Mr. C. Umney* has recently examined three specimens of nitrite of amyl as met with in the English market, and found them all to be impure, one containing in fact very little of the true nitrite. This new remedial agent has also attracted some attention in this country; to what extent it is made here I have no means of ascertaining, nor am I prepared to give an opinion of the purity of the few samples I have seen. Since, however, its preparation is rather tedious, and since it is very apt to be contaminated with other ethers, the requisite care and precautions are probably not always applied.

Having had occasion, some time since, to prepare it repeatedly for medicinal purposes, the following remarks are offered as indicating a way of making nitrite of amyl on a convenient scale. Mr. Umney prefers the process of passing nitrous (hyponitric) acid into amylic alcohol. I regard this process as unnecessarily complicated, since purification by fractional distillation cannot be avoided, as demonstrated already by Rieckher.† According to Bunge,‡ 5½ oz. amylic alcohol require from eight to nine hours, before becoming completely saturated with nitrous acid; volatile products are given off, and the residue contains nitrite and valerianate of amyl, besides a black non-volatile body, crystals of nitrate of ammonia and probably nitrate of amyl. The process which was first suggested in 1844 by Balard, it seems to me, will answer all requirements, if the observations of W. Hoffmann§ regarding the formation of nitrate of amyl are not disregarded; ethyl-amylic ether, amylic aldehyde and hydrocyanic acid are likewise formed.

Of the three last-named compounds, the hydrocyanic acid is readily removed from the distillate by treatment with an alkali, which also separates any nitrous and nitric acid that may have come over. The aldehyde has its boiling-point at 93° C. (Kopp), and the ether above 110° C. These figures indicate the necessity of the cautels recommended by Balard, Hoffmann, Rieckher, etc.

It is advisable to use only rectified amylic alcohol, since the previous removal of ethylic alcohol is much easier than the removal of the products after the reaction with the nitric acid has been completed. This purification is most readily and economically effected by Hirsch's method,|| with solution of table salt and subsequent distillation with water.

The purified amylic alcohol with about an equal bulk of nitric acid is introduced into a capacious glass retort,

|| See Amer. Jour. Pharm., 1862, p. 139, 328.

and a moderate heat is applied and very gradually increased. As soon as the mixture approaches boiling, the fire is removed and the reaction allowed to continue. If the application of the heat has been too rapid or too long continued, considerable frothing occurs and the contents of the retort are apt to foam over. With a moderate and slowly increased heat the reaction is less violent, and the temperature rises gradually after the removal of the fire and the beginning of boiling. As soon as the thermometer, inserted into the tubulus, rises above 100° C. (212° F.) the receiver is changed, the distillate now becoming more and more mixed with ethyl-amylic ether and nitrate of amyl, readily perceived by the change in odour.

The distillate obtained below 100° C. is now agitated with an aqueous solution of caustic or carbonate of potash, to remove free acids, and after separation the oily liquid is introduced into a clean retort and again slowly heated. The first portion coming over contains the amylic aldehyde. When the very slowly increased heat has risen to 96° C., the receiver is again changed and the distillate now collected as nitrite of amyl, until the thermometer reaches 100° C., when the distillation is stopped.

It will be observed that the process for the preparation of this compound consists of two distinct operations; first, the production of the amyl-nitrous ether, and, secondly, its purification. In both operations the *very gradual* application and increase of heat is very essential. The yield is small; not having kept any record of the yield, I am unable to give the percentage obtained. All the amylo-nitrous ether dispensed by me was made by this process.

After the publication of Redwood's process for spirit of nitrous ether,* it was repeatedly tried with entirely satisfactory results, and the idea naturally suggested itself to apply the same process to the similar compound amylo-nitrous ether. Accordingly, amylic alcohol was mixed with sulphuric acid, the mixture introduced into a retort together with some copper wire, and, after cooling, nitric acid was added. In a very few moments the evolution of gas was observed, the liquid became hot without the external application of heat, and the reaction very rapidly increased to such a violence that the entire charge was lost, it being impossible to condense any vapours in a Liebig's condenser, or to retain much of the liquid forced over, in the receiver. The experiment was never repeated.

Nadler† gives a process which he says readily yields the pure nitrite. It having come but lately under my notice, I am not prepared to speak about its merits; it consists in distilling amylo-sulphate of potash with nitrate of potash.

The composition of the nitrite of oxide of amyl is $C_{10}H_{11}O, NO_3$; it appears to me that we ought to discontinue this long name, as well as also nitrite of amyl. Amylo-nitrous ether expresses the chemical relations of this compound, and the similarity of names also indicates its analogy to the officinal ethylo-nitrous ether, which may well be continued to be called nitrous ether, just as ethylic alcohol and all its direct derivatives are called by their generic names merely—alcohol, aldehyde, ether—without any prefix.—*American Journal of Pharmacy.*

NEUTRAL CRYSTALLIZABLE PRINCIPLE IN BLACK SNAKE ROOT (CIMICIFUGA ACEMOSA).

BY T. ELLWOOD CONARD.

As this plant is a very common one, and has been fully described in articles heretofore written, I will not enter into any description of it, but merely state the condition of the root acted upon; and of the very many experiments made I will give those only which resulted most satisfactorily.

In order to get the advantage, if there should be any, in using the perfectly fresh root, I obtained it in this way directly from the ground. It was dug in the latter part of July, at which time the roots were quite well developed.

A portion of these, thoroughly cut and bruised, were put in a still with water, and a varied and continued heat was applied, but without producing in the distillate any preceptible amount of volatile principle. The addition of liquor potassæ to the mixture and redistillation was tried, which also failed to develope a volatile oil or other substance; there was no separation of anything from the water which distilled over, nor had it any taste or smell, except an earthy, rooty taste, characteristic of any inert vegetable matter. From these facts we infer the root does not owe its active properties to the possession of a volatile substance.

The next experiments I will give in outline. Three and a half pounds of the root, cut and bruised, were treated with four and a half pints of strong alcohol by maceration for four weeks and filtered. Two pints of this tincture was treated with three fluid ounces of the solution of subacetate of lead, which completely precipitated the resin, tannin, etc. and most of the colouring matter, as will be seen below. The lead was separated from the filtered liquid by means of sulphuretted hydrogen in excess; after agitating for some time together, filtered. A repetition of the process proved the solution to be entirely free from resinous or gummy substances, also from much colouring matter. The tincture was set aside and allowed to evaporate spontaneously. The resulting powder was treated repeatedly with benzine. The several washings were mixed and evaporated, yielding a minute portion of a disagreeable nauseous, fatty substance without colour. The *powder* was freed from the odour of benzine, placed on a filter and thoroughly washed with water; then dried and dissolved in sixteen times its weight of strong alcohol, forming a saturated solution. This was mixed with one hundred and twenty grains of pure alumina, moistened with a few drops of water, and agitated for twenty-four hours, then put in a capsule and evaporated spontaneously to a very dry light mass. This was put on a filter, and hot alcohol poured on it until entirely exhausted. This was allowed to evaporate, and there remained a crystalline substance of a light yellow colour, not of a very regular or decided shape, but of a massy appearance, resembling almost exactly the crystals of sulphate of alumina on a small scale. But under the microscope, at a low power, their crystalline form was more distinct, presenting an appearance similar to that of rock candy. This substance, in powder, has little taste, on account of its extreme insolubility in the liquids of the mouth. But its solution in alcohol has the intensely acrid and sharp taste that characterizes recent cimicifuga.

The crystals have the following characteristics:—They are very soluble in cold alcohol, more so when heated. Dissolve readily in dilute alcohol, also in chloroform, and slightly in ether; but are entirely insoluble in benzine, turpentine and bisulphide of carbon. Fusible at a moderate temperature, at a higher taking fire, and at a red heat entirely dissipated.

This substance, from the following experiments and their results, appears to be a neutral principle:—

A small quantity moistened on a jar lid with liquor potassæ, and approached with the stopper of a muriatic acid bottle, did not give off the characteristic white fumes of a volatile alkaloid, nor did it produce fumes when heated with liquor potassæ and brought near muriatic acid, as an ordinary alkaloid. A small quantity with liquor potassæ put in a tube with a small outlet, was gently heated, but no odour of ammonia was given off. Reddened litmus paper remains unchanged by continued contact with its solution. Entirely incompatible with

* See Amer. Journ. Pharm. 1867, p. 330.

† Ann. Chem. und Pharm. vol. cxvi. p. 176.

all acids, refusing to unite with them in any form or proportion. These few facts point very strongly to the conclusion that it is neither an alkaloid nor an acid principle, being entirely indifferent to the alkalies and not reddening litmus paper. The therapeutic properties of this substance have not been ascertained.—*American Journal of Pharmacy.*

THE USE OF LIQUID CAOUTCHOUC AS AN ADDITION TO EMP. BELLADONNÆ AND OTHER PLASTERS.

BY J. WILLITTS WORTHINGTON.

The author has treated this subject at some length in his inaugural essay before the Philadelphia College of Pharmacy, from which we abstract the following:—

Much difficulty has been experienced by pharmaceutists in preparing belladonna plaster so as to retain its adhesiveness when kept ready spread for some time. The proposed improvement consists in the addition of indiarubber used in the form of a solution, made as follows:—

Take of pure Caoutchouc, cut in small pieces, 1 oz.
Benzine (from Petroleum), 1 pint.

Macerate with occasional agitation in a suitable stopped, wide-mouthed bottle until a thick, saturated solution is obtained. To prove its efficacy in preserving the pliability of plasters, the author prepared a mixture of 3 ounces of Burgundy pitch, 4 drachms of yellow wax, 2 drachms of rosin and 2 drachms of lard; melted and strained. This, when spread and kept two months, became very brittle and cracked on handling.

The same ingredients, with the addition of 4 drachms of liquid caoutchouc incorporated when they were in a fused state, possessed the following characters:—

Very little tendency to crack, retains its pliability, is more adhesive, and has a beautiful smooth glossy appearance. After two months, part of it very cold weather, this plaster retained its pliability.

Experiments were then made with officinal belladonna plaster, which resulted in the following proportion being considered most suitable:—

Take of Belladonna Plaster (U.S.P.), 7 drms.
Liquid Gum Elastic, 1 drm.

The belladonna plaster to be melted by a water-bath, and the liquid rubber then added and stirred well until united thoroughly.

The odour of the benzine disappears when the solution is added in this way. It is quite important to avoid an excess of heat, and hence the water-bath is recommended.

Liquid rubber will be found to act admirably in all plasters which may be made to keep through the summer. —*American Journal of Pharmacy.*

CRYSTALLIZATION OF SULPHO-CARBOLATE OF QUINIA.

BY C. J. RADEMAKER, M.D.

Having had occasion to prepare sulpho-carbolate of quinia for hospital use in this city, the following process was resorted to:—

Crude sulpho-carbolic acid was saturated with plumbic carbonate, the sulpho-carbolate of lead crystallized and decomposed with sulphate of quinine. The solution of sulpho-carbolate of quinine filtered and evaporated, but it was found almost impossible to crystallize the salt, owing to the gelatinous condition of part of the solution, which adhered to the small amount of crystals formed. The gelatinous mass was redissolved in alcohol, and set aside to evaporate spontaneously, with the same result, it being found impossible to remove the crystals with any degree of nicety from the gelatinous mass.

I then made a solution of sulpho-carbolate of quinine of definite strength, a teaspoonful of the solution representing two grains of the crystallized salt, or as near two grains as I could calculate from the amount of substance used. The liquid was composed of three parts water and one part alcohol, and set aside for prescription use. In about four or five weeks I noticed small crystals forming, which gradually increased in size, the large crystals resembling those of perchloride of iron. Under the microscope they made a beautiful prismatic appearance, but to what system of prisms they belonged I was unable to determine. Part of the crystals were taken out of the bottle and examined and found to be sulphocarbolate of quinine.

In about two months about one-third of the salt had crystallized out of the solution. The salt was freely soluble in water, but slightly soluble in alcohol, and not deliquescent.—*American Journal of Pharmacy.*

CONTRIBUTIONS TO THE HISTORY OF THE OPIUM ALKALOIDS.

*Part I.—On the Action of Hydrobromic Acid on Codeia.**

BY C. R. A. WRIGHT, D.SC.

It has been shown by the late Dr. A. Matthiessen, in conjunction with the writer,† that when codeia is heated with a large excess of strong hydrochloric acid the following reactions successively take place:—

$$\underset{\text{Codeia.}}{C_{18}H_{21}NO_3} + HCl = H_2O + \underset{\text{Chlorocodide.}}{C_{18}H_{20}ClNO_2}.$$

$$\underset{\text{Chlorocodide.}}{C_{18}H_{20}ClNO_2} = CH_3Cl + \underset{\text{Apomorphia.}}{C_{17}H_{17}NO_2}.$$

It appeared of interest to examine the action of hydrobromic acid under similar circumstances, and for this purpose Messrs. Macfarlane, of Edinburgh, with their wonted liberality, put a considerable quantity of pure codeia at the writer's disposal.

The aqueous hydrobromic acid employed was obtained by the action of H_2S on Br in presence of water, and subsequent rectification over pulverized KBr; it was free from SO_4H_2 and other sulphur compounds, had a sp. gr. of about 1·5, and contained about 48 per cent. of HBr.

When codeia is heated with from three to six times its weight of this acid, either on a water-bath or to gentle ebullition over a flame, the liquid, which at first produces no precipitate with solution of carbonate of soda, gradually darkens in colour, and acquires the property of yielding a dense white precipitate with this reagent. No appreciable quantity of methyl bromide is evolved during the first stages of this change, but, subsequently, this body is produced in some little quantity.

The precipitate thrown down by carbonate of soda before this further change ensues, appears to consist of a variable mixture of at least three substances, two of which are readily soluble in ether, while the third is but sparingly soluble in that menstruum; all are bases, the one insoluble in ether, and one of those soluble containing bromine: the one apparently first formed is produced by a reaction precisely analogous to that whereby chlorocodide is generated, viz.:—

$$\underset{\text{Codeia.}}{C_{18}H_{21}NO_3} + HBr = H_2O + \underset{\text{Bromocodide.}}{C_{18}H_{20}BrNO_2},$$

and is, therefore, termed bromocodide; this base appears to be acted on further with great ease, giving rise ultimately to the other two, the first of which has the constitution of codeia less one equivalent of oxygen, or $CH_{21}NO_2$, and is, therefore, provisionally named deoxycodeia; whilst the second has the composition of four molecules of codeia coalesced together, one of the 84 H atoms in the product being replaced by Br; it is, therefore, provisionally termed bromotetracodeia, the simplest

---

* Extracted from the 'Proceedings of the Royal Society.'
† Proc. Roy. Soc. vols. xvii. p. 460; xviii. 83.

mode of representing the simultaneous formation of these two bases being as follows:—

$$\underset{\text{Bromocodide.}}{C_{18}H_{20}BrNO_2} + \underset{\text{Codeia.}}{4C_{18}H_{21}NO_3}$$
$$= \underset{\text{Deoxycodeia.}}{C_{18}H_{21}NO_2} + \underset{\text{Bromotetracodeia.}}{C_{72}H_{83}BrN_4O_{12}}.$$

Owing to the ease with which bromocodide is altered, it is a matter of some difficulty to obtain it in even an approximately pure condition, as the complete separation of deoxycodeia appears impracticable when this base has once been produced. The product of the action of three parts 48 per cent. acid on one part codeia on the water-bath for from one to two hours is precipitated by excess of sodium carbonate and the precipitate collected on filters; unaltered codeia is for the most part separated thus, being contained in the filtrate. Extraction of the mass with ether and agitation of the ethereal solution with HBr furnishes crude bromocodide hydrobromate, which may be purified by a repetition of the process, fractional precipitation being resorted to to get rid of traces of colouring-matters: the purified hydrobromate thus obtained was a viscid colourless liquid which utterly refused to crystallize, and dried up to a gum-like mass over SO_4H_2. Dried at 100°, the powdered gum gave these numbers:*—

0·3500 grm. gave 0·6340 CO_2 and 0·1580 H_2O.

0·230 grm. boiled with NO_3H and $AgNO_3$ gave 0·1900 AgBr.

	Calculated.		Found.	
C_{18}	216	48·76	49·40	
H_{21}	21	4·74	5·01	
Br_2	160	36·12	——	35·08
N	14	3·16		
O_2	32	7·22		
$C_{18}H_{20}BrNO_2HBr$	443	100·00		

The slight excess of carbon and deficiency in bromine thus found are doubtless due to the presence of a little deoxycodeia, the hydrobromate of which requires 59·34 per cent. carbon and 21·98 per cent. Br. Another specimen of bromocodide hydrobromate, prepared as above from the product of three hours' digestion at 100° of one part codeia and three parts 48 per cent. HBr, yielded numbers indicating 51·6 per cent. carbon, 5·3 and 33·4 per cent. Br.; whilst a repetition of the purification process scarcely altered the numbers. Owing to the great difficulty in preparing the pure salt in quantity, no attempt to isolate and analyse the base itself was made, the more so that the precipitate thrown down by carbonate of soda from the pure hydrobromate appeared to tally in every respect with the chlorocodide formerly examined; their qualitative reactions, too, are identical.

The crude bromocodide hydrobromate obtained after five or six hours' digestion of codeia with from three to five times its weight of 48 per cent. HBr deposited, on standing for some days, crystals not readily soluble in cold water; recrystallized several times from boiling water, minute snow-white crystals were ultimately obtained; these slightly darkened on drying over SO_4H_2, and more so at 100° and gave the following numbers on analysis:—

0·3565 grm. gave 0·7760 CO_2 and 0·1960 H_2O.

0·3245 grm. gave 0·7045 CO_2 and 0·1790 H_2O.

0·2200 grm. burnt with soda-lime gave 0·0570 Pt.

0·1380 grm. boiled with NO_3H and $AgNO_3$ gave 0·0700 AgBr.

These numbers agree with those calculated for deoxycodeia hydrobromate, as the following comparison shows:—

* All combustions given in this paper were made with lead chromate and finished in a stream of dry oxygen.

	Calculated.	
C_{18}	216	59·34
H_{22}	22	6·05
N	14	3·84
O	32	8·79
Br	80	21·98
$C_{18}H_{21}NO_2HBr$	364	100·00

Found.			
59·36	59·21		
6·11	6·13		
——	——	3·69	
——	——	——	21·59

The yield of this base from the codeia used being but small (about 4 per cent.), no attempt was made to isolate the base itself; carbonate of soda throws down from the hydrobromate solution a white precipitate which is soluble in alcohol, ether, benzol and chloroform; by exposure to air it rapidly becomes coloured, and finally acquires a very dark green tint. Its qualitative reactions are identical with those of apomorphia; the colour-reactions of the two with Fe_2Cl_6, NO_3H, and $SO_4H_2 + K_2Cr_2O_7$ being indistinguishable when examined side by side. Its physiological effects, however, are different; three-tenths of a grain of the hydrobromate administered by the mouth to a dog producing no appreciable effect, whilst a much less dose of apomorphia produces speedy vomiting.

(*To be continued.*)

Wasps and the Stamens and Pistils of Fuchsias.—The use of the petals of various flowers by bees is generally known, but it is not so well known that wasps remove the stamens and pistils of fuchsias for their own use. What this use may be appears somewhat uncertain, but the fact of their removal is chronicled by M. Ch. Morren, who states that, having frequently noticed that the stamens and pistils of certain fuchsias were removed by some unexplained means, he set a watch, and it was then ascertained that the wasps were the culprits. That they are employed by them for some purpose seems evident from the fact that the wasps were observed flying about the garden with the stamens in their mandibles. M. Morren believes that *Vespa nidulans* is the species which acts in this manner, as in localities where this wasp does not occur the flowers remained intact. It would be interesting to ascertain whether a similar phenomenon has been noticed in England.—*Gardeners' Chronicle.*

Turmeric.—The genus *Curcuma* is known as furnishing the yellow powder called turmeric, which is used as an aromatic ingredient in the preparation of curry-powder, and also in various branches of Eastern cookery as well as in medicine, and as a colouring matter and a test for alkalies. The young tubers, which are colourless, also yield a kind of arrowroot, that known as East Indian arrowroot being the produce entirely of species of this genus, such as *C. angustifolia*, Roxb., *C. rubescens*, Roxb., etc. In Borneo, *C. purpurascens*, Bl., is a common plant, and the older rhizomes are dug up, beaten to pieces, and washed to separate the farina from the fibre. The powder is not only used in the preparation of native dishes, but, mixed with water and perfumes, it is smeared over the faces and bare arms and necks of brides and bridegrooms when they sit in state before marriage, or receive their first visits of ceremony. Perhaps our perfumers may take a wrinkle.—*Gardeners' Chronicle.*

Annatto.—In an article in the *Milk Journal* a resemblance is pointed out as existing between annatto and those well-known coal-tar products,—the salts of rosolic acid; and a suggestion is made that it is worthy of investigation whether the rosolates might not be tried as substitutes for annatto.

The Pharmaceutical Journal.

PHARMACY IN AUSTRIA.

AMONG the many political and social questions which are discussed in Austria just now, the relation of the pharmacist to the State is not forgotten. There, as in Germany, the pharmaceutical business is strictly under Government control; the number of pharmacies is limited, etc.

Some members of the profession at Vienna—for it is a profession there and not a trade—have lately petitioned their parliament, the Reichsrath, in favour of free trade, and they are strongly opposed by the Austrian United Society of Apothecaries, consisting of more than 500 members from different parts of the empire. They contradict point after point the arguments adduced by the free-traders in a long document, likewise addressed to the parliament.

As to the state of pharmacy generally, they say the Pharmacopœia is the Codex, prescribing what articles are to be kept, and of what quality. Professional inspectors ascertain by personal visits every year the efficiency of the pharmaceutical establishments, and their annual reports are most favourable.

In order to prove that the limitation of the business to a certain number is most conducive to the true interests of the public, they point to those countries in which free trade in pharmacy does exist.

It is stated as a matter of fact, that in all large towns in this country a few only of the many pharmacies enjoy public confidence. In London, it is asserted not more than 20 out of 3000 pharmacists' shops command undoubted confidence; but these 20 establishments are of such an extent as to employ 30 assistants each. The natural consequence is, that prescriptions are often sent many miles to the distant shop; and of what use, it is asked, are the undeserving 300 or 400 places on the way?

In regard to France, M. Dorvault, Director of the Pharmacie Centrale at Paris, is quoted, who said, "If the pharmacists are allowed to multiply without limitation, and to enter into competition as keen and bitter as in any other trade, a lamentable falling off in these establishments must be the consequence, and many pharmacists will be forced to adopt means they themselves despise to gain a decent living."

Next, the fixed charges in dispensing, regulated by the State, are discussed, and the question is ventilated which system is most advantageous to the public. It appears the principle followed in the scale of prices is as follows:—Drugs, if sold in comparatively large quantities, are charged the wholesale price, with an addition of 25 per cent., and in small quantities with an addition of 50 per cent. Another charge is made for work, bottles, etc., so that the price of a medicine includes four or five items.

To compare the charges in Austria with those made in England and France, the prices as agreed upon by the Manchester pharmacists, and copied in full from this Journal of 17th December last, are given, and also a copy of a tariff from M. Dorvault's work, 'L'Officine.' The result of this comparison is, that the prices are in the proportion of Austria 1, France 2, England 3, or the French charges for medicines are twice as high, the English three times as high as the Austrian.

The explanation for this great difference the petitioners find in the fact that, after all, the dispensing business is fixed within certain limits, and that the number of pharmacies in France and England so vastly exceeds the real demand, that each can get only a small share, and tries to make up by higher prices. But even these high prices are not sufficient to ensure the existence of so many participators, and they are driven to sell all sorts of patent and proprietary articles. On this subject the Austrians wax very warm indeed. They quote words of the celebrated Professor Boudet, spoken at the Pharmaceutical Congress at Paris in 1867:—"You high and mighty patrons of specialism, do not barricade yourselves behind sophisms, which mislead nobody. You have made slaves of your colleagues; you have degraded them to retailers of your patent medicines; you have deprived them of their self-confidence and of their professional honour; you have sacrificed the good-fellowship of your brethren to your egotistical designs, and you speculate only on the weakness and ignorance of the sick, on the suffering of life, and every one becomes without compassion a victim of your guile. Oh! if your principles were realized; if in the civilized world pharmacy were handed over to freedom as you demand, what a flood of specialities! what international rivalry of miraculous remedies would rush down upon us! how the diploma of pharmacy would be degraded! Yes, I do not shrink from saying so; and if that diploma might be had for the trouble of picking it up, where is the man of honour to be found who would stoop to drag it out of the mire into which it has fallen? And as to the millions you realize by your specialities, keep them for yourselves; I value the honour of my country higher!"

The gist of the petition is embodied in three points, viz.:—

1. The principle of free trade is not applicable to the pharmaceutical business.

2. Free trade in pharmacy is antagonistic to the true interests of the public, and must ruin the profession, hitherto so highly esteemed.

3. The present system of licences is the best both for the public and for the proprietors of pharmacies.

And, finally, the petition complains that the Government has removed the two apothecaries from the sanitary council of the empire at a time when in Russia two members of the Pharmaceutical Society of St. Petersburg have been appointed members of the supreme sanitary council, in order to report on all points connected with their profession.

DISPENSING CHARGES.

The question of securing a uniform rate of charges by chemists and druggists has been already debated in our columns.* The Manchester Chemists and Druggists' Association gave the discussion a practical turn by agreeing upon a list of dispensing charges, which they recommended for adoption by the trade generally.† This proceeding has now been followed by the issue of a list of retail prices and dispensing charges, recommended by the Bath Chemists and Druggists' Association. We have been favoured with a copy of this list, to which the following preface is attached:—

"At a meeting of the Association, held February 3rd, a Committee was appointed to draw up a price list with a view to promote uniformity amongst pharmaceutists in our own city, and partly also with the hope that other towns, in the West especially, will also issue and exchange lists to the same end.

"It will be seen that the prices obtained in Bath agree very nearly with the Manchester list, and on comparing them with those of other towns, so far as it has been possible to do so, it has been found that they represent a fair average.

"As a matter of course, prices will always vary in different towns, and in different parts of the same town; but still much may be done to remove the reproach that pharmaceutists are now liable to, that the same prescription dispensed at respectable establishments in various parts of the kingdom is rarely charged for twice alike.

"Our Bath brethren are urged to abide as much as possible, especially in dispensing, by this list, the prices of which are certainly far from excessive. Cheapen physic as we will, the public will never swallow an extra dose of it, and since we must live, cutting prices simply mean inferior drugs. It is as much therefore for the interest of the medical profession and the public generally as for ours that we should be properly remunerated.

"Even if ours were a mere trade, which it is not, our incomes are ridiculously small as compared with those of our neighbours who are grocers, drapers, wine merchants, etc., and this, too, in spite of the educational demands now very properly made upon us, and notwithstanding our long hours of responsible and hard work during the *seven* days of the week.

"It is requested that all prescriptions be marked under the stamp of the first dispenser."

---

YOUNG'S PATENT POISON CABINET.

Those of our readers who were able to visit the Exhibition of Objects relating to Pharmacy, held at Liverpool in connection with the last meeting of the British Pharmaceutical Conference, may perhaps remember seeing a model of a poison cabinet, exhibited by Mr. J. C. Young, of Warrington. A practical application of this plan, with some modification in the details, is now being submitted to the trade by its inventor, which, it is claimed, will render difficult the occurrence of mistakes in dispensing. It consists of a certain number of shelves, according to the space allotted to it, and the quantity and size of the bottles to be accommodated. Each bottle is labelled, and has its proper place in the cabinet, into which place it is securely fastened. On the front edge of the shelf are painted names corresponding with the labels on the bottles which are supported by it. But these names are—with one exception, for the sake of variety—not immediately beneath the bottles to which they relate. Under each shelf is a movable indicator. When a certain bottle is required, the indicator is pushed along until it rests directly below the name painted on the front of the shelf, when it will be found that that particular bottle is released, but no other. Thus, should the strychnia be required, the name has first to be found and the indicator brought under it, and then the bottle itself, which may be five or six or more spaces off. This operation, although occupying a very short time, necessitates the reading of the name twice; and should an error be made either time, the bottle cannot be taken out.

By another provision any mistake from putting one bottle into the place of another is prevented. Not only is it necessary for the indicator to be in its proper place before a bottle can be replaced, but should two bottles be out at one time and the wrong one be taken up, it is not possible to put it into the wrong space, as each bottle is made to fit its own place and no other.

One great advantage of such an arrangement as this is that it requires the intelligent reading of the label twice, and thus the dispenser's attention is called to the nature of the substance which he is about to use. One objection to all previous mechanical contrivances for the same purpose has been their tendency to lead dispensers to trust in them entirely instead of using them as aids; transferring, as Mr. Squire pithily puts it, a man's brains from his head to his fingers. Mr. Young's invention, however, is hardly open to this objection, as by a simple mechanism, not likely to get out of order, it prevents any poison-bottle being taken out of the cabinet without the dispenser being well aware of what he is doing. At a time when there is so much discussion upon the subject as at present, and when pharmacists are generally desirous of adopting any additional methods for securing safety from accidents, we think this Patent Poison Cabinet worthy of their consideration.

POOR-LAW TENDERS FOR MEDICINES IN IRELAND.

The following list of prices, showing the anomalies which may exist under the present system of tenders for the supply of medicines to unions in Ireland, is published in the *British Medical Journal* as representing the prices quoted in tenders to the North and South Dublin Unions

	North.			South.		
	s.	*d.*		*s.*	*d.*	
Acidum aceticum fortius	26	8	per gall.	3	6	per gall.
Acidum sulph. aromat.	2	0	per lb.	28	0	per lb.

Sulphur sublimatum	4	8	per stone	1	6	per st.

If the opposition to Mr. Lowe's match tax had not caused its withdrawal, it would have been possible to urge a new argument to overcome his reluctance to entertain any application for grants in aid of science. It might then have been said that the application of science to industrial arts afforded the Chancellor of the Exchequer a means of obtaining additions to the revenue, and that consequently, from his point of view, promotion of science was a thing to be desired as a financial expedient.

An interesting plant is figured in the present number of the *Botanical Magazine* under the name of *Chlorocodon Whitei*, H.f. It is a climbing, leafy plant, sometimes reaching to the tops of the most lofty trees, and sending its roots out among the surrounding rocks and stones to a distance of fifteen to twenty feet. It is a native of Natal, but is never found more than a few miles from the sea. The roots, under the name of "Mundi roots," are extensively collected and sold by the Kaffirs, who eat large quantities of them, chewing them for their agreeable aromatic taste and stomachic properties. The consumption has been so great in the district where the plant was discovered that it has become rare. It is said that the roots have a sweeter and better flavour the nearer they are grown to the sea. Some of the living roots have been received at Kew, from which plants have been raised and they flowered last autumn. The fresh roots have a powerful odour, somewhat resembling that of the Tonquin bean.

At the Annual General Meeting of the proprietors of the London Institution, held on Wednesday last, Mr. Daniel Hanbury, F.R.S., was elected a Manager, in the room of Mr. S. J. Fletcher, resigned.

EXAMINATION IN EDINBURGH.

April 19th, 1871.

Present—Messrs. Ainslie, Aitken, Baildon, Brown, Buchanan, Kemp, Young and Mackay.

Twenty-two Candidates presented themselves; eight for the First or Preliminary Examination, eight for the Minor, one for the Major and five for the Modified. The following fifteen passed, and were declared to be duly qualified to be registered:—

FIRST, or PRELIMINARY (as Apprentices or Students).

	Cairns, Thomas	Edinburgh.
	Hinksman, John	Edinburgh.
	Swan, Peter	Edinburgh.
	Weddell, George	Kelso.
Equal.	Brown, Allan	Glasgow.
Equal.	Ferguson, William James	Gorebridge.
Equal.	Macmillan, James Laker	Glasgow.

MINOR (as Chemists and Druggists).

*Mackay, George Duncan	Edinburgh.
Coldwell, Peter	Edinburgh.
Lunan, Alexander	Aberdeen.
Hardie, Alexander	Edinburgh.

The above names are arranged in order of merit.

MAJOR (as a Pharmaceutical Chemist).

*Linton, Ralph Tait .... Edinburgh.

MODIFIED (as Chemists and Druggists).

Lockerbie, James	Helensburgh.
Midgley, Charles	Manchester.
Ritchie, Andrew Wemyss	Alford, Aberdeen.

Errata.—Page 851, col. 1, line 5 from bottom, *for* Hensley, Robert Place, *read* Hensby, Robert Place; page 851, col. 2, line 51, *for* Nash, William, *read* Neish, William.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Eleventh General Meeting of this Association was held at the Royal Institution on Thursday evening, the 13th instant; the President, Mr. John Abraham, in the chair.

Mr. Alfred E. Tanner asked the opinion of the members upon the incompatibility of persalts of iron with infusion of chirata. A mixture of inf. chiratæ with liq. ferri pernit. had been returned to him by a physician because it was dark coloured and slight decomposition had taken place.

Mr. S. G. Hilditch said that if the infusion was prepared in accordance with the Pharmacopœia, persalts of iron were incompatible with it, and the mixture would be a dark brown colour; but if the infusion was prepared with cold water, the mixture would not be effected. The intensity of colour would vary according to the temperature of the water used to make the infusion, hot water taking up much more gallic acid than cold water; he noticed that the characteristic inky taste was not present, but this might be covered by the intense bitter of the chirata.

Mr. Charles Symes, Pharmaceutical Chemist, thought the process given in the Pharmacopœia for making linimentum hydrargyri was unnecessarily tedious, melting

* Passed with Honours.

the mercurial ointment being quite undesirable; taking the quantities given in the Pharmacopœia, he agitated the ammonia with one-half the camphorated oil; rubbed the mercurial ointment with the other half, and mixed the two results together. A few minutes sufficed for the operation, heat was not used, and the product was quite satisfactory.

Mr. James Blair concluded his paper upon "The Chemistry of Calico Printing."

The paper was illustrated with photographs, charts, specimens of materials dyed and printed, and by experiments showing the effects of some of the processes employed.

[We purpose printing this paper in a future number.]

At the conclusion of the paper, Mr. Blair replied to several questions asked by those present, and after a short discussion, the President congratulated Mr. Blair upon the copious and strictly scientific manner in which he had treated his subject, and moved a vote of thanks, which was carried unanimously.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Anderson's University.

The Fourteenth and concluding Meeting of the Session, Wednesday, April 19th, 1871; Mr. Thomas Davison, President, in the chair.

A paper was read by Mr. J. L. Macmillan on "Volatile Oils," in course of which he called attention to the difficulty in testing these, and their liability to adulteration, stating that turpentine, from its resemblance in chemical composition to most volatile oils, was frequently used. He then referred to the specific gravity and blotting-paper tests, stating that while the latter answered for fixed oils, they were both unreliable tests in some cases, and suggested to the Council that a prize offered for a reliable test might bring out some satisfactory result.

Mr. Kinninmont remarked that the adulteration of volatile oils was one which deserved attention, and he would recommend Mr. Macmillan to proceed in his investigations. He said he had lately come across a sample of ol. lavand. which was adulterated with castor oil, and from its solubility in alcohol it was with much difficulty detected.

Some remarks were afterwards made by Messrs. Paterson and Fairlie, and, on the motion of the President, a unanimous vote of thanks was passed to Mr. Macmillan for his paper.

The report of the Early Closing Committee was then submitted, and being considered favourable, the Committee was instructed to take further action as soon as possible.

Mr. Fairlie, Hon. Secretary, afterwards stated the arrangements that had been entered into with the "Popular Class Committee" of Anderson's University, for the conducting of a botany class for students in pharmacy; about thirty names were given in, and Professor Hennedy had arranged to begin on Wednesday evening, April 26th.

The President, Mr. Davison, then delivered his Valedictory Address, in course of which he congratulated the members on the importance of the position their Society had now attained. In referring to the early history of the Society, he said it was instituted in 1854 as an Early Closing Association, and, at the end of three years, having partially attained its object, it was reorganized into a Mutual Improvement Society. For many years their only place of meeting was in a temperance hotel, but latterly, through the kindness of Dr. Moffat, they were permitted to meet in his laboratory, till last year, when the Council thought it desirable that some change should be made, both for the good of the Society and the trade. Negotiations were entered into with two of the scientific institutions of the city, the result being, that they were now located within the walls of a University. They had still much to undertake, yet, however, before they could take the position they ought, he therefore counselled the members to greater diligence and perseverance in their studies.

Mr. Kinninmont, in proposing a vote of thanks to Mr. Davison for his services as President, remarked that he thought he (Mr. Kinninmont) was the only member present who had attended the first meeting on the early closing movement in 1854, and on looking back over the years that had intervened, he thought they had much to congratulate themselves on in the advance that had been made. Those present could have no conception of the struggles of these early years. He thought they had been exceedingly fortunate this session in the choice of President and Secretary, and to his mind the amount of work they had gone through was extraordinary. He trusted that the same energy would characterize all the members, that at no distant date we might see a school of pharmacy established in this important district. He had much pleasure in proposing a hearty vote of thanks to the President and Secretary, which was responded to with acclamation.

Messrs. Davison and Fairlie briefly replied, acknowledging the compliment paid them.

The Secretary then called attention to the 'Register' of Chemists and Druggists, which had been presented to the Association by the Council of the Pharmaceutical Society.

The President, in moving the thanks of the Association to the Council for their donation, stated that Mr. Joseph Ince was engaged in preparing a book of autograph prescriptions for Glasgow, and that it was expected to be ready in May, when any member would have an opportunity of examining the collection.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

April 20th.—Professor Odling, F.R.S., Vice-President, in the chair.

The following gentlemen were elected Fellows: C. C. Grundy, S. B. Lee, G. Sutcliffe, W. Ward.

Mr. C. Haughton Gill read a paper "On some Saline Compounds of Cane Sugar." Peligot has described a compound of cane-sugar and salt, to which he ascribed a formula of $C_{24}H_{42}O_{21}NaCl$ ($C=6\ H=\cdot5\ O=8$), which requires 14·92 per cent. of sodic chloride:—this indicates the replacement of 9 parts of water by 58·5 parts of sodic chloride. Bondeau de Carrolles subsequently examined a similar compound to which he ascribed the formula $C_{24}H_{20}O_{20}$, $NaCl, 3HO$, which includes water of crystallization of which Peligot makes no mention. Subsequently Mitscherlich denied the existence of the body, and Hochstetter mentioned that other chemists had failed to obtain it. Mr. Gill, being at first unsuccessful in preparing Peligot's compound by the method described, boiled a solution of sugar with an excess of salt for some time, filtered, and set aside the apparently uncrystallizable syrup. At the end of some months a few small, not very transparent, but individually distinct crystals, had formed. They were drained, rinsed, pressed and analysed. The numbers lead to the formula $2(C_{12}H_{22}O_{11})$, $3NaCl$, $4H_2O$. This compound of an unexpected composition having been obtained, a number of solutions of sugar, with various proportions of different salts, were made up and set aside to crystallize. The salts employed were the chlorides of potassium, sodium, lithium and ammonium, the bromides of potassium and sodium, and the iodides of potassium, sodium, lithium and ammonium. In each case four solutions were prepared, having one, two, three and four molecules of the salt to the double molecule of sugar, $2(C_{12}H_{22}O_{11})$. None of the potassium salts gave compounds of a definite composition. The mixture containing the chloride in the smallest proportion gave crystals of pure sugar, those containing the two largest proportions gave a crop of the pure potassic chloride.

The solutions containing potassic bromide behaved in a very similar manner, giving crystals often very clear and sharp, and sometimes five or six m.m. in extreme dimensions, but always *anhydrous* and of irregular composition. The solutions containing potassic iodide evaporated to very thick sticky masses, sometimes containing a number of minute crystals which could not be separated from the mother-liquor.

The sodium salts gave more definite results. In the case of the chloride, the solution containing least salt first gave crystals of pure sugar, and then on further concentration deposited crystals, which are doubtless the same as those of the compound examined by Peligot, and are identical with those obtained from the liquid containing the next higher proportion of salt, viz. $NaCl$ to $C_{12}H_{22}O_{11}$. This compound crystallizes in prisms terminated by pyramids, is very soluble in water, less so in spirit. When to its solution in spirit of not more than 75 per cent. ether is added, an oily layer is formed at the bottom of the vessel, and in this crystals form, which have the composition $C_{12}H_{22}O_{11}$, $NaCl$, $2H_2O$.

The solutions containing sodic bromide can hardly be made to crystallize at all. A small quantity of minute confused crystals were deposited after some months from the solution containing $3NaBr$ to $2C_{12}H_{22}O_{11}$; these when pressed and dried over oil of vitriol gave numbers which would point to a formula, $NaBrC_{12}H_{22}O_{11}\,1\frac{1}{2}H_2O$, but it is more probable that when pure it is similar in composition to the analogous compound of sodic chloride.

The solutions containing sodic iodide give crystals of definite and constant composition with remarkable ease. These crystals always have the same composition, whatever the proportions of the constituents in the mixture, unless one be in such large excess that it can in part crystallize out before the liquid becomes saturated with the compound. The solutions containing a moderate excess of sodic iodide yield the best crystals and quickest growth. It can be recrystallized as often as desired from water or dilute spirit without suffering decomposition, forming large transparent crystals even from small quantities of solution. Their constitution is expressed by the formula $2(C_{12}H_{22}O_{11})$, $3NaI$, $3H_2O$. None of the mixtures containing lithium gave any crystals other than those of sugar.

The mixtures containing ammonic salts gave no definite compounds.

No results were obtained from the solutions containing ammonic iodide.

The crystals of sugar containing ammonic chloride, and the equally distinct, though generally smaller ones, containing potassic bromide, and those deposited from a hot alcoholic solution of the lower salt-compound, must be built up by an *anhydrous* compound of the salt and sugar, isomorphous with sugar itself, crystallizing out together with an excess of the latter.

That the crystals are not simply sugar with adhering ammonic chloride is shown by their individual perfection, and by the fact that they are deliquescent, whereas neither constituent is so.

The solutions of all the bodies described in this paper, especially that of the lower salt compound, exhibit persistent supersaturation in a remarkable degree. A saturated warm solution, when cooled and shut up in an airtight vessel with several crystals of the solid body, continues to deposit more of the compound for several months.

The composition of the sodic iodide compound makes it seem probable that the true molecular weight of cane-sugar should be represented by $C_{24}H_{44}O_{22}$.

The measurements of the various crystals mentioned in Mr. Gill's paper were kindly executed by Professor W. H. Miller.

BRITISH MEDICAL ASSOCIATION.—METROPOLITAN COUNTIES BRANCH.

At the Ordinary Meeting of the above Branch, held at the Charing Cross Hotel on Friday, April 21st, Dr. E. C. Seaton opened a discussion on 'Some of the Lessons to be derived from the present Epidemic of Smallpox.'

Dr. Seaton, after alluding to the severity of the present epidemic, proceeded to give statistical details which had been compiled, and which, he argued, proved very strongly the great value of vaccination for the prevention and mitigation of the virulence of smallpox. Thus, in the cases which had occurred in London there had been forty-five per cent. of deaths among the unvaccinated, whilst among the vaccinated they only amounted to nine per cent. A rule had been adopted in the metropolitan smallpox hospitals that all persons engaged in those establishments should be revaccinated before entering upon their work. The result had been that, with three exceptions, they had hitherto escaped infection. These three exceptions proved the rule, for it was found upon inquiry that in each case, for one reason or another, the regulation had not been carried out. He mentioned that while on a visit to Rotterdam, he had been surprised to notice the small proportion of infants brought for vaccination compared with the proportion in this country. Upon inquiry he found that throughout Holland vaccination was frequently deferred until the children were five or six years of age, the consequence being a death-rate from smallpox far in excess of that of this country. He thought one lesson to be learned from this epidemic was the necessity of the compulsory registration of all births. Next that the compulsory provisions of the Vaccination Act should be thoroughly carried out. At the same time, while it was proper to compel people to do that which was right in the matter, they ought also to be shown that it was their duty. Much might be done in this way by members of the profession taking the trouble to explain and refute the groundless objections that were brought against vaccination. He had found in several towns and rural districts that by means of a little persuasion, it had been possible to carry out the provisions of the Act without an appeal to the law. In conclusion he said that, in his opinion, vaccination successfully performed once in infancy and again at the age of puberty, was a most valuable safeguard against the smallpox.

Dr. Steele, of Liverpool, furnished some information concerning the epidemic in that town. The death-rate there had been twelve per cent. among vaccinated cases and sixty per cent. among unvaccinated. In Liverpool there had been but one case of smallpox among the large number of persons employed at the hospitals, and that had been in a person who had been exempted from the rule of revaccination.

Mr. Liddle, Medical Officer of Whitechapel, said that medical officers were greatly cramped in their action by the amount of "red tape" they had to contend with, and mentioned an instance where a person who had been sent from Whitechapel to the Homerton Asylum was sent back again because a printed form was not filled in which had not been previously supplied.

Dr. Lankester considered that the fact that after so long a time the disease was still in our midst was a disgrace to the country. If it had been a cattle disease, and oxen or sheep had been the victims, we should have stamped it out long ago. He advocated the compulsory registration of all births. Then he would appoint inspectors in every parish who should have the power to go into every house and see that vaccination was strictly attended to. He considered also that medical men should immediately inform the medical officer of health of cases of smallpox, in order that he might take the necessary steps to prevent its spread. They ought not, as in many cases, to assist in keeping its existence secret, for fear of loss of custom to their patients, thus allowing them to become *foci* of contagion. Proper means for disinfecting bedding, clothing, etc., should also be provided in sufficient quantity. He had himself met with a poor man who complained that the stench of smallpox in his house was so great that he had not been able to sleep for several nights. In the parish of St. James's, Westminster, he had tried gas apparatus, but it was not sufficiently effective. He had now an oven in which the infected material was placed and the heat raised to 250°; this was found to be effectual for disinfecting beds, etc., without pulling them to pieces. He considered these measures should be carried out universally by some higher authority and not left to the action of individual vestries. In the parish of St. James's he had ascertained that in a population of 40,000 there was an annual emigration of 2000, replaced by an immigration of a like number; and unless similar measures had been carried out in the parishes from whence these persons came, they rendered useless a great deal that had been done. As coroner he had held inquests in cases where unvaccinated children had died from smallpox, and although that had been looked upon by some persons as rather a sharp proceeding, he believed it had been of service by bringing home to the parents the effects of their negligence.

An animated conversation followed, in which more than one speaker expressed a doubt as to the utility of revaccination, one gentleman saying that it was no more possible for a person who had been properly vaccinated once to be successfully revaccinated, than for him to have the measles or hooping-cough a second time.

In reply, Dr. Seaton said that he thought results had proved the efficacy of revaccination. At the same time vaccination in the adult is a much more serious affair than in the infant, and he looked with disfavour upon a great deal of the revaccination which had been so fashionable lately at the West-End. He thought that, as a rule, the operation performed once in infancy and once in adolescence was sufficient, except in cases where the constitution might be supposed to have undergone a great change, as after eruptive fevers, etc.

MEETINGS FOR THE ENSUING WEEK.

Monday, May 1. ......*Medical Society*, at 8 P.M.—Annual Oration.
Royal Institution, at 2 P.M.—Annual Meeting.
London Institution, at 4 P.M.—"On Astronomy" (Educational Course). By R. A. Proctor, F.R.A.S.

Tuesday, May 2. ......*Royal Institution*, at 3 P.M.—"On the Geology of Devonshire, especially of the New Red Sandstone." By W. Pengelly, F.R.S.

Wednesday, May 3. ...*Society of Arts*, at 8 P.M.—"The Production of Artificial Cold." By Professor John Gamgee.

Thursday, May 4. ......*Royal Society*, at 8.30 P.M.
Linnean Society, at 8 P.M.
Chemical Society, at 8 P.M.—"The Productive Powers of Soils in Relation to the Loss of Plant Food by Drainage." By Dr. Voelcker, F.R.S.
London Institution, at 7.30 P.M.—"Economic Botany." By Professor Bentley.

Friday ....*Royal Institution*, at 8 P.M.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

VACANCY.

The Justices of the County of Worcester propose, at their Midsummer Sessions, to appoint an Analyst of articles of Food and Drink purchased within the said county. For particulars, apply to Mr. W. N. Marcy, Clerk of the Peace, at his office in Worcester.

Parliamentary and Law Proceedings.

Suicide by Carbolic Acid.

Messrs. W. E. Jeffreys, M.R.C.S., and J. Hainworth, F.R.C.S., report in the *Medical Times and Gazette* a death from poisoning by carbolic acid, which occurred on the 1st inst. The deceased, who had been discharged recently from Bethlem Hospital, was found by his housekeeper on his bed, insensible and "snorting." There was a strong smell of carbolic acid in the room, and a bottle containing some, which had been kept in the kitchen for cleansing purposes, was found on the drawers. Medical assistance was promptly obtained, but death followed in about fifty minutes after the supposed time of his taking the poison. The housekeeper estimated the quantity taken as between one and two tablespoonfuls.

