stuff I'm about to give you is as precious as gold, so there's but very little for twopence; but it's sure to do your mother's toothache good." I regret the name of the specific has not been preserved.

J. BURT.

M. F. S.—Most of the information you ask for is usually obtained at school, and may be found in any biographical dictionary. We are obliged for your suggestion, but do not think our readers would generally appreciate such articles as you indicate.

N.—The cloudiness and deposit you speak of probably arise from impurity of the water used in making the lemonade. The change has been noticed by Dr. Heisch in his paper on "Organic Matter in Water," an abstract of which will be found in No. 1, p. 13, of the present series.

A. W. V.—No blame could have been attached to the dispenser for using either of the mint waters, as both are officinal: we should, however, have used aq. menth. pip., as being the one commonly prescribed.

"*Vinum*" will find a letter on the subject in No. 26, p. 519.

"*Parenchyma.*"—The work mentioned is published by Messrs. Macmillan, price 4*s.* 6*d.*

"*Henley.*"—No. 2.

J. W.—We believe an apparatus similar to the one mentioned, of foreign manufacture, was introduced to the trade by Messrs. Gilbertson, of Ludgate Hill.

"*Indoctus*" has omitted to send his name.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. F. Johnson, Mr. M. C. Cooke, Mr. C. R. C. Tichborne, Mr. F. M. Rimmington, Mr. J. W. Jackson, Mr. Hustwick, Mr. J. Winser, M. F. S., J. S., N., "Delta," "Inquirer," "Aqua Pura," "Somerset," "Student."

PHARMACY IN PRUSSIA.

BY ERNEST J. T. AGNEW.

German unification being likely to assimilate all branches of technical education, a description of pharmacy in Prussia, with a few notes on its variations in the other States of the great German Empire, will, we trust, be found acceptable and interesting. A superior medical Council is held at Berlin, and provincial councils (*Regierungs-medicinal-rath*) in the chief towns of each province. Generally there is no special school or college of pharmacy; but students, as in other professions, are expected to follow the usual university courses, before which they must have undergone four years' apprenticeship, and must have been assistants to chemists for three years more before passing the final examination. An apprentice must be over fourteen years of age, and must pass a stiff examination by the *Physicus* of the district in Latin, German, and the elementary physical and natural sciences. On receiving his examination certificate he enters the service of an apothecary, who is bound to instruct him, and even to keep an herbarium of the indigenous medicinal plants for his benefit. How different to the colour-grinding and alum-powdering instruction on which most English apprentices have to base their future pharmaceutical education! On emerging from his apprenticeship, he passes before the Medical Commission, who examine him in chemistry, pharmacy, etc. This assistants' examination is certainly much more searching than the "major" of London. The final ordeal takes place when the student has reached the age of twenty-five, and is held by a special Board at the University. There are eight separate examinations, which are as follows:—

1. Written: Mineralogy, Botany and Toxicology.
2. To prepare a certain number of galenical preparations in the laboratory.
3. To prepare three chemical preparations used in pharmacy.
4. The qualitative and *quantitative* analysis of a mixture of salts.
5. The analysis of some mixture containing one or more poisons.
6. The physiological examination of drugs and medicinal plants.
7. An essay on some chemical subject, to which great importance is attached. The student is allowed every facility for references (which he has to name), and the time is unlimited. These essays are often complete monographs, and are preceded by a *curriculum vitæ* of the student.

The eighth is a *vivâ voce* and public interrogation on all pharmaceutical studies and a discussion on the essays. This last examination is passed before the whole Board, and entails many important and imposing ceremonies. In some parts of Germany there are second-class pharmacists, who pass their examinations before local boards in the chief provincial towns; but their privileges are few, and they can only establish themselves in small country towns or villages. It is easy to see that the eminent position occupied by German chemists is due to their extensive knowledge and the privileges accorded to them in consequence. The Government alone authorizes the establishment of new pharmacies; but such is the degree of opposition on the part of those already in business, that but very few are annually established, although the population of the large towns is rapidly increasing.* Berlin, with a population of 700,000, has 43 pharmacies, Pesth only 14. In Russia, by some most extraordinary anomaly, German apothecaries alone are permitted to practise, to the exclusion even of natives, unless they have been educated in a German university and possess the German diploma. Thus, in St. Petersburg there are 45 pharmacies to 532,000 inhabitants; in Moscow, 30 to 380,000, or over 12,000 persons to support a single druggist. One large shop in the former place keeps over forty assistants, and as the business consists only in dispensing, enormous fortunes are realized. The German Pharmacopœia has long been considered official in Russia; but a new Russian Pharmacopœia is about to be, if not already, issued. In Germany, as in all other countries where the number of druggists is limited, the medical commissioners fix a tariff of prices which is revised every year. At the death of a pharmacist, his widow may carry on the business until her children, should she have any, have attained their majority, by employing a duly-qualified manager. Should it, however, be left to other heirs, it must be sold within a year. Before the druggist commences business, he must take the professional oath before the *Kreis-physicus* or the university authorities.

A peculiarity of German pharmacists is the adoption of a sign. The number of Pelicans, Golden Eagles, etc. in Germany is only to be equalled by that in the Licensed Victuallers' columns of the London Post-Office Directory. In general nothing is exposed in the windows, and the interior seems redolent with professional gravity. The principal pharmacies consist of two or more rooms; the first, a kind of waiting-room for the public, who dare not penetrate into the sanctum where a number of silent and spectacled assistants dispense the prescriptions brought to them by a kind of shop-walker or "provisor," who returns them with medicines to the customers. The law compels them to write on each label the name of the medicine, that of the person for whom it is intended, how to be taken, and the date of its preparation. Coloured labels are used for poisons and external remedies. The apothecaries (as pharmacists are designated in Germany) prepare nearly all their chemicals and galenicals, for, owing to the restrictive measures in force and ensuring immense profits to the proprietors of drug-stores in large towns, nearly every pharmacy is provided with vast laboratories, containing every convenience for practice or research. Steam is commonly used for every purpose where heat is required, such as for drying, distilling and evaporating. Another reason conducing to raise the status of pharmacy in Germany is, that a great number of men possessing diplomas are unable to buy or obtain the necessary concession from the Government to establish them-

* About thirty years ago, the apothecaries at Hamburg agreed that the number of their establishments, then more than 40 to about 200,000 inhabitants, far exceeded the actual requirements of the public; in consequence of which many places scarcely enabled their owners to earn a scanty living. A society of the apothecaries of the town existed already for scientific and social meetings; and this society undertook to raise funds by annual subscriptions, and to gradually buy up the smaller establishments until the total number should be reduced to 24. This object has been carried out with such perseverance that at the present time there are less than 30 pharmaceutical establishments, although it has been found necessary to establish several new ones in recently built suburbs.—ED. PHARM. JOURN.

selves, and are consequently obliged to seek situations as managers or assistants; a staff of such painstaking, well-educated men necessarily gives a considerable *cachet* to the house they may be employed in. The inspection of pharmacies is no dead-letter in Germany, as it has proved to be in France and Italy. Here it is a long, searching operation, generally performed by two delegates in the presence of the *Kreis-physicus* of the district. It is compulsory every three years; but often judged necessary to perform it oftener. Not only are the drugs examined, but also the assistants and apprentices. The inspectors require the production of the pharmacists' diplomas, Act of Concession, tariff, herbarium of indigenous plants, prescription-books, and the prices paid for executing the formula therein. Assistants and apprentices are required to show their examination certificates, are asked questions on chemistry and pharmacy, and have to translate passages of the pharmacopœia, which is quite Celsus-like in the excellence of its Latin construction. The apprentices are bound to have certain hours allotted to them for study, and it is the inspector's duty to see that this rule has been complied with. Nearly every drug and preparation is carefully examined, and often analysed if any doubt be entertained as to their genuineness. Laboratories, stores, cellars, all are inspected most minutely. A *procès-verbal* of each visit is sent to head-quarters, where a *résumé* of it is made, and transmitted to the pharmacist, with the addition of either praiseworthy reflections, counsels for his benefit, or firm but polite reprimands. In some parts of Germany, corporations or guilds of apothecaries still exist, which Government can hardly interfere with, as they possess exclusive privileges, and do all in their power to prevent new-comers from establishing themselves. A system enjoying so many and great advantages is naturally and properly subjected to very severe legislative measures. The laws relating to the storage of poisons are so similar to those in force elsewhere, that it is useless to recapitulate them here. The German chemists enjoy great advantages and privileges, which are counterbalanced by the severest of examinations and the most searching of inspections. I am indebted for much of this legal information to M. Labélonye, of Paris, whose work on 'L'Organisation Pharmaceutique en Europe' is highly interesting and instructive.

THE CHEMICAL NOMENCLATURE OF THE PHARMACOPŒIA, WITH SUGGESTIONS FOR ITS REVISION.

BY PROFESSOR ATTFIELD.

(*Concluded from page* 804.)

The proposed Names.

The following is a table of names of all the chemical substances in the British Pharmacopœia. Column I. contains the official names; Column II. the names now suggested for employment in pharmacy, medicine and the next edition of the British Pharmacopœia; Column III. the unitary nomenclature of modern chemistry. The advantages claimed for the proposed names are that they are more consistent with each other than the old; they are formed on one uniform system instead of two; they include less of theory, and therefore have greater elements of stability than the old; and they are harmonious, whilst the old is absolutely inconsistent, with both modern scientific nomenclature and the only chemical notation now employed. Their newness, so far as they are new, is their only disadvantage, and even this disadvantage is, in practice, reduced to insignificant proportions.

Column II. also contains a few exceptional alterations, to which I shall allude subsequently.

Old Names.	*Proposed Names.*	*Synonyms.*
Acetate of ammonia.	Acetate of *ammonium.*	*Ammonium acetate.* *Ammonic acetate.*
Acetate of copper.	Acetate of copper.	*Cupric acetate.*
Acetate of iron.	Acetate of iron.	*Ferric acetate.*
Acetate of lead.	Acetate of lead.	*Lead acetate.* *Plumbic acetate.*
Acetate of morphia.	Acetate of morphia.	*Morphia acetate.*
Acetate of potash.	Acetate of *potassium.*	*Potassium acetate.* *Potassic acetate.*
Acetate of soda.	Acetate of *sodium.*	*Sodium acetate.* *Sodic acetate.*
Acetate of zinc.	Acetate of zinc.	*Zinc acetate.*
Acetic acid.	Acetic acid.	*Hydrogen acetate.* Acetic acid.
Acid tartrate of potash.	Acid tartrate of *potassium.*	*Acid potassium tartrate.*
Aconitia.	Aconitia.	Aconitia, *or aconitine.*
Albumen.	Albumen.	Albumen.
Alcohol.	Alcohol.	*Ethyl hydrate.* Alcohol, *or ethyl alcohol.*
Alum.	Alum.	Alum.
Ammonia.	Ammonia. *Hydrate of ammonium (syn.).*	Ammonia. *Ammonium hydrate.*
Ammoniated mercury.	Ammoniated mercury.	*Mercuric-ammonium chloride.*
Ammonio-nitrate of silver.	Ammonio-nitrate of silver.	*Argent-ammonium nitrate.*
Ammonio-sulphate of copper.	Ammonio-sulphate of copper.	*Cupro-diammonium sulphate.*
Ammonio-sulphate of magnesia.	Ammonio-sulphate of *magnesium.*	*Ammonio-magnesian sulphate.*
Amylic alcohol.	Amylic alcohol.	*Amyl alcohol.*
Arseniate of iron.	Arseniate of iron.	*Ferrous arsenate.*
Arseniate of soda.	Arseniate of *sodium.*	*Sodium arsenate.*
Arsenious acid.	*White arsenic.*	*Arsenious oxide.*

Old Names.	*Proposed Names.*	*Synonyms.*
Atropia.	Atropia.	Atropia, *or atropine.*
Benzoate of ammonia.	Benzoate of *ammonium.*	*Ammonium benzoate.*
Benzoic acid.	Benzoic acid.	*Hydrogen benzoate.* Benzoic acid.
Benzol.	Benzol.	*Benzene or Benzine.*
Bicarbonate of potash.	Bicarbonate of *potassium.*	*Acid potassium carbonate.* *Hydrogen potassium carbonate.* *Mono-potassie carbonate.*
Bicarbonate of soda.	Bicarbonate of *sodium.*	*Acid sodium carbonate.* *Hydrogen sodium carbonate.* *Mono-sodic carbonate.* *Hydro-sodic carbonate.*
Bichromate of potash.	*Red chromate of potassium.*	*Potassium anhydrochromate.* *Potassium bichromate.*
Bismuth.	Bismuth.	Bismuth.
Black antimony.	Black *sulphide of* antimony.	*Antimonious sulphide.*
Black oxide of manganese.	Black oxide of manganese.	*Manganese dioxide or peroxide.*
Boracic acid.	Boracic acid.	*Hydrogen borate.* *Boric acid.* Boracic acid.
Borax.	Borax.	*Sodium anhydroborate.* Borax.
Bromide of ammonium.	Bromide of ammonium.	*Ammonium bromide.*
Bromide of potassium.	Bromide of potassium.	*Potassium bromide.*
Bromine.	Bromine.	Bromine.
Calomel (syn.).	Calomel (syn.).	*Mercurous chloride.* Calomel.
Camphor.	Camphor.	Camphor.
Carbolic acid.	Carbolic acid.	*Hydrogen carbolate.* Carbolic acid.
Carbonate of ammonia.	Carbonate of *ammonium.*	*Ammonium carbonate.*
Carbonate of bismuth.	*Oxycarbonate* of bismuth (syn.).	*Bismuth oxycarbonate.*
Carbonate of iron.	Carbonate of iron.	*Ferrous carbonate.*
Carbonate of lead.	Carbonate of lead.	*Lead carbonate.* *? Triplumbic dihydrate diearbonate.*
Carbonate of lime.	Carbonate of *calcium.*	*Calcium carbonate.*
Carbonate of lithia.	Carbonate of *lithium.*	*Lithium carbonate.*
Carbonate of magnesia.	Carbonate of *magnesium.*	*Magnesium earbonate.* *? Tetrahydrous dihydric tetramagnesic tricarbonate.*
Carbonate of potash.	Carbonate of *potassium.*	*Dipotassic carbonate.* *Potassium carbonate.*
Carbonate of soda.	Carbonate of *sodium.*	*Disodic carbonate.* *Sodium carbonate.*
Carbonate of zinc.	Carbonate of zinc.	*Zinc carbonate.*
Caustic potash.	Caustic potash. *Hydrate of potassium (syn.).*	Caustic potash. *Potassium hydrate.*
Caustic soda.	Caustic soda. *Hydrate of sodium (syn.).*	Caustic soda. *Sodium hydrate.*
Chalk.	Chalk.	*Calcium carbonate.* Chalk.
Chlorate of potash.	Chlorate of *potassium.*	*Potassium chlorate.*
Chloride of ammonium.	Chloride of ammonium.	*Ammonium chloride.*
Chloride of antimony.	Chloride of antimony.	*Antimony trichloride.* *Antimonious chloride.*
Chloride of barium.	Chloride of barium.	*Barium chloride.* *Baric chloride.*
Chloride of calcium.	Chloride of calcium.	*Calcium chloride.* *Calcic chloride.*
Chloride of gold.	*Per*chloride of gold.	*Auric chloride.*
Chloride of sodium.	Chloride of sodium.	*Sodium chloride.*
Chloride of tin.	*Stannous chloride.*	*Stannous chloride.*
Chloride of zinc.	Chloride of zinc.	*Zinc chloride.*
Chlorinated lime.	Chlorinated lime.	*Chloride of lime.*
Chlorinated soda.	Chlorinated soda.	*Chloride of soda.*
Chlorine.	Chlorine.	Chlorine.
Chloroform.	Chloroform.	*Methenyl chloride.* Chloroform.
Citrate of ammonia.	Citrate of *ammonium.*	*Ammonium citrate.*
Citrate of bismuth and ammonia.	Citrate of bismuth and *ammonium.*	*Bismuth ammonio-citrate.* *Ammonium and bismuthous citrate.*
Citrate of iron and ammonia.	Citrate of iron and *ammonium.*	*Ferric ammonio-citrate.* *Ferric and ammonium citrate.*
Citrate of iron and quinia.	Citrate of iron and quinia.	*Ferric quinio-citrate.* *Quinia ferri-citrate.* *Ferric and quinia citrate.*

Old Names.	*Proposed Names.*	*Synonyms.*
Citrate of lithia.	Citrate of *lithium.*	*Lithium citrate.*
Citrate of potash.	Citrate of *potassium.*	*Potassium citrate.*
Citric acid.	Citric acid.	{ *Hydrogen citrate.* Citric acid.
Citro-tartrate of soda.	Citro-tartrate of *sodium.*	*Sodium citro-tartrate.*
Conia.	Conia.	Conia *or conine.*
Copper.	Copper.	Copper.
Corrosive sublimate (syn.).	Corrosive sublimate (syn.).	{ *Mercuric chloride.* Corrosive sublimate.
Digitalin.	Digitalin.	Digitalin.
Dried alum.	Dried alum.	Dried alum.
Dried carbonate of soda.	Dried carbonate of *sodium.*	Dried *sodium carbonate.*
Dried sulphate of iron.	Dried sulphate of iron.	Dried ferrous sulphate.
Ether.	Ether.	{ *Ethyl oxide.* Ether.
Ferrocyanide of potassium (syn.).	Ferrocyanide of potassium.	*Potassium ferrocyanide.*
Gallic acid.	Gallic acid.	{ *Hydrogen gallate.* Gallic acid.
Gelatine.	Gelatine.	Gelatin.
Glycerine.	Glycerine.	{ *Propenyl alcohol.* Glycerin.
Granulated sulphate of iron.	Granulated sulphate of iron.	Granulated *ferrous sulphate.*
Hydrated peroxide of iron.	*Peroxyhydrate of iron.*	*Ferric oxyhydrate.*
Hydrochlorate of morphia.	Hydrochlorate of morphia.	*Morphine hydrochlorate.*
Hydrochloric acid.	Hydrochloric acid.	{ *Hydrogen chloride.* *Chlorhydric acid.* Hydrochloric acid.
Hydrochloric sol. of arsenic.	Hydrochloric sol. of arsenic.	Hydrochloric sol. of arsenic.
Hydrocyanic acid.	Hydrocyanic acid.	{ *Hydrogen cyanide.* Hydrocyanic acid.
Hyposulphite of soda.	Hyposulphite of *sodium.*	*Sodium hyposulphite.*
Indigo.	Indigo.	Indigo.
Iodate of potash.	Iodate of *potassium.*	*Potassium iodate.*
Iodide of cadmium.	Iodide of cadmium.	*Cadmium iodide, or cadmic iodide.*
Iodide of iron.	Iodide of iron.	*Ferrous iodide.*
Iodide of lead.	Iodide of lead.	*Lead iodide, or plumbic iodide.*
Iodide of mercury, green.	Iodide of mercury, green.	*Mercurous iodide.*
Iodide of mercury, red.	Iodide of mercury, red.	*Mercuric iodide.*
Iodide of potassium.	Iodide of potassium.	*Potassium iodide.*
Iodide of sulphur.	Iodide of sulphur.	*Sulphur iodide.*
Iodine.	Iodine.	Iodine.
Iron.	Iron.	Iron.
Lime.	Lime.	{ *Calcium monoxide.* Lime.
Magnesia.	Magnesia.	{ *Magnesium oxide.* Magnesia.
Magnetic oxide of iron.	Magnetic *oxyhydrate* of iron (syn.).	*Ferroso-ferric oxyhydrate.*
Mercury.	Mercury.	Mercury.
Mercury with chalk.	Mercury with chalk.	Mercury with chalk.
Moist peroxide of iron.	Moist *perhydrate* of iron.	*Ferric hydrate.*
Nitrate of lead.	Nitrate of lead.	*Lead nitrate.*
Nitrate of mercury.	*Per*nitrate of mercury.	*Mercuric nitrate.*
Nitrate of potash.	Nitrate of *potassium.*	*Potassium nitrate.*
Nitrate of silver.	Nitrate of silver.	{ *Argentic nitrate.* *Silver nitrate.*
Nitrate of soda.	Nitrate of *sodium.*	*Sodium nitrate.*
Nitric acid.	Nitric acid.	{ *Hydrogen nitrate.* Nitric acid.
Nitro-hydrochloric acid.	Nitro-hydrochloric acid.	Nitro-hydrochloric acid.
Nitrous ether, spirit of.	Nitrous ether, spirit of.	{ *Ethyl nitrite, spirit of.* Nitrous ether, spirit of.
Oxalate of ammonia.	Oxalate of *ammonium.*	*Ammonium oxalate.*
Oxalate of cerium.	Oxalate of cerium.	*Cerous oxalate.*
Oxalic acid.	Oxalic acid.	{ *Hydrogen oxalate.* Oxalic acid.
Oxide of antimony.	Oxide of antimony.	{ *Antimony trioxide.* *Antimonious oxide.*
Oxide of iron, magnetic.	*Oxyhydrate* of iron, magnetic (syn.).	*Ferroso-ferric oxyhydrate.*
Oxide of lead.	Oxide of lead.	*Lead oxide, or plumbic oxide.*
Oxide of mercury, red.	Oxide of mercury, red.	*Mercuric oxide.*
Oxide of silver.	Oxide of silver.	{ *Silver monoxide.* *Argentic oxide.*
Oxide of zinc.	Oxide of zinc.	*Zinc oxide.*
Perchloride of iron.	Perchloride of iron.	*Ferric chloride.*
Perchloride of mercury.	Perchloride of mercury.	*Mercuric chloride.*

Old Names.	*Proposed Names.*	*Synonyms.*
Perchloride of platinum.	Perchloride of platinum.	*Platinum tetrachloride.* *Platinic chloride.*
Permanganate of potash.	Permanganate of *potassium.*	*Potassium permanganate.*
Pernitrate of iron.	Pernitrate of iron.	*Ferric nitrate.*
Peroxide of iron, hydrated.	*Peroxyhydrate of iron (syn.).*	*Ferric oxyhydrate.*
Peroxide of iron, moist.	*Perhydrate of iron, moist.*	*Ferric hydrate.*
Persulphate of iron.	Persulphate of iron.	*Ferric sulphate.*
Phenic acid (syn.).	Phenic acid (syn.).	*Hydrogen phenate.* Phenic acid.
Phosphate of ammonia.	Phosphate of *ammonium.*	*Ammonium phosphate.*
Phosphate of iron.	Phosphate of iron.	*Ferrous phosphate.*
Phosphate of lime.	Phosphate of *calcium.*	*Calcium orthophosphate.*
Phosphate of soda.	Phosphate of *sodium.*	*Disodiohydric phosphate.*
Phosphoric acid.	Phosphoric acid.	*Hydrogen phosphate.* Phosphoric acid.
Phosphorus.	Phosphorus.	Phosphorus.
Platinum.	Platinum.	Platinum.
Potash, solution of.	Potash, solution of.	Potash, solution of.
Prussiate of potash, red.	? Prussiate of *potassium,* red.	*? Red potassium prussiate.*
Prussiate of potash, yellow.	? Prussiate of *potassium,* yellow.	*? Yellow potassium prussiate.*
Reduced iron.	Reduced iron.	*Reduced iron.*
Santonin.	Santonin.	*Santonin.*
Slaked lime.	Slaked lime.	*Calcium hydrate.* Slaked lime.
Soda, solution of.	Soda, solution of.	Soda, solution of.
Starch.	Starch.	Starch.
Strychnia.	Strychnia.	Strychnine.
Subacetate of copper.	*Oxyacetate* of copper (syn.).	*Cupric oxyacetate.*
Subacetate of lead.	*Oxyacetate* of lead (syn.).	*Basic lead acetate.* *Lead oxyacetate.*
Subchloride of mercury.	Subchloride of mercury.	*Mercurous chloride.*
Subnitrate of bismuth.	*Oxynitrate* of bismuth (syn.).	*Basic bismuth nitrate.* *Bismuth oxynitrate.*
Sugar.	Sugar.	Sugar.
Sulphate of atropia.	Sulphate of atropia.	*Atropine sulphate.*
Sulphate of beberia.	Sulphate of beberia.	*Beberine sulphate.*
Sulphate of copper.	Sulphate of copper.	*Cupric sulphate.*
Sulphate of indigo.	Sulphate of indigo.	*Sulphindigotic acid.*
Sulphate of iron.	Sulphate of iron.	*Ferrous sulphate.*
Sulphate of lime.	Sulphate of *calcium.*	*Calcium sulphate.*
Sulphate of magnesia.	Sulphate of *magnesium.*	*Magnesium sulphate.*
Sulphate of mercury.	*Per*sulphate of mercury.	*Mercuric sulphate.*
Sulphate of potash.	Sulphate of *potassium.*	*Potassium sulphate.*
Sulphate of quinia.	Sulphate of quinia.	*Quinine sulphate.*
Sulphate of soda.	Sulphate of *sodium.*	*Sodium sulphate.*
Sulphate of zinc.	Sulphate of zinc.	*Zinc sulphate.* *Zincic sulphate.*
Sulphide of ammonium.	*Sulphydrate* of ammonium.	*Ammonium sulphydrate.*
Sulphide of iron.	Sulphide of iron.	*Ferrous sulphide.*
Sulphur.	Sulphur.	Sulphur.
Sulphurated antimony.	Sulphurated antimony.	*Antimonious oxysulphide.*
Sulphurated potash.	Sulphurated potash.	Sulphurated potash.
Sulphuretted hydrogen.	Sulphuretted hydrogen.	Sulphuretted hydrogen.
Sulphuric acid.	Sulphuric acid.	Sulphuric acid. *Hydrogen sulphate.*
Sulphurous acid.	Sulphurous acid.	Sulphurous acid. *Hydrogen sulphite.*
Tannic acid.	*Tannin (syn.).*	*Tannin.*
Tartar emetic (syn.).	Tartar emetic (syn.).	Tartar emetic.
Tartarated antimony.	*Tartrate of antimony and potassium.*	*Potassio-antimonious tartrate.*
Tartarated iron.	*Tartrate of iron and potassium.*	*Potassio-ferric tartrate.*
Tartarated soda.	*Tartrate of sodium and potassium.*	*Potassio-sodium tartrate.*
Tartaric acid.	Tartaric acid.	Tartaric acid. *Hydrogen tartrate.*
Tartrate of potash.	Tartrate of *potassium.*	*Potassium tartrate.* *Dipotassic tartrate.*
Tin.	Tin.	Tin.
Valerianate of soda.	Valerianate of *sodium.*	*Sodium valerianate.*
Valerianate of zinc.	Valerianate of zinc.	*Zinc valerianate.*
Veratria.	Veratria.	Veratrine.
Verdigris.	Verdigris.	Verdigris.
Water.	Water.	Water.
Zinc.	Zinc.	Zinc.

Résumé.—The chief alterations in pharmacopœial nomenclature now proposed amount to this, that the compounds of the alkali-metals and alkaline-earth-metals instead of being named as hitherto on two distinct systems, should follow but one:—that instead of salts of potassium and of potash we should have salts of potassium only; instead of sodium and soda compounds, sodium only; and so with preparations of ammonium, lithium, calcium, magnesium and aluminium. This is a step in the direction of simplicity and permanency, and away from that of theory.

Synonyms.—Modern scientific chemical names, and the old dualistic names should, I think, be included as synonyms of the leading names in all Pharmacopœias. Many might be mentioned in addition to those in the third column: I have given a selection because the complete and consistent sets (for, unfortunately, there are more than one) would have occupied too much space.

Exceptional Alterations.— Constitutional objections to the name *acidum arseniosum* would be obviated by the old name *arsenicum album*. Some other bodies, apparently similar in constitution to white arsenic, are alluded to in the text of the British Pharmacopœia as *anhydrous acids*—a most ambiguous and self-contradictory term; for the bodies in question either are acids or they are not acids; whereas the term indicates that they are both—which is impossible. The not very satisfactory word "anhydride" is coming generally into use for these bodies, and this might be employed officially; but all objection would be avoided if the strength of the pharmacopœial acids, which are mostly aqueous solutions of acids, were solely given in terms of real acid (the hydrogen salt). The correlative of the word *anhydrous*, I would suggest, should be *hydrous*, never *hydrate*; especially as the latter word is now given to the members of a class of bodies derived from water, as *hydrate of potassium*, and not to bodies containing water. The compound from which *anhydrous sulphate of copper* is prepared is *hydrous sulphate of copper*, not *hydrated sulphate of copper*. In view of the peculiar composition of *bichromate of potassium* the first word of its name is most unsuitable, and would be advantageously replaced by *red chromate*, a name which would usefully distinguish the salt from *yellow chromate of potassium*. The names of the bismuth powders are not at present consistent with each other; if the one be termed *subnitrate* the other should be *subcarbonate*, not "*carbonate*." But these preparations and the similar compounds of copper and lead are normal rather than "sub" salts, containing oxygen in the place of an exactly equivalent quantity of the acidulous radical of the neutral salts, and might well be termed respectively *oxycarbonate of bismuth, oxynitrate of bismuth, oxyacetate of copper, oxyacetate of lead*; at all events the latter names would do good service as synonyms. Similar remarks apply to the *peroxhydrates of iron*. The prefix "sub" is most usefully and indeed indispensably applied in the case of calomel, which is the "lower" or under-chloride of mercury: it would be well if the meaning of the syllable could be always thus restricted to its etymological signification, and never again used in its old conventional sense. The names *tartarated antimony, tartarated iron, tartarated sodium*, I do not like at all. The sister terms *sulphurated antimony* and *sulphurated potash* are most happy, their utter vagueness fairly representing the nondescript character of the preparations. But *tartrate* (or *oxytartrate*) *of antimony and potassium, tartrate of iron and potassium*, and *tartrate of sodium and potassium*, are at least as definite in composition as the citric trio which are already honoured with the definite names (or, rather, with the old forms of the names) *citrate of bismuth and ammonium, citrate of iron and ammonium* and *citrate of iron and quinia*. "Prussiates" might now, I think, be relegated to the synonymic category. Instead of *Liquor Sodæ Effervescens*, B. P., which might possibly be confounded with *Liquor Sodæ*, I would prefer *Aqua Sodæ Effervescens*, and so with *Potash Water*. These are the prominent exceptional alterations to which I would draw attention. Their acceptance is not insisted on, nor is the list exhaustive. Allusion is made to them in the hope that discussion may show which names, on the whole, possess the greatest number of advantages. The alterations I do urge are those considered in the main portion of this paper, those of which I have already given a *résumé*.

In conclusion, I would state that the Lavoisierian names now proposed for use in medicine and pharmacy have already been freely adopted by many authors, and used as the leading nomenclature of my own and some other Manuals of Chemistry. I commend them to the medical practitioners and pharmacists of Europe, America and the Colonies.