At the *post-mortem* examination all the parts over which the acid had flowed were found whitened and hardened by the superficial cauterization of the epidermis and epithelium, while a longer contact, as in the stomach, had caused a corrugation of the epithelium and the breaking of it up into small particles. Upon the application of the B. P. test to the contents of the stomach, the characteristic reaction of carbolic acid was observed.

Collision at the Stepney Station.

By a collision which took place at the Stepney Junction of the Blackwall Railway, on Sunday afternoon, April 9th, a carriage belonging to a Blackwall train was driven by the engine of a Bow train partly over the railings and brickwork, so that it was only prevented by the couplings from falling into an engineer's yard. The only passenger in the carriage was Mr. George Hunter, son of Mr. J. Hunter, Pharmaceutical Chemist, of High Street, Gosport. He was bruised and very much shaken, and has received a severe shock to his system, but is now progressing favourably.

Poisoning by a Salt of Copper.

A singular instance of poisoning by copper was investigated on Thursday by Mr. Price, coroner for Salford Hundred, at Audenshaw. The inquest was held on the body of a young married woman, named Sarah Rogers, twenty-four years of age, who died at Hooley Hill, on the 24th ult., under circumstances that led the police to arrest her husband on a charge of administering poison. The inquiry had been adjourned for the purpose of an analysis of the contents of the stomach of the deceased. Dr. Calvert stated that he was induced to search for an irritant poison. He looked in vain for traces of oxalic acid, arsenic, baryta, antimony, lead, bismuth, tin, mercury, and at last tested for copper, though he thought this substance was less likely to be found. Never during an experience of thirty years had he found such difficulty in detecting the presence of the poison for which he was in search, owing to the stomach and intestines being emptied by excessive vomiting and purging. After much careful examination, he found a very small quantity of copper in the stomach, a larger quantity in the intestines, and portions in the liver. Bearing in mind the statement made by one of the witnesses that deceased had been purged, and had vomited for some days (seventy-two hours altogether), that only a small quantity of a salt of copper was required to produce death, and that it was easily removed from the body by vomiting and purging, he was not surprised that only a small quantity was found. He was of opinion that the inflammation was produced by the toxic action of a salt of copper. Although some toxicologists entertained a belief that in certain instances copper was a natural element of the body, he was of opinion that in this case the quantity found was too large to admit of its existence under such circumstances. There were cases on record of persons having been poisoned by partaking of food cooked in utensils lined with copper; and it was well known that others had died from eating sweetmeats, jams and *sauerkraut* made in culinary utensils of the same material. Taylor, in his work on poison, mentioned the case of some seamen poisoned by eating fatty matter cooked in a copper vessel. There were many other instances of persons partaking of copper sufficient to produce death without its being administered as a poison. Cases of intentional poisoning by copper were exceedingly rare, owing to its easy detection from the powerful metallic taste it produced. There was one exception, however, a substance used by painters,—verditer,—which had no taste. Something like a drachm would, in his opinion, cause death. In reply to various questions, it was stated that no copper vessels were used in the house of deceased, or at the hat manufactory where she and her husband were employed. Professor Calvert added that the contents of a bottle of which deceased had partaken contained no traces of copper. The jury returned a verdict to the effect "That deceased died from the effects of poisoning, but how, when, or by what means taken or administered there was no evidence to show."

Death from Bichloride of Methylene.

An inquest was held on Friday last, at Charing Cross Hospital, to inquire into the circumstances attending the death of David Skelton, a labourer, who died while under the influence of bichloride of methylene, for the purpose of an operation.

Mr. Ewin Canton, surgeon to the Charing Cross Hospital, stated that the deceased attended the hospital for treatment of an injury to one of his fingers, which he had received while killing a pig, the tusks of the animal having severely lacerated it. Mr. Canton advised amputation of the finger, to which deceased assented, and expressed a wish to have it done under the influence of chloroform. On the previous Tuesday the operation was performed, he having previously inhaled $1\frac{1}{2}$ drachms of bichloride of methylene. This was administered by the regular administrator of the hospital, and was not more than half the quantity usually given. The deceased having become insensible, the finger was removed, the operation not lasting more than one minute, when it was noticed that his head had fallen on one side, his eyes were upturned, and breathing and pulsation had ceased. Every effort was made to restore animation, but without success. Upon a *post-mortem* examination he had found all the organs in a perfect state of health; the heart and brain, the organs usually affected when chloroform is administered, not presenting any traces of the action of the methylene. The only way in which he could account for the death was by supposing that the man being in a state of great nervous excitement at having to undergo the operation, the methylene had acted upon the nervous system, causing instant death. He had known death to occur under an operation from excitement, without the administration of an anæsthetic. There was no doubt that in the case under inquiry death had resulted from the use of the bichloride of methylene. Cases of death while under the influence of this agent were very rare, but he never allowed it to be administered except with the patient's full consent.

The jury returned a verdict "That the deceased died from the effects of methylene properly administered during an operation."

HOUSE OF COMMONS.

The Proposed Tax on Matches.—*April* 20.—In making the annual financial statement, the Chancellor of the Exchequer announced an estimated deficiency amounting to £2,713,000, for which it would be necessary to provide. In order that this might be done, he proposed, amongst other things, to impose a tax upon matches, an idea that he confessed to having borrowed from American finance. He spoke of matches as being one of the most splendid boons which science has given to man, to enable him to dispense with the flint and steel. He proposed to put a halfpenny stamp upon every box of matches containing not more than a hundred, and a penny stamp on a box containing not more than one hundred wax lights or fusees. He said that 560,000,000 boxes of matches and 45,000,000 of wax lights and fusees were made in this country annually. The revenue estimated from this source was £550,000. Having noticed that the device of an ark on some boxes was a very odd and inappropriate one,—suggestive of a watery idea,—he proposed to adopt as a motto for the stamp the words *Ex luce lucellum.**

Dr. Playfair, in supporting the proposition of the Chancellor of the Exchequer, said that, although when he was examined before the Committee of 1867 as to the propriety of levying a tax on matches, he was not able to see how it could be done, he had given the subject his consideration occasionally since, and had come to the conclusion that it might be done. Nearly $1\frac{1}{2}$ per cent. of the fires arose from the careless use of matches. The careless use of matches had led to carelessness in their manufacture. He believed the proposed tax would give an impulse to the manufacture of safety matches. A competition in the manufacture of improved quality would have a good effect on the workers; it would tend largely to remove that horrid disease,—the worst that medical men had to deal with,—disease of the jawbone.

April 25.—Mr. Disraeli having given notice of his intention to move that the financial proposals of the Government were unsatisfactory to the House, the Chancellor of the Exchequer announced that, in view of the disfavour with which the match tax had been received in many quarters of the House, the Government had decided to withdraw it.

Review.

Handbuch der Pharmacognosie und Pharmacologie für Aerzte, Studirende der Medicin und Pharmacie, Apotheker und Droguisten. By Prof. Dr. Archimedes von Schwartzkopff, Teacher of Pharmacognosy, National Economy and Commercial Science at the University of Basle, and Teacher of the Germano-Swiss Commercial School. Part I. Leipsic and Heidelberg: C. F. Wintersche Verlagshandlung. 1871.

It is almost impossible to imagine a more difficult task than to write a book on pharmacognosy and pharmacology which would meet all just demands of the day, for the simple reason that it must embody all the information which the student of medicine or pharmacy, the medical man and the pharmacist may require in order to ascertain the physical and chemical properties of their remedies, distinguishing marks of purity and adulteration, of their physiological actions and therapeutical applications.

The writer or compiler of such book must have an intimate acquaintance not only with chemistry, natural philosophy, botany and mineralogy, but also with pharmacy and its practical applications, and with some of the most important branches of medical science, viz. the

* The *Times* suggests that Mr. Lowe should now adopt for his crest a match smoking *proper*, with the motto "*Et Lucifer et Luctifer.*"

action of remedies on the human system and their mode of application.

Very rarely indeed do we find a single man to have mastered, in all their details, half-a-dozen sciences, and it is a fair question to consider whether the division of such a vast undertaking among different specialists would not result in a work more satisfactory to the authors and to their readers. We do not pretend to be endowed with sufficient insight into all these sciences to pass a critical verdict upon this book as a whole, and gladly we will restrict ourselves to the pharmaceutical or rather chemical part; we do so the more readily, because the first volume now before us,—after a short introduction and a discourse on general pharmacology,—embraces that part of special pharmacology which treats of remedies derived from the inorganic world.

The author states in the preface that in the general plan and arrangement of his book he followed Pereira's 'Elements,' third edition of 1851,—the last edition of 1864 is evidently not known to him; he also gives a number of other books used by him generally, and for pharmaceutical preparations he quotes Mohr's 'Commentar' as his authority; *i.e.* he has copied him wherever possible.

We might have expected in this volume, which treats chiefly of the elements and their combinations, some references, however slight, to chemistry in general, to the development and changes in the interpretations of a science which, during the last twenty years and more, have made its study both so difficult and so fascinating; but not a word is said on the subject: there are the antiquated names and formulas, as if settled for all time; the formulas very often wrongly given, and, on reading article after article, one is often tempted to look back to the title-page to see whether the book really has been written in this century.

It is evident chemistry is not the author's speciality; it is also equally evident that the chemical part, written in the most dreary style imaginable, must deter any student, be he ever so enthusiastic, from following up his chemical pursuits, if left to this book.

The author has not the grasp of mind to see before him the whole field, to systematically work out a plan; it is only too clear that in compiling the work he has consulted many others; he has copied here a bit and there a bit, without having the capacity of welding the parts into one homogeneous and harmonious whole. The inevitable consequence is—as the result of much labour, we are sorry to say so—complete failure and disappointment.

Now, in a book of reference like this, including so many different topics, the strictest adhesion possible to a clear and well-digested system is absolutely necessary; and, we must confess, it is exactly the defiance of this necessary rule which struck us first on reading this book.

To substantiate such serious accusations, we have only one difficulty, viz. to select a few from the many proofs we meet with on every page.

The inorganic world is divided into Class I., non-metallic substances; and we expected, of course, to come in due time to Class II., metallic substances, but at the end of the ten non-metals and their compounds, grouped into so many orders, the author has forgotten his system, goes on without division to Order XI., potassium, and so on to the end of the book with all metals.

A confusion more tantalizing, because constantly repeated, is the truly impartial freedom with which the different scales of temperature are made use of. Fahrenheit, Celsius and Réaumur are given indiscriminately; and this is the more surprising in a German book, as Fahrenheit's scale is utterly unknown in Germany. Sometimes two scales, in charming harmony, are brought together in one sentence; so on page 100, we read, "water expands at 32° F., it forms crystals (a novel way of describing the freezing of water), and it boils at 100° C."; or at page 151, "iodine melts at 107° C., and becomes gaseous at 140°–144° R." Then again, sometimes no scale is given at all, as under iodoform, page 165, where an alcoholic solution of iodine is to be warmed to 35°–40°.

From the liberal use of Fahrenheit's scale, and much internal evidence, it is only too apparent that the book is chiefly a mere translation of Pereira of 1851; but by great curtailment of the original, much valuable information is omitted. There is not a single woodcut; the diagrams of chemical decomposition, giving such clear representation of the process, are left out, and verbal descriptions, often hazy and incorrect, are substituted.

The greatest carelessness is shown in the enumeration of the elements and their compounds; sometimes their symbols and equivalents are given, sometimes not, as under Na, Ba, Al, etc.; the same with pharmaceutical preparations, the composition of which is given after the name, but just as often not.

After carbon we read, vapour density (?) of carbon = 1; and we must assume from the query, that the author could not realize the idea of carbon vapour density.

Most apparent is the absence of systematical arrangement in nomenclature. We will quote a few of the headings of the iron salts. Here we have, ferrum sulphuricum crystallizatum, persulphas ferri, ferrum chloratum, ferrum bromatum in maximo, ferrum ammoniato-sulphuricum, ammoniacum hydrochloratum ferratum;—and this is a fair specimen of the style throughout the book.

We will conclude with a few extracts, taken at random, which, better than any words, will show the value of the book.

Creasote and petroleum are essential oils.

Graphite is brought from Borrowdale to London, and sold by auction, or in a public-house in Essex Street, Strand, every first Monday in the month.

Phosphorus is made from bone-ash ($3\,CaO\,PO_5$), which on being mixed with water and sulphuric acid, gives off carbonic acid.

Sulphuretted hydrogen is at 55° F. a transparent liquid;—the slight matter of a pressure of 15° to 16° atmosphere being forgotten.

Sesquicarbonate of ammonia is frequently used for effervescing powders.

Kali picronitricum, nitrophenol and picric acid are one and the same substance.

Kali causticum, the formula of which is KO, is brought into the market in solution, as a fine powder and fused.

Forty pages further on, we find again kali hydricum fusum and solution, as separate articles.

British soda-water often contains copper and lead.

Soda-saltpetre is only found in South America.

And so we might go on and copy the whole book.

The directions for making the pharmaceutical preparations are throughout correct; as before stated, they are taken from Mohr's 'Commentar,' a valuable book, well known in this country, as translated by Dr. Redwood.

Altogether we must agree with the author of this book, when he states in the preface, it is possible—nay, even probable—that a more experienced pen than his might have been more successful in collecting, arranging and digesting the different substances.

Obituary.

The *American Journal of Pharmacy* announces the death by an accident, at the age of thirty-four, of Mr. FERRIS BRINGHURST, of Wilmington, Delaware, a prominent and much-esteemed member of the American Pharmaceutical Association. The deceased gentleman was engaged in the preparation of a quantity of oxygen from chlorate of potash, for the illustration of a lecture he was about to deliver to the members of a working men's institute, when the iron apparatus he was using burst. One of the fragments struck him on the forehead, inflicting a dreadful wound and causing his death a few days afterwards.

The following journals have been received:—The 'British Medical Journal,' April 22; the 'Medical Times and Gazette,' April 22; the 'Lancet,' April 22; the 'Medical Press and Circular,' April 26; 'Nature,' April 20; the 'Chemical News,' April 21; 'Journal of the Society of Arts,' April 19; 'Gardeners' Chronicle,' April 22; the 'Grocer,' April 22; 'Produce Markets Review,' April 22; the 'English Mechanic,' April 21; the 'Food Journal' for April; the 'Photographic Journal,' April 18; the 'Journal of the London Institution,' April 18; 'Proceedings of the Royal Institution;' the 'Brewers' Guardian,' April 24; 'Philadelphia Medical and Surgical Reporter,' Nos. 733, 734; the 'New York Herald,' April 5.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department*, 17, *Bloomsbury Square, W.C., and not to the Publishers.*

[191.]—WHITE SHELLAC.—To obviate the annoyance occasioned by the alteration that white shellac sooner or later undergoes, dissolve it as soon as received from the maker in methylated spirit, so that one fluid ounce shall contain half an ounce by weight. In this fluid form it is at once available for polishes; and should a little of the solid be required, it can readily be obtained by precipitation with hot water. This suggestion is addressed, of course, to small and unfrequent consumers only.—T. B. GROVES.

[220.]—DISPENSING.—

℞. Quiniæ Sulphatis ℈ij
Acid. Hydroch. Dil. ʒivss
Pot. Iodid. ʒiss
Tinct. Iodi ʒiij
Syr. Aurant. ℥iv
Spt. Chlorof. ʒij
Aq. ad ℥viij. M.

This prescription is one of those which never give satisfaction to the dispenser, and often creates a feeling of distrust in the mind of the patient for whom it was written. It is impossible to mix it and not have decomposition. I consider the following to be the best manner of preparing it:—

After selecting the 8-oz. bottle, let an ounce of water be put into it, and then introduce the "iodide of potassium;" when perfect solution has taken place, add the "diluted acid" and the "syrup of orange," shake well together; then, having previously weighed the "quinine" and powdered it finely by passing a knife over it, introduce it into the bottle and shake well. Mix the "tinct. of iodine" and the "spt. of chloroform" together, and add this gradually (shaking well at each addition) to the mixture.

When prepared in the above manner, it assumes a reddish, opaque colour, but, after standing for some time, changes its appearance and becomes almost bright, a precipitate is thrown down (iodide of quinine?) and a scaly film is formed on the surface of the mixture, both of which, to a certain degree, disappear when the mixture is well agitated.

If the prescribed dose be mixed with a wineglass of water and well stirred, it still does not form a perfect solution.—C. T. J.

[221.]—SULPHATE OF LIME is valuable to farmers; 10 cwt. per acre being used as a top dressing for clovers, trefoil, cinquefoil, etc.—H.

[*** It should be remembered that there is a difference between the sulphate of lime used, in the form of gypsum, as manure and the residue from the production of carbonic acid gas, inasmuch as the latter contains free sulphuric acid.—ED. PHARM. JOURN.]

[222.]—TINCTURA COLOCYNTHIDIS, known also as "Dahlberg's Tincture."—The following is from the Prussian Pharmacopœia:—

Colocynth Pulp (cut small and free from seeds) ℥j
Aniseed ʒj
Proof Spirit, 1 lb.

Digest for eight days, express and filter.
Dose.—6 to 20 drops.—C. T. J.

A similar answer has been received from F. O. Collins.

J. T. C. thinks that *J. Whitfield* is wrong in stating the time for *maceration* of the above to be *three* days. According to Beasley's 'Book of Prescriptions,' Neligan prescribed the Prussian formula, which is—

Colocynth ℥j
Aniseed ʒj
Proof Spirit, 1 lb. (not 14 oz.)

Digest for *eight* days, express and filter.

[226.]—COD-LIVER OIL JELLY.—*C. E. L. N.*, if he can meet with some true sweet almond flour (I have none), is recommended to try my glycylæum. See article of that name in the proceedings of the Dundee meeting of the Pharmaceutical Conference. A little ingenuity spent upon it would make it, I think, a useful item of elegant pharmacy.—T. B. GROVES.

[228.]—SYRUPUS TONICUS.—Easton's syrup, flavoured with orange flower-water, is largely prescribed in Manchester and its neighbourhood under the name of "syrupus tonicus."

Each fluid drachm of this preparation contains:—

Phosphate of Iron	. . . . .	1 grain.
,, Quinine	. . . .	1 ,,
,, Strychnine	. . .	$\frac{1}{32}$,,

—JAMES WOOLLEY, *Manchester.*

[229.]—STRAINERS.—In answer to *J. W.*, I beg to say that a piece of fine muslin placed in the neck of the funnel is very useful. It must not be pressed in too tight.—GEORGE ADAMS.

During the cotton famine a substitute for cotton wool, prepared from flax by the process of the late Chevalier Clausen, was offered for sale by Messrs. Bourne and Taylor. For some years I saw, much to my annoyance, some pounds of it lying about in my wareroom unsaleable, for it did not take. Now I am equally annoyed to note its gradual disappearance, for I have devoted it to the purpose indicated by *J. W.*, and do not certainly know whence to obtain a fresh supply. Its advantages are these—it is cleaner and finer than tow, not so fine as cotton wool, and *is not repellent of water*, which is its crowning superiority.

The best woven strainer that I have discovered is crinoline, or at least a cheap cotton material that goes by that name. Its stiffness—due to starch or some cereal flour—must be removed by washing in very hot water. Then it appears like a coarse and strong muslin. For press bags I have selected strong serge, after trying canvas, duck, etc. I am told that a kind of twilled flannel is still better. I saw it in use at the laboratory of Messrs. Evans, Liverpool, but have not yet succeeded in finding out where it can be purchased in the ordinary way of business. I may add, though, that Messrs. Evans kindly offered to spare me some at, I think, about 5*s.* per yard.—T. B. GROVES.

[231.]—BEETLE POWDER.—In reply to "*Give and Take's*" request for a beetle powder, he will find the following very good:—

R. Red Lead, 4 oz.
Flour, 1 oz.
Powdered Sugar, 1 oz.

M. Place a little of the powder on a small piece of paper. Cats or dogs will not touch it. I will warrant it to kill any amount of beetles.—S. G. M.

[234.]—A PROBLEM FROM DOVER.—

R. Liq. Quiniæ Ammon. ℥iss
Syr. Ferri Phosph. ℥j
Ferri Ammon. Citr. ℈j
Acid. Phosph. Dil. ʒiss
Aquæ Menth. Pip. ʒiis
Ammon. Phosphat. ℈iij

M. ft. mistura.—A. B.

Ferri ammonio-citratem in aqua menthæ piperitæ solve, ammoniæ phosphatem in acido phosphorico diluto; ferri phosphatis syrupum quinæ ammoniatæ liquori adde, denique simul omnia misce.—SCOTICUS.

[240.]—DISPENSING.—The following prescription was brought to me to dispense:—

R. Sp. Ætheris,
" Lavandulæ,
" Ammon. Ar., aa. ʒij
Mist. Camph. ad ℥viij.

M. ft. mist.

The person called the day following to say that some mistake must have been made in its preparation, as it had been made up at one of the first houses in London, and was of a reddish colour. My mixture was colourless.

Please inform me what appearance the mixture should present when properly dispensed.—J. CROOKES.

THE TASTE OF COD-LIVER OIL.—Dr. Aubrey Wicks, in a letter to the *Lancet*, says that the fishy taste of cod-liver oil may be modified by placing a few grains of chloride of sodium on the tongue before taking a dose. "With this simple adjunct, patients who before rejected the oil will take it with apparent relish, describing the taste as that of herring or sardine." A piece of bread may be eaten afterwards. Dr. A. S. Hudson, writing to the *American Medical Gazette*, says that the taste may be wholly disguised by adding to one pint of the oil half an ounce of tincture of gum guaiacum and a drachm of essence of gaultheria.

[236.]—DISPENSING.—The following prescription was brought to me to dispense a few days since; as the quantity of bromide was so excessive, will some of your readers kindly say what they would do in such a case?—

R. Potassæ Chloratis ʒij
Potassii Bromidi ℥j
Inf. Gent. recentis ad ℥viij

A sixth part thrice a day.—J. H. G., *South Hants.*

[237.]—RED INK.—Can any of your readers give me a good receipt for bright red ink?—J. H. G.

[238.]—TOBACCO PAPER.—Please give me in your next impression a formula for making the "tobacco paper" used by gardeners to burn in greenhouses to kill insects.—A. P. S.

[239.]—CREAMY FURNITURE POLISH.—*C. W. S.* would feel obliged if any correspondent would favour him with a formula for a cream of furniture polish.

CULINARY ESSENCES.

(*From the Chicago Pharmacist.*)

Flavour of Ginger.

Take of Ginger Root, bruised, 2 oz. troy
Wild Ginger (Asarum), bruised, 1 drm.
Lemon Peel, bruised, 1 oz. troy
Diluted Alcohol 16 fl. oz.

Macerate for fourteen days and filter.

Flavour of Lemon.

Take of Lemon Peel (fresh), cut thin, 2 oz. troy.
Oil of Lemon (fresh) 1 fl. oz.
Alcohol, 95 per cent., 12 fl. oz.
Water 4 fl. oz.

Digest for eight or ten days and filter.

Flavour of Nutmegs.

Take of Nutmegs (grated) 1 oz. troy.
Oil of Nutmegs 2 fl. drms.
Diluted Alcohol 16 fl. oz.

Digest for eight to ten days and filter.

Flavour of Orange.

Take of Orange peel (fresh), cut thin, 2 oz. troy.
Oil of Orange (fresh) ½ fl. oz.
Alcohol, 95 per cent., 12 fl. oz.
Water 4 fl. oz.

Digest for eight to ten days and filter.

Flavour of Rose.

Take of red Rose leaves, in coarse powder, ½ oz. troy
Oil of Rose, pure, 5 drops
Alcohol, 95 per cent., 6 fl. oz.
Water 10 fl. oz.

Dissolve the oil in the alcohol, mix with the water and macerate the rose leaves for eight to ten days in the menstruum and filter.

Flavour of Tonqua Bean.

Take of Tonqua Bean, bruised, 4 oz. troy
Orris Root, in powder, ½ oz. troy
Diluted Alcohol 16 fl. oz.

Digest for fourteen days and filter.

Flavour of Vanilla.

Take of Vanilla Bean, cut very small, 2 oz. troy
Diluted Alcohol 16 fl. oz.

Digest for three to four weeks and filter.

Flavours of banana, pineapple, raspberry and strawberry, termed fruit essences, are alcoholic solutions of the amyl and ethyl ether series.

Flavour of Pineapple.

Take of Essence of Pineapple (artificial) 6 fl. drms.
Diluted Alcohol 14 fl. oz.
Simple Syrup 1 fl. oz.
Tincture of Cinnamon 2 fl. drms.

Mix.

Flavour of Raspberry.

Take of Essence of Raspberry (artificial) 1 fl. oz.
Diluted Alcohol 12 fl. oz.
Syrup of Raspberry (fruit) 2 fl. oz.
Tincture of Orris Root (4 oz. to the pint)
Tincture of Cochineal, of each ½ fl. oz.

Mix.

Flavour of Strawberry.

Take of Essence of Strawberry (artificial) 1 fl. oz.
Diluted Alcohol 13 fl. oz.
Syrup of Raspberry (fruit)
Syrup of Pineapple (fruit) of each 6 fl. drms.
Tincture of Cochineal ½ fl. oz.

Mix.

Correspondence.

The Preliminary Examination.

Sir,—Would you kindly allow me space for a few words in reply to the letter of your correspondent B. S., contained in your last issue?

Whilst I think it highly desirable that every encouragement should be given to those who are desirous of possessing the Minor or Major qualifications, yet I think it unfair that they should be admitted to this ground by passing along the temporary bridge of "the Modified" instead of by the proper road from the Preliminary. The Modified Examination, as I understand, was provided for those young men who were thought to have a vested interest in the trade sufficient to entitle them to a less stringent examination, and thus far I think their case was met; but there were others who would gladly have availed themselves of the "Modified," and who had been even longer in the trade than some of those eligible for the "Modified," but were kept out by reason of their age, not having attained twenty-one years. Those young men, after having been six or seven years in the trade, were compelled (as I know in many cases where they have gone to business young) to work up what "they" had never learnt at school, viz. their Cæsar, etc. I don't see that it would be doing this class of young men justice, who have not had what I should almost call the privilege of laying claim to the "Modified," to allow those who have been thus privileged to take step No. 2 before having taken step No. 1.

But lastly, and chiefly, in your editorial article of last week on the Preliminary Examination, you state that the objection raised by your correspondent B. S. loses all its force from the mere fact that two of the passages given are actually such as might occur for translation in every-day business. I am quite of your opinion, Sir; and, moreover, I cannot see that there would be much gained by being admitted to the "Minor" without having passed the "Preliminary" (although the Latin is of a medical character, and consequently more familiar to persons in the trade); still I think that where the elementary knowledge required in the Preliminary is wanting, there would be an inability to render in full Latin the prescriptions given in the Minor.

13, *Hereford Road, W.* Minor Associate.

Sir,—In perusing your Journal of to-day, my attention was drawn to the above subject, on which I may, perhaps, be allowed to make these few remarks. Although the examination questions of the 3rd inst. were more stringent than those formerly selected by the Board of Examiners, still there was not the stringency in them which should prevent the candidate from obtaining the number of marks entitling him to registration as an apprentice. I hope that those who did not prove successful will persevere with the subjects, in order that they may be more successful when they offer themselves again. There are some candidates who ought not to be surprised to find themselves plucked. I have known those who thought to pass this examination by simply studying each alternate book of Cæsar or the first half of Book I., and acting similarly with the declensions and rules of the Latin grammar, etc. But if the candidate wishes to pass without having to offer himself a second time, I would strongly recommend him to study the subjects throughout. In the 43 per cent. of unsuccessful of the 3rd inst. I have no doubt there were several who knew very little or nothing whatever of the Latin language before they entered their term of apprenticeship. It must, of course, then be extremely difficult for them to study classics and attend to the routine of their business. In order to obviate this difficulty of apprentices, some step should be taken by the Society in distributing papers respecting the subjects of this examination to most of or all public schools where the Latin language is taught, in order that the principals of such schools might make known the subjects to those boys who wish to enter the business of a chemist and druggist. This would obviate a great difficulty of apprentices, as they would then be aware of the classical examination that they had to undergo during their apprenticeship, which many would pass before leaving school. I have heard apprentices who are in the trade say they wished that they had known in their school days that such an examination was compulsory, as they would have then taken the opportunity of passing it before leaving school instead of being troubled with it during their apprenticeship, while they might be studying other subjects in order to enable them to pass the other examinations of the Society. And I have not the least doubt that there are numerous apprentices in the trade who have not yet passed the Preliminary Examination, but who would have been too glad to have passed it before leaving school for their term of apprenticeship, had they known it before. If the Society would adopt the above or some similar plan, I think the Board of Examiners would not only find an increase of successful candidates in the Preliminary, but also in the Minor and Major Examinations.

Atherstone, April 22nd, 1871. George Sant.

Syrup of Phosphate of Iron.

Sir,—In looking over recent suggestions as to syr. ferri phosph., I notice a letter from Mr. Rose in the Journal of the 8th of this month, commenting on a form given by Mr. Carteighe in a previous number, and suggesting the addition of more sugar.

Mr. Rose recommends that 12 fl. oz. should contain $8\frac{1}{2}$ oz. sugar. Now Mr. Carteighe, in his form, adds to the 2 fl. oz. acid and water, containing the iron, 10 fl. oz. syrup, which contain $8\frac{1}{2}$ sugar (if made according to the Pharmacopœia); therefore I cannot see any improvement in Mr. Rose's form, as it takes the longer of the two to prepare, and gives exactly the same result as Mr. Carteighe's.

Notting Hill, April 22nd, 1871. E. B. Starkey.

Sir,—Desiring to make some syr. ferri phosph. in accordance with the formula proposed by Mr. Carteighe, and having no phosphoric acid of the required strength, I determined to prepare a quantity from some glacial phosphoric acid which I had in sticks. The necessary amount was dissolved in a composition evaporating basin, and the solution heated until it ceased to give a precipitate with solution of albumen, and afforded the necessary reactions with the ammonio-nitrate of silver test; it was then evaporated to the sp. gr. 1·500. Freshly precipitated ferrous phosphate treated in the prescribed manner, became dissolved in a few seconds, but (the solution) became quite milky on dilution with water, or syrup; an older sample of phosphate was only dissolved in part, a white-looking compound remaining insoluble, and on filtration, the clear filtrate behaved in a like manner, when similarly treated. If any of your correspondents could inform me as to what was the probable change the acid had undergone, which is not indicated by the ordinary reagents, they would help me out of a difficulty.

London, April 22nd, 1871. Aliquis.

The Sale of Poisons.

Sir,—Allow me to inquire, through the medium of your Journal, if the trade generally are aware that tinct. opii is frequently retailed from small village shops (not registered) as narcotic tincture, opiated tincture, etc., and supplied to them by many who call themselves leading chemists? I know instances where pharmaceutical chemists have even done this. Is it fair play to those young men who study for months together to pass the required examination, for them to find that a complete novice can sell the same poison under a different nomenclature? If this is to continue, what benefit has the registered chemist over the shopkeeper as to the sale of prohibited drugs?

Grantham, April 21st, 1871. A. P. S.

Jury Service.

Sir,—As the time is drawing very near when the Pharmaceutical Society will hold its annual meeting, may I again trouble you for space to suggest to our Council the desirableness of recommending to the Privy Council a regulation which would tend much more to the safety of the public than poison cupboards, keys, etc. *i. e.* "That *all* chemists on the Register be exempt from serving on juries." Indeed Dickens, in his trial of Pickwick, puts the reasonableness of the suggestion very clearly before the public, where he says "The chemist on being summoned to the trial as a juryman begged off, on the plea that he had only a boy to mind the shop, who did not know Epsom salts from oxalic acid."

I do not think it fair that a man should be compelled to leave his business, when upon the proper fulfilment of his own duties in that business depends the safety of many lives, or even the ruin of his business.

Manchester, April 22nd, 1871. W. B. O.

A Proposal to Enforce Early Closing.

Sir,—May I ask you to be good enough to spare me a small space to bring before the members of the profession a subject which has appeared several times before in this Journal, but unfortunately no person, having any amount of influence over the profession, having taken it up, it was allowed to drop as an impossibility? It is that of early closing. Now that the Pharmaceutical Society requires so much scientific as well as practical knowledge, there ought to be some measures taken to enforce early closing, that assistants and apprentices (more especially in Town) might have an opportunity of preparing themselves for the requisite examinations. I think as the Council have the power to revise and amend the laws, etc. relating to pharmacy, they might make an addition to the new Act of 1868, very advantageous to the rising generation of pharmacists. If I might be permitted to suggest the following addendum, to be made to the eighth clause of the Pharmacy Act 1868, 15 & 16 Vict. c. lvi., I am sure it would be hailed with delight by all young persons engaged in the metropolis; some such words as the following might be used:—"And to enable persons to attain the necessary qualifications, all persons in Great Britain practising as denoted in clause 3 of the Pharmacy Act 1868, 31 & 32 Viet. c. xxi., shall, after the —— day of —— 1871, close their shops, or cause them to be closed, and shall suspend business entirely (except in case of urgent medicine being required, which, of course, some person must be at home to attend to) at eight o'clock, P.M., and no persons in their employ shall be detained after that time, but shall be allowed to study or otherwise make use of their time, neither shall they be employed more than twelve hours in each day, including an hour and a half for meals; in violation of this law such persons to be fined such sum as the Council may think fit." I can safely say that if the Council would give this matter their consideration, a material difference would be seen in the attendance by members, etc. at the various meetings of the Society, and Mr. Haselden, V.P., would no longer have to complain of the poorly attended meetings. The Society would be remunerated by a greater number of candidates presenting themselves for the respective examinations. I am longing to see this matter taken up by some of our influential members.

Aspirant to the "Major Qualification."

The Fraternity of the Profession.

Sir,—Now that the poison regulations question is fairly on its way to an end, I think the Council would do well by endeavouring to infuse a more fraternal spirit amongst the whole body of chemists. Without the exception of any other profession, we are, I think, the most jealous of each other, whereas it should be quite the reverse of this; for surely an educated chemist ought by virtue of his education, apart from even any higher motive, to be above such behaviour as is too often shown towards those of the same calling.

I had occasion some few days since to visit one of these brethren, wishing to obtain from him a small quantity of chloral hydrate. I asked for half a drachm, and, having omitted taking a bottle, I requested that I might be furnished with one. This was done by supplying a one-ounce wide-mouth stoppered one. I then asked the price of the whole, and was told one shilling. Note, this price was to one of the profession; what it would have been to the public it is impossible to say; but I think there are few London establishments where more would have been charged in the retail.

While such ill-feeling as this exists amongst us, we cannot expect the cause of pharmacy to make much advancement; but were we more friendly towards each other, and tried to facilitate each other's "common interest" (even if nothing more) in everything pertaining to the profession, with such a union we should possess strength.

Bloxham, April 11th, 1871. J. T. Newey.

A Queer Customer.

Sir,—As I think the enclosed might contribute to amuse your readers, I hope you will give it a place when there is a spare corner in the Pharmaceutical Journal. You see it is indited on elegant tinted paper, and it was presented by a small boy at my counter with the modest accompaniment of 1*d.* to pay for its prescribing and dispensing.

Marlow, April 19th, 1871. Charles M. Foottit.

"if yow plees will you send me soom iwas
porely for three days no it stopt iam in such
pain in my belley and stomek aged 48
willam ilowers
cookham
deen"

Cautions.

Sir,—The communication in your Journal of the 22nd inst. from Mr. Eve respecting a person who calls himself Fischer, recalls a slight personal experience of my own. Many months ago Mr. Fischer called upon me in a town quite remote from London, and begged for money to enable him to travel a stage further, using the names of scientific chemists in the north of England with much freedom.

Mr. Eve's letter convinces me that anything which I gave him was badly bestowed, and that it will be well for the future that our body should be relieved from Mr. Fischer's importunities. F. C. S.

Sir,—In your issue of March 18th, I saw advertised a literal translation of the first book of 'Cæsar's Commentaries' at the price of 2*s.* 6*d.*, to apply to "Casticus," General Post Office, Birmingham. Being an apprentice studying for the Preliminary Examination, I applied for the translation, enclosing thirty-one stamps. Not having received a reply, I wrote to inquire the cause, and have never yet received a reply, neither in the shape of book or otherwise. I should be very much obliged to you if you would furnish me with the proper name and address of the advertiser, as I think it very hard indeed for young apprentices as myself, anxious to acquire knowledge and to "get on" in the pharmaceutical profession, to forfeit our money to unprincipled persons, in the attempt to get books for the furtherance of our knowledge.

I enclose stamped and directed envelope for reply.

M. Leigh.

[*** In reference to this communication, we are informed by the Publishers that they are unable to comply with our correspondent's request to be furnished with the proper name and address of the advertiser, the order for the advertisement being only dated "Birmingham." It is just possible that it is *bonâ fide*, but it is more probable that it is a swindle, so we insert our correspondent's letter in order to prevent, as far as possible, any further mischief being done.—Ed. Pharm. Journ.]

"Inquirer."—Apply at Apothecaries' Hall.

"Boiler Composition."—Boiler incrustation generally consists of the carbonate and sulphate of lime contained in the water used for generating steam.

J. T. Robertson.—We are informed that Mr. Gerrard's improved suppository mould may be obtained from Mr. Mather, of Newgate Street. The prices are for six, 5*s.*; twelve, 13*s.*; twenty-four, 32*s.* each.

W. J.—We have no means for furnishing formulæ of proprietary articles.

T. S. Johnson.—Our correspondent was in error. It is unnecessary to label the medicine "poison," provided the formula be copied in a book.

G. Adams.—You would be right in using the preparation of the London Pharmacopœia.

"July."—Certificates cannot be issued from the office in an imperfect state.

"An Inquirer."—We have no knowledge of any such Bill having been introduced.

Communications, Letters, etc., have been received from Mr. G. Adams, Mr. M. C. Cooke, Mr. F. Thompson, Mr. H. J. Baildon, Mr. R. Hedley, the Secretary of the Liverpool Chemists' Association, W. R., J. T. C., S. G. M., "Guaco," "Scoticus," "Inquirer," "Southsea," "Pro Bono Publico." We have also received communications from "Spes," "Errata," and E. B., in which the requirements as to anonymous letters have not been complied with.

PARCHMENT PAPER AS A FILTERING MEDIUM.

BY CHARLES R. C. TICHBORNE, F.C.S., ETC.

The Bunsen filter is now well known and familiar to most manipulators. It merely consists of a funnel and filter connected with an air-tight vessel, in the interior of which a partial vacuum can be produced, either by a Sprengel or ordinary air pump; in fact, by any contrivance by which a downward pressure of some considerable power is exerted upon the fluid washing some precipitate, or upon a liquid it is desirable to filter quickly.

To give us the opportunity of doing this properly, it is necessary to have a nicely prepared support beneath the nozzle of the filter, to enable it to bear the considerable pressure to which it is exposed; the nozzle of the filter being the point of weakness. This is generally done by very carefully forming a little cone of platinum foil, which must exactly fit the bend of the funnel. If the fit is not perfect, it generally results in the breaking of the filter and the failure of the experiment. This is at once obviated, and the platinum nozzle dispensed with, by using parchment paper as a filter. Parchment paper bears, under such circumstances, any reasonable pressure; and yet it is a perfect filtering medium. As regards the strength, Dr. Hofmann says that it becomes five times as strong as the paper before it is parchmentized; and I think that, when speaking of moist bibulous paper, it is no exaggeration to say its strength is increased at least twenty times.

In making the parchment paper for this purpose, the following method should be adopted. It differs very little from the ordinary one, except as regards a few precautions:—I use one part of pure sulphuric acid and one-half part of distilled water well mixed in a dish or shallow vessel. Where practical, this mixture should be ice cold, and under no circumstances must it be used while it is warm. Pieces of Swedish filtering-paper should then be dexterously floated upon the acid, so as to bring every particle of the surface in contact with it. But it is not necessary to parchmentize both sides. The next point of importance after the cooling of the acid mixture is the quickness used in the washing, which must be thorough.

This paper, which has proved itself so useful to us for dialytic purposes, forms the most perfect filtering medium, if properly managed, with which I am acquainted. Although, under ordinary circumstances, it is nearly impervious to fluids, they pass through with perfect facility under pressure. The structural change produced by sulphuric acid upon cellulose is the converse of most of the other acids. Thus in paper converted into pyroxylene by the action of nitric acid the fibres are seen, when examined with the microscope, to be more or less contracted, and the result is a non-contiguous, or friable structure, covered with small holes; but in parchmentized paper the fibres are swelled considerably in bulk, and are converted into a colloid or gelatinous substance, which, although slowly pervious to fluids, is very homogeneous in texture, and hence its strength.

In Bunsen's original paper he speaks of the difficulty of preventing filaments of the paper used from becoming mixed with precipitates. "Thus," he says, "another and an inestimable advantage springs from the peculiar condition of a precipitate filtered by this method,—the surface of the filter becomes injured and torn, so that the precipitates become mixed with filaments of paper. Gelatinous precipitates (when washed under pressure) adhere to the filter in a thin coherent layer, and may be removed piece after piece so completely that the paper remains perfectly clean and white." Now parchment paper is of that nature that it might be scraped with a knife or brushed, without invalidating a quantitative analysis.

Parchment paper would be perfection for filtering by pressure; but, alas! it has one drawback. The practical difficulty is in making the filter lie close to the funnel, so as not to permit atmospheric air to pass down by the side, instead of exerting its pressure upon the surface of the liquid in the filter. This difficulty is removed by placing an inner filter of ordinary filtering-paper larger than the parchment-paper one; therefore, the latter should be thin, and only treated with acid on one side. It is from this reason that parchment paper may be used more advantageously in a Bunsen filtering-apparatus made on the principle of a percolator—the bottoms of the upper vessel being covered with good strong paper, strengthened with muslin; such an apparatus as this is applicable to many purposes, such as quick and thorough exhaustion of a powder by any menstruum, or the separation of crystals from a viscid liquid.

BRISTOL PHARMACOLOGY.

BY W. W. STODDART, F.C.S., F.G.S.

(*Continued from page* 843.)

Nat. Ord. Valerianaceæ.

This is another very singular Order of plants, most of them having an extremely powerful odour, which is due to an extraordinary series of chemical products.

Valeriana officinalis (Linn.).

This attractive plant is found growing in moist places. It is found in the Leigh Woods, Lock's Mills, Bedminster, Baptist Mills and on the banks of the Avon. The pink flowers are very conspicuous among the grasses and sedges of the water's edge. The leaves are used by the country people, under the name of Allheal, as a cooling application to whitlows and boils.

The roots (or rather rhizomes, from which spring fibrous roots) are a yellowish-white, becoming brown when dry. They contain 6 per cent. of resin and $1\frac{1}{5}$ per cent. of a volatile oil.

The essential oil of valerian is yellowish-green, having a strong odour of the plant, an acid reaction and a sp. gr. 0·9. It consists of 70 per cent. of valerol ($C_6H_{10}O$), which is a crystalline principle, easily changing into valerianic acid by the absorption of oxygen. The other constituent is borneine ($C_{10}H_{16}$) a liquid hydrocarbon isomeric with oil of turpentine. The valerianic acid ($C_5H_{10}O_2$) is, however, the most important to the chemist.

It is a colourless, oily liquid, and was first discovered by Chevreul in the fat of the dolphin. It occurs in the berries of *Viburnum Opulus*, and is produced whenever fatty matters undergo oxidation, or albuminous substances putrefy, so that it is frequently present in animal secretions.

For trade purposes valerianic acid is generally manufactured by the oxidation of amylic alcohol (fousel oil).

$$\underset{\text{Amylic Alcohol.}}{C_5H_{11}HO} + O_2 = \underset{\text{Valerianic Acid.}}{C_5H_{10}O_2} + H_2O.$$

For experimental purposes this acid may be produced by distilling valerian root with sulphuric acid and bichromate of potash. By this means, not only the acid naturally present in the plant passes over into the receiver, but also that produced during the operation by the oxidation of the valerol.

$$\underset{\text{Valerol.}}{C_6H_{10}O} + O_3 = \underset{\text{Valerianic Acid.}}{C_5H_{10}O_2} + CO_2.$$

Valerianic acid stands in exactly the same relation to amylic alcohol that acetic acid does to ethylic alcohol (C_2H_5HO), thus,—

$$\underset{\text{Amylic Alcohol.}}{C_5H_{11}HO} + O_2 = \underset{\text{Valerianic Acid.}}{C_5H_{10}O_2} + H_2O.$$

and—

$$\underset{\text{Ethylic Alcohol.}}{C_2H_5HO} + O_2 = \underset{\text{Acetic Acid.}}{C_2H_4O_2} + H_2O.$$

Another example showing the analogy is, that an ether is formed from the combination of valerianic acid and the base of amylic alcohol.

$$\underset{\text{Amyl.}}{C_5H_{11}} + \underset{\text{Valerianic Acid.}}{C_5H_{10}O_2} = \underset{\text{Valerianate of Amyl.}}{C_5H_{11}, C_5H_9O_2} + H.$$

This product is sold under the name of oil of apples.

It will, therefore, be seen how extensive a series of combinations may arise from the constituents of so simple a plant as valerian; indeed, far more than can be described in a paper like the present.

Nat. Ord. Compositæ.

From this, the most comprehensive group in the vegetable kingdom, only three English plants are mentioned in our materia medica. It is so named because the flowers are compounded of many smaller ones, enclosed in a calyx-like assemblage of bracts, termed an involucre. The general properties of the plants composing this Order are tonic, astringent and carminative.

Anthemis nobilis (Linn.).

This well-known plant is found on most of the waste places near Bristol, as at Hanham, Crew's Hole, Pill, Sea Mills, etc.

It is a common supposition among country people, that the more the Chamomile plant is trodden, the faster it grows. This idea is made use of by Shakespeare when speaking of the effects produced on the human constitution by an intemperate life, "For though the Chamomile the more it is trodden the faster it grows; yet youth, the more it is wasted the sooner it wears."

Both the common, or single, and the cultivated, or double, flowers are sold in the shops, and although the latter look the more handsome and are therefore often preferred, yet the single are far more efficacious, because they contain more essential oil. The oil is found in the disc, but in the double flower, the yellow, tubular, oil-bearing florets of the disc, are changed into the barren white rays.

The two principal constituents of the Chamomile are the volatile oil and bitter extract. One hundredweight of the flowers yields about two ounces of oil and forty-eight pounds of extract.

Oil of chamomile, like that of anise, is a compound of a peculiar substance, with a hydrocarbon isomeric with oil of turpentine ($C_{10}H_{16}$). The former is termed angelic aldehyde (C_5H_8O). When oil of chamomile is heated with dry hydrate of potassium, this aldehyd is converted into angelic acid ($C_5H_8O_2$), identical with that found in the roots of Angelica and Sumbul.

$$\underset{\text{Angelic Aldehyd.}}{C_5H_8O} + KHO = \underset{\text{Angelate of Potassium.}}{C_5H_7KO_2} + H_2.$$

Should the heat used be too strong, the angelic acid is washed and decomposed into propionic and acetic acids.

$$\underset{\text{Angelic Acid.}}{C_5H_8O_2} + 2H_2O = \underset{\text{Acetic Acid.}}{C_2H_4O_2} + \underset{\text{Propionic Acid.}}{C_3H_6O_2} + 2H.$$

The official extract is made by evaporating a watery infusion to a proper consistence, and adding fifteen minims of the essential oil to every pound of flowers employed, to restore that wasted during the process.

Taraxacum Dens-leonis (DC.).

This very common and ubiquitous plant has the credit for far more virtues than it probably ever possessed. Whether fresh or as preserved juice, as an extract or when actually torrefied, it seems all one and the same, with the same comprehensive attributes of a resolvent, aperient and tonic!!!

The juice of the root only is made use of in the Pharmacopœia. When expressed in the autumn months it changes its milky colour to a brown, and immediately coagulates and deposits caoutchouc. The juice also contains taraxacin, grape sugar, gum, a peculiar resin, inulin, and the usual alkaline and earthy salts. When pressed in the spring, the juice has a much less percentage of solids, and is more bitter from an excess of taraxacin. The latter, by the action of frosts and cold weather, becomes converted into mannite and glucose, producing the well-known sweet taste perceptible when the roots have been gathered in the latter part of the year.

The fresh roots yield about half their weight of juice. In the spring months, one pound of extract is afforded by eight or nine pounds of juice, while in the autumn only four pounds will yield that quantity.

When freshly-pressed taraxacum juice is received in water, and heated to 212° F., resin, caoutchouc and albumen separate. The filtered juice, after evaporation, yields crystals of taraxacin. They are slightly bitter, melt easily, and are soluble in water, alcohol and ether. When dissolved in the mineral acids, they do not suffer decomposition. The coagulum separated by the filter is then exhausted with hot alcohol, and set aside for spontaneous evaporation, when the so-called resin is obtained. This resinous substance is unaltered by alkalies or nitric acid. Sulphuric acid dissolves it, forming a yellowish liquid.

The dandelion roots, roasted and mixed with coffee, are sold under the name of dandelion coffee, but very commonly chicory roots, purchased in Covent Garden market, are used as a substitute. The so-called dandelion cocoa is nothing more than a mixture of ext. taraxaci with soluble cocoa.

The fruit of the taraxacum, with its stipitate pappus, is an interesting object, forming

"The schoolboy's clock in every town."

So beautifully is the seed balanced, that the slightest breeze carries it away like a miniature balloon.

Lactuca virosa (Linn.).

This plant does not occur very plentifully near Bristol, but may be gathered on St. Vincent's rocks and at Leigh. Its usual height is about two feet, and it never attains the size frequently seen in the south-eastern parts of England.

Bentham considers *Lactuca virosa* to be a variety of *L. Scariola*, only differing by the leaves being less glaucous and broader in form. If this opinion be correct, it would reconcile Dr. Sibthorp's objection to Sprengel's assertion, that *Lactuca virosa* was the θρίδαξ ἀγρία of Dioscorides. The lettuce is common in Greece and Italy, and was undoubtedly used by the Romans as a salad and medicine. Horace (Sat. 2. 8) speaks of its use as a provocative to the appetite :—

> "Rapula, lactucæ, radices; qualia lassum
> Pervellunt stomachum."

In another place (Sat. 2. 4), he says that lettuces are indigestible things for the habitual drinker, when suffering from dyspepsia and acidity :—

> "Nam lactuca innatat acri
> Post vinum stomacho."

The lettuce owes its medicinal virtues to the presence of lactucarium, or lettuce opium, a mild narcotic, and, like its poppy congener, is a compound of various principles. Its composition appears to be,—

Lactucone	48·95
Lactucin and Lactucic Acid	16·61
Caoutchouc	4·76
Albuminous substance	7·33
Mannite	2·65
Oxalic Acid	1·00
Resin, moisture, etc.	14·40
Ash	4·30
	100·00

Lactucone ($C_{40}H_{61}O_3$) is obtained from lactucarium by boiling alcohol, when it forms colourless, insipid crystals, which melt between 150° and 160°. They are insoluble in water, but readily so in alcohol, ether and oil.

Lactucin ($C_{22}H_{28}O_3$) is a yellowish, bitter, crystalline substance, which is not very soluble in ether, but more so in alcohol and acetic acid.

Lactucic acid is a yellow amorphous substance, obtained by the action of dilute sulphuric acid on lactucarium. Like mannite and glucose, it reduces cupric sulphate.

The *Lactuca sativa*, or garden lettuce, contains lactucarium, but in much less quantity. Schultz says a plant of *L. sativa* will yield 17 grains, while one of *L. virosa* will yield 56 grains.

Extractum lactucæ consists chiefly of lactucarium mixed with chlorophyll. One hundredweight of the plant will produce from four to five pounds of extract.

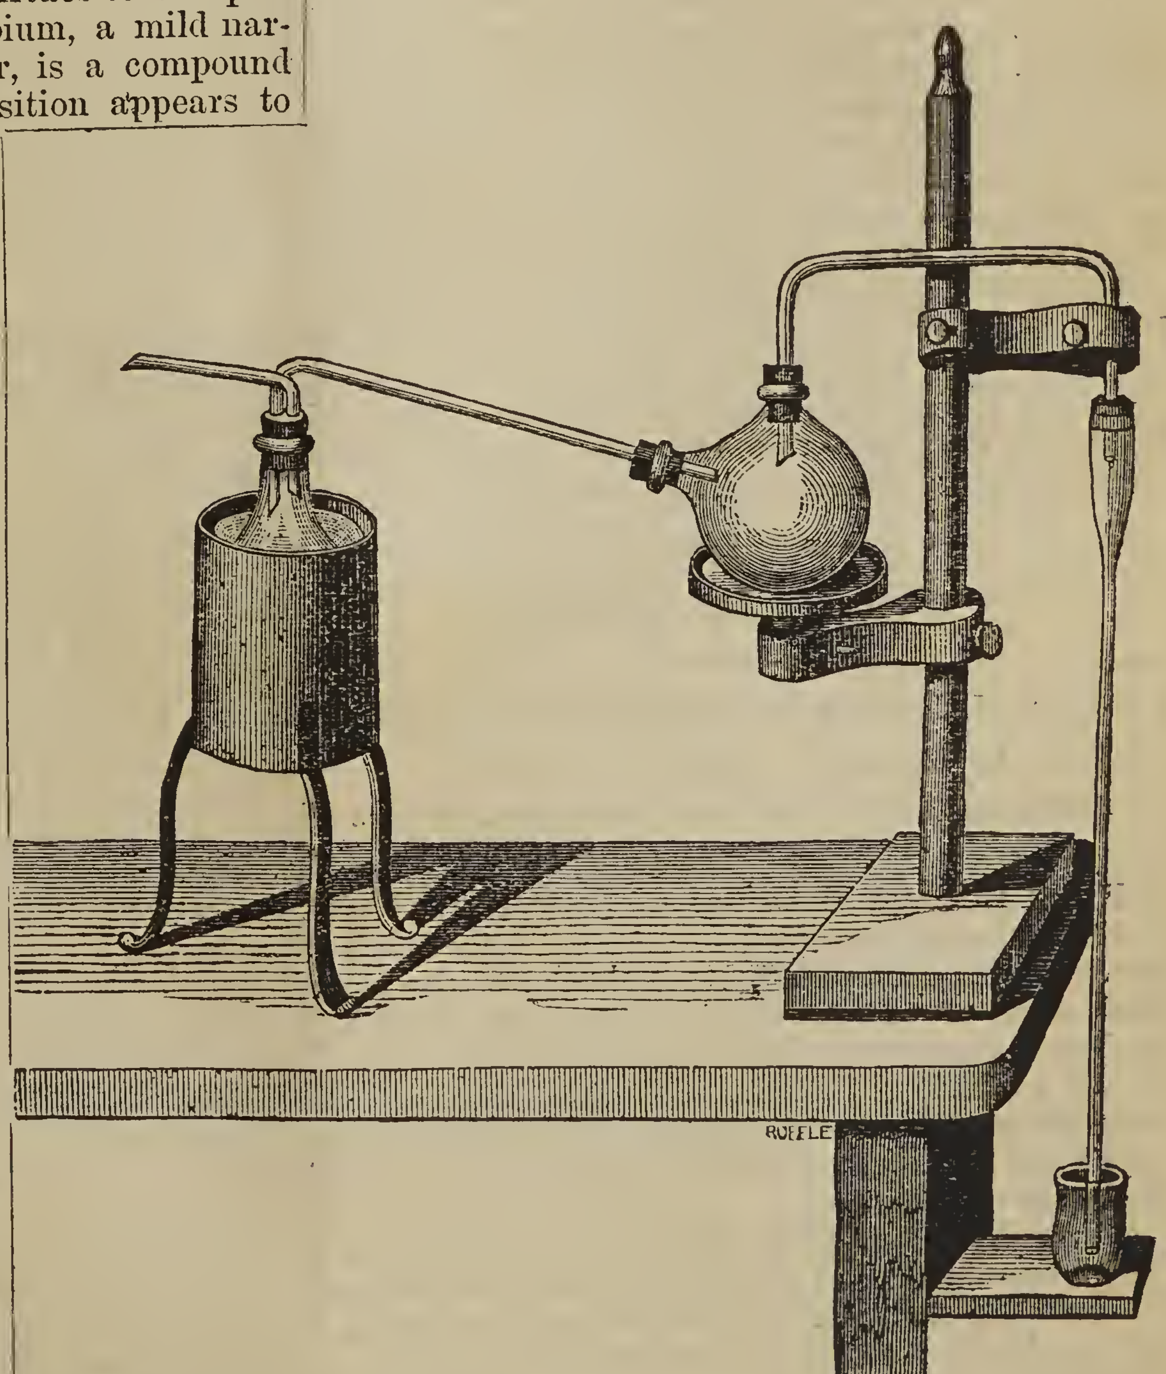
The proper time for gathering the lettuce for pharmaceutical use is about the *middle* of the time of inflorescence.

(*To be continued.*)

DISTILLATION IN PARTIAL VACUO.

The vessel in which the liquid is to be distilled may be either a flask or a tubulated retort, with a narrow neck fitting into a large, tubulated globe. Bend a glass tube twice at right angles, pass the short leg through the tubulus of the globe, and the long leg by means of an india-rubber cork into a wide tube holding about 100 c.c., and terminating in a very narrow tube at least 30 in. long; the lower end of this long tube to dip into a mercury trough.

Fit a bent tube into the flask or tubulus of the retort, and draw it out at a point outside the retort; attach a carbonic acid apparatus to this tube, and pass carbonic acid through the apparatus to expel all atmospheric air, or until the gas escaping from the long tube at the other end is completely absorbed by a solution of caustic potash. Now seal the tube by which the carbonic acid entered, at the narrow



point, pour about 100 c. c. of caustic potash lye on the mercury, and lower the trough until the tube dips into the lye.

Gently warm the globe, to expel a few gas bubbles; on cooling, the potash solution will rise to the widened part of the tube, after which the trough must be raised so that the tube dips into the mercury.

The absorption of the carbonic acid by potash produces a partial vacuum, indicated by the rise of mercury in the long tube, which at the same time shows that all the joints are air-tight.

The column of mercury must remain stationary for some time at a height of 15 in. above the surface of the mercury in the trough, when the liquid in the retort will be under a pressure of only half an atmosphere.

Then heat the retort and well cool the globe.

The use of an air-pump supersedes the potash apparatus. A T tube is introduced instead, one leg of which is connected with the air-pump, to draw out the air before and after the distillation, the second leg connects the globe, and the third is attached to a long tube dipping into mercury.

The success of the operation entirely depends upon the absolute perfection of the joints, for which india-rubber is the best material. Vulcanized corks and tubes are first boiled in a weak solution of caustic soda, they are then well dried and immersed in molten tallow; after several hours they are taken out and well cleaned with a cloth. Corks and tubes thus prepared make perfectly air-tight joints, they do not become hard and brittle, but preserve their elasticity. India-rubber melts at about 150° C. (302° F.). In case the heat applied during the distillation exceeds this temperature, the connection at the tubulus of the retort must be made with a sound cork, which is made air-tight by soaking it in molten wax or paraffin, and by painting a solution of caoutchouc in chloroform over the part above the tubulus.

Many organic substances, partially decomposed by distillation under ordinary pressure, such as glycerine, may be volatilized without decomposition, provided the receiver is well cooled to prevent the tension of the vapours from exerting any pressure.—*Commentar zur österreichischen Pharmacopœ.*

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Ferri Sulphas Exsiccata.—$FeSO_4H_2O$.

Sulphate of iron dried at a temperature which is gradually raised to 400°, loses six out of the seven molecules of water which it contains. This last molecule is only expelled by a much stronger heat; but if a solution of the salt be mixed with sulphate of potassium or ammonium, a double salt is produced in which the alkali sulphate replaces this seventh molecule of water.

Thus $FeSO_4, K_2SO_4, 6H_2O$. The sulphates of magnesium, zinc and copper form double compounds of a similar formula. Heated to redness, sulphate of iron leaves a residue of red ferric oxide, Fe_2O_3.

Ferri Sulphas Granulata.—A solution of freshly prepared sulphate of iron is filtered into rectified spirit. The salt being insoluble in spirit is precipitated in small granular crystals. Some experiments made by a student in the laboratory of the Society showed that this preparation is of the same composition as the ordinary sulphate of iron, having lost none of its water of crystallization. It is supposed to resist oxidation longer than the crystallized salt. To retard such change, it has been recommended to keep in the bottle containing sulphate of iron a small piece of camphor wrapped in paper.

Ferrum.—[§ Wrought iron in the form of wire or nails free from oxide.]

Chemically pure iron is almost unknown. The Pharmacopœia orders wrought iron to be employed for preparing the ferruginous compounds, because in that form it is practically least contaminated with foreign substances. The impurities contained in iron wire are chiefly minute quantities of carbon (average ·3 per cent.), silicon, phosphorus and sulphur. When ordinary iron is dissolved in dilute hydrochloric or sulphuric acid, the evolved hydrogen possesses an odour which is due to the presence in it of minute quantities of the hydrogen compounds of these elements. A small quantity of carbon also floats undissolved. This is much more noticeable when cast iron is used. Other substances are usually present, but in proportions smaller still, and interfere in no way with the employment of the iron for pharmaceutic purposes.

Iron filings are objectionable, as they are not only usually very dirty, but contain particles of other metals.

Ferrum Redactum.—[§ Metallic iron, with a variable amount of magnetic oxide of iron.]

Hydrated peroxide of iron contained in a gun-barrel is heated to redness in a current of pure and dry hydrogen gas. The greater part of the iron is thus reduced to the metallic state:—

$$Fe_2O_3, H_2O + 3H_2 = Fe_2 + 3H_2O + H_2O$$

A small quantity of it, however, does not lose the whole of its oxygen, and thus a certain proportion of magnetic oxide of iron is retained in the product.

$$3Fe_2O_3, H_2O + H_2 = 2Fe_3O_4 + H_2O + 3H_2O$$

At the end of the process, the current of hydrogen is continued until the tube is cold. If exposed to the air whilst still hot, the pulverulent iron becomes red-hot from the rapid reabsorption of oxygen, and the product is spoiled.

[§ A fine greyish-black powder, strongly attracted by the magnet, and exhibiting metallic streaks when rubbed with firm pressure in a mortar. It dissolves in hydrochloric acid with the evolution of hydrogen.] This hydrogen should be odourless, that is, free from sulphuretted hydrogen, the evolution of which indicates the presence of a little sulphide. "As the hydrated peroxide of iron of the Pharmacopœia is made by precipitation from a solution of persulphate of iron with caustic soda, this, as produced by manufacturers, generally retains a small portion of sulphate, which is not completely washed out in the process, and this sulphate is afterwards reduced to sulphide by the hydrogen during the conversion of the oxide to reduced iron. The liability to such a result would be obviated if the oxide used in the process were directed to be obtained from chloride of iron by precipitation with ammonia."—Redwood.

Strong ignition of the oxide before use would also probably effect the same object.

[§ 10 grains added to an aqueous solution of 50 grains of iodine and 50 grains of iodide of potassium, and digested in a small flask at a gentle heat, leave not more than 5 grains undissolved, which should be entirely soluble in hydrochloric acid.] This residue unacted upon by the iodine is, of course, the oxide which is present, the metallic iron being removed in solution in the form of iodide.

Ferrum Tartaratum (see Ferri et Ammon. Cit. and Ferri et Quinæ Cit.).—The tartarated iron is generally recognizable by its deep colour and sweetish taste. The tests indicated in the Pharmacopœia are intended to show that it is free from ammonia, that it is made from cream of tartar, and that it contains a due proportion of iron, viz. 30 per cent. of the peroxide.

KOUMISS.

BY VICTOR JAGIELSKI, M.D.

(*Concluded from page 865.*)

The fermentation which milk undergoes by the process which converts it into koumiss, presents many differences from those changes induced in milk by the ordinary methods of souring and curdling it, such as exposure to air and heat, addition of acids or rennet, etc. In all these cases lactic acid is formed; but in the fermentation process for koumiss, that product is accompanied with other derivatives of the milk which impart a peculiar character, physical as well as chemical. This character not only distinguishes the fresh koumiss, but pushes it on, under the influence of time, into further changes, which are not common to milk under ordinary circumstances. According to With, Stahlberg, Hartier, and, more recently, Weinberg, koumiss is composed of *alcohol, lactic acid, sugar, finely divided caseine, fat, salts, carbonic acid and water.* This composition represents the mare's milk (koumiss) in its fresh or No. 1 state. After having been in bottle for from five to ten days, according to the temperature of the atmosphere, it has changed by progressive fermentation into koumiss No. 2. This latter differs chemically from the former in containing more alcohol and carbonic acid, but less of solid matters. At the same time, its external or physical character has perceptibly changed, for it is homogeneous when well shaken and sparkles like champagne. It is also more acidulous than sweet, owing to the development of traces of acetic acid. By further age it becomes spontaneously No. 3; and this modification not only contains all the elements of the koumiss Nos. 1 and 2, but more or less butyric acid, succinic acid, acetic acid, and glycerine in addition. The proportion of alcohol and carbonic acid, moreover, has largely risen at the expense of the solid constituents. This koumiss is also more acidulous and sparkling than even No. 2, and rushes through the top of the bottle as a rich foaming liquor. It will be observed, then, that the fermentation progresses with age, and also that the older a koumiss becomes, the higher rises its proportion of alcohol and carbonic acid, and the lower falls its amount of solid matters.

Cow's milk koumiss should be made to correspond in composition with that from mare's milk; nevertheless it is sometimes necessary to make different modifications to suit the varying exigencies of disease and personal idiosyncrasy. This, of course, requires a certain chemical knowledge and skill which will give thick koumiss, skimmed koumiss, whey koumiss, diabetic koumiss, medicated koumiss, or any other modification that may be desired.

According to Morfit, the koumiss No. 2, from cow's milk, contains traces in variable degree of certain fragrant compounds, to which it may owe its character of a delicious beverage. These, he supposes, are generated from the volatile elements of the fat under the influence of the fermenting action and of the strong gaseous pressure in the bottle. There are other original and suggestive views by this able chemist upon the relations of koumiss, and as they tend to confirm my own observations, I propose to make them the subject in part of a more scientific paper at some future leisure.

Mare's milk koumiss runs through the transition state of No. 2 much more quickly than the koumiss from cow's milk. It is also more acid in the No. 3 state, and preliminary to its decay assumes a bitter taste. This bitter taste differs from the slight bitter of No. 3, cow's milk koumiss, which is a pleasant peculiarity and not a sign of approaching decay. All the different numbers have the colour and appearance of milk, and it should be noted here, that the cow's milk koumiss is a most agreeable beverage throughout.

Koumiss, unlike milk, agrees well with the feeblest stomach; and the molecular condition of its butter and caseine, together with the presence of lactic acid and other aids to digestion, render it the type of assimilable nutriments.

The foregoing description applies equally to the mare's milk koumiss of the steppes and the cow's milk koumiss of this country, with the differences noted. This latter, or cow's milk koumiss, as made on the Continent, does not retain its soundness so long, and, moreover, is not so agreeable to the taste.

The next point in sequence is the physiological relations of koumiss: but to elucidate these would require more space than the limits of this paper allow. I will, however, embrace the general physiology of the subject in the remarks which I am about to make upon its therapeutics. Moreover, I have already discussed the special physiology of the several constituents of koumiss in my treatise of the last year.

The high reputation of koumiss on the Continent has been fully confirmed in my own private practice and that of my professional brethren who have used it. With its aid, I have been able to treat certain diseases with gratifying results to both patient and physician. Most remarkable benefit is obtained by its use in all those complaints arising from feeble digestion, whether caused by impoverishment of the gastric juice or catarrhal complications, in nervous irritation and in the different phases of dyspepsia. Although the general properties correspond throughout the three numbers, the chemical and physical modifications which make the differences between them, give to each, in addition, a special character, and by this character it is adapted for special cases. In like manner these special koumisses, which are designated severally as *thick, skimmed,* whey, and diabetes *koumiss*, are modifications prepared to suit particular diseases.

In commencing the koumiss treatment, the physician must judiciously consider the condition of his patient, and regulate the use of this remedy accordingly. If debility be so great that the patient must keep in bed, then the koumiss is to be given only in very small quantities at short intervals, that is, about an ounce every hour. In such case it is necessary, and indeed in all cases it will be better, to restrict the diet solely to this beverage for a period. The power of assimilation will improve gradually, and sometimes even rapidly, and as this improvement advances, so will the taste for koumiss increase, and enable the patient to drink all that is required for a wholesome nutrition.

In this connection it must be remembered that the koumiss not only contains all the plastic, *respiratory* and heat-giving elements of the body, but presents them in such a form that they are rapidly absorbed to renew the wasted tissues of the body. In this respect koumiss is notably distinguished from milk, which, in any other modification, is intolerable to many stomachs, even in small quantities. When the patient is drinking the second quart of koumiss per day, his increase of flesh and strength will be very perceptible. I have had cases in which the gain amounted to as much as ten pounds in a month, where the only food taken with the koumiss was dry bread. Every quart that is drunk carries into the body about four ounces of solid food, so that koumiss supplies every rational want. Of course invalids in lesser degree, and those who go about actively, may drink according to their appetite, even though they consume as much as a gallon per day.

Patients in the adynamic stage of febrile disease regain wonderfully appetite and strength, and recover from stupor; their dry, black tongue clears up by perceptible gradations daily, the nervous tremor subsides promptly, the respiration becomes free, and the diuresis augments. This shows how thorough is the digestibility of koumiss, and how great is the restorative power of its elements. It is because the entire nutriment of the original milk is presented in those forms which greatly facilitate the natural action of the enfeebled organs of digestion; in other words, chemical skill has done in the preparation of koumiss nearly all the preliminary work which would otherwise fall on the digestive organs.

As has been noted already, koumiss can be made of any consistence or composition; therefore, if the amount of caseine in the normal koumiss is too great for any individual case, it must be replaced by another of lesser richness in that element. Again, for example, feverish persons require a thin or whey koumiss. The physiological explanation of whey koumiss in this connection is, that it not only gives less plastic material, but is very rich in sugar and salts.

For stout people the internal qualities of the koumiss must be so adjusted as to exclude the nourishing tendency, and therefore whey koumiss is thus indicated. But if a fat person has any morbid condition, such as chronic bronchitis, the koumiss must be not only whey koumiss, but have the special action suited to that morbid condition. The No. 2, or in more severe cases, the No. 3 koumiss of whey have this special action by reason of their much greater proportien of lactic acid.

That exercise in open air, after each dose, augments the appetite for koumiss I have already stated; but it must be added, that the warmer the season the more rapid is the progress in the cure; for then the koumiss has the immediate effect of allaying thirst and exciting appetite.

Fresh or No. 1 koumiss is a mild aperient, and promotes the flow of bile;—it is indicated, therefore, in constipation, especially when the complexion is sallow and the conjunctiva yellowish. So beautifully does it clear the skin, that its effect in this respect is proverbial in Moscow as the 'koumiss complexion.'

No. 3 koumiss applies to chronic diarrhœa, relaxation of the mucous membranes, and to nervous debility; it is, therefore, well suited for bronchitis, winter cough, and consumption. In such cases it is a benignant friend which has no rival; for, though not a specific, it is always a great palliative, and oftentimes a means of cure. It is necessary, however, to be used under the advice of a physician, so that it may be associated with other treatment as might be thought expedient.

Diaphoresis appears to be greatly increased by koumiss in summer, but in the colder seasons diuresis is strongly marked, and sometimes both effects follow together, especially in dropsies without organic lesion.

The pulse at first shows no change, but when the koumiss has been taken for a few days, then during the hours which follow its ingestion, the frequency diminishes, but there is more softness and fulness of volume. From this it might be inferred that koumiss is contra-indicated in hæmorrhage; but such is not the case, for in fact the blood itself is modified so favourably in its plasticity, and the walls of the blood-vessels are so strengthened, that the tendency to bleeding becomes lessened.

Koumiss produces a general calmness of feeling, sometimes accompanied with slight drowsiness; and the continuous use of it in its normal state produces plumpness in degree greater as the emaciation has been more advanced. Experience has shown in this connection that the average gain of weight ranges from the minimum of one ounce to the maximum of ten ounces per day. The weight of the patient should therefore be taken at the commencement of the treatment, and from time to time afterwards in order to observe the effect. If, in ten days, there is no sign of an increase, then it is better to stop the koumiss.

In conclusion, No. 2 koumiss is neither aperient nor constipating, but in other respects is midway between Nos. 1 and 3. It may be substituted advantageously for other drinks at meals, as it has a very agreeable taste, and is a great promoter of digestion.

If it should be desired to impart an aperient property to either Nos. 2 or 3, it is only necessary to drink the latter with one-half of fresh milk. By this admixture, the milk also becomes very digestible.—*The Milk Journal.*

CONTRIBUTIONS TO THE HISTORY OF THE OPIUM ALKALOIDS.

Part I.—On the Action of Hydrobromic Acid on Codeia.

BY C. R. A. WRIGHT, D.SC.

(*Concluded from page 868.*)

The third base is conveniently obtained, as hydrobromate, by treating codeia with three times its weight of 48 per cent. HBr for two hours on the water-bath, precipitating the product (diluted with water) by excess of carbonate of soda, collecting on filters, and well draining from the mother-liquors, and finally extracting with ether until scarcely anything more is taken up; care must be taken to have as little watery fluid as possible present, otherwise the insoluble substance forms a sort of lather on agitation from which the ether will not separate. The insoluble substance is then dissolved in the least possible quantity of weak hydrobromic acid and fractionally precipitated by cautious additon of stronger acid; the second precipitate is dissolved up in water, in which it is readily soluble, and a few drops of carbonate of soda solution added. The filtrate from this yields, with strong HBr, nearly white flakes, which are wholly void of crystalline character under the microscope. These remain solid at 100° if previously completely dried over SO_4H_2; but if warmed whilst moist, become a more or less coloured tar. Dried at 100°, the following numbers were obtained:—

0·3440 grm. gave 0·6810 CO_2 and 0·1740 H_2O.
0·3425 grm. gave 0·6685 CO and 0·1680 H_2O.
0·5615 grm. burnt with soda lime gave 0·1310 Pt.
0·3200 grm. boiled with NO_3H and $AgNO_3$ gave 0·1330 AgBr and 0·0315 Ag.

	Calculated	
C_{72}	864	54·03
H_{87}	87	5·44
N_4	56	3·50
O_{12}	192	12·01
Br_5	400	25·02
$C_{72}H_{83}BrN_4O_{12}, 4HBr$	1599	100·00

5·61	5·45		
—	—	3·33	
—	—	—	24·97

Carbonate of soda throws down from the hydrobromate a nearly white precipitate, which rapidly darkens, and finally turns a deep green, nearly black. Dried at 100° rapidly, the product gave the following numbers, which fall below those required for the formula $C_{72}H_{83}BrN_4O_{12}$, but which agree with those required for a similar formula but containing more oxygen:—

0·3810 grm. gave 0·8460 CO_2 and 0·2080 H_2O.

0·4430 grm. boiled with $AgNO_3$ and NO_3H gave 0·059 AgBr.

	Calculated.		Found.	
C_{72}	864	60·89	60·56	
H_{83}	83	5·85	6·07	
Br	80	5·64	——	5·67
N_4	56	3·95		
O_{21}	336	23·67		
$C_{72}H_{83}BrN_4O_{12}+O_9$	1419	100·00		

It hence happens that the free base rapidly absorbs oxygen. In confirmation of this, 0·11 grm. of the hydrobromate treated with caustic potash and injected by a pipette into 15 cubic centims. of air over mercury absorbed 0·9 cubic centim. in the course of an hour, or 6 per cent. of the total volume of the air; the salts, however, when dry, may be kept without alteration, and only slowly darken by exposure to air when moist.

This welding together of four molecules is not wholly without parallel in the history of the opium alkaloids and their derivatives: thus opianic acid heated* furnishes a body containing four times as much carbon as the original acid; thus

$$4C_{10}H_{10}O_5 = H_2O + C_{40}H_{38}O_{19}.$$

The qualitative reactions of bromotetracodeia appear to be identical with those of bromo- and chlorocodide. The base itself, when freshly precipitated, is slightly soluble in water, being thrown down again by addition of strong brine; in ether and benzol it is almost insoluble, and in alcohol but sparingly soluble.

When crude bromotetracodeia, got by extraction with ether of the mixture of bases thrown down by carbonate of soda, is dissolved in weak hydrochloric acid, and precipitated twice or thrice by excess of stronger acid, nearly white flakes are ultimately obtained, resembling in all their physical properties the bromohydrobromate of tetracodeia. These flakes, however, contain no bromine, the absence of this element being ascertained by the negative results obtained on examining with chlorine-water and ether the acidified solutions of the lime-salts got by combustion with quicklime, and of the sodium-salts got by boiling with NO_3H and $AgNO_3$, and fusing with carbonate of soda the silver-salts thus got. Dried over SO_4H_2 and finally at 100°, this body gave numbers indicating a base of constitution analogous to that of bromotetracodeia; it may therefore be termed chlorotetracodeia.

Specimen A.—0·3880 grm. gave 0·1970 AgCl.
0·3645 grm. gave 0·8395 CO_2 and 0·2120 H_2O.
0·3940 grm. burnt with soda lime gave 0·1080 Pt.

Specimen B.—0·4460 grm. gave 1·0150 CO_2 and 0·2560 H_6O.
0·2350 grm. gave 0·1250 AgCl.

	Calculated.	
C_{72}	864	62·77

$C_{72}H_{83}ClN_4O_{12}4HCl$	1376·5	100·00

Found.

Specimen A.		Specimen B.	
62·81	——	62·07	
6·46		6·38	
——	3·90		
12·56	——	——	13·16

Specimen A had been three times precipitated by HCl in large excess, while specimen B had only been thrown down twice, and probably retained a trace of bromotetracodeia.

Specimen A converted into platinum-salt gave the following numbers after drying at 100°.

0·4215 grm. gave 0·0810 Pt = 19·22 per cent.

The formula $C_{72}H_{83}ClN_4O_{12}$, 4HCl, $2PtCl_4$ requires 19·18 per cent.

Like bromotetracodeia, the free base appears to absorb oxygen with avidity. Dried as rapidly as possible at 100°, the precipitate thrown down by carbonate of soda gave these numbers:—

0·3880 grm. gave 0·9190 CO_2 and 0·2230 H_2O.
0·3100 „ 0·0330 AgCl.

	Calculated.		Found.

$C_{72}H_{83}ClN_4O_{12}+O_{6\frac{1}{2}}$	1334·5	100·00		

In all its physical and chemical properties chlorotetracodeia closely resembles bromotetracodeia: their qualitative reactions are identical; they have an intense bitter taste and apparently but slight physiological action, at any rate in small doses.

My thanks are due to Mr. J. L. Bell, in whose laboratory the above experiments were carried out.

YEAST AND OTHER FERMENTS.*

BY C. A. WATKINS.

In this paper I shall endeavour to lay before you some of those chemical changes which take place in certain substances when under the influence of other substances called Ferments. In some of these transformations the microscope shows us that there exists an intimate connection between the processes and the growth of some minute organisms, while in others the changes are purely chemical. The subject, which is of interest alike to the physiologist, microscopist and chemist, has received great attention from many excellent observers; nevertheless, very little is known about it, and at present the whole matter is involved in great mystery.

I therefore feel considerable diffidence in addressing you on such a subject, and should not have attempted it had I not observed that many writers fall into serious errors when discussing the chemical operations of the ferments.

I may at once tell you that the matter contained in this paper is perhaps more chemical than microscopical; but the fact is, these two investigations are inseparable if we desire accurate knowledge, and it is impossible to view ferments broadly, if treated only as a chemical or only as a microscopical subject.

Fermentation is a term applied to various chemical transformations, which certain ordinarily stable compounds, such as starch and sugar, undergo when in contact with a small quantity of an azotized or albuminous substance, which is itself in an active state of alteration. This active substance is called a ferment, and one of the peculiar properties of such a body is that it receives nothing from, nor imparts anything to the matter which is undergoing fermentation, but is itself decomposed and destroyed as a ferment in proportion to the matter fermented, which is gradually split up, or unfolded into two or more substances of simpler composition, sometimes with and sometimes without the assimilation of water.

This unfolding under the action of ferments is totally different to that chemical change known as catalysis, which takes place in one substance by mere contact with

* Reprinted from the 'Journal of the Quekett Microscopical Club.'

another, such as the unfolding of alcohol into ether and water by contact with sulphuric acid; for although the acid causes such a wonderful change, it is not destroyed by the operation, and consequently, when once the process is set going an unlimited quantity of alcohol may be converted by the original acid.

All the ferments are highly complex azotized substances allied to albumen; but while they possess this character in common, they may be divided into two groups—the one being living organisms, as yeast, and the other substances derived from various organic sources, such as albumen, gluten, casein, diastase, emulsin and a variety of others, all of which decay most rapidly when in a moist state.

The authors of the 'Microscopical Dictionary' would "exclude these substances from the ferments, and desire that the term fermentation be restricted to those changes which take place only through the agency of living organisms or fungi;" regarding which they also say, "A general law appears to prevail throughout the fungi that their nutrition differs from that of all other plants in depending exclusively on the absorption and decomposition (with the evolution of carbonic acid gas) of organic compounds, therefore consisting of the performance of the operation of fermentation on the organic matters on which they feed." But as the chemical operations of the ferments are so similar, notwithstanding the wide difference in their organization, I consider there would be no advantage in separating them as proposed, as they form a distinct class of chemical phenomena. I have also to observe that it is not true that carbonic acid gas is always given off during fermentation, nor is it proved that it is evolved during the growth of all the fungi. The ferments to which I desire to call your attention are—

Mycoderma vini, or yeast, which converts sugar into alcohol.

Boiled yeast, which converts sugar into gum and mannite—this transformation being called the viscous fermentation.

Casein, which converts sugar into lactic acid and butyric acid; this last conversion, however, being attributed to the action of the vibrio and diastase, which converts starch into sugar.

I shall have a few words to say on *M. aceti*, or the vinegar plant as some call it, which, although included by many among the ferments, is not so considered by chemists, for reasons I will hereafter explain.

When a saccharine solution is left in contact with casein either in the form of fresh curd or cheese, the sugar is slowly transformed into lactic acid according to the following equation:—

Cane sugar, $C_{12}H_{11}O_{11} + HO = 2C_6H_6O_6$ lactic acid.

In this fermentation water is assimilated, but no gas is evolved.

A solution of lactic acid, similarly treated, is transformed into butyric acid thus:—

$$\text{Lactic acid, } 2C_6H_6O_6 = \underset{\text{Butyric Acid.}}{C_8H_8O_4} + \underset{\text{Carbonic Acid.}}{4CO_2} + \underset{\text{Hydrogen.}}{4H.}$$

In this fermentation both carbonic acid and hydrogen gases are evolved. It is a question not yet answered, whether these chemical changes are induced by mere contact with the decomposing casein which is regarded as the ferment, or whether the minute organisms developed in these solutions are the real ferments living on the matters therein. One thing is certain, that in both fermentations living organisms abound, and they cannot grow without chemical changes taking place.

"M. Pasteur considers that a specific ferment is concerned in the production of the lactic acid fermentation, which spreads itself out as a grey substance over the surface of the sediment; and he asserts that this organism, when once obtained, and a small quantity added to a solution of sugar, very rapidly converts it into lactic acid, provided the solution contain a small quantity of some nitrogenous substance. When this grey matter is examined by the microscope it is seen to consist of very small globules or very short articulations, either isolated or in threads, much smaller than yeast, and to exhibit very rapid gyratory motion."

I have not succeeded in obtaining this grey matter, but as the lactic acid fermentation goes on very slowly, and as this season of the year is not favourable for experiments on fermentation, it may not have had time to make its appearance.

In order to observe the organisms which accompany the transformations of sugar, I watched the progress of the lactic acid fermentation of cane sugar, that of milk sugar by the gradual decomposition of milk, and also the viscous fermentation of cane sugar; for although I have seen no notice of any living organism being concerned in this fermentation, I thought it likely that the viscid ropy matter which is formed therein was probably due to some organic growth.

Now in all these experiments I found that as soon as decomposition commenced, or at least was appreciable, but not until then, organic life was found in all the fluids; that in all cases they appeared on the surface before they were seen in the body of the fluid, and that when first discovered they were not in an active condition, but as the decomposition progressed they became so, and moved through the fluid with rapidity, but those at the surface continued to be the most active. These bodies are species of *Vibrio* and *Bacterium*.

The milk used in the experiments was obtained perfectly fresh and divided into three portions—one containing the cream after the milk had stood twenty-four hours, the second was simply the skimmed milk, while the third portion was some of the same, with the addition of chalk to neutralize the lactic acid as it was formed. During four days the milk remained sweet, and I detected no organism in any part of it; but at the end of the fourth day the cream had a sour odour, indicating that lactic acid had been formed, and a small speck taken from the surface with a needle exhibited a mass of Bacterium-like bodies which, when some distilled water was passed between the glass slide and cover, swarmed through the fluid with rapid and various capers.* On the fifth day the milk had become sour, and exhibited the same active organs, but in the portion to which the chalk was added they were neither so numerous nor so active. On the eighth day fungus spores and mycelia appeared on the surface of the cream, and the same was noticed, but in a lesser degree, some days afterwards on the two portions of milk; but as a considerable amount of lactic acid was formed before these objects made their appearance, I do not imagine they were concerned in the fermentation which was going on.

But it was in the mixture of boiled yeast and sugar solution to produce the viscous fermentation that I found these bodies developed most rapidly, for in twenty-four hours after the mixture was made the fluid was covered with a thin film, which proved to be entirely these organisms packed closely together, so that no motion could be seen until some distilled water was added, when their activity was fully displayed. In the course of a few days the film had become a thick viscid scum, consisting entirely of these minute bodies, without a sign of any fungoid growth.

From the fact that these organisms grow most rapidly, and are in the greatest activity at the surface, it appears that air is necessary to produce these results, for in the mixture of milk and chalk from which carbonic acid was given off as the lactate of lime was formed, they were always in smaller quantity and less active condition: this vessel, too, was covered with a plate of glass, while all the other solutions were covered with paper.

(*To be continued.*)

* The motion here referred to is not due to the currents produced by capillary attraction, evaporation, etc.

The Pharmaceutical Journal.

CHEMICAL NOMENCLATURE IN PHARMACY.

HAVING but recently urged on our readers the necessity of improving the character of the monthly Evening Meetings of the Society, it was with great pleasure we witnessed Professor ATTFIELD'S endeavour to give practical effect to our suggestions, and we therefore desire to express our thanks to him for having so promptly taken the matter in hand, as well as our hearty congratulations on the very successful issue of his exertions. We doubt not that all members of the Society, and especially all attendants at the Evening Meetings, will participate with us in these feelings, while hoping that in the ensuing season there may be a succession of papers brought forward as interesting and useful as that to which we refer.

It is satisfactory to find that Professor ATTFIELD'S suggestions for the revision of the chemical nomenclature of our Pharmacopœia do not involve any violent changes, but that, while seeking to attain uniformity consistent with chemical science, those suggestions are conservative in their tendency, and influenced by the sound principle that for medical and pharmaceutical purposes it is more important that names should denote things rather than our ideas as to the nature or constitution of those things. Moreover, the simplicity of the plan by which uniformity is to be attained in the designation of chemicals in pharmacy is so great as to constitute a strong argument in favour of Professor ATTFIELD'S proposals being generally adopted, and on this ground alone we are not surprised to find they have met with general approval both by the medical men and chemists who took part in the discussion and by the medical press. The few points in regard to which there were differences of opinion were only of minor importance, and would probably be settled without difficulty by having regard to the essential requisites of a name for medical and pharmaceutic purposes, and by making the possession of chemical propriety subordinate to them.

We should be glad to see the main features of Professor ATTFIELD'S plan adopted, not only in the British Pharmacopœia, but also in that of the United States, as well as the Pharmacopœias of Europe, so as to secure the very great advantage of a permanent and uniform nomenclature.

PHARMACY IN AMERICA.

THE School of Pharmacy in connection with the College of Pharmacy at Chicago, which was reorganized last October, has had a prosperous session under the new faculty, Professors BLANEY, BARTLETT and HAMBRIGHT. The class numbered thirty, of whom one was a lady.

The Annual Meeting of the College was held on the 15th March. Mr. E. H. SARGENT, in an address delivered upon vacating the presidential chair, urged upon the members the advisability of co-operating with the officers in obtaining employment for students coming from a distance, and also of enabling the "clerks" in their employ to attend the lectures. In reference to the system of instruction, he suggested that in future years it would be advisable to give a course of lectures to the junior class separate from the senior. Such a system, he thought, would possess greater thoroughness, and the subjects would be presented in better order. It seemed to him plain that if the lectures were adapted to the senior class they could not be suited to the junior, and if suitable to the junior class they were unfit for the senior. This plan would be attended with more labour and demand a greater sacrifice of time by the teachers, but the advantage to the taught would, in his opinion, be sufficient to warrant both. The publication of the *Pharmacist* had been continued, and it had proved a valuable auxiliary to the College. Its success, both in a scientific and pecuniary view, has been very encouraging. The growing importance of the varied interests of the College are such as necessitate the provision of a permanent home for the institution, and a committee has been appointed for the purpose of considering and reporting upon the subject. The following are the names of the officers for the ensuing year:—President, E. H. SARGENT; Vice-Presidents, JOHN W. EHRMAN and E. T. SCHLOETZER; Treasurer, A. C. VANDENBURGH; Secretaries, G. M. HAMBRIGHT and ALBERT E. EBERT. Mr. JOSEPH INCE and Mr. C. R. C. TICHBORNE have been elected honorary members of this College.

The Philadelphia College of Pharmacy commenced its fiftieth session on March 15, when the degree of "graduate in pharmacy" was conferred upon sixty-nine persons who had passed their examination. The Board of Examiners reported that they have found it advisable to change the examination for the diploma from a verbal to a written one. The entire number of candidates are accommodated in two rooms at separate desks, so as not to communicate with each other; a professor attending in each room to reply to proper queries. One branch is considered each day, and as soon as a student announces that he has completed his task, he is shown ten specimens relating to the particular branch under consideration, the names of which he has, according to his judgment, to write down, so that the answers of each student to all queries and specimens are recorded.

At the Annual Meeting the Committee appointed to select a suitable person for Editor of the *American Journal of Pharmacy* reported that they had agreed to recommend Professor JOHN M. MAISCH for that office. The business of the journal is now conducted at the College, where all correspondence is to be sent. A balance of 1424 dollars in favour of the Journal was announced in the Treasurer's report. The officers chosen by this Society for the ensuing year are—President, DILLWYN PARRISH; Vice-Presidents, W. PROCTER, jun., and ROBERT SHOEMAKER; Treasurer, AMBROSE SMITH; Secretaries, C. BULLOCK and ALFRED B. TAYLOR.

The Maryland College of Pharmacy commenced its nineteenth annual session on the evening of the 10th of March. The Act of Incorporation, empowering the Society to confer the degree of Doctor in Pharmacy upon suitable persons, having been read, that title was awarded to Professor WILLIAM PROCTER, Professor JOHN MAISCH and Professor ISRAEL J. GRAHAME, of Philadelphia, and Professor DAVID M. STEWART, M.D., of Delaware. A list of nine persons who had successfully passed their examination was read, and the degree of Graduate of Pharmacy was publicly conferred upon them by the President. The evening's proceedings concluded with an address to the students by Professor CLAUDE BAXLEY, M.D. As in the case of the Philadelphia College, the examinations at the Maryland College are conducted in writing. It is expected that the Act passed last year by the General Assembly of Maryland for the regulation of the practice of pharmacy in the city of Baltimore, will greatly increase the welfare and influence of this College.

The Annual Meeting of the College of Pharmacy of the City of New York was held on March 16. Ten diplomas of Graduate in Pharmacy were conferred upon members of the graduating class and two prizes of fifty dollars each were presented, one to the student passing the best general examination, and the other to the student passing the best examination in botany and materia medica. At a meeting of the students, called for the purpose, resolutions were passed thanking the Professors and other officials for the manner in which the classes had been conducted, and urging other pharmaceutical students to avail themselves of the opportunities for instruction afforded by this College. The officers elected to serve during the ensuing year are,—President, W. HEGEMAN; Vice-Presidents, T. FROHWEIN, J. CODDINGTON and W. NEERGAARD; Treasurer, W. WRIGHT, jun.; Secretary, EDWARD L. MILHAN.

With respect to legislation affecting pharmacy, we may say that the Ontario Act* has now become law. The New York Drug Clerk Bill† has been somewhat modified: the board of examiners, which it was originally proposed should consist of six, being reduced to four members, viz. one skilled pharmaceutist, one practical druggist and two physicians, who are to be appointed by and hold office during the pleasure of the mayor of New York. The salary is to be not more than 2500 dollars per annum for each commissioner, and the secretary, who is to be a practical druggist elected by the board: the amount to be fixed by the Board of Supervisors of New York. Any deficiency that may exist after the payment of the expenses of the Act out of the fees received is to be raised by a tax on real and personal property in the city of New York.

A Bill to appoint an examiner of drugs in Pennsylvania is now before the Legislature of that State. At the Annual Meeting of the Philadelphia College of Pharmacy, a committee was appointed to examine this Bill, and to take steps to prevent its becoming law if found to be objectionable.

* *Ante*, pp. 752 and 772. † *Ante*, p. 772.

A COURSE of eight lectures upon Economic Botany, with especial reference to Vegetable Substances used for Food, will be delivered by Professor BENTLEY, in the Museum in the Royal Botanic Society's Gardens, Regent's Park, commencing on Friday, May 12th. They will be open to Fellows and Members of the Society, and to bearers of ivory tickets, or the ordinary orders of admission to the gardens.

AT the Annual Meeting of the Royal Institution, on Monday last, the following gentlemen were unanimously elected as officers for the ensuing year:—President, Sir HENRY HOLLAND, Bart., M.D., D.C.L., F.R.S.; Treasurer, WILLIAM SPOTTISWOODE, M.A., F.R.S.; Secretary, HENRY BENCE JONES, M.A., M.D., D.C.L., F.R.S.

ARRANGEMENTS have been made in York for opening a school for instruction in Pharmaceutical Science, under the superintendence of W. PROCTER, M.D., F.C.S. The Summer Course of Lectures, commencing on Friday, May 5, will be continued weekly through May, June and July, and the Winter Session, will extend from October to March. Fees for both Sessions (to Pupils or Assistants of Subscribers), one guinea, which may be paid to the Honorary Treasurer, Mr. T. COOPER.

THE collection at the Twickenham Economic Museum, which had been got together by Mr. THOMAS TWINING, at considerable trouble and expense, for the purpose of illustrating the various branches of domestic economy, has, we regret to say, been destroyed by a fire that originated in one of the cellars.

OUR readers will find in the correspondence columns a letter from Mr. BOTTLE, having reference to the qualities of the paper now in general use, which is well worthy of perusal.

PHARMACEUTICAL SOCIETY, EDINBURGH.

The last Scientific Meeting of the North British Branch took place in St. George's Hall, on Monday evening, 24th April, at half past eight o'clock; Mr. AITKEN, President, in the chair.

Mr. PATON, Assistant-Keeper in the Industrial Museum, was introduced by the President and read a paper, "On the History of Oriental Spices."

The paper was illustrated by coloured drawings and specimens. It will be printed in a future number.

A vote of thanks to Mr. Paton for his interesting communication was proposed by Mr. YOUNG, seconded by Mr. LEITCH, and carried with acclamation.

The PRESIDENT then proceeded to give his Valedictory Address:—

Gentlemen,—We are now come to the close of the last meeting of another session, and I think we may congratulate ourselves on this being in all respects the best attended, the most agreeable, and fully as instructive as any of former years.

During the past session we have had various and valuable papers on scientific subjects from gentlemen of the highest standing in science and the arts.

In November last Dr. Stevenson Macadam favoured us with an able paper on Fermentation. In the course of this lecture, after having referred to the old theory, the lecturer introduced the more recent improvements of Dr. Tyndall, Monsieur Pasteur and Dr. Angus Smith. Dr. Macadam, in his usual happy manner, illustrated these with many diagrams and tables.

At our next meeting, which took place in the Masonic Hall on the evening of the 23rd January, Dr. Balfour, Professor of Botany in the University, very kindly gave a lecture on Ipecacuanha-root and its Cultivation in the Royal Botanic Gardens here. The Professor had a large and an attentive audience. This lecture, most ably delivered, was illustrated by many specimens, diagrams and a number of living plants, together with a large collection of drawings, beautifully painted from nature by Mrs. Balfour.

Again, in February we had a very popular lecture from Professor Archer, of the Museum of Science and Art, the subject being the History and Properties of Isinglass and Allied Substances, with the manner in which it is procured, prepared and used. Specimens of the air-bladders of fishes in the different forms in which they are dried for preservation and use were shown in illustration.

After making a few observations on some of the peculiarities and fondness of the Chinese, Japanese and other Oriental nations for gelatinous substances similar to isinglass, the Professor concluded by stating the great difficulty and expense incurred in procuring such forms as these, and specially mentioned the fabulous prices given for edible birds'-nests, etc.

Our fourth scientific meeting, on the evening of the 22nd February, was enhanced by a paper on a discovery of Priestley, given by James Dewar, Esq., F.R.S.E. & F.C.S. This lecture was exceedingly well illustrated by several practical experiments and was much applauded throughout.