THE PROPOSED POISON REGULATIONS.

MEETING AT GLASGOW.

A Special General Meeting of the chemists of Glasgow and West of Scotland (convened by the officers of the Glasgow Association) was held in the West Hall, Anderson's University, on Monday, 3rd inst., at 12 o'clock noon. Mr. Thomas Davison, President of the Glasgow Association, was called upon to preside.

The Chairman read the circular calling the meeting, and the proposed regulations. These, he thought, sufficiently explained the object for which they were met, while the resolutions to be proposed, if adopted unanimously, would be regarded as expressive of the opinion of the chemists of this important district. He would have preferred that some person who could have maintained a more neutral attitude should have been appointed chairman of this meeting, as he felt that the result might be looked upon as a foregone conclusion. The proposed regulations were put forth for the avowed object of securing the safety of the public, but if so, he could not see why surgeon-druggists should be exempted, and more especially in Glasgow and Paisley, where medical practitioners had by far the largest share of dispensing. He contended that in Scotland generally there were few cases of poisoning from carelessness on the part of chemists, and even in England they were comparatively few. He therefore thought there was no necessity for the safety of the public being guaranteed by any such regulations as those proposed. He further thought it was quite clear that if the chemists accepted the regulations, they would be continually interfered with. If the Pharmacy Act of 1868 had been adopted in its entirety, the result would have been that all surgeons who kept open shop would have had to get themselves registered under the Act as chemists and druggists; they then would have been liable to the same restrictions. But the Amended Act of 1869, he believed, was intended for no other purpose than to have medical practitioners entirely exempted from the operations of the Act of 1868, and any one who reads it carefully will see that it was intended that medical men were *not* to be interfered with in their capacity as dispensers, if they chose to carry on a dispensing trade. He himself had had some communication with the medical department of the Privy Council, in the course of which he showed the position in which the Glasgow chemists would be placed, and requested them to take steps to put all on an equality; the reply he received was to the effect, that if an opportunity occurred for such legislation, his suggestion would be taken into consideration. He thought if the opportunity were given by the Society rejecting the regulations, we should hear no more of them, as the medical men who kept open shops would object far more strongly than chemists against any compulsory enactments.

Mr. John Jaap, Pharmaceutical Chemist, moved the first resolution:—"That this meeting is opposed to the restrictive measures for the sale and keeping of 'poisons,' recommended by the Council of the Pharmaceutical Society (with consent of the medical officers of her Majesty's Privy Council) for adoption at the annual meeting in May next, as we consider it is highly impolitic to interfere in any way with the conducting of our business otherwise than as recommendations; and being convinced that the greatest security for the public lies in the education of the dispenser, and such education being now not only improved, but made a necessary qualification, is to all intents and purposes a guarantee of our ability to conduct our business for the public safety." Mr. Jaap said he had nothing to add to the resolution, as it fully expressed his opinions on the matter.

Mr. Daniel Frazer, Pharmaceutical Chemist, in seconding the resolution, confessed that he did so with no hesitancy, because he held very decided opinions on the subject. He, however, thought it necessary that there should be means taken by all chemists to distinguish poisons which resembled each other in appearance. He would go further, and say that the public should have some security against accidents happening. But he wished to be at liberty to accomplish that object himself, as best suited his circumstances, without any undue interference on the part of the Privy Council; he also wished his brethren in the trade to be on the same footing, for he could not believe that there were many chemists, if any, who would be careless enough to keep morphia, arsenic or tartarized antimony on the same shelf with bicarbonate of soda or powdered sugar. He thought that a separation of such poisonous articles,—some on high shelves, others among liquids, and poisonous liquids among solids,—was all that was necessary.

Mr. Glen (Renfrew), in supporting the motion, said the proposed regulations would be gross injustice to them, who had already taken steps in the matter, and had endeavoured to protect the public and themselves from any injury arising out of accidents with poisonous drugs.

Mr. Alexander Kinninmont, Pharmaceutical Chemist, moved the second resolution as follows:—"That this meeting is further opposed to the proposed compulsory regulations, as their adoption by the Society in their present form will tend to give an undue and invidious advantage to one class of retailers over another,—creating, in fact, a body of 'privileged traders;' for, while the regulations will be binding *only* on those registered under the Pharmacy Act, all persons registered under the Medical Acts will be exempted, and at liberty to act as they think proper,—it being the custom of many medical practitioners throughout the country to keep open shop and carry on a retail trade in the same manner as chemists and druggists, and as especially in this city fully two-thirds of the drug retailers are physicians." Mr. Kinninmont said he thought there was little to add to the resolution. Chemists generally did not want to interfere with medical men, even in dispensing, if they dispensed only their own prescriptions; but all felt it to be an anomaly that, in a city such as Glasgow, out of 180 retailers of drugs, 120 of those belonged to medical practitioners, and that, if the regulations were enforced, those 120 would be at liberty to adopt them or not as they liked, while the remaining 60 would be compelled to do so; and yet there was, practically speaking, no difference between their establishments and the conducting of their business. He therefore held that, if the regulations were to be enforced, they should not be applied to one class alone, but to all engaged in the dispensing and selling of poisons.

Mr. D. P. Walker seconded the motion, and said he thought it was now time that the dispensing of medicines should be taken out of the hands of the medical practitioners altogether, for he thought it was a disgrace to a city like Glasgow, that boys of eight or twelve years of age, and sometimes girls, were all that could be seen at the back of the counters of these doctors' shops from morning till night. He thought that the Council of the Pharmaceutical Society had entirely mistaken whom the regulations were needed for. It was in shops of this description where they were required.

Mr. Black wished to know whether all who kept open shop for the sale of poisons were not equally liable to the same restrictions as chemists.

Mr. Harvie (Airdrie) said he thought he could supply the desired information. He had always been of opinion that medical men who kept open shop came under the poison clauses of the Pharmacy Act, the same as druggists, which to all intents and purposes they were, so far as the sale of poisons is concerned at least, and he naturally thought they should act in the sale of poisons the same as they who were professed druggists; but, while he held this opinion, a medical man who had a shop near him, thought differently, and said he would sell as much poison as he could, and would register none of it. He (Mr. Harvie) told the doctor that if he persisted in doing so he would make a case of it, while the doctor said he was quite agreeable. A party called shortly afterwards at his shop for half an ounce of corrosive sublimate; he not knowing the person, asked him to bring a witness whom he knew; the man said he needed no witness and could get it at Dr. So-and-So's. He (Mr. Harvie) advised him not to go there without a witness either, or if he did, the consequences might be serious to himself; the man paid no attention however, but went straight to the doctor's shop to which he followed him, and witnessed the doctor weigh the stuff, wrap it up in paper and hand over the counter *without even a label;* he called a policeman at once, gave the man in charge and lodged the case with the procurator-fiscal. The fiscal wrote to Edinburgh for instructions, and in a day or two a reply came from Mr. Kimberly, giving orders not to proceed with the case; it was thus decided in favour of the doctor, and he continues to sell poisons without registering them, and, in many cases, not even labelling them.

Mr. John Currie, Pharmaceutical Chemist, proposed the third motion, as follows:—"That this meeting being convinced that it is impossible to frame a set of rules equally suited to the varied requirements of different pharmaceutical establishments, and because we feel that no restrictions under the authority of the law are likely to prove successful, we hereby resolve to give the proposed *compulsory* regulations our most strenuous opposition, while we will respectfully consider any well-devised scheme, if sent out as a recommendation, and act in accordance therewith, so far as our circumstances will permit." He said that the best security to the public against mistakes from the sale of poisons is, first, the exercise of sound discretion on the part of the dispenser as to whom poisons should be sold to, when not prescribed by a physician; secondly, by the adopting of a uniform rule of labelling everything carefully and by affixing on mixtures, etc., for internal use and containing ingredients of a dangerous nature in an overdose, a label, 'poisonous in an overdose;' and on liniments, lotions, embrocations, etc., 'for external use only,' together with a 'poison' label in red ink, if made up of dangerous compounds.

Mr. HAMILTON, M.P.S., seconded the motion. He said that one great objection he had to the action of the Council, was the persistent manner in which they had brought the regulations forward without first consulting the feelings or wishes of the entire trade; of course the final decision was left to the members of the Society at their Annual Meeting, but it would have spared the members a great deal of anxiety, not to say of expense, had their proposition not been so arbitrary.

Mr. GLEN (Renfrew) supported the resolution.

Mr. JOHN BLACK moved the fourth resolution as follows:—"That an Association be formed to be called 'The West of Scotland Chemists' Defence Association,' to co-operate with other similar organizations in opposing all compulsory and partial legislation; that every contributor of 2*s.* 6*d.* and upwards be a member, and that a general committee be appointed to have full powers to adopt such means as they may think necessary to attain the object of the Association." Mr. Black said he thought they would all see the necessity for having a standing committee to watch over their interests, even although the regulations were rejected at the forthcoming meeting in May.

Mr. J. M. FAIRLIE, M.P.S., said he would have preferred to have sat a silent listener, but a desire to refute some of the arguments put forth lately in support of the regulations must be his excuse. Mr. Abraham, of Liverpool, and others, had said that an understanding was come to with Parliament during the passing of the Pharmacy Act in 1868, that regulations were necessary. He himself remembered well the passing of the Act, and also the poison clauses that were tried at the time to be inserted into it, but when they were withdrawn, he thought it was that we should hear no more of them. As to the statement that it was then understood that the Pharmaceutical Society was the proper party to make such regulations, it seemed to him an excuse for getting them conveniently shelved.

Mr. CARR (Dumbarton) supported the resolution.

Mr. GREIG moved that the following gentlemen constitute the committee, with power to add to their number, viz., Messrs. D. Frazer, Jaap, Kinninmont, Black, Davison, Currie, Hamilton, Alexander, Walker, Harvie, Borland Moore, Carr, Fairlie and Hart, Mr. Davison, convener.

Mr. MOORE, Pharmaceutical Chemist (Stirling), seconded the motion.

Mr. ALEXANDER, Pharmaceutical Chemist (Greenock), moved the sixth resolution as follows:—"That the Committee be entrusted to prepare a memorial embodying the foregoing resolutions, which all chemists in the district shall have an opportunity of signing, and present it to the members of the Pharmaceutical Society at their Annual Meeting in May, and also to the medical department of the Privy Council." Mr. Alexander supported his resolution in a lengthy and interesting speech, in course of which he showed that the comparatively few accidents that arose through carelessness on the part of the dispenser, and especially as there had been less accidents since the passing of the Act, there was no need for further legislation in that direction. He thought that the Council should turn their attention a little to a proper definition of who should sell and who should *not* sell drugs. He knew that in England many hucksters made a regular practice of travelling through the country, selling drugs along with their other merchandise.

Mr. HARVIE (Airdrie) seconded the motion.

A general conversation then took place with reference to other points involved in the proposed regulations (in which Mr. BORLAND, Pharmaceutical Chemist, Kilmarnock, took an active part), at the close of which the CHAIRMAN put the various motions to the meeting, which were unanimously agreed to, and, on the motion of Mr. CARR (Dumbarton), a hearty vote of thanks to Mr. Davison for presiding brought the proceedings to a close.

REGULATIONS

(FRAMED IN PURSUANCE OF HER MAJESTY'S ORDER IN COUNCIL OF THE 4TH JUNE, 1870) FOR AN OPEN COMPETITIVE EXAMINATION FOR THE SITUATION OF ASSISTANT DISPENSER IN HER MAJESTY'S NAVAL ESTABLISHMENTS.

1. The examination will be in the following subjects, viz.:—
   1. Handwriting.
   2. Orthography.
   3. Arithmetic (to vulgar and decimal fractions).
   4. English Composition.

NOTE.—Candidates will be required to show that they possess the Minor* qualifications of the Pharmaceutical Society, and they must satisfy the Civil Service Commissioners on this point before they can be admitted to the competition.

2. A fee of 7*s.* 6*d.* will be required from each candidate attending the examination.

3. No candidate will be eligible whose age on the first day of the competitive examination is less than 20 or more than 25.

Civil Service Commission, 29th March, 1871.

An open competition will be held in London, under the above regulations, on Tuesday, April 25. Five persons will be selected, if so many should be found qualified; two to fill vacancies* now existing at Jamaica and Ascension Naval Hospitals, and three to fill, in order of merit, the next vacancies that may occur while they are eligible in respect of age.

The daily pay is as follows:—

Under 5 years' service.	Under 8 years' service.	Under 11 years' service.	Under 14 years' service.	Under 17 years' service.	Under 20 years' service.
5*s.*	5*s.* 6*d.*	6*s.*	6*s.* 6*d.*	7*s.* 6*d.*	8*s.* 6*d.*

and for every additional year an addition of 6*d.* per diem till 10*s.* a day is reached. When in charge of stores an additional allowance will be granted, viz. 1*s.* per day. An allowance of 6*d.* a day in lieu of food and light and quarters will be provided.

Superannuation will be allowed in accordance with the Superannuation Act of 1859. Assistant dispensers will not be eligible for promotion to the rank of dispenser, or to be placed in charge of stores, until they have obtained the Major qualifications of the Pharmaceutical Society.

Persons wishing to be admitted to the examination must fill up the annexed form, and return it so as to reach the Civil Service Commission on or before April 15th. An order for examination will then be sent to them in due course.

FORM OF APPLICATION.

To the Secretary, Civil Service Commission.

Sir,—I hereby apply for permission to attend the examination to be held in London on the 25th April for the situation of assistant-dispenser in her Majesty's naval establishments, under the regulations of 29th March, 1871.

If I should be successful in the competition, I shall be prepared to satisfy the Civil Service Commissioners that my age on the 25th April, 1871, was not under 20 nor above 25; that my health and character are such as to fit me for public employment; and that I possess the Minor qualifications of the Pharmaceutical Society.

Name in full_______________

Address in full_______________

Date_______________

---

* As the persons who may be appointed to these two vacancies will be in charge of stores, no one will be eligible for them who does not possess the Major qualifications of the Pharmaceutical Society.

The Pharmaceutical Journal.

SATURDAY, APRIL 15, 1871.

POISON REGULATIONS.

From the report of the proceedings at the late meeting of the Council, it will be seen that there was ground for the statement made in anticipation last week as to the removal of any reason for the continuance of such hostile action as we have with regret seen commencing within the last few weeks. Since then we have received a letter on the subject from Mr. Sandford, and as the resignation of the President is an exceptional circumstance, we insert it here. We do not doubt that even those who differ from Mr. Sandford will recognize the strength of the convictions which have guided his action, and we believe that all will agree with him as we do in deprecating anything like personal contention.

"TO THE EDITOR OF THE 'PHARMACEUTICAL JOURNAL.'

"Sir,—In your Journal of last week you announce my resignation of the Presidency, '*which followed immediately on the carrying of Mr. Dymond's amendment.*'

"It is not to disconnect the one circumstance from the other that I desire to address some words of explanation through you to my fellow-members, but to show them that the same devotion to the interest of the Pharmaceutical Society which has animated me for so many years past, has impelled me in my present course.

"When the Government insisted on introducing into the Bill of 1868 the principle of regulations as to the keeping, dispensing and selling of poisons, two courses were open to us; either to accept the duty of framing those regulations for ourselves, or to allow the power of doing it to be placed in other hands,—in the hands, perhaps, of men utterly unacquainted with our business. I need scarcely say the former course was accepted as by far the best arrangement. In 1869 the Council, feeling that the time had arrived for action, with great care and deliberation framed the regulations about which we have had so much controversy, and submitted them to the Privy Council, in order that there might be harmonious action in the event of the Society agreeing to them; they were accordingly brought before the general meeting in May last.

"Time rolled on, and desiring to know before the meeting of Parliament what steps the Pharmaceutical Society had taken in the matter, the medical officer of the Privy Council wrote to the Registrar for information. Again the approved code was brought before our Council and repeatedly confirmed by overwhelming majorities. But the opponents, although in minority at the Board, had a good cry for the country,—for nothing stirs up the minds of men more than the information, whether true or untrue, that their liberties are about to be trampled on,—and a wild, unreasoning clamour was raised on a mere sentimental grievance. I say a sentimental grievance, because on all hands we find the very precautions we proposed have been in use (and, for the matter of that, were proposed because they had been in use) in many establishments throughout the country. The regulations in themselves have been declared good, but their compulsory observance altogether unbearable. No man courts personal restrictions, just, perhaps, as no man pays taxes for the mere love of paying, but men consent to pay taxes and to conform to laws as a duty to their fellow-men; therefore, although the task of opposing seems to have become almost a pleasure, I believe throughout the length and breadth of the land, many of our best and wisest members, although naturally silent, would have cheerfully submitted to the *terrible restrictions* (!) which were being prepared for them. In this belief, Sir, I was not shaken by the 'tall talk' resounding about us, and for that reason felt it my duty still to support the introduction to the Annual Meeting of the regulations as compulsory; not without hope that when calmly deliberating on our position, the Society would have risen to a sense of the duty it had undertaken when great privileges were accorded to it, and in the full confidence that when such a step had been taken, no charge of neglect, and consequently no plea for foreign interference, could be brought against us. It was, therefore, according to my judgment, in the best interest of the Society that I laboured, and at last laboured alone.

"In the discussion arising on Mr. Dymond's motion, I had the great satisfaction of hearing from those gentlemen with whom I had voted during two long and trying years, that their opinions remained unchanged although their votes were now to be given in an exactly contrary direction. Time will prove whether other parties than those who best understand the matter will not try their hands at the work which we have just abandoned, and if they do, I for one shall be unable to say, 'Gentlemen, there is no cause for interference.'

"It should be remembered that the tendency of the present day is to departmental action in the executive. That which was formerly the business of any Government office now becomes the duty of one, and is consequently more narrowly looked after.

"Matters concerning the public health seem to have fallen to the Privy Council, and more immediately to the medical department of that Council. Any man who reads the periodical reports issuing therefrom, must be at once convinced of the extreme activity of the heads of that department, and with an active official to guide them and a large majority in the House of Commons, Ministers may succeed sooner than is expected in doing that which they had entrusted—with misplaced confidence they will say—to our hands. The question before us is entirely apart from 'free-trade'; it is one of public protection.

"Thus much, Sir, for my persistent perseverance in an unpopular course, for my seeming disregard of the wishes of many men who had shown me so much kindness, showered on me so many honours.

"And now for my withdrawal at the moment of defeat from the high office I had held so long. I resumed that office in June last under very difficult circumstances. Death had deprived me of my partner, and I could no longer spare time from my own business to watch the interests of the Society as they should be watched. At Christmas I had determined to vacate the chair, but then arose the clamour which I felt must render the office of President a most unpleasant one, and I could not in honour leave such a bed of thorns to a successor. I told you in a former letter that I simply held on for this reason. The moment the vote of the Council extinguished the compulsory regulations I felt at liberty, and availed myself of that liberty, to retire. It may be asked why I retired when but a few weeks would have relieved me of the duty? And here again, Sir, I felt that in doing so I best advanced the interest and honour of the Society. I hold that the President, who is constantly called on to act on behalf of the Council, should fairly and faithfully represent its opinion; and I could not fail to see that when my hand, and mine alone, was held up to support a particular line of action in regard to the vital question of the year, I had ceased to be in accord with my fellow-councillors—therefore retirement was the only honourable course open to me.

"You doubtless rejoice that the pages of your Journal will no longer be encumbered by this controversy, to the exclusion of more valuable matter; that contention in our body will cease, and I heartily join you in that view; but I may say at parting that it has puzzled me sorely to discover why there should ever have been anything approaching to *personal* contention. The question was one on which men were quite entitled to differ, but it was one to be settled solely by *the votes of the Society, not by the Council*, who would only have presented the regulations to the Society with a recommendation that it would be wise and politic to adopt them rather than bring the Pharmaceutical Society into antagonism with the public as represented in Parliament.

"George W. Sandford.

"47, *Piccadilly*, *April* 10, 1871."

We have also received from the Honorary Secretary of the "Metropolitan Chemists' Defence Association" a copy of the circular addressed to Registered Chemists who "have no vote at the meetings of the Pharmaceutical Society," together with a tatement of the resolutions passed at the meeting held on the 20th ult., and a memorial for signature and presentation to the Pharmaceutical Society—at the annual meeting in May—expressive of disapproval of "compulsory legislative enactment" in regard to regulations for the Storing and Dispensing of Poisons. However, the opposition to the Pharmaceutical Society suggested by this memorial is no longer possible even in appearance. We congratulate the Association that in this respect its occupation is gone, and that there is no longer any need to publish the memorial.

This is also, to a great extent, the case as regards the meeting at Glasgow on the 3rd inst.; but we publish that report, since it illustrates the sore grievance of "medical druggists," already mentioned in our last number as having attained most serious proportions in that city. Here would, indeed, seem to be a very fitting opportunity for exercising the regulative action of the Privy Council. This grievance is one which merits the attention of the whole trade, and it is sufficiently general to call for the endeavours of all pharmacists to put an end to it.

There is one point in the circular of the Metropolitan Chemists' Defence Association that we cannot omit to notice, and that is the reason assigned for considering it advisable to prepare a memorial viz. that Registered Chemists have no vote at the meeting of the Pharmaceutical Society by which their views may be recorded. We have but recently pointed out* that this disability is not a grievance but voluntary; while, at the same time, it is one which affords room for suspecting indifference to the general interests of the trade.

We hope the experience now gained of the disadvantage attending it, may be the means of inducing members of the trade to avail themselves of their capability of legitimately influencing the action of the Society, rather than by spasmodic efforts of association, which cannot be altogether without a show of hostility.

We may perhaps the more reasonably urge the adoption of this course, since there is a belief that the application of compulsory regulations will yet be attempted, and, as suggested by Mr. Sandford, perhaps by those who understand the matter less than the Council of the Pharmaceutical Society.

* *Ante*, p. 771.

We are glad to see a prompt disposition to abandon contention on the subject of regulations, and have no doubt Mr. Wilkinson's letter, published in another column, will open up a discussion that will be useful in defining the form the recommendations of the Society should take. Judging from the general feeling of respect for the Society entertained by the trade at large, we believe that, with proper management, its recommendations in regard to the storing and dispensing of poisons would effect all that could be desired.

We have been requested to call the attention of members of the Pharmaceutical Society to Section I. Clause 10 of the Bye-Laws, which provides that all subscriptions shall become due on the 1st of January in each year, and that the names of Members who have not paid their subscriptions before the 1st of May shall be omitted from the Register certified by the Council at the Annual Meeting. Those who fail to conform with this rule would thereby become disqualified from taking any part in the proceedings of the Society at the approaching annual meeting.

It is sometimes amusing to observe the ignorance of people in matters which they are presumed to have thoroughly mastered. Here is a good illustration. The Austrian United Society of Apothecaries, in a petition against free trade in pharmacy, addressed to the "Reichstag," bases some of its arguments upon the state of pharmacy in those countries where no restrictions whatever are enforced. They gravely inform their Parliament that in London, among 3000 dispensing establishments, not more than twenty enjoy or deserve public confidence, and that people often pass three or four hundred druggists' shops before they come to one where they like to have their prescriptions made up. True, these enviable twenty shops are described as establishments on the most gigantic scale, each of them employing as many as thirty dispensers. This wonderful information, no doubt as new to our readers as to ourselves, reminds us of a statement made in the Prussian Chambers some seven or eight years ago by Herr von Kucke, one of the then leading statesmen of the country. In a debate on the same subject, viz. the introduction of free trade into the practice of pharmacy in Prussia, Herr von Kucke after proudly, but not less justly, dwelling on the high *status* of the German pharmacist as compared with that of his foreign brethren, went on to say that in England the vastly superior education of the German apothecary was fully recognized by the general public, and that, as a matter of fact, the shortest way for London pharmacists to gain public confidence was to place a board in their windows with the inscription, "Deutsche Apotheke"—German pharmacy. It may be interesting to notice that in the course of this debate, it was argued against free trade that the value of the existing pharmaceutical establishments in Prussia represented a capital of 72,000,000 thalers, about £11,000,000, which the State would be bound to pay to the owners before the introduction of free trade.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

April 5th, 1871.

MR. SANDFORD, PRESIDENT, IN THE CHAIR.

MR. HASELDEN, VICE-PRESIDENT.

Present—Messrs. Abraham, Atherton, Bottle, Bourdas, Brown, Carr, Deane, Dymond, Edwards, Evans, Groves, Hills, Mackay, Savage, Stoddart, Sutton, Williams, Woolley.

The minutes of the last meeting were read and confirmed.

The Secretary reported that he had received forty-five nominations for the ensuing election of Council, and that the following twenty-two had signified their willingness to accept office if elected:—

ABRAHAM, JOHN, 87, Bold Street, Liverpool.
ATHERTON, JOHN HENRY, Long Row, Nottingham.
BETTY, SAMUEL CHAPMAN, 6, Park Street, Camden Town, London.
BROWN, WILLIAM SCOTT, 113, Market Street, Manchester.
CARR, JOHN, 171, High Holborn, London.
COLLINS, JOHN RICHARD, 81, Chalk Farm Road, London.
COOPER, GEORGE, 101, Fore Street, Exeter.
DYMOND, GEORGE, 17, Bull Street, Birmingham.
FRAZER, DANIEL, 113, Buchanan Street, Glasgow.
GREENISH, THOMAS, 20, New Street, Dorset Square, London.
HASELDEN, ADOLPHUS FREDERICK, 18, Conduit Street, Regent Street, London.
HILLS, THOMAS HYDE, 338, Oxford Street, London.
MACKAY, JOHN, 119, George Street, Edinburgh.
OWEN, JOHN, 234, Upper Street, Islington, London.
SANDFORD, GEORGE WEBB, 47, Piccadilly, London.
SHAW, JOHN, 24, Great George Place, Liverpool.
SMITH, EDWARD, 8, The Strand, Torquay.
STOTT, WILLIAM, Sowerby Bridge, Yorkshire.
WADE, JOHN, 174, Warwick Street, London.
WILLIAMS, JOHN, 5, New Cavendish Street, London.
WOOLLEY, GEORGE STEPHEN, 69, Market Street, Manchester.
YARDE, GILES, 60, Lamb's Conduit Street, London.

That the following Members of the Society had been nominated for election as Auditors for the ensuing year, and had signified their willingness to accept office:—

BARRON, FREDERICK, 2, Bush Lane, London.
BOWER, WILLIAM, 96, Tottenham Court Road, London.
HODGKINSON, WILLIAM, 127, Aldersgate Street, London.
MACKAY, JOHN BRUNT, 2, Bouverie Street, London.
SQUIRE, WILLIAM, 5, Coleman Street, London.

The Reports and recommendations of the Finance Committee were received and adopted.

The Reports and recommendations of the House Committees of 2nd of March and 4th of April were received and adopted.

The Report and recommendations of the Library, Museum and Laboratory Committee were received and adopted.

Resolved—That Free Laboratory instruction be given to the Bell Scholars for the Session 1871–72.

It having been reported by Professor Redwood that Messrs. Hopkin and Williams had presented to the Society's Museum some rare and valuable specimens of Thallium and its compounds (twenty-four in number), it was unanimously

Resolved—That the best thanks of the Council be given to Messrs. Hopkin and Williams for their valuable donation.

The Report and recommendations of the Benevolent Fund Committee were received and adopted: a grant of Ten Pounds was made to a chemist and druggist residing in Sheffield.

The Report and recommendations of the Parliamentary Committee were received and adopted.

The Society's Solicitor (Mr. Flux) attended and advised the Council on several legal questions.

The Report of the Provincial Education Committee was received, and it was

Resolved—That in future the names of "Apprentices or Students" should be omitted from the *published* list in the Calendar after a period of seven years from the date of their first registration, but that their names be retained on the General Register of the Society.

Resolved—That the following Conditions and Forms of Application under which grants and loans in aid of Provincial Schools of Pharmacy are to be made be adopted and published in the Journal:—

Form of Application for Grants in Aid of Provincial Schools of Pharmacy.

Name of Association applying for Grant ____________________

(In the following divisions state the object or objects for which the grant is required, and the amount it is desired to appropriate to any or each of the following purposes)—

A For providing apparatus, specimens, diagrams, etc. Specify the articles required, and the amount of grant requested . . . ____________________

B For providing books, etc., for library. State the particulars of the number of books already in the library of the Association, the titles and prices of the books it is now desired to purchase, and the amount of grant requested . . . ____________________

C For any other object. State the purpose for which the grant is required, and the amount requested . . ____________________

As the relative claim of any town to receive aid from the Society must be indicated by the earnestness and efficiency of local effort, state here any consideration which, in the opinion of the applicants, entitles them to a grant from the Society's funds . ____________________

Conditions for Making and Receiving Grants and Loans in Aid of Provincial Schools of Pharmacy.

1. Grants in aid of Provincial Education in Pharmacy shall be made for the purpose of supplying materials for class-teaching, such as apparatus, specimens, diagrams, chemicals, class-books, etc., and also towards the formation of libraries.

2. That applications for such grants be made in writing to the Council on forms provided for the purpose, by local Associations of Chemists and Druggists, signed by the Secretary of the Association and by three resident Members of the Pharmaceutical Society.

3. That each application shall state the kind of aid required, and, where a money grant is applied for, shall indicate the sum intended to be applied to each specific purpose.

4. That where a grant is made for the purpose of providing *materials for class-teaching*, etc. the applicants *shall guarantee* their safe custody for a period of three years. The said materials to be *the loaned property of the Pharmaceutical Society for three years*, after the expiration of which they may be resumed by it, or otherwise disposed of. The Council may, in special cases, forego this guarantee where it deems it not desirable.

5. Applications for the use of apparatus from the "*loan collection*" of the Society may be made by local Associations of Chemists and Druggists, and grants made for periods of fourteen days, in accordance with the following rules:—

> 1. A list of the apparatus which the Society is prepared to lend, or which may be hereafter added to the collection, shall be published in the Journal, and printed for circulation in a separate form. Such list may be obtained from the Secretary of the Pharmaceutical Society.
>
> 2. This apparatus shall only be lent to Associations of Chemists and Druggists, and applications for their loan must be made in writing, on forms provided for the purpose, signed by the Secretary of the local Association, describing the articles required, and directed to the Secretary of the Pharmacetical Society.
>
> 3. The Secretary of the Pharmaceutical Society shall refer any application so received to Dr. Redwood, who, with the assistance of the Curator, shall supply the same, subject to approval of the President or the Vice-President of the Society, and to the following conditions:—
>
> A. No apparatus shall be lent for a longer period than fourteen days, unless a renewed application is made for it.
>
> B. All apparatus so lent shall be at the risk of the borrowers, who shall defray the cost of any damage that may occur to it.
>
> C. Packing-cases and packing will be provided and paid for by the Pharmaceutical Society, but cost of carriage must be paid for by the borrowers.
>
> D. A list of the apparatus lent to local Associations shall be sent to the Secretary applying for it, who shall sign and return it as a receipt for the apparatus when received.