Mr. Dewar, having given an interesting account of the successive experiments made by Joseph Priestley in 1772 in connection with fixed air, how produced and its effects on vegetable life, traced the discoveries subsequently made by scientific inquirers into the connection betwixt light and the life of plants. A few beautiful specimens of these were exhibited, and the lecture brought to a termination by Mr. Dewar promising at some future time to favour us with another paper on some popular subject connected with our profession.

Then again to-night, being the winding-up of the business of this session, we have been earnest listeners to the very admirable paper 'On the History of Oriental Spices' from Mr. Paton, Assistant-Keeper, Edinburgh Museum of Science and Art. The excellence of this example of Mr. Paton's researches on the subject, and the able and fluent manner in which it has been illustrated and brought before us, has already drawn from you unmistakable evidence of the pleasure afforded,—I think also of your desire to hear him again; and I have no doubt, should the learned gentleman see his way to favour us with a like paper next session, the obligation will be acknowledged and appreciated by every one of us.

I am glad to say, gentlemen, that the large number of candidates presenting themselves for examination, and who have been successful in passing during this session, testify most clearly to their careful attention and study. The proficiency in many cases being so decidedly marked, manifested on their part an anxiety to get through creditably and with honour.

I might here, gentlemen, take some notice of the *quæstio vexata*, which is causing such a sensation at the present time amongst the members of the drug trade. Both sides, however, being so ably championed, and the feelings of each so well ventilated in the PHARMACEUTICAL JOURNAL, and also in the *Chemist and Druggist*, I think it advisable to leave this alone, seeing that to-night we have so little time for any discussion upon the subject. At the same time, my own conviction is, should legislative enactments be necessary for enforcing compulsory poison regulations on us, they ought certainly not to be one-sided, but include surgeon-druggists as well, and all others who sell or dispense poisons in any shape whatever. In the establishments of this city the greatest care is taken to secure the public from danger; and while we are all anxious and willing to make such arrangements, and use such precautions and safeguards as suit our own places of business, with every satisfaction to our customers, I cannot see that any Legislative Council whatever has the right to burden us with their enactments, unless with the full consent of those so deeply concerned.

You will have observed a very modest intimation of some six or eight words at the bottom of the billet calling this meeting. It simply states that subscriptions to the Benevolent Fund are earnestly requested. You are all well aware that in every large community many do fall somehow into difficulties; it may be through some severe dispensation of Providence, or it may have been their own imprudence, or their want of sufficient care, attention and energy in conducting their business. In whatever way this has happened, they are kept down by the heavy hand of misfortune and poverty, rarely able to get up again. It is to such as these the Benevolent Fund brings relief, and it has been the means of making the widow's heart sing for joy, and it has brought, in many cases, some degree of comfort and happiness to many a poor and desolate fireside. We are commanded to remember the poor, the surety is unquestionable: For he that giveth to the poor, lendeth to the Lord.

And now, gentlemen, before retiring from the position of president, to which you so kindly elected me, and having enjoyed the honour for three successive sessions, may I venture to express the hope that the duties of the chair have been conducted to your satisfaction.

I would wish also to tender my sincere thanks to those gentlemen who have evinced such an interest in our meetings, and have ever readily and handsomely come forward and given us so many valuable papers, lectures and communications on scientific subjects.

And to all of you, gentlemen, my sincere acknowledgments are due for your continued good will and courtesy on every occasion of our meeting together. I trust a large measure of like kindness may be accorded to my successor, Mr. Baildon, a gentleman well known to all of you, of the highest standing as a pharmacist, and one of the oldest members of this Society in Scotland.

As to the younger brethren, and those who have already passed or are about to pass their first examination, I would just say, having made a good beginning, see that you do not fall back or lag behind. Be up and doing; never rest content with the appearance merely, but acquire knowledge on every subject, and more particularly on that connected with your profession, for such as it is you will be compelled, in all probability, to rest upon it your whole dependence in after life. Bear in mind that

"In youth's gay season of delight,
When all around is fresh and fair,
We think not of its rapid flight,
It costs us not a single care.
But grey hairs come, and wrinkles too,
And many a thought that makes us sad;
Ah! then we think how fast they flow,
Those few short years when we were glad."

In conclusion, gentlemen, as intelligent members of this Association, we ought to have, as it were, one mind and one heart—a heart beating in unison with each other, and diffusing with every pulse life and health and joy to the remotest member of the Society. Some of you make a beginning, and come forward next session with a will and in earnest. Give an essay or a lecture on some subject bearing upon ourselves, or on the business with which we are connected, or on the Society we have all so much at heart. There are not a few young men in this hall to-night perfectly able, and I trust not unwilling, to lend a helping hand to keep up and sustain the dignity, the prosperity and the high standing of the North British Branch of the Pharmaceutical Society.

At the close of this address, Mr. Ainslie moved a vote of thanks to Mr. Aitken for his services as President to the Society. This was seconded by Mr. Young, and carried amidst hearty applause.

At this stage of the proceedings, visitors and others were requested to withdraw, the members of the Society remaining to take part in the Annual Meeting.

The Secretary then read the

Annual Report.

The Council, at the close of another session, beg to congratulate the members of the Society on the continued progress of pharmaceutical education.

It must be evident to those interested that the compulsory power obtained under the recent Act of 1868 is already bearing good fruit, and that the taunt of want of proper culture in the chemist and druggist as appertaining to his daily walk and avocation is fast becoming a thing of the past. This is not only highly satisfactory, but is also very encouraging. Long and arduous has been the struggle; for while the privileges vested in the Society by the Bill of 1852 left the matter of examination only optional, it was felt that the very establishment of Boards of Examiners in London and Edinburgh was in reality paving the way for the more compulsory powers which were obtained in our last Act of Parliament.

It is true that the Bill of 1868 was far from being perfect, mixed up as it was with poison schedules, yet its existence gave both position and power, which the Society had vainly struggled for many years to acquire. Government recognition, with a definite organization, has, however, now placed the affairs of our Society on such a firm basis that it only requires we should be true to ourselves to enable us to emerge from the gloom and confusion by which we were formerly surrounded.

A glance at the Journal from time to time shows very plainly how many candidates present themselves for the various examinations. In London especially the numbers are considerable. During 1870, those coming before the Edinburgh Board were—Major 6, Minor 31, Preliminary 62, Modified 44; total 143. Of these there were rejected 9 Minor, 13 Preliminary, 8 Modified, or roughly an average of 20 per cent. spread over the whole. In connection with the rejections, it is a satisfactory thing to note that many of those candidates who fail, and come again before the Board for re-examination, admit that it was a benefit to be sent back to their studies, as it compelled them to become thoroughly acquainted with the various departments in which they had been found deficient.

The Council cannot avoid at this time expressing their satisfaction that the very vexed question of compelling chemists and druggists to adopt certain precautions for keeping, storing and selling poisons has been settled and arranged. It is freely admitted that it is most desirable all due precautions ought at all times to be taken in keeping and dispensing highly dangerous articles; and while they conceive that in most places of business such care is already exercised and in full operation, they can scarcely admit the propriety of compulsory measures in connection with this departmant of a chemist's ordinary business, believing as they do that in all probability such an enactment would have led to the appointment of an inspector or other Government official. The recent vote at one of the Council meetings has set the matter at rest, and the members here very heartily concur in the resolution that certain poison regulations be very earnestly recommended for general adoption.

The Museum of the Society in Edinburgh has been enriched by a very handsome contribution from Mr. Ransom, of Hitchin, in the form of a series of carefully and beautifully prepared and mounted specimens of many of the medicinal plants, and for which the Council feel the Society is much indebted to the donor. A few other specimens have been added during the year, but additional contributions will be gladly received.

The Library continues to be supplied with volumes from time to time, and arrangements have now been in operation for a considerable period by which books can be had at any time by applying to the Curator.

As St. George's Hall, which has now been so long used as a place of meeting, will be required for other purposes, steps are being taken to obtain suitable accommodation for Museum, Library, Examinations and place of meeting. Due notice will be given to those interested when the matter has been arranged.

The Council think it due to Professor Balfour and to Dr. Stevenson Macadam, who have so kindly lent their assistance in enabling students in pharmacy to attend their lectures on botany and chemistry, and trust that as the same liberality continues to be exercised pupils will evince an appreciation of the kindness shown by those gentlemen, by taking the opportunities now placed within their power of gaining instruction in such important branches of pharmaceutical education.

The Council cannot conclude without tendering their thanks to those who have contributed during the past session to render the scientific meetings so interesting and instructive. The attendance throughout has been very gratifying, and it is confidently hoped in succeeding sessions that the Society may continue to record the kind assistance of their friends and others in keeping up the character and increasing the number of these meetings, which are now recognized as being so useful and instructive.

After some remarks by Mr. Mackenzie and others, various explanations were given by the Secretary, when the adoption of the Report was formally moved by Mr. Anderson, of Musselburgh, seconded by Mr. W. Gilmour, and carried unanimously.

The following office-bearers, for 1871–72 were then severally proposed and unanimously elected:—

President: Mr. H. C. Baildon, 73, Princess Street.

Vice-President: Mr. Buchanan, 52, North Bridge.

Council: The President and Vice-President; Messrs. W. Ainslie, W. Aitken, D. R. Brown, G. Blanshard, J. Gardner, W. Gilmour, Kemp (Portobello), W. Noble, R. Raimes, J. R. Young, J. Mackenzie, Kinninmont, Davison and Fraser (Glasgow), with the President and Vice-President in London *ex officiis.*

Board of Examiners: The following gentlemen were proposed as members of the Board:—Messrs. H. C. Baildon, W. Aitken, D. R. Brown, J. R. Young, J. Buchanan, W. Ainslie, D. Kemp, W. Gilmour.

Secretary: Mr. John Mackay.

Library and Museum Committee: President and Vice-President; Messrs. Aitken, D. R. Brown and Mackay; Mr. D. R. Brown to be Convener.

Curator of Museum: Mr. Paton.

Honorary Secretary: Mr. John Mackay.

At the close of the meeting a very special vote of thanks was proposed by Mr. Young to Mr. Mackay for all the labour and trouble he had taken during the past year as Honorary Secretary to the Society in Edinburgh: this was seconded by Mr. Gilmore, and was enthusiastically carried.

Mr. Mackay shortly replied, and the proceedings were brought to a close.

The Annual Supper of the North British Branch of the Pharmaceutical Society of Great Britain was held in the Café Royal Hotel. There were upwards of a hundred gentlemen present. The chair was occupied by Mr. H. C. Baildon, who was supported on the right by Professor T. C. Archer, Dr. Angus Macdonald, Dr. Sidey, Mr. Davidson (Glasgow), Mr. Paton of the Industrial Museum, Mr. D. R. Brown and Mr. Ainslie; and on the left by Dr. Peel Ritchie, Mr. Aitken, Mr. Kinninmont (Glasgow), Mr. George Blanshard and Mr. D. Kemp (Portobello).

The croupiers were Messrs. Buchanan and Mackay. They were supported by Messrs. J. R. Young, Gilmour, Leitch, Noble, James Aitken, Nisbet (Portobello), Connacher (of Markinch), and Dodwell (of London).

After the usual loyal and complimentary toasts, the Chairman, in proposing "The Pharmaceutical Society of Great Britain," congratulated the company on the progress that had been made since the Society was instituted by Mr. Jacob Bell. The position the Society had taken up was now impregnable,—everything showing that it was prospering and likely to prosper. Among the other toasts were, "The President and Council in London and Mr. Mackay," by Mr. Aitken; "The Honorary Members of the Society, and Professor Archer," by Mr. Buchanan; "The Royal College of Physicians and Surgeons and Dr. Angus Macdonald," by Mr. Leitch; "The Secretary, Mr. Mackay," by Mr. Baildon; "Friends from a distance," by Mr. Ainslie; "The Chairman," by Mr. Kemp; "The Croupiers," by Mr. Young. A number of songs and recitations were given in the course of the evening.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

APPOINTMENT.

Mr. Albert Ager has been appointed Dispenser to the Surrey Dispensary, in the room of the late Mr. Nathaniel Staddon, who held the office for forty-five years.

MEETINGS FOR THE ENSUING WEEK.

Tuesday May 9. ......*Royal Institution*, at 3 P.M.—"On Force and Energy." By Mr. C. Brooke.

Quekett Club, at 8 P.M.

Saturday ......*Royal Botanic Society*, at 3.45 P.M.

Parliamentary and Law Proceedings.

POISONING OF THREE CHILDREN BY CARBOLIC ACID.

An inquest was held last week in the Manchester workhouse, at Crumpsall, upon the bodies of three girls who had died in consequence of having carbolic acid administered to them in the place of a cough mixture.

Mr. Richard Wharf, the master of the workhouse, said there was a cupboard in the workhouse that was under the sole charge of Miss Lees, the assistant-schoolmistress, in which medicine and other stores were usually kept, and also carbolic acid, for use as a disinfectant. He could not say whether any caution had been given to Miss Lees as to the use of the carbolic acid. After the death of the first girl he had a conversation with Miss Lees, when she said she thought she had administered the cough mixture.

Mr. Brebner, the resident medical officer, said he believed the bottle containing carbolic acid had been in the girls' school about two years. There were in the cupboard mentioned a bottle, marked poison, containing carbolic acid; another with a cough mixture for the girls in the room; a third bottle contained tincture of iron, to be taken in cod-liver oil. It was astringent, but not hot like carbolic acid. Upon being called to see the children, he ordered brandy and an emetic. He could not tell from the symptoms by what cause they had been produced. He obtained other medical assistance, but the girls all died. A *post-mortem* examination showed that death had been caused by carbolic acid. The organs of the body were in a highly congested state, and there was the smell of carbolic acid in the stomach.

After having been cautioned by the coroner, Elizabeth Lees said,—About ten minutes to eight o'clock on Saturday the three girls who are dead came to me for their cough medicines. I invariably kept the carbolic acid at the back of the cupboard, in a corner along with the Condy's fluid, but, by some means or other which I cannot explain, the carbolic acid bottle had got to the front, and was standing side by side with Catherine Kearney's medicine bottle. Since Catherine Kearney had been taking that medicine, I had frequently made a mistake in taking hold of the carbolic acid bottle instead of the cough bottle, but I had found out the mistake by looking at the label. But on Saturday night, having been very unwell all day, I went to the cupboard, and on opening it the gaslight shone on the label of Catherine Kearney's medicine, and I immediately put my hand on the next bottle, fully believing that it was the cough mixture, because I always kept them together. I administered the contents to the girls, giving them a little over one teaspoonful each, and not quite two, that being the quantity of cough mixture I was ordered to give.

There was another glass of medicine poured out, and, having had a bad cough, I was myself in the act of raising it to my lips to take some when Maria Hughes, a nurse, came in. She had previously complained of a cough during the day. I said, "Take this, Maria; this will do you good." As soon as she had taken it, she said, "Oh, dear! how it burns my mouth!" Being rather astonished, I turned round to the cupboard, and I saw the carbolic-acid-labelled bottle standing by the side of Catherine Kearney's. Feeling sure that I could not have made that mistake, I said, "Why, I must have given you Catherine Kearney's medicine, which was to be taken in cod-liver oil." Thinking that was the cause of it burning, I at once poured out some oil and gave it to Hughes. It seemed to make her sick. The other girl, Mary Ann Monaghan, was still waiting in the passage, and I also gave her some oil. She at first refused to take it, but I told her she had better. She drank it, and then seemed very ill. I then went for the doctor.

The coroner, in summing up, explained the law on the subject. Where a person, while doing a lawful act in a lawful way, unfortunately killed another person, the act was in law an excusable homicide. It was for the jury to judge whether this was the case in the present instance.

The jury, after consulting for a short time, returned a verdict "That the deceased girls died from misadventure." They added a recommendation that the board of guardians should take into consideration the use of carbolic acid and other poisonous disinfectants in the workhouse, and by what means and by what persons these disinfectants be used in future.

The nurse Hughes is progressing favourably towards recovery.—*The Manchester Courier.*

Review.

ANÆSTHETICS. By EDWARD R. SQUIBB, M.D. New York. 1871.

Dr. Squibb, of Brooklyn, has recently published a pamphlet on the subject of anæsthetics. The work is, in fact, a paper read before the Medical Society of the State of New York, and was published in advance of the volume of "Transactions of the Society," in the *New York Journal of Medicine* for April, 1871.

We are in England peculiarly well supplied with information on the subject of anæsthesia. We have had many industrious and able investigators on the subject, and are accustomed to find in it a rich and varied literature. To us, consequently, Dr. Squibb's paper is somewhat barren; he speaks only of three anæsthetic substances, viz. nitrous oxide, ether and chloroform, and offers no suggestion in respect to research after other and better substances for general anæsthesia.

The paper evidently is written to support one position, viz. that ethylic ether of specific gravity 0·728, yields the best and safest narcotic vapour; to which is added an endeavour to prove that the same vapour may be made the most applicable agent for general administration. On the question of the safety of ethylic ether, we agree with Dr. Squibb; on the question of its efficiency as a general anæsthetic, when it is efficiently administered, we agree with Dr. Squibb; but on the final question of the facility of its administration, we cannot for a moment agree with him, neither do we think his book in the slightest measure removes the well-known and widely felt objections to ether, on the ground of its indifferent applicability. Dr. Snow hit the mark admirably when he was once called to task, by some critic, for inconsistency. He had expressed his opinion freely, that ether was safer than chloroform. "Then," inquired the critic, "why do you not act consistently, and give ether to your many patients, instead of chloroform?"—"I use chloroform now instead of ether," replied Snow, "for the same reason that you use lucifer matches instead of the tinder-box; an occasional risk never stands in the way of ready applicability." This is strictly true, and it would always hold good as between ether and chloroform, if we were absolutely bound to these two fluids, *i. e.* the one would give us the convenience, the other the safety, and the convenience would prevail; happily, we are not so bound.

We have said that Dr. Squibb's advocacy of the applicability of ether is not borne out by his description of the fact; we think rather that his advocacy lies the other way. For instance, after describing an apparatus of his own construction for the administration of ether, and which we can but admit is a sensible and ingenious device, he proceeds to give us the details of the practice of it. In every case, after the patient is ready, the apparatus, which consists of a sort of double-cone muslin bag, is wetted completely through with water, and afterwards squeezed until it no longer drips. A tin tube is then introduced into the narrow part of the bag, the measured quantity of ether is poured out into a tumbler, a roll of flannel and blotting-board is immersed into the ether to absorb it, and this roll is finally put into the tin tube. Now the bag is charged and ready; the open end is applied to the face of the patient, so as to cover the mouth and nose, and the inhalation commences. The quantity of ether required for the first charge is $1\frac{1}{2}$ to 2 fluid ounces for an adult man, and the administrator is recommended to commence his operations about ten minutes before the surgeon begins his part. When the stage of restless excitement occurs, the bag is to be kept to the mouth with gentle force; if vomiting occur, the bag must be momentarily removed. And when the full stage of insensibility is attained, the bag is for a time removed, so as to avoid the fourth or snoring stage of sleep.

In the close of the account certain precautions are offered for preventing "that supersaturation of the body with ether, which tends to the more certain occurrence of prolonged nausea and vomiting, which so often induce septicæmia, and thus cause death." The author adds that he has sustained anæsthesia with ether for sixty-five minutes, the quantity of ether consumed being less than 5 fluid ounces.

We have given these particulars fairly and fully, because they support what we have indicated, that they are against the reintroduction of ether into practice. When we can narcotize with a fluid which requires fluid drachms only instead of fluid ounces, which can be carried in the waistcoat pocket, which can anæsthetize in from three to four minutes, which can keep up the insensibility for any required time, and which does not nauseate more than ether, we may be sure that fatal accidents from it in the proportions in which such accidents happen, will not cause it to be displaced by so inconvenient an agent as ether. No, the secret of perfecting anæsthesia lies in procuring a fluid as good as chloroform, as convenient as chloroform, and as safe as ether. Already many advances have been made in this direction of research; the action of various narcotic agents has been the subject of much laborious investigation; the reasons of the faults of ether and chloroform have been conspicuously demonstrated, and the actual requirements for a safe and ready anæsthetic have been formulated. This is the true line of progress, from which it is now as impossible as it were unwise to recede. The bad effects of anæsthetics, the vomiting, the convulsion, the syncope, the asphyxia, the occasional death, are, according to one of our most diligent authorities, all accidental and unnecessary attendants on the process of production of insensibility to pain: they depend, that is to say, simply on qualities in the agents as yet employed distinct from the pure anæsthetic qualities of the agents. We prefer, therefore, rather to look forward to the new triumphs of science than, with Dr. Squibb, to go backwards to the old.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[230.]—SILVERING FOR PILLS.—For this process two vessels should be used, a small cup gallipot and an ordinary covered pot. Having placed the silver leaf in the former and the pills in the latter, shake over the pills a very little compound tragacanth powder. Introduce a few drops of proof spirit, according to the number of pills (about one drop to the dozen or less), and disperse it thoroughly by agitation, shaking till the pills are nearly dry. Then turn them out into the silver, cover with a piece of clean paper, and a few turns in the hand will produce a very brilliant result.

I have adopted this plan for some years with unvarying satisfaction.—L. H.

[231.]—BEETLE POWDER.—Powdered borax sprinkled in their haunts is certain destruction to them. I can vouch for its efficacy.—H. C. B.

[236.]—DISPENSING.

R. Potassæ Chloratis ʒij
Potassii Bromidi ℥j
Inf. Gent. recentis ad ℥viij

A sixth part thrice a day.

In reference to the foregoing prescription sent by *J. H. G.*, South Hants, we have received the following communications:—

I should, if possible, have seen the prescriber—presuming, of course, that he was what is called a duly qualified medical man—to call his attention to the unusual and excessive dose ordered, and been guided by his instructions; or if this had not been convenient, I should have dispensed it with potassii bromid. ʒj, which was doubtless the quantity intended,—especially so as this quantity, if taken as directed, would give the usual full dose of ten grains.

I should also have made a note on the margin of the prescription, saying what I had done, partly for the guide of future dispensers, but chiefly to attract the attention of the prescriber, should he again see it.—J. B. LESLIE, *Sheffield*.

No doubt the sign ℥j was a slip of the pen, and was intended for ʒj by the prescriber. I should have felt justified in dispensing ʒj of bromide of potassium, as the sixth part of an ounce would be so much in excess of the maximum dose of the B. P.—H. J. B.

The ℥j is evidently a mistake, ʒj no doubt having been intended; and, in the event of *J. H. G.* being unable to communicate with the physician, he would be perfectly justified in refusing to dispense such a prescription.—GEORGE MASSON.

[*** We do not think the opinion expressed by our correspondents is correct, for notwithstanding the dose stated as the maximum in the B. P., it is a fact that bromide of potassium is given now in very much larger doses, and we do not think the quantity stated in the prescription is at all excessive or unusual.—ED. PHARM JOURN.]

[237.]—RED INK.—I have found the following answer very well:—

R. Carminæ ℈j
Liq. Ammon. Fort. ʒss
Gum. Acaciæ ℈j
Aq. Destil. ℥iij.

Misce.—H. J. BLACKBOURN.

[239.]—FURNITURE CREAM.—The following will be found an excellent furniture cream:—

R. Ceræ Flav. 2½ oz.
„ Alb. 1 oz.
Sapo. Cast. ʒj
Ol. Terebinth.,
Aq. Bull. ana 10 oz.
Potass. Carb. ʒj.

Melt the wax and turpentine together, dissolve the soap and potass. carb. in the aqua, and mix while warm, stirring till cold.—S. D.

[240.]—DISPENSING.

R. Sp. Ætheris,
„ Lavandulæ,
„ Ammon. Ar., ana ʒij
Mist. Camph. ad ℥viij.

M. ft. mist.

The above, if properly dispensed, would be colourless or very slightly milky. Tinct. lavand. co. must have been put in the London mixture by mistake.—W. B. ORTON.

The London dispenser must have used tinct. lavand. co. (which in E. Ph. was called sp. lavand. co.) instead of sp. lavand. as ordered. This would account for its being of a reddish colour.

Properly dispensed, the mixture should be colourless, and perhaps almost imperceptibly turbid.—J. B. LESLIE, *Sheffield*.

There can be no doubt, I think, that the prescription, as dispensed by Mr. Crookes, was correct, and as little question that in the former instance the compound tincture of lavender was employed in place of the spirit, which may, or may not, have been intended. It may be urged against this conclusion that the spirit is rarely, if indeed ever prescribed, and more especially so in combination with spt. ammon. arom.; but the duty of the dispenser in such a case as the present, seems to me to be to send the substance ordered, and not what he may choose to think was intended, and the more so when the substance is an official one; such a course of procedure at once removes any blame from the dispenser to the prescriber, whilst an opposite course might lay him open to censure. Every dispenser must be aware that in nine cases out of every ten, the compound tincture of the Pharmacopœia is designated a compound spirit, and for this reason and the liability to error by the accidental omission of the word comp., I think it is to be regretted that a substance of so little value and so seldom used, as the spirit of lavender, should have found its way into the Pharmacopœia. Here we have a case in point of the value of an assertion made by Professor Attfield in his paper on the "Nomenclature of the Pharmacopœia," that one name should be applied only to one substance (and surely synonyms are not required here); and if we are to have a compound tincture of lavender, do not let us have a compound spirit one time and a tincture the next. In such cases the dispenser is powerless to remedy the evil, and if physicians will persist in such a course, little else can be expected than embarrassment to the dispenser, and consequent inconvenience, perhaps danger to the patient. How much needless perplexity would be saved, if the present nomenclature were studied and adopted by prescribers! What is a dispenser to do when sodæ carb., or, worse still, sodæ sesquicarb. is ordered, say in a doubtful case? or in a mixture where he feels tolerably sure the bicarbonate is intended? or aq. menthæ without any clue as to whether viridis or piperitæ is to used? Every one knows such illustrations might be multiplied, they occur every day, and are productive of much uncertainty and anxiety.—GEORGE MASSON.

I believe, in most large dispensing establishments, tinctura lavandulæ compositæ would be used, and would account for the reddish colour.—H. J. B.

[241.]—WARTS.—Will any reader kindly inform me of a good application for warts. Caustic and acetic acid have been tried, but failed?—OMEGA.

[242.]—IODIDE OF STARCH.—I require a method of making this in powder. I have already made some, but it appears to be in solution and I cannot filter any out; by evaporation, the colour disappears.—J. T. B.

[243.]—HYPOCHLORIDE OF SULPHUR.—I should be glad if some of your chemical readers can give me any information on the subject of the "hypochloride of sulphur," which Mr. E. Wilson orders in the ointment he so frequently prescribes. What is it, what is its composition, and how is it made?—E. B.

Correspondence.

The Society and the "Outsiders."

Sir,—The defence committees, metropolitan and provincial, have effected their object—all fear of compulsory resolutions concerning the storage of poisons being extinguished,—and the selected representatives for the new Council are pledged to resist Government interference. Having, on request, allowed myself to be put in nomination for the Council for a special purpose, which no longer exists, I now beg to state my desire to withdraw from competition against those gentlemen who have been considered best fitted to represent the interests of pharmacy for the ensuing year.

Being no longer a candidate, I feel at liberty to remark that, confident as many are in their security under the protection of the new Council, there will never be either safety or repose whilst the trade is divided against itself. Why is the Society to stand in its chilly isolation, a mournful spectacle of mistaken purposes? Why does it not endeavour to draw within its embrace the strength and power of numbers, that when interference is attempted, it may present an unbroken front and a formidable opposition? As it exists it is useless for any great effort. It may drag uphill an educational element, but its weakness is apparent so long as there is a pharmaceutic body and an army of "outsiders."

The first round only of the poison battle has been fought, and, fortunately for the Society, there was no difference of opinion in the trade,—another instance of the benefit arising from unity. But it is not to be supposed that the Privy Council will consent to have its requirements ignored, and our danger lies more in the division amongst ourselves than even in the power of Government officers. The Society is indebted to the "outsiders" for their antagonism, which gave them power over the education of the future pharmacist; but it was never intended to constitute or establish a Society with one idea only. Education is of primary importance, but protection to trade interests and convenience is equally great; and if the members of the Society are to be gratified with their success in placing men of their choice on the governing board, what guarantee will the outside trade have that their position will be considered? In your leader of the 15th ult., you very justly pointed out that the outsiders' inability to influence the action of those in power was "voluntary;" and that if they did not "avail themselves of their capability of legitimately influencing the action of the Society" their abstinence arose from "indifference," while their apathy rendered them unworthy of the sympathy expressed on their behalf.

I quite agree with you that "outsiders" did obtain that concession legally, as a reward for the assistance given to obtain the Pharmacy Bill; and there was also "a tacit understanding" between the leaders of the two parties, quite as clear as that with the Government respecting the poisons, that there should be every facility given to "outsiders" to swell the list of membership of the Society, but no sooner was the power vested in the Council, than they treacherously put aside "a tacit understanding" and created a disgust not easily to be effaced.

This short-sighted policy of the conservative Councillors is now producing thistles where there might have grown figs. If the petty jealousy which animated these gentlemen in their desire to keep the Society for the future generation and their own domination, had given place to a broad and liberal spirit, there would now have existed one united body of chemists, having a common interest to support. The strength political is not in the education of its members, but in the number; and if the miserable policy which has hitherto prevailed could be exchanged for one which recognized every member of the trade, then not only would the revenue be doubled, but a friendly feeling would spring up, and when interference was attempted, there need be no division,—all would fight under the same banner. It is very odd that hitherto those belonging to the Society from its formation, have been chiefly instrumental in retarding its growth and preventing the dream of its founder from being fulfilled.

May 3rd, 1871. John Wade.

Paper Notes for Circulation.

Sir,—May I crave a corner of the Journal to indicate to our brethren the necessity that at present exists for careful examination of the paper that is daily passing through their hands? I do not allude to the daily press, or the paper currency, but to the paper in current use for the purpose of wrapping powders. The demies and other makes of white paper now in use in the trade are very generally impregnated with sulphur compound, introduced for bleaching purposes; and such paper, when used for wrapping pepsine or other powders containing free acid, will in a short space of time, and particularly so upon a damp day, give off sulphuretted hydrogen in unmistakable quantity. My attention has been drawn to this fact by the circumstance of detecting the vile smell of this gas in a recently-dispensed packet of pepsine powders, and fortunately prior to their having been sent out. A first impression led to the inference that the pepsine, although recent stock, was either impure or undergoing spontaneous decomposition; having satisfied myself to the contrary, my attention was naturally directed to the paper in which the powders were folded, a demy of presumed good quality, and which, to the unassisted nose and eyes, appeared to be as good as could possibly be desired for the purpose; but, upon placing a small roll of it in a test-tube, and saturating with dilute acid, it gave out unmistakable evidence of the source of the annoyance.

I have since tested, with similar result, several other papers which I had in stock, and some obtained in the district, also the samples of a London dealer,—and, I may add, the paper now being used for the Journal, which will, in a minor degree, afford illustration.

A prompt and facile mode of examination is to sprinkle a few drops of dilute acid upon a small piece of the paper to be examined, and in about one minute evidence will be obtained by the olfactory organs more than sufficient to damage the historic reputation of any first-class dispensing establishment using such paper for containing pepsine powders. It may be remarked that the gas is more freely eliminated from the under surface of the paper than the upper and sprinkled one, illustrating the high density of this obnoxious gas.

Alexander Bottle.

Dover, April 29th, 1871.

Poison Regulations.

Sir,—You will oblige by allowing me a small space to address my fellow pharmacists again upon the poison regulations. I think I may say we are all agreed that they have lost their most objectionable feature in ceasing to have the character of iron shackles. But it must be remembered that that is not the only question we have to ask ourselves regarding them. Could it be proved that they were free from evil tendencies, I should still protest against their being put forth as the recommendation of our Society, unless it were also evident that they were practically useful, and the most desirable that could be suggested. It is not my wish now to go over the whole argument again; enough has been said to show that the proposed code has been found wanting in many respects, besides the want of liberty to adopt any other precautions instead of them, if others were found to be more applicable. It was stated in the circular of Reasons which the Council issued that the regulations, when proposed to be made compulsory, would not be enforced; how then can we expect that the same regulations, brought forward as a simple recommendation, can meet with general adoption? Enough has been said against them to show that, as a code, they will be a dead letter.

I do not think we could expect the outgoing Council to bring forward any modification of the code, nor do I think that the Society would do well either to pass the code as it now stands, or to attempt to modify it at the annual meeting. More satisfactory results would probably be obtained by requesting the incoming Council to examine the objections raised and the suggestions made in the correspondence you have already published, and in the reports of meetings already held, and endeavour to frame a code which would be more generally useful.

I have no hesitation in saying that recommendations would be of more value if made more definite, and if based upon the use of a poison label, a label stating the dose, and a label "not for internal use," and if every article to which any of these labels was recommended to be applied was distinctly specified.

There will, no doubt, be found other suggestions equally worthy of their attention. BARNARD S. PROCTOR.

11, *Grey Street, Newcastle.*

CONVERSAZIONE, SOUTH KENSINGTON MUSEUM.

Sir,—Last year I observed on the admission card to the Conversazione the direction "Evening Dress."

Now, many of our country members, when upon rare occasions they visit the metropolis, leaving, for a few days,

"Their homely joys and destiny obscure,"

do not carry many changes of dress, and yet, perhaps, they are not intended to be excluded from this gathering.

Could not a more definite statement of what is required be made than "evening dress"?

While many of our London members and their assistants never wear an apron, many of our more humble country associates consider themselves in evening dress when they take off their apron!

Others—old men, like myself—may be accustomed to wear the same dress in the evening as they wear in the morning.

Court dress is defined; and if members are required to appear at the Conversazione in black, or in velvet, let it be so stated. JOSEPH LEAY.

Downside, Chilcompton, Bath,
April 29th, 1871.

PROPOSAL TO ENFORCE EARLY CLOSING.

Sir,—Would you kindly allow me, through the medium of your valuable Journal, to agitate the early closing proposal, which appeared in your last issue. I think the Council might as justly enforce it as the examinations are enforced. After being behind the counter from 7.30 A.M. until 10 P.M. and Saturdays until 12 P.M., may I ask what time is there for study? (Even on Sunday three hours night and morning are required respectively.) If in the meantime an hour's study was allowed daily, it would certainly, in a slight degree, alter the case; but that is out of the question altogether, for the mere appearance of a book within the said hours, makes the too general cry of "Look alive, so-and-so wants making or doing," vibrate through the place.

Without exception do Mr. Newey's statements concerning "existing jealousy" (which also occupied a portion of last week's Journal) apply to certain members of the profession in a town, where apprentices have repeatedly tried and failed to pass their Preliminary examination. What else but failures can be expected amidst *such privileges*, where neither an association is formed or classes to attend? whereas in a neighbouring town, much smaller, all the chemists open and close at eight prompt, and have formed an association and classes, and find it to answer admirably.

I mean jealousy, not only in Mr. Newey's instance, but most particularly respecting the closing of their various establishments. As ten o'clock approaches, those who are severally situate in sight, watch each other like a cat watching a mouse. Eventually one has the *good resolution* to close, then out of a kind of shame the others follow suit, but still don't find their coffers any better filled than some wise exceptionals, who close at eight prompt and find the day's work quite long enough. I think the suggested addendum of your last week's correspondent, would do away, in a great measure, with the ill-feeling amongst members, and greatly facilitate the apprentices and assistants in passing the examinations now set before them.

I hope you will insert this, as it will give those in the metropolis an idea of how business is carried on in the country, and that some influential exertions will be brought to bear to supply the deficiency in the Pharmacy Act of 1868.

JUSTICE.

Sir,—Your correspondent "Aspirant to the Major Qualification" is acting on the maxim of Oliver Cromwell, that, while "it is good to strike when the iron is hot, it is better to make the iron hot by striking." The iron has got cold; so much has been said and written about that all-absorbing topic, the poison regulations, that the old grievance of which your correspondent complains has been lost sight of. I am glad to see the subject introduced again. I do not see the practicability of "Aspirant for the Major Examination's" suggestion, that early closing should be made compulsory; but, if the question were fairly discussed by employers and assistants, I think some improvement on the present state of things might be made, with equal advantage to both parties. Early closing would not only be a boon to those who are preparing for their examinations, but also for those who have passed, and who wish to retain and add to the knowledge they have gained.

ONE WHO HAS PASSED THE MAJOR EXAMINATION.

Sir,—I observe a letter in your impression of last week, signed "Aspirant to the Major Qualification," which, to my mind hits the greatest drawback to our business, namely, the absurdly long hours of business.

His object in writing is to gain for students the time necessary for study—a worthy object. But when "Aspirant" has passed his Major Examination, and finds himself in business some day, will not the burden of his imprisonment be even yet harder to bear? He will find himself opening his shop at 7.30 A.M., from which time until 10.30 or 11 P.M. he will not be able to leave his occupation. Can any position be more pitiable?—a recluse *nolens volens*, debarred from all those social enjoyments and relaxations which make life's journey pleasant.

A gentlemanly profession, forsooth! Certes, had I known, or been in a position to calculate, what would follow when I served my apprenticeship of five years to a worthy man in a country town, with plenty of spare time and freedom, I had quickly abandoned all idea of adopting pharmacy.

And I ask any sensible chemist why, in the name of all that's rational, we glue ourselves to our counters for two and three hours after other tradesmen are enjoying that rest which a long day's work demands? I venture to think no one will assert that the exigencies of the profession require it. All the thought the public takes for us is embodied in a remark made to me last night by a gentleman who brought his prescription at 10 P.M.: "I should have come earlier, but I knew your shop would not be closed." Therefore, we must act for ourselves. This would be easy enough if those in high places amongst us so willed it.

Pray pardon me for occupying so much of your space, but, when on this subject, I can't help, as Sam Weller says, "opening the valve a inch or two."

A PHARMACEUTICAL CHEMIST.

Brighton, April 29th, 1871.

"JURY SERVICE."

Sir,—The letter of "W. B. O." in your last Journal, appealing for the Council's consideration of exemption from "jury service," is a just and reasonable one; and this subject may be urged upon the Privy Council very appropriately.

The amended Pharmacy Act imposes upon all chemists and druggists regulations which require the constant attention and personal inspection of the proprietor, to see that they are carried out, he being responsible for any omissions by any one left in charge.

Is it therefore just or right that such regulations should be imposed by the Legislature unless, at the same time, there is provided "exemption from jury service" for all upon "the register?" W. J.

Leek, May 1st, 1871.

THE PHARMACEUTICAL EXAMINATIONS.

Sir,—I ask leave to express my satisfaction with the letter of "Minor Associate" in your last week's issue on the above subject. I think with him that the case of the "Modified" men was as well met as could be under the circumstances; although there was a degree of hardship in the retrospective character of the Pharmacy Act.

As one who was compelled to avail himself of the less stringent examination, I beg, however, to protest against the "Ah, me miserabile!" style of some of your "modified" correspondents.

Doubtless there are many of these, even as of pharmacists of, say, ten or fifteen years ago, to whom the present Preliminary would be an impassable barrier; but on the other hand, let it be borne in mind that there are not a few to whom it would be a trifle, who have neither time nor inclination to superadd to their present duties that of acquiring proficiency for an examination in technical science. "Modified" gentlemen desirous of pharmaceutical honours ought not to shrink from the conditions upon which they are obtainable.

My own opinion is that with the qualifications necessary to pass the "Modified," £1000 and a good opening for business, any one may leave all doubts about getting on to "aspiring" members of the profession.

ANOTHER ASSOCIATE.

Sir,—I quite agree with *B. S.* that the Council ought to be a little more just in their rules, etc. in respect to the examinations. I will not take up much of your valuable space, but I should like to say a word on the separate examinations for chemists who were in business at the time of the passing of the Pharmacy Act. I was in business myself at the time, and made application to the Secretary for examination, but was informed that I either must have been in business five years or be not less than thirty years of age. I could not comply with either, as I had only been in business about a year and was only twenty-eight years of age. I was anxious to pass the examination; but I could not think of starting with the Preliminary Examination at my age and with the cares of business. It may be said that a line has to be drawn somewhere and that it must be hard for somebody. Now I contend if a line is to be drawn, why not in all fairness draw it thus, viz., that all who were in business for themselves at the time the Act was passed ought to have been entitled to pass the separate examination irrespective of their age? What has age got to do with it so long as a man is in business? Will some one plead my cause? if they do they will plead for many in like circumstances. The Council ought to revise their regulations on the above subject and give all a fair start.

PRO BONO PUBLICO.

Sir,—Your correspondent *George Sant*, in last week's Journal, is quite correct, I am sure, in his assumption that "many of the unsuccessful in the last" Preliminary knew little or nothing of the Latin language before entering their apprenticeship, and I am glad he has opened up the subject in order that it may be thoroughly ventilated. I should like to see some of your abler correspondents give some hints and recommendations to those who are in the following position, and they are not a few. A young man not having received a classical education, possibly educated at a British school, and whose parents were not in a position to give him a liberal education, aspires to the trade of chemist and druggist; he becomes an apprentice before the passing of the Pharmacy Act, not knowing that examination would be compulsory, and twelve or eighteen months after he has been apprenticed the Act is passed, compelling him to learn Latin during his business hours and to undergo a thorough training—a most desirable thing, but which, if he had known it before, would have turned his attention to some other trade or profession, possibly as remunerative and requiring no classical knowledge.

In your leader of the 22nd ult. you say the questions apart from Latin "were not at all more difficult than a boy who has received a liberal education might be expected to answer." Unfortunately all have not received a liberal education, and it is on behalf of such I write and ask for information for their direction. Can anything be done to meet their case? May they expect any mercy at the hands of the examiner?

To a youth having just left school and knowing such an examination has to be passed before entering on the study of chemistry, botany, etc. it is nothing, but to such an one as I have described the case is widely different; and you would be conferring a great benefit upon such if you would open your columns for a little interchange of ideas upon this particular subject, and upon which our future pharmacists depend.

SYMPATHETIC.

[**** In reply to our correspondent's inquiry, we would suggest that since a liberal education is a necessary qualification for the practice of pharmacy, those who are wanting in that respect should either overcome this deficiency or abandon the idea of becoming pharmacists. At the same time, we think it would not be any great hardship to acquire a knowledge of such Latin as is of daily use in ordinary business.—ED. PHARM. JOURN.]

Sir,—In the beginning of the year 1869 I was one of a number of gentlemen who passed the Modified Examination. Several months later, whilst busy at my work of preparing for the Major Examination (my progress being but slow, in consequence of the calls of business), I heard that some bye-laws had passed which took from me the right of presenting myself for examination, and swept away whatever privileges I had possessed upon my election as an Associate of the Pharmaceutical Society.

Had I been in the least warned of such a step, in all probability I should have taken immediate steps for entering my name on the list of candidates for a Minor Examination, or, to say the least, if I had had any degree of foresight I might have avoided, as a snare and a delusion, the Modified Examination,—which, in truth, I had elected solely on grounds of economy.

To an outsider, such a case may appear trivial, and nothing worse than a mild dose of red tape; but to many assistants who have already passed middle age, it is far otherwise. I refer especially to those who are engaged in some of our bustling shipping and manufacturing towns, where the hours of business range from 6.30 or 7 A.M. to 10 P.M., and not unfrequently midnight. I know of situations where it would puzzle the boldest to find any time for study; but, for the sake of brevity, I will not multiply instances. Is it reasonable that the meaning of the Pharmacy Act should be so affected by stringent bye-laws as to withdraw the only bond of sympathy that connected the most intelligent part of our assistants with the Pharmaceutical Society?

I hope the Council will reconsider their cruel decision, and prevent the estrangement of a large body of well-meaning gentlemen. The result will be, I feel sure, a source of encouragement to many who are striving, by self-instruction and other means, to fulfil their part in the elevation of their profession.

SPES.

Warrington, April 28th, 1871.

A CHEMISTS' CLUB.

Sir,—Having frequently been asked by young men in the country, "Where can we stay if we come up to town to attend the Pharmaceutical Society or in search of situations?" it has induced me to address those in the trade through your columns on the subject of a "chemists' club" being formed, where young men could have the comforts and accommodation of home at a moderate expense. I am fully convinced it would be well supported, not only by those in the country, but also those resident in town, and there are many advantages which would be derived from such an institution. I should much like to see the matter further discussed in your Journal.

A SUBSCRIBER.

C. P.—The plant sent is not *Ranunculus bulbosus*, but is the common celandine, figwort or pilewort, *R. Ficaria*, Linn. var. *α. divergens*, F. Schultz. Its acrid property has led to its use for outward application in some forms of tumours, but this acridity is easily dispelled by heat,—indeed it is used as a potherb in some parts of Sweden. It is not nearly so acrid as some of the buttercups, though moist grass lands are sometimes dressed with coal or wood ashes to destroy it. We do not remember an instance of its injurious effects to man or beast. Figures of that plant and *R. bulbosus* can be seen in Sowerby's 'English Botany,' vol. i.

F. Thompson.—You had better apply to the Secretary for a Syllabus of the Examination.

E. Hall.—Yes.

C. G. B.—The sum of 10*s.* 6*d.* paid annually by a registered apprentice or student of the Society is not paid by him for the Journal, but as the subscription attached to connection with the Society. In virtue of this connection he is entitled to be supplied with a copy of the Journal free, to the free use of the library and museum, and to attend the lectures of the professors at half fees. The Jacob Bell scholarships, also, are, under certain restrictions as to age, open to him.

Querist.—See the information on this subject already published, *ante*, pp. 590, 752, 772, 791, and in this week's number, p. 890.

G. H.—A formula for "Pick-me-up" has already been given at p. 497.

W. Clark will find a formula for peppermint cordial on p. 497 and one for aniseed cordial on p. 737.

ORIENTAL SPICES.*

BY JAMES PATON,

Assistant-Keeper in the Museum of Science and Art, Edinburgh.

In the early history of the world, and down to comparatively modern times, the trade in spices occupied a very different position from that in which we now find it. The name itself indicates that they were the chief medium of international exchange; and in our language, to the present day, we have the word specie applied to gold used for such exchange. Both words are derived from the Latin *species*, kind or quality; thus both spice and specie mean *the* special kind or medium of trade. Spice was thus in ancient times the staple of foreign commerce, as cattle was that of domestic trade; in process of time men found it convenient, instead of dragging about their oxen, to use the image of an ox on a bit of leather, hence pecunia and pecuniary, or cattle transactions; so also in foreign commerce specie or gold tokens came into the place of, or to exchange for spices.

As the primary object of this paper is to give an outline of the commerce in these substances, only such notes of their natural history will be prefixed as may enable us to comprehend what we mean by Oriental spices, and some of the conditions under which they grow.

All spices have in common a hot pungent taste, and are possessed of stimulant properties, in which their value chiefly lies; they possess, in addition, a more or less pleasing aromatic flavour, and these properties reside in an essential oil, or other chemical bodies they contain. They are drawn from widely different sections of the vegetable kingdom, and from very various organs and parts of plants. Thus we have spices from rhizomes or root-stocks, from bark, twigs, leaves, flower-buds, fruit and from the appendages of the fruit, so that almost every part of the living plant is in turn employed to yield these precious products. Notwithstanding this, the series of substances used to any considerable extent in the form of spice is not at all extensive; and it is only to the two or three, which have had much commercial importance, including cinnamon and its allies, common pepper, the clove, the nutmeg and mace, that we may at the present time refer.

Foremost in order of antiquity, most highly prized for delicacy of flavour, and most generally esteemed, stand the spices of the cinnamon series. In regard to these, a considerable amount of confusion long existed, and still, to some extent, remains. Cinnamon, cassia, or cassia lignea, and cassia vera are the recognized commercial distinctions of these substances; and as regards properties and value they are quite sufficient. They are the barks of various species of trees or shrubs belonging to the Natural Order *Lauraceæ*, or Laurels; and, as cultivated, are in their foliage and general appearance not unlike the so-called laurels or bay bushes common along all garden and park walks. Were the plants allowed to develope they would become trees of considerable size; but as the most valuable bark is procured from young shoots, the coppice system is pursued in their cultivation; that is, they are treated as we treat our plantations for yielding oak bark, the main stem being cut down, a vigorous growth of shoots springs from the roots, and from these shoots cinnamon and cassia are prepared.

The true cinnamon of modern times is derived from *Cinnamomum Zeylanicum;* so named from the impression that Ceylon is the native country of cinnamon. Undoubtedly the best, and, till within very recent times, the only true cinnamon brought to Europe, since the Portuguese opened up the Cape passage, came from Ceylon. But it is remarkable that, previous to the settlement of the Portuguese in Ceylon, only the most obscure hints regarding its existence in that country are to be found. And it was not till well into the seventeenth century, after the Dutch had long held the island and devoted very great attention to the cultivation of this spice, that the fame of Ceylon cinnamon arose, as being the finest and richest in the world. Ceylon may, notwithstanding, have been its native country; but, in that case, the cinnamon of the earlier ages must have been a variety of cassia, which we find by Pereira is in much greater esteem than cinnamon in the East of Europe—the countries of the early overland traffic. Or it has also been suggested that cinnamon, as well as coffee, is a native of north-east Africa, the country marked in ancient maps Regio Cinnamomifera or Aromata; now known as Guardafui, from two Arabic words, meaning the promontory of spices; and that the enterprising Arabs conveyed the plants to both the Malabar coast of India and Ceylon; in the latter of which all the conditions for the most perfect development of their properties existed, whereas in India they quickly degenerated, and have only left their traces in valueless wild plants found among the Coorg Hills.

The sources of the less delicate spice, cassia, are more numerous, being produced by several species of *Cinnamomum;* and geographically, it is comparatively widespread. The species of *Cinnamomum* yielding cassia have not yet been very clearly established; but there is no doubt that Chinese cassia, which is most largely imported, is yielded by a different species from that which flourishes in Hindostan. The old Dutch naturalist Rumphius remarked that cinnamon, cassia, and clove bark, though so very much alike, are scarcely ever found in the same countries; it is, therefore, probable that cassia is produced in the different regions where it grows from different but allied species. However, as no commercial distinction is maintained betwixt these, it is sufficient for our purposes to know that cassia is a comparatively widespread spice, cultivated in China, the Malay Peninsula, Hindostan, and many of the islands of the Indian Archipelago.

The bark known as *Cassia vera*, is the thick pieces taken from the old stems of the species of *Cinnamomum*, and differs from the others only in containing a very large proportion of woody fibre to an exceedingly small percentage of aromatic matter.

The less important spices yielded by the Order *Lauraceæ* we simply enumerate as cassia buds, the flower-buds of species of *Cinnamomum;* clove bark, the Culitlawan or Kulit-lawang bark (*Cinnamomum culitlawan*) of the Moluccas or Spice Islands; and the Ravensara nuts of Madagascar (*Agathophyllum aromaticum*). The commercial relations of these are unimportant.

Cloves, which are the flower-buds of a tree, the *Caryophyllus aromaticus*, belonging to the Natural Order *Myrtaceæ* or Myrtles, were originally confined

* Paper read before the North British Branch of the Pharmaceutical Society at Edinburgh, April 24, 1871.

to five exceedingly small islands in the Moluccas. The culture was transferred to Amboyna by the Dutch, who, for the purposes of their monopoly, made the most strenuous and barbarous efforts to extinguish the growth in all other parts. Even a removal of this small distance had such an effect upon the highly sensitive clove-tree, that it threw back the period of bearing from the seventh or eighth year of its age in its native islands to the twelfth or fourteenth in the Amboyna group. On this account Rumphius, who calls the clove "the most beautiful, most elegant and most precious of all known trees," says, "Hence, it appears, that the Great Disposer of things in His wisdom, allotting His gifts to the several regions of the world, placed cloves in the kingdom of the Moluccas, beyond which, by no human industry, can they be propagated or perfectly cultivated." For many centuries the truth of this assertion remained unassailable; and it was only about the beginning of this century that the tree was successfully grown away from the Archipelago, being then introduced to several French colonies in the Indian Seas, Guiana and the West Indies, and Zanzibar on the East African coast, from which last the chief supply of cloves now comes. But this feat against nature, as Rumphius would assert, was only accomplished after long-continued efforts and repeated failures, and owed its measure of success to the bitter monopoly of the Dutch, who, to maintain their monopoly prices, were often obliged to burn their superfluous stores; and it is on record that in two days in 1760, 8,000,000 florins' worth of cloves were burned at Amsterdam, perfuming the air with delicious fragrance, and distilling spicy streams of essential oil from the burning mass.

The following is a fanciful description of the clove-tree by Sir Thomas Herbert:—"'Tis most part of the year green, having leaves long and small distending into many branches. It blossoms early, but becomes exceedingly inconstant in complexion, from a virgin white varying into other colours; for in the morning it shows a pale green, in the meridian a distempered red, and sets in blackness. The cloves manifest themselves at the utmost end of the branches, and in their growing evaporate such sense-ravishing odours, as if a compendium of Nature's sweetest gums were there extracted and united."

It is at the point when the opening flower-bud from being first a delicate green has passed through a pale yellow to a blood-red that the spice is ready for harvesting. If left on the tree after this period, the calyx rapidly swells, the fruit ripens, nearly all aroma disappears, and what are known as mother-cloves are produced.

The clove-tree is remarkably variable in its yield; some years there is almost no harvest, and at varying intervals of from three to six years there is an extraordinary crop. Seven pounds is a large average for a tree, but some trees have been known to yield regularly from 40 to 60 lb. Rumphius mentions a remarkable tree, 130 years old, which one season yielded the enormous quantity of 1100 lb., and next season half that quantity. At that time the produce of this single tree for these two years would yield nearly £300; and that was a much larger sum then than it now represents.

(To be continued.)

KALA NEMUK, OR BLACK SALT.

BY M. C. COOKE, M.A.

This drug is in high esteem amongst the natives of India, and appears to be nothing more than an impure chloride of sodium containing a little sulphuret of iron. It has the appearance of a brown, dirty table salt, discoloured with soot, not by any means prepossessing. Under the heading of sodii chloridum, it is briefly alluded to in the Pharmacopœia of India. The Hindustani names are Kala-nimuk, Bit-loban or Bit-noben, Pud-loon, Nimuch-seeyah and Sownchurloon. In Persian and Arabic it is named Melk, Melk-nuft, Melk-aswed, Nimue-i-nuft, Nimue-i-sed and Nimue-i-hindi. It is probably the sal asphaltites and sal sodomenus of Galen and other ancient authors.

The following is the description of this substance as given by Dr. Waring. It occurs in large irregular masses, for the most part of a dark brown colour. It has a strong saline taste, communicating a peculiar sensation diffused over the mouth, which is not easily described. At first the taste is disagreeable, but those who are in the habit of using it, declare that it not only becomes pleasant, but is often taken to remove a disagreeable taste from the mouth. When the salt is perfectly dry, it has scarcely any perceptible smell; but when moistened it sends forth a strong smell of sulphuretted hydrogen. It dissolves readily in a small portion of water, forming a solution of a greenish colour, which emits a strong sulphureous smell, resembling bilge-water, or the foulest gun-scourings. By exposure to the air the smell gradually abates, the greenish tint disappears, the liquor becoming clear as the purest water; when this has taken place, if the solution has been pretty strong, on pouring out the water the inside of the vessel in which it was contained is found lined with a crust of a dark brown colour—a phenomenon observed in most sulphur wells; this will be best discovered if the experiment is made in a glass vessel.

It was for some time considered doubtful whether or not this was a natural or artificial product. That there is a dark-coloured natural salt to which the name of Kala-nemuk, or black salt, is applied there can be no doubt; but it is equally certain that the drug so highly extolled by the natives for its medicinal virtues is an artificial combination of common salt with iron and sulphur. It is this artificial product, therefore, which is the subject of these observations, and which possesses pharmacological interest.

The following analysis and method of preparation are given on the authority of Playfair's translation of the 'Taleef Shereef':—Black oxide of iron, 6 grains; sulphur, 14 grains; muriate of lime, 12 grains; muriate of soda, 444 grains; loss 4 grains = 480 grains. It is thus prepared:—Take two seers (about 4 lbs.) of anula (fruit of *Emblica officinalis*), one seer (about 2 lbs.) of Ashkhur (iron scoriæ?), bruise both and mix them with 20 seers (about 40 lbs.) of rock-salt, also bruised; put the whole into a vessel, cover the vessel with a cloth, all except the mouth; lute this cloth well with soft clay, and place it in the sun to dry. When perfectly dry, put it on the fire (let the mouth of the vessel be rather small). Keep constantly stirring it with an iron spatula or spoon; when well boiled and mixed, take it off and allow it to cool, then add tinkhar (borax), jawakhar (an impure borax), tilkh (talc, probably), kibreeth (sulphur), sweet salt and soot, equal parts; mix all well together and add a quantity of salt water; then boil the whole down and strain slowly through a cloth by drops, then boil the clear fluid till crystallization takes place.

This appears to be the genuine medicinal salt such as we have met with, and which was known to Dr. Waring when he wrote the description we have quoted. In the Punjab an artificial black salt is made without iron or sulphur, according to Mr. Baden Powell, who gives the following mode of manufacture in his recent volume of 'Punjab Products.' It may be remarked incidentally that there are several compounds known to the natives under different names which have chloride of sodium as a principal ingredient:—"One maund of Sambar, or Dindwa salt; $\frac{1}{4}$ seer of 'baherah' (fruit of *Terminalia belerica*), $\frac{1}{4}$ seer of 'har' (fruit of *Terminalia chebula*); $\frac{1}{4}$ seer of 'aonla' (fruit of *Emblica officinalis*); $\frac{1}{4}$ seer of black sajii (impure carbonate of soda): all these are put into an earthen pot over a fire and kept there till scorched; when about 35 out of 41 seers remain, the pot is taken off and the black salt is made. About two maunds of wood are used. The price is now in Bhawani three rupees per maund. It is used only as medicine, and is exported to the North-Western Provinces and to the Punjab. No tax is levied at Bhawani, but it pays duty as salt when taken across the customs' line." It is called Kala nimak or Nimak sonchal. There is no indication of iron in this process. Probably both methods are employed, and hence the 'black salt' may or may not contain iron according to its mode of manufacture. The name given in the 'Taleef Shereef' is Nemuk-soonchur or Nemuk-sia, called also Bitlaban and Kala-nemuck. It is described as a tonic in dyspepsia or gout; a deobstruent in obstructions of the spleen and mesenteric glands of children; a stimulant in chronic rheumatism and palsy; a vermifuge. Dr. Henderson and Mr. Twining consider that there is reason to believe that in chronic enlargements of the spleen and liver, the result of malarious poisoning, it possesses considerable powers. Twining advises its administration in doses of gr. x. with ʒss of the black myrabolan every morning, in the intervals between the employment of his famous spleen mixture. It is held in high esteem in various forms of paralysis, especially in that in which the organs of speech are affected, and it is extensively used by native farriers in the diseases of cattle.

THE PREPARATION OF CHLORAL.

Extracted from the remarks of DR. E. R. SQUIBB *before the American Pharmaceutical Association.*

Chloral is the ultimate product of the action of chlorine on alcohol, as its name implies, the first syllables of the two words being formed into the name; "chlor," the first syllable of chlorine, and "al," the first syllable of alcohol, making "chloral." When chlorine gas in a dry state is passed into absolute alcohol, a series of changes appear to take place which may depend on the abstraction of hydrogen and the substitution of chlorine. The first portions of chlorine gas that pass into absolute alcohol are converted, or appear to be converted, at once into hydrochloric acid, and that hydrochloric acid is absorbed by the remainder of the alcohol and reacts with it, producing hydrochloric ether. The second step in the reaction is to again decompose or supersaturate this hydrochloric ether with chlorine, and then hydrochloric acid escapes; and finally, as heat is applied in the process, the hydrochloric ether escapes and a substitution appears to take place, whereby chlorine is substituted for hydrogen in the already-decomposed alcohol. This is but a rude outline of the process. Chloral was discovered by Liebig in 1829 or 1830, although the paper in which it was described was not published until about 1832; therefore it is commonly stated that he discovered it in 1832, which is incorrect. Dumas was the next who investigated it, and these two observers investigated it as a table specimen product. Last year, Dr. Otto Liebreich, in his physiological investigations regarding the group of anæsthetic chemicals, reasoned back to this substance the known effects of chloroform, and tried it first upon animals, then upon patients. At first he supposed it was an anæsthetic, but afterwards modified this view, and now I believe regards it as a hypnotic, and, in some cases, an anodyne. The apparatus for making chloral consists, first, in the means of generating chlorine; second, in the means of drying the chlorine; third, in the means of passing it into absolute alcohol without loss; and, fourth, having the absolute alcohol in such a position that it can be gradually warmed. The process requires about twenty-eight days for the current of chlorine to be passed into the absolute alcohol, and I believe the slower the current passes into the absolute alcohol the better; that is to say, the longer the time which is taken to produce the chloral the better; I think there is less waste and more chloral obtained for the same quantity of alcohol. It is a curious circumstance that hydrate of chloral is produced by passing the chlorine into absolute alcohol, and this shows that water is one of the results of the decomposition of the alcohol; yet if hydrated alcohol be used, the product is different. I have tried different degrees of strength of alcohol, from absolute down to ninety-two per cent., and have obtained good results only from absolute alcohol. 16 gallons of such alcohol, in twenty-eight days, with the use of about a ton and a quarter of mixture of binoxide of manganese and common salt, and about the same quantity of sulphuric acid,—the 16 gallons of absolute alcohol weighing about 92 pounds,—I obtained about 160 pounds of crude hydrate of chloral. This crude hydrate of chloral, as it is made by the passage of the chlorine into the alcohol, is contaminated with several other products which pass over in the distillation, and cannot be separated by simple distillation. It is necessary, therefore, to apply sulphuric acid in the purification of the chloral. Concentrated sulphuric acid is shaken with the crude hydrate of chloral, and the dehydrated chloral is then distilled off from the sulphuric acid. In this way we get chloral that is free from water. After purifying this by one or two applications of sulphuric acid, then the stœchiometric proportion of water is added, and it is either sublimed or crystallized. In connection with this hydrature allow me to go back to the name of chloral. I propose to call it simply chloral,—not hydrate of chloral, nor chloral hydrate. It seems to me surplusage, as we do not in our language commonly call hydrated compounds hydrates; that is, we do not usually recognize the presence of combined water in the names of chemical compounds.

We do not say hydrate of sulphuric acid, or hydrate of hydrochloric acid, and in this case we shall save a good deal of nomenclature that is useless by calling it simply chloral. We heard yesterday, that the bees by taking a little honey from each flower gathered thirty millions of pounds. Every flower and every bee helps to make the aggregate. A certain amount of nervous force is expended on every word we utter, and if we save this word now (and now is the time to start), it will save an aggregate of nervous force which, in the future, will amount to a great many lives. I do not believe in useless language, particularly where it can so well be avoided, and, therefore, think we had better call this from the beginning, simply chloral, although the other name is pretty generally used.*

The difficulties in the way of making chloral are very numerous. The apparatus I have now at work is about the tenth modification from the first one, and I started with all the knowledge on the subject then in the books. The liberation of chlorine from common salt and black oxide of manganese by running sulphuric acid into it is easy enough, but unless the current be steady the result is imperfect, and there can be no good or definite calculations made as to the time or the quantity. The black oxide of manganese and common salt need both to be assayed and added together in their equivalent proportion, and then the calculated amount of sulphuric acid in any given specimen is to be made upon its specific gravity, and the acid can only be added to the mixture by calculation, because, if added until chlorine ceases to be eliminated a great excess will be used. I mix 100 pounds of the mixture of black oxide of manganese and common salt with about ten gallons of water in a still, and then run seven gallons of 60° slowly into it, using "pan acid," 1562 specific gravity, using a mechanical stirrer, and heating the mixture. In this a tolerably uniform current of chlorine is eliminated. This is then conducted to the drying apparatus, which consists of a three-neck Woulfe's bottle, with a long, narrow glass percolator ground into the middle neck. This percolator is filled with pieces of broken glass from which the fine particles have been sifted out, and into the top of this broken glass, concentrated sulphuric acid is supplied from an elevated reservoir. This acid percolates through the broken glass, and accumulates in the Woulfe's bottle below until it reaches the level of an adjusted siphon, by which it is discharged through one of the necks of the bottle. Through the third neck the chlorine enters by a tube which dips under the acid in the bottle. Thus the gas is made first to bubble through the acid in the bottle, and then to pass over the extended surface of broken glass in the tall percolator, this surface being kept moistened with fresh portions of acid, and thus becomes thoroughly dried and in the proper condition to enter the alcohol. The chlorine thus passed down into the alcohol at first increases the volume of the alcohol by one-fourth. At first, the whole of the bubbles of gas are absorbed, and the alcohol increases in volume and becomes heated, the bottle requiring to be kept cold; but after about three days the reaction between the chlorine and alcohol becomes more sluggish, and then a little heat in the bath is necessary. From that time the bath is made gradually warmer until the end of the process, which is determined by the gas pressing unchanged through the hot liquid in the bottles. The product is then the crude hydrate of chloral. Then if the contents of the bottles be allowed to cool, a large proportion crystallizes. It will not run from one part of the bottle to another, but still is very moist. This is taken in portions of about twenty pounds at a time and shaken up with six to eight pounds of strong sulphuric acid, the whole mixture poured into a tubulated retort and the chloral distilled off. This is received in a clean, dry vessel, is weighed, and then partially hydrated with a weighed quantity of water. Carbonate of lime and slaked lime are then added in the proportion of four ounces to each twenty pounds, and the mixture is again distilled from a clean apparatus. The result of the distillation now is partially hydrated chloral; it distils better partially hydrated than when hydrated entirely. The remainder of the water required by stœchiometrical calculation is now added, and the hot liquid poured on plates to crystallize, the plates being covered by a bell-glass. In a few hours the crystallization is complete, and if well managed the contents of the plates are in a solid cake, which is rubbed into a coarse, damp powder in a clean mortar, and filled into bottles.

I obtained from 16 gallons of absolute alcohol 160 pounds of crude chloral, which, when purified, yielded about 125 pounds of purified hydrate of chloral. That is about the best yield I have yet obtained. I have now about 65 gallons in process all the time, by a series of baths, by which I expect to get 140 pounds, or thereabouts, every week, or every ten days; that is, each bath being of a different age, and being finished in about thirty days, will give one bath or process every ten days. It will thus be seen that it is not a very profitable preparation to make, particularly when made in competition with the German article, and I believe I should never have undertaken to make it, except for my conviction that it is the most important of all the additions to the materia medica for many years past, and very commonly sent to our market from abroad of bad quality, and without any traceable responsibility in regard to quality or make.

Some accidents of an apparently trivial nature seemed to indicate that chloral is very liable to decomposition from contact with organic matter, but experiments have shown that it is not equally liable to this decomposition from all kinds of organic matter. Even the same kind of organic matter does not always produce the same effect with the same chloral. For example, where syrup of orange-peel is used as a vehicle, decomposition, with the production of hydrochloric acid, will sometimes commence in a day or two, and sometimes not for weeks, though the apparent conditions be the same. One observer will testify that with simple syrup it never spoils or decomposes, while another, equally trustworthy, will find the same chloral decompose with simple syrup very promptly. Under such circumstances, the only safe practice is to keep chloral as free as possible from all organic matter until we know more about it; and this particularly in view of the harm it does when given in even a partially decomposed solution. It appears to be by far the best practice to dispense it in simple watery solution in glass-stopped vials, since in this condition it keeps

* While this note is being prepared for publication a serious mistake, by abbreviating the words hydrate of chloral to "hyd. chlor." in prescription, was corrected in time to avoid danger.—E. R. S.

indefinitely, and can be added to any desired vehicle at the time of taking; and ice-water appears to be about as good a vehicle for this, as for all saline substances, as any yet devised. When given to patients who have been long fasting it is often found to disagree with them, or at best to affect them less favourably than when given near a meal, or when the gastric secretions are not in the condition of long fasting. Hence, the syrup of orange-peel, or the mucilage, etc., with which it is common to give it, may not be without useful effect, and those physicians who have now abandoned these mixtures for the simple solution, often if not generally, advise their patients to eat a cracker, or take some other light food in small quantity, before or immediately after a hypnotic dose. When the medicine affects persons unfavourably, it should always be examined for hydrochloric acid by smelling and tasting, and by litmus paper. Nitrate of silver is too sensitive a test, for if the solution have been some time made, and especially when water containing organic matter is used, a cloudiness may be produced with this test which it is quite safe to disregard.—*Proc. Am. Ph. Association*, 1870.

FILTERING-PAPERS AND FILTERS,

With General Remarks on the Important Branch of Practical Pharmacy in which they are employed.

BY JOSEPH M. HIRSH, OF CHICAGO.

Original suggestions are almost impossible upon this practical topic, which, for we know not how many centuries, has busied not only the master minds occupying themselves with the sacred healing art, but everybody almost in all vocations of life; and the excellent suggestions regarding filters, laid down in all works on practical pharmacy, will be a sufficient apology for confining the present essay to a few observations on the filtering-paper and filters in general use. The main object of filtration, with especial reference to pharmacy, being the separation of a clear liquid from a solid residue, we must demand as of prime importance of the filtering medium, that it offers a dense, uniform, unbroken surface to the liquid passing through it, so that no solid particles may pass through the same, the complete separation of which from the liquid is aimed at.

The most ordinary objects of filtration at the pharmacist's are the preparations of clear tinctures, and the restoration of such liquid preparations as have grown turbid or deposited a sediment by standing, respectively by decomposition; these latter instances being, a pity to say, by no means exceptional. For this object paper is mainly employed as a cheap and convenient medium.

The general characteristics of good filtering-paper, like complete dense felting, uniformity, poverty in soluble salts, constituting its ashes, are well known, and your reporter can only repeat the experience of many who have found good Swedish filtering-paper to fulfil all claims of prime quality made upon it. But it was always selected with some partiality, because upon repeated tests of the ordinary filtering-paper, obtainable in our backwoods town of Chicago, a sad deficiency was found. Three qualities were chiefly obtainable.

The French grey filters, coming in *round* sheets, ready for folding; *square* grey sheets, sometimes of lighter colour and white; square sheets, so-called Swedish filtering-paper, which it might be, although the coolness with which it keeps its name is the only sign of its northern home. It is not felted evenly, some spots being quite heavy, while others are so thin as to be semi-transparent, and others again permit not only the passage of light, but of solid tangible substance. In fact I could never obtain any Swedish filtering-paper here but what had at least some pinholes. Of the grey filtering-paper, the round French, as also the square, twenty sheets in each hundred examined contained pinholes. Such paper is perfectly useless for the separation of some precipitates, while it may answer for the separation of others, such as would fill up even the gigantic pores of imperfect filters. In this case the first turbid filtrate would have to be returned upon the filter, upon which the deposition of the first precipitate then forms the true filtering medium.

The safest way in using such filtering-paper is to use a double filter, when the dense, unbroken sheet of the one, upon being moistened, will closely press against the sides of the second filter, thus closing up any imperfections present in the same, although there is one much better way, namely, not to use such filtering-paper at all. In some cases the use of double or even quadruple filters becomes necessary, even if the quality of the paper is excellent, as in the filtration of concentrated aqueous solutions of oils or carbolic acid, when a clear solution is desired. In this case the benefit resulting from the use of several layers of paper is not only due to the greater depth of the filtering medium through which the liquid has to pass, but to the different direction given to the liquid during its passage through each filter, so that it pursues a zigzag course through the different strata of paper, which is equivalent to a longer and more obstructed passage, with which the good effect of filtration increases. Paper filters, on account of the feeble strength of the material and its limited size, can only be used for operations upon a small scale; and for such we often find a preferable substitute in clean, well-washed cotton batting, a small quantity of which is pressed into the neck of a common funnel, which then is filled with the liquid to be filtered. The cotton plug may be made as loose or firm as the filtering liquid demands; its dimensions, respectively to its depth, may also be increased or decreased at pleasure, liquids of great fluidity passing readily through a dense and deep cotton plug; while syrups filter only through a loose plug, unless pressure is applied. For this purpose, also, cotton is preferable, as considerable pressure can be used to increase the speed of filtration; while paper would not be strong enough to resist that pressure without especial care and precaution, such as using at the same time a filter of cotton cloth, which sustains the pressure, and upon which the paper filter lies, so as to make no folds, while the funnel which supports the filter must have exactly an angle of 45 degrees, so as to ensure the close adherence of the filter to the walls of the funnel. A small platinum cone may also be slipped over the joint of the filter, having the same angle, to add to its strength to sustain the pressure. The further construction of pressure-filters has been so fully a subject of discussion in the pharmaceutical press, that I may safely pass it by with the suggestion that tho simplest pressure-filter is a siphon, where filtration would take place upward through the short arm of the same. To do this successfully, the opening of this short arm must be very wide, narrowing down funnel-like to the tube, which should be of very small calibre. The difference in width between the short and the long arm must be very great, to render the siphon useful as a filter, for the reason that only a large opening closed by the obstructing filtering medium will admit through the latter a sufficiently large amount of liquid to keep the long arm of the siphon-tube filled. Should less than that amount of liquid pass through, air will enter and will at once disturb the action of tho siphon.

On a large scale the pharmacist rarely has occasion to use filters except in percolation, which perhaps hardly belongs within the scope of this paper, since filtration has simply the object of separating a liquid substance from a solid one, while percolation proper, in the customary pharmaceutical sense of the term, by means of filtration accomplishes also the extraction of soluble substances from the filtering medium. But the process being mainly one of filtration, your reporter ventures to present a few suggestions which he deems as applicable to pharmaceutical percolation as to filtration proper.

Filters or percolators should be constructed tall and narrow, so that the filtering or exhausting liquid should have to travel a great distance through a large mass of filtering material, or powdered drugs in the case of percolation, as only with the increased contact and surface the efficiency of a filter is increased. If of two filters of the same capacity, the one is twice as tall as the other, the tallest will be almost twice as effective, since in the shorter filter the liquid passes but half as long through the filtering material, withdrawing itself soon from the same, while each particle of liquid comes in contact with but half the quantity of filtering material, the paths which the filtering-liquid passes, being increased in number in the same ratio as they are decreased in length.

Although used in the arts for many years, the practical application of this principle in pharmacy is of but recent date; namely, the use of fractional percolation, an apparatus for the same, or a series of filters, being in fact no more than a long tall filter cut into many short filters for the sake of more convenient handling, and more convenient separation of the exhausted part of the filter in the first one of the series. Here I would beg leave to remark that various suggestions in regard to fractional percolation, dictating the exchange of different filters in an especial order, with retention of some of the first filtrate (percolate), prior to its passage through *all* of the filtering material (powdered drug) appears to me arbitrary, since no percolate, no matter how concentrated, is so strong but that its passage through some fresh portions of unused drugs would increase its strength, the active principle of that part of the drug being exhausted at the same time to some extent, thus rendering more complete the work of exhaustion of subsequent portions of filtering liquid.

Fractional percolation, no matter whether two or an indefinite number of filters are used, should be so conducted that *each* particle of the filtering-liquid would pass through *all* of the filtering material. This will ensure a thorough exhaustion of the filtering material, and a corresponding thorough purification (in the case of percolation through saturation) of the filtering liquid.

Another point worthy of consideration is the difference in the results between upward and downward filtration. In the latter, the liquid, following its own gravity only, will select those paths where it finds the least resistance, namely, *around* the single particles of the filtering material, which to a great extent it will leave untouched and therefore unused. In upward filtration, on the other hand, the passage of the liquid is guided by hydrostatic pressure in a straight upward direction regardless of resistance, and the filtering material is more thoroughly exhausted. For liquids of low specific gravity, like oils, this mode of filtration is well established, because the water used in displacing the last portions of the oil is quite effective, consequent upon the difference of the specific gravity of the two liquids. But if an extract, a syrup, or other liquid, heavier than water, is to be displaced by that liquid, a partial diffusion of the same through water will take place. This is quite trifling if the liquid is well followed up by the displacing fluid (water), but has been deemed sufficient by some to form an obstacle to the practical application of upward filtration.

In experiments made in this direction, your reporter found that syrup weighing thirty-five degrees Beaumé, displaced by water, soon yielded a filtrate of but two degrees Beaumé, if the filter was kept at a temperature of about ninety degrees F., to ensure fluidity of the syrup; the filtering material in this case was bone-black.

Where the thorough exhaustion of the last trace is of great significance, the filter, which for pharmaceutical purposes is rarely of great dimensions, might be made revolvable around an axis, so that top or bottom could be interchanged for the reception or discharge of the liquid filtered. Here the filtration might be carried on upwards, and the exhaustion of the filter downwards. Pressure filtration, as also that with the exclusion of air, can be carried on well and simply in the manner of upward filtration.

As to the material most useful for filtration to the pharmacist, I will mention besides filtering-paper, cotton batting for most ordinary liquids, for which might be substituted in many cases white clay, fuller's earth, when only turbidity is the motive for filtration.

In several instances it has come to the notice of your reporter that otherwise good pharmacists, who never would buy or make an inferior preparation, would filter liquids, like ferrated elixir of Calisaya, through large quantities of bone-black. The great absorbent power of bone-black was completely lost sight of. A plug of cotton batting would have been more appropriate. If bone-black is used for filtering pharmaceutical preparations, it should be completely freed from its phosphates by muriatic acid, the nitrogenous carbon remaining behind being a much more powerful substance for filtration (decolorization) than the ordinary bone-black, while it contains nothing soluble that would contaminate any pharmaceutical preparation.

For chromic acid, or similar oxidizing agents or caustics, the proper filtering medium is glass-powder or gun-cotton, while for the filtration of mercury a double layer of good chamois skin should be taken, and gentle pressure applied to effect the passage of the metal.—*Proceedings of the American Pharmaceutical Association.*

TESTING COCHINEAL.

BY J. M. MERRICK.

I give in the following article the outlines of the method I am in the habit of using for testing samples of cochineal to ascertain their comparative colouring powers. I have not seen it described in print, and while it is a much closer and more accurate method than that which is based upon dyeing strips of mordanted woollen stuffs, it is preferable to the bleaching with chloride of lime method,—as the oxidizing substance used, viz. potassic permanganate, does not precipitate the colouring matter of the cochineal.

I grind to a fine powder the samples to be tested, weigh out two or two and one-half grammes, and boil this amount in a capacious narrow-necked flask, with 750 c. c. of water, for one hour. The liquid is immediately filtered through dry paper filters, and tested when cold. To test it, 50 c. c. are measured in a flask of that capacity and poured into another flask of about 200 c. c., and the measuring vessel rinsed with a definite quantity of water, say 10–15 c. c.

A weak solution of permanganate is then run in from a burette with a glass cock, the flask being shaken well after the addition of every 10 c. c.

So much permanganate solution is added that the cochineal extract shall be changed from its original colour to a pink of the very faintest shade, almost yellow, in fact, but never reaching a full yellow. This pink shade should be persistent, that is, it should not turn yellow after standing fifteen minutes; and after a little practice it will be found very easy to obtain the tinge, which shows that the colouring matter is almost but not quite destroyed.

When a number of samples are to be compared I arrange an equal number of 200 c. c. flasks and test-tubes on the table, a tube standing in its rack in front of each flask. Then the *same* number of c. c. of the permanganate solution (which should be at least so weak that bulk for bulk of this and the cochineal solution will be required) is run into each flask, taking care to use too little to completely destroy the colouring matter in *all.*

The flasks are well shaken and allowed to stand for ten minutes.

Part of the contents of each is then poured into the corresponding test-tube, and a glance at the tubes as they stand side by side will show which is the least affected by the bleaching liquid. This sample having been selected to serve as a standard, the contents of the test-tube are returned to this flask, and more permanganate solution is cautiously added, until a very faint pink tinge, which a fraction of a c. c. will turn to a full yellow, is obtained.

The number of c. c. used having been noted, a fresh trial is made, in which the c. c. required, minus one, are used, the flask agitated, and the last c. c. or part of it, as the whole may not be necessary, added. If the two results agree, the next sample is treated in the same way, and so on until all are tested.

I usually make a final trial by measuring the 50 c. c. of each solution into its flask, running in the permanganate in the ascertained amount into each as quickly as possible, letting the flasks stand ten minutes, and then making a comparison of all in the test-tubes.

If the shades are not exactly alike, a pretty good guess can generally be made of the fractions of c. c. required, which should be added, the contents of the tubes being joined to that in the flasks, and a second or third comparison thus made.

This is a rather long description of what in practice is a very simple and good process, the three principal points to be borne in mind being,

1. To use a weak solution of permanganate.
2. To have a very faint pink colour as a standard of comparison.
3. To let the liquids remain after agitation together 10–15 minutes before comparing them.

I may add, that it is very remarkable how little can be told of the value of a sample of cochineal by a mere physical examination, and that the frequent inconsistency between value and price is equally surprising. I have known samples to differ *thirty* per cent. in colouring power, and only one or two cents per pound in price.—*American Chemist.*

TINCTURE OF HYOSCYAMUS.

BY M. DONOVAN.

Some years since I published, through the medium of the *Medical Press*, an account of trials made on myself and others, with a view to discover what dose of tincture of hyoscyamus should be given in order to produce its sedative effects. The experiment was made on several persons, beginning with a drachm dose, increasing it to six drachms, and in my own case to one ounce, of the tincture of the Dublin Pharmacopœia. In no case were any effects observed beyond dryness of the throat and fauces. The experiments were made with tinctures prepared from the dried leaves of garden-grown plants, from wild plants collected in a mountainous district of North Wales, and from the same leaves dried and undried.

I was under the impression that some of the plants employed in making the tinctures on which I experimented were in the second year of their growth, but the trials now to be described have convinced me that none of them could have been more than one year old. At that time I was not acquainted with the means which I have since discovered of testing the age of the plant.

I satisfied myself by these experiments that tincture of hyoscyamus prepared, as I believe it generally is in this country, from leaves of one year's growth, is all but powerless. I was strengthened in this opinion by finding that M. Hertz has given upwards of fifteen grains of the extract, most probably made from the plant in its first year, without any sensible effect.

Mr. Houlton had long before affirmed the inertness of the one-year-old plant, and the activity of that of two years old.

In order to come to some determination on this subject, I adopted means of procuring a tincture certainly made from the latter, and from trials with it soon convinced myself that it was an article of very different value from a tincture of the one-year-old plant, and that all my former experiments must have been made with the latter, although I was led to believe that, in some of them, the plant of two years' growth had been used.

My first trial was on myself. I took one drachm, and for an hour or two felt no effect beyond dryness of the mouth. On a subsequent occasion I took two drachms, and in two hours had proof that I had taken a sufficiency. My sensations were indescribable: one was a feeling of uncertainty of my steps in walking, although they were really quite steady, and a slight sensation of giddiness. This trial convinced me that I had taken as full a dose as prudence would permit. To a lady who suffered from headache I gave, at her own request, one drachm of this tincture. In about two hours she felt so overcome by sleepiness that she could scarcely keep her eyes open; the headache was, however, greatly relieved. On another occasion she took a similar dose, and, being in bed, she soon fell into "a delightful sleep," and, on awaking, found that the headache was almost gone; but she complained of dryness of the fauces and throat, although on the first occasion she did not experience either of these effects. Some months after the same lady suffered from headache, and did not receive any benefit from a similar dose; nor did another person experience any relief from toothache nor any other effect beyond slight dryness of the fauces, which soon passed off.

Convinced by the foregoing considerations that the medicinal properties of hyoscyamus reside exclusively in the plant of two years old, and that the plant of one year's growth is therefore useless, I sought to discover an easy test by which the age of the plant from which a given tincture had been prepared could be determined. The following has at least the advantage of simplicity: add a little of the tincture to a glass of water; if the mixture become slightly milky, the tincture was made from a two years old plant; if it remain transparent, the plant was in its first year.

The British Pharmacopœia gives no information as to what shall be the age of the hyoscyamus from which the tincture is to be made; it is, therefore, a matter of chance whether it will have any effect or be powerless. Given in the dose of twenty or thirty drops, as is sometimes done, it is hard to believe it can have any effect in either case.—*The Medical Press and Circular.*

YEAST AND OTHER FERMENTS.

BY C. A. WATKINS.

(*Continued from page* 888.)

When starch or sugar is transformed* into butyric acid, vibriones are sure to be found in the fluid, whether they produce this fermentation or not; and lately a most remarkable statement has been published by M. Béchamps regarding this matter. This gentleman asserts that he has discovered that there exist at the present time, in

* During the transformations which took place in these experiments, I detected no organism having the slightest resemblance to yeast; the only fungus being *Oidium lactis*, which does not grow in the fluid, and, in my opinion, has no reference to the fermentation. In all the instances in which lactic acid was formed, I noticed only bacteria or vibriones, and while I admit that under more favourable conditions of temperature other growths may appear, I do not consider any of these organisms to be the specific lactic acid ferment.

large blocks of chalk taken at a depth of 200 feet from the surface of the soil out of a tunnel driven in a mountain, large quantities of microscopic animalculæ, which he has named *Microzyma Cetæ;* and he also states that if some of this chalk be placed in a saccharine solution, lactic and butyric acid fermentation ensue.

Yeast is so well known that its description here is quite unnecessary, and the fact that it converts sugar into alcohol is patent to all. The chemical formula of this change is thus:—

$$\underset{\text{Grape Sugar.}}{C_{12}H_{12}O_{12}} = \underset{\text{Alcohol.}}{2C_4H_6O_2} + \underset{\text{Carbonic Acid.}}{4CO_2}$$

Yeast is supposed to be the conidial condition of *Penicillium glaucum*, but much light is required to be thrown on this matter to raise it from its present obscurity.

The yeast cells consist of an outer membrane of cellulin —the same material as the cellular tissue of other vegetables—in the interior of which is a highly complex gelatinous substance allied to albumen.

The appearance of yeast under the microscope varies considerably with its condition; when at rest, that is, when fermentation is arrested, its form varies from globular to ovoid, frequently with an uneven outline, as if the cells were very partially empty; but when they are put into a fresh solution of sugar they swell out, and during active fermentation appear globular or nearly so, and more transparent than before.

When yeast is added to brewer's wort it increases rapidly, and grows to six or eight times its original quantity during fermentation; the wort being a solution which contains in abundance the elements required for its development, namely, grape sugar and some albuminous substances derived from the malt and hops.

During fermentation these albuminous matters disappear from the solution in proportion to the development of the yeast, and the sugar also disappears in the same ratio. When the fermentation is complete, we find that in place of the complex albuminous matters in the wort, we have simpler chemical combinations, such as salts of ammonia, and in place of the sugar we have alcohol. These chemical changes take place simultaneously; but with this important difference, that the amount of nitrogen in the original wort is reduced by about one-half, while the alcohol and carbonic acid nearly correspond to the weight of the sugar, the remainder being converted into lactic acid, etc., a small quantity of which is always formed during vinous fermentation. But the yeast consisting almost entirely of albuminous matters, and having increased to several times its original quantity, fully accounts for the disappearance of so large a proportion of the nitrogen from the wort.

Thus it will be easily understood that yeast, in order to grow, must be supplied with some soluble azotized matter, such as albumen; and it is as easily proved that it will not grow without.

To ferment one hundred parts of sugar, one part of yeast is required; when the fermentation is complete, the yeast is exhausted, and in its place ammoniacal salts and cellulin are found. As the vinous fermentation takes place only during the growth of the yeast, it may be said that it will grow in simple saccharine solutions. In a certain sense this is correct, but such growth is degenerate and exhaustive, and not the healthy growth which increases and multiplies, for in such a solution the yeast positively lives on its own substance: this has been proved by Pasteur in the following manner:—"He took a quantity of washed yeast and divided it into two equal portions,—one of these was placed in a solution of pure sugar, the other portion was boiled in water, the decoction filtered, and the filtrate added to a similar solution of sugar, to which a very minute quantity of fresh yeast was added. In the first case twelve parts of sugar were converted into alcohol in six days, when the yeast became exhausted. In the second case the liquid became turbid; fresh yeast was formed at the expense of the azotized matter derived from the boiled yeast, and ten parts of sugar were fermented in nine days."

Some years ago, when experimenting on bread-making, I was much puzzled by finding that when the yeast was thoroughly washed the sponge did not rise so quickly, nor was the bread so light as when made with yeast as received from the brewery. I have since learned that a portion of the yeast is soluble in water, and that when it has been dissolved out by washing, the yeast is less active; on exposure to the atmosphere, however, it recovers its activity.

Yeast causes a curious and important change to take place when added to a solution of cane sugar, converting it into fruit sugar by causing it to combine with one equivalent of water, during which operation the solution increases in specific gravity. This transformation is attributed to the soluble portion of the yeast; but be this as it may, some of it is evidently destroyed by the process, as a larger proportion of yeast is required to convert cane sugar into alcohol than grape sugar. It is a fact scarcely known to brewers, who use it, that cane sugar cannot be fermented into alcohol; for although when yeast is added to a cane sugar solution the vinous fermentation eventually ensues, it nevertheless does not commence until the yeast, without any apparent change in itself, has transformed the whole of the cane sugar into fruit sugar. The progress of this transformation may be witnessed by polarized light: the cane sugar producing a right-hand rotation of the ray = 73°, while the fruit sugar causes a left-hand rotation of 26°.

I have one more observation to make in reference to yeast. When it has been kept some days, of course, according to temperature, it loses the pleasant smell it had when fresh, and acquires some fermentive properties, which, as far as I am aware, have not received much attention. It is well known to brewers that if the yeast be allowed to stand on the beer for a day or two after fermentation has been stopped, a very disagreeable effect is produced; the beer is not acetified, but the flavour is entirely changed; it is unpalatable, and the brewers call it yeast-bitten.

Now I am not in a position to throw any light on this change; but if stale yeast be examined with the microscope, there will be found interspersed among the ordinary cells a large number of minute globular bodies, which are generally in motion; and I have also noticed a larger proportion of short, straight vibrio-like bodies, than are to be found in yeast during active fermentation.

Whether these organisms produce the disagreeable effects referred to, I am unable to say, and merely point to them as one of the changes which take place in yeast when left to itself.

Diastase is a ferment, which has the property of converting starch into sugar, by causing it to assimilate the elements of water without evolving any gaseous products.

The transformation is represented thus:—

$$\underset{\text{Starch.}}{C_{12}H_{10}O_{10}} + \underset{\text{Water.}}{2HO} = \underset{\text{Sugar.}}{C_{12}H_{12}O_{12}}$$

Diastase is extracted from malt by soaking it in water, in which, at moderate temperature, it is soluble; it may be taken as the type of the ferments produced in all germinating seeds,—for as all seeds contain starch, which must be rendered soluble in the form of sugar before it can become food for the embryo—so they all contain some azotized matters, as albumen, gluten, etc., which are capable of passing into the form of a ferment, allied to diastase.

(*To be continued.*)

The Pharmaceutical Journal.

SATURDAY, MAY 13, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE COUNCIL ELECTION.

THE approaching Annual Meeting of the Society bids fair to rival that of last year in importance, though we trust it will be free from its disagreeable features. If we may judge from the letters of Mr. BALKWILL and Mr. ELLWOOD, there is likely to be no small difference of opinion as to the policy of the course taken by the Associations formed in reference to the question of Poison Regulations; and it is probable that those who are in favour of compulsory regulations will not be altogether silent when that question is brought forward.

As regards the election of Council, there is one point which we would earnestly press on the consideration of the Society at large, and that is the desirability of avoiding even the appearance of any feeling of personal antagonism. We do this because it is a thing that happens readily, though unintentionally, in discussion among earnest men who are really interested in the question at issue, and another reason why we do so is, the noteworthy fact that, although there were originally 45 nominations for the 14 vacancies on the Council, there are only 22 candidates for election.

We need not urge upon our readers the importance of having at command the services of competent and influential men for conducting the business of this Society, and the fact just referred to that so few have been found willing to accept office is, we think, one that should be regarded as a warning against manifestations of intemperate zeal, and as a cogent reason for the suppression of any proceedings calculated to render the office of a councillor one that is in any degree disagreeable or invidious. It is not long since that the Council of the Society was collectively denounced by a self-constituted authority as being "unworthy to occupy the position which has been delegated to it," while more recently the same anathema has been launched against an individual member of the Council because he dared to defend the opinions he held. But though such rhetoric may seem to outside factions a fitting means of obtaining influence, we trust the deliberations of the pharmaceutical body will always be animated by a more rational spirit.

THE CONVERSAZIONE.

AFTER the notices that have appeared in our advertising columns during the last few weeks, it is scarcely necessary to remind our readers of next week's entertainment at South Kensington. Each member of the Society is entitled to a card of admission for himself and a lady. Each Associate and Apprentice of the Society, and each Chemist and Druggist on the Register, may, on application, obtain a card of admission for himself. Cards of admission may be obtained on application to the SECRETARY, at 17, Bloomsbury Square. Some correspondence has reached us in reference to the dress that should be worn on the occasion, but we do not anticipate there will be any such difficulty on that score as to call for special directions. We may, however, state that it will probably be conducive to the comfort of visitors if, on this occasion, they lay aside the conventional "chimney-pot" hats, since the authorities of South Kensington decline to provide for their custody during the evening.

THE BENEVOLENT FUND.

THE publication in this number of the Journal of a list of contributions received towards the Benevolent Fund of the Society affords an opportunity of calling attention to the great inequality that exists in the amounts received from different parts of the kingdom. Of the total sum acknowledged, more than one-third has been contributed from London, which is greatly in excess of the proportion existing between the trade there and in the country.

That this does not altogether arise from indifference on the part of country members, but apparently rather from the absence of organization in many towns, would appear from the fact that while a few small places make a creditable return, some of the largest towns in the kingdom have contributed but a nominal sum. We must also take this opportunity of suggesting that contributions to this Fund, the benefits of which are available to the whole trade, should be very much more general than would appear to be the case, judging from the list of subscriptions which we now publish. Taking the trade in round numbers at ten thousand, the sum subscribed does not represent one shilling a head. This is a subject that might well engage the active attention of the Local Secretaries of the Society.

PROFESSOR BENTLEY will commence his Demonstrations on the parts of plants and the Natural Orders, at the Gardens of the Royal Botanic Society, on Friday morning next, at 8 o'clock. Students must apply to the SECRETARY, 17, Bloomsbury Square, for cards of admission.

MEDICAL PAPYRUS WITH ANCIENT PRESCRIPTIONS.

THE medical papyrus presented to the British Museum by the Royal Institution is about 7 ft. 6 in. long by 7 in. wide. It is unfortunately much mutilated, and has been considerably worm-eaten. The commencement is wanting, but its contents are a series of recipes or modes of cure for different maladies, unaccompanied by any diagnosis or account of the disease itself. The papyrus is written on both sides, and is a palimpsest, and on the endorsement is the commencement of a second series of cures for a malady, the nature of which is not known, but the remedy for which is said to have been miraculously found in an old book discovered in a hole in the wall of a certain temple by a priest. The book so found was written in the days of CHEOPS, the celebrated monarch of the 4th dynasty, and the builder of the great pyramid. The remedy for this malady consisted of incantations and prayers, and no drugs were employed. Other recipes are given for the eyes, both right and left. Amongst the drugs mentioned for some maladies are wax, fat, and incense. One remedy is for a stoppage of hæmorrhage from the head and other parts of the body,—shavings or twigs of acacia, grains of a substance called *kaspr*, to be burnt, also milk, branches of olive, the hair of a cat, and honey. One prescription orders the chapter to be said, and the breast to be rubbed with drops of the water of an animal called *tesh-tesh*, some extract of a material called *matn*, and wax and honey mixed with a preparation called *tart*. Another mixture was a preparation of sycomore and lizards. Fig leaves, gum, and excrementitious matter were also employed, and eked out with prayers and adjurations, but the meanings of the names of many of the substances are as yet not interpreted. This papyrus has not, like that of Berlin, the quantities attached, but many of the recipes date from an early period, as that of AMENOPHIS III. of the 18th dynasty. The papyrus is, however, very remarkable for its mention of these drugs at all, as some of the other medical ones known, as that of Leyden, have prayers and adjurations only.

A SOCIETY has lately been formed under the presidency of Mr. HENRY DEANE, F.L.S., with the title of the South London Microscopical and Natural History Club. It is proposed to hold its meetings monthly, so that by the delivery of lectures and the reading of papers, and occasional excursions into the country, a taste for the study of microscopy, zoology and botany may be developed among the members. It is also hoped eventually that a cabinet and herbarium may be formed, illustrative of the indigenous fauna and flora of East Surrey. The first meeting was held on April 1, at Gloucester Hall, Brixton. The annual subscription is fixed at ten shillings.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

May 3rd, 1871.

MR. HASELDEN, F.L.S., VICE-PRESIDENT, IN THE CHAIR.

Present—Messrs. Abraham, Atherton, Bottle, Bourdas, Carr, Dymond, Edwards, Evans, Groves, Hills, Sandford, Savage and Williams.

The Minutes of the last meeting were read and confirmed.

Mr. Haselden was elected President, in the place of Mr. Sandford, resigned.

It was moved by Mr. Edwards, seconded by Mr. Hills, and

Resolved unanimously—That the best thanks of this Council be given to Mr. George Webb Sandford for the very efficient manner in which he has always conducted the affairs of the Council, and they regret that any circumstance should have arisen to necessitate his retirement from a position so ably filled by him.

The Report of the House Committee was received and adopted.

The Report and recommendations of the Finance Committee were received and adopted.

The Report of the Library, Museum, and Laboratory Committee was received and adopted.

The Annual Report of the Council presented by this Committee, after careful consideration, was agreed to.