6. Applications for aid to libraries must be accompanied by particulars of the number of volumes already contained in such library, and the name of each book applied for and its price specified.

7. The relative claim of any town to receive aid from the Society must be indicated by the earnestness and efficiency of local effort. A complete curriculum of chemistry, practical chemistry, materia medica, pharmacy and botany, is the standard to be aimed at.

8. All applications to the Council for aid may be referred to a standing Committee appointed annually for this purpose. The recommendations of the Committee to be laid before the Council for action thereon.

Form of Receipt for Temporary Loans of Apparatus, etc. from the "Loan Collection" of the Pharmaceutical Society.

List of apparatus, etc. and number of the same in the Society's catalogue, forwarded in loan for fourteen days to____________________

No.	

To the Secretary of the Pharmaceutical Society, London.

I acknowledge having received the above apparatus, etc., and agree to return it, within fourteen days, to the Society's House in London, unless a renewed application for it and a fresh grant be made; and to be responsible for its safe custody and to defray the cost of any damage that may occur to it whilst it remains at my risk.

(Signed) Name________________

Address________________

Secretary of the____________

The following is a list of that portion of Apparatus belonging to the Society which may be lent to Provincial Associations on the foregoing conditions:—

Frictional Electricity.

Glass rod, half coated with sealing-wax.
Large electrophorus on insulating stand.
Jointed electrical discharger and curved ditto.
Large framed glass, and two smaller ones, with tinfoil figures for showing luminous electrical discharge.
Two glass tubes for discharge of electricity in vacuo.
Set of four glass columns arranged on mahogany stand to exhibit luminous discharge of electricity.
Henley's universal discharger.
Cuthbertson's balance electrometer.
Harris's unit jar without stand.
Cuthbertson's quadrant electrometer.
Sir William Snow Harris's balance electrometer.
Peal of electrical bells.
Battery of five quart Leyden jars in frame.
Five Leyden jars in box.
Electric firehouse for igniting wool saturated with spirits of wine by electric spark.
Brass cannon for igniting gases by electricity.
Electrical mortar.
Electrical flask for showing discharge in vacuo.
15-inch cylinder electrical machine.
Electrical whirl on insulating stand.
Apparatus for passing electrical spark through liquids.

Galvanic Electricity.

Grove's battery, 20 cells, complete in frames.
Set of platinum wires on frames for illustrating heating and magnetic effects of galvanic electricity.
Decomposing cell.
Daniell's apparatus for the electrical decomposition of salts.
Bunsen's apparatus for decomposing water by electricity.
Small galvanometer.
Apparatus for exhibition of electric light in vacuo and in gases, mounted on tall bronze pedestal.
De la Rue's electric light apparatus.
Small medical induction coil, made in such way as to illustrate the construction.

Magnetism.

Bar magnet, 3 feet long.
Ditto for showing magnetic dip.
Compound magnet (six bars) 1 foot long.

Electro-Magnetism and Magneto-Electricity.

Electrical globe for illustrating magnetism of the earth.
Apparatus to show rotation of electric current under influence of magnetism.
Electric conductor rotating between poles of a magnet.
Disc rotating between poles of a magnet.
Whirling-table for rotating disc of copper beneath suspended magnet and for many other purposes.
Faraday's apparatus for showing rotation of current of electricity round permanent magnet.
Faraday's apparatus for showing rotation of permanent magnet round current of electricity.
Watkins' apparatus for showing rotation of magnet under influence of electric current.
Saxton's magneto-electric machine.
Model illustrating Wheatstone's needle telegraph.

Light.

Alcohol lime-light apparatus.
Glass prism on brass stand.
Solomon's magnesium lamp with clockwork motion.
Apparatus for circular polarized light. In case.
Copper bottle for "fire-cloud."
Polarizing apparatus.
A pair of thickly-silvered copper parabolic mirrors by Watkins and Hill, with supports provided with ball and socket movements.

Crystallograph, Hydrostatics, Pneumatics, etc.

Numerous models of crystals in glass and wood.
Common goniometer.
Wollaston's reflecting goniometer.
Set of five turned iron pendulum weights from 20 lb. downwards (provided with points and screw-plugs for suspension) for the pendulum experiment illustrating the rotation of the earth.
Large revolving table for use with the above.
Large diffusion-tube and stand.
Lung glass.
Mercury shower cup.
Large Magdeburg hemispheres.
Small air-pump.
Apparatus for illustrating principles of ventilation.

A letter was read from the Glasgow Chemists and Druggists' Association, applying for a copy of the "Register," whereupon it was

Resolved—That a copy of the Register be forwarded to the Glasgow Chemists and Druggists' Association for the use of its members.

Resolved—That the Editor be requested to draw the attention of members to Section 1 Clause 10 of the Bye-Laws, reminding them that the non-payment of their annual subscription (due Jan. 1st) before the 1st of May, excludes them from the privilege of voting or taking any part in the proceedings at the ensuing election.

Proposed Poison Regulations.

Memorials and protests against their adoption were presented from Hull, Newbury, Maidstone, Bradford, Canterbury, Sheffield, and Manchester.

Pursuant to notice, it was moved by Mr. Sutton and seconded by Mr. Atherton,

That an appeal to the members of the Society for their opinion, "Yes" or "No," upon the proposed Compulsory Regulations for the Storing and Selling of Poisons be made by means of a printed form to be issued with the voting-papers for the election of Council in May, and that members be requested to return such papers to the Registrar previous to the Annual Meeting on the 17th May, and that the President, together with the Mover and Seconder of the Resolution, be requested to frame the necessary paper.

This Motion was subsequently withdrawn in favour of the following—

Moved by Dymond, seconded by Mr. Abraham,

That considering the numerous and strongly expressed objections to the compulsory character of the suggested Regulations for the keeping and dispensing of Poisons by members of the Society and others who will be affected by them, and in order to obtain the more cordial adoption of these Regulations by chemists throughout the country, it is resolved to present them to the Annual Meeting with such alterations as will divest them of a compulsory character, but accompanied by the earnest recommendation of this Council that all "Pharmaceutical Chemists" and "Chemists and Druggists" in business in Great Britain do make use of these recommended Regulations in the keeping and dispensing of Poisons enumerated under the Pharmacy Act of 1868.

On a division the following voted:—

For the Motion—

Messrs. Abraham, Atherton, Bottle, Bourdas, Brown, Carr, Deane, Dymond, Groves, Mackay, Savage, Stoddart, Sutton, Williams and Woolley.

Against—

Mr. Sandford.

Messrs. Edwards and Haselden were present, but did not vote.

The Motion was therefore carried; whereupon,

Mr. Sandford stated that as during the last few months he had continued to hold office simply that his successor might not commence with so troublesome a question on his hands as the Poison Regulations, now virtually withdrawn, and as he felt that the President should at the Annual Meeting represent the views and opinions of the Council, he deemed it his duty at once to resign the Presidency.

Resolved—That the following Committee be appointed to revise the wording of the Poison Regulations, in order to bring them within the terms of the Resolution to-day passed and to make any alteration in the wording of the third clause it may suggest.

Committee—Messrs. Carr, Deane, Dymond, Groves and Williams.

REPORTS OF THE BOARDS OF EXAMINERS.

	Candidates examined.	Candidates passed.	Candidates failed.
March 15, Major	5	1	4
,, ,, Minor	17	9	8
,, 17 Minor	17	14	3
	39	24	15

Preliminary.—5 Certificates approved.

A Committee, consisting of Messrs. Sandford, Bourdas, Carr and Williams, was appointed to confer with the Board of Examiners with respect to certain proposed alterations in their regulations.

Resolved—That Walter Scott, being duly registered as a Pharmaceutical Chemist, be granted a diploma, stamped with the seal of the Society.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be elected Members:—

Arkinstall, William .... Ludlow.
Speechly, Edward .... Vauxhall.
Swain, William Thomas ...... Boroughbridge.
White, James Walter .... Hampton.

Two members, having paid their arrears of subscription and a nominal fine of 1*s*. each, were restored to their original status in the Society.

Resolved—That the following Registered Chemists and Druggists be elected

MEMBERS OF THE SOCIETY.

Ault, John .... Eastwood.
Bell, Wm. Middlewick ...... London.
Bosley, John Lawrence ...... London.
Cowles, Charles .... Stratford.
Dodds, George F. .... Kelso.
Dodds, Nicholas .... Coldstream.
Dun, Robert Thompson ...... Glasgow.
Dunmore, John .... Birmingham.
Dunsford, Samuel .... Wigan.
Frost, Wm. Toogood .... Lee.
Hammond, Charles Thomas .. Hull.
Higgins, James .... London.
Hughes, Lancelot Steele ...... London.
Hughes, Richard .... Bangor.
Hughes, Thomas .... Llandilo.
Jones, Richard .... Chipping Sodbury.
McDonald, James .... Glasgow.
Morris, Edwin .... London.
Pettigrew, John Wesley ...... Glasgow.
Roberts, John .... London.
Vincer, Frank .... Sevenoaks.
Westwood, Robert Fleetwood. .London.

Resolved—That the following, having passed their respective Examinations, be elected "Associates in business:"—

MINOR.

Warman, William Albert .... London.

MODIFIED.

Atkinson, Leonard .... Greenwich.
Bowler, William Samuel .... Belper.
Covell, William Mann ...... London.
Dickie, James .... Glasgow.
Fleming, John .... Glasgow.
Gamble, Henry Arthur ...... London.
Greig, William .... Glasgow.
Lambert, William R. .... London.
Mundy, Alfred Octavius ...... London.
Pratt, Edward Jonathan ...... Great Yarmouth.
Smith, Joe .... Wath-upon-Dearne.
Willson, Cornelius .... Grimsby.

Resolved that the following, having passed their respective Examinations, be elected Associates:—

MINOR.

Bird, Matthew Mitchell ...... Lynn.
Bothamby, Richard Broughton. Guildford.
Churchman, James .... London.
Clarke, George Ernest .... Stowmarket.
Dowson, Joseph .... London.
Earee, Edwin Thomas .... Staines.
Farrow, Charles Henry ...... Diss.
Ground, William Davie ...... Grantham.
Guy, Frederick .... Louth.
Hetherington, Martin Luther . . Highbury.
Holmes, Nathaniel Wheatcroft. Grantham.
Jaques, William .... Beverley.
Jasper, Frederick William .... Penzance
M'Neil, James Norton .... Macclesfield.
Martin, William Thomas .... Lewes.
Peters, David .... Llandilo.
Pound, Henry William ...... London.
Read, Henry Holditch .... Peterborough.
Roberts, Joseph Elliott .... Leeds.
Thompson, George Alfred .... Tunbridge.
Wilson, John Herbert .... Lee.

MODIFIED.

Allden, John .... London.
Bennett, Joseph .... Bristol.
Clark, John .... Sheffield.
Fox, George Clement .... London.
Gibbs, William Duirs .... Winchester.
Kermath, William Ramsay .... Glasgow.
Sirett, Henry, jun. .... Buckingham.
Smith, William Henry ...... Cheltenham.
Watts, Walter .... Peterborough.

PHARMACEUTICAL MEETING.

Wednesday, April 5th, 1871.

MR. G. W. SANDFORD, PRESIDENT, IN THE CHAIR.

The following donations to the library and museum were announced:—

The Half-yearly Abstract of the Medical Sciences: from the Editors (per Publishers),—The Year-Book of Pharmacy and Proceedings of the British Pharmaceutical Conference, 1870: from the Conference,—On a Localized Outbreak of Typhoid Fever in Islington during the months of July and August, 1870, traced to the use of Impure Milk, by Edward Ballard: from the Author (per Publishers),—The History and Present State of Electricity, with Original Experiments, by Joseph Priestley, LL.D., F.R.S.; a Volume containing pamphlets as follows:—1, A Series of Experiments relating to Phosphori, and the Prismatic Colours they are found to exhibit in the dark, by B. Wilson, F.R.S., etc., together with a Translation of two Memoirs from the Bologna Acts upon the same subject; 2, A Lecture on the Perpetual Motion; 3, A Continuation of New Experiments Physico-Mechanical, touching the Spring and Weight of the Air, and their Effects. The I. part. Whereto is annexed a Short Discourse of the Atmosphere of Consistent Bodies, by the Honourable Robert Boyle, F.R.S.: from Mr. Alexander Bottle,—Durham University Calendar, 1871,—London University Calendar, 1871: from the Universities,—Guy's Hospital Reports, Vol. XVI., 1870–71: from the Editors (per Publishers),—On the Claims of Science to Public Recognition and Support, with Special Reference to the so-called "Social Sciences:" from W. A. Guy, M.B., F.R.S., etc. (the Author),—Zeitschrift des allgemeinen österreichischen Apotheker-Vereines, several numbers,—List of the Fellows, etc., of the Royal College of Physicians: from the College,—The Chemists and Druggists' Compendium, a Handbook of Practical Receipts and Processes: from R. J. Owen, St. Mary, Charterhouse,—Reports on the Progress of Practical and Scientific Medicine in Different Parts of the World, 1870, Vol. II.: from Dr. Dobell,—Curiosités de l'Alimentation: from Dr. J. Léon Soubeiran,—Introductory Address delivered at the opening of the Session, 1870–71 (Queen's Hospital, Birmingham): from Alexander Fleming, M.D.,—25 beautifully-prepared Specimens of Thallium and its Salts, viz., Thallium (metallic in hydrogen) acetate, antimoniate, sulpho-antimoniate, benzoate, bromide, carbonate, chlorate, chloride, sesquichloride, platinochloride, carbazotate, chromate, bichromate, iodide, molybdate, nitrate, oxalate, peroxide, silicate, sulphate, bitartrate, thallio-carb., tungstate; thallium alum: presented by Messrs. Hopkins and Williams,—Specimen of Coumarin: prepared and presented by Mr. Fredk. Janson Hanbury,—Two Specimens of Penguin Oil: presented by Mr. P. L. Simmonds,—Sugar of Ergot: presented by Mr. Rimmington (Bradford),—Specimens of Maple Sugar, Beetroot Sugar, Crystallized Cane Sugar, a fine crystal of Sucrose from Beet Sugar and Glucose from Starch as imported: presented by Mr. Stoddart.

The CHAIRMAN drew attention to several samples of poisonous articles which had been laid on the table by Mr. Bland, none of which bore any label intimating the poisonous nature of the contents, saying he apprehended Mr. Bland's object was not to anticipate any discussion on the subject of storing poisons, but rather to show the facility with which very dangerous articles might be obtained notwithstanding the clauses in the Pharmacy Act. It certainly seemed a great grievance that whilst pharmaceutical chemists were placed under numerous and heavy restrictions as to the manner in which they should carry on their business, traders of an inferior class were allowed to sell oxalic acid, acetate of lead, sulphate of zinc, cyanide of potassium and such-like articles without any protection whatever. There could be no doubt that such a mode of selling these articles was illegal, but he supposed there was no means of knowing whether the person who supplied the articles was connected with the Society or not.

Mr. BLAND said he could trace every article; they had all been supplied by totally unqualified persons.

The CHAIRMAN said in that case it was clearly a matter for the interference of the police.

Professor ATTFIELD then read a paper on "The Chemical Nomenclature of the Pharmacopœia, with Suggestions for its Revision," which will be found printed at pp. 801 and 822.

The CHAIRMAN said there was one remark in the paper which he considered of primary importance, viz. there should in all cases be a perfect understanding and unanimity in nomenclature between prescribers and dispensers, and if any system could be introduced which would increase that understanding, it would be an immense advantage to all parties. Another point of detail of considerable importance was the recommendation that different but analogous names should be distinguished by the prefix rather than the termination, on account of the inveterate habit amongst medical men of abbreviating pharmaceutical Latin. They could not very well cut off the beginning of a word, and it would be a great relief to dispensers if they could see by the first syllable what article was intended. Great difficulties had sometimes arisen in this matter, even with regard to calomel.

Professor FRANKLAND said there seemed to have sprung up two systems of chemical nomenclature, which had in many cases two distinct objects. The scientific chemist, in pursuing his investigations, was led to modify his nomenclature, and frequently also his notation; whilst, on the other hand, the pharmaceutist had to maintain as strictly as possible a uniform and intelligible system, for he quite agreed that nothing could be more mischievous than frequent or unnecessary changes of names in pharmacy. It was peculiarly fortunate, therefore, that Professor Attfield's scheme retained most of the old names, and only introduced changes where they had become almost indispensable. In the first place, there could be no doubt that the name ought to individualize the substance named; and he might be pardoned for pointing out one or two cases in the list where this rule was hardly complied with. In the case of sulphate of iron there were two substances which claimed that designation, the ferrous and the ferric sulphates, or the protosulphate and the persulphate. There might perhaps be a difficulty in the way of finding euphonious names for these two salts, but he would suggest the terms ferrosum and ferricum, instead of the word iron. There was also another point to be kept in view, viz. that, as far as possible, the nomenclature of applied chemistry should be consistent with that of chemistry exclusively scientific; and there were some instances where this consistency was somewhat departed from. At the head of the list was placed acetate of ammonium, and a little lower down acetate of morphia. Now, in two compounds so analogous, consistency required that you should be able to substitute one basic constituent for the other without altering your conception of the chemical composition; in other words, morphia ought strictly to represent ammonium, which it did not, seeing that it was the analogue of ammonia and not of ammonium. He would suggest, therefore, that the word morphium should be introduced, which he thought would lend itself as well as morphia to prescribers, especially as they would be sure to omit the termination in either case. But this would render the names of the compounds of these acids with natural alkaloids consistent with the names of the salts of the metallic elements and compound radicals such as ammonium. With regard to the naming of these alkaloids, he observed that Professor Attfield had adopted the system which was probably more in use amongst medical men than the opposite plan, to a great extent used by pure chemists, viz. the termination *ia* instead of *ine*. He did not know that any important objection could be urged against these names; and if the terminal *ia* be changed to *ium* in naming salts, it would entirely get rid of the difficulty with regard to that portion of the name representing a metallic element, or similarly constituted compound radical, which performed precisely the same functions in the different compounds. These appeared to him the only cases of inconsistency, and he was very glad to see that so slight an amount of alteration brought the system of pharmaceutical names so nearly into harmony with that of purely scientific chemistry.

Professor Redwood said that whenever the Pharmacopœia had been submitted to revision there had always been, more or less, alterations effected in the names of the substances described, and these changes had generally, although not always, been made with the view of assimilating them to those employed by scientific men. This had been the case in the last edition; the other object, and perhaps the more important, being to make each name more specific, and less liable to misconception. As such changes had been made on former occasions, so he had no doubt that whenever a new edition came out, the same thing would take place, and perhaps to a still greater extent, the foundation having been already laid by the introduction of the new notation, although it was not thought expedient then, on account of the unsettled state of the subject, to relinquish the old notation which was best understood. The old notation being retained, the old names were necessarily retained likewise, though the introduction of the new notation paved the way for such a change of names on a future occasion, as Professor Attfield had indicated. As to the time, however, when a new Pharmacopœia would be prepared it was impossible to say; but the average life of an edition having been about ten years, it would probably be some considerable time yet before another was brought out. He was not quite sure, therefore, that it was advisable to discuss the matter so long beforehand, though, were a new edition in course of preparation, he should advocate in the majority of cases precisely the changes proposed by Professor Attfield, being a change from the representation of salts of alkalies and alkaline metals to a representation of their being salts of the metals themselves, thus bringing about a consistency and uniformity in this part of the nomenclature with the other part which hitherto had not existed either in pharmacy or amongst scientific men themselves. This system had been adopted in labelling the specimens in their museum for some time; as there were two notations given in the Pharmacopœia, there was an old name which corresponded with the old notation, and a new name precisely the same as those which Professor Attfield proposed. If nothing more than this were suggested, he should have no doubt of the principle being adopted, and should himself go with the author of the paper entirely, and even to concur in what had been suggested by Dr. Frankland, that the alkaloids, morphia, quinia, and so on, should be changed to the better-known and more-easily expressed names, morphine, strychnine, quinine and so on. Such a change he thought could be made without any inconvenience or difficulty, for these were the names generally used in commerce. Dr. Frankland had remarked that there would still be, in some cases, a want of distinctness, instancing sulphate of iron, which, he said, represented two salts which required to be distinguished from each other. Now in the present Pharmacopœia both were ordered, and the names there used were, as he conceived, sufficiently distinct. The rule had been never to make a name longer than necessary to its being perfectly understood; therefore, the term sulphate of iron was applied to the ferrous sulphate or protosulphate, which was rather a long name, and, perhaps, a little theoretical; and the ferric sulphate was designated by the prefix *per*, without which the name could not be written, so that there could be no ambiguity. Whilst, however, he agreed with much that had fallen from Professor Attfield, and especially with the principles he had laid down, he could not concur in all his proposed changes, though the number to which he objected was but small. In the first place white arsenic was suggested in place of arsenious acid; and it was suggested that the term 'acid' should not be used to designate a body which contained no hydrogen, as such were not really acids according to modern views. If arsenious acid of pharmacy were the only body of the kind used, or likely to be used, in medicine, he did not know that there would be any great objection to the change, although he preferred the older term as being more distinctive, for the name "white arsenic" might be applied to arsenic acid as well as to other compounds of arsenic, while arsenious acid was not so liable to misconception. But there were other bodies which stood in precisely the same category, for instance, chromic acid, which was used as an escharotic; and if the term 'acid' must not be applied to arsenious acid, neither should it be applied to chromic acid. What then could it be called? Chromic anhydride would be a proper term, but he should not be prepared to import it into pharmacy. It was unsatisfactory, for even scientific chemists differed upon it, and it was uncertain how long it would maintain its position, and it would be very unwise, therefore, to introduce it into pharmacy, where, above all things, permanence was required. No one could have any doubt as to what was meant by arsenious acid or chromic acid, and, therefore, although the terms might be open to a little objection theoretically, he thought for practical purposes they were the best that could be adopted at present. Exception had been taken to the term bichromate of potash, and he only wondered that the proposed change to red chromate of potash had not been made before; but consistency would require that a like change should be made in the cases of bicarbonate of soda and bicarbonate of potash. These names, however, were, he thought, properly retained, being so well understood, although they were not quite satisfactory theoretically. Then, again, there was the term black sulphide of antimony, which it was proposed to substitute for the ordinary name, black antimony. In his opinion brevity was a very important consideration and he was quite satisfied with the old term, which had been thoroughly understood for generations both in commerce and in pharmacy. Then came the substances subnitrate of bismuth and carbonate of bismuth. Professor Attfield said both these were of analogous composition, and that if one was called subnitrate, the other ought to be called subcarbonate. Theoretically he should be disposed to agree with this view, but, practically, he thought it better to leave the names as they stood. The subnitrate was in the former Pharmacopœia called nitrate, but it was necessary to distinguish it from the crystalline salt which was acid in its reaction, and the prefix *sub* was used for that purpose. With regard to the carbonate of bismuth, although undoubtedly it was an oxycarbonate, yet, as there was no other carbonate of bismuth with which it could be confused, he should not be in favour of introducing a longer name when the short one was sufficiently explicit. The same theoretical objection would apply to carbonate of lead and carbonate of zinc, both of which were oxycarbonates, but no proposition was made to alter them. Chloride of tin, which was ordered as a reagent, was proposed to be changed to stannous chloride, but he was not prepared to adopt that as the only case in which this particular kind of nomenclature should be introduced. With the citrate of iron and ammonium, and the citrate of bismuth and ammonium, he would include the tartrates, which Professor Attfield took great objection to, proposing to substitute tartrate of iron and potassium for tartarated iron. The latter name was adopted as being shorter and more convenient to use than the full name, and thus the terms tartarated antimony and tartarated iron arose. They were not given as scientific names, but nevertheless they did indicate the composition, because both were tartarated products. Just as chlorinated lime was lime treated with chlorine, so the iron and antimony were treated with tartar. However, he should not object to the names tartarated iron, etc. being changed, but not for those suggested. He should prefer going back to the old names, which were familiar to all, and sufficiently explicit and euphonious, viz. ammonio-citrate of iron—potassio-tartrate of iron, which names were still used in commerce. As for the termination in *um*, which made the name so much more of a mouthful, he was quite sure that neither commercial men nor pharmacists would ever use it. Potassio-tartrate of antimony again was the old name for emetic tartar; and the new preparation called citrate of bismuth and ammonium might, in like manner, be called ammonio-citrate of bismuth. Citrate of iron and quinia, or quinine, as it was commonly called, would then require to be altered for the sake of uniformity. He did not like ammonio-quiniate of iron, and should therefore suggest ferro-citrate of quinia or quinine. There was only one other case he wished to refer to, and that was where it was suggested that the familiar name hydrated peroxide of iron should be changed to peroxydrate of iron. He was not at all favourable to such a change, thinking the old names far preferable.

Professor Odling said Professor Attfield had produced a very useful paper, and upon the whole had steered tolerably clear of difficulties. He was happy to find that in most instances where he should venture to differ from the conclusions arrived at, he had been forestalled by his friend Dr. Redwood; but at the same time he could not agree with all the remarks of the latter. With regard to the propriety of discussing such a subject at the present time, and to the probability of a new edition of the Pharmacopœia being speedily issued, he thought such discussions as the present were always useful, as they opened the way for the time when action became necessary, however long it might be deferred; and looking to the great merits and completeness of the present edition, he had no doubt that a long time would elapse before another was called for. He had been somewhat surprised at the delicacy which Dr. Redwood felt about introducing the term "white arsenic," but he was quite satisfied shortly afterwards on hearing his remark on "black antimony." Professor Attfield, he thought, had shown great discretion, both in the new names he had proposed and in regard to the old ones which he thought should be discontinued. He quite agreed that names involving the use of abbreviated Latin or Greek numerals were to be avoided as far as possible, if not altogether, and the use, where necessary, as distinctions of red and yellow, where such-like definitions obviously applied, was much to be recommended, as, for instance, green iodide and red iodide, red prussiate and yellow prussiate, yellow chromate and red chromate; for these names had at any rate the element of stability, as there was no reason to suppose that the various salts would alter their colour within the next generation or two. He also concurred in what had been said as to the use of the word 'acid.' It was well known that this term had been applied for a long series of years to two distinct classes of compounds,—those which were ordinarily bought and sold under that name, such as oxalic, citric or tartaric acids, and also to the substances which were considered to exist within these bodies, and to give them their characteristic properties. Now it was obvious that the same name should not be given to two totally distinct substances or even be applied to bodies belonging to different classes. If it were the case, which he believed it was, that the body called "white arsenic" belonged to an entirely different class of bodies from those to which the word 'acid' was now almost universally restricted by chemists all over Europe and in America, it was a pity that it should not be distinguished and called as was suggested, "white arsenic," rather than arsenious acid. Originally it would have been but a matter of little consequence to which class the word 'acid' should be applied, but, inasmuch as it was now applied by general consent to salts of hydrogen, it would be better to restrict it to that. Although, as Dr. Redwood had said, the term arsenious acid was perfectly definite, there being no true salt of hydrogen recognizable, and although it was not always necessary in pharmacy to give strictly accurate names, yet it was undesirable to suggest by similarity of name a similarity of character where such had no existence. The staple recommendation in Professor Attfield's paper was the substitution of the metallic names potassium, sodium, calcium, for the alkaline or earthy names, potash, soda and lime, and, on the whole, he thought this recommendation a wise one. At the same time he was not prepared to go quite so far as Professor Attfield had gone with regard to the history of that class of names, or with regard to the importance and necessity of the change. He was quite aware of the fact that in the writings of Lavoisier and his colleagues, sufficient would be found to warrant Professor Attfield's proposition, but there were also to be found there a large number of remarks of a totally different character and tendency. It would be found in reality that the habit of expressing the constituents of salts as binary compounds, did not originate until long after the Lavoisierian period; in fact, not until the days of Davy and Berzelius, when the electro-chemical theory was founded. It would be found that the Lavoisierian nomenclature could be traced, in a great measure, to De Morveau, and his older names were of a different character. His notion was not so much to define the composition of bodies as to define their chemical nature; what were now called sulphates he called "vitriols," and what we call nitrates, he called "nitres," differentiating them as iron vitriol and copper vitriol, and he might have gone on to say potash vitriol, and so on; as he did with the nitres, for he spoke of potash nitre and soda nitre. He did not imply by this that the former was a compound of nitric acid on the one hand with potash on the other, but that it was a substance of one particular kind, which was called a nitre or a vitriol or a fluor, as the case might be, and that the varieties were expressible by the words *de fer*, potash, etc. This was well seen in the older Latin names; for instance, what is now called chloride of sodium was called indifferently muriaticum nitratum or nitratum muriaticum, which did not associate the idea of the constituents, but rather endeavoured to indicate clearly the nature of the substance or class of the substance without expressing its ultimate composition. The idea of ultimate composition, although it was to be found in Lavoisier, was rather superadded by the results of the electro-chemical theory. Under these circumstances, therefore, he should not hesitate to use the term iodide of potash, meaning that the salt was the potash variety of iodide; still, on the whole, it was objectionable that one set of potash compounds should be called potash, and the word potassium used in other cases. Then, again, with regard to ammonium and ammonia; ammonia was such a many-faced substance that it was difficult to say which should preponderate. When the salts were analogous to those of potassium, and bore a mineral character, the word 'ammonium' might obviously be used; but when they were related to the class of amides on the one hand, or seemed more nearly related to alkalies on the other, he was not quite sure whether the balance of advantage was not the other way. At any rate, this was a point which should be left open, and the words ammonium and ammonia might be used indifferently. Again, in some of these longer names, he thought Professor Attfield had striven to arrive at that which he himself reprobated, viz. strict scientific accuracy where it was not required, and some of these names he did not think particularly fortunate; for instance, oxyhydrate of iron magnetic, peroxyhydrate of iron and perhydrate of iron moist. Strictly speaking, the last was not chemically accurate, inasmuch as it was not a hydrate which was a hydrate alone; the compound was partially a hydrate and partially an oxide; it did not correspond with a perchloride by substituting for each atom of chlorine an atom of hydroxyl. If accuracy were attempted it should be carried out, or the whole scheme would call for further revision. Then came the question of the salts, which it was proposed to call oxyacetate of copper and lead, oxynitrate of bismuth and oxycarbonate of bismuth. In these cases he much preferred the word *sub*, because, at any rate, it was not pretentious, and did not profess to give the exact definition of the body, while some of these names were scarcely accurate. He was not at that moment prepared to say whether oxyacetate of copper was strictly correct; but in some cases the salts were really hydroxyacetates, and if a name of that kind were introduced at all it might as well be strictly accurate. Under the circumstances, however, he should repudiate strict accuracy, and would suggest the use of the prefix *sub* where necessary for distinction. Where substances belonged to two different classes it would be sufficient to distinguish one class only; for instance, in the majority of cases it would be sufficient to say sulphate of iron and persulphate, but if it that were not sufficient there would be no difficulty in using the word protosulphate. In the case of chloride of mercury this would hardly, perhaps, suffice, and in that case the word *sub* might judiciously be used to distinguish the sub-chloride, although the word *sub* would then be used not in a strictly analogous sense to that in which it was applied to acetates and carbonates, basic salts, but would be applied in an exceptional manner to an exceptional substance, to fulfil an exceptional purpose. One other remark with reference to the modification of bodies by means of suffixes or affixes. Such terminations as mercur*ous* and mercur*ic* lent themselves very well to express the composition of bodies, much better indeed than the prefixes *per* and *proto*, but yet the argument seemed a very fair one which had been raised by Professor Attfield and the President, that for pharmaceutical purposes these names were scarcely practicable. In the two sulphates of iron, the persulphate and protosulphate, it was scarcely possible to distinguish between the sulphate element of the two by any mode of reaction whatever, and thus the part which was distinguished in name was hardly distinguishable in fact; whereas the part not distinguished in name—the iron—it was well known was in the two states known as ferrous and ferric, more dissimilar than the two metals nickel and cobalt, or even than nickel and iron. Therefore that portion was altered in name which was scarcely found to be altered in any way in its properties, while those things remained the same in name which were really most distinct. He could not therefore approve of such names for chemical purposes; but still, considering the difficulties which had been raised with regard to the practice which physicians adhered to of curtailing names, he did not see that in pharmacy any better plan could be adopted.