The Report of the Parliamentary Committee was received and adopted, and it was

Resolved—That the Registrar be authorized to erase from the Register the name of Catherine Forman, of Glasgow.

POISON REGULATIONS.

The Regulations to be submitted to the Annual Meeting of the Society for *voluntary* adoption, in conformity with the Resolution passed at the last meeting of the Council, were presented by the Committee appointed to revise them, and, with some amendments, were agreed to in the following form:—

1. That in the keeping of poisons each bottle, vessel, box or package containing a poison be labelled with the name of the article, and also with some distinctive mark indicating that it contains poison.

2. Also that in the keeping of poisons, each poison be kept on one or other of the following systems, viz.:—

(*a*) In a bottle or vessel tied over, capped, locked or otherwise secured in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop or dispensary; or

(*b*) In a bottle or vessel rendered distinguishable by touch from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop or dispensary; or

(*c*) In a bottle, vessel, box or package kept in a room or cupboard set apart for dangerous articles.

3. That all liniments, embrocations and lotions containing poison be sent out in bottles rendered distinguishable by touch from ordinary medicine bottles, and that there also be affixed to each such bottle (in addition to the name of the article, and to any particular instructions for its use) a label giving notice that the contents of the bottle are not to be taken internally.

The Report of the Conversazione Committee was received and adopted.

Resolved—That the Registrar's Report presented at the March meeting of the Council be published in the next number of the Journal (6th May), as also the attendances of Council and Committees for the year 1870–71 to the present time.

The Secretary submitted the names of thirty-one Members and two Associates in Business who had tendered their subscriptions subsequent to the 30th April, and it was

Resolved—That they be restored to their former status on payment respectively of a fine of 1*s*., and that the Secretary be authorized to issue to each Member and Associate so restored voting-papers for the ensuing election.

REPORTS OF THE BOARDS OF EXAMINERS.

England.

Sproat, Robert ....Derby.
Stokes, Walter Edward ......Sandgate.
Targett, Charles George......Salisbury.
Thomas, Horace Alfred ......Norwich.

A grant from the Benevolent Fund of £10 was made to an orphan daughter of a late member at Southampton, and also a grant of £10 to the widow of a deceased annuitant.

The Secretary was requested to publish in the Journal a list of contributors to the Benevolent Fund for the current year.

SUBSCRIPTIONS AND DONATIONS TO THE BENEVOLENT FUND FOR 1871.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Twelfth General Meeting of this Association was held at the Royal Institution on Thursday evening, April 27th; the President, Mr. John Abraham, in the chair.

The following donations were announced:—Hooker's 'Student's Flora,' Tyndall 'On Sound,' Naquet's 'Modern Chemistry,' 'The Life and Letters of Faraday,' 2 vols., Tuson's 'Veterinary Pharmacopœia,' Roscoe's 'Spectrum Analysis,' Fresenius's 'Quantitative Analysis' (last edition), Williams's 'Chemical Manipulation,' Prior's 'British Plants,' 'The Homœopathic Pharmacopœia,' Miller's 'Chemistry' (last edition), 3 vols.: from the British Pharmaceutical Conference, Bell and Hills Fund—'Proceedings of the American Pharmaceutical Association at the Eighteenth Annual Meeting, held in Baltimore, September, 1870': from Professor Maisch, of Philadelphia—'The Chicago Pharmacist': from Mr. Ebert, Chicago—'The New York Druggists' Circular': from Mr. Mercer, Montreal—'The Pharmaceutical Journal': from the Society—'Journal of the Liverpool Polytechnic Society': from the Society.

The President informed the members that the Council had felt great difficulty in selecting suitable books for the appropriation of the Bell and Hills Fund, their Library being well supplied with many standard works; they had, therefore, solicited the assistance of Professor Attfield, who had kindly selected and sent down the books on the table. He was sure they would all agree with him that it was a very useful selection, and would prove a valuable addition to the Library, and that they would feel much indebted to Professor Attfield for his kindness. He would remind the members that the Committee of the British Pharmaceutical Conference were enabled to make this handsome donation through the thoughtful liberality of Mr. Thomas Hyde Hills, of London, honorary member of the Association.

Unanimous votes of thanks were voted to the donors for their valuable donations.

The paper for the evening was by Mr. A. Norman Tate, "Some Thoughts on Iron." The Secretary announced that he had received a communication from Mr. Tate, regretting his being compelled unexpectedly to go out of town.

A short discussion arose upon the safe keeping of poisons, after which the members adjourned.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

On Monday, 1st inst., the first of a series of lectures, intended to replace, during the summer months, the classes held throughout the winter, was given at the rooms of the above Society, by Mr. A. J. Caley, subject "The Tests of the Pharmacopœia."

The Lecturer began by stating that it was his intention to go through the reagents alphabetically, and to endeavour to maintain a simplicity in treating the subject which should adapt it to the comprehension of the youngest apprentice amongst them. After enlarging upon the paramount importance of cleanliness during the application of tests, and advising that the strength of the solutions employed should correspond to those ordered in the Pharmacopœia, the lecturer adduced several examples indicating the great care that had been taken in compiling the Pharmacopœia to provide means for the detection of adulteration. He then passed to the consideration of the reagents, explaining their sources and processes of manufacture, the purposes for which they are employed, and methods of application, at the same time noticing the origin of the various adulterants.

The subject was handled in a most able manner, and, being well illustrated by experiments, elicited frequent applause from the audience.

The meeting terminated with the usual vote of thanks.

MEETINGS FOR THE ENSUING WEEK.

Tuesday, May 16. ......*Royal Institution*, at 3 p.m.—"On Force and Energy." By Mr. C. Brooke.

Wednesday, May 17. ...*Pharmaceutical Society of Great Britain*, at 11 a.m. for 12: Annual Meeting. At 8 p.m.: Conversazione at South Kensington Museum.
Society of Arts, at 8 p.m.—"The Utilization of Prison Labour." By Captain E. F. Du Cane, R.E.

Thursday, May 18. ......*Royal Institution*, at 3 p.m.—"On Sound." By Professor Tyndall.
Chemical Society, at 8 p.m.—"On a New Double Salt of Thallium." By R. J. Friswell. "On a New Benzolic Derivative." By D. Armstrong.

Friday, May 19. ....*Royal Institution*, at 9 p.m.
Royal Botanic Society.—"Economic Botany." By Professor Bentley.

Obituary.

At Teignmouth, Devonshire, April 19th, Richard Bayly Cornelius, Pharmaceutical Chemist, aged twenty-seven.

Review.

Chemistry: General, Medical and Pharmaceutical, including the Chemistry of the U.S. Pharmacopœia. By John Attfield, Ph.D., F.C.S., etc. From the second and enlarged English edition. Revised by the Author. Philadelphia: Henry C. Lea. 1871.

We have already had occasion more than once to speak in terms of very high commendation of Professor Attfield's excellent manual. It is therefore a matter of little surprise to us that we are called upon to welcome its reappearance in a new dress from the other side of the Atlantic, notwithstanding that so little approbation is usually accorded by our American brethren to the productions of the old country.

So much success, however, has attended the use of the book in the English School of Pharmacy and generally among the pharmaceutical students of Great Britain, that we venture to predict for it a very wide circulation among the pharmacists of the United States. The general plan of the book we have before described in detail and it is now familiar to the majority of our readers. That plan we still look upon as excellent. We have no faith in any attempts to teach or to learn chemistry otherwise than by experiment, and in Dr. Attfield's Manual experiment is the leading and characteristic feature. Every theoretical conclusion is led up to and supported by a series of experiments, for the most part simple enough to be performed without difficulty by a novice, and requiring the employment of but little special apparatus.

We almost wish the author had thought good to extend and develope a little further the chapter on chemical philosophy, and also some of the theoretical considerations interspersed through his pages. Whilst entertaining all due appreciation of the enormous labour of which every page is witness, in the multitudes of formulæ, notes and references which are to be found therein, we venture to think it would have contributed to elevating the philosophical character of the book, without diminution of its usefulness, if some portions of it had presented less of the character of a dictionary. An earnest student will sometimes, with mistaken diligence, commit masses of this kind of matter to memory, and, as we have before observed, leave off with too large a notion of what he has learned, and too small a conception of what there is yet to acquire. Under the guidance of judicious teachers, however, this is not likely to interfere to any serious extent with the generally valuable qualities of the work.

In this American edition all necessary corrections seem to have been very carefully attended to. The headings of the sections are now in thick type, so as to very greatly facilitate reference. The chemistry of the Preparations and Materia Medica of the United States Pharmacopœia has been introduced side by side with that of the British Pharmacopœia, and evidently every care has been taken to render the book worthy of the reception which we feel sure it will meet with at the hands of the pharmacists of America.

The following journals have been received:—The 'British Medical Journal,' May 6; the 'Medical Times and Gazette,' May 6; the 'Lancet,' May 6; the 'Medical Press and Circular,' May 10; 'Nature,' May 4; the 'Chemical News,' May 5; 'Journal of the Society of Arts,' May 5; 'Gardeners' Chronicle,' May 6; the 'Grocer,' May 6; 'Produce Markets Review,' May 6; the 'English Mechanic,' May 5; 'Food Journal' for May; the 'Practitioner' for May; the 'Canadian Pharmaceutical Journal' for April.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department,* 17, *Bloomsbury Square, W.C., and not to the Publishers.*

[222.]—TINCTURA COLOCYNTHIDIS.—Mr. J. Whitfield sends a further communication on this subject, and, according to his request, we print here the formula given in the last edition of the Prussian Pharmacópœia:—

Colocynth (free from seeds), 8 parts by weight
Star Anise Fruit . . . . 1 part „
Alcohol, sp. gr. ·830 to ·834, 96 parts „
Maccrate for eight days.

[236.]—DISPENSING.—BROMIDE OF POTASSIUM. —In looking over the Journal this morning, my attention was directed to the replies to *J. H. G.'s* inquiries, and I am quite in accord with the Editor as to the British Pharmacopœia dose; but still I think that 80 grains three times daily is excessive, notwithstanding that much larger doses are given in practice than that sanctioned as the maximum of the B. P. I have seen it myself administered in 15 and 20 grain doses thrice daily, but I very much question the practice. Three distinct cases have come under my notice where such doses have produced a feeling as if the interior of the skull was being scraped. However, Dr. Ainstie, in the February number of the *Practitioner*, gives two cases where large doses were given; in the first 90 grains, and in the second 120 grains daily, with decided success. In both cases, smaller doses had been tried without benefit. I should certainly endeavour to communicate with the physician, or learn, if possible, some history of the case, before I should feel justified in dispensing so large a dose.—G. J. G.

[240.]—DISPENSING.—Further communications have been received from Mr. H. H. Pollard, Mr. A. Marshall and Mr. E. Skipper in reference to the prescription ordering sp. lavand.

We have no doubt that in this case the compound tincture was intended by the prescriber.—Ed. Pharm. Journ.

[241.]—WARTS.—"*Omega*" will find a very successful application in commercial chloride of ammonium. The wart should be first moistened with a little water, and then rubbed with a piece of the above, repeating it daily.—L. A. S. A.

[242.]—IODIDE OF STARCH POWDER.—*J. T. B.* will find the following formula serve his purpose:—

℞. Iodine Resublimed gr. xxiv
Sp. Vini Rect. ♏xxiv vel q. s.
Pulv. Amyli Pur. ℥j.

Rub the iodine to powder by means of the spirit; gradually add the starch, and triturate until the mass assumes a uniform colour.—L. A. S. A.

[243.]—HYPOCHLORIDE OF SULPHUR.—In most establishments, I believe a powder prepared in a similar manner to the following would be dispensed for "sulph. hypochlor.":—

"Into a vessel containing a thin layer of 'washed' sulphur let chlorine be passed, until the gas ceases to be absorbed."

The true hypochloride is a volatile liquid, obtained by passing a current of chlorine over "melted" sulphur, and distilling the liquid. This preparation is not so often used in ointments, etc., as the impregnated powder.—J. T. C.

Hypochloride of sulphur is prepared by spreading washed sulphur thinly on the bottom of a wooden box, or other chamber, and passing chlorine gas slowly over it until it ceases to be absorbed.—L. A. S. A.

[*** A more convenient apparatus for working on a small scale would be a wide glass tube.—Ed. Pharm. Journ.]

[244.]—LOVAGE.—*W. Clark* wishes for a recipe for making lovage.

[245.]—CLOVES CORDIAL.—A correspondent asks for a formula for the preparation of cloves cordial.

[246.]—INSECT POWDER.—Can any reader give me a good recipe for a powder to kill insects?—A. P. S.

[247.]—DISPENSING.—To-day the following prescription was brought to be dispensed:—

℞. Ferri et Quinæ Citr. ʒj
Amon. Sesquicarb. ʒij
Sp. Myristicæ ℥ss
Syr. Simpl. ℥ss.

M. A tablespoonful with a tablespoonful of lemon juice in a wineglassful of water effervescing.

Will some of your readers inform me of the best manner to dispense it, and what appearance it should present? I may add that ammonia was spelt with one *m*, and the *m* underlined.—Alfred Marshall.

[*** It seems to us that in this prescription the water was left out. Probably a six-ounce mixture was intended.—Ed. Pharm. Journ.]

[248.]—SIPHON BAROMETER TUBES.—Can any of your correspondents acquaint me with the best method for filling the siphon barometer tubes?—Hydrargyrum.

[249.]—BRILLIANT ELASTIC BOOT VARNISH.—I should be glad if any of your readers could furnish me with a good recipe for the above varnish for patent leather, etc., which can be sponged off.—C. H. H.

[250.]—CRYSTAL VARNISH.—Would you kindly, through the Pharmaceutical Journal, inform "*Indoctus*" how to make a good crystal varnish, such as is used in positive photographs?

Correspondence.

The Forthcoming Election of Council.

Sir,—I have received the enclosed circular from the Honorary Secretary of "The Chemists' Defence Association," Manchester.

No doubt all members of the Pharmaceutical Society have received a similar circular; it puts forward a list of candidates, backed by the Committee, for election, and I must say I consider it a highly objectionable and ill-advised document,—its originators, no doubt well-meaning individuals, attempting a most uncalled-for interference with the free exercise of the elective rights of the Society.

This proceeding is objectionable, because it attempts to create an *imperium in imperio.* It announces the existence of a supervising body, which endeavours to control the governing body of the Society.

It is objectionable because it is impertinent. The Society has never delegated any powers to this Committee, nor asked it to select a list in its behalf—not being appointed by the Society, it has no right to usurp the power of doing so, especially as it does so professedly to prejudge questions,—to warp the judgment and bind the votes of the future Council.

It is objectionable, because there are always a number of undecided men ready to vote for any list rather than to use their independent judgment; doubly so, because these loose voters, being aggregated, are likely to swamp independent ones. It cannot be denied that the candidates named on such a list, if elected, are mere nominees of a clique, and that at any time they could be influenced by a vote of the Committee which put them in.

Unless a counter list be issued this one may be carried, and if a counter one be issued it becomes a question of party spirit, and not as to the best men.

The attempt is therefore most vicious in the sense of unsound and bad, and I trust the Society will not be led by the nose by wire pullers, but will prefer managing its own affairs, electing its own rulers,—men of known capacity and worth,—and then trust its affairs to their hands rather than to that of a Committee whose members, thinking they know better than the Council, are bent upon reforming it according to their own crude and conceited notions.

F. P. Balkwill, M.P.S., F.L.S., etc.

Plymouth, May 4th, 1871.

Sir,—The London and Manchester Defence Associations have united in issuing a circular, in which they recommend to the constituency the names of certain gentlemen for election to the forthcoming Council.

The ground of their selection appears to be the views which these gentlemen are supposed to entertain upon the question of "poison regulations," though as there are those amongst them who voted for the compulsory nature of these regulations, the reason of their choice does not appear very clear. It is a misfortune that associations which have sprung up under special circumstances and for special objects, should attempt to direct events which have a wider significance; because, the compulsory character of these regulations being withdrawn and no ground of opposition to them being left, the claims of the various candidates ought to rest upon a broader basis than that of one question only, the significance of which has now nearly passed away.

It should also be remembered that other questions of importance to the welfare of pharmacy are impending, and that the very men required in the Council, the working members and the men elected as the representatives of provincial pharmacy, are those whom the combined associations would employ the powers given them for other purposes to exclude from its debates. An examination of the statement of attendance of members of the Council on committees shows, that whereas 4 of the Associations' favourites attended in all 25 committees, the 4 gentlemen they seek to keep out of the Council attended 139, as follows:—

Atherton	8	out of	24	meetings.
Brown	2	„	19	„
Mackay	6	„	37	„
Woolley	9	„	31	„
Total	25	„	111	„

Abraham	14	out of	51	meetings.
*Bourdas	50	„	63	„
Dymond	26	„	37	„
Sandford	49	„	80	„
Total	139		231	„

There is one question of the utmost importance that the associations fail to notice, viz. the admission of reporters to, and the publication of, the monthly proceedings of the Council. Had this measure been adopted by the Council a year ago, we should not now be again in the dark as to the sentiments of many members of the Council on other popular questions besides poison regulations; and it is probable that the opposition to these and to the proceedings of the Council in respect of them, would not have proceeded so far or have been so productive of personal recriminations, had the constituency and their representatives, by means of the inevitable criticism of the press, become better acquainted with each other.

Referring to the past action of the Council on the question of the publication of its proceedings, I find that at the meeting of Council, October 6th, 1869, the following resolution was moved by Mr. Dymond and seconded by Mr. Stoddart:—

"That as the universally expressed feeling of the Anniversary Meeting was in favour of the publicity of the proceedings of the Council of the Society, it is expedient that its proceedings be fully reported in the Pharmaceutical Journal, and that reporters desiring to represent other Journals be permitted, at the discretion of the Council, to be present, but that any portion of the proceedings which the Council shall declare to be unsuited for publication shall not be reported."

To this resolution an amendment was moved by Mr. Orridge and seconded by Mr. Squire, the object of which was to postpone and upset the resolution. The following voting then took place (see Journal, Vol. XI. page 255.)

For the Amendment—Messrs. Abraham, Bottle, Bourdas, Deane, Edwards, Haselden, Hills, Ince, Morson, Orridge, Sandford and Squire.

Against the Amendment—Messrs. Brady, Carteighe, Dymond, Savage, Stoddart, Williams.

The motion, was therefore lost, and the amendment retaining the secret sittings carried.

Again I find at the meeting of Council on June 1st, 1870, it was once more moved by Mr. Dymond and seconded by Mr. Stoddart:—

"That it is desirable at the commencement of the new series of the Pharmaceutical Journal, that the proceedings of the Council be more fully reported in that and other Journals, and that, under regulations, reporters be admitted to the meetings of Council."

To this resolution an amendment was again moved, but this time by Mr. Abrahams and seconded by Mr. Edwards, the object of which was to quash the motion. The following voting took place:—

For the Amendment—Messrs. Abraham, Atherton, Bottle, Bourdas, Deane, Edwards, Evans, Groves, Haselden, Hills and Sandford.

Against the Amendment—Messrs. Brady, Brown, Dymond, Reynolds, Savage, Stoddart and Woolley.

The motion was therefore again lost, and the amendment carried.

These facts speak for themselves. Let us hope, at any rate, that the constituency will support those men who have so persistently urged and voted for the publication of the Council's proceedings, and those who show by their attendance on committees a willingness to serve the Society's interests.

Michael John Ellwood.

Leominster, May 8th, 1871.

---

* Our correspondent is here in error. Mr. Bourdas is not a candidate for election.—Ed. Ph. J.

The Poison Regulations.

Sir,—Previous to the Annual General Meeting next week, I wish, with your permission, to say a few words on the above.

Although much has been written on the subject, but little conclusion seems to have been arrived at, beyond losing to the Society one of the best Presidents it ever possessed, and I take leave to say the only sensible man on this subject at the Council table.

The opposition to the Poison Regulations was started and sustained by the very self-same party who opposed the Pharmacy Act in 1866, to wit, the party who are the adherents of the *Chemist and Druggist;* for, all opposition ceasing, that party and its exponent cease also; and it is so far unfortunate, that readers of that periodical are not, as a rule, readers of the Journal, and *vice versâ;* so that there has been no true communion of thought on the subject, and, therefore, no real expression of feeling of the profession in its entirety.

Feeling this I shall, if no one else is found to do so, bring the subject formally before the meeting on the 17th instant, in order that the question may receive a definite answer.

My reasons for deprecating the opposition that has been offered to the enforcement of these regulations are:—

1. That while all admit the necessity of regulations, and actually adopt them, yet, unaccountably enough, some object to them for no discoverable reason except that they are in future to be compulsory.

2. That the proposed regulations, while complying with the order of the Medical Council, and satisfying the public by clauses 1 and 2, virtually make the case our own, and ought to disarm all opposition from our own body by clause 3. For, while it might no doubt, in certain cases, be highly objectionable, if not impracticable, to use peculiar bottles and poison cupboards, yet no one could take the smallest objection to making the poison-containing vessel sensible to the *touch;* the remedy was the easiest conceivable, and applicable alike to bottles, casks and jars.

The turmoil that has arisen on this subject seems to me to be totally unreasonable, and utterly devoid of any sensible objections, equalled only by the disgraceful scene enacted at the General Meeting in May last year, which, with due deference to those who differ from me, I must say, is little calculated to raise a body of men who claim an educational qualification, and who have recently obtained a valuable Act of Parliament, in the esteem of either the medical profession or the public.

The only objection put forward at all worthy the name is, that the restrictions would not apply to medical men, but should they? Have they not, as a matter of fact, quite as much right to dispense their own medicines as to hand them over to the chemist to dispense for them? And does it not, as another fact, pay them better to do so?

I do not consider that the warning our Council received, that they had failed in fulfilling the provision of the Pharmacy Act relating to poisons, had no significance; we went to Parliament for a Bill, and Parliament who had had, be it remembered, the question of poisons before them for years, gave us a Bill, but a Bill having a poison clause; they, of course, not caring a jot for our ideas of vested interest and monopoly, but having simply the welfare of the public at heart.

And having got our Bill, which we did want, but containing a poison clause, which we did not want, what do we do? Why, our utmost to stultify all that the Society has done for the advancement of pharmacy during the last twenty years, by ignoring the most important clause in the Bill, arraying ourselves against the medical men, and showing to the public, by whom we live, that we care less for their safety and welfare than for our own pockets.

The question of poisons having been so prominently introduced, even by the daily papers, we could hardly have done anything that would have told so much in our favour as to have adopted these compulsory regulations.

But, Sir, the not improbable cause of much of the present opposition is, no doubt, to be found in the bad odour of the profession of a pharmacist at the present time; what with dispensing surgeons on the one hand, and co-operative stores on the other, surely the pharmacist is in great tribulation.

Still, that is no reason why he should stumble over a present imaginary grievance and forget the future good, and that good is only to be obtained by union, and a constant endeavour to raise his professional and social status as much as possible, so that when the change for the better does come, he may be in a position to reap the full benefit of it.

Above all, let us avoid even apparent contempt for our new Act, avoid anything tending to an unpleasant collision with the medical profession, and avoid all dissensions among ourselves, or, too late, we may find that Parliament, having given us the power of self-legislation, and seeing us incapable of using that power, ignores all future appeals, and quietly resigns us to the tender mercies of the Medical Council.

John H. Baldock.

Norwood, May 8th, 1871.

The Early Closing Question.

Sir,—Will you again allow me to make a few remarks with regard to "early closing"?

In last week's impression I noticed several letters referring to the one which you so kindly inserted for me, and at the conclusion of which I styled myself "Aspirant to the Major Qualification." Unfortunately, one of the gentlemen who wrote does not see the practicability of making early closing compulsory. I am sure that without compulsion we should only get a few to act up to the mark, as was the case before examinations were made compulsory. I am glad to see that this gentleman, who has passed the Major Examination, does not discountenance the movement altogether; and, I think, if he considers the matter he will see that there is not the slightest chance of the question being discussed by employers; whereas we have a faint hope of the compulsory system being adopted if we can only get the majority in our favour, which, I think, there is little doubt about, as, bearing directly on all, there will be no room to express dissatisfaction. The compulsory movement would be quite as practicable as the law which limits the hours of confinement of milliners and factory girls, also the Compulsory Education Act, both of which may be taken as examples. We know there will always be some persons who will only be too ready to throw cold water on matters of this kind, but we must disregard them, and make *nil desperandum* our motto.

Another thing I wish to mention is "Sunday work." We are too lenient and obliging to persons on Sunday when they come for a pennyworth of cough lozenges or a pound of linseed-meal which they may have forgotten to fetch on Saturday. Now, I ask, why should this be? Why should we be confined to the house for the bad memory and failings of the public? The fact is, that we are so ill-remunerated that we cannot show that independence which would have the desired effect, as may be seen in all other trades. Of course it would not do to send a person away, when we know that our neighbours will only be too pleased to serve them. They should not be served by anybody on Sunday; we could all then show a more independent spirit.

Allow me to say, in conclusion, that once these matters are considered and put into force, the great advantages and benefits derived therefrom will be clearly seen. I am sure if the Council would consider this early-closing question, it would reflect a much greater amount of credit than the most absurd poison question, about which so much has been said, and on which even now no satisfactory results have been arrived at.

I hope with "One who has Passed the Major Examination" the iron may be kept hot by striking.

London, W., May 6th, 1871. T. S. M.

Sir,—I would suggest that there is a difference between *late* and *long* hours. If chemists' assistants were capable of combination for such a purpose, long hours would be doomed. As it is, a little consideration on the part of principals would remove every grievance on this score.

After a five years' apprenticeship, during part of which business hours were from 6.30 A.M. until 10 P.M., and during the remainder from 7 A.M. until 9 P.M., it was, perhaps, natural that I should rebel against long hours. Hence, during an assistantship of twelve years I made it a rule to accept no situation involving more than twelve hours' work per diem, including meal times.

As a principal, circumstances necessitated the keeping of my shop open more than twelve hours a day (though still an hour and a half less than my neighbours); but it is my rule to demand of no one in my employment, whether assistants, apprentices or errand boys, more than twelve hours' work per diem, including meal times. The adoption of the principle of division of labour would meet the requirements of long hours of business (where such are necessary), and the demands of assistants for short hours of work.

May 8th, 1871. JUSTUS.

EXAMINATIONS.

Sir,—Where the shoe pinches it is only reasonable to expect the sufferer to cry out, and, if possible, remove the cause of the evil.

My opinion is that the Modified ought to test the practical capabilities of the candidate, and if (after passing the Modified) a man is not competent to pass the Minor, then I say the Modified Examination is a sham—a mere "delusion and snare."

If the Modified examination is not a guarantee of competence, why have that examination at all? I cannot see why men who have only passed the Modified should not be competent to enter for the Minor. They enjoy the same privileges as regards the dispensing and compounding of medicines as Pharmaceutical Chemists, and yet they are not considered competent to enter even for the Minor. Now, Sir, is not this absurd? Surely, if a man acquits himself to the satisfaction of the Examiners in the Modified, he need not be compelled to undergo a second ordeal by a Preliminary? If so, I repeat, the Modified examination is a mere farce, and no dependence can be placed on it.

Cannot this subject be brought before the Council or the Annual Meeting to be dealt with on its own merits?

There are always certain people in every community who carp at any little privileges they imagine their neighbour enjoys. But take the calm and unprejudiced opinion of our Council, and, I think, I may venture to predict that our request will be granted. By the tone of your article a fortnight ago, I think that you are not altogether against our proposals; and I am sure if you use your influence in our favour, it will go a long way towards furthering our object. We all know the readiness with which the PHARMACEUTICAL JOURNAL takes up arms in any good cause, and I trust we may in this instance reap the benefit of your co-operation. B. S.

Sir,—I think the reply you make to "Sympathetic" exactly meets the case.

If a young man cannot, or will not, qualify himself for the duties devolving upon him in the sphere of life he has chosen, he had better take to another calling where the standard of qualification is lower.

Not one word will I say against a youth having a good amount of education to begin with; and I do not think that any should enter the drug trade without being pretty well up in Latin, Arithmetic, etc. But with regard to those whose education has been neglected, let me say, only "put your shoulder to the wheel,"—adopt for your guidance the motto (affixed to a trade-mark which I frequently see) "Ora et labora," and you need fear nothing.

The writer of this letter entered the drug trade before even the foundation of the Pharmaceutical Society, and therefore no necessity to prepare for meeting an examination existed. He left school at the early age of fourteen to go apprentice, and certainly was not a prodigy in educational acquirements; nor was his career commenced under the most favourable circumstances—apprenticed in a county town, engaged from six in the morning until ten at night, employed two-thirds of the time in powdering, grinding paint, putting up casks of oil, stacking bath-bricks and other abnormal operations of a similar character,—"the pursuit of pharmaceutical knowledge under difficulties" was certainly a marked characteristic of his early experience.

Books on chemistry, pharmacy, etc. were scarce, dear and of very different style to the excellent manuals now so numerous. We had no journals, no schools of pharmacy (even in our largest cities), in fact no help of any sort. At all events I speak of things as I found them.

It is not pleasant to speak of one's own performances, but as the writer's name will not appear to this article, it can serve no purpose of vanity, if he had any. I may, therefore, say that although I have had a hand in teaching many, I have, so far as my own education is concerned, had no help except "self-help."

And yet in the few leisure hours I could steal from a very active life, I managed to acquire a pretty good knowledge of botany, materia medica and elementary chemistry, including qualitative analysis. As for my Latin, although hundreds of prescriptions passed through my hands, I do not remember ever meeting with one I could not translate.

I undertook the management of the laboratory in a large provincial business, where I was able to prepare the various chemicals and pharmaceutical preparations in a most satisfactory manner, and afterwards became senior dispenser and manager of the laboratory at one of the principal London hospitals.

Now, after saying all this, let me enter my sincere protest against the abominable system of late hours, so justly complained of by your various correspondents; it is as iniquitous as it is unnecessary. It is quite time this state of things was altered; the members of the trade have the remedy entirely in their own hands, and if a feeling of fraternity, instead of a spirit of jealousy, did but animate us, there would be no difficulty about the matter.

Wherever classes can be formed and pharmaceutical schools established, by all means let it be done,—let our young men have all the facilities for acquiring knowledge we can place in their way. But whether classes or no classes, with schools or without them, let our would-be students learn this one great truth, that Providence helps those who help themselves.

If the apprentices (in the neglected town) mentioned by "Justice" in your last impression, who have repeatedly failed in passing the Preliminary Examination, did but bear this in mind, they might avoid the risk of failure.

The fact is (I am speaking from every-day experience), the majority of our apprentices and assistants seem to desire to imbibe knowledge in the same way they take their meat and drink, by having it poured down their throat. There are a few noble exceptions, and these are workers, not complainers.

Let the most be made of the system of late hours, which so extensively and almost universally prevails; still, it is a great disgrace to young men who have served an apprenticeship of four or five years in a chemist's shop, to know so little of their business as is the case with far too many of them.

The following may, perhaps, be useful to "Sympathetic" and others. One of the cleverest young men it has been my lot to have in my employ, came to me as an improver at the age of nineteen; and he surprised me wonderfully by stating that he had scarcely ever been to school in his life, having been employed in field labour. At fourteen he went as errand-boy to a chemist; with part of his wages he bought a Latin and English Grammar, and paid a schoolmaster a trifle for giving him occasional lessons in Latin. He was with me two years, at the end of which time I obtained him a situation in a very first-class house, where, at the age of twenty-three, he became resident manager. Since then he has given up the drug trade and is now at college, where he last year obtained the highest number of marks for Greek and Latin, and above the average for Hebrew.

His brother (also an errand boy) followed in his footsteps and succeeded him as manager, where he now remains.

ONE WHO HAS KNOWN THE DRUG TRADE MORE THAN THIRTY YEARS.

Evening Dress.—We have received several letters on this subject, in which our correspondents express their opinion, that it is a duty to the Society, as well as to the fairer element of the Conversazione, that visitors should appear in "evening dress;" and they suggest that any one who may be in doubt as to what that should be had better refer to his tailor.

"*Spes.*"—The Board of Examiners occasionally decide that a candidate may present himself for re-examination in some special subject or subjects in which he has previously failed, but this is a matter quite at their discretion.

"*Chemicus.*"—In the present state of the law, it is not illegal to carry on a business in the manner indicated by you.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. T. S. Pellors, Mr. P. Howman, Mr. J. R. Jackson, C. H. H., F. C. S., T. S. M., J. T. C., J. S. B., M. P. S., T. B., A. Z., H. W. H., "Alpha." "A Country Chemist," "Cantharides" and "Botanist" have not complied with the rule as to anonymous correspondence.

BRISTOL PHARMACOLOGY.

BY W. W. STODDART, F.C.S., F.G.S.

(*Continued from page* 883.)

Nat. Ord. SOLANACEÆ.

This Order of plants is well known for producing the most deadly poisons. In some genera the juice of the plant will be strongly deleterious, while the solids will be nutritious. It is so with the common potato. The water in which the tuber has been boiled and the juice of the shoots and leaves are very noxious, while whole nations use the boiled tuber as a common and wholesome food.

Hyoscyamus niger (Linn.).

This singular plant delights in waste, sandy places, and may be found at Aust, Shirehampton, Hanham and Clevedon.

Its clammy, sticky feel, with an oppressive, disagreeable odour, produces an unfavourable impression on the collector, which is, however, partly removed by its elegant yellow corolla, relieved by dark purple veins.

Authors have been undecided as to whether the biennial and annual plants should be regarded as distinct varieties, or the latter only a more mature growth of the former. Judging from the general anatomy of the plant, and the spectroscopic appearance of the juice, the latter is probably the true state of the case. At all events, the biennial is the only one that ought to be used for making the extract and tincture, both of which are very favourite preparations. One cwt. of the fresh leaves will produce six pounds of extract.

The microspectroscope will immediately decide whether the tincture has been made from the biennial plant. Five dark bands are distinctly seen, which are not visible in that from the annual. They are so well marked that the tinct. hyoscyami is a beautiful object for exhibition on a screen by the electric or oxyhydrogen light.

The Henbane seeds are very pretty objects for the binocular microscope. They are flattened, greyish-green, and marked with small reticulations resembling the balls used by schoolboys made with netted string.

The active properties of the Henbane are supposed to be due to hyoscyamin, an alkaloid existing in the plant as malate.

It in some degree resembles atropine in its action on the system, and has a peculiar soothing, tranquillizing effect, without many of the objectionable qualities of opium.

Hyoscyamin is most readily prepared from the seeds by exhaustion with alcohol and diluted sulphuric acid, when the alkaloid is removed by potassic carbonate and ether.

It crystallizes with difficulty in tufts of acicular crystals. When dry, it is inodorous, but when moistened gives off a tobacco-like odour. It is soluble in water, alcohol, and ether. It is decomposed by caustic alkalies like the alkaloids of all the solanaceous plants, as pointed out by Dr. Garrod, so that preparations of Henbane, Belladonna, Stramonium, or Tobacco should never be prescribed with liq. potassæ. Hyoscyamin is completely precipitated by tincture of iodine.

Solanum Dulcamara (Linn.).

This pretty climbing plant is very common in the hedges and conspicuous in the month of July with its potato-like flowers. The bright yellow pointed anthers project from the purple corolla, each segment of which is marked by two green spots at the base.

Dulcamara owes its active properties to a poisonous alkaloid named solanin ($C_{43}H_{71}NO_{16}$), which abounds in every part of the plant.

A very ready method for obtaining solanin on a small scale for microscopic observation, is to let a potato germinate in a dark cellar, when the etiolated shoots will proceed for a long distance towards the light. On macerating these colourless shoots with very dilute sulphuric acid, solanin may be precipitated from the filtered solution by a little warm ammonia. Care must be taken that the acid used be not too strong, or the alkaloid will be decomposed.

Another very good method is to add lime to the expressed juice of the potato germs, or berries of the Dulcamara, and exhaust the precipitate with alcohol. By evaporating a drop of the solution on a glass slip, very beautiful and characteristic crystals may be obtained. Under a high power they appear as slender, right-angled, four-sided prisms. Solanin is soluble in alcohol, but nearly insoluble in ether and water. With chromic acid a sky-blue colour is produced, with nitric acid a rose-red, and with sulphuric acid an orange-red, passing to a violet.

By the action of dilute hydrochloric and sulphuric acids, solanin is decomposed into solanidin ($C_{25}H_{41}NO$) and glucose.

$$\underbrace{C_{43}H_{71}NO_{16}}_{\text{Solanin.}} + 3H_2O = \underbrace{C_{25}H_{41}NO}_{\text{Solanidin.}} + 3\underbrace{(C_6H_{12}O_6)}_{\text{Glucose.}}.$$

Solanidin differs from solanin by being soluble in ether.

Strong hydrochloric acid converts solanin into another alkaloid, solanicine ($C_{50}H_{78}N_2O$). Zwenger, who was the discoverer, says it is nearly insoluble in alcohol, ether and water. It, however, requires further investigation.

Nat. Ord. SCROPHULARIACEÆ.

Only one of the many genera comprised in this group is employed medicinally, although the Figwort, Mullein and Eyebright were formerly in great request.

Except perhaps the *Mimulus moschatus*, so well known in gardens, every species is devoid of any aromatic flavour.

Digitalis purpurea (Linn.).

This handsome and attractive plant is found wherever the sandstone occurs, as at Brislington, Westbury, Leigh Woods and Ashton.

It derives its name from Digitabulum (a thimble), on account of the shape of its flowers, and was called by an old writer "Thimble-wort."

It was a favourite remedy of Dr. Withering, who largely used it in his own practice, and first drew the attention of physicians to its valuable properties.

> "The rapid pulse it can abate,
> The hectic flush can moderate,
> And blest by Him whose will is fate
> May give a lengthen'd day."

The Foxglove owes its peculiar sedative and diuretic properties to a glucoside, named digitalin

($C_{27}H_{45}O_{15}$). It is white, inodorous, and so intensely bitter that it can be distinctly tasted when dissolved in 200,000 parts of water. It is much more soluble in alcohol and ether.

When sulphuric acid is added to digitalin, it first blackens it and changes it into a brown liquid, afterwards becoming crimson. When this brown liquid is dropped into a small quantity of water it produces a rich green colour.

The dried leaves yield ·78 per cent., the seeds 3 per cent. and the seed-capsules ·3 per cent. of digitalin.

When digitalin is boiled with sulphuric acid, it is converted into glucose and another base, called digitaliretin, ($C_{15}H_{25}O_5$).

$$\underset{\text{Digitalin.}}{C_{27}H_{45}O_{15}} + 2\,H_2O = \underset{\text{Digitaliretin.}}{C_{15}H_{25}O_5} + 2\,(\underset{\text{Glucose.}}{C_6H_{12}O_6}).$$

M. Labourdais says that the digitalin may be removed from the infusion by animal charcoal, from which it may be recovered by means of boiling alcohol.

The Foxglove is said to contain a large number of bases and acids, but further researches are necessary.

ORIENTAL SPICES.

BY JAMES PATON,

Assistant-Keeper in the Museum of Science and Art, Edinburgh.

(Continued from page 902.)

Nutmegs and mace are the products of a tree, *Myristica moschata*, belonging to the Natural Order *Myristicaceæ*. The nutmeg-tree, which is diœcious, having the male or barren flowers on one tree, and the female fertile flowers on another, is described as in appearance somewhat like the clove, though rather loftier, averaging 30 but reaching to 50 feet. The leaves are shaped like those of the pear-tree, but larger and of a beautiful glossy green upper surface, and soft grey below. The fruit is exceedingly like a nectarine or large plum; but furrowed all round instead of on one side only, as in the case of the nectarine. When the fruit is ripe, this furrowed exterior, which is a thick fleshy covering, bursts open and discloses what is undoubtedly the most beautiful fruit in the world. Surrounding an oval nut of a dark coloured glossy surface, are seen the broad veins of mace, an arillus of the brightest vermilion. Within this glossy shell is the nutmeg of commerce, and the vermilion arillus is what we receive as yellow mace. Here is the quaint Sir Thomas Herbert's description of the fruit:—"The nut is clothed with a defensive husk like those of a baser quality, and resembles the thick rind of a walnut, but at full ripeness discovers her naked purity, and the mace chastely entwines (with a vermilion blush) her endeared fruit and sister, which hath a third coat, and both of them breathe out most pleasing smells. The mace in few days (like choice beauties), by the sun's flames, becomes tawny; yet in that complexion best pleases the rustic gatherer."

The nutmeg-trees are in constant bearing,—flowers and fruit in all stages of advancement, being at all times found on the same tree. But in its native haunts, there are three harvests from the tree annually, first in April, when the finest spice is gathered; next in the end of July, producing the largest quantity, and finally in November, which Mr. Crawford says is a supplementary gathering. A good tree yields steadily about 10 lb. of nutmegs and mace; but taking plantations overhead, including male and female trees, the produce will not exceed 4 lb.

The Dutch made the same strenuous efforts to limit the production of nutmegs which they applied to the clove-tree; but with this they had greater difficulty. Originally of somewhat wider distribution, they endeavoured to confine the trees to the three small islands forming the Banda group, and for that purpose organized annual expeditions for the extermination of all other trees. The efforts of two species of pigeon to spread the tree constantly baffled the watchfulness of the Dutchmen. The pigeons swallowed the nutmegs, the mace of which was easy of digestion; but the shell enclosing the nutmeg was too much even for the all-absorbing maws of pigeons; consequently they took their flight to neighbouring shores, and there safely planted the uninjured nutmegs, in defiance of the most stringent and threatening proclamations of the governor-general of the Dutch East Indies.

The Dutch guarded their nutmeg parks in Banda with greater jealousy than did the Hesperides their fabled golden apples. It was not till these islands passed first for a short time into the hands of the French under the first republic, and next into our own possession, till the settlement of the then existing European turmoils, that an opportunity was fairly afforded of attempting the propagation of the valued fruits away from these islands. The difficulty, though long apparently surmounted, has proved more insuperable than in the case of cloves; and it may be said that now no nutmegs are grown, on a commercial scale, beyond the east part of the Archipelago. Under our East India Company the first apparently successful introduction of nutmegs into the Straits settlements took place about the beginning of this century. The company expended great sums on the transport and care of the trees; but in their impatience at the little progress the plants appeared to make, they ordered the plantations to be abandoned or sold. They were handed over to private enterprise, and soon they began to yield productively. The commercial success was immense, and a nutmeg mania seized upon the inhabitants. Everywhere nutmeg-trees were planted; flower-gardens were dug up, and the prized trees, which were with no trouble to heap wealth upon their fortunate possessors, were substituted. The jungle was cleared and planted with nutmegs, and their overshadowing kanary trees, according to the most approved method, when in the height of the planting fever, a sickly yellow patch was seen on the topmost boughs of some of the hitherto flourishing trees. Steadily it descended, and steadily it spread; attacked plants were rooted out, and healthy ones stimulated with manures, yet the blight continued its deadly progress. Plantations were even cleared and renewed, and again the fatal patch appeared, and no power of man was able to stay its progress. A great revulsion then occurred; plantations were abandoned, and the fruit of many healthy trees was left to rot on the ground; the production steadily declined till it has well-nigh ceased; and now amidst the tangled hiding-places of the deadly snake, and the lair of the equally dreaded tiger, may be found many blasted stems, and some yet green and flourishing nutmeg-trees, marking the place where not long ago, with great care and trouble, the precious plants were eagerly tended.

Pepper stands on a somewhat different footing from any of the already noted spices. These are, at most, of the luxuries of this life; pepper we are almost warranted in putting in the higher category of necessities. While the consumption of the first described is chiefly confined to the wealthy and luxurious, and for many causes has been steadily declining, pepper is eagerly sought for by all classes, is in constantly increasing demand, and now of much greater commercial importance than all the rest combined.

Under the generic name pepper, are included the products of more than one species of plant. There is first and chiefly the black pepper plant, *Piper nigrum*, of the Natural Order *Piperaceæ*, from which the common white and black pepper of commerce are derived. Secondly, the long-pepper plant, *Chavica Roxburghii*, allied to and used like the former, but not largely imported to this country. And thirdly, Cayenne pepper, yielded by several species belonging to the *Solanaceæ*, or Deadly Nightshade Order, an Order most important, both for its dietetical and medicinal products.

The common pepper plant is a native of the Malabar or Western Coast of India, where it is found growing wild, and from thence it has long been naturalized in the western islands of the Archipelago, chiefly in Sumatra, and from these localities the supplies of the world are drawn; for though introduced to the West Indies, the product of the west has not been able to compete with that of the east. The pepper plant or vine, as it is called, from its appearance, is a twining plant, growing to a height of 25 feet, with dark green heart-shaped leaves, short brittle branches, and spiked fruit, which is first green, then red, and finally black. Our ordinary black pepper is produced from the berries in their red or not quite ripe state; white pepper, on the other hand, is prepared from the black or ripe seeds, by soaking in water for some days, and peeling off the dark husk. There is a likely enough story that instructions were at one time sent to the East India Company's servants to cultivate the white pepper plant rather than the black, as white pepper always commanded the best market. Two harvests are gathered yearly from the vines, an average yield per plant being scarcely half a pound. The Malabar pepper always commands the highest price in European markets.

We can only name the other spices which have their homes in the far East, and which have at one time or another figured in European commerce. Capsicums or chillies are the fruit of various species of *Capsicum*, and are now cultivated for both spices and pickles in all tropical regions. Singularly, notwithstanding the richness of the Indian Archipelago in rare and delicate spices, it is only the capsicum that is cared for and consumed by the natives. Ginger, turmeric and cardamoms all belong to the Order *Zingiberaceæ*. Ginger is now extensively cultivated in the West Indies and in tropical Africa, as well as in its widely extended native regions in the East. Turmeric, as a spice, we know chiefly through its share in the composition of curry-powders; and cardamoms, though anciently much appreciated by the Greeks and Romans, and still used as a spice in the East, have been by us entirely relegated to the province of a medicine. Various umbelliferous seeds have also always held a place among spices, several of them being peculiar to the East, but of these we may take no note in the meantime.

The following figures represent the imports and estimated value of the spices of 1869 in Britain:—

Cassia, 527,000 lb., value £25,000.
Cinnamon, 2,700,000 lb., value £327,000.*
Pepper, 18,000,000 lb., value £343,000.
Cloves, 4,800,000 lb., value £72,049.
Mace, 76,000 lb., value £10,556.
Nutmegs, 800,000 lb., value £57,000.

(To be continued.)

SOLUTION OF GUAIAC RESIN FOR MEDICINAL USE.†

BY JAMES T. SHINN, OF PHILADELPHIA.

There are two officinal liquid preparations of guaiac, the tincture and ammoniated tincture, both of which are perfect solutions of the drug, but are very disagreeable in taste when given alone, or even when diluted with four or five parts of water. The great desideratum is to find a menstruum which is a good solvent, readily miscible with water and palatable; and, although unsuccessful in this attempt, I will give some results of the experiments made.

Alcohol dissolves all the resinous portion of commercial guaiac, leaving from 20 to 25 per cent. of impurities, chiefly chips of the wood and sand; and the purified guaiac obtained by evaporating the alcohol from this solution is readily dissolved by its weight of that fluid. The officinal tincture (three ounces to a pint), will bear an equal volume of water or syrup and remain clear, and is miscible in any proportion with glycerine and liquor potassæ without producing turbidity.

Thinking a reduction in the amount of spirit might be an advantage, the following formula was tried:—

Take of Purified Guaiac ℥ij
Alcohol f℥iij
Solution of Potash f℥ij
Glycerin f℥xj.

Dissolve the guaiac in the alcohol, and add the solution of potash and glycerin.

This forms a clear and permanent solution, of pleasanter taste than the tincture when given alone, but when mixed with water producing about the same turbidity, and leaving the same acrid taste in the fauces. Glycerin does not mask this acridity so well as sugar, but the substitution of part syrup produced a precipitate of the resin.

Decidedly the most agreeable manner of administering guaiac in liquid form, so far as tried, is that of a syrup prepared as follows:—

Take of Guaiac ℥j
Solution of Potash f℥ss
Sugar ℥xiv
Water sufficient.

Macerate the guaiac in the solution of potash,

---

* Ceylon cinnamon entered at 2*s.* 6*d.* per lb.; cinnamon from other parts at 3*d.* per lb.

† Paper read at the meeting of the American Pharmaceutical Association, in answer to the query, "What is the best and most eligible liquid form for the preparation and administration of guaiac resin?"

mixed with f℥ij of water, for two or three days; then percolate with water till 8 fluid ounces of liquid are obtained, in which dissolve the sugar.

This syrup is quite pleasant to the taste, and can be taken alone or mixed with water; it has been prescribed for several years by Dr. Ludlow, of Philadelphia, with decided benefit in cases of rheumatism, and can be given for a long period without exciting disgust.

The quantity of solution of potash may be doubled without rendering the syrup unpalatable, and thus would increase the amount of guaiac dissolved.—*Proc. Amer. Pharm. Assoc.* 1870.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

GLYCERINUM, $C_3H_8O_3$ or $C_3H_5(HO)_3$.—Glycerine is obtained from fats or fixed oils by one or other of several processes:—

1. In the manufacture of emp. plumbi (q. v.). The aqueous solution, separated from the plaster, is, if necessary, treated with a little sulphuretted hydrogen, to remove from it a small quantity of oxide of lead retained in solution. The precipitated sulphide of lead is removed by subsidence, and the clear liquid evaporated to a syrup.

2. By throwing steam previously heated to about 500° F. into heated fat contained in a boiler a distillate is obtained, which separates on standing into an aqueous solution of pure glycerine and an oily layer consisting of the acids of the fat. (Price's Glycerine.) Suppose stearine to have been the material employed:—

$$\underset{\text{Stearine.}}{C_3H_5 3C_{18}H_{35}O_2} + \underset{\text{Water.}}{3H.HO}$$
$$= \underset{\text{Glycerine.}}{C_3H_5 3HO} + \underset{\text{Stearic acid.}}{3HC_{18}H_{35}O_2}.$$

3. The spent leys from which hard soap has been separated contain a quantity of glycerine. Thus—

$$\underset{\text{Oleine.}}{C_3H_5 3C_{18}H_{33}O_2} + \underset{\text{Hydrate of Sodium.}}{3NaHO}$$
$$= \underset{\text{Glycerine.}}{C_3H_5 3HO} + \underset{\text{Oleate of sodium.}}{3NaC_{18}H_{33}O_2}.$$

This is now recovered in some works by neutralizing the alkaline liquid by an acid, evaporating to a low bulk, and distilling the residue in a current of steam.

Pure glycerine should be colourless and odourless, sp. gr. 1·25 (B.P.). The glycerine of the Pharmacopœia contains a small percentage of water. Much of the glycerine of commerce, particularly the foreign, which is generally made by the lead-plaster process, contains chlorides of sodium and calcium, and will not therefore form a clear mixture with nitrate of silver. Glycerine is readily oxidizable, and is therefore incompatible with such agents as permanganates. It is slightly volatile at the boiling-point of water, but cannot be distilled in the ordinary way without much decomposition, intensely irritating vapours of acrolein being evolved. It may, however, be distilled without change in a current of superheated steam or in a partial vacuum. The vapour of glycerine is inflammable. Glycerine, as shown by the formula $C_3H_5(HO)_3$, is the hydrate of a trivalent radicle. The action of acids upon it gives rise to the formation of salts (of which the fats are examples) analogous to the compound ethers formed from ordinary alcohol,—the difference between them being that, whereas ordinary alcohol is the hydrate of a *uni*valent hydrocarbon, it can form with a monobasic acid only one such compound, as acetic ether, $C_2H_5 . C_2H_3O_2$.

Glycerine, being the hydrate of a *tri*valent hydrocarbon, may form with such an acid as acetic or stearic three different compounds.

Glycerine	$(C_3H_5)'''(HO)_3$.
Glyceryl mono-acetate .	$(C_3H_5)'''(HO)_2C_2H_3O_2$.
„ di-acetate . .	$(C_3H_5)'''(HO)(C_2H_3O_2)_2$.
„ tri-acetate . .	$(C_3H_5)'''(C_2H_3O_2)_3$.
„ mono-stearate.	$(C_3H_5)'''(HO)_2C_{18}H_{35}O_2$.
„ di-stearate . .	$(C_3H_5)'''(HO)(C_{18}H_{35}O_2)_2$.
„ tri-stearate .	$(C_3H_5)'''(C_{18}H_{33}O_2)_3$.
(Common stearine.)	

The relation of glycerine to oil of mustard is interesting. When distilled with biniodide of phosphorus, it yields the iodide of a radicle containing the same elements as glyceryl, but univalent.

$$2C_3H_5 3HO + P_2I_4$$
$$= \underset{\text{Iodide of allyl.}}{2C_3H_5I} + \underset{\text{Phosphorous acid.}}{2PHO(HO)_2} + I_2.$$

And this iodide, digested with sulphocyanide of potassium, yields mustard-oil and iodide of potassium.

$$C_3H_5I + KNCS = KI + \underset{\text{Mustard oil.}}{(C_3H_5)N(CS)''}.$$

HYDRARGYRI IODIDUM RUBRUM.

Four parts of perchloride of mercury are dissolved in boiling distilled water and mixed with five parts of iodide of potassium similarly dissolved. The scarlet precipitate is collected, washed and dried at 212°.

$$HgCl_2 + 2KI = HgI_2 + 2KCl.$$

In the process of precipitating the iodine, a salmon-coloured precipitate is first thrown down; this is a compound of iodide and chloride, which is changed by the further addition of iodide of potassium into pure iodide. An excess of iodide of potassium causes the precipitate to disappear.

It may also be prepared by rubbing together in a mortar mercury and iodine in the proportions represented by the formula.

$$\begin{array}{ccccc} Hg & + & I_2 & = & HgI_2 \\ 200 & + & 127\times 2 & & 454 \end{array}$$

Red iodide of mercury is almost absolutely insoluble in water, but is slightly soluble in alcohol, freely so in ether, and in a solution of iodide of potassium, forming in the last case a double salt, HgI_2KI.

It is also dissolved by hydrochloric acid, common salt, sal ammoniac and by a solution of corrosive sublimate, in which case it gives a double iodo-chloride, $HgI_2 2HgCl_2$.

One of its most curious properties is that of changing into a yellow allotropic modification when heated gently. When sublimed it forms magnificent thin prismatic crystals, which, whilst warm and undisturbed, are yellow, but resume the red colour spontaneously after a time, or immediately on being rubbed.

Specific gravity of vapour

$$\frac{200 + 2(127)}{2} \times \cdot 0693 = 227 \times \cdot 0693 = 15\cdot 73.$$

(See Ether.)

Hydrargyri Iodidum Viride.

200 parts of metallic mercury are triturated with 127 parts of iodine, and the combination is assisted by moistening with a small quantity of spirit, the use of which also prevents the development of heat. In the Pharmacopœia 1 ounce (=437·5 grains) of mercury is employed with 278 grains of iodine; these proportions are almost identical with those given above, which are the numbers theoretically required. The product of the official process is a dull greyish-green powder, which is directed to be dried in a dark room on filtering paper, without heat.

This substance is very liable to variation in properties and composition.

When prepared according to directions, the green powder is a mixture of red or mercuric iodide, mercurous iodide and metallic mercury; combination is incomplete. But when the trituration is continued, mixture becomes yellow, and then assumes the character of true mercurous iodide HgI. It changes in colour upon exposure to light, and when heated so as to cause sublimation, is resolved for the most part into metallic mercury and the red iodide.

YEAST AND OTHER FERMENTS.

BY C. A. WATKINS.

(*Continued from page* 908.)

The action of diastase on starch is so well described in all chemical works which treat of the vegetable products, that it seems strange any one should attribute the conversion of starch into sugar, during germination, to any other cause, without assigning some sound reason. Yet, in a popular book by Dr. Carpenter, on 'Vegetable Physiology,' published a few years ago, he says:—"Starch differs but little from sugar, in chemical composition, except in containing one additional proportion of carbon. When germination commences, oxygen is absorbed by the seed in the substance of which it combines with the carbon that is to be set free from it; and a large quantity of carbonic acid is then given forth again to the air, whilst in the same proportion, the starch is converted into sugar."

This implies that the conversion of the starch into sugar, and the evolution of CO_2 gas in germination, are the results of the same process; but if you will refer to my diagram, you will see that starch does not contain an additional proportion of carbon, as compared with sugar, but that it requires two equivalents of HO to equal it; and that were one or two equivalents of carbon to be oxidized and abstracted, we should not have sugar as the result.

It is a well-known fact that in germination the starch is converted into sugar by the diastase, which is probably formed from the azotized matters by the vital action of the embryo. The oxidation of some of the carbon contained in the seed is more likely to be due to the decomposition of the sugar and other matters by the growth of the embryo, the cells of which appear to me to perform chemical functions similar to some of the fungi, for at this period of its growth it must be remembered the vegetable action is reversed, that it is now living on organic compounds and evolving CO_2 gas; whereas, when it has expanded its leaves to the light and atmosphere, its food must be reduced to simpler forms before it can assimilate it, and it will then construct organic compounds and decompose CO_2 gas, eliminating oxygen.

Malt contains about $\frac{1}{500}$th part of its weight of diastase, and as one part of diastase will convert 2000 parts of starch into sugar, it evidently contains a much larger quantity than is necessary for the conversion of the remaining starch in the grain. This is taken advantage of in various ways by distillers, etc., for the purpose of converting unmalted grain and starch from other sources into sugar.

The action of diastase and other similar soluble ferments is supposed to be instantaneous when the matters on which they act are also made soluble.

As an illustration of this, I will tell you what is done at one of the large distilleries in the North.

Starch and grain are ground into a fine powder and put into a mash tun capable of holding several hundred quarters, and heated till the starch granules burst, and a thick paste is formed. When at the proper temperature, an infusion of malt is run in and agitated, and in about two minutes the whole of this stiff mass becomes perfectly fluid, the starch being at once converted into sugar by the diastase in the infusion.

In the instances of fermentation I have brought to your notice I have shown only the chemical transformations of the matters fermented, these changes resulting in the rearrangement of the atoms or the molecules of which those matters are built up, thereby giving rise to entirely new structures.

The ferments themselves suffer differently, being always reduced to the simplest combinations.

Looking at the result of a fermentation, it would appear that the ferment and the matter fermented did not enter into combination, but that its transformation is due to the force generated in the decomposition of the ferment with which it is in contact. It is, however, clear that the changes which take place in the two substances are collateral, for the same ferment will produce various chemical transformations of a substance according to the phase of its own decomposition. "Thus diastase, when fresh, converts starch into sugar; if kept for a few days, it converts it into gum instead of sugar; while at another period it converts the starch first into sugar, and then transforms it into lactic acid."

Therefore the transformations always depend on, and are relative to, the peculiar changes which take place in the ferment.

The commercial production of vinegar appears to be due to the agency of one or more microscopic organisms, the mass being called the vinegar plant, which, as I have said, is not regarded as a true ferment by chemists, and for this reason: all the ferments proper, such as I have described, produce the transformations entirely within the solutions, receiving nothing from, nor imparting anything thereto; but the conversion of alcohol into vinegar is a case of simple oxidation, in which the oxygen is derived from the atmosphere, each equivalent of alcohol absorbing four equivalents of oxygen to become acetic acid, according to the following formula:—

$$\underset{\text{Alcohol.}}{C_4H_6O_2} + 2O = \underset{\text{Aldehyd.}}{C_4H_4O_2} + \underset{\text{Water.}}{2HO}$$

$$\underset{\text{Aldehyd.}}{C_4H_4O_2} + 2O = \underset{\text{Acetic Acid.}}{C_4H_3O_3} + HO$$

In countries where no duty is imposed on the manufacture of alcohol, it can be made into vinegar cheaply and rapidly. The alcohol diluted with water, and a small quantity of some azotized substance added, is allowed to trickle over beech shavings placed in a vat, so arranged that a current of air circulates freely throughout.

For some days the process goes on very slowly; but the shavings become gradually covered with a slimy fungus, called mother of vinegar, and then acetification proceeds much more rapidly.

Pure dilute alcohol, exposed to the air, undergoes no chemical change, and its conversion into vinegar is undoubtedly due to some complex action of the growth of the fungus on the matters in solution; but the exact chemical operations of this vegetation are unknown.

Since writing the above my attention has been called to some observations on this plant by Mr. Slack (vol. v. p. 2), and published in the 'Microscopical Transactions.' He states, and I have no doubt of the truth of the assertion, that, "If some of the gelatinous portion of the plant be examined with high powers, it will be found to contain millions of minute bodies, resembling bacteria, some of them not exceeding $\frac{1}{16000}$th of an inch in length."

I have recently examined a dilute solution of alcohol, which is being converted into vinegar, and find these bacteria in abundance. They may be seen distinctly when magnified 250 diameters, though a high power must be used to resolve their structure.

The study of these minute organisms, though very uninviting to the general microscopist, would richly reward any patient investigator; for until we know more of the chemical processes which take place in and through them, the subject of putrefactive decomposition must remain a blank, as it is at present.

The vinegar plant and yeast are said to be different conditions of the same vegetation; the Brothers Tulasne have shown us that these lower species of vegetation pass through various phases during their growth, each having previously been considered as a distinct plant; and I see no reason why these minute organisms should not produce different chemical combinations at the different stages of their development, since we see, in the higher order of certain plants, that some of their chemical processes are reversed at points of their existence, namely, during germination, flowering and the ripening of the fruit, when they absorb oxygen and give off carbonic acid to the atmosphere.

In conclusion, allow me to observe that I am fully aware of having written a paper with a very slender knowledge of the microscopic organisms, whose chemical operations I have discussed; therefore I hope those parts which I have left in darkness will now receive the light of your experience and knowledge as microscopists. I am very anxious to obtain information concerning the part which those minute vibriones and bacteria play in nature's economy, for there can be no doubt that those remarkable bodies, appearing everywhere and springing into active existence almost at a moment's notice, must perform some important part in many of the changes which surround us.—*Journal of the Quekett Microscopical Club.*

THE USE OF ANIMAL CHARCOAL FOR THE PURIFICATION OF SACCHARINE SOLUTIONS IN POLARIMETRICAL ANALYSIS.

(*From the French of Dr. Stammer.*)

A certain quantity of animal black, in powder or in grist, is often employed to decolour and purify saccharine solutions intended for polarimetrical analysis. It is true that some chemists avoid this use of char, in which they think they see a cause of error; but it is generally admitted that in these conditions the char does not absorb the sugar, and therefore does not affect the results.

As this opinion does not appear to have been based on special experiment, M. Scheibler, in concert with M. Daunal, undertook a series of researches on the absorption of sugar in the treatment of saccharine solutions by means of char, which have placed beyond doubt the fact of this absorption in such a way as to prevent, henceforth, the use of this method of clarification for exact analysis.

The following tables contain the results of some experiments, in which different sorts of sugar have been used. The proper quantity of these sugars was dissolved in 50 cubic centimetres of water, and purified in the ordinary way by means of acetate of lead (except the samples marked by an asterisk in the table), and first examined in the polariscope. The same solution was then mixed with the quantity of powdered char shown in the third column of the table, and the action prolonged during the time indicated in the fourth column. The filtered solution, decoloured, was polarized afresh, and the proportion absorbed calculated. It is needless to say that every possible precaution was taken to prevent any cause of inaccuracy; consequently, the results are entirely conclusive.

It will be seen that the char absorbed some sugar in every case, and that the quantity absorbed was proportionate to the quantity of char employed.

Some hours' contact sufficed to render the absorption sensible. The previous clarification by acetate of lead, and the degree of purity of the sugars, appear to have had no influence.

TABLE I.—*Absorption of Pure Sugar by Char. Dried to 230° F.*

We must conclude from these results that the use of char in analyses of sugars is not allowable, and that the general opinion on the non-absorption of sugar is erroneous.

[That char will absorb a proportion of sugar is conclusively proved by the above experiments; therefore, in every exact analysis, its use should be avoided, if possible. But, in the analysis of low raw sugar, subacetate of lead will not sufficiently decolour the sugar solution for the disk to be plainly visible through the solution placed in the tube of the polariscope. The use of char is then necessary, but the char will in a short time become saturated with sugar from the solution flowing through it, and, in fact, only that portion which runs through first will be much affected; so that the only precaution necessary is to run off a quantity of the solution through the char, sufficient to saturate it with sugar before filling the tube of the polariscope. That the quantity necessary for saturation may be easily ascertained is shown in the following experiment:—

A solution of pure loaf sugar, of the ordinary density for examination by Soleil's polariscope, was filtered through 130 cubic centimetres of new char of $\frac{16}{20}$ grist.

	Degree of Polarization.
Before filtration	100·
1st 25 c.c. of filtered solution .	88·9
2nd 25 c.c. ,, ,, .	97·9
3rd 25 c.c. ,, ,, .	99·7
4th 25 c.c. ,, ,, .	100·

It will thus be seen that it was needful to run off three times the quantity of sugar solution contained by the tube of the polariscope before the filtered solution gave results unaffected by the absorptive power of char.—Ed. S. C.]—*American Chemist, from the 'Sugar Cane.'*

THE PREPARATION OF FERRIDCYANIDE OF POTASSIUM.

BY WILLIAM T. WENZELL.

Ferridcyanide of potassium is usually prepared by the process of Gmelin, the discoverer of this salt, by passing chlorine slowly into a dilute solution of yellow prussiate of potash, until the liquid ceases to yield a precipitate on the addition of a persalt of iron. The chemical reaction which takes place in this process depends upon chlorine abstracting one equivalent of potassium from two molecules of ferrocyanide of potassium, which coalesce to form one molecule of the ferridcyanide of potassium, chloride of potassium being formed at the same time, as follows:—$2(K_2Cy, FeCy) + Cl = K_3Cy, Fe_2Cy_3 + KCl$.

This process is no doubt one of the best, and when the action of the chlorine can be interrupted in time to prevent the decomposition of a portion of the product into chloride of cyanogen and various secondary compounds, which are known to act injuriously by their presence in preventing, to some extent, the subsequent crystallization of the salt. This loss and inconvenience is avoided, according to Professor Reichardt, of Jena,* by substituting bromine for chlorine, which will prevent the occurrence of the decomposition to which the ferridcyanide is liable by the prolonged action of chlorine. Aside from this advantage, the author recommends his process on the ground of greater facility with which the salt is prepared. The reaction is in every way identical with that of chlorine, the product being ferridcyanide of potassium and bromide of potassium:—$2(K_2Cy, FeCy) + Br = K_3Cy, Fe_2Cy_3 + KBr$. In regard to the economy of a process, which calls for the use of bromine,—an article although of late years greatly reduced in value,—few manufacturers could be induced to adopt such an expensive substitute.

The process which I have used for years, and for which I claim results as advantageous as the bromine process, with the additional desideratum of cheapness, is based on the action of chlorine, which is formed and made to act upon the yellow prussiate *in statu nascenti* during the process. Four equivalents of hydrochloric acid and one of bichromate of potash are made to act upon a boiling solution of ferrocyanide of potassium, with the formation of two equivalents of ferridcyanide of potassium, three of chloride of potassium, one of sesquioxide of chromium, one of water and one of chlorine, as exemplified by the following equation:—

$$4(K_2Cy, FeCy) + KO\,2CrO_3 + 4HCl = 2(K_3Cy, Fe_2Cy_3) + 3KCl + Cr_2O_3, 3HO + HO + Cl.$$

Reduced from equivalent to working quantities, the following formula will give satisfactory results:—

Bichromate of potash, 1 part, by weight.
Ferrocyanide of potassium, cryst., 5·72 parts, by weight.
Muriatic acid, spec. grav. 1·16, 3 parts, by weight.
Water, 60 parts, by weight.

Dissolve the two salts in hot water, add the acid, heat to boiling, continuing the ebullition, replacing the water evaporated during the process until a portion of the filtered liquid is not precipitated on the addition of sesquichloride of iron. When reaction is completed filter the liquid, and wash the hydrated sesquioxide of chromium, unite the liquids, and concentrate to crystallization. If the evaporated liquid possess an acid reaction, the addition of caustic potash, in sufficient quantity to cause a weak alkaline reaction, will greatly facilitate the subsequent crystallization. Generally, there is no difficulty experienced by following these processes if the relative proportions are used in the prescribed equivalent amounts. An excess of muriatic acid should be studiously avoided, inasmuch as an excess will contaminate the solution of red prussiate of potash with sesquichloride of chromium, which will communicate an emerald-green colour, and give a green precipitate of hydrated sesquioxide of chromium on the addition of ammonia.—*The Pharmacist.*

CALIFORNIA CASTOR OIL.

The *Marysville Appeal* has the following account of a recent visit to the castor-oil manufactory of Dr. M'Daniel, situated in Marysville:—"Being a novice in the preparation and pressing of the castor-bean, and the process employed to produce the pure oil, we were surprised at the simplicity of the machinery and everything connected with the *modus operandi.* The beans are first subjected to a dry heat of an hour or so in a furnace. This softens them and brings them to that peculiar state required in expeditious pressing. They are then taken out and placed in a screw-press, run by horse-power, and capable of pressing between 80 and 100 gallons of oil per day. From the press the oil is conveyed into a vessel, and from thence into a large iron tank or boiler. In this is placed 60 gallons of oil and the same amount of water, the latter serving to cleanse the oil of all impurities. The oil is then boiled about an hour, and kept standing until the next morning, when the water is drawn off and the oil transferred to the clarifiers, which are composed of zinc, and capable of holding from 60 to 100 gallons each. After standing about eight hours in the sun, it is taken out and put into cans, and is ready for the market. Beans of a superior quality are worth about $90 per ton, and 100 pounds are supposed to produce 5 gallons of oil."—*Druggists' Circular and Chemical Gazette.*

---

* Dingler's Polytechn. Journal, Dec. 1869.

The Balsam Bog of the Falkland Islands is one of the most singular and interesting plants of the *Umbelliferæ*. *Azorella Selago*, Hf., has a similar habit, covering the ground in Kerguelen's Land, near the sea, with brown masses many feet in extent, and often so soft that the traveller plunges into or through them up to the middle. Like the *Bolax glebaria*, the living part of the plant forms a crust over a vast amount of débris, the decayed or decaying remains of former years' growth, through which the living roots descend into the ground. It is the most abundant plant in Kerguelen's Land. In Fuegia it is much more scarce, occurring only in small tufts on the mountains.—*Gardeners' Chronicle.*

The Ink Plant.—There is a plant in New Granada which if our inkmakers could only grow in sufficient quantity in this country, would prove a fortune to them. The plant in question (*Coriaria mymifolia*) is commonly known as the ink-plant, and the juice is used without any preparation. According to a tradition in the country, its properties were discovered during the Spanish administration. A number of documents which had been sent to the mother country got wetted by the salt water while the vessel was passing round the Cape; those written with common ink became nearly illegible, while those written with "chanchi," as the juice is called, remained unaltered. A decree was therefore issued that all Government communications should in future be written with the vegetable juice. The ink is of a reddish colour when freshly written, becoming perfectly black after a few hours, and does not corrode a steel pen so readily as ordinary ink.—*Nature.*

Boxwood.—At the present day, when the columns of our newspapers teem with advertisements of various preparations for promoting the growth or changing the colour of the hair, the following account of the results of the use of a preparation of boxwood for that purpose may be of interest. Boxwood, according to the old herbalists, was used from a remote period to render the hair auburn; and we are told by Phillips that a young woman in Lower Silesia, whose hair had fallen off after a severe attack of dysentery, was advised to wash her head with a decoction of boxwood, in order to induce it to grow again. This she did; and "hair of a chestnut colour grew on her head, as she was told it would do; but, having used no precaution to secure her face and neck from the lotion, they became covered with red hair to such a degree that she seemed but little different from an ape or a monkey!"—*Nature.*

Cultivation of Tea in the United States.—The American Commissioner of Agriculture reports that tea culture is fast becoming a feature of importance in the western and southern States, and that in a few years enough tea will be grown in those sections to meet the home consumption. The department has sent out to various parts of the country over 50,000 plants, nearly all of which have lived; and it is now distributing seed which came from plants raised in South Carolina.—*Grocer.*

Another Use for Coal Oil.—Samuel Bryant, of Carrollton, Miss., has discovered that petroleum will make the hair grow. The way that he found out this new property of coal oil was simply this: he had a large boil on the bald place on his head, which gave him much pain, and, in the absence of anything else, he rubbed coal oil on it. He says it relieved the pain almost instantly, so he continued to rub on the oil until the boil was entirely well, when, to his surprise, he found a thin coating of hair coming out over the bald place. He continued the use of the oil for a month or two, and now has a heavy coat of hair on his head.—*Democrat, Ballston Spa, N.Y.*

A Deposit of Alum of considerable magnitude has been discovered in the Kuhu valley in Madras, by shepherds. As a rule, the headmen of villages prefer even now not to disclose mineral discoveries.—*Nature.*

CONVERSAZIONE OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

On Wednesday evening, in response to the invitation of the President and Council of the Pharmaceutical Society, a large company of ladies and gentlemen assembled in the South Kensington Museum. The meeting was a most successful one, and the presence of many ladies, who thronged the various courts or listened to the fine selection of music performed by the band of the Grenadier Guards, under the direction of Mr. Dan Godfrey, gave a picturesqueness and charm to the scene which must have added considerably to the pleasure of those who were privileged to witness it. In the Lecture Room, the Orpheus Glee Union, under the leadership of Mr. W. Fielding, sang a selection of glees and madrigals, and here, again, every corner of the room was crowded.

By the courtesy of the authorities at the South Kensington Museum the south court, with the gallery at the end, was for the first time thrown open, the screen which formerly parted off one end of it having been removed.

The company numbered close upon three thousand, and among the visitors present were Lord Bathurst, Lord de L'Isle and Dudley, Sir Walter Stirling, Sir G. Duncan Gibb, Sir John Bowring, Sir Charles Locock, Sir W. Ferguson, Captain Stacpoole, M.P., Dr. J. A. Lush, M.P., and very many eminent medical and scientific men both of this and other countries.

ANNUAL DINNER OF THE MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The First Annual Dinner of this Association was held on Thursday evening, April 27th, 1871, at the Mitre Hotel; the President in the chair; the vice-chair being occupied by Mr. Allcock.

After a few suitable remarks from the President, and the usual loyal toasts, the following were the toasts of the evening:—

"The Success of the Manchester Chemists' Assistants' Association," by the Vice-Chairman; "The Manchester Chemists and Druggists' Association," by Mr. W. Lane; "The Pharmaceutical Society," by Mr. Yeats; "The health of the retiring Officers and Committee," by Mr. Dickinson.

The special health of the Secretary (Mr. B. H. Cowgill) was then proposed for the very great service he had rendered the Association.

The Secretary briefly responded, and thanked the members for the great mark of respect shown to him; he sincerely hoped that on future sessions every success would attend them.

The remainder of the evening was very agreeably spent with music, singing, etc.

A Disease in the Coffee Plant has lately appeared in the coffee plantations of Ceylon, which may prove a serious one. The Rev. M. J. Berkeley, in a communication to the *Gardeners' Chronicle*, says that he has received specimens forwarded by Mr. Thwaites, in which the albumen of the seed (the portion so universally used) has been developed sufficiently to present the usual convoluted appearance; but the growth seems to have been suddenly arrested. In consequence the substance is not perfectly solidified, so that it contracts and acquires a dark dusky tinge, in some cases becoming black. On examination under the microscope, every seed up to a certain point appears normal, nor is there the slightest trace of fungi. Mr. Thwaites attributes the disease, and as Mr. Berkeley thinks, correctly, to sudden changes in the weather, and it is hoped that it will not extend beyond the present season.

The Pharmaceutical Journal.

SATURDAY, MAY 20, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ANNUAL MEETING.

Anticipating the full report of the proceedings of Wednesday, we now place before our readers some of the most important points. The chair was occupied by the newly elected President, Mr. Haselden, who commenced his address by referring briefly to his unanticipated appearance in the Presidential chair; and in alluding to the retirement of Mr. Sandford, eulogized that gentleman's uprightness, ability and patience as President. Speaking of the custom which had obtained with his predecessors of noticing the pharmaceutical novelties of the year, he referred to the importance assumed by hydrate of chloral, but said that the results of scientific research were now so freely published that he who runs may read. The early closing question, which had recently been discussed in the Journal, was one of great difficulty; as a rule what would be practicable with one class of business would not be so with another. With regard to the examinations, he thought that the report made by Dr. Greenhow was very gratifying. Opinions had been expressed that the Preliminary Examination was made too stringent, especially in the Latin, but he could scarcely see how the examination could be made lighter, if it were to be an examination at all, for the pharmaceutical Latin required is only such as should be known by every one behind a chemist's counter. He also expressed a hope that when the subject of the poison regulations came before the meeting, they would bestow upon it that quiet and calm consideration the subject deserved.

The adoption of the Council's report and the financial statement was then moved by Mr. Wiggins and seconded by Mr. Carteighe.

In the discussion that followed, several members called attention to the fact pointed out in this Journal last week, that the subscriptions from some of the large towns to the Benevolent Fund were very trifling, while the names of others were absent from the list altogether. Several suggestions were made; one that a circular should be supplied to the local secretaries by means of which they might canvass their districts, and it seemed to be the general opinion that upon these gentlemen much would depend as to the amount of contributions that would be obtained. Mr. Vizer thought that it would be advantageous to add a separate column to the Calendar, showing the subscription or lack of subscription of each of the members, also that a more frequent publication of donations would be advisable.

This gentleman also mooted another subject that has been alluded to in our columns, the imperfect state of the Register and the absence of any provision for securing notification of any change of address.

Mr. Schacht again brought forward the subject of provincial education, and said that while not wishing in any way to check contributions to the Benevolent Fund, he thought that was not a matter of primary importance for the Society in its corporate capacity. He complained that while £500 had been voted towards that Fund from the general funds of the Society, so little money had been spent in the interest of provincial education.

He also pointed out that while the accommodation for students in the London School is only sufficient for a hundred pupils a year, that is not more than a twentieth part of the number who have to be educated; and, in reference to the complaints that more do not pass the examinations, he declared his opinion that the opportunities for acquiring pharmaceutical knowledge are virtually no greater than they were thirty years ago.

After these and some other remarks which—though relating to matters of deep interest to the Society—took only a subordinate part on this occasion, the resolution was put to the meeting and carried.

The most important feature of the day's business was then introduced by the President, who said, that in reference to the Poison Regulations, he should merely read a letter that had been received from Mr. Simon, and then move the resolution, "That this meeting having considered the recommendations prepared by the Council, desires the Council to propose them for voluntary adoption, but does not desire and does not prescribe them as or to become regulations within the meaning of the Pharmacy Act, 1868."

This resolution was seconded by Mr. I. Bourdas.

An amendment was proposed by Mr. Giles to the effect that, by virtue of the power granted by the Pharmacy Act of 1868, the Pharmaceutical Society of Great Britain prescribed the regulations, and resolved that they be submitted to her Majesty's Privy Council for their consent. He remarked that the occasions were few when a Society should differ with the recommendations of its executive, but the present was one. The Council had yielded, he thought wrongly, their own judgments to an expression of opinion which was informal. He said that the Society was bound to prescribe regulations in accordance with the pledges made in its behalf on the passing of the Pharmacy Act, 1868, and he proceeded to read various extracts from that Act, from leading articles in the Pharmaceutical Journal, and from the debates in the Houses of Paliament,—particularly from the speeches of Mr. Lowe, Mr. Bruce, Lord Granville and Lord Redesdale,—to show that the obligation was generally known and recognized at that time. The consequence of a repudiation of the contract by the Society would be injurious to its influence, and would inevitably lead to inspection by causing the Privy Council to seek further legislation.

Mr. Giles's amendment was seconded by Mr. Baldock, and a long discussion took place, the result of which was, that on division 85 votes were given for the amendment and 104 against it. The resolution moved by the President was then put and carried.

In the course of the discussion which followed Mr. Giles's amendment, some of the speakers took occasion to point out that it had been suggested the meeting was not competent to dispose of the question as to Poison Regulations, because many who were opposed to the compulsory application of those regulations were not present. It is satisfactory to find that this fallacy was not lost sight of, for if it were to be seriously entertained, the performance of the Society's functions might be indefinitely suspended. If the Annual Meeting of the Society be not a representative of the Society in its corporate capacity, it ought to be so; it is the absentees who are in fact responsible and to blame for any unfitness in the acts of the corporate body, or for any disregard of the opinions held by them, and there can scarcely be any more emphatic condemnation of those opinions than absence from the general meetings.

Quite on a par with this idea is the outcry raised against the action of the Society by those who do not belong to it,—who, in the spirit of Uriah Heep, rejoice in calling themselves "outsiders." Several of those who took part in the discussion on Wednesday, expressed opinions quite in accord with our recent remarks on this point; and though Mr. Urwick pleaded the existence of a bar as an excuse for not entering the Society, we were glad to see indications of the opinion that every one practising the art of Pharmacy should be a member of the Society. We fully believe with Mr. Humpage that the more "outsiders" are brought in contact with the Society, the more readily will their prejudices be dispelled, and the more powerfully will the pharmacists of Great Britain be in the position to substitute for mere clamour, a public opinion entitled to respect and able to command it.

At the moment of going to press, we learn that the voting for Members of Council has resulted in the election of Messrs. Atherton, Betty, Brown, Carr, Frazer, Greenish, Haselden, Hills, Mackay, Sandford, Shaw, Smith, Williams and Woolley.

It was announced by the President of the Royal Academy, at the recent annual banquet of that body, that it had been decided to establish a Professorship of Chemistry in connection with the Academy. The object of its institution is to promote the study of the properties of colours, varnishes, etc., so as to ensure as far as possible purity, and, above all, permanency of colour. In the recent exhibition of the ancient masters the fact has been apparent that while many of the old pictures—some of them three or four hundred years old—still retain their original brilliancy and purity of colour, some of those painted within the last fifty years by painters of European renown, have greatly deteriorated. The professor will be required to deliver practical lectures on the properties of colours, which will be open to the students and members, as well as artists generally, who may wish to be present. He will also be expected to give information respecting oil painting and mural decoration to any artist seeking it. In connection with this chair it is intended, as soon as the Government buildings are completed, to erect a laboratory for carrying out experiments with regard to colours.

The following papers, which are copies of the agreements entered into with pharmacists by assistants and apprentices in Hamburg, may be interesting to some of our readers as supplementary to the articles which have recently appeared in this Journal on the practice of pharmacy on the Continent. They may also assist in affording an idea of the relations existing there between assistants and apprentices and their principals.

The documents are signed by the Pharmaceutical Members of the Sanitary Council, and every pharmacist there is obliged to have his assistants or apprentices registered within a month of their engagement.

Obligation of a Pharmaceutical Assistant.

"I, ——, after having been engaged at Mr. ——'s business, promise, upon my honour and conscience, to show due respect and obedience to the Hon. Sanitary Council, especially to their medical and pharmaceutical members, also to my principal as my superior, to dispense all prescriptions without delay, by day or by night, with due attention and care, without the least alteration, not to take one article for another, nor to permit the apprentices to do so; to prepare all chemical or other compounds, according to the legal Codex Medicamentarius, to keep everything properly and clean, to sell drastics, opiates, or poisons only with the knowledge of my principal, or, in his absence, as far as the laws permit me, and, with due precaution, to follow strictly in dispensing the legal tariff, and in retail sales the instruction of my principal; not to allow strangers to read the books in which the prescriptions are entered, to be polite and modest towards everybody, to abstain from all prescribing, not to receive any visitors during business hours, to fulfil all my duties diligently and faithfully, and to act in every respect as an honourable and upright pharmaceutical assistant."

Obligation of a Pharmaceutical Apprentice.

"I, ——, apprentice in Mr. ——'s business, do hereby promise most faithfully to endeavour, to the best of my abilities, honestly and conscientiously to fulfil the obligations I have entered into as a pharmaceutical apprentice, willingly and cheerfully to obey my principal or other superiors, to execute any work intrusted to me with care and cleanliness, in doubtful cases never to follow my own opinion, but always to ask the advice of my principal or of the assistants placed over me; without their permission never to sell emetics or purgatives, drastic or poisonous substances; to behave towards the public with politeness and modesty, not to receive any visitors during business hours, nor to occupy my time with extraneous matters, diligently and carefully to apply the time allowed to me for my own instruction, and thankfully to receive any information; above all to endeavour practically to apply any knowledge acquired, to avoid or to despise no practical work however trifling, and not, as is frequently the case, to any but practical work in favour of scientific study; finally, at all times to behave as may be expected from an honourable and upright pharmaceutical apprentice."

These obligations may appear one-sided, all in favour of the principal, but it must be stated that he has his duties as well; the Sanitary Council has arranged weekly lectures on chemistry, botany, etc. which the assistants are desired, but the apprentices obliged to attend; in like manner weekly botanical excursions are arranged, under the guidance of an experienced botanist, which makes it easy, almost natural for assistants and apprentices to collect their own herbaria, and these scientific instructions are paid for by the Principal as a member of the local Pharmaceutical Society.

According to an estimate in the *Grocer*, the imports of beetroot-sugar in the Clyde during the seven months from September 1, 1870, to March 31, 1871, amounted to nearly 36,000 tons.

The *British Medical Journal* is enabled, from information derived through private and trustworthy sources, to state that Ceylon gives fair promise to take rank at no very distant time as one of the chief quinine-producing countries. Until recently it was thought that the bark of the cinchona plant, as cultivated in that colony, did not yield an appreciable quantity of quinine, but only cinchonine or other of the less valuable medicinal alkaloids; consequently little attention was bestowed on its cultivation. But in a recent analysis of some barks sent to this country, 289 grains of sulphate of quinine, 47 grains of quinidine, and 14 grains of alkaline cinchonine were found in one pound of bark. Thus an ounce of sulphate of quinine was obtained from one pound eight ounces and a quarter. As the supply from Peru has greatly diminished, and as India, it is said, consumes its own quinine, there is reason to believe that the cultivation of cinchona will secure some of the attention of cultivators in Ceylon which has hitherto been almost exclusively devoted to the growth of the coffee plant. As another cause which may give an impetus to the cultivation of cinchona in Ceylon, it is stated that the red bark is highly praised in Paris for tooth-powders, as it gives them a delicate tinge, and, at the same time, a bitter flavour.

A milk-yielding tree, native of the valley of the Amazon, and known as the Maçaranduba or Massaranduba, has lately been introduced to notice in Europe. It is a large tree, and appears to be a species of *Mimusops*, belonging to the Natural Order *Sapotaceæ*. It is abundant in the Amazon valley, in the province of Rio de Janeiro, Pará, Minas Geraes, etc. The wood is hard, as is the case with most of the *Sapotaceæ*, and is used both for ship and house building. The milk is quite white, and flows from the trunk freely upon incisions being made, but hardens on exposure to the air, when it has similar elastic properties to gutta percha and balata. When fresh it is used both medicinally and as an alimentary article, but never in its pure state, being either mixed with a small quantity of water, or used as we use ordinary milk, with coffee or tea.

A prize of £10 and another of £3 are offered by the Royal Horticultural Society for the best two collections of British insects injurious to any one plant, the choice of the plant being left to the collector. The insects are to be shown as much as possible in their various stages of development, and a preference will be given to those collections which most successfully illustrate the life-history of the insect, and exhibit the mischief done, whether by specimens, drawings, models, or other means, examples of which may be seen in the Society's collection in the South Kensington Museum. Two other prizes of £5 and £2 are offered for the best miscellaneous collection illustrating similarly any branch of British economic entomology. The collections are to be sent to Mr. J. Richards, Assistant-Secretary of the Society, on or before the 1st of May, 1872, each collection bearing a motto, and accompanied by a separate sealed envelope with the motto on the outside, and the name of the competitor within.

We regret to say that Mr. Ferdinand Kohn, of whose paper on "The Different Methods of Extracting Sugar from Beetroot and Cane," recently read before the Society of Arts, we this week give an abstract, died, after a few days' illness, on the 2nd inst.

We learn from the *Athenæum* that an Italian Chemical Society has been established, under the auspices of Dr. Canizzaro. The Society will publish a journal under the joint editorship of MM. Schiff, Tassinari, Korner, Paterno and Gabbas.

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

May 12th, 1871.

Present—Messrs. Allchin, Bird, Carteighe, Cracknell, Davenport, Deane, Edwards, Gale, Garle, Haselden and Ince.

MODIFIED EXAMINATION.

Forty-seven Candidates were examined; the following twenty-seven passed, and were declared to be qualified to be registered as

CHEMISTS AND DRUGGISTS.

Archer, James .... Lechlade.
Bowen, Joseph William ...... Holyhead.
Burnham, Henry .... Preston, Yorkshire.
Coates, Henry .... York.
Coates, Richard .... Croydon.
Crackle, William Henry...... Nottingham.
Elliott, William .... Wandsworth.
Fogg, Robert .... Bolton.
Gilliatt, William .... London.
Gray, James Thomas .... Padiham.
Green, John .... New Cross.
Gunn, Daniel .... Paddington.
Hardcastle, William, jun. .... Darlington.
Kay, John Broomhead ...... London.
Oakley, Robert Henry ...... Birkenhead.
Plumb, James Edwin .... Surbiton.
Raw, James Harrison .... Beverley.
Saunders, John .... London.
Spratt, George Uriah .... Boston.
Spyer, Newton .... Watlington.
Steeper, Samuel .... Roughton.
Thomas, Joseph Josiah ...... Ryde.
Wade, Thomas Taylor ...... Cotham, Bristol.
Wakefield, Thomas .... Birmingham.
Willan, James Henry Burton . London.
Williams, James .... London.
Woodcock, Arthur .... London.

The Certificates presented by the undermentioned were received in lieu of the First or Preliminary Examination:—

Bird, Lewis John .... Northampton.
Vidler, William Thomas...... Hendon.

The above should be read as part of the proceedings of the Board of Examiners at the meeting held on April 19th, 1871, see p. 851.

Provincial Transactions.

SUNDERLAND CHEMISTS' ASSOCIATION.

The Annual General Meeting was held on April 3rd, in the Society's Rooms, Fawcett Street; Alderman THOMPSON, President, in the chair.

The Report and Balance Sheet for the past year were read by the SECRETARY, and adopted by the meeting.

"In presenting the Second Annual Report to the Members and Associates, the Council is happy to be able to state that the Society progresses favourably, and during the past year has amply justified the hopes that were entertained of its usefulness and success.

"During the session the rooms at 60, Fawcett Street, have been open nightly for purposes of study, provided with books, contributed by several members, scientific periodicals, the property of the Society, and the materia medica, cabinet, and text-books, presented by Messrs. Evans and Co.

"Lectures have also been delivered by the following gentlemen:—In October, 1870, by Mr. Nicholson, on 'The Progress made in Practical Chemistry during the past year.' In November, by Mr. Sharp, on 'Sulphur, its History, Sources and Properties.' In December, by Mr. Cockburn, on 'Cinchonas and their Alkaloids.' In February, 1871, by Mr. J. Harrison, on 'Heat and its Applications.'

"Various subjects connected with the business have been brought forward for discussion, and the decision of the Society acted on; among others, a petition was sent up to the Council of the Pharmaceutical Society, at the last Annual Meeting, against the Poisons Regulations.

"The Society has also, by a large majority, passed a resolution in favour of steps being taken to extend the exemption from service on juries, now enjoyed by Pharmaceutical Chemists only, to all registered chemists and druggists.

"At the end of this, the second year, the members of the Council venture to hope that the members will give them credit for having done all in their power to promote the welfare of the trade, and that they will bestow the same amount of encouragement and support on their successors as they have upon them."

The Balance Sheet showed an expenditure of £18. 16*s*. 9*d*. and a balance of 2*s*. 9*d*. in the Treasurer's hands.

The following officers were elected for the ensuing year:—W. Thompson, Esq., President; Mr. H. Thompson, Vice-President; Mr. Robinson, Treasurer, and Mr. Nicholson, Secretary. Council:—Messrs. Harrison, Nasbet, Sharpe, Thompson, Lord, Bird, Ritson, Cockburn and Burn.

It was resolved that the Monthly Meetings be held on the first Tuesday in the month, instead of the Monday, as formerly.

That the annual subscription be reduced to 5*s*. for members, and 2*s*. 6*d*. for associates.

That this meeting, "considering that all Chemists and Druggists now require registration, and that they discharge the same duties and incur the same responsibilities as Pharmaceutical Chemists," is of opinion that the exemption from service on juries, now enjoyed by Pharmaceutical Chemists only, ought to be extended to every registered Chemist and Druggist.

That the Council of the Pharmaceutical Society be requested to take steps to secure this object.

Votes of thanks were then passed to the officers and lecturers for the past year.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The First Annual Meeting of this Association was held on Thursday evening, April 20th, 1871, in the Council Room, Mitre Chambers; the President, Mr. W. METCALFE, in the chair.

On rising he reviewed at some length the benefits to be derived from such an Association as their own. He felt happy that they had been so successful during this their first session, as the report which he would call upon the Secretary to read would show; besides the Society being a source of mutual improvement, it had also been a means of creating a more friendly feeling amongst the Assistants and Apprentices of Manchester than had hitherto existed; he then called upon the Secretary to read the report as follows:—

"The Committee, on presenting this their first Annual Report, are happy to be able to congratulate you upon the great success attained by this Association during its first session; since its commencement on November 3rd of last year, 1870, the following papers have been read:—'Water,' by Mr. Miles Atkinson; 'The Alkaloids Morphia, Strychnia and Quinine,' by Mr. Raworth; 'Mercury and its Preparations,' by Mr. J. Hodson; 'Iron and its Preparations,' by Mr. W. Metcalfe; 'Adulteration of Drugs,' by Mr. Nicholson; 'The Examinations of the Pharmaceutical Society and Pharmaceutical Titles,' by Mr. Gill; 'The Materia Medica of the Pharmacopœia,' by Mr. Clark; 'Opium,' by Mr. Lane; 'Metrical System of Weights and Measures,' by Mr. Spencer; 'Medicinal Uses of Vegetables and their Preparations,' by Mr. Binns; 'Vegetable Tissue,' by Mr. Yeats; 'The Proposed Poison Regulations,' by Mr. B. H. Cowgill; 'Concentrated Infusions,' by Mr. Mercer.

"Besides the above, on four occasions, Mr. Clark has examined and explained the nature, etc. of the specimens contained in the cabinets of the Chemists and Druggists' Association. There have also been some very interesting discussions upon 'The Dispensing of Prescriptions,' and the various modes of prescribing adopted by the medical profession.

"On referring to the poison regulations question, we are of opinion that the course to be pursued as decided at the meeting of the Pharmaceutical Council on April 5th, will meet with your entire approval.

"The memorial signed by the members of this Association and other assistants, numbering in all 97, against the passing of any compulsory regulations for the keeping and dispensing of 'poisons,' was presented at the above meeting of the Pharmaceutical Council by Mr. W. S. Brown.

"We are happy to state that in a pecuniary sense our affairs are satisfactory, there being a balance in the hands of the Treasurer of 15*s.* 10*d.*

"On retiring from our office, we unanimously express a wish that this Association may prosper. We are sure that in many ways it has been, and will continue to be most advantageous in point of usefulness, instruction and intercourse."

The report being confirmed, the election of officers and committee for the ensuing year then took place (by ballot), when the following were elected:—

President, Mr. W. Lane; Vice-President, Mr. Allcock; Secretary, Mr. Clark; Treasurer, Mr. Dickinson; Committee, Mr. Cooper, Mr. Harrison, Mr. Headley, Mr. Mercer, Mr. Nicholson, Mr. Tyson.

After a vote of thanks to the retiring officers and committee, the meeting terminated.

DUNDEE CHEMISTS AND DRUGGISTS' ASSOCIATION.

A Meeting of the above Association was held in their room, 71, High Street, on Tuesday evening, May 2nd; Mr. W. Laird, President, in the chair.

The Secretary, Mr. James Russell, presented a collection of drugs from Messrs. Hodgkinson, Stead and Treacher; and also, in the name of Messrs. Evans, Sons and Co., wholesale druggists, Liverpool, one of their cabinets of materia medica, containing upwards of 300 specimens of drugs and chemicals, with descriptive tables.

The President, in accepting the gift, expressed a hope that the Association—particularly the junior members, for whose benefit the gift was especially intended—would largely avail themselves of the advantage that so complete a collection of the articles used in their profession placed within their reach, and moved that a special vote of thanks be sent to the firms, and acknowledgment made in the local and trade journals.

Mr. Jack seconded, and Mr. Doig and others supported the motion, which was carried.

Mr. F. Young presented a copy of 'Barber's Medical Botanical Chart of the World,' the gift of Mr. Charles Kerr, and suggested that the assistants should combine and form a class for the study of materia medica, to which end the chart would be a useful companion to the cabinet, and said that from his own experience of the benefits derived from his attendance at the class for chemistry, conducted by the President during the past two sessions, the time would be well spent.

A collection of crystals, the gift of Mr. Laird, was also exhibited during the evening.

Mr. Ross proposed a vote of thanks to the Chairman, which was cordially carried.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

The Extraction of Sugar from Beetroot and Cane.