Dr. Quain said he had listened to both the paper and the discussion with the greatest pleasure. He had come not to take any part in the discussion, but simply in a conservative capacity, intending, if he heard any proposals for rashly changing names, which he was very happy to state he had not, humbly to protest against it, for nothing was more deprecated by physicians than to find the names of the materials with which they worked, altered, whilst the materials themselves remained the same. It might be true that "the rose would smell as sweet by any other name," but if the same drug were presented to a patient by a different name, in many cases they would not believe it had the same action. And not only so, but when scientific chemists were constantly, and of necessity he admitted, changing the names of bodies in accordance with the views they formed of their composition, it was sometimes very hard for practical physicians to keep up with them. As had been said repeatedly, names should be short, clear and expressive; and if they were so, and persons knew what was meant, whether it was, for example, black antimony, or tartarated iron, these names were just as good as if they were called by the long high-sounding titles that had been mentioned. For his own part, he should say the simpler the name the better, and if possible, whenever a new edition of the Pharmacopœia was issued, he hoped the names would be made still simpler and more expressive, always keeping in view that a minimum of change was desirable. With regard to the time when a new edition might be looked for, he hoped it would be a long time yet; and considering the great favour with which the present edition, prepared under the supervision of Dr. Redwood, had been received, he saw no reason to believe it would be soon superseded. At the same time he thought it advisable that any proposed changes of names should be brought forward and discussed early, in order that there might be less difficulty when the time for a new edition did come.

Mr. Groves said it was the common practice of prescribers to write both diluted hydrocyanic acid and diluted hydrochloric acid as *acid hydroc.*, which sometimes occasioned a difficulty. He suggested the propriety of going back to the old name prussic acid. *Acidum prussicum dilutum* was perfectly definite, and expressed no theoretical notions.

Dr. Redwood thought the great objection to that would be that it was too readily understood by patients. The same difficulty had been urged in other cases.

Mr. Groves said he believed the public were getting so wide awake that they recognized hydrocyanic acid as easily as prussic acid.

Professor Attfield, in reply to the observations which had been made, said his paper was divided into two distinct portions; five-sixths related to the alteration in the names of salts of the alkali-metals and alkaline earth-metals, and the other sixth to certain exceptional alterations, and it was peculiarly gratifying to him to find that his remarks on the nomenclature of the alkaline and earthy salts were pretty much confirmed by every speaker. Most of the exceptional alterations had been introduced with the view of starting a discussion on certain unsatisfactory names; he was quite willing to leave several of these names as they stood.

The Chairman said he could not help thinking he had seen during the last few years more or less inclination to call things by their wrong names. Certain preparations had been called by definite chemical names which did not really answer to their composition, and thus a practice had grown up which was a disgrace to pharmacists, and the alteration of which would certainly be attended with great advantage.

Oxyhydrogen Light.—The *Scientific American* states that a prism cut out of the mineral dolomite may be substituted with advantage in place of the lime cylinders now generally employed. As dolomite is an abundant rock, its application in this way may prove useful for purposes of lighting.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Tenth General Meeting of the Session was held at the Royal Institution on Thursday evening, the 30th March; the President, Mr. JOHN ABRAHAM in the chair.

Donations of periodicals to the Library were announced, and votes of thanks accorded to the donors.

Mr. S. G. HILDITCH called attention to the presence of phosphate of lime in animal charcoal. He thought the formula given in the Pharmacopœia for the manufacture of pure animal charcoal was incomplete, and suggested the necessity of testing for phosphate of lime before using it for chemical investigation. He promised to make further experiments and report at a future meeting. Mr. E. Davies, F.C.S., had made several experiments, and found it was not an easy matter to rid the animal charcoal of this impurity.

The paper for the evening, on "The Nomenclature of the Natural Sciences," by Mr. Charles Symes, Ph.D., etc., was read by Mr. ALFRED H. MASON, F.C.S., in the unavoidable absence of the author.

Mr. E. DAVIES, F.C.S., was glad to find that the science with which he was associated had merited praise from Dr. Symes for its system of nomenclature; there had not been so many difficulties to contend with as in some of the other sciences, as old names were changed before the great mass of new chemicals were introduced. He thought it would be a difficult matter to alter nomenclature, and in some cases not desirable. Take British Ferns, for instance, with their many varieties, alteration would not make their nomenclature more expressive. Mineralogists had the greatest difficulties to contend with; and it was there, where reform was most wanted, he thought it would be unwise to make changes upon individual authority.

The PRESIDENT thought some minerals might be described by their chemical composition. He could not see any objection to the nomenclature of diatoms being associated with the name of the first exhibiter of them. Speaking of chemistry, he regretted to note the changes in nomenclature which had taken place of late years; take, for instance, chlorides of mercury. Chemists differed in their nomenclature; for instance, sulphate of soda might be called sulphate of soda, sulphate of sodium or sodic sulphate.

Mr. DAVIES thought the change in chlorides of mercury was a very desirable one, as we now had definitely mercuric chloride and mercurous chloride.

The Secretary was instructed to convey a unanimous vote of thanks to Dr. Symes for his paper and the meeting closed.

MEETINGS FOR THE ENSUING WEEK.

MONDAY April 17.	*Medical Society*, at 8 P.M. *London Institution*, at 4 P.M.
TUESDAY April 18.	*Royal Institution*, at 3 P.M.—"On the Geology of Devonshire, especially of the New Red Sandstone." By W. Pengelly, F.R.S.
WEDNESDAY April 19.	*Society of Arts*, at 8 P.M.—"The Economical Construction of Workmen's Dwellings." By J. H. Stallard, M.D.
THURSDAY April 20.	*Royal Society*, at 9 P.M. *Linnean Society*, at 8 P.M. *Chemical Society*, at 8 P.M.
FRIDAY	*Royal Institution*, at 8 P.M.
SATURDAY	*Royal Botanic Society*, at 3.45 P.M.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

VACANCIES.

A Competitive Examination for two appointments as Navy Dispensers, with care of stores, will be held on the 25th April. For particulars, see p. 828.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department, 17, Bloomsbury Square, W.C., and not to the Publishers.*

[186.]—BAKING POWDER.—I see in your number for March 11th that "*Farina*" wishes for a good form for baking powder. The following is one I can confidently recommend, as I frequently have pastry, etc. made from it, besides which it is inexpensive.

R. Sodæ Carb. Exsicc. ℥viij
Acid. Tart. Exsicc. ℥vj
Pulv. Curcumæ ℥j
Magnes. Carb. Levis ℥ij

Mix. The soda and acid must be properly dried before mixing the other ingredients, otherwise the powder spoils by keeping. To be kept in stoppered bottles.—A. T. GIRDLER.

[193.]—LIQ. OPII SEDATIVUS.—An excellent formula for the above is given by Mr. T. B. Groves, F.C.S., in the PHARMACEUTICAL JOURNAL for January, 1869; but, as some readers may not be able to refer to it, I send an abridgment.

Opium, in coarse powder, $1\frac{1}{2}$ oz.
Prepared Chalk, $\frac{1}{4}$ oz.
Rectified Spirit, 5 oz. (f.)
Distilled Water, q. s.

Boil gently for half an hour the opium and chalk with one pint of distilled water; filter; wash up to 15 oz. and add the spirit. After a few days' repose filter again. It improves by keeping. Of course, the finer the opium the better the liquor. This is of the same strength as tr. opii, B. P.—A. P. BAKER.

CONDITION POWDER.

Take of Fenugreek, in powder, 16 parts.
Sulphur, in powder, 8 parts.
Cream Tartar,
Liquorice Root, in powder,
Nitrate of Potash, in powder, of each, 4 parts.
Black Sulphuret of Antimony, in powder, 2 parts.
Gentian Root, in powder,
Anise Seed, in powder.
Common Salt, in powder, of each, 1 part.

Mix.—*Pharmacist.*

[220.]—DISPENSING.—The following is a copy of a prescription brought to me, whilst living in Sussex, to be dispensed:—

R. Quiniæ Sulphatis ℈ij
Acid. Hydroch. Dil. ʒivss
Pot. Iodid. ʒiiss
Tinct. Iodi ʒiij
Syr. Aurant. ℥iv
Spt. Chlorof. ℥ii
Aq. ad. ℥viij. M.

Ft. Mist. cujus sumat coch. j mag. ex cyath. vinos. aquæ bis in die.—H. H. S.

The price I charged was 4*s*. 6*d*. Will any of your readers kindly inform me how they would prepare it?—G. C. ALLEN.

[221.]—SULPHATE OF LIME.—Can any commercial use be made of the sulphate of lime left after making the carbonic acid gas?—N.

[222.]—TINCT. COLOCYNTH.—*J. S.* would like to be supplied with a receipt for preparing tinct. colocynth.

[223.]—LIQUID GOLD.—Will any reader inform me how to make a liquid gold for lettering on metal?—C. J. B.

[224.]—GENERAL HAMILTON'S TOOTH POWDER (a preparation of some twenty years ago).—*X. C.* will be obliged for a recipe for the above.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Poison Regulations.

Sir,—The decision of the Council at their last meeting "to issue the regulations simply as recommended by the Society" will give general satisfaction, and is a great relief to us all.

The most objectionable part of the proposition being thus withdrawn, we can now discuss the matter more calmly, and it is to be hoped we may produce some plan that will be acceptable to all. The chief objection now to the regulations is, that they apply to numerous articles which require no special care in keeping them, and to many which it would be almost impossible to keep under any of the proposed systems. There is no doubt that cantharides, ergot, oil of savin, tartar emetic and chloroform were not included in the schedule on account of their *poisonous* properties, but because they had been, or might be, used for improper purposes, and were put into the list of poisons simply in order to limit their accessibility to the public; and it is clearly unnecessary to apply the regulations to the keeping of them or their preparations.

Then with regard to vermin killers, red and white precipitate, oxalic acid, opium and others, which are commonly kept weighed ready for retail sale,—the very object of their being so kept ready is to prevent delay in serving customers; and no man could *really* keep these articles according to the regulation, whatever *pretences* of doing so he might adopt. Further, with regard to many of the "preparations" of opium, belladonna and others not particularly dangerous, but in frequent use as medicines, it is by no means desirable either to acquaint the public with their dangerous qualities, or to alarm timid customers unnecessarily by placarding them as poison.

I would, therefore, suggest that the regulations should only apply to the more dangerous articles, and would propose, that in the keeping of poisons the following precautions be recommended:—

1. That every box, bottle, vessel, or package in which any poison is kept, be distinctly labelled with the name of the article it contains; also, that every box, etc., containing arsenic or its salts, prussic acid, the poisonous alkaloids and their salts, metallic cyanides, oxalic acid, corrosive sublimate, white precipitate, liniments of aconite and belladonna, ess. oil of bitter almonds and laudanum, be labelled "Poison."

2. That the poisonous alkaloids and their salts, prussic acid, liniments of aconite and belladonna, be kept in dark blue bottles with red or orange-coloured labels.

3. In dispensing the prescriptions of medical practitioners, all liniments, lotions and embrocations containing poison be sent out in bottles distinguishable by touch or colour from ordinary medicine bottles, and that the labels used be red or orange.

By the foregoing plan every really dangerous article is subject to special precaution, which may be adopted, and the use of such further precautions as each person may think desirable is not prevented. The use of blue bottles and red labels is suggested for the sake of uniformity, and because they are becoming very generally adopted for dangerous articles.

Should, however, the plan now proposed be considered not sufficiently extended, the proposition of the Council may be shorn of most of its objectionable features by the following alterations:—

Proposed Recommendations as to the Keeping and Dispensing of Poisons.

1. That in the keeping of poisons each bottle, vessel, box, or package containing a poison be distinctly labelled with the name of the article, and that each bottle, etc. containing arsenic, prussic acid, the poisonous alkaloids or their salts, metallic cyanides, oxalic acid, corrosive sublimate, white precipitate, liniment of aconite and belladonna, ess. oil of bitter almonds and laudanum, be labelled "poison."

2. Also, in the keeping of poisons, that prussic acid, the poisonous alkaloids and their salts, liniments of aconite and belladonna, be kept on one or other of the following systems, viz.:—

(*a*) in a bottle tied over, capped, locked or otherwise secured in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop, or dispensary; or

(*b*) in a bottle or vessel readily distinguishable by touch or colour from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop or dispensary; or

(*c*) in a bottle, vessel, box or package kept in a room or cupboard set apart for dangerous articles.

3. In dispensing the prescriptions of medical practitioners, all liniments, embrocations, and lotions containing poison be sent out in bottles readily distinguishable by touch or colour from ordinary medicine bottles, and that there also be affixed to each such bottle (in addition to the name of the article, and to any particular instructions for its use) a label giving notice that the contents of the bottle are not to be taken internally.

By either of these plans the object in view, namely, that of guarding against accidents and mistakes, will be secured as far as can be done by any mechanical means; but it should never be forgotten that *reading the labels* is a far more important thing than locks and keys, safety caps and sand-paper, and that if a man neglect that first and most important duty,—reading his labels carefully,—neither poison-cupboards nor angular bottles nor corks set round with pins, nor any other mechanical contrivance will save him from the consequences of that neglect.

Cheetham Hill, April 11th, 1871. W. Wilkinson.

C. J. B.—(1.) The subscription to the Pharmaceutical Society after passing the Preliminary Examination is a voluntary one, and has no connection with the Minor Examination. Apply to the Secretary for a prospectus. (2.) The name of the informant would not be disclosed.

"*Somerset.*"—We consider any sum under £100 very moderate. No master who does his duty conscientiously can afford to devote the necessary time for a less remuneration than the amount named.

W. W.—Reasonable service only can be lawfully exacted. What is "reasonable" would be determined by the character and usages of the trade, which differ much in every town. Lay your grievances before your master, and ask him for as much consideration as circumstances will afford. If he decline to entertain your proposals, state your case to some solicitor, clergyman or medical man, with a request to act in a friendly way as arbitrator between yourself and your employer.

"*Cerium.*"—We believe such bottles may be obtained of any dealer in medical glass.

J. B. should apply at the College of Surgeons.

W. S. M.—(1.) We do know. (2.) Blaine's 'Outline of the Veterinary Art,' published by Messrs. Longmans.

"*A Student.*"—(1.) No. (2.) Because the ammonia citrate is the solvent of the oxide of iron. (3.) Saxony. (4.) The foreign metals are oxidized and separated in the slag formed.

"*Boiler*" has omitted to send his name and address.

The following journals have been received:—The 'British Medical Journal,' April 8; the 'Medical Times and Gazette,' April 8; the 'Lancet,' April 8; the 'Medical Press and Circular,' April 12; 'Nature,' April 6; the 'Chemical News,' April 7; 'Journal of the Society of Arts,' April 5; 'Gardeners' Chronicle,' April 8; the 'Grocer,' April 8; 'Produce Markets Review,' April 8; the 'English Mechanic,' April 7; the 'Practitioner' for April; the 'Canadian Pharmaceutical Journal' for March; the 'Philadelphia Medical and Surgical Reporter,' Nos. 730–732; the St. Neots Chronicle, March 25.

Communications, Letters, etc., have been received from Mr. J. E. Howard, Dr. De Vry, Mr. T. Collier, Mr. E. K. Campbell, Mr. Hustwick, Mr. T. Buck, Mr. C. Ekin, Mr. M. C. Cooke, Messrs. M'Master, Hodgson, and Co., Mr. T. Lowe, Mr. J. T. Newey, Mr. C. Eve, Mr. W. W. Stoddart, T. P. B., J. W., C. E. L. N., "A Country Member," "Moelline."

THE PARIS SCHOOL OF PHARMACY.

BY WALTER HILLS.

During a stay last year in Paris, I had an opportunity of working for three months in one of the laboratories of the School of Pharmacy in that city. It is probable that very few of those interested in pharmacy, who have visited Paris, are acquainted with the old edifice in the Quartier Latin, bearing the name "l'École Supérieure de Pharmacie." The following remarks, therefore, concerning this institution, and the kind of study carried on in it may be of interest:—The building, which is situated near the Panthéon, is unpretending—in fact, rather ugly; but I hear that it is proposed to erect a more commodious school. One-half of the botanical gardens, by which it was surrounded, has lately been taken for a new faubourg or boulevard, thus affording a proof that not even the abode of science is respected by the agents of Haussmann. There is a museum, similar to that at Bloomsbury Square, which is always open to the public, and a not very extensive library which is open every day from twelve to four o'clock; most of the volumes are kept under lock and key, thus necessitating an application to the librarian, on the part of the student, for the book required.

The full term of study being three years, there are three sets of laboratories. The first year's men occupy themselves with the manufacture of chemical and pharmaceutical preparations; the second with physics, and the third with analysis. These laboratories are only open to the regular students, viz. those who are following the whole curriculum; consequently, I, as a visitor, had some difficulty in gaining admission, but after numerous applications to the secretary, and writing to the Minister of Public Instruction, I was at last, thanks to Professor Soubeiran, allowed, on the payment of £4, to work in either of the three laboratories. I chose that of the third year, which is under the direction of M. Personne, and it being then about Easter, there remained twelve weeks' work, previous to the half-yearly examinations which commence about the third week in July, the subsequent vacation lasting till the commencement of November.

The laboratory for students in their third year is open every day (except Thursday) from twelve to four o'clock. Once a fortnight, there is a lecture by the managing director, stating the work to be pursued, and the methods employed for the following two weeks. All the necessary apparatus and chemicals are provided, but the students are arranged into groups of three or four, each group possessing one set of apparatus, which is continually changed according to the work to be done. This arrangement has a disadvantage, as in many cases two of the same group cannot occupy themselves at one time on the same analysis, and the old adage is exemplified "first come, first served." I should think there were about sixty or eighty students on the books of the third year, but I never saw more than about twenty working at the same time. I now give the heads of the work of each week.

1871, *le* 25 *Avril.*

1. Recherche de phosphor dans une matière organique.

4. Examen microscopique et chimique de diverses farines, pures et mélangées.
5. Recherche d'un alcaloïde dans une matière alimentaire.
6. Recherche de plusieurs métaux.

I hope on another occasion to give a few particulars of the lectures, examinations, etc., held at the School of Pharmacy.

BRISTOL PHARMACOLOGY.

BY W. W. STODDART, F.C.S., F.G.S.

(*Concluded from page 663.*)

Nat. Ord. Rhamnaceæ.

This Order is interesting to the pharmaceutist because it comprises several plants of great repute in earlier times. One of these is the Jujube-tree (*Rhamnus zizyphus*), whose plum-like fruit originated the well-known jujubes, which at first were formed from the juice, made into a proper consistence with gum and sugar, and extensively sold in Spain and Italy. Those now sold are only a very indifferent imitation. Another member of this Order claims to be the tree from which our Saviour's crown was made. Homer (Odyss. ix. 94) speaking of one genus, the *Zizyphus lotus*, says it furnished a juice so delicious, that for its enjoyment men would forsake their homes, country and friends.

Rhamnus catharticus (Linn.)

Is the only plant now retained in our Pharmacopœia, though why such an agent is continued in that work must be left to its compilers. Its use is confined to dogs and infants, whose cries have often borne testimony to its torturing effects on the intestines. Its use can certainly never be recommended except for punishment.

The Buckthorn occurs abundantly in the hedges around Bristol, and fine examples may be gathered at Hanham and Filton.

Its dark purple berries yield a large quantity of juice, which, boiled down with spices and sugar, forms the syr. rhamni of the B.P.

The pigment termed sap green is made by evaporation of the juice and treatment with lime.

The chemistry of the Buckthorn has never been satisfactorily worked out. According to M. Biswanger the juice contains rhamnin, rhamno-cathartin, colouring matter and gum. Rhamnin ($C_4H_{16}O_9$) is a yellow crystallizable substance, very soluble in boiling alcohol, but insoluble in ether and cold water, soluble in alkalies, but precipitated again by acids. Rhamno-cathartin is bitter and uncrystallizable, and remains after the rhamnin has been separated. It forms a yellowish, translucent mass, yields picric acid with nitric acid, and unlike rhamnin, is very soluble in water.

Nat. Ord. Leguminosæ.

This large and extensive group of plants, although containing the names of a great number with useful and medicinal qualities, yet, with one exception, is indigenous to foreign localities. From it we obtain our indigo, logwood, liquorice, gum arabic, tragacanth, catechu, kino, sandalwood, senna, cassia and copaiba. This Order is said to comprise from 6000 to 7000 species.

Sarothamnus scoparius (Wimmer).

This is the only Bristol representative of the *Leguminosæ* used in medicine. It is very common in many places. Both the yellow and white varieties may be gathered at Cook's Folly, St. George's, Stapleton, Hanham and Brislington. This pretty and attractive plant seems to delight in dry heaths and hilly ground.

> "It minds me of my native hills,
> Clad in the heath and fern;
> Of the green strath and flowery brae,
> Of the glen and rocky burn."

There seems to be some uncertainty to which of the chemical constituents Broom owes its well-known diuretic properties. Dr. Stenhouse attributes them to scoparin. The ashes, like those of most land plants, contain a large percentage of potassic carbonate. One pound of Broom tops will yield ninety grains of that salt.

When dec. scoparii is evaporated to one-tenth of its bulk and laid aside for twenty-four hours, it forms a kind of jelly. This gelatinous mass is thrown on a filter and well washed with cold water. The filtrate, when distilled with an excess of soda, yields a colourless oil, which collects at the bottom of the receiver. This is spartein ($C_{15}H_{26}O_2$), an oily, viscid base. It is sparingly soluble in water and possesses narcotic properties. Four grains will kill a large rabbit.

Scoparin ($C_{21}H_{22}O_{10}$), before mentioned as the probable diuretic principle, is obtained from the residue on the filter, after the separation of spartein. The residual jelly is boiled with water, slightly acidulated with hydrochloric acid, filtered, evaporated and set aside to crystallize, which it does with considerable difficulty. Yellow acicular crystals are formed, having neither taste nor smell. Sparingly soluble in cold water, but readily so in alkaline solutions.

Nat. Ord. Rosaceæ.

This extensive Order contains a great variety of plants in constant use among pharmaceutists.

Some of them are poisonous from the large quantity of hydrocyanic acid they contain; others are remarkable for delicious ethers, which render them esteemed among our choicest fruits, as Almonds, Peaches, Nectarines, Apricots and Plums. The only truly indigenous member of this family used in our materia medica is the Dog-rose.

Rosa canina (Linn.).

This well-known and ornamental plant is familiar to every observer of our hedgerows by its pink and white flowers, guarded by hooked prickles, reminding one of Clare's country maiden, who—

> "Eager scrambled the Dog-rose to get
> And woodbine flowers at every bush she met."

Both Hippocrates and Pliny speak of the κυνόροδον, or Dog-rose, so named, it is said, on account of its efficacy in curing the bite of a mad dog.

The part of the plant used in medicine is the fruit, which has for many years past been employed in making the conserve of hips, a useful ingredient in electuaries and tinctures, as well as an excipient in pill masses.

Nat. Ord. Umbelliferæ.

This extensive group comprises a vast number of plants, all differing in well-marked properties. Some are famed for their esculent qualities, as the Carrot, Parsnip, and Celery. Some afford a milky juice hardening into a strong-smelling resin, as assafœtida, ammoniacum, galbanum, and opoponax. Some are extrely poisonous, as Hemlock. Others supply essential oils, well known for their carminative properties, as Caraway, Anise, and Dill. These oils are very interesting. Many of them, although produced from distinct genera, have the same chemical characters, and form a distinct series. The oils of Anise, Fennel and Dill are examples; they consist of one-fifth of hydrocarbon isomeric with oil of turpentine ($C_{12}H_{16}$), and four-fifths of a solid crystallizable compound ($C_{16}H_{12}O$), sometimes called anise camphor. This it is which is so abundantly deposited when ol. anisi is affected by a cold atmosphere. The fruits of every genus are so singular and constant in their configuration, that the name may be readily ascertained. The fruit is composed of two carpels adhering to a central stalk. Each carpel is marked by five ridges separated by vittæ or channels. A transverse section placed under the microscope shows these vittæ filled with essential oil in a very beautiful manner.

Conium maculatum (Linn.).

This plant is familiar, in name at least, to all classical students, as being the poison used for destroying Athenian criminals. It is thus supposed to have caused the deaths of Socrates, Phocion and Theramenes. The name *Conium* is derived from the Greek κώνειον.

The Hemlock is found in damp places, such as the banks of the Avon, at Shirehampton and Hanham, at Bishport, Horfield, Stapleton, Bedminster, and Westbury-on-Trym.

Conium was called by the Romans cicuta; hence probably arises a very common confusion between the true Hemlock and the spotted Cowbane of North America (*Cicuta maculata*). The fruit of the former differs in the deeply-furrowed albumen. Hemlock is said to be poisonous to all animals except sheep.

The proper time for collecting Hemlock is just after flowering and when the fruit is beginning to form; before that time the active principle is not so fully developed.

Conium maculatum is known at once by the smooth stem and dark purple spots. All parts of the plant when bruised have the odour of mice, especially when moistened with liq. potassæ. This is evidently caused by the evolution of ammonia, and is exactly similar to the odour given off when crystallized nitrate of ammonia is melted.

The *Conium* owes its active properties to two alkaloids, conin and conhydrin.

Conin ($C_8H_{15}N$) is a volatile liquid, with ·89 sp. gr. showing an alkaline reaction with turmeric, and has a horribly repulsive smell like tobacco, but when diluted, like mice. This smell disappears when united to an acid, and a neutral salt formed. It is prepared by distillation with lime or potassic carbonate when ammonia, conin and conhydrin pass over.

Conin is very slightly soluble in water, but when dissolved in four parts of alcohol is miscible in all proportions. Its vapour is inflammable. Conin is most abundant in the seeds. Six pounds of unripe seeds or nine pounds of ripe seeds yield one ounce of conin. When the leaves are dried, all the conin volatilizes, so that they are useless as medicine. For the same reason, most samples of extract. conii are inert. A large number taken from several shops would not even give any odour of conin when treated with liq. potassæ. During the preparation of the extract, the evolution of ammonia may be plainly detected. One cwt. of the leaves yields about 4 or 5 pounds of extract.

The other alkaloid, conhydrin ($C_8H_{17}NO$), as its name denotes, is the hydrate of conin. During the preparation of the latter, conhydrin crystallizes in extremely thin, pearly and iridescent scales. When heated with three times its weight of phosphoric anhydride, it is decomposed into conin and water.

Nat. Ord. Caprifoliaceæ.

The Honeysuckle group is not now so much used as it once was by the pharmaceutist, only one being named in the Pharmacopœia.

Sambucus nigra (Linn.).

The flowers are used in the preparation of the water and ointment, to both of which they give a pleasant perfume. The Elder is very common throughout the district, both the usual ovate-leaved and the variety with the more finely divided leaves.

The flowers contain a volatile oil which is very soluble in water. The best method of obtaining it is to distil the flowers with as small a quantity of water as possible. Then saturate with chloride of sodium, shake with sulphuric ether and evaporate. The essential oil of Elder is colourless and solidifies at zero.

The berries contain malic acid, but the bark contains valerianic acid. The pith is a well-known microscopic object, and is extremely useful for polishing the glass of optical apparatus.

Elderberry juice is used for the adulteration of port wine, or for making a factitious substitute.

The presence of the juice in port wine is easily detected by the precipitate from cupric or plumbic acetate. The spectrum is also very distinct after the addition of alum. According to M. Fauré sophistication by elderberry juice in red wines may be detected by tannin and gelatine.

A little gelatine is dissolved in the wine and precipitated by the tannin; if the wine be genuine, all the colouring-matter is also thrown down, whereas that of the elder-juice is still kept in solution.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Ferri Peroxidum Humidum.—Solution of persulphate of iron is diluted with distilled water and poured with constant stirring into solution of soda. The brown precipitate which forms is collected, washed thoroughly to free it from sulphate of sodium, drained and preserved in the moist state. (See Ferri et Ammon. Cit.)

This preparation is employed as an antidote to arsenic; an insoluble ferrous arseniate together with ferrous hydrate being probably formed :—

$$2\,Fe_2\,6\,H\,O + As_2\,O_3 = Fe_3\,2\,As\,O_4 + Fe\,2\,H\,O + 5\,H_2\,O.$$

To be effective it must be freshly prepared, since ferric hydrate loses the elements of water even when preserved, as in this case, in contact with excess of water. The hydrates form a class of salts which are by most chemists regarded as compounds of the radicle $H\,O$ with the metals. Some of them are, however, so readily resolved into the corresponding oxides and water, that they may possibly be only molecular combinations. For example, ferric hydrate may be written $Fe_2(H\,O)_6$ or $Fe_2O_3, 3\,H_2O$. With the exception of the hydrates of the alkali metals, they are, as a general rule, insoluble in water. Graham, however, prepared soluble modifications of many of them, such as ferric and aluminic hydrates, by submitting solutions of the chlorides to dialysis. In the case of ferric chloride, a red transparent liquid remains on the dialyser. It is probable that this contains the real hydrate, $Fe_2\,6\,H\,O$, capable of existing only in solution, and that all the solid forms which we obtain as precipitates are in reality oxyhydrates.

Ferri Peroxidum Hydratum.

$$Fe_2\,O_2\,(H\,O)_2 \text{ or } Fe_2\,O_3,\ H_2\,O.$$

Moist hydrate of iron is dried at a temperature of 212° until it ceases to lose weight.

This seems to be one of the most stable and definite of the hydrates of iron. [§ Heated to dull redness in a test-tube, it gives off moisture.] The residue is $Fe_2\,O_3$: this test shows that it has not been dried at too high a temperature. When such is the case, the preparation ceases to be easily soluble in acids.

A brown ferric oxyhydrate is commonly sold in the shops under the name of "carbonate of iron." This is generally prepared by precipitating a solution of ferrous sulphate with carbonate of sodium, and exposing the resulting ferrous carbonate freely to the air during washing. It then absorbs oxygen and loses carbonic anhydride. It generally retains a minute quantity of unchanged ferrous carbonate, and so effervesces when treated with acids.

Ferri Phosphas.—[§Phosphate of iron, $Fe_3\,2\,P\,O_4$, partially oxidated.]

A solution of sulphate of iron is mixed with a solution of phosphate and acetate of sodium. The precipitate is collected and washed, to free it from the acetic acid and sulphate of sodium which are retained in solution. The use of the acetate of sodium and the nature of the reaction are explained under ferri arsenias, which is prepared in a manner precisely similar.

[§ A slate-blue amorphous powder insoluble in water, soluble in hydrochloric acid. The solution yields a precipitate with both the yellow and red prussiate of potash, that afforded by the latter being the more abundant (because the salt is essentially ferrous); and when treated with tartaric acid and an excess of ammonia, and subsequently with the solution of ammonio-sulphate of magnesia, lets fall a crystalline precipitate.]

This precipitate is $Mg\,N\,H_4\,P\,O_4\,6\,H_2\,O$; the arseniate gives an analogous compound of similar appearance, $Mg\,N\,H_4\,As\,O_4\,6\,H_2\,O$. [§ When the salt is digested in hydrochloric acid with a lamina of pure copper, a dark deposit does not form on the metal.] This test shows that it is not the arseniate. [§ 2 grains dissolved in hydrochloric acid continue to give a blue precipitate with red prussiate of potash until 25 cubic centimetres of the volumetric solution of bichromate of potash have been added.] This would indicate the presence of ·895 gram of ferrous phosphate in the 2 grams, or 44·75 per cent.

One molecule of red chromate will convert two molecules of ferrous into ferric phosphate. Ferric phosphate has the formula $Fe_2'''\,2\,P\,O_4$; it is not now used in medicine.

The syrup of phosphate of iron of the Pharmacopœia is a solution of ferrous phosphate in dilute phosphoric acid with sugar, but the proportion of phosphoric acid ordered is too large.

The deepening of colour to which this preparation is liable is often referred to change in the sugar, under the influence of the acid present; it generally arises, however, from the phosphate of iron, owing to having been imperfectly washed, retaining small quantities of acetic acid or an acetate. As oxygen is absorbed, ferric acetate is generated, and betrays itself by its deep brownish-red colour.

Ferri Sulphas.—Iron wire is dissolved in dilute sulphuric acid, aided by a gentle heat; and when the effervescence caused by the escape of the hydrogen ceases, the liquid is filtered and set aside to crystallize—

$$Fe + H_2\,S\,O_4 = Fe\,S\,O_4 + H_2.$$

Undiluted sulphuric acid has scarcely any action upon iron in the cold; but, when water is added, hydrogen gas is freely evolved. The same is the case with zinc.

In former Pharmacopœias the green vitriol of commerce was employed as the source of the sulphate of iron. It was ordered to be redissolved in water, a small quantity of sulphuric acid added, and the solution digested upon some iron wire. In this way the brown rusty ferric oxysulphate, which is always present, is reduced to the ferrous state by the hydrogen which the iron wire evolves from the sulphuric acid. Thus—

$$Fe_2\,(S\,O_4)_2\,O \;+\; H_2\,S\,O_4 \;+\; Fe \;=\; 3\,Fe\,S\,O_4 \;+\; H_2O.$$

The common green vitriol of commerce, being prepared from pyrites, generally contains more or less copper; this may be removed by digesting it in solution upon scraps of iron; but it is far better to prepare pure sulphate of iron for medicinal purposes by the official process.

Sulphate of iron should be in pale greenish-blue, not deep green, crystals; it should give a nearly white or light blue precipitate with yellow prussiate of potash. It should also give no precipitate with sulphuretted hydrogen, which would show its freedom from copper. A better test for copper is to dissolve some of the crystals in distilled water, and immerse in the solution a clean knife-blade; if copper is present, it will be deposited as a metallic coating upon the iron.

SULPHO-CARBOLATES.

BY T. H. HUSTWICK.

From communications to this and other journals on the preparation of some of the above salts, I have gathered that the formation of sulpho-carbolate of zinc is best accomplished by a process of decomposition or displacement. In a late number of this Journal (No. 39) is given a process for the preparation of this salt by decomposing sulpho-carbolate of lead by metallic zinc; doubtless the salt of zinc thus formed is of great purity, but is it not possible that a salt of equal purity may be obtained by direct combination, saving both time and trouble? My own experience leads me to suppose that it may. I have made considerable quantities of sulpho-carbolates, and the *modus operandi* followed by me has been, in its essentials, that recommended by Mr. C. H. Wood in this Journal (Vol. X. 2nd ser. No. 7); this process, however, gives a salt more or less coloured and less crystallized than when pure. Where one of the alkalies or alkaline earths is the base, nothing more is required than to evaporate the neutral solution so far as to produce a good crop of crystals; these are to be well drained and redissolved for a second crystallization. For the zinc salt I have saturated the diluted acid with the oxide, evaporating the solution till, when quite cold, a nearly solid mass of crystals is left in the bottom of the basin: this reddish-coloured magma is well broken up and allowed to rest a short time, when the supernatant liquor may be removed, the remainder placed in a calico cloth and strongly pressed, by which a further quantity of red mother-liquor is got rid of, leaving a cake of sulpho-carbolate nearly pure; this, when again dissolved, filtered and sufficiently evaporated, yields the salt in a state of purity far surpassing any other sample I have ever seen. As the expressed cake is so nearly pure, almost the whole of it may be recovered by further evaporation. This procedure applies equally to iron and copper. To obtain the copper-salt, the diluted acid is saturated with freshly-prepared moist carbonate of copper, producing a beautiful intensely green solution, which, no doubt will make an excellent colour for druggists' show-bottles. The crystals, when large, are a brilliant blue, and form clusters of great beauty, but difficult to obtain as single crystals; when small, they are green, probably from containing less water of crystallization.

The iron salt was obtained by the action of the acid on fine iron wire; the colour of the crude solution is a most intense violet, and, like that of copper, would doubtless make a good colour for show-bottles. The expressed cake, though almost white, when dissolved, reproduces the characteristic violet in almost its original intensity; the crystals produced from this solution are violet-green, the green predominating; before their removal from the evaporating basin, they should be carefully washed with ice-cold water by means of a syringe, in order to free them from the coloured mother-liquor which adheres with great pertinacity. A peculiarity of this salt is, that a freshly prepared solution is almost colourless, and without a trace of violet, but as it absorbs oxygen, peroxide of iron is precipitated, the violet tinge once more appears, and increases in intensity till it almost equals, in that respect, the crude solution.

These salts are all easily prepared, are very stable, and as they crystallize from pure solutions with great facility, and into regular geometric forms, they make capital show-objects. Some crystals of the calcium salt that I now have are perfect rhombs. The way in which all these solutions, during the progress of crystallization, climb up and over the sides of the basin, by the force of capillary attraction, is rather astonishing, unequalled, as far as my observation goes, by any other compound; it is rather a nuisance, but may be completely prevented by slightly greasing the inside edge of the vessel. Into the chemical part of the question it is not my purpose to go, but the remarkable changes exhibited by some, at least, of the sulpho-carbolates, under the action of high temperatures, shows there is room for further investigation. Exposed to the heat from a Bunsen's burner, the soda and potash salts exhibit all shades of colour from pale pink to intense purple; and afterwards placed on the glowing embers of a bright fire, combustion takes place in a very similar manner to the old Pharaoh's serpents, leaving an ash equally bulky and eccentric.

AN ALKALOID FROM CINCHONA BARK HITHERTO UNDESCRIBED.

BY DAVID HOWARD, F.C.S.

In experimenting upon impure crystallizations of quinine salts obtained from the mother-liquors of the manufacture of sulphate of quinine, I have occasionally been perplexed by an unusual loss in recrystallizing, which the mechanically adhering mother-liquor did not seem to account for.

A more careful examination of some of these substances shows that the cause, in some cases at least, is the presence of an alkaloid hitherto undescribed, the extreme solubility of the salts of which, both distinguishes it at once from the cinchona alkaloids already known, and renders it very difficult to separate from the uncrystallizable quinoidine.

The most convenient method of obtaining it is to purify the alkaloids contained in the mother-liquor from the recrystallization of such impure products as I have mentioned, by solution in ether, and after evaporation of the ether to dissolve with oxalic acid in as small a quantity of water as possible, and allow it to crystallize.

The oxalate thus obtained may be purified by recrystallization from water, with addition of animal charcoal, but I have never been able to free it entirely from a yellow colour.

The most satisfactory salt for analysis is the platino-chloride, which is prepared in the usual manner; it is almost insoluble in water or in cold hydrochloric acid, but soluble with difficulty in hot strong acid; it forms a crystalline powder by precipitation, and well-defined crystals by solution in acid.

The analysis shows that it is isomeric with the platino-chloride of quinine, but anhydrous, instead of containing one atom of water of crystallization, given off at 120°, as does the salt of quinine.

The ultimate analysis for which, as well as for the other combustions which I shall have to mention, I am indebted to the skill of Mr. Huxley and Mr. Gray, of the Royal College of Chemistry, gives the following results:—

	C.	H.	Pt.
Experiment I. . .	32·67	3·67	26·63
„ II. . .	32·67	3·82	26·62

Gerhardt's formula for the anhydrous platino-chloride of quinine, $C_{20}H_{24}N_2O_2$, $2HCl$, $PtCl_4$ requires

C 32·60 H 3·53 Pt 26·76

The salt taken for analysis was precipitated from a hot acid solution, and was a distinctly crystalline powder.

The composition is the same whether it be precipitated cold in a neutral solution, or crystallized from a strong acid solution, as the following results will show:—

Platino-chloride precipitated cold .	. Pt	26·50
„ crystallized . . .	.	26·62

The oxalate, as I have before mentioned, though it is the most easily crystallized of the salts of this alkaloid, is unfortunately very difficult to purify entirely, and changes so readily under the influence of air, light or heat, that I have been unable to obtain it colourless. When a dilute aqueous solution is concentrated by evaporation in a water-bath, the change of colour shows that decomposition has, to a certain extent, taken place, and on the addition of water, a brown resinoid matter separates from the solution. To find out if this was caused by impurities or was a property of the salt itself, I decomposed the platino-chloride of known purity by several processes, but in each case the resulting oxalate had the same colour and the same tendency to decompose. Even when prepared from perfectly colourless solutions of the alkaloid in ether, I have still found the oxalate of a greenish-yellow hue, even before the application of heat; in fact, I am not sure that this colour may not be inherent in the salt itself.

It is extremely soluble in water, the wet crystals melting at 100°, but much less so in cold water; insoluble in ether, but very soluble in alcohol, and to a less degree in amylic alcohol, from hot concentrated solutions in either of which menstrua it crystallizes freely on cooling. The water of crystallization is partially given off in vacuo, and entirely at 100° after previous drying; if the salt is at once heated to 100° without previous exsiccation, it is apt to fuse.

The combustion proved exceedingly difficult; the usual process with cupric oxide was found inadmissible, the oxalate assuming a dark brown colour as soon as it touched the oxide. The only practicable method is burning in oxygen gas, and even in this mode of analysis, the low temperature at which the substance partially decomposes, makes it difficult to accomplish successfully. It will be seen that the results, though agreeing very closely among themselves, differ considerably from the probable formula, showing plainly the difficulty of obtaining a pure product.

The hydration and the oxalic acid point to the formula $2(C_{20}H_{24}N_2O_2), C_2H_2O_4 + 9aq.$, the numbers obtained being:—

	C.	H.	$C_2H_2O_4$.	H_2O at 100.	H_2O in vacuo.
Theory . .	56·00	7·55	10·00	18·00	
Exp. I. . .	57·57	8·64	10·07	17·98	14·23
„ II. . .	57·42	8·74	9·98	17·98	14·09
„ III. .	57·74	9·14	10·08	17·89	14·02
„ IV. . .	57·85	8·79	10·23	17·72	13·82
„ V. . .	—	—	10·19	17·98	—

The water lost by drying in vacuo agrees very closely with 7 atoms, viz. 14·00 per cent.

The salt thus differs from oxalate of quinine by three atoms of water of crystallization, the formula of the latter being $2(C_{20}H_{24}N_2O_2), C_2H_2O_4, + 6aq$.

The properties of the other salts which I have examined are as follows:—The sulphate, tartrate, citrate, hydrochlorate, phosphate and acetate are all exceedingly soluble in water; on evaporation in vacuo they form semi-crystalline masses, impossible to obtain in a state fit for analysis.

The hydrobromate and ferrocyanide obtained by double decomposition form oily strata at the bottom of the solution, soluble in an additional quantity of water, but even on long standing they show no sign of crystallization.

The hydriodate also forms an oily stratum in strong solutions, but on standing it becomes semi-solid by the formation of crystals; weaker solutions also deposit a small quantity of flocculent crystals, but in neither case can they be separated from the mother-liquor.

The sulphocyanide, while also forming an oil when in concentrated solutions, crystallizes from a somewhat larger quantity of water in long silky needles, almost white, very soluble, and readily decomposed by heat.

The iodo-sulphate I have not as yet succeeded in forming. I much regret this, on account of the great importance of this salt in the cinchona alkaloids, and further experiments are needed, either to form it or to prove its absence.

The alkaloid itself, as obtained by precipitation from a solution of its salts by potash or soda, is a yellowish oil. I have not been able to obtain it pure in the solid state, for it will not bear heat without decomposition, and holds water too strongly to dry in vacuo. It is very soluble in alcohol, soluble to a large extent in ether, from which it separates as an oil when the ether is allowed to evaporate. It is a strong base; the salts are neutral to test-paper; a small excess of the base strongly restores the colour of reddened litmus. Ammonia precipitates its solutions but imperfectly, and, if we may judge from this it is even a stronger base than quinine.

Chlorine-water followed by ammonia, produces in solutions of its salts the green colour and precipitate of dalleiochin which distinguishes quinine and quinidine. Strong acids, even in the cold, produce a change of colour, and even when diluted with a considerable quantity of water; heat renders the action much more rapid. This coloration is strongest when nitric acid is used, an excess of which, with the aid of heat, will develope a strong yellow-green colour, even in a weak solution. In this reaction, as well as in the persistent colour of its salts, this alkaloid shows a curious resemblance to aricine.

The yellow colour renders the examination of its optical properties difficult, but, as far as has been hitherto tried, it is inactive. I have not been able to recognize fluorescence in its solutions.

Its taste is a peculiar bitter, very much less, both in intensity and permanence, than that of the other cinchona alkaloids.

I have not been able to find out whether this alkaloid is contained in all the species of cinchona, or, if not, to which it belongs, for the difficulty of the crystallization of the impure salts makes it a matter of uncertainty to obtain it.

My uncle, Mr. J. E. Howard, when investigating the leaves of the *Cinchona succirubra*, from India, found minute quantities of an alkaloid, soluble in ether, from which an alcoholic solution of oxalic acid precipitated it in a crystalline form; but the small quantities at his disposal prevented his examining it further than to show its analogy with quinine; his present conviction is that this substance is identical with the alkaloid I have been describing, and though the evidence is not yet sufficient to enable us to speak with certainty, it tends strongly to prove it. It seemed so desirable to settle this point, and to throw some light, if possible, on the order of formation, and possibly on the far more important and far more difficult question of the mode of formation of the alkaloids of the descending sap, that he has written to Mr. Broughton, and we hope shortly to receive a quantity of the leaves sufficient to enable us to investigate it.
—*Journal of the Chemical Society.*

COMPOUND SYRUP OF SQUILLS, SYRUP OF SENEKA AND SYRUP OF IPECACUANHA.

BY J. C. WHARTON.

The tendency of some officinal syrups to ferment is strikingly manifested by the three above named, and although the present formulæ for their preparation are improvements upon older ones, there are still serious difficulties in following implicitly the directions laid down in the U. S. Dispensatory. As a consequence, there are various inequalities in the resulting syrups, and, as I believe, fermentation is sometimes actually promoted by the tedious and lengthy proceedings required.

It will be sufficient to offer as an instance the compound syrup of squill. As it is not necessary to give the formula in detailed proportions, the reader is referred to the U. S. Dispensatory, where it will be seen that after a percolated tincture of three pints is obtained, the directions read: "Boil this for a few minutes, evaporate it by means of a water-bath to a pint, add six fluid ounces of boiling water and filter. Dissolve the sugar in the filtered liquid, and having heated the solution to the boiling-point, strain it while hot. Then dissolve the tartrate of antimony and potash in the solution while still hot, and add sufficient boiling water through the strainer to make it measure three pints. Lastly, mix the whole thoroughly together."

In following these directions as strictly as possible, I have almost invariably found that a large amount of albuminous or "pectin-like" matter was deposited, and in fact this is the stated design of raising the liquid to the boiling-point. Here arises the chief difficulty, in my opinion; at any rate I have found it to be a great one, for in attempting to remove this deposit by filtration, especially if a considerable quantity of liquid is prepared, the filter is soon clogged by the gummy matter, and the liquid filters very slowly. I have known filtration to cease towards the close of the operation. In such a case, the best that can be done is to provide a new filter and empty the old one into it, expressing it to avoid loss as much as possible. This is tedious and wasteful of the virtues of the drug. On one occasion I prepared a quantity of the tincture, and such was the tardiness of filtration that several days were occupied in completing it. Towards the end I noticed a few patches of a mouldy growth that had formed on the surface of the albuminous matter in the filter, and by smelling it perceived that the liquid was spoiled before the syrup was made. The failure was suggestive; and I concluded that if a few days were enough to spoil the liquid, a few hours' time might injure it, and, in fact, the germs of fermentation might begin to work as soon as the liquid was cold, since the protective agency of alcohol was gone.

Reasoning as above, I resorted to a method of filtration often used when a difficult precipitate is to be removed, namely, rubbing the muddy liquid with magnesia. In this case it acted with the double advantage of mingling its particles with the albuminous matter, thus facilitating filtration and neutralizing any free acid that might be present from incipient fermentation. The result was very satisfactory. Filtration was greatly hastened, and the syrup produced was not muddy-looking or translucent, as is generally the case, but was beautifully transparent. It was kept a year without fermenting, though almost daily in use.

I have since tried the same method of filtration with syrup of ipecacuanha and syrup of seneka, with like results.

There is a point that may seem objectionable in using magnesia or its carbonate as above, and it has been duly considered before offering these suggestions. It is this: magnesia is alkaline in its reactions, and as the active principle of seneka is considered to be acid (polygalic), it would seem that they are incompatible, but as they are both feeble in their affinities and as filtration proceeds rapidly, there is practically no objection to mixing them. There is, it is true, a very slight escape of carbonic acid when the carbonate of magnesia is rubbed with the concentrated liquid, but it may be due to a small amount of free acid of a different character, and even though a little polygalic acid should be removed by the magnesia the amount is so trivial as to be of no importance, and the objection is more than counterbalanced by the complete removal of the albuminous and pectinous deposit which generates fermentation, and would soon decompose more polygalic acid than the magnesia removes.

I therefore submit the following formulæ, adhering as closely to the U. S. Dispensatory as practicable, and would remark that the use of carbonate of magnesia is sanctioned by that authority in the case of the active principle of ipecacuanha, which the reader will see by referring to the method of preparing impure emetia, U. S. Dispensatory, under the article "Ipecacuanha:"—

Syrupus Scillæ Compositus.

Take of Squill, in moderately coarse powder,
Seneka, in moderately fine powder, each 4 troy oz.
Tartrate of Antimony and Potash, 48 grs.
Sugar (refined) in coarse powder, 42 troy oz.
Diluted Alcohol,
Water, each a sufficient quantity;
Carbonate of Magnesia, 60 grs.

Mix the squill and seneka, and having moistened the mixture with half a pint of diluted alcohol, allow it to stand for an hour. Then transfer it to a conical percolator and pour diluted alcohol upon it until three pints of tincture have passed. Boil this for a few minutes, evaporate it by means of a water-bath to a pint, add six fluid ounces of boiling water, rub the liquid with the carbonate of magnesia in a mortar until thoroughly mixed, filter, and add through the filter sufficient warm water to make the filtrate measure twenty-two fluid ounces. Dissolve the sugar in the filtered liquid, and having heated the solution to the boiling-point, strain it while hot. Then dissolve the tartrate of antimony and potash in the solution while still hot, and add sufficient boiling water through the strainer to make it measure three pints when cold. Lastly, mix the whole thoroughly together.

Syrupus Senegæ.

Take of Senega, in moderately fine powder, 4 troy oz.
Sugar (refined), in coarse powder, 15 troy oz.
Diluted Alcohol, 2 pints,
Water, a sufficient quantity,
Carbonate of Magnesia, 30 grs.

Moisten the seneka with two fluid ounces of the diluted alcohol, then transfer it to a conical percolator and gradually pour upon it the remainder of the diluted alcohol. When the tincture has ceased to pass, evaporate it by means of a water-bath, at a temperature not exceeding 160°, to half a pint. Rub it with the carbonate of magnesia in a mortar till thoroughly mixed, filter and add sufficient warm water through the filter to make the filtrate measure half a pint, and having added the sugar, mix well together, and note accurately the measure of the mixture while cold; then dissolve the sugar with the aid of a gentle heat, strain the solution while hot, add sufficient warm water through the strainer to bring the syrup, when cold, to the previously noted measurement and mix them thoroughly.

Syrupus Ipecacuanhæ.

(Modified from former editions of the U. S. Pharmacopœia.)

Take of Ipecacuanha, in fine powder, 2 troy oz.
Diluted Alcohol,
Water, each, a sufficient quantity,
Sugar (refined), in coarse powder, 29 troy oz.
Carbonate of Magnesia, 45 grs.

Moisten the ipecacuanha with one fluid ounce of the diluted alcohol, let it stand for twenty-four hours. Then transfer it to a conical percolator and gradually pour upon it diluted alcohol until one pint of tincture has passed. Evaporate this by means of a water-bath to six fluid ounces, add ten fluid ounces of warm water, and having rubbed it thoroughly with the carbonate of magnesia in a mortar, filter and add sufficient warm water through the filter to make the filtrate measure one pint; then add the sugar and dissolve it with the aid of a gentle heat, and having strained the hot syrup, add sufficient warm water through the strainer to make it measure two pints when cold.

It will be seen that the chief point of difference between the two first formulæ above given and the U. S. Pharmacopœia requirements is the filtration of the evaporated tinctures through carbonate of magnesia instead of paper only; but I would call the attention of the authors and revisers of both the Pharmacopœia and Dispensatory to the lack of explicit directions in many of the formulæ for syrups, from which I, with many others, have suffered loss and trouble. The difficulty is mainly in the want of full and accurate directions in regard to the various measurements. For example, the closing directions in the formula for compound syrup of squill read thus:—"Add sufficient boiling water through the strainer to make it (the hot syrup) measure three pints" (while hot?). In view of the tartar emetic, the design of the formula must be to make the syrup measure three pints when cold, but a fair interpretation of the directions cannot mean that. Now it is plain that three pints of hot syrup will not, upon cooling, be three pints of cold syrup, admitting that no evaporation takes place in the act; but most commonly a considerable evaporation will take place during the process, and of necessity a crystallization of sugar takes place. The fault is even worse in the formula for syrup of seneka. The directions read: "Filter, and having added the sugar, dissolve it with the aid of a gentle heat and strain the solution while hot." No account is taken of the loss of liquid in filtering, nor of evaporation in dissolving the sugar. If the directions are followed precisely in such cases, crystallization will inevitably take place, even if the amount of sugar prescribed is not a little too great, as I am of opinion it is in the two first of the syrups herein discussed. I believe that in practice twenty-nine troy ounces would be found to answer as well as thirty troy ounces, or a proportional reduction of other quantities.

It should be remarked that, in filtering through carbonate of magnesia, the first portions of liquid often pass through *cloudy*, and should be returned to the filter until the filtrate is *quite clear*. This will ensure a transparent syrup.—*Amer. Journ. Pharm.*

THE EXTEMPORANEOUS BENZOATING OF OINTMENTS.

BY CHARLES F. BOLTON.

The subject of benzoin in ointments has for some time past attracted the attention of the profession, and there is nothing in the whole range of pharmacy that gives more satisfaction than a perfect ointment, not only to the druggist who dispenses it, but also to the physician who prescribes, and the patient who uses it. There is nothing that reflects more credit on the pharmacist than an elegant and well-dispensed ointment. To accomplish this requires not only experienced manipulation, but something more; it needs that the unctuous matter should be fresh and free from the least trace of rancidity; it should not only be this way when dispensed, but, if possible, should be made in such a manner that it would remain in a perfectly sweet condition for a considerable length of time, thus affording the patient an opportunity of using the whole of the ointment in a sweet state. This can be effected in many instances by using the officinal unguentum benzoini as the base of the ointment, but often the physician directs the ointment to be prepared and benzoated extemporaneously. To benzoate the ointment by the officinal process involves time, but by the plan that I suggest it can be accomplished in a very short time without the aid of heat, thus saving a great deal of time and trouble. In many instances time is quite an important object. The formula that I have decided upon, after making several experiments, is as follows:—

℞. Benzoin. Pulv. (select.) ℥ij.
Ether. Sulphuric. ℥iv
Ol. Ricini ℥j.

Introduce the benzoin into an 8-ounce bottle, add the ether, macerate for twenty-four hours with frequent agitation, pass through a filter, to the filtrate add ol. ricini, and shake until dissolved; then transfer to a shallow vessel, in order to allow the ether to evaporate spontaneously; lastly, when the ether has entirely disappeared, place in a wide-mouthed bottle ready for use. With a view to economy I experimented with alcohol and benzine as solvents; the former of the specific gravity ·817 gave moderate satisfaction, the result being of a much darker colour, owing to the foreign matter in the benzoin being more soluble in alcohol than in ether; this I considered a serious objection, as it discoloured the ointment considerably, while that made with the ether did not, at least not more than if it were benzoated by the officinal process. The benzine experiment, however, was a complete failure, it extracting from the benzoin only a very small amount of benzoic acid, leaving entirely undissolved the resin, cinnamic acid and volatile oil. The result from the formula that I have given is of the consistency of a soft extract, one ounce of the extract fully representing an ounce of the benzoin in a state that is perfectly miscible with unctuous substances. I benzoated several ointments with this extract in the early part of last April, and allowed them the greater portion of the time to be exposed to the atmosphere, and when I examined them in the fall I could find none of them oxidized in the least, and in the case of ung. hydr. oxidi rubri the bright orange colour was perfectly preserved. I also used it in several prescriptions, and it always gave perfect satisfaction. I used it in the proportion of half drachm to the ounce of ointment: it can also be used very advantageously in preparations for the hair, it being very soluble in alcohol and perfectly miscible with ol. ricini in combination with alcohol, but insoluble in the fixed and volatile oils in a free state. It is also freely soluble in chloroform.—*American Journal of Pharmacy.*

SYRUP OF IODIDE OF POTASSIUM AND IRON (OF LAHACHE).

Take of

Iodide of potassium	308 grains.
Iodide of iron (in solution 1 to 3)	230 ,,
Orange-flower water	462 ,,
Simple syrup (concentrated) . .	33½ fluid ounces.

Dissolve the iodide of potassium in the orange-flower water, add the other solution and incorporate the syrup. Preserve it cool and free from light.—*Union Pharmaceutique.*

The Candle-berry Tree (*Aleurites triloba*) is well known in the Moluccas and the Pacific Islands on account of its valuable oil-seeds, which are strung on sticks and used as candles; the oil is also expressed and used for culinary purposes, and has been imported in small quantities into this country. In China another species of *Aleurites* (*A. cordata*), known as the Tungshu-tree, yields such an abundance of oil that it is said to be one of the largest products of the province of Szechuen. In point of quality it is inferior to that of the camellia, but it is very extensively used for lighting purposes. The natives call it tung oil.—*Gardeners' Chronicle.*

Galuncha.—Amongst East Indian medicinal plants the Galuncha (*Tinospora cordifolia*, Miers) has been considered of sufficient value to be placed in the new Indian Pharmacopœia. The roots and stems are the parts used, and their properties are tonic, antiperiodic and diuretic. They are used in cases of general debility after fevers, in rheumatic affections, etc., and are administered either in the form of tincture, infusion or extract. It is called Penawar Sampei (all-sufficient medicine) in Borneo, and is in daily use amongst the natives as well as by many Europeans. The plant is very tenacious of life, a portion of a stem hung up in a dry room for more than twelve months, without touching earth or water, having been known to throw out roots during the whole time.—*Gardeners' Chronicle.*

The Pharmaceutical Journal.

SATURDAY, APRIL 22, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

DEFECTS IN THE PHARMACY ACT.

IN a recent number of the Journal,* when calling the attention of our readers to the issue of the Register for 1871, we mentioned some of the difficulties attending its compilation, which greatly interfered with its correctness. At the same time, we pointed out that serious consequences might follow from an incorrect entry, caused by the omission of the person registered to give notice to the Registrar of any change of residence on his part. An additional source of error is unreported deaths.

Confirmation of our opinion as to the prevalence of this neglect is to be found in the statement made by a contemporary that no less than 1438 communications which were posted recently, addressed according to the Register, have been returned marked "gone away," "deceased," "not known," or with some other indorsement, indicating that the entry in the Register is incorrect. This is a state of things that, however much to be regretted, the Registrar is powerless to remedy, without the active co-operation of the registered chemists and druggists throughout the country, inasmuch as in many instances no communication is received by him from or respecting a registered person after his registration. To secure the correctness, and therein the value of the Register, any information concerning deaths or removals that may come under the notice of members of the trade should be communicated immediately to the Registrar; but hitherto this has rarely been done.

The authors of the Bill now before the State Legislature of Illinois, of which we have already given an abstract,† have foreseen this difficulty, and propose to meet it by a clause which provides that a registered pharmacist, upon changing his place of business, shall send a notice of it to the Board, and that once a year every pharmacist is to notify whether he still practises pharmacy at his registered place of business, in default of which, after one letter of inquiry from the Registrar, the name is to be omitted from the Register. Each notice is to be accompanied by a fee of one dollar, in return for which the Registrar will have to furnish him with a copy of the Register. This clause appears to furnish the machinery for securing a greater amount of accuracy in the Illinois Register than is at present found in our own, and probably the adoption of a similar rule would be advantageous here.

THE PRELIMINARY EXAMINATION.

THE Report of the Board of Examiners relating to the Preliminary Examination on the 3rd inst., which is printed in another column, suggests matter for grave reflection. The fact that out of two hundred and ninety-four candidates who presented themselves for examination, no less than one hundred and twenty-nine, or forty-three per cent., failed to obtain the number of marks which would entitle them to registration as apprentices, seems to imply that either the standard of the examination was too high, or that a large proportion of the candidates were deficient in the knowledge which they might fairly have been expected to possess.

A perusal of the questions proposed,—which are likewise printed,—will, we think, sufficiently prove that the first alternative does not at all explain the result. To take them in the order in which they are printed. In the Latin section there was a choice given of five passages for translation, two only being required; while the questions that followed were of the most elementary kind.

With regard to this portion of the examination, we do not lose sight of the point raised by a correspondent in this week's Journal, that in consequence of all persons having to undergo the Preliminary Examination before proceeding to the Minor and Major, some who have passed the Modified are prohibited from seeking to pass the higher examinations. It is true that many men in the drug trade have very little time to spare for the study of the classics, and we know that there is a certain amount of sympathy felt for them in some quarters, which may possibly lead to steps being taken to meet their case. But we think this objection loses nearly, if not quite all its force, from the fact that two of the passages for translation—the number required—are actually such as they might be called upon at any time, in the ordinary course of their business, to render into English.

The questions in the other sections are not at all more difficult than a boy who has received a liberal education might be expected to answer, and that so many have failed to do so is strongly suggestive of the necessity of regulations for compulsory education; at any rate, it does very little credit to our present system.

It is worthy of notice that the largest proportion of failures occurred where an opposite result might fairly have been expected. Eleven candidates failed who were younger than sixteen years of age; ninety-three between sixteen and twenty; and the remainder beyond that age.

In the recent Report of Dr. Letheby to the Corporation of London and the Metropolitan Board of Works, on the quality of gas supplied to the Metropolis, it was stated that the gas had been found free from sulphuretted hydrogen, and that the quantity of ammonia had not exceeded the amount prescribed by the referees, viz. 5 grains per 100 cubic feet of gas. The presence of sulphur in illuminating gas would be particularly obnoxious to the pharmacist, on account of the destructive action of the sulphuric acid or sulphate of ammonia produced, and the consequent corrosion of brass fittings, etc. It is reported to have been found in very variable proportions, averaging from 11·5 grains to 36·11 grains per 100 cubic feet. In reference to this difference, we may here remark that there is reason to believe that much of it is referable to a variation in the results obtained in testing for sulphur; and only recently we have had occasion to notice that the actual result obtained in testing gas for sulphur by the method known as Letheby's is in reality very much a matter of accident, being so much influenced by the conditions under which the experiment is conducted.

We have been favoured with an opportunity of examining a Poison Cabinet, designed to promote the safe keeping and dispensing of poisons, which has been patented by Mr. Young. We propose to give a description of it in our next number.

The *Gardeners' Chronicle* states that in the centre of the great conservatory of the Royal Horticultural Society there is a plant upwards of 20 feet high, of the old *Rhododendron arboreum*, which has this year borne innumerable trusses of deep blood-red flowers, realizing all that the late Dr. Wallich ever wrote of the glorious effect produced on the northern slopes of the Himalaya, where vast tracts are entirely covered with them.

The *Athenæum* announces that the Educational Department of the International Exhibition is making progress, and is likely to prove not only attractive but useful, particularly in reference to science teaching. We understand that Professor Frankland has been requested to report on this branch, and we may therefore expect good service to be done towards the removal of our strange deficiencies in regard to science.

Favourable reports have been received concerning the cinchona cultivation in the West Indies. *Nature* informs us that in the Jamaica plantations the trees are seeding plentifully. About 40,000 seedling plants of *C. succirubra* have also been raised from Jamaica seed. Another hundred acres of land have been prepared for planting this spring, and there appears to be a probability of a still larger quantity being put under similar cultivation.

Among the lectures which have been announced for delivery at the Royal Institution are two "On Force and Energy," by Charles Brooke, F.R.S., May 9 and 16; and one "On the Gaseous and Liquid States of Matter," by Thomas Andrews, F.R.S., June 2.

The *British Medical Journal*, referring to a suggestion made in its columns,* and already quoted in this Journal, to the effect that an alcoholic solution of sulphurous acid would be a convenient vehicle for setting free sulphurous acid, as a disinfectant, says that Messrs. Herring and Co. have taken the hint then given, and have prepared such a solution. Articles of clothing, valuable instruments and delicate materials may be effectually disinfected by dropping a measured quantity of this solution on the bottom of a closed box in which they are placed. Pathological preparations may be preserved fresh. An antiseptic and wholesome atmosphere may in like manner be obtained in a bed or bed-chamber. As a parasiticide, on rag under impermeable tissue, it will be found most energetic.

At a recent meeting of the Royal Colonial Institute a paper was read on the "Appointment of a Reporter on Trade Products for the Colonies." After discussion, a committee was appointed to ask the Secretary of State for the Colonies to establish such a department, and further to suggest the formation of a Colonial Museum on a similar basis to that established at the India Office.

The Mezereon (*Daphne Mezereon*, L.) and the Spurge Laurel (*D. Laureola*, L.) are the only British representatives of the Natural Order *Thymelaceæ*; and the former, grown as it is in many of our gardens and shrubberies for its fragrant pink flowers opening at so early a period in the spring, is a very creditable example of the Order. The whole plant is acrid and powerfully irritant, and the bark has been used in medicine in this country. In some parts of France it is applied to the skin as an irritant in the form of a blister, a piece of the fresh bark being simply cut out, steeped in vinegar, and placed on the affected part. The leaves are likewise used in medicine in various parts of the Continent. *D. Laureola* has similar properties, indeed the same acrid principle pervades the whole Order. In Borneo the bark of a species of *Wikströmia*, probably *W. indica*, is used to allay toothache, a small piece being chewed with lime. It has also a wide reputation in that country for the cure of whitlow. The natives take a long strip of the fresh bark and bind it tightly round the finger above the diseased part, it soon produces a sore encircling the finger, which is supposed to prevent the spread of the inflammation and effect a speedy cure.

* See Pharmaceutical Journal, *ante*, p. 465.

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

April 19*th*, 1871.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Deane, Edwards, Gale, Garle, Hanbury, Haselden and Ince.

Dr. Greenhow was also present on behalf of the Privy Council.

Twenty-three candidates presented themselves, viz. four Major and nineteen Minor; the following fourteen passed, and were declared to be duly qualified to be registered:—

MAJOR (as Pharmaceutical Chemists).

*Deane, James	Clapham.
Fowler, William Ratcliffe	Ipswich.
Bannard, Henry	London.

MINOR (as Chemists and Druggists).

*Saunders, Charles Price	Haverfordwest.
Cole, Walter Benjamin	Weymouth.
Pentney, James Chapman	Gorleston.
Smith, William John	Leicester.
Ritson, George	Sunderland.
Morgan, Richard	London.
Harradine, Henry Ground	March.
Ballard, Frank Perry	Ludlow.
Baker, Samuel	Chichester.
Pratt, Henry James	Thirsk.
Dawson, Cautley	Stockport.

The above names are arranged in order of merit.

FIRST OR PRELIMINARY EXAMINATION.

Two hundred and ninety-four Candidates presented themselves for this Examination on the 3rd April; the following One hundred and sixty-five passed, and were declared to be duly qualified to be registered as

APPRENTICES OR STUDENTS.

	Wade, Robert Brady	Shoreham.
Equal.	Cole, Walter Benjamin	Weymouth.
Equal.	Knight, Alfred George	Swansea.
	Reece, Thomas	Llandilo.
	Dowding, Alexander W. W.	Weston-super-Mare.
	Pitchford, William	Newton Abbot.
	Williams, Wm. Lloyd Owen	Llanberis.
	Smailes, Robert	Grantham.
	Kirkup, John	Liverpool.
	Jackson, Joseph John	Bridgnorth.
	Kempster, Fredk. Augustus	Clapham.
Equal.	Bamford, Henry William	London.
Equal.	Smith, Samuel	Leeds.
	Lloyd, Frederick	Clay Cross.
Equal.	Appleby, Edward Joseph	Brighton.
Equal.	Blunt, George	Upton-on-Severn.
Equal.	Fryer, Richard Green	Swansea.
Equal.	Good, George Arthur	Weston-super-Mare.
Equal.	Harris, William	Llandilo.
Equal.	Leach, Isaac	London.
Equal.	M'George, John	Belfast.
Equal.	Mager, William Kelk	Doncaster.
Equal.	Turner, Richard Vicary	Exeter.
	Roberts, Robert	Bala.
	Perry, John	Congleton.
	Walker, Joseph	Stoke-on-Trent.
Equal.	Cutter, Herbert	Bristol.
Equal.	Hensley, Robert Place	Maidstone.
Equal.	Jones, David William	Llandilo.
Equal.	Munday, John	Bridgnorth.
Equal.	Walker, Joseph	Whitby.
Equal.	Coates, Thomas	Malton.
Equal.	Frowd, Edward Francis	London.
Equal.	Young, Charles S.	Grantham.
Equal.	Ascott, Tom	Exeter.
Equal.	Farr, Joseph	Peterborough.
Equal.	Kendall, John	Truro.
Equal.	Priestley, Walter Herbert	Barnstaple.
	Kirk, John Robert	Leeds.
Equal.	Fuller, Thomas	Fallowfield.
Equal.	Tamplin, Charles Edward	Kingston-on-Thames.
Equal.	Walker, Thompson F.	York.
Equal.	Woolnough, Harry Arnold	Norwich.
	Longley, Joseph	Barnsley.
Equal.	Abington, Leonard Yates	Newcastle-u.-Lyne.
Equal.	Badcock, Daniel	Barnard Castle.
Equal.	Chadwick, Joseph Dunhill	Barnsley.
Equal.	Roberts, Joseph	Liverpool.
	Bambridge, Arthur John	Lancaster.
Equal.	Goodwin, J. Henry Gerrard	Ashton-under-Lyne.
Equal.	Margetts, Usher	Eastwood.
Equal.	Davies, Peter Hughes	Peterborough.
Equal.	Dawson, Francis Robert	Bolton.
Equal.	Donald, William	Aberdeen.
Equal.	Horsfield, Robert F. W.	London.
Equal.	Kirby, Thomas William	Liverpool.
Equal.	Laird, William Alfred	Portsmouth.
Equal.	Tuxford, James Edward	Boston.
Equal.	Wright, George	Sheffield.
Equal.	Carrol, George	Bath.
Equal.	Robbins, Alfred Farthing	Launceston.
	Pottinger, Thomas	Darford.
	Thompson, George	Derby.
	Jackson, George	Worksop.
	Simpson, Allwood	Stalybridge.
	Stamps, Frederick	West Bromwich.
Equal.	Carlton, Thomas Wokes	Hull.
Equal.	Hannath, Wm. Henry Wyatt	Worksop.
Equal.	Jones, Thomas	Merthyr Tydfil.
	Davison, John	West Hartlepool.
Equal.	Chesterton, William Peter	Walsall.
Equal.	David, Albert	Neyland.
Equal.	Ferriday, William	Ardwick.
Equal.	Gibson, John Chambers	Manchester.
Equal.	Kennett, James	Eastbourne.
Equal.	Marin, Ferdinand Baptist	London.
Equal.	Moore, George Brass	Barnard Castle.
Equal.	Pomeroy, Francis Thomas	South Petherton.
Equal.	Wardley, Oliver Edward	Mildenhall.
Equal.	Woollerton, Edwin Goodburn	Melton Mowbray.
Equal.	Judson, Charles Thomas	Leeds.
Equal.	Nash, William	Aberdeen.
Equal.	Ballard, John Smyth	Carmarthen.
Equal.	Humphreys, John	Ashton-under-Lyne.
Equal.	Hutchinson, George	South Shields.
Equal.	Mitchell, Thomas Maxwell	Leeds.
Equal.	Branson, Frederick Woodward	Northampton.
Equal.	Parrott, John	Norwood.
Equal.	Sell, William Henry	Bath.
Equal.	Canner, William	Derby.
Equal.	Cook, Frank	Herne Hill.
Equal.	Monkman, James Dixon	Leicester.
Equal.	Rhodes, Samuel	Oldham.
	Beverley, George	Aberdeen.
	Williamson, William	Altrincham.
	Symons, William Henry	Barnstaple.
	Michie, Henry Esson	Aberdeen.
Equal.	Jones, George Marsh	Sheffield.
Equal.	Wellington, Frederick	South Petherton.
	Davidson, Louis	Newcastle-on-Tyne.
Equal.	Bathe, Frederick James	Chippenham.
Equal.	Chubb, Richard	Launceston.
Equal.	Morley, Thomas Walter	Derby.
Equal.	Batchelor, Alfred Ernest	Fareham.
Equal.	Forster, Francis Alexander	Norwich.
Equal.	Haley, William Henry	Norwich.
Equal.	Jenkins, Henry	Salisbury.
Equal.	Jones, William	Bagillt.

* Passed with Honours.

	Brumwell, William Preston	Newcastle-on-Tyne.
Equal.	Milton, Thomas Clement	Exeter.
	Shepherd, John William	Settle.
	Green, Vittery	London.
	Newton, Alfred Henry	Kenilworth.
	Winpenny, Frank Walker	Barnard Castle.
	Brown, Horace	Thrapston.
Equal.	Dolman, William	Cheltenham.
	Rutter, Thomas Dixon	Scarborough.
Equal.	Harding, Frederick William	Norwich.
	Robinson, John Edward	Boston.
	Heald, Charles	Sleaford.
Equal.	Foster, George	Andover.
	Geldart, John	Whitehaven.
	Hammond, William Henry	Northampton.
	Helmsley, Alfred	York.
	Lewis, David	Cardigan.
	Hitchcock, James	Whittington Moor.
Equal.	Robinson, Thomas Ward	Hull.
	Sangster, William	London.
Equal.	Birrell, George	London.
	Boorne, Charles James	Reading.
	Brothers, John	Ashford.
	Goodrick, John	Aldershot.
	Heald, Samuel Haldane	Wakefield.
	Hume, John William David	Stokesley.
	Pearse, William Francis	Yarmouth.
	Howell, John	Carmarthen.
Equal.	Grayson, Charles	Bawtry.
	Parkinson, Thomas Edmund	Leeds.
	Richardson, John Richard	Leeds.
	Smith, John Thomas	Donington.
Equal.	Bannerman, Charles Alexander	Belfast.
	Lea, Frederick James	Folkestone.
	Marlee, Jonas James	Birmingham.
	Murison, Alexander A. W. P.	Macduff.
	Radley, William Gibson	Newton Abbot.
	Smithard, Herbert Henry	Guernsey.
Equal.	Barnes, William James	Dover.
	Crampton, Joseph	Leeds.
	Ellis, Thomas Wokes	Hull.
	Garry, Walter Finch	Canterbury.
	Hill, Francis	Horncastle.
	Hurley, Edward William	Reading.
	Knight, Frank	Farnham.
	M'Intyre, William	Wakefield.
	Neale, Edgar	Farringdon.
	Pidd, Arthur Joseph	Hulme.
	Rowley, John	Willenhall.
	Saunders, James Edwin	Stamford.
	Taylor, Charles Edward	Lancaster.
	White, Robert	Durham.
	Allen, William	Stratford, Essex.
	Bishop, Edward James	Leicester.
	Milner, Thomas	Thirsk.
	Adams, Herbert Richard	London.
	Jones, Owen Williams	Flint.

The above names are arranged in order of merit.

The following is a list of the towns in which examinations were held, with the number of candidates annexed:—

Aberdeen	8	Bridgnorth	2
Abingdon	2	Brighton	2
Altrincham	1	Bristol	3
Andover	1	Bury St. Edmund's	1
Ashton-under-Lyne	3	Canterbury	1
Barnstaple	2	Cardigan	2
Bath	4	Carmarthen	4
Bedford	3	Carnarvon	1
Belfast	2	Cheltenham	2
Birmingham	9	Chesterfield	3
Bideford	1	Chichester	1
Bolton	2	Chippenham	1
Boston	5	Congleton	1
Bradford	1	Coventry	2

Darlington	4	Peterborough	4
Derby	6	Portsmouth	1
Doncaster	1	Preston	3
Dover	3	Reading	3
Dudley	1	Retford	2
Durham	2	Ripon	1
Exeter	3	Rochdale	1
Farnham	2	Rochester	2
Flint	2	Ruthin	1
Grantham	3	St. Austell	1
Guernsey	1	St. Ives (Cornwall)	1
Hartlepool	3	Salisbury	1
Hertford	1	Sheffield	4
Horncastle	1	Sleaford	2
Hull	5	Southampton	1
Lancaster	3	South Shields	2
Launceston	3	Stamford	1
Leeds	10	Stockport	1
Leicester	5	Stoke-on-Trent	1
Lewes	2	Sunderland	2
Lincoln	3	Swansea	5
Liverpool	5	Taunton	4
London	44	Tewkesbury	1
Maidstone	2	Thirsk	1
Manchester	12	Torquay	2
Merthyr Tydfil	3	Truro	1
Middlesborough	1	Wakefield	6
Newark	1	Walsall	2
Newcastle-un.-Lyne	1	Weston-super-Mare	2
Newcastle-on-Tyne	6	Whitby	1
Newport (Mon.)	1	Whitehaven	3
Northallerton	1	Winchester	1
Northampton	3	Wolverhampton	1
Norwich	4	Wycombe	1
Oldham	3	Yarmouth	2
Pembroke	1	York	4

The Questions for Examination were as follows:—

LATIN.

1. Translate into English two at least of the following sentences:—

   Suam innocentiam perpetuâ vitâ, felicitatem Helvetiorum bello, esse perspectam. Itaque se, quod in longiorem diem collaturus esset, repræsentaturum, et proximâ nocte de quartâ vigiliâ castra moturum, ut quam primum intelligere posset, utrum apud eos pudor atque officium aut timor valeret. Quod si prætcrea nemo sequatur, tamen se solâ decimâ legione iturum, de quâ non dubitaret, sibique eam prætoriam cohortem futuram. Huic legioni Cæsar et indulserat præcipuè, et propter virtutem confidebat maxime.

   Cognito Cæsaris adventu, Ariovistus legatos ad eum mittit, quod antea de colloquio postulasset id per se fieri licere, quoniam propius accessisset, seque id sine periculo facere posse existimare.

   Postulavit deinde eadem quæ legatis in mandatis dederat, ne aut Æduis aut eorum sociis bellum inferet, obsides redderet: si nullam partem Germanorum domum remittere posset, at ne quos amplius Rhenum transire pateretur.

   Coque per horam dimidiam, subinde agitans, et ubi liquor refrixerit adjice aquæ destillatæ quantum satis sit ut octarios sex impleat, denique cola. In vasis bene obturatis servetur.

   Misce. Fiat haustus, quintâ quâque horâ sumendus, et tempore usûs, adde singulis, si opus fuerit, ad præcavendum diarrhœam, tincturæ opii guttas tres.

2. State to which declension each of the following nouns belongs, and give the accusative:—*emplastrum, tinctura, syrupus, pulvis, manus.*

3. What is the ablative absolute? Give one or more examples.

4. Which case do the following prepositions take after them?—*circiter*, *inter*, *apud*. Illustrate by examples.
5. Explain the difference between personal and impersonal verbs. Give examples.
6. State how the nominative to a verb is found, and exemplify the same.

ARITHMETIC.

7. A boy having 100 marbles, lost 25 at play, and then won 18, after which he lost 28: how many had he left?
8. If 100 workmen finish a piece of work in 12 days, how many will finish it in 3 days?
9. If £100 in 12 months gain £7 interest, what is the interest of £571 for 6 years?
10. Multiply $\frac{3}{5}$ of $5\frac{1}{6}$ of $\frac{5}{7}$ by $3\frac{1}{8}$ of $5\frac{1}{6}$ of $17\frac{1}{8}$.
11. Divide 5·714 by 8275·

ENGLISH.

12. Of what does etymology treat?
13. How many parts of speech are there? Name them.
14. How many cases have nouns, and which two are alike?
15. Give the plural of the following nouns:—shelf, wolf, goose, scarf, staff, tooth, ally, deer, court-martial, knight-errant, index, and penny.
16. Parse the following:—Virtue ennobles the mind, but vice debases it.
17. Write from 15 to 25 lines upon *one* only of the following subjects:—
    A. The employment of time.
    B. Perseverance.
    C. Memory.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

A General Meeting of this Association was held on Friday, April 14th; Mr. STODDART, President, in the chair.

After the routine business of the meeting, a lecture was delivered by W. A. TILDEN, Esq., B.Sc., Demonstrator of Chemistry in the Laboratory of the Pharmaceutical Society, upon "Heat considered as an Agent in Chemical and Pharmaceutical Operations."

At its conclusion, a cordial vote of thanks to the lecturer was carried by acclamation.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Sixth and last ordinary Monthly Meeting of the Session was held in the Memorial Hall, Albert Square, on Friday evening, April 14th; Mr. W. S. BROWN, President, in the chair. There was a large attendance of Members and Associates.

The CHAIRMAN drew attention to the 'Book of Autograph Prescriptions' on the table. These had been collected by Mr. Joseph Ince, of London, and presented to the Association by the Council of the Pharmaceutical Society. The great value of this collection would, he hoped and believed, be appreciated by the students who frequented the rooms at Mitre Chambers. Alluding to the classes which had been held during the Session at Owens College, he said the attendance had been, on the whole, satisfactory to the Professors, though considerably smaller than the promoters of the course had hoped. A summer course of lectures on botany would be given, if a sufficient number of names were sent in to Mr. Benger, the Hon. Sec. He congratulated the members on the present aspect of the Poison Regulations, which were now to be issued as recommendations only, and he hoped that, with the modifications which would be made in them, they would be applicable to most businesses, and he trusted that chemists would apply them to the best of their opportunity, so as to ensure the safety of the public.

Mr. W. BOSTOCK then moved, "That the best thanks of this Association be forwarded to the Council of the Pharmaceutical Society, and especially to Mr. Joseph Ince, for his kindness in collecting and arranging the 'Book of Autograph Prescriptions,' presented to the Association."

Mr. G. S. WOOLLEY, in seconding the vote of thanks, said that in future much greater value would be attached to the proficiency of candidates in pharmacy and practical dispensing in the Examinations of the Pharmaceutical Society, and he would strongly advise all those who were preparing for those examinations to avail themselves of the opportunity now afforded of studying a great variety of styles of prescribing.

The resolution was carried with acclamation.

Mr. J. T. SLUGG, F.R.A.S., Vice-President, then delivered a most interesting lecture on "The Stars, what they are, where they are, and why they are." Mr. Slugg's lecture was listened to throughout with the greatest attention, and at its conclusion a hearty vote of thanks was conveyed to the lecturer.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

April 6th.—Professor Frankland, F.R.S., President, in the chair.

The PRESIDENT, occupying the chair the first time since his election, returned his thanks to the Society for the honour conferred upon him, and expressed his readiness to discharge the duties of his office to the best of his abilities.

The following gentlemen were elected Fellows: F. Coles, C. E. Groves, E. W. T. Jones, L. T. MacEwan, J. L. Shuter.

The following papers were read:—"On Burnt Iron and Burnt Steel," by W. MATTIEU WILLIAMS. Iron, which has been damaged by reheating, or excessively heated and exposed after balling in the puddling furnace, is designated "burnt iron" by the workmen. It is remarkable that no amount of heat applied to the iron in the blast-furnace, or in the early stages of the puddling process, produces burnt iron. Burnt iron is brittle, its fracture is short and what is called crystalline, it has lost the fibrous character of good iron. If steel is raised to a bright red heat and suddenly cooled, it is rendered hard and brittle, but these conditions may be modified by the process of tempering; if, however, the steel be raised to a yellow or white heat, and then be suddenly cooled, it is no longer capable of being tempered by mere reheating. It is worthless for ordinary uses of steel unless it is again raised to a welding heat and rolled or hammered while hot, then allowed to cool gradually. The fracture of burnt steel presents a coarse grain and a crystalline appearance. Careful investigation, however, shows something more, viz. that the facets of the aggregated granules have a more or less conchoidal form. The name of "toads' eyes" has been given by practical men to these concavities. Mr. Williams found that a piece of burnt iron contained oxide of iron dispersed through its mass. A sample of burnt steel, however, investigated in the same manner as the iron, showed no indications of the presence of oxide. This of course was to be expected, as the carbon of the steel must more or less completely protect the metal from oxidation. That iron, when unprotected by combined carbon, should oxidize not merely on its surface, but through its whole substance, when exposed at a sufficiently high temperature, and for a sufficient length of time to the action of the atmospheric oxygen, is not difficult to conceive, since the researches of Deville, Troost and Graham have shown red-hot iron to be permeable by certain gases. In the case of steel, as Mr. Williams states, the burning is limited to the oxidation and consequent removal of the carbon which takes place even at a low red heat. The permeability of red-hot steel by oxygen and carbonic oxide enables us to understand the process of the internal oxidation of the carbon. The "toads' eyes," or conchoidal facets of the so-called crystals, Mr. Williams explains by supposing a piece of steel at the temperature most favourable to the rapidest endosmosis of oxygen and the exosmosis of carbonic oxide to be suddenly cooled, and the possible occlusion of the carbonic oxide to be arrested. The result would be a certain molecular disintegration and porosity of the steel, presenting those conchoidal spots. This view is further supported by the fact that burnt steel may be cured by reheating and hammering, or rolling at a welding heat.

"On the Formation of Sulpho-acids," by Dr. Armstrong. Occupied with an investigation into the constitution of sulphuric acid, the author turned his attention to chlorhydric sulphate, a body discovered some years ago by Professor Williamson. When that substance, SO_2HOCl, is made to react on benzol, the chief product of the reaction is sulphobenzid, sulphobenzolic chloride and sulphobenzolic acid being also formed, but in relatively very small quantity. This led Dr. Armstrong to commence a series of experiments to determine, if possible, the conditions under which the one or the other of the above reactions took place, and to arrive at a general expression for the action of chlorhydric sulphate on organic bodies. The bodies he had until now acted upon with SO_2HOCl are brombenzol, nitrobenzol, nitrophenol (both modifications, the volatile and the non-volatile), and naphthalin. The results of his experiments lead the author to conclude that the normal action, so to speak, of SO_2HOCl is to form a sulphacid, the Cl of the chloride removing H from the body acted upon and replacing it by the group SO_3H; it is only under certain conditions that both Cl and HO are removed from the chloride, and a sulphobenzid-analogous compound formed. What these conditions are, Dr. Armstrong hopes to establish by further experiments.

"On a Water from the Coal-Measures at Westville, N.S.," by Professor How. The contents of this paper bear upon the relation of the constitution of a water and the nature of the geological stratum from which it takes its origin. The water above-mentioned comes from what Dr. Dawson terms the Middle Coal Formation of Nova Scotia, which includes the productive beds of coal, and which, according to the same authority, are destitute of properly marine limestone. The analysis of the water seems to bear out the latter assertion, since the water is very poor in chlorides.

MEDICAL SOCIETY OF LONDON.

At the meeting of the Medical Society on Monday, March 13, Dr. B. W. Richardson read a paper, entitled "Some Further Additions to Therapeutics: Organic Bromides, Metachloral; with a Note on Sulphur Alcohol." After reference to the methods of research in therapeutics, he introduced some new medicinal bromides, viz. bromide of quinine, bromide of morphine, and bromide of strychnine, together with some combinations of them. He said that bromides were best administered in the form of syrups, containing one grain of the bromide of quinine, one-eighth of a grain of morphine, or one thirty-second part of a grain of bromide of strychnia in the drachm of each of the respective syrups. Compounds of the syrups of the bromides of quinine and morphine, and of quinine, morphine and strychnine were also useful. In each drachm of these the same proportion of dose was maintained. He had found the bromide of quinine of great service in syphilitic ulceration. Repeated doses of syrup of bromide of quinine and morphine in cases of neuralgia, and the syrup of quinine, morphine and strychnine, in a case of diabetes, had been signally successful. He believed the bromide of quinine to be the best preparation in cases of remittent or intermittent fever. Dr. Richardson next mentioned bromal hydrate, which he said was less soluble, and produced more convulsive action than chloral hydrate, and could not, he thought, replace it. He then exhibited a specimen of pure anhydrous chloral, which by the addition of pure water was converted into chloral hydrate. He suggested that as chloral itself was a fluid caustic, abstracting water rapidly, it might be usefully employed in some cases where soft fungous growths had to be removed. A specimen of metachloral, an insoluble white substance, obtained by the action of sulphuric acid upon chloral hydrate, was then shown. It is isomeric with chloral, and when treated with an alkali is resolved into chloroform and chlorate of the alkali employed. It seemed to act as a gentle narcotic when administered to inferior animals. Lastly, Dr. Richardson exhibited a specimen of mercaptan, or sulphur alcohol (C_2H_6S), in which the oxygen of ordinary alcohol is replaced by sulphur. He furnished considerable information concerning the action of this agent, and specially mentioned the mental depression produced by it even when taken in very minute quantities. He said also that it communicated to the breath a peculiar odour like that met with in wasting diseases, a fact which might furnish the groundwork for a new line of research in the diagnosis of disease.

SOCIETY OF ARTS.

The Cultivation of the Beet-root in England.

At the Ordinary Meeting of this Society held on Wednesday, March 8th, a paper was read by Dr. Augustus Voelcker, F.R.S., on "The Cultivation and Uses of Sugar-Beet in England." The author commenced by stating that scarcely more than half a century had passed since the first beetroot sugar manufactory was erected in Germany and sugar was extracted from beetroot on a commercial scale; yet in spite of many hindrances in the shape of vexatious fiscal regulations, and the want of experience inseparable from a new manufacture, the cultivation of the beetroot was largely extending in France, the north of Germany, Belgium, and Austria. It had also found its way into Russia, Sweden and the United States. At present there were over 500 beetroot sugar factories and distilleries in France, nearly 200 in Belgium and about 300 in Prussia. Probably the number of Continental factories did not fall far short of 2000, most of which were reported as doing a lucrative business. Notwithstanding the success which had attended the industry abroad, few attempts had been made in England to cultivate this useful crop, which he attributed to the fact that while on the Continent the manufacturer was often himself a farmer, this was not the case in England; and, therefore, the farmer in this country did not pay such special attention to the cultivation of roots rich in sugar.

In speaking of the cultivation of the beetroot, Dr. Voelcker described it as a biennial plant, growing wild in the south of Europe. It was introduced into the Netherlands by the Spaniards, and thence brought into Germany. The common field beet, of which the German name is "mangelwurzel," was introduced into this country from Germany during the last century. The sugar-beet is a variety of the common mangelwurzel obtained by crossing and culture. Of the different sorts, the white Silesian root (*Beta alba*) is the most valued as being particularly rich in sugar. When grown in perfection it is pear-shaped, white in the body, shows very little above ground, penetrates about twelve inches into the soil and has numerous radicles. It is light green on the top, has white flesh, green leaves with lighter coloured ribs, and strong long petioles. The specific gravity of the beetroot affords a good test of its quality; the greater its specific gravity the richer, as a rule, will it be found in sugar. A better test is the specific gravity of the juice, which, when of good quality, usually varies in sp. gr. from 1·07 to 1·06, or even 1·078. These roots contain over 14 per cent. of crystallizable sugar. The juice of roots poor in sugar invariably falls below sp. gr. 1·06.

After treating of the character of the soils suitable or ill-adapted for the growth of beets, the manure, the time of sowing, distance of planting and various other points connected with the cultivation, the author proceeded to discuss the composition of sugar-beets. He said that all the sugar present in fairly ripe roots is crystallizable, and when perfectly pure, identical in composition with crystallized cane-sugar. Beetroots do not contain any glucose, or grape sugar, and the glucose contained in the molasses produced in beet-sugar manufacture is the result of changes which cannot altogether be avoided in extracting the crystallizable sugar from the roots. In addition to sugar, which is the principal solid constituent of beets, there is found in them water, albuminous or nitrogenous compounds, vegetable fibre, pectinous compounds, and mineral constituents taken up from the soil.

The following is the report of an analysis of a root grown in the neighbourhood of Lavenham, in Suffolk. The root is described as having a red top, rose-coloured skin, and weighing 2 lb. 4½ oz. The specific gravity of the juice was 1·0689 at a temperature of 64° F.

Moisture	82·72
Albuminous compounds (containing ·231 of nitrogen)	1·44
Crude fibre (pulp)	3·38
Crystallizable sugar	10·94
Pectin, colouring matter, etc.	·45
Mineral matter (ash)	1·07
	100·00

Other roots grown at Lavenham, and in Norfolk, Berkshire and Buckinghamshire, contained from 9 to 11 per cent. of sugar.

As an illustration of the importance of a judicious use of manure in the cultivation of beet, Dr. Voelcker mentioned that the highest percentage of sugar, amounting to 13 per cent., which he had obtained from any of the numerous specimens that had been sent him was from a rose-coloured Silesian beet weighing little above two pounds, which had been grown at Barking with London sewage. On the other hand, in another specimen raised by the same sewage in the same season, he found only 3 per cent. of sugar. The author then described the process of the manufacture of beetroot sugar, an account of which we purpose giving in noticing another paper read before the Society at its next meeting.

Beetroot distillation was the next subject passed under review, a business which on the Continent is often added to the sugar manufacture, as it enables the manufacturer in a season when the beetroot is too poor to extract the sugar with profit, to utilize the crop by fermenting the sliced roots or their saccharine juice, and obtain by distillation the spirit which has been produced by the process of fermentation. The roots which are comparatively poor in sugar also contain a larger proportion of albuminous and saline constituents which interfere with the production of sugar-crystals, but have no influence on the fermentation, and do not diminish the amount of alcohol. In addition to water, the first distillation of the fermented roots contains certain bye-products of fermentation which are poisonous, and have a very unpleasant taste and smell. They are volatile, and popularly known under the name of fousel oils. From these volatile impurities the weak crude spirit is separated by rectification.

The paper concluded with a reference to the value of the beetroot pulp, or refuse, which is produced in the sugar manufactories or distilleries, as a feeding material. In its natural state the pulp contains from 70 to 72 per cent. of water, while in the ordinary mangold the water amounts on an average to 88 or 89 per cent. In round numbers the refuse pulp of sugar factories where presses are used contains, in 100 parts:—

Water	70·0
Sugar	1·5
Albuminous compounds (flesh-forming matters)	2·5
Crude fibre and a little lactic acid	24·0
Mineral matter (ash)	2·0
	100·0

Taking into consideration the probable difference in the feeding value of sugar and vegetable fibre, Dr. Voelcker said he was inclined to think that a ton of fresh beetroot pulp, as it comes from the presses, or old pulp, not containing more water than fresh, is worth fully as much for feeding purposes as 1½ tons of the beetroots from which it is obtained, or two tons of common mangolds.

LONDON CHEMISTS' ASSOCIATION.

At the Meeting on Thursday, March 9th, Mr. Cox occupying the chair, Mr. Jessop made some remarks on Structural Botany. He endeavoured to show in what way the structure of plants, both with regard to their internal and external organs, may best be studied.

By the help of a number of well-executed diagrams, he pointed out the differences in shape of the various kinds of cells, explaining how they became modified, and how they were all traceable back to the original oval shape. He carried out the same plan with roots and bulbs, and showed how the different forms of these may be derived from certain primary forms; several diagrams were exhibited, in which leaves were traced from a few simple lines to their many modifications of shape. The arrangement of leaves upon their stems was next spoken of. It seemed, Mr. Jessop remarked, that leaves followed some arithmetical rule of growth; it was almost the only instance in which figures were of any use in botany. The theory that the veins of leaves strike off from the primary vein at the same angle as the stems of the plants on which they grow was also gone into; there could be no doubt, he said, that similar species, and even genera, of plants followed such a law. Mr. Jessop next spoke of plants becoming modified, so as to suit themselves to certain conditions of life; of how plants grow in classes and compose the scenery of certain districts and countries. After explaining why botany was not, and could not, be a science made up of abstract laws, he said he certainly thought more might be done to simplify the study in the manner he had attempted.

After discussing some notes in the "Inquiry Box," a vote of thanks to Mr. Jessop and the Chairman terminated the meeting.

PHILADELPHIA COLLEGE OF PHARMACY.

At the Pharmaceutical Meeting on March 21st, Mr. Boring referred to several specimens from a large natural deposit of phosphates, recently utilized by the Charleston (South Carolina) Mining and Manufacturing Company. Some of these are bones, vertebræ, etc., of large animals, but others appear of irregular and indefinite shapes, so as to obscure their origin. The quantity of this material is immense, and it is readily obtained near the surface. According to the published analysis it contains about 29 per cent, of phosphoric acid, equal to about 63 per cent. of bone phosphate of lime; its chief use at present is in the fabrication of fertilizers.

Prof. Maisch exhibited samples of *Vanilla planifolia*,—Bourbon Vanilla. This variety does not possess the same delicacy of odour as the Mexican. The bean differs from the Mexican, being shorter, wider and terminating more abruptly at the ends. Prof. Maisch also made some remarks upon several varieties of Rhubarb not met with in the United States markets. These rhubarbs are grown in Austria, and called *Rheum Emodi* and *Rheum palmatum*. They are cultivated to a considerable extent, principally for dispensing to the poor, being very much cheaper in price. A sample exhibited was handsome in appearance, and sold at \$5 to \$7.20, gold, for 108 pounds. This variety is so well prepared that it is very difficult, except upon close examination, to distinguish it from good Chinese rhubarb.

Mr. Gailard spoke of the elixir of pepsin, bismuth and strychnia, and the difficulty experienced by most apothecaries in preventing precipitation, and suggested forming a citrate of the quinia and strychnia with excess of citric acid, neutralizing the excess of acid with ammonia; by this means he obtained a satisfactory preparation.—*Amer. Journ. Pharm.*

MEETINGS FOR THE ENSUING WEEK.

Monday April 24. ......*Medical Society*, at 8 P.M.
London Institution, at 4 P.M.—"On Astronomy" (Educational Course). By R. A. Proctor, F.R.A.S.

Tuesday April 25. ......*Royal Institution*, at 3 P.M.—"On the Geology of Devonshire, especially of the New Red Sandstone." By W. Pengelly, F.R.S.
Royal Medical and Chirurgical Society, at 8.30 P.M.

Wednesday April 26. ...*Society of Arts*, at 8 P.M.—"Photography in the Printing Press, being a Description of the Working of the Heliotype Process." By E. Edwards.
London Institution, at 12.—Annual Meeting of Proprietors.

Thursday April 27. ......*Royal Society*, at 9 P.M.
London Institution, at 7.30 P.M.—"Economic Botany." By Professor Bentley.

Friday April 28. ....*Royal Institution*, at 8 P.M.
Quekett Club, at 8 P.M.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

VACANCY.

The office of Dispenser at the South Staffordshire General Hospital. For particulars, see advertisement in last week's Journal.

Parliamentary and Law Proceedings.

Poisoning of a Child through the Mistake of the Doctor.

At Counden, near Bishop Auckland, the child of a pitman has been accidentally poisoned, in consequence of the wrong powders having been given. Directly the mistake was discovered the doctor, Mr. M'Intosh, was sent for, who said it was entirely his fault, that he had sent the powders for the mother instead of the child. The child died on Sunday, March 26th. An inquest was opened by the deputy-coroner on the following Wednesday, but the inquiry was adjourned for a fortnight.—*South Durham and Cleveland Mercury.*

Poisoning by Cyanide of Potassium.

An inquest has been held at St. Neots to inquire into the death of William Peek, the evidence given at which illustrates the carelessness with which poisons are kept by many persons who are in the habit of using them for the purposes of their business.

It appeared that the deceased had been transacting some business with Mr. Chambers, a watchmaker of that town, and asked for a glass of beer, which was given him. Shortly afterwards he was seen by an acquaintance leaning against a wall, apparently very ill. He was taken back to Mr. Chambers's, and medical assistance obtained, but died about an hour afterwards.

Mr. W. Chambers said that the deceased having asked for a glass of beer, he told his wife to bring the bottle of beer from the parlour, and pour out a glass. She did so, and the deceased drank it, and remarked that it was very nice. He had another bottle in his workshop, labelled "gilding solution," containing cyanide of potassium, muriatic acid, ammonia and water. Since the accident he had labelled that bottle "Poison." An hour or two before Peek came in he sent for some beer, a portion of which he mixed with the gilding-solution; the remainder was put into a bottle. He supposed that after he had done gilding he had poured the remainder of the gilding solution into the same bottle, as it was standing side by side with the gilding-solution bottle, but he had no recollection of so doing. He afterwards took the bottle into the parlour, with the intention of drinking the beer it contained at supper, and, if Peck had not come in when he did, undoubtedly himself and his wife would have drunk it. The bottle containing the gilding solution was generally kept, with several other bottles containing acids, etc., in a cupboard on the cellar stairs.

Mr. Wright, surgeon, said that he found the deceased in a state of great nervous depression, and insensible. He placed him in a semi-erect position, and poured some solution of ammonia down his throat. A galvanic battery was also used with some apparent benefit, but death ensued soon afterwards. He was sure it had been caused by cyanide of potassium. He remarked that in his opinion there was enough cyanide of potassium in the glass of beer which the deceased drank to poison upwards of twenty people.

The coroner said that from the evidence there could be no doubt that the poison was placed in the beer accidentally, but Chambers had been guilty of gross carelessness. The bottle of poison, also, was left in such a manner that any person might have drunk from it, not even the word poison having been put on it till after the fatal occurrence.

The jury returned a verdict "That death was caused by poison administered accidentally, but under circumstances of gross carelessness on the part of Mr. Chambers."

TUBA ROOTS.—We have received the following communication from Dr. J. E. De Vry:—In reference to the notice on tuba roots on p. 790 of your valued periodical, I take the liberty to inform you that the natives in Java use under that name *Dalbergia heterophylla* and *D. purpurea* to narcotize fishes with the intention to catch them. I suppose these are the same plants which are used in Borneo under the name of tuba or tooba.

The Hague, 6th April, 1871.

PARRISH'S SYRUP OF THE PHOSPHATES, OR CHEMICAL FOOD.—For the information of several of our correspondents, we reproduce the formula for the above, from Parrish's 'Practical Pharmacy.'

Parrish's Compound Syrup of Phosphates.

Take of Protosulphate of Iron ʒx
Phosphate of Soda ʒxij
Phosphate of Lime ʒxij
Phosphoric Acid, Glacial, ʒxx
Carbonate of Soda ℈ij
Carbonate of Potassa ʒj
Muriatic Acid
Water of Ammonia, of each, sufficient
Powdered Cochineal ʒij
Water, sufficient
Sugar lb.ij ℥viij, offic.
Orange-flower Water f℥j.

Dissolve the sulphate of iron in f℥ij of boiling water, and the phosphate of soda in f℥iv of boiling water. Mix the solutions and wash the precipitated phosphate of iron till the washings are tasteless. Dissolve the phosphate of lime in four fluid ounces of boiling water with sufficient muriatic acid to make a clear solution; when cool, precipitate it with water of ammonia, and wash the precipitate.

To the freshly-precipitated phosphates, as thus prepared, add the phosphoric acid previously dissolved in water; when clear, add the carbonates of soda and potassa, previously dissolved in water, and muriatic acid to dissolve any precipitate. Now dilute with water till it reaches the measure of 22 fluid ounces, add the sugar, and towards the last, the cochineal; dissolve by the aid of heat, strain, and, when cool, add the orange-flower water.

As thus made, each teaspoonful contains about $2\frac{1}{2}$ grains of phosphate of lime, 1 grain of phosphate of iron, with fractions of a grain of phosphates of soda and potassa, besides free phosphoric and hydrochloric acids. The solution is perfect, the taste agreeably acid and the flavour pleasant. The disposition to precipitate a bulky sediment of the insoluble phosphates is one of the greatest annoyances in this preparation, when made on a large scale, and can be obviated best by substituting hydrochloric acid for a suitable portion of the phosphoric acid used, taking care to separate the liquid into two portions, and adding the carbonate of soda and potassa to that consisting exclusively of the phosphoric acid solution, lest portions of chloride of sodium and chloride of potassium should be formed and contaminate the resulting solution.

Owing to the uncertain strength of phosphoric acid of commerce, being a mixture of the monobasic, bibasic, and tribasic acids, and always being contaminated with earthy phosphates, there is some uncertainty about the proportions to be employed in the above formula. These considerations have induced the trial of a method by double decomposition, which should always furnish a uniform strength of acid from a cheap and accessible source.

E. Scheffer, of Louisville, Ky., has proposed to take 49·25 drachms of phosphate of lime, 34·125 monohydrated sulphuric acid, diluted with three times its weight of water, put them in a thin dish and heat on a water-bath for half a day. By this process only 37·25 drachms of phosphate of lime will be decomposed by the sulphuric acid which combines with the lime of these 37·25 drachms to form sulphate of lime, while the phosphoric acid is set free and holds the other twelve drachms of phosphate of lime in solution. After it has cooled, the magma is pressed, macerated with fresh water, and again pressed, and the liquid evaporated, if necessary, to twenty fluid ounces, cooled and filtered. The phosphate of iron and carbonate of potassa and soda are now added as in my own recipe, and the whole made into a syrup *secundum artem.*

The washing of the precipitated sulphate of lime is best performed in a funnel, the water being thrown upon the middle in a kind of reservoir formed by raising the precipitate on the sides of the funnel; the last portions are collected separately and evaporated until, with the stronger portion, they have the desired measure.

Dr. Joseph G. Richardson, of Philadelphia, has proposed to use citric acid as the solvent for the phosphates in the compound syrup; this substitution, though probably modifying the therapeutic properties of the preparation, furnishes it in a very agreeable form.

We are indebted to the *Chicago Pharmacist* for the following formulæ:—

BORAX AND GLYCERINE.

Take of Borate of Soda in fine powder, 1 part.
Glycerine, 2 parts.

Mix, perfume, and colour with cochineal.

MEDICATED PRUNES.

Take of Senna leaves, 2 parts.
Boiling water, 16 parts.

Macerate for an hour and strain; add to this infusion,

Prunes (stoned), 32 parts.
Sugar (crushed), 10 parts.

Boil together, with constant stirring, for about ten minutes, and evaporate by means of a water-bath, until reduced to a pulpy consistence; add to each pound of this confection,

Citric Acid, in fine powder, 1 drachm.
Tincture of Ginger, 1 fluid ounce.

Mix.

CULINARY ESSENCES.

Flavour of Almond.

Take of Oil of Bitter Almonds 1 fl. drm.
Alcohol, 95 per cent. 10 fl. oz.
Water 6 fl. oz.

Dissolve the oil in the alcohol and add the water, and filter. This flavour should not be sold without a caution as to its poisonous nature, and directions as to the quantity to be used.

Flavour of Caraway.

Take of Caraway Seed, bruised, 1 oz. troy
Oil of Caraway Seed 2 fl. drms.
Diluted Alcohol 16 fl. oz.

Digest for eight or ten days and filter.

Flavour of Celery.

Take of Celery Seed, bruised, 4 oz. troy
Diluted Alcohol 16 fl. oz.

Digest for eight or ten days and filter.

Flavour of Cinnamon.

Take of Ceylon Cinnamon, brused, 2 oz. troy
Oil of Cinnamon ½ fl. drm.
Diluted Alcohol 16 fl. oz.

Digest for fourteen days and filter.

Flavour of Cloves.

Take of Cloves, bruised, 1 oz. troy
Oil of Cloves 2 fl. drms.
Diluted Alcohol 16 fl. oz.

Digest for eight or ten days and filter.

[225.]—CONCENTRATED INFUSIONS.—*G. M.* would be glad to receive information as to the best method of preparing concentrated infusions which will keep.

[*** We think the best way is to avoid concentrated preparations, and use fresh infusions. These may be prepared in a very short time. See a paper by Mr. Barnes on the subject, *ante*, p. 368, and another by Mr. Allchin, *ante*, pp. 421, 481. —Ed. Pharm. Journ.]

[226.]—COD-LIVER OIL JELLY.—*C. E. L. N.* would be obliged if any one would favour him with particulars of the manipulation for the formula which appeared in the Journal for April 8 [210]. The ingredients and proportion were named, but not the way of mixing. He has tried it several ways, but failed to make anything like an *elegant* preparation.—A. P. S.

[227.]—PREPARATION OF POMADES.—I should be glad if any reader could inform me of a remedy for preventing the steamed appearance on the sides of pomade bottles after they are filled and the pomade becomes cold. I have tried warming the bottles, and deferred putting the pomade into the bottles until almost solid, but with no better result. —"Moelline."

[228.]—SYRUPUS TONICUS.—You will oblige by saying in next publication of your Journal what should be dispensed for *syrupus tonicus* in a prescription (a Manchester prescription).—T. P. B.

[229.]—STRAINERS.—What is the best straining material for the dispensing counter—*tow* excepted?—J. W.

[230.]—SILVERING FOR PILLS.—What is the best substitute for mucilage of gum arabic in silvering pills?—J. W.

[231.]—BEETLE POWDER.—Can any reader oblige me with a good formula?—"Give and Take."

[232.]—LIQUID DENTIFRICE.—I should be obliged by a formula which is effectual and agreeable.—Tooth.

[233.]—PLATE POWDER for polishing brass, silver, etc. Will be obliged for a good recipe.—G. H.

[234.]—A PROBLEM FROM DOVER.—What should be the colour and consistence of this medicine, and in what order should the ingredients be mixed? The person who brought the prescription said he never had it made up twice consecutively the same colour.

M. ft. mistura.—A. B.

[235.]—MINERAL OILS.—Would any scientific reader tell me to what is attributable the peculiar "bloom" so characteristic of refined mineral oils, and inform me if there is any process by which this may be got rid of? The "bloom" much resembles that of quinine in solution.—A. P. B.

[*** The character referred to is an instance of fluorescence similar to that familiar to pharmacists in a solution of quinine. See an article by Professor Flückiger, *ante*, p. 682.—Ed. Pharm. Journ.]

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Has Public Opinion, as indicated by the Press, demanded Compulsory Regulations for the Storing, etc. of Poisons?

Sir,—I beg to hand you the enclosed correspondence.

So lately as March 31st, Mr. Dymond reiterated in a public meeting the argument in favour of accepting the compulsory regulations, "that the press demanded it, and they knew that the public approved it."

In a parenthesis, Mr. Dymond is reported to have thrown in a contradiction of something which he wrongly assumed I had said, and he attempts to thrust forward this side issue as a shield against my demand for the proofs of his own assertion.

I am not aware that any public interest or advantage would result from my complying with Mr. Dymond's request to make a particular statement, in order that he may disprove it. But, on the other hand, I recognize great importance in the main issue between us, and I now publicly ask Mr. Dymond to tell us how many of the "3370 newspapers and periodicals" he can put forward to support his assertion?

I forbear to allude to other aspects of the general question, beyond expressing the hope that the sound common sense of the trade, which has averted the immediate danger of compulsion, will closely scrutinize the alternative scheme to be offered. To be led into the approval and recommendation of any system which closely resembled the original one would be an illogical act, not unlikely to bring speedy punishment by the compulsory enactment of the measures which we had declared to be desirable, and had recommended for adoption.

Morecambe, April 17th, 1871. Rich. Reynolds.

(No. 1.)

"*April* 8, 1871.

"My dear Mr. Dymond,—I notice in the Pharmaceutical Journal of to-day, that at a meeting held in Birmingham you referred to me in the following words, viz., 'Mr. Reynolds was quite mistaken when he declared that only two papers had spoken on the subject' (that of regulating the storing, etc. of poisons).

"After this public statement of my being 'quite mistaken,' I must ask you to give the evidence requisite to support it, viz. the names and dates of the papers other than the *Lancet* and *Pall Mall Gazette*, and what they said in favour of the regulations.

"I will consider your reply as being public, and am, faithfully yours,

"Richd. Reynolds."

(No. 2.)

"*April* 11, 1871.

"My dear Mr. Reynolds,—Owing to my absence from home, your letter has not come into my possession until this afternoon.

"I cannot recognize your demand that I should prove a statement of my own, until I have an assurance from you that you are prepared to prove the truth of the inference of yours which is opposed to it. In your letter of Feb. 14 (Pharm. Journ., Feb. 18), you draw the conclusion that because the Pharmaceutical Journal had not reproduced articles on the suggested poison regulations from more than two papers, therefore no more than two papers had contained articles on the subject. Such a statement would have been amusing from its simplicity, if an absurd inference had not been drawn from it which was intended to damage the Council, of which you are a member, and you now ask me to disprove your remark!

"There are, as you doubtless know, about 3370 newspapers and periodical publications of various kinds unconnected with the drug trade, making about 180,000 appearances in the course of the year. If you will first plainly assert, and be prepared to prove, that from the date of the publication of the suggested poison regulations (Jan. 1, 1870) to the date of your statement (Feb. 14, 1871) no more than two of these papers contained any notice of or articles on the subject, I will then upset your proof by naming another daily newspaper (which will be enough for the present purpose) in which such an article did appear.

"I am, yours very faithfully,
"GEORGE DYMOND."

THE PRELIMINARY EXAMINATION.

Sir,—If you will kindly allow this a corner in your much-esteemed Journal, perhaps it may be the means of directing the attention of some one (more competent than myself) to the subject which I wish to lay before your readers.

When up at Bloomsbury Square for the Modified Examination, I heard many express regret at being compelled to pass the Preliminary Examination (even although successful in the Modified) before being eligible for the "Minor" or "Major." Now, Sir, I am confident many would go in for the Minor and Major qualifications were it not for that great stumbling-block, the Preliminary. Those gentlemen who go up for the Modified are mostly men well up in years, and the greater part of them have forgotten any smattering they may have had about Cæsar and other Latin authors. In fact, many have never had any acquaintance with that ancient worthy. Few men in the drug business have time to spare for the study of classics. But in working up for the Minor and Major, the student feels that he is studying subjects which are of practical and lasting benefit. I do not advocate the abolition of the Preliminary Examination; far from it. I think it is only fair and reasonable to expect the young members (who, for the most part, have just left school) to be able to show that they have a fair classical education. But I must say it is hard for us older members, who have "grown grey with age," to be compelled to "fight our battles o'er again," and study up the "History of the Gallic War," etc. I hope the Council will "be merciful," and grant the request of those who have passed the Modified, and admit them to the Minor and Major without enforcing the Preliminary. I am sure they will have the gratitude of all "Modified men," and by adopting this "liberal policy" the number of Pharmaceutical Chemists will be increased threefold, and will crush the jealousy which now exists between Pharmaceutical Chemists and "Chemists by Examination," as some individuals term themselves. Therefore, let me urge upon the Council the propriety of sweeping away the Preliminary in the case of those who have passed the Modified, and I think that it ought to count for something. I hope that some one will champion our cause. B. S.

POISON REGULATIONS.

Sir,—This poison question has drawn my attention so forcibly to the influence and position of the Council of the Pharmaceutical Society, that on receiving the Journal of last week, I read over the names of the gentlemen who have been nominated for election for the ensuing year with critical curiosity. Some of the names are quite unknown to me, and as to their opinions on what I consider the vital points of pharmaceutical advancement, I have not the remotest idea; and in a short time I shall receive my voting-paper, drawn up in accordance with the bye-laws, leaving me in the same blissful ignorance.

The present Council some time ago sent me a code of regulations as to the storing of poisons, recommended by them for our adoption at the next general meeting. I assumed, therefore, that they meant to take their stand on their principles of action. The next thing I hear is that only one Councillor dared to nail his colours to the mast to meet the coming storm.

I ask, is the question of storing poisons to be discussed at the general meeting or not?

What is the line of policy marked out in the brains of the coming men who aspire to constitute, in part, the future Council?

And what is this question? The Pharmaceutical Society was founded for the advancement of pharmacy and for the protection of our privileges. We are becoming eminently qualified by our education to undertake the dispensing of this country, awaiting the time when public opinion shall demand that the man who prescribes a poison shall not compound it.

Every one knows where the *great bulk* of the medicine of this country is dispensed, and every man in our calling knows perfectly well what a growing dissatisfaction there is among the people against secret medicine and possible secret error. The Parliament has passed a Poison Bill and the Privy Council are desirous its provisions should be carried out. It appears to be met by the chemists with a determined opposition. Could anything, as a matter of policy, be more eminently suicidal? A greater blow could not have been delivered at the surgeries of this land than the adoption of a system of poison regulations in chemists' shops *where prescriptions are dispensed.*

Many of us who know the heavy responsibilities resting upon us adopt some system of poison closets; but we are a slow people. I instance the question of poison bottles and the stupid arguments brought against them some years ago. How has that opposition died? Are poison bottles adopted by dispensing-houses? Here and there possibly some obstinate chemist will not use them,—and it is just so with our poisons. Some obstinate employers will keep their tincture of aconite next their tincture of orange, their laudanum next the tincture of rhubarb, or their arsenic not far from the magnesia, and so long as they use them themselves it is their own matter; but if they believe the Privy Council will allow them to impose such terrible risks on others, they are very much mistaken. Parliament, now that attention has been called to it, will see the necessity of enforcing some plan, and who are so able to design it as ourselves? hence the vast importance we ought to attach to the election of the Council this year arises. Who are the men? What is their standing in the trade and the Society? and above all, what are their opinions? Are they the right men to meet the emergency, or is this spasm of discontent but a nightmare of apathy?

GEORGE MEE.

79, Grosvenor Road, Highbury New Park, N.
April 18th, 1871.

Sir,—I heartily congratulate the Council on the wise course it has taken in abandoning the intention of proposing any compulsory poison regulations at the next General Meeting.

Mr. Reynolds's letter in the Journal of February 18th quite prepared me for the President's retirement, and I deeply regret he has left on record any animus towards a large majority of our brethren, whom he accuses of raising "a wild unreasoning clamour on a mere sentimental grievance," sneeringly stating "that he was not shaken by the 'tall talk' resounding about him."

It is most clear Mr. Sandford is not the man to uphold our reputation and independence. He plainly tells us, "that should other parties try their hand at the work of compulsory poison regulations, he, for one, should be unable to say there is no cause for interference." I, therefore, fully agree with his explanation as touching his immediate retirement, "that in doing so he best advanced the interest and honour of the Society."

I forbear making any further comment, as these few lines are written more for the purpose of tendering my best thanks to the members of the Council for the manly course they have taken in upholding our position, and I shall be most happy in supporting them all at the next General Meeting.

Kilburn, April 17th. JOHN BEATON.

THE ADULTERATION BILL.

Sir,—Allow me, through the medium of the Journal, to urge upon the Council of the Pharmaceutical Society immediate action against Mr. Muntz's Adulteration Bill. I do not hesitate to affirm that if that Bill should become law, no chemist, however straight he might desire to keep, would be safe. We have already an Adulteration Act, which answers all practical purposes. It is well known that nearly all adulterations of drugs take place abroad, and therefore if this Bill is to pass, it must be insisted that all drugs shall be analysed before imported into this country; there must be supervision of chemical manufactories, and there ought also to be appointed a staff of analysts to examine and test drugs and chemicals for those who have not the time or the skill to do so.

Is it not much better to take the bull by the horns than calmly to wait till mischief is done? According to our present laws no chemist dare prescribe for a patient over the counter a cough mixture of oxymel of squills and paregoric without labelling the same with the ominous word "poison," unless he renders himself liable to a fine! All chemists may not be aware of this fact. Neither must he sell a 6*d.* bottle of benzine collas, or benzine anything else, unless he has a special licence for so doing,—which no one, at least in this town, has been able to obtain,—without rendering himself liable to a penalty of £20! All chemists may not be aware of this.

And yet such is the absurd state of the law. And if absurd, why has it not been repealed? I answer, because of the difficulty of getting any law repealed.

A COUNTRY MEMBER.

Maidstone, April 8th, 1871.

THE NOMENCLATURE OF THE PHARMACOPŒIA.

Sir,—To the accident of my name being mentioned by Prof. Attfield at the last Evening Meeting you owe this letter.

I aim at the every-day and practical only, not the theoretic or scientific.

I would again urge upon those having power and authority the great desirableness of distinguishing in the next B.P. between oils proper and "Essential"—so called. Why should the word "Essence" be diverted from its strict meaning and common acceptation only when employed in pharmacy? Ordinarily it signifies the distinguishing quality of a thing, or, at least, a concentration of its strength or efficacy; but in the Pharmacopœia it stands for—a dilution of one part to four; and in retail usage for proportions often much weaker. Let the essential oils be denominated "Essences," and their dilutions S. V. R. spirits. Surely no precise strength is necessary to constitute a "spirit."

What objection can there be to substituting "massa" for "pilula," seeing that it has long been so far sanctioned in practice as to make it impossible to misunderstand it? Or, perhaps better still, "pila" for the lump, "pilula for its small subdivisions?

Again. What more absurd than to call a plaster ready for use by the same name as the Composition from which it is made?—as common-sense-like as to call a table "a wood." What objection to "plasma," "plastum," or "plastrum," whichever be the best Greek?

The same objection holds to "glycerinum" for "glyceridum."

I have often regretted that Sir Humphry Davy ever invented that awkward and unmanageable (in composition) word "chlorine." "Murine," which must have first suggested itself, and for which chlorine was substituted, would have been more euphonious, more manageable, and would have affected no disturbance whatever. For my own part, I am decidedly of opinion that it would be, even now, a *gain* to go back to "muriatic," "muriates," and to coin "murine," and, if needful, "murides."

Many have been the suggestions for effectually distinguishing between calomel and corrosive sublimate. Here is another. Let the textual name for the first be "calomelas," with an authorized chemical synonym, for disguise, underneath, and for the other "calomelas *muriata*." The utmost extreme of hasty contraction *must* add the "*m*" for the more dangerous article, and that would be effective; whilst "calom. muriat." could not possibly be misinterpreted.

T. LOWE.

Breckfield Road North, Liverpool, April 8th, 1871.

PREVIOUS SEWAGE OR ANIMAL CONTAMINATION IN POTABLE WATERS.

Sir,—It is with the greatest diffidence that I venture to put myself, even in the slightest degree, in opposition to so eminent an authority as Dr. Frankland, but I cannot allow his charge of misquotation and misrepresentation contained in his letter to you of last week to go unanswered.

In the paper he refers to, I made use of the term "previous sewage contamination;" and Dr. Frankland says that this is a misquotation, and that it should have been "previous sewage and animal contamination (estimated)."

On reading Dr. Frankland's letter, I immediately referred to his latest published paper, viz. that read before the Chemical Society a few weeks ago, "On the Development of Fungi in Potable Waters," and there, although I found mention twice of the term "previous sewage and animal contamination," I could nowhere find any mention of "previous sewage and animal contamination (estimated)." Where, then, is my misquotation? And even if I had omitted the word "estimated," what difference could it possibly have made?

In the same paper, Dr. Frankland gives the results of several analyses of potable waters that he has lately made I will take the first three on the list.

	1.	2.	3.
Ammonia	·161	·027	·110
Organic nitrogen . .	·106	·100	·126
Nitrogen as nitrates, etc.	4·384	1·637	0
Total combined nitrogen	4·603	1·760	·217
Previous sewage or animal contamination	44850	16270	590

It will be seen that, as a matter of course, the "nitrogen as nitrates and nitrites" is contained in the "total combined nitrogen," and also that from this "total combined nitrogen" the "previous sewage or animal contamination" is calculated; and yet Dr. Frankland denies my statement, "that from the nitrates present he calculates how great the previous sewage contamination has been!"

I did not for a moment suppose that Dr. Frankland would consider the evidence I have brought forward in favour of nitrates being produced otherwise than by the oxidation of sewage or animal matter conclusive. I am glad to learn he is investigating the subject, and, as my only object is to get at the truth, I shall equally welcome his decision whether it be for or against me.

Bath, April 10th, 1871. CHARLES EKIN.

We have been requested to publish the following correspondence:—

Hampstead, April 8th, 1871.

Gentlemen,—I beg leave to inquire if you have any knowledge of a person calling himself Fischer or Fisher, representing himself as a scientific chemist, a Dane by birth, but long resident in Germany? The fact that in making an application to me for relief, he used your name, stating that you had offered him temporary employment, induces me to apply to you for information, with a view, should your reply not be of a satisfactory nature, of publishing the facts in order to put a stop to further depredation among chemists and others.

I am, gentlemen, yours very truly,

Messrs. F. C. Calvert and Co. CHAS. EVE.

Tower Chemical Works,
Bradford, Manchester,
April 10th, 1871.

Chas. Eve, Esq., Hampstead.

Sir,—In reply to your inquiry, we have to inform you that the man Fischer or *Fisher*, to whom you refer, is totally unknown to us. We are, Sir, yours respectfully,

F. C. CALVERT AND CO.

Tenax.—(1.) No. (2.) Hooker's 'Student's Flora,' published by Messrs. Macmillan, price 10*s*. 6*d*. (3.) The presence of lead in glycerine may be detected by means of sulphuretted hydrogen. (4.) Messrs. Macmillan, price 4*s*. 6*d*.

Delta.—An article, by F. C. Calvert, on "The Adulteration of Oils" will be found in the PHARMACEUTICAL JOURNAL, 1st Series, Vol. XIII. p. 356.

Medd's 'Pharmacopœial Botany.'—We are unable to give any information concerning the publication of the above work.

G. G.—The names referred to are those of persons who have been restored to membership upon payment of their arrears of subscription according to the bye-laws.

Walter Plumbly.—'Selecta è Præscriptis' is published by Messrs. Churchill, New Burlington Street, price 5*s*.

The Royal Nuptial Bouquet.—We beg to acknowledge the receipt of a sample case of this perfume, and regret that we are unable to chronicle its merits, otherwise than in our advertisement columns.

J. H. Talbot.—You need not have any fear of any explosion under the circumstances stated.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Wilkinson, Mr. W. W. Stoddart, Mr. Jackson, Mr. E. Hall, Mr. G. C. Kernot, Mr. A. H. Mason, Mr. F. O. Collins, Mr. J. T. Robinson, Mr. A. R. Walden, Mr. A. W. Gerrard, Mr. G. Adam, A. P. B., H., C. T. J., W. J., P. C., C. W. S., "Delta," "Boiler Composition," "Inquirer."

VARIABILITY IN THE ACTIVITY OF LEAVES.

BY M. C. COOKE, M.A.

It is well enough known that the parts of plants collected for pharmaceutical purposes are subject to considerable variation, that they are by no means uniform in the proportions of their constituents, and hence are sometimes likely to fail. Many instructions have from time to time been given for the collection of roots, rhizomes, bark, etc., in order that uniformity might be more readily predicated. The plant just before the period of flowering is, in many of its parts, stronger or weaker in certain constituents than at other periods. Of all parts, perhaps, roots require the greatest care as to the time at which collected. Next in order, as it seems to us, are leaves. There are not many leaves of indigenous plants that are of much importance as articles of materia medica; but there are a few, and if these few are to maintain their position, it is of the utmost importance that they should be uniform in their action, which cannot be the case if no regard be paid to certain facts associated with plant life.

It may be asked with reason, is there any season or any condition which so influences the development of active principles in the leaves of plants as materially to affect their value as remedial agents? Undoubtedly there is, but not so much affecting cultivated as wild plants, because in the former the conditions are more uniform. Setting aside all question about periods of flowering or fruiting, or, in fact, of any period in the history of any individual plant, there seems to be one very important influence which is very much ignored, as affecting condition. This may be illustrated by reference to an example in which active principles are developed in a high degree, and in which the opportunity for testing is easily secured. The facts which seem to manifest themselves clearly and unmistakably in tobacco leaf, may be supposed to influence belladonna leaves, stramonium leaves, and even the leaves of other plants not in the least allied to them.

It is admitted that tobacco grown in a cold climate is much stronger than that grown in a mild one. In other words, active principles are more concentrated in leaves grown in cold climates, where the vegetation is less vigorous, than in warm ones. When the tobacco plant is forced on to a rapid growth, with a plentiful supply of moisture, the leaf is found to contain less of its characteristic principles than when stunted, starved, and but slowly developed.

Not only is this true of tobacco, but it is true also of other plants which have been tested. It is true of cultivated celery that the petioles and leaves are much more strongly flavoured when grown slowly than when grown rapidly, and under favourable conditions of soil and moisture. Except as they influence rapidity of growth, it is very doubtful whether the chemical constituents of a soil affect in any appreciable degree the active principles of leaves.

Take another example, although not, perhaps, quite so pertinent. In a very dry season, or when growing in very dry localities, the leaves of the common nettle are much more highly charged with their irritating poison than when grown rapidly, in a wet season, or in a moist locality.

From these and similar instances, therefore, we are led to the conclusion that rapid growth, with a plentiful supply of moisture, is least favourable to the development of those properties in leaves which are of value in medicine. Whether this principle holds good with glandular plants, secreting essential oil, such as the *Labiatæ*, we are not prepared to affirm from actual experience. The inference is, that leaves grown in a dry season would, *ceteris paribus*, be more active than leaves grown in a wet one; that plants grown in a damp situation or a rich stimulating soil would be milder than those grown under less favourable conditions. In fact, we have found the leaf of *Arum maculatum* to vary considerably in its biting acrid properties in proportion to its development. Leaves from large rapidly growing plants in moist situations are by no means so acrid as the small leaves of stunted plants growing on dry banks. This is an experiment which any one can perform for himself during a country stroll.

It would be of interest to ascertain by careful analysis what is the difference in the proportions of the constituents of such leaves as belladonna and stramonium, grown under the two conditions of vigorous and retarded vegetation. The very rough test applied to the leaves of arum, and the inexact one applied to tobacco, indicate strongly enough that there must be a very appreciable difference; but this is in itself insufficient, it should be determined what *is* the difference; and we have no doubt it will be sufficient to account for much of the variability in the action of leaves.

A less important circumstance, but one which should not be lost sight of in this connection, is the difference between fully matured and young leaves from the same plant. There can be no doubt that there is a difference, but the proportion of young leaves, weight for weight, to mature leaves will not be great when dried, because the larger percentage of water in young leaves will reduce the disproportion, as well as the excess of mature leaves which will be collected from a full grown plant, over immatured ones.

From these suggestions it seems to us that the pharmacologist may collect some of the causes that influence the variability in activity of leaves gathered and dried indiscriminately. It is quite possible that in some instances foliaceous drugs have been condemned for their uncertainty, when the fault has really been traceable to an unsystematic and indiscriminate mode of collection. The results of recent experiments on the influence of climate, soil, moisture, and other external circumstances, upon the development of active principles and aroma in tobacco leaves, incline us to the opinion that, not only in that instance, but in many others, the circumstances and their influences have been too much forgotten or ignored. With this impression we have ventured to direct attention to the subject, in the pages of a journal which is interested more than any other in pure and uniform drugs.

Vinca Major.—Mr. Spencer Wells states that in some cases of menorrhagic bleeding he has found a preparation of *Vinca major*, the well-known Greater Periwinkle of our shrubberies, preferable to lime, gallic acid or ergot. He was first told of it by Mr. Squire, and has prescribed it according to the formula given in that gentleman's 'Companion to the British Pharmacopœia,' viz. an infusion of 2 ounces of dried herb to 20 ounces of boiling water, and strained when cold.—*British Medical Journal.*

ADDITIONAL REMARKS ON

THE CHEMICAL NOMENCLATURE OF THE BRITISH PHARMACOPŒIA.

BY PROFESSOR ATTFIELD.

The discussion on this paper at a recent Pharmaceutical Meeting extended so much beyond the usual hour of adjournment that I could only express my appreciation of the support the chief suggestions received; I would now reply to one or two of the points raised, and make some additional observations.

The Proposed System of Pharmaceutical Nomenclature.—It will be remembered that my leading proposition was, "that the compounds of the alkali metals and alkaline earth metals, instead of being named as hitherto, on two distinct systems, should follow but one; that instead of salts of potassium and potash we should have salts of potassium only; instead of sodium and soda compounds sodium only; and so with preparations of ammonium, lithium, calcium, magnesium and aluminium." The eminent chemical and pharmaceutical authorities who spoke on the occasion—Professors Frankland, Odling, and Redwood—entirely concurred with this suggestion, and I have now the gratification of stating that the leading weekly medical periodicals—the *Lancet*, *Medical Times and Gazette* and *British Medical Journal*—have given their support to the plan; in short, that no objection to it has at present been raised.

With respect to the question of Professor Frankland as to the method of distinguishing between similar salts of one metal, *e. g.* the two sulphates of iron, I would, whenever such a course may become necessary, add to the name a word or an initial syllable recalling some prominent difference in the properties of the two compounds: thus, *green* sulphate of iron and *per*sulphate of iron; these names are, to the pharmacist, more familiar and distinctive than the more chemically useful names Professor Frankland proposes, "sulphate of ferrosum" and "sulphate of ferricum;" moreover, I fear that physicians in writing prescriptions would contract both the latter to *fer. sulph.* Again, there are two chlorides of tin, stannous chloride and stannic chloride, neither used in medicine, and only as analytical reagents in pharmacy; hence they might well be distinguished pharmaceutically as well as chemically by the names just given; or if it be undesirable to introduce this one exception to the general principle advocated, the compounds might be termed respectively *solid* chloride of tin and *liquid* chloride of tin, or *crystalline* chloride of tin and *per*chloride of tin.

With regard to the history of the chemical nomenclature at present employed in Pharmacopœias, I have said that it was only "mainly" devised by Lavoisier, and believe that I have followed general custom in speaking of it as the Lavoisierian method; at the same time there can be no doubt, as indicated by Professor Odling, that it was gradually developed by the contributions of many minds. "The system of nomenclature—the joint production of Lavoisier, De Morveau, Berthollet and Fourcroy—published in 1787 under the title 'Méthode de Nomenclature Chimique, proposée par MM. de Morveau, Lavoisier, Berthollet, et de Fourcroy,' still continues the foundation of the language which, with many variations in minor points, is employed by all chemists at the present day." (Professor G. C. Foster's article on "Nomenclature" in Watts's 'Dictionary of Chemistry.') I may add that the system I propose for adoption in medicine and pharmacy was employed in 1858 in Conington's 'Handbook of Chemical Analysis,' is much used in the dictionary just cited, is the leading nomenclature of the 'Manual of Chemistry' I first published in 1867, has since been included in the labels of the chemical specimens in the Pharmaceutical Society's museum, and for some years has been placed on the labels of at least one firm of English chemical manufacturers (Messrs. Hopkin and Williams). Hence it works well in practice. For scientific purposes it is scarcely sufficiently comprehensive; and for two or three years I have hesitated in proposing for applied chemistry a system of names not identical with the nomenclature of pure chemistry. As, however, there is still no indication that the two or three systems of names used by teachers of pure chemistry will ever merge into one, and as it would be impossible to employ more than one in applied chemistry, I do not think I act disloyally to, or influence otherwise than beneficially, the science I follow by selecting and adapting one of the current systems for permanent employment in medicine and pharmacy.

The Exceptional Alterations.—I adhere to the opinion that the old and perfectly well-understood name *arsenicum album* is preferable to *acidum arseniosum*. The body is not an acid in the sense in which every other acid in the Pharmacopœia is an acid, and, therefore, should not officially be termed an acid. Such irregularities are prejudicial to the interests of chemistry and confusing to students. As for other anhydrides, it will be time enough to discuss their nomenclature when good indications appear of their official recognition. Chromic anhydride, or chromic caustic, might be termed red caustic, or red oxide of chromium. In the cases of the subcarbonate and subnitrate of bismuth, and the subacetates of copper and lead, it has been considered by Professors Redwood and Odling that the prefix "sub" is not well substituted by "oxy," and I am disposed to agree in this opinion. Indeed, I have never strongly urged the adoption of the terms oxycarbonate, oxynitrate, oxyacetate, oxyhydrate as leading names, but have suggested that they would be highly serviceable as synonyms; I would now thus restrict the suggestion, and include in it the hydrato-carbonates of lead, magnesium and zinc. With respect to the "scale" preparations and some substances similarly named (tartarated antimony, tartarated iron, tartarated soda), I am glad to find that Professor Redwood coincides with me in thinking that the existing names admit of improvement. I have suggested that alterations in these names should go so far as to make them consistent with the corresponding names of the three citrates. My only objection to the six names my colleague mentioned (ammonio-citrate of bismuth, ferro-citrate of quinia or quinine, etc.), is that similar compound words (aceto-nitrate, methyl-ethyl) are employed in chemistry for the express purpose of suggesting intimate union between the bodies whose names are included in the compound word, no such union being pretended to exist in the case of these scaly and other preparations. There are some advantages to set against this objection, at the same time it is desirable that the nomenclature of chemistry and pharmacy should harmonize as much as possible. As for the names of the alkaloids, the balance of usage is in favour of "ine," instead of "ia," as the terminal syllable of the words; thus, morphine, quinine, strychnine,—not morphia, quinia, strychnia.

THE TAMARIND.

BY JOHN R. JACKSON, A.L.S.
Curator of Museums, Royal Gardens, Kew.

The Tamarind (*Tamarindus indica*, L.) is well known in this country as an agreeable and useful medicinal preserve. There is only one species of the genus, of which, however, there are two varieties, one growing in the East, and the other in the West Indies. The chief difference is in the length of the pods, those of the Eastern plant being from three to six inches long and slightly curved, and containing from six to twelve seeds, while the Western variety is shorter and seldom has more than four seeds. The trees grow to a great height, attaining in the East Indies eighty feet. The pinnate leaves and racemes of yellow and red-streaked flowers, with purple filaments, give it a pleasing and graceful appearance.

The wood is excessively hard, and so heavy that it sinks in water. It is peculiarly marked with broad chocolate-brown streaks. In the East Indies it is used for furniture and for general building purposes. Tamarinds, as seen in commerce, consist of the pulpy or fleshy part of the pods—after the outer shell has been removed—preserved in syrup or sugar. The mode of preserving them is either by throwing hot sugar from the boiler on the ripe, pulpy portion of the pods, or by placing alternate layers of tamarinds and sugar in stone jars: preserved in this way they are said to have a finer flavour and better colour. Tamarinds are valued with us, as well as in nearly all the countries where they grow, for their gentle laxative and cooling properties; they are, moreover, used in tropical countries as an article of food. In Sumatra they are salted and used in cooking and served at table, and in Western India they are used in preserving or pickling of fish. The leaves partake of the acid property of the fruit, and a decoction is employed in Ceylon for fomentations and in ophthalmic cases; they are, moreover, taken internally for the cure of jaundice. In Bengal an infusion is made from them and used in preparing a fixed yellow dye, in which silks, after having been previously dyed in indigo, are dipped and changed to a green.

The Tamarind-tree is said to exhale a large amount of acid, and the damp air becoming impregnated with it during the night, sensibly injures the fabric of cloths exposed to its influence for any length of time. On this account the natives have a strong objection to sleep under the trees. It has been said that no plants will grow under the shade of the Tamarind; but this is evidently a mistake, though it is not impossible that the acid has an injurious effect on some plants. The flowers are employed in Ceylon in the preparation of a confection which is considered valuable in liver complaints. The seeds, in times of scarcity, are eaten as food, being first roasted and then soaked for some hours in water, by which the hard outer skin is removed; they are afterwards boiled or fried and eaten. Simply pulverized, they are mixed with water into a thick paste, and applied to boils to promote suppuration. The powder is also boiled with thin glue, and is said to constitute one of the strongest of wood cements. Besides all these various uses of the Tamarind-tree, it is said that the native silversmiths in Southern India use a strong infusion of the acid fruits mixed with sea salt for cleaning and brightening silver.

EXTRACTUM CINCHONÆ FLAVÆ LIQUIDUM.

BY A. W. GERRARD,
Dispenser, Guy's Hospital.

Having some time since obtained this preparation from a different wholesale house than whence we usually purchased it, I was much surprised at the difference in taste, odour and colour from that we had been previously using. I was still further astonished when, on dispensing it with an alkali, it gave neither precipitate nor turbidity. I at once set some of this aside for examination, and at the first opportunity prepared some by the British Pharmacopœia; and having purchased three other samples, I engaged myself to determine their relative value.

We know that its medicinal properties are due to the alkaloids therein; and if it is made as instructed with the yellow bark, which should not contain less than two per cent. of quinine, a measured quantity should yield on precipitation with an alkali an amount of alkaloids not below a certain standard; what that standard is should, I think, be determined and introduced as a test in a future edition of the Pharmacopœia.

The following table shows the amount of washed and dried precipitate obtained from two drams of each on the addition of solution of potash:—

No.		Weight of Precipitate.	Colour.	Taste.
1	Home made.	grs. 10	Dark brown.	Aromatic bitter.
2	Purchased.	„ 10	„ „	„ „
3	„	„ 7	Brown.	Less bitter.
4	„	„ 3	Pale brown.	Slightly bitter.
5	„	„ 0	Very pale brown.	Sweetish and faintly bitter.

I subjected each of them to the test for quinine by the ether chlorine water and ammonia process, 1, 2, 3 and 4 gave the emerald green colour, 5 failed; 1 and 2 left the largest amount of quinine upon the watch-glass after the evaporation of the ether. I may here mention that a quick and ready method of proving the presence of quinine in this preparation is to place a thin layer on a piece of window-glass on drying and exposing to transmitted light, it will show the well-known fluorescence.

It is evident that this article, as met with in our pharmacies, is a very varying product. All of the samples except No. 1 came through respectable wholesale houses; that they should supply chemists with such diluted forms as 4 and 5 is deserving of censure, and warns us to be vigilant. The remedy for this is in our own hands. Every-day experience teaches that many preparations which are usually purchased should be home made. What proofs have we, that bought pill-masses, powders, liniments, etc., are not made with the commonest instead of the best materials? The chemist should get the root bark and leaf, and operate for himself; the result will amply repay the labour, and he has the self-gratification of knowing that what he sells is pure and unsophisticated. If the performance of these duties were the rule instead of the exception, we should not hear so much of the neglected apprentice, for had he the opportunity of handling the specimens and assisting to obtain their products, it would leave a far deeper impression on his memory than cramming from books, and fill him with that spirit of emulation which is the road to excellence.

THE ARTIFICIAL PREPARATION OF MANNITE.*

BY JOSEPH M. HIRSH, OF CHICAGO.

The preparation of artificial mannite, attempted at the instance of this honourable body, has been but a partial success, in so far as I could not in every instance obtain a product of exactly the same composition from the raw material, commercial glucose. Trials with pure grape-sugar invariably failed, in my hands, to produce that peculiar nauseous principle characteristic of manna.

For the sake of brevity, I shall mention the outlines of my experiments in this direction.

I made glucose in the usual manner from starch, leaving about 10 per cent. of dextrine in the same undecomposed, but did not concentrate the glucose more than to 15° Beaumé. To this solution I added 5 per cent. of wheat flour, 5 of molasses, and as much of common malt vinegar, when the mass was at a temperature of 100° F. In twenty-four hours a lively fermentation had set in, which continued for three days, when I concentrated the liquid, which then showed the peculiar nauseous taste and odour of manna. Digested with alcohol, mannite dissolved, crystallizing upon evaporation of the alcohol, while dextrine and other impurities remained behind undissolved.

The peculiar nauseous principle appears to be partly decomposed matter, undergoing a gradual change into humus. Whoever has been in a vinegar factory, badly conducted, where poor ventilation produces an incomplete oxidation of the alcohol, but rather decay, must at once be struck by the resemblance of this odour to that of manna. It was this experience which induced my experiments in the manner mentioned above, the gluten of the wheat-flour forming, together with the vinegar, an excellent ferment of putridity, which not only produces the nauseous, humus-like parts existing in manna, but also the molecular change of cane- and grape-sugar which converts it into mannite.

This artificial manna, in its action as a laxative, equals the true manna; and very likely the presence of a substance in a state of change, the active principle, is the same both in the true and the artificial manna. The mannite produced in this manner does not reduce aklaline cupric tartrate, showing the complete change of the glucose; but your reporter would beg leave to complete his researches, viz. on the elementary analysis of the artificial product, which pressure of business has prevented him from completing.

An accompanying sample of the manna produced will show how far my attempts have been successful. —*Proc. Amer. Pharm. Assoc.* 1870.

* Paper read at the meeting of the American Pharmaceutical Association, in answer to the query, "Can mannite be prepared artificially? and if so, how? And has it the same physiological properties?"

KOUMISS.

BY VICTOR JAGIELSKI, M.D.

The modern progress of physiological chemistry has advanced the position of dietetic remedies to great prominence in the practice of medicine. A particular knowledge of their properties becomes indispensable, therefore, to every physician who would keep pace in learning with the obligations due to his patients. Presuming, then, upon my long experience in the science and art of the subject, I offer these remarks upon Koumiss, for I was the first to introduce it to the British medical profession.

Koumiss accomplishes the twofold beneficence of a grateful food, which nourishes the debilitated body, and a potent physic that renews its failing vitality. It is the most important derivative of milk, which latter, in its various forms, has risen to such a value as a dietetic remedy, that special institutions in connection with its use in the treatment of disease are multiplying yearly throughout the Continent. Already 150 are in existence, with double that number of physicians attending at them, and many of these physicians are eminent in their profession.

In these milk institutions milk is used in its normal state—as buttermilk, as thick milk, and as whey, and sometimes even in association with mineral waters. Although there are no institutions of the kind in this country, yet milk and its derivatives are daily assuming a greater importance as aids to other systems of treatment in British medical practice.

In certain severe diseases, accompanied by emaciation and debility, they have recently established a high character as restoratives. Remedies of this kind, more especially in the expectant mode of treatment, have the advantage over hazardous medicines in being harmless at the worst. They are free from any anxiety to the physician, and are much more likely to produce the good effect which he desires in his patient; especially are they the more rational means with which to commence the treatment, for they may soon produce results in a comfortable way, which will dispense with the necessity of co-operative medicines.

To the habitual use of these natural hygienic beverages the inhabitants of certain territories owe their immunity from particular diseases. In that district called the Steppes of Russia, lying between lat. 55° 30′ N. to 40° N., and long. 40° E. to 79° 50′ E., and bordered by the river Don and the Lake of Baikal, inhabited by Kirgheses, Tartars, Bashkurs, etc. consumption is unknown. Moreover, the people of these lands are distinguished by their robust health and iron constitutions, notwithstanding that their nomadic habits subject them to a life of exposure and poverty; and yet almost their only food and drink is koumiss, for their religion, which is Mahommedan, forbids the use of other liquors.

The exemption of these people from phthisis was so remarkable as to induce travellers to comment upon it on their return home. Their reports soon attracted the attention of the Russian Government, and led to the organization of a scientific commission of inquiry into the general character of the country. One of the results of these investigations was to settle the fact that the health of the inhabitants is due chiefly to their simple diet of koumiss, which combines all the elements of nutrition in most digestible and assimilable forms.

The origin of the word Koumiss is unknown, but in the Tartar language it signifies 'silver.' This definition is probably intended to be suggestive of the *noble* qualities of that beverage. True koumiss is prepared from mares' milk by fermentation. It is a piquant, sweetly acidulous fragrant liquor, which, when taken *in very large quantities, at once* produces a pleasurable excitement, without any bad after effect, owing to a small quantity of alcohol which it contains. In the East this alcohol is separated by distillation into a liquor, which is called 'aracu.' This latter, however, differs from the koumiss in being an intoxicating liquor of the most injurious kind. Emaciated by their meagre rations of smoked meat during the long and rigid winters, the Tartars hail the approach of spring with great rejoicing, because it brings back to them the season of koumiss. The meadows, warmed and vivified by the thick snows of the winter, now bloom forth in luxurious pastures to restore the drooping bodies of the half-starved mares; and the poor animals, once more natural in blood and flesh, give abundantly of milk to make the koumiss, which serves in turn to nourish and invigorate their masters. It is the grateful feeling which is natural to this change from a bare subsistence to one of wholesome plenty that inspires the Tartars to reverence koumiss as of 'Divine origin.'

It should be here remarked that the mares of the Steppes are a hardy race of animals, and it not unfrequently happens that one of a drove which may drop her foal during the march will be able, with her colt, to resume the journey two hours afterwards. When the colt is weaned, the mare can only be induced to yield her milk by a *ruse*, which consists in making the colt stand by the side of the milker, and if the colt has been taken away, then it must be simulated by a stuffed dummy. The daily product of a good mare is two or three litres of milk, but only when the mare is milked frequently, say at intervals of every four hours.

Mare's milk assimilates closely in composition with woman's milk; and qualitatively it is not different from cow's milk, but it contains more of sugar (lactose) and less of butter and caseine than the latter. Mare's milk has a peculiarity which distinguishes two other kinds only, viz. those of the ass and the woman, and that is, rennet scarcely coagulates it.

Milks in general consist of 84 per cent. to 95 per cent. of water, and 16 per cent. to 5 per cent. of solid matters. The solid portion is made up of lactose, butter, caseine, albumen and mineral salts. The mineral salts consist chiefly of alkaline and earthy chlorides and phosphates. In addition, there are traces of various other constituents, some of which are doubtful. Although the milks of different animals resemble each other in quality, they are quite at variance as to the quantitative relations of their components; that is, in other words, species, race, and season, mode of employment, and, measurably, the kind of food, are controlling influences on this point.

The following table will show the average composition of the more important kinds of milk:—

	Woman	Cow.	Goat.	Sheep.	Ass.	Mare.
Sugar . . .	4·8	4·6	4·3	5·4	6·4	7·3
Butter . . .	2·9	3·6	3·4	2·4	1·3	2·1
Cheesy Matter .	2·9	5·1	4·4	4·8	1·9	} 1·5
Salts	2·21	0·6	0·8	0·9	—	
Total . . .	10·9	13·9	12·9	13·5	9·6	10·9

It will thus be seen that the milk of the ass and the mare are nearly alike as to the proportion of butter and caseine, and very nearly similar in the same respect to that of the woman; but the amount of sugar in woman's milk is much less than in either of the two others. Doubtless, therefore, it is the large proportion of sugar which these three contain that renders them pre-eminently suitable for the manufacture of koumiss; and of the three, mare's milk is the most favourable. But the reasons which cause cow's milk and sheep's milk to be less adapted for koumiss making have not yet been determined; possibly it may be owing to the greater amount of caseine, and some peculiarity of physical condition. Be that as it may, my own studies and experiments have enabled me to surmount all the practical difficulties in this connection, and to produce a koumiss which, for all therapeutic purposes, is the counterpart of that from mare's milk. By the skill thus acquired, I am also enabled to make koumiss of different modifications, as may be required for different diseases. This art of substitution enables us to have koumiss at our own homes: whereas it would be compulsory otherwise to go and drink it on the steppes of distant Tartary, as nowhere else are the mares in that requisite number and condition for being milked advantageously. The manipulations are of a nice character, and require experience and attention.

(*To be continued.*)

NOTE ON AMYLO-NITROUS ETHER.

BY JOHN M. MAISCH.