At the Meeting of the Society of Arts on the 15th March, Mr. Ferdinand Kohn, C.E., read a paper on the "Different Methods of Extracting Sugar from Beetroot and Cane," of which the following is an abstract:—

The two plants at present principally used in the manufacture of sugar are beetroot and cane. The sugar in both these plants exists dissolved in the juice which is held within the vegetable cells; but the character and composition of the solutions are different in the two kinds of juice. Beetroot juice contains from 7 to 15 per cent. of sugar, a considerable proportion of insoluble and soluble albumen and a quantity of salts, which generally give to it an alkaline character. The cane juice contains insoluble nitrogenous matter, soluble albumen and certain salts; but its reaction is always acid, and its contamination with salts is less in proportion than that of the beetroot. The percentage of sugar in cane juice ranges widely, but may be taken as averaging from 15 to 20 per cent. in that from ripe cane. Cane juice generally contains also a sensible proportion of glucose, different in composition from cane sugar, and incapable of being crystallized in the ordinary processes of sugar manufacture; but beetroot contains only a small percentage of it. The beetroot contains about 96 per cent. of juice and only 4 per cent. of a solid insoluble substance which forms the pulp. The sugar-cane is composed of 90 per cent. of juice, the remaining 10 per cent. being wood-fibre, in the shape of cane-trash or bagasse. The sugar is extracted from these plants by separating the saccharine solution from the surrounding solid masses.

The traditional and most primitive method of extracting the juice from beetroot and cane is by mechanical pressure. By the compression of the raw material the cellular structure of the tissues is destroyed, and the liquid contents of the individual cells forced out from the solid residue. Juice so expressed is consequently charged with the impurities originally contained in the plant, and intermixed with minute fragments of the fibrous solid mass that have been disintegrated by the action of the mechanical force. The beetroot before being exposed to this process of extraction requires to be reduced to a fine pulp by means of a so-called "pulper," or rasp. It generally consists of a double revolving drum fitted with toothed saw blades or scrapers, which being rapidly rotated, effects the disintegration of the roots and converts the mass into a fine soft pulp. The pulp is then placed into woollen bags and subjected to pressure in a powerful hydraulic press, by which process the juice is forced through the meshes of the bags and the solid residue formed into a dry dense cake. In consequence of the imperfect breaking up of the vegetable cells by the action of the rasp, a quantity averaging about 14 per cent. of the juice remains in the residue, which is not sensibly affected by increase or longer duration of the pressure. About another five per cent. of juice, however, may be obtained by the expedient of mixing the water with the pulp in the process of rasping; the water, by the action of endosmosis and exosmosis, effecting a partial extraction of the sugar contained in the unbroken cells.

The extraction of sugar from the cane by the application of pressure in the ordinary roller-mill, is a method defective in several important points, which were well set out by Mr. Henry Bessemer in the specification for a patent of a hydraulic press invented by him twenty years ago. In order to extract the juice by its means the rollers must be set sufficiently close to give a very tight pinch, but not close enough to break up the cane-trash, which would be thereby lessened in value as fuel, or to force out certain other matters with the juice which are prejudicial to it. This uniformity of pressure, in consequence of the variability in the size of the canes and the knots and rind being harder than the other parts, is practically impossible under the present method, and thus a quantity of green wax, chlorophyll and other objectionable matters is expressed from the knots and the rind which should have escaped pressure altogether. The presence of the fragments of cane and of the small pieces of cellular tissue in the juice greatly increases its tendency to fermentation and impedes the process of defecation. Notwithstanding many improvements introduced into the construction of modern sugar mills, the amount of juice obtained by the best of them only averages about 70 per cent. of the weight of the cane. As the theoretical quantity of juice in the cane is 90 per cent., there is about 20 per cent. of juice still left in the cane after undergoing the process of crushing.

If the results of pressure, as applied to beetroot and to cane be considered, the proportion of unexpressed juice in the beetroot, amounting to 9 per cent., compares favourably with the 20 per cent. left in the cane. But the placing of the beetroot pulp into bags, and the proper building up of the piles of bags in the hydraulic press, are operations which take up much time and require considerable skill to perform well. The expense of washing and mending the bags also forms a serious item in the cost. To obviate these disadvantages several methods have been invented.

The first of these in chronological order was designed by M. Schutzenbach for the extraction of the juice by the means of centrifugal force. The beetroot pulp is placed in a cylindrical sieve or perforated drum, which is made to revolve on a vertical spindle at the rate of 1000 or 1200 revolutions a minute, and is enclosed in an outer cylindrical casing. The action of centrifugal force, corresponding to the velocity of the rotation, effects a rapid displacement of the juice, while the solid portion of the pulp is retained in the cylinder. A quantity of water, amounting to about 30 or 40 per cent. of the weight of the pulp, is injected into the turbine, in finely-divided streams, during the operation, for the purpose of assisting the displacement of the juice. By this method, under careful management and supervision, the yield of juice from the beet has reached 88 per cent., while, as compared with the hydraulic press system, the manual labour is greatly reduced, and the expense of the pulp bags is avoided altogether. The centrifugal system has, however, not gained ground on the Continent, principally from its success depending too much upon the skill and care in the working of the turbine; the slightest variation in the quality or quantity of the pulp with which it is charged requiring a scientific readjustment of the quantity of water injected and of the speed of the revolutions.

Another method, invented by the same gentleman, consisted in the pulp undergoing a process of maceration. This was effected by causing water to pass successively through a series of ten or twelve tanks charged with pulp, which were placed so that the juice might drain off from one tank into the next until the last was reached. The process is very economical in the amount of labour required, and is capable of a good yield under careful management.

But this invention is superseded by that of Herr Julius Robert, of Seelowitz, in Austria, one of the most eminent beetroot sugar manufacturers on the Continent, which is a process of diffusion, dispensing entirely with the application of direct mechanical force, and based upon Graham's celebrated discovery of the osmotic properties of organic cells. By it the saccharine matter is extracted from the closed cells without bursting them open. The name of diffusion was given by Graham to a process which takes place when two liquids containing different bodies in solution are separated only by an organic membrane; the liquids mutually exchange their soluble matters and gradually equalize their degree of concentration. There is, however, a great difference in the speed with which this exchange and equalization take place; crystallizable bodies, such as sugar and salts, passing through the organic partition at a quicker rate than non-crystallizable, such as albumen and other nitrogenous compounds. By this property, therefore, the unbroken cells of beetroot or cane immersed in water or weak saccharine solutions are capable of yielding part of their sugar and salts to the surrounding liquid. A slice of beetroot or sugar cane, containing 10 per cent. of sugar in its juice, immersed in an equal weight of water, will gradually part with its saccharine contents until the juice in the cells and the water outside each contain 5 per cent. of sugar. If a fresh slice, containing 10 per cent., be placed in this 5 per cent. solution of sugar, the resulting equalization will produce a solution of $7\frac{1}{2}$ per cent. On the other hand, the partially-exhausted slice, containing 5 per cent. of sugar, will part with $2\frac{1}{2}$ per cent. of it to a fresh supply of water. Thus, by a series of operations, bringing the pure water into contact first with nearly exhausted slices, and then passing the weak saccharine solutions over slices which have parted with a smaller proportion of their sugar, the solution produced may be brought very nearly to the density of the natural juice of the plant; while the slices coming in contact successively with weaker and weaker saccharine solutions, and finally with pure water, give up nearly all their sugar and become completely exhausted. Another advantage resulting from this process is, that in consequence of the difference of speed between the diffusion of sugar and that of the nitrogenous compounds in a given time, which, if sufficient for the proper proportion of sugar and soluble salts to pass into the surrounding liquid, only a small portion of the nitrogenous compounds will be given up; while the insoluble impurities are prevented entirely from leaving the cells of the plant and passing into the diffusion juice. Thus the juice produced by the diffusion process is always purer and less liable to spontaneous decomposition or fermentation than that expressed by mechanical force. This process has been applied to beetroot and to sugar-cane with an equally complete and decided success.

In practically carrying out this system, the beetroots are first washed, and then cut by machinery into slices of about $\frac{1}{4}$ in. or $\frac{3}{8}$ in. in width and thickness, and of a length according to the size of the roots. They are then ready for placing in the diffusion battery. This consists of nine or ten cylindrical vessels, containing slices in different stages of exhaustion and juice of different degrees of density. As each portion of the operation is completed, the solution is conveyed to the vessel containing the slices with the next highest proportion of sugar. Thus in each vessel in turn the slices having the least sugar are brought into contact with fresh water, and are discharged from it with only about $\frac{1}{2}$ per cent. of sugar; while at the other end of the process the rich solution which has passed successively through the other vessels is passed into that containing the fresh slices, and is discharged thence into the clarifying-pan. The exhausted slices are equally valuable as a food for cattle with the pulp from the hydraulic press, but they hold a large surplus of water, which is a drawback when it is necessary to convey them from one place to another. This has been to some extent obviated by submitting them to the action of a hydraulic press, which removes the water without to any great extent expelling the elements of food.

With the sugar-cane the process is very similar, and it has been successfully carried out by a company in Madras. The juice so procured is very pure; it has a bright yellow colour, and gives off but little scum in the clarifier. When the cane is perfectly ripe and in good condition, the diffusion juice requires no filtration through animal charcoal, and may be passed at once into the evaporators and vacuum pans, producing good high-class raw sugar. The diffusion juice, however, contains an excess of about 20 per cent. of water, the cost of evaporating which has to be taken into account. To balance this on the other side, the yield of juice by diffusion (when reduced to the natural density of the juice of the cane) is about 82 per cent. against 70 per cent. obtained by the mill. Moreover, in consequence of its greater purity, a larger proportion of crystallizable sugar is obtained from it, amounting in some cases to 43 per cent. The capital and labour required for the two methods are about the same.

Herr Robert has recently invented a modification of his process by which it is carried on in one vessel. The fresh slices are introduced at the bottom of a single vessel, and gradually carried upwards, the solution as it becomes of greater specific gravity, in consequence of its increased richness in sugar, descending to the bottom, and being drawn off as concentrated juice.

The above processes for sugar extraction are equally applicable for the production of spirits, since the saccharine juice so obtained is easily fermented and rendered fit for distilling.

CHEMICAL SOCIETY.

May 4th.—Dr. Warren de la Rue, F.R.S., Vice-President, in the chair. The following gentlemen were elected Fellows:—R. S. Best, C. S. Cross, W. H. Darling, G. H. Ogston, J. Schweitzer, W. A. Smith. Dr. Völcker delivered a lecture "On the Productive Powers of Soils in Relation to the Loss of Plant Food by Drainage."

The lecturer began by showing the futility of the belief that a soil analysis could reveal whether a land was productive or not. To those who only imperfectly know the teachings of modern agricultural science, it appears very simple to remedy a deficient soil by finding out, through analysis, the wanting constituents, and then to supply them. But this is not so. Not only is it difficult exactly to analyse a soil, but many other conditions besides the composition of a land have to be observed. The state of combination in which the mineral constituents of a land are found, the physical condition of the soil, the presence or absence of some matter injurious to the growth of plants,—all these are as many important points upon which soil analysis throws no light whatever. The lecturer equally opposes the views of those who advocate that in a system of national farming there should be kept up a debtor and creditor account as regards the constituents which are removed from the soil in the crop grown upon it, and the quantity of fertilizing matter restored to it in the shape of manure. The fertility of the soil cannot be maintained, much less increased, if only as much fertilizing constituents were applied to the land as were removed from it in the crops.

Dr. Völcker then discussed the relative values of various mineral salts as manures, quoting in support of his views the results of the classical field experiments of Lawes and Gilbert, and this then led the lecturer to speak of the examination of land-drainage waters. Lawes and Gilbert throughout a long series of experiments on the growth of wheat have experienced a great loss of nitrogen. The amount of nitrogen supplied in the manures was greater than that recovered in the increased produce. It appeared to Dr. Völcker that the nitrogen lost might have passed into the drains. Careful collection of such drainage waters and their analysis proved Dr. Völcker's supposition to be correct. It became clear that in whatever form the nitrogen is applied to the soil, a large proportion of it is carried off chiefly in the form of nitrates.

At all times of the year, but especially during the active period of growth of the crops, nitrates are found in the watery liquid which circulates in the land, whereas ammonia salts are never met in any appreciably large quantities. It may, therefore, be assumed that it is chiefly, if not solely, from the nitrates that the crops build up their nitrogenous organic constituents.

Dr. Völcker's analyses of drainage waters further showed that potash and phosphoric acid, which certainly are the most important mineral constituents for the plant, are almost entirely retained in the soil, whilst the less important, as lime or magnesia or sulphuric acid, pass with greater readiness out of the land.

MEETINGS FOR THE ENSUING WEEK.

Monday May 22. ......*Royal Geographical Society*, at 1 p.m. Anniversary.
Tuesday May 23. ......*Royal Institution*, at 3 p.m.—"Animal Mechanics." By the Rev. Professor Houghton.
Royal Medical and Chirurgical Society, at 8.30 p.m.
Wednesday...*Linnean Society*, at 3 p.m. Annual Meeting.
Thursday May 25. ......*Royal Institution*, at 3 p.m.—"On Sound." By Professor Tyndall.
Royal Society, at 8.30 p.m.
Friday May 26. ....*Royal Institution*, at 8 p.m.
Quekett Club, at 8 p.m.
Saturday ......*Royal Botanic Society*, at 3.45 p.m.

VACANCIES AND APTPOINMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

APPOINTMENT.

Mr. Frederick John Barrett, Pharmaceutical Chemist (late student in the School of Pharmacy), as Dispenser to the South Staffordshire General Hospital, Wolverhampton, in the place of Mr. T. Weaver, resigned.

Parliamentary and Law Proceedings.

Death from Overdose of Chloral Hydrate.

The death of Dr. Bruce, resident surgeon in the Dundee Infirmary, consequent upon an overdose of chloral hydrate, is reported. It appears that Dr. Bruce was suffering much pain from a swollen finger, arising, he thought, from an accidental puncture during a dissection. As the swelling increased, he resorted to doses of chloral hydrate to deaden the pain, and on Monday, the 8th instant, he seems to have taken an extra quantity. He was seen by his colleague, Mr. Moon, to whom he complained of the continued swelling and pain. That gentleman desired an attendant to apply a poultice, and proceeded round the wards. Upon his return, he found Dr. Bruce dead. The deceased gentleman was twenty-seven years of age. He graduated last year, and had held the post in the infirmary but three weeks.

Poisoning by Carbolic Acid.

Dr. Gerrard reports in the *Lancet* a case from Jamaica, in which a sailor was poisoned by carbolic acid. It appeared that the captain kept in a cupboard in his cabin two bottles similar in appearance, but one of them containing rum and the other carbolic acid. It is supposed that the deceased, searching for the rum, drank from the carbolic acid bottle instead, as it was found halfway out of the cupboard, but with the cork in it. When discovered, he was comatose, with contracted pupils and intermittent pulse, stertorous breathing and frothing at the mouth. There was also a peculiar livid appearance about the eyelids, lips and ears. The odour of carbolic acid was present. Medical aid was obtained, but death followed within three-quarters of an hour of the supposed time of his taking the poison. It was said that the deceased, whilst searching for liquor on a previous voyage, had swallowed some lamp-oil in mistake for rum.

A Large Dose of Chloral Hydrate.

As illustrating the variable effects of this drug, a correspondent of the *Lancet* mentions a case where a patient saved up five draughts, each containing twenty-five grains of chloral hydrate, for the purpose of committing suicide. He found her just woke from a very deep sleep in an excited state, crying and complaining of great pain at the heart. Knowing that she was addicted to drink, and being told that she had taken more than half a bottle of brandy besides other liquor, he attributed her state to that cause. Afterwards, however, she confessed to having taken the five draughts, making a dose of 125 grains. The next morning, with the exception of being unable to sleep or take food, and the pulse being irregular, she seemed as usual.

Obituary.

SIR JOHN FREDERICK WILLIAM HERSCHEL, BART.

On Thursday, the 11th instant, a man whose name has been for the greater portion of the present century honourably associated with those of the pioneers of science, passed away. The announcement of the death on that day of Sir John Frederick William Herschel, Bart., chronicles the last stage of a long life spent in active scientific investigation, which resulted in discoveries that have added considerably to the stores of human knowledge.

John Herschel was born in 1792 at Slough, where his father, Sir William Herschel, had just previously completed the erection of his forty-foot telescope, at that time looked upon as one of the marvels of the day. Being the only child in the house, and continually surrounded by the appliances for astronomical study, it is not surprising that he early displayed a love for natural philosophy; the inherent mathematical powers of his mind being developed under the most favourable circumstances.

His early education he received from a private tutor. At Cambridge, where he entered St. John's College, he was senior wrangler and Smith's prizeman in 1813. The same year he published his first work, 'A Collection of Examples of the Application of the Calculus to Finite Differences.' His father's great discovery of the motion of the binary stars seems to have produced a powerful impression on his mind, and in 1816 he commenced to examine and catalogue the nebulæ and clusters of stars. This work was continued by him—part of the time in conjunction with the late Sir James South—until 1830, the results being recorded in the Philosophical Transactions and the Memoirs of the Astronomical Society; the importance of the services being recognized by the award to him of the astronomical prize of the French Academy of Sciences and the gold medal of the Astronomical Society. In 1822 he published a treatise on the absorption of light by coloured media; another, on Sound, was also supplied by him to the 'Encyclopædia Metropolitana.' In 1830 his Preliminary Discourse on the Study of Natural Philosophy appeared in 'Lardner's Cabinet Cyclopædia,' and caused a considerable amount of discussion. Although it has not taken the rank which its admirers at first claimed for it, it gives abundant proofs of the writer's eloquence and learning.

Being dissatisfied with the small amount of time during which our changeable climate allowed of the use of the telescope, and being desirous of making a survey of the southern heavens, he, in November, 1833, left England for the Cape, and fixed his residence in the neighbourhood of Table Bay. There he set up his instruments, and for four years devoted his energies to the work he had proposed for himself. At the end of that time he returned to England. The scientific world had watched with great interest his proceedings in connection with this visit to the Cape, and upon his return the public approbation was manifested in the liveliest manner. He was entertained at a great public dinner in London, and the Government of the day offered to reimburse him all the expenses of the expedition, a proposition that he disinterestedly declined. He had previously received from King William IV. the Guelphic order of Knighthood, and on the occasion of the coronation of Queen Victoria he was made a baronet. The presidency of the Royal Society having become vacant by the resignation of the Duke of Sussex, it was proposed to elect Herschel to the honourable office, and, but for his declining to stand, he would probably have been chosen. In 1842 he was elected Lord Rector of Marischal College, Aberdeen, and in 1848 he became president of the Royal Astronomical Society. In 1850 he was appointed to the Mastership of the Mint, a post which he resigned in 1855, when he was succeeded by the late Professor Graham.

Sir John Herschel's scientific acquirements were not limited to the particular branch of astronomy with which his name is more generally connected. He also made some original researches in optics, and was an accomplished chemist and electrician. We do not propose here to give a complete list of his writings, nor of the honours which he received from many other countries. But we would mention the peculiar charm with which he contrived to invest somewhat abstruse subjects, and the successful manner in which he popularized scientific teaching. After his retirement he still occasionally used his pen in the service of the public, and within the last two or three years he contributed to 'Good Words' a series of popular articles on the wonders of the universe.

At the request of many eminent scientific men, Sir John Herschel was buried in Westminster Abbey, on Friday, the 19th instant.

Sir John Herschel married in 1829 Margaret Brodie, daughter of the Rev. Dr. Alexander Stewart, by whom he had nine daughters and three sons. He is succeeded in the title by his son Mr. William Herschel, of the Bengal Civil Service, who was born in 1833.

JAMES YATES, F.R.S.

We regret to have to announce the death of Mr. James Yates, M.A., F.R.S., which took place at his residence, Lauderdale House, Highgate, on the 7th inst. Although better known of late years as the chief and liberal promoter of the International Association for the introduction of the Metric System of Weights and Measures into this country, he was distinguished by his classical and scientific attainments. His learning was not only very extensive, but profound and accurate, and he contributed largely to several classical and archæological works. He always took an active interest in the proceedings of the Royal Society. He was also an influential member of the Geological Society, and of other learned and scientific bodies.

Review.

Commentar zur österreichischen Pharmacopœ, ein Handbuch für Apotheker, Sanitätsbeamte und Aerzte, mit Rücksicht auf die wichtigsten Pharmacopœen des Auslandes. By F. C. Schneider, Professor at the Imperial Josephinum, and Dr. Aug. Vogl, Lecturer at the Vienna University. 3 vols.; 2nd edition. Vienna: Manz'sche Buchhandlung.

This is a capital book, every page of which bears witness not only that the authors are fully at home in the matters they treat of, but also that they have the rare gift of communicating their information in a lucid and attractive manner. The student is carried along from one subject to the next, seldom without gaining some new and useful information; he soon learns to handle the book as a reference on any subject connected with practical or theoretical pharmacy, and will not readily lay it aside.

The authors have divided their labour in such manner that Dr. Vogl has, in the first volume, worked out pharmacognosy, and Dr. Schneider, in the second volume, treats the chemico-pharmaceutical part; whereas the third volume contains a German translation of the Latin sixth edition of the Austrian Pharmacopœia, with many additional remarks and references to foreign Pharmacopœias.

The first volume, on pharmacognosy, by Dr. Vogl, is divided into a general part, treating of methods of microscopical investigations, and of the origin and condition of vegetable drugs, the collecting, drying and storing of the same; and a special part, classifying the drugs according to their origin, from the vegetable, animal, or mineral kingdom. Those derived from the first source are of course vastly predominant, and they again are grouped under three divisions, viz. :—

Plants or parts of plants, directly recognized as such.

Vegetable substances, the organic structure of which can be recognized only by the microscope.

Vegetable substances without organic structure.

There are, of course, many subdivisions, botanically arranged, which we cannot enter into just now, but the principal classification will at once show the scientific character the author imparts to his book. He does full justice to the botanical, chemical and physical characteristics of the different articles, their adulteration, etc., but above all, and wherever possible, he calls in the aid of the microscope, either to bring out new characteristics or to strengthen those hitherto known. He dwells so strongly on the value of microscopical investigations that we must give his own words in the preface.

The microscope, he says, opens up to us the structural relation of organized parts; not only does it present to us a clear view of the manner in which primary organisms combine into membranes, and how these, in wonderful variety, build up vegetable substances, but it also affords us an insight into the workshop and habitation of the products resulting from the processes of vegetable life.

By placing the structure of drugs before us, the microscope collects for us a series of characteristics, which, because not changeable, are highly valuable for the recognition and distinction of substances which defy other means of inquiry. And further, while obtaining a clear representation of the distribution of the active principles in the different parts of plants, we may often form an opinion of the quality of a substance, or obtain information in regard to the most suitable season for collecting, or the best manner of preparing and storing different vegetable remedies.

The author has most carefully studied the characteristic elementary construction of the plants, he has recorded the results of many micro-chemical investigations, often illustrated by capital woodcuts from original drawings, which assist in distinguishing in a simple manner many officinal herbs, even in powder, such as belladonna, hyoscyamus, digitalis, senna, etc.

The general part opens with a detailed description of the microscope, aided by clear woodcuts, and often containing good practical advice. For instance, it is often of great advantage to sketch the object under the microscope, *i. e.* to reproduce the microscopic view as accurately as possible. Many forms of apparatus, often very expensive, have been constructed for this purpose: the glass prism, the camera lucida, Soemmering's mirror; but they may all be dispensed with by acquiring the "double sight." If we look with one eye into the microscope, and with the other on a sheet of white paper placed at the side of the instrument, the sight with the picture of the object will be projected into the other eye, and with steadiness of the eyes the outlines of the picture may be drawn very accurately.

Under preparation of objects, the difficulty of getting fine sections of small or thin substances, such as leaves, is overcome by cutting a cork in two, placing the leaf between the two halves, and binding them firmly together with a string; it is easy to cut off thin slices of the cork, and each will carry a very thin slice of the leafwith it.

We are much tempted to follow Dr. Vogl's details of micro-chemical reagents, but we will only quote the application of colouring matters.

Organic compounds are divided into two classes, those which take up colouring matter, and those which do not do so. The first class comprises albuminous compounds, tannin, certain alkaloids, etc.; the second cellulose, starch, gum, etc.; but the latter by being permeated by the members of the first group, acquire the quality of taking up colouring-matter, either directly or after treatment with mordants, caustic lye, sulphuric acid, alum.

The coloration brings out certain structural arrangements, otherwise indistinct or invisible; the gradation in colour separates whole parts of membranes more completely than in the colourless state, and the presence or absence of colour, indicates the presence or absence of certain substances, their locality, and to a certain extent even their relative proportion.

We next come to an exhaustive treaty on cells, cell-membranes and their contents, which are described as under starch, inulin, sugar and dextrine, gum and mucilaginous matter, tannin, protein, fat, essential oils and resins, colouring matter, alkaloids, crystals (acid, alkaline or neutral salts), gases. This part is richly illustrated by wonderfully clear woodcuts; it is almost a book within a book.

The last division of the general or introductory part speaks of the origin and condition of vegetable substances, and it is perhaps more important to the German reader, because in Germany many plants or parts of plants which have been excluded from our Pharmacopœia, are still officinal, and also because German pharmacists, wherever possible, collect herbs, flowers, roots and seeds when fresh, and dry them, and store their supply from year to year. As the amount of active principle in the plants—and hence their medicinal value—is greatly influenced not only by cultivation, by the season, the climate and the soil, but also afterwards by the drying, preparing and storing, all these different considerations are fully gone into and carefully described.

The work is so rich in a variety of matters, that it is impossible to do justice to the authors in a single article; and as the readers of the Journal will not be disinclined to have before them a more detailed exposition of the advanced and earnest manner in which pharmacy is taught and treated on the Continent, we purpose giving a series of extracts from this last and valuable addition to pharmaceutical literature.

A New Wellingtonea Gigantea, forty feet four inches in diameter, which exceeds by seven feet the largest previously known, has been discovered near Visalia, in Southern California. A section of one of these trees is now being exhibited in Cincinnati, which is seventy-six feet in circumference and fourteen feet high. It was cut last year about two hundred and fifty miles south-east of San Francisco, far up the western slope of the Sierra Nevado mountains, and was carried on three waggons drawn by seventeen yoke of cattle.—*Nature.*

The following journals have been received:—The 'British Medical Journal,' May 13; the 'Medical Times and Gazette,' May 13; the 'Lancet,' May 13; the 'Medical Press and Circular,' May 17; 'Nature,' May 11; the 'Chemical News,' May 12; 'Gardeners' Chronicle,' May 13; 'Journal of the Society of Arts,' May 12; the 'Grocer,' May 13; 'Produce Markets Review,' May 13; the 'English Mechanic,' May 12; the 'Chemist and Druggist,' May 15; 'Journal de Pharmacie et de Chimie' for November and December; the 'American Journal of Pharmacy' for May; the 'New York Druggists' Circular' for May; the 'Photographic Journal,' May 16; the 'Brewers' Guardian,' May 15.

Notes and Queries.

⁂ *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department, 17, Bloomsbury Square, W.C., and not to the Publishers.*

[227.]—PREPARATION OF POMADES.—Not having seen any reply to the inquiries of your correspondent "*Moelline*," of the 22nd ult., I think I may venture to suggest to him to use less solid matter in the preparation of his pomades, and to have his bottles just warmed through, and the pomade just beginning to set before pouring in. At this season of the year I find 2 oz. of genuine beeswax is sufficient for 1¼ lb. of oil for solid pomade; in winter, 1¾ oz. is sufficient.

For crystalline pomade, "*Moelline*" will find 2½ oz. spermaceti sufficient for 1 lb. of oil in summer, and 2¼ oz. in winter.—W. PARRINGTON.

[231.]—BEETLE POWDER.—The recommendation of the *New York Druggists' Circular* of borax as a cockroach exterminator has been going the round of the papers to such an extent as to create a popular demand for the article for this purpose. I should like to know how it is to be applied, for it seems to me that nothing short of subcutaneous exhibition will suffice. It is recommended to be sprinkled in their haunts, but there must be some magic in "putting the salt on their tails," for I have nearly smothered them with borax, and kept them for seven days in a glass; but I might as well have subjected them to the pope's anathema, for "none of them seemed a penny the worse," but they were as brisk and lively at the end of the saline treatment as at the beginning. The experience of some housekeepers would lead to the opinion that what is poison at one period is food at another. Can any entomological correspondent explain?—HENRY H. POLLARD.

Powdered borax is a delusion and a snare as a poison for my blackbeetles. A quarter of a pound has been expended for their benefit, not mine; for they have eaten it all up, and are more numerous than ever.—J. B.

[241.]—WARTS.—If "*Omega*" has tried caustic and acetic acid, and failed, let him try liq. potassæ or Lugol's caustic solution of iodine.—J. B.

[242.]—IODIDE OF STARCH.—
Iodi gr. xxiv
P. Amyli ℥j.

Triturate the iodine with a little water; add the starch gradually, and continue the trituration till the compound is of a deep and uniform colour. Dose, ʒss to ʒij.—J. B.

[251.]—INKSTAINS.—Would any one favour me with a recipe for taking out inkstains?—QUERIST.

[252.]—DISPENSING.—Would any reader kindly inform me the best way of dispensing the following recipe?—

℞. Zinci Sulphatis ℈ij
Cupri Sulphatis gr. x
Mucilaginis Acaciæ ℥iv
Tr. Ferri Muriatis ʒiv
Aquæ ℥xij.

Mft. Injectio ℥ss ter die interdum.—ALPHA.

[253.]—ESSENCE OF RATAFIA.—What is the strength ess. ratafia is usually sold? I have been for some years in the habit of selling it in the proportion of 1 part essential oil to 7 parts s. v. r. (or sixteen times the strength of the formula given in the Journal of the 22nd April); and, as I think a uniformity in this article very desirable, it may be useful to have the opinions of our brethren through your "Notes and Queries" column.—AMYGDALA.

[254.]—ACIDULATED GINGER SYRUP.—Will any reader oblige with a form for making acidulated ginger syrup for aerated gingerade that will not exhibit flocculence after being bottled one or two months?—M. P. S.

[255.]—LIQUID GLUE.—*T. C. L.* would be glad if any reader could inform him what adhesive substance is used for joining cardboard or willow boxes together; something that sets hard directly.

COPAIBA JELLY.—At a clinical lecture delivered by Mr. Berkeley Hill, in University College Hospital, he exhibited a new preparation of copaiba in the form of a jelly, which he said was taken by his patients readily. It was bright and almost as firm as calf's-foot jelly, very attractive by its rosy-red colour to the eye, and not repulsive to the palate, its flavour being masked by peppermint. It contained 50 per cent. of copaiba. A piece as large as a filbert, rolled in wafer-paper, might be swallowed without being tasted at all. The after effects of nausea, diarrhœa, etc. are not more than, if so frequent as, from other preparations of copaiba. The specimen had been prepared by Mr. Martindale, dispenser to the hospital, according to the following formula, which was an improvement made by him upon the original one:—

Take of Thick Copaiba ℥viij
Powdered Sugar ℥iv
Honey (not crystallized) ℥iv
Distilled Water ℥v
Oil of Peppermint ʒj
Roseine (dissolved in ♏xx water) $\frac{1}{15}$ gr.

Put the honey, sugar, copaiba and water into an evaporating dish. Keeping it well stirred, heat the mixture gently till it boils, and continue the agitation and ebullition about five minutes. In the first part of the operation two distinct strata are formed,—the upper, the copaiba; the lower, the honey, etc. As the water is evaporated, numerous bubbles of steam are given off, just as the whole becomes a homogeneous jelly. When it has partly cooled, stir in the roseine and oil of peppermint. When well made, it should resemble raspberry jelly. Should this very minute quantity of roseine (one of the aniline pigments) be objected to, an ammoniacal solution of carmine gives a very good colour.—*Lancet.*

OIL OF SANDAL-WOOD.—The following formula for the administration of oil of sandal-wood is suggested by Dr. Henderson:—

Oil of Sandal-wood ℥j
Rectified Spirits of Wine ℥ij
Oil of Cinnamon ♏xxv.

Dose, one or two drachms three times a day.—*Lancet.*

ZINC WATER TANK.—M. Zinrek reports in the *Lyon Médical* the results of examinations of water that had been kept for a long time in zinc tanks. He found that the water dissolved the zinc in proportion to the chlorides it contained, and the length of time during which it was in contact. Boiling does not precipitate the zinc from water charged with it. In a sample of water, containing a small proportion of chlorides, but which had been a long time in a zinc-tank, as much as fifteen grains of zinc was found in each quart. To prevent this state of things, the author recommends that zinc tanks be coated inside with an oil paint of which ochre or asphalte forms the basis. No minium, ceruse, or carbonate of zinc should be used. Fifteen grains in a quart seems an enormous proportion, nor does the author say whether he found the actual metal or a salt of oxide of zinc.—*Lancet.*

ANHYDROUS GLYCERINE.—M. Eberhard has called attention to the power possessed by absolutely anhydrous glycerine of withdrawing water by an exosmotic process from tissues to which it is applied. Marion Sims some time ago demonstrated that a ball of lint dipped in glycerine and applied to a freely suppurating surface arrests the secretion. Fürst has also applied the glycerine plug in a large number of cases of fluor albus, and M. Eberhard states that he has been very successful in applying the same means in similar cases.—*Practitioner.*

GLYCEROLE OF IODINE.—This preparation, recommended for loss of the voice, is composed of a solution of 16 grains of iodine in 1 oz. of inodorous glycerine.—*Medical Record.*

Correspondence.

Early Closing.

Sir,—I am happy to find that the importance of early closing to pharmaceutical students has been commented upon in your columns, and I think that if it were thoroughly investigated by the Council, the desired issue would be obtained. I have often wondered why drapers, grocers, etc., could close at an early hour, merely to give their young men an opportunity of enjoying themselves after their day's toil, whilst chemists cannot entertain the idea, although it would only afford those facilities for study which might be reasonably expected from an employer, especially during apprenticeship.

I quite agree with T. S. M. that compulsion is the only means by which early closing could be carried out effectually. The jealousy generally existing between pharmacists prevents anything being settled amicably by them. Like the dog in the manger, if they cannot derive any good from it themselves, they all take good care that no one else does.

Milford, May 15th, 1871. Filix.

Some Abuses.

Sir,—The ethical code of pharmacy dates even before the formation of the Pharmaceutical Society, and when Mr. Ince indited his well-meaning paper pharmaceutical ethics were practically a long stride ahead of what he apparently wished to inculcate. That a pharmacist be a gentleman is now generally admitted, the examinations proving an ordinary collegiate education without the special technical instruction required before obtaining the diploma. Jacob Bell, the founder of the Society, could never have wished that *in statu quo* in the matter of pharmaceutical progress that has characterized pharmacy since his lamented demise.

We require, as pharmacists, the respect, not only of the public, but of the medical profession. But very few of our craft are aware of the contemptuous manner in which the majority of doctors are in the habit of depicting to their patients our supposed contumacious, ignorant and unauthorized acts. That some enlightened, liberal and generous intellects would scorn so to do I am fully aware and gladly admit, but they unfortunately are the exceptions that prove the rule.

How many country surgeons or general practitioners, well able to diagnose a disease, and capable of calmly calculating the effect of quinine or iron on a debilitated system, rush to their dispensaries, and hurriedly throw together a mixture with enough sal volatile to precipitate the quinine or carbonate of soda, to render a soluble tincture insoluble and nearly inert.

As long as we, qualified pharmacists, are content to remain inactive on the subject of our rights and our just monopolies, so long must we—in order to obtain a livelihood, and some even a bare pittance—endeavour to snatch what few crumbs drop from the professional table. It has now passed into an axiom that as long as medical men dispense, pharmacists will prescribe. And yet I venture to say that no pharmacist ever does so without certain twinges of conscience. But what is he to do? Send the patient to Dr. X., who dispenses his own medicine? Nay! Why should he? To be rewarded by Dr. X.'s injunctions to the patient to distrust the whole body of chemists, and himself in particular, as ignorant meddlers? It is probable that the less enlightened members of the profession think that, if they were to give up dispensing their own medicines, the chemists would not give up counter-prescribing.

Then *crede experto!* I have lived on the Continent a number of years, and have made a study of pharmacy in its relation to medicine in various countries, and nowhere have I found so cordial an *entente* between two such hand-in-hand professions as in those countries where an official and recognized status is given to each. And when the pharmacist, instead of wasting his time in listening to a long detail of a child's health, sends the patient to Dr. L., in the certainty of seeing ere long a customer with a prescription and a contented countenance, is he likely to interfere in any such arrangement so eminently advantageous and mutually beneficial? Then why this apparent distrust on the part of the profession? They could now perform a graceful act, raising their own status, by recognizing, as Parliament has done, the separate and distinct qualifications of an educated and examined body of pharmacists.

Optimists say that this desired change is gradually being effected. I do not think that on reflection we can endorse that statement. Eminent men of large practice, and others whose increasing calls on their time necessitate the employment of every means to expedite their visits, naturally prefer writing a prescription to the bother of dispensing and sending out medicines. But in country towns and throughout England generally, I am sure that three-fourths of the work that ought to fall to the pharmacist is withheld from him, to the prejudice of a class legally qualified and officially intended to perform it. True principles of political economy are here violated, and continental countries, whose legislators it is the fashion to sneer at, have at least the merit of a clearer appreciation of the respective functions of medical and pharmaceutical science. Having obtained a legal status, it is the duty of pharmacists as a body to use their utmost endeavours to ensure their right of being the only legally-qualified dispensers of medicine, and to bring to an end the illegal dispensing by surgeons and other practitioners. The heads of the profession are in its favour, and a wholesome and firm agitation on the part of those most concerned could but be fruitful of ultimate benefit and success. We are certainly entitled to some privileges and considerations for all the stringent examinations and regulations voluntarily imposed upon ourselves in deference to the wishes and opinions of the public. A recent writer in the *Standard*, on the abandonment of the Poison Regulations Bill, mentions "the great privileges accorded to pharmacists." As yet, they seem totally intangible and imaginary, unless the exemption from serving on juries be considered a set-off to the innumerable difficulties which beset the thorny path that attends the obtainment of even a bare livelihood as a chemist and druggist.

E. A.

The Minor Examination and the Provincial Associations.

Sir,—In your Journal of May 6th are two or three letters on the subject of early closing,—want of time for study being brought forward as the main argument. One writer takes it for granted that where early closing is introduced, an association with classes, etc., will follow. In many towns this has been the case, but do these associations fulfil their purpose? With some honourable exceptions, I think they do not. In the city of 80,000 people from which I write, and which we will call Cathay, is an association of this sort. The following rough statistics will show how it is getting on:—

Number of pharmacies in the city, 40.
" assistants, 12.
" apprentices, 40.
Average time of closing, 7.30.

The association was started last autumn (solely through the laudable exertions of two assistants) with ample funds and about forty members, with many of the masters as honorary members.

Three classes on separate subjects have met each week, and the result is that the attendance at these classes averaged twenty-two for the first three weeks of the session and nine for the last three, at which number, I fear, it will remain all through the next session, should the association survive so long.

I attribute this falling off to the fact that the class-teachers go into their subjects thoroughly. To do this is not the object of the great majority of apprentices. They prefer to solve the problem as follows:—Given, utter ignorance of theoretical pharmaceutics as a base for three months' desperate cramming; required, to wriggle through the Minor Examination and then to fling up study *in toto*.

Till the Major is looked upon as the natural sequence to the Minor and the need is felt of getting up each subject thoroughly, the comparatively slow method of teaching by classes will not answer, except for students who have the whole day at their disposal. Let additional inducements (such as the title of Fellow) be held out to pass the Major, and this state of things will be altered. Instead of being regarded as a hideous ogre, holding up the bar of the Minor which must somehow be got over, under or round, the Pharmaceutical Society will be looked on as a guardian spirit, striving by its examinations and by other means to raise the trade in public estimation and to increase its *esprit de corps*.

Cathay, May 12th. PHILIP H. MASON.

P.S.—Will some correspondent kindly point out what advantage beyond the honour of the thing is, at present, gained by passing the Major?

UNIFORMITY OF CHARGES.

Sir,—Allow me to express my opinion that pharmaceutists, as a body, could not more effectually conduce to the future aggrandizement of their profession—for such it now strictly is or should be—than by manifesting their determination to suppress petty and unseemly jealousies, and to arrive at an amicable understanding with each other regarding uniformity of charges.

One naturally jumps to the conclusion that adulteration must be extensively in vogue when prescriptions such as the following are brought to be dispensed for sixpence, as happened to me:—

℞. Sp. Am. Co.
Tr. Opii,
Sp. Camph.
Tr. Rhei Co.
Ess. Menth. Pip.
Tr. Capsici, ana ʒij.
M. Cap. guttæ xx per dosis.

When I expostulated and urged that it was at the rate of cost price, I was informed that it had frequently been obtained at Mr. ——'s for that price; consequently, having dispensed it I had no alternative but to let the customer have it. Had I known this before preparing it, I should certainly have refused to stain my conscience and measure-glass with such a disgusting and glaring specimen of the worse than grocer-like system of cutting one another's throats.

The following, though somewhat notorious, is not one of Stratford's *protégés*, but was dispensed at Mile End for sixpence:—

℞. Lin. Saponis Co. ℥j
Tinct. Cantharidis,
Sp. Ammon.
Ol. Succinis Rect., ana ℥iij. M.

Unless Dame Fortune intervenes, we must evidently suffer the same fate as the proverbial Kilkenny cats of old.

Stratford, E. ROBERT H. KEELEY.

UNQUALIFIED ASSISTANTS.

Sir,—Among the various matters touched upon by your correspondents I am surprised that of allowing errand boys to serve behind druggists' counters has not been referred to. We hear much of professional qualifications, conscientious discharge of duties towards customers and the high position pharmacy should aim at, but not a word is said against these qualifications being diluted by an errand boy behind the counter.

In old times, errand boys were brought forward and many eventually became masters, then there was silence concerning qualification and position.

Things have changed. The Pharmacy Act prevents any person carrying on retail except under restriction, but it allows any compliant person's wife or errand boy to retail medicines during the absence of the principal. This seems anomalous, and affords little security to many of those for whose welfare the Pharmacy Act was passed.

It may be said that in a neighbourhood where the druggist's wife dispenses her smiles and medicines, and the boy mixes up the "antibilious," a poor population preponderates, but have not the poor quite as much claim as the rich to legal protection? M.P.S. BY ELECTION.

Notting Hill, W.

WHO DISCOVERED ETHER ANÆSTHESIA?

Sir,—As the public generally are always in an unhappy fog of innocent doubt as to the name of the first discoverer of Anæsthetics, and not five people in a thousand could tell the name of the man who made the first application of ether vapour to take away pain in surgical operations, perhaps you would find a corner for the interesting fact that a monument has been set up this year in America to commemorate the discovery. It may appear to some a little in the spread-eagle style; but all who have studied the history of anæsthetics will agree with the truth of the inscription.

A committee of American citizens at Boston have erected at Mount Auburn an appropriate monument to the memory of Morton. The inscription tells its own tale:—

"W. T. Morton, inventor and revealer of Anæsthetic inhalation.—Before whom in all time Surgery was Agony.—By whom Pain in Surgery was averted and annulled.—Since whom Science has controlled Pain."

The inscription is in four parts on the four faces of the monument. Next to his name stands, perhaps, that of Waldie, the chemist, who taught Sir James Simpson the use of chloroform, and first directed his attention to it, as set forth in this pamphlet of Waldie's brother, so disingenuously ignored, as well as this monument to Morton, by our medical journals; but the next generation will do honour or credit to Morton's memory. There are two monuments in the Hôtel Dieu in Paris, put up by the French people, one to Bichât, the other to Magendie. When shall we have one to Dalton or Davy, Wells or Morton?

CHARLES KIDD, M.D.

Sackville Street, W., April 25th, 1871.

BORAX AND BLACKBEETLES.

Sir,—I don't know how it is that paragraphs are concocted and go the round of the papers, and then disappear; when, if the information conveyed in them were only true, they would be immortal.

If, for example, it were only true that that domestic pest, the blackbeetle, can be got rid of by means of a little borax, as you state on the authority of the *New York Druggists' Circular* (p. 762, *ante*), there is not, I imagine, a druggist's shop in the kingdom that would not be besieged for supplies of borax. But, alas! English cockroaches, unlike their American congeners, have a profound contempt for pounded borax; they crowd over it and trample it underfoot, and, instead of "fleeing in terror from it, and never appearing again where it has once been placed," they seem rather to rejoice over it, and to haunt my kitchen in greater force than ever. And yet I have applied it three times!

If the other part of the paragraph is equally reliable, I shall not be disposed to tempt my laundress to "save nearly one-half her soap" by the use of borax.

I cannot, however, conclude without congratulating all pharmaceutical chemists on the excellent journal that reaches us weekly. T.

London, May 11th, 1871.

[*⁎* There seems to be a considerable diversity of experience on this subject. Only a fortnight since we printed (p. 897) a communication from a respected correspondent, in which he said that powdered borax, sprinkled in the haunts of blackbeetles, was certain destruction to them, and that he could vouch for its efficacy.—ED. PHARM. JOURN.]

QUALIFICATIONS FOR SUCCESS IN BUSINESS.

Sir,—"Another Associate" says, "with the qualifications necessary to pass the Modified, £1000 and a good opening for business, any one may leave all doubts about getting on to 'aspiring' members of the profession."

£1000 and a good opening for business are, I grant, at all times desirable aids, but not necessary qualifications, as I can testify from personal experience, for I had neither; and yet I have succeeded admirably, thanks to the professors in town.

My opinion is, that gentlemen holding the Major qualification, and possessing besides ordinary business capacities, are almost certain of success and that "Another Associate" will find their success greater than those who simply have £1000. F.C.S., PHARMACIST WITH HONOURS, ETC.

May 6th, 1871.

F. R. Riggall.—Blaine's 'Outlines of the Veterinary Art,' published by Messrs. Longman.

J. S. B.—The preparation inquired about is advertised as being prepared by Mr. Chapman, of 10, Duke Street, Portland Place, London.

SATURDAY, MAY 27, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

LOCAL SCHOOLS OF SCIENCE.

THE increased attention that has been devoted during the last few years to the subject of scientific education, and the consequent recognition of the great benefits which would result from the more general possession of scientific knowledge, have already resulted in some practical attempts to supply the great defect which had previously existed. The universities have, to some extent, acquiesced in the claims of science to a place among the studies of those who are able to resort to them for education, whilst public and private efforts have been made here and there throughout the country to supply the needs of students in other ranks of society.

But the rate of progress has hitherto been comparatively slow, and the question from whence the funds are to be obtained for defraying the expenses attending the inauguration of science schools is one that has had and will have very great influence upon it. The thoughts of many who have been working for the spreading of such knowledge have often been turned to the rich educational endowments existing in this country, and many wishes have been expressed that the trustees of these funds should consider whether they might not be utilized to assist in gaining the desired end.

Such help has come in a recent offer from the authorities of the University of Durham of £1000 a year for six years towards the foundation of a school of science in Newcastle-upon-Tyne, with a promise that if the institution answers their expectations, the grant of £1000 annually shall be made perpetual. In order that the school might be carried on efficiently, it was desired by the University that their offer should be met by a guarantee of a like amount from Newcastle and the district. The matter has been taken up with great spirit. At a preliminary meeting subscriptions to the amount of £350 a year for six years were promised, and in addition the sum of £3000 spread over six years guaranteed. This amount has since been increased to £16,000, and it is hoped that a capital fund of £30,000 may be raised, with which it is intended to establish a college for the teaching of physical science as applied to engineering, mining, manufacture and agriculture.

As an instance of the valuable results arising from the union of scientific and practical knowledge may be mentioned the process invented by Mr. JULIUS ROBERT for the extraction of sugar from beetroot and sugar-cane by diffusion, as described by the late Mr. FERDINAND KOHN, in a paper read before the Society of Arts a few weeks ago, an abstract of which will be found in a previous number. Here was a manufacture which had been carried on for centuries upon what was acknowledged to be a primitive and imperfect principle, even the most perfect machinery failing to give a satisfactory result. But coming under the notice of a man who, while cognizant of one of the latest-revealed scientific truths, was also acquainted with the practical details and requirements of the manufacture, a process was invented which has already proved of great importance, and which was well described by the chairman of the meeting, Mr. G. C. T. BARTLEY, as "a most remarkable instance of the application of pure science to practical and commercial purposes."

On the other hand, Mr. MATTIEU WILLIAMS, in a paper on "Burnt Iron and Burnt Steel," read before the Chemical Society last month, illustrated the large amount of empirical knowledge sometimes acquired by workmen, which is either allowed to die with them as a trade secret or is not made generally useful, through the inability of those possessing it to explain the "reason why." Speaking of the difficulties which had to be overcome in the rolling of large iron plates and in the reheating of such great masses without burning them, he referred to the large wages which were offered to workmen who could conduct these furnace operations successfully. He said that he knew an illiterate black-faced workman who earned as much as £40 weekly by payments received as tonnage upon work done under his direction. Having watched this man and others similarly successful in furnace operations, he found that, by various devices—the philosophy of which they did not dream of understanding—they subjected the iron to the action of a reducing flame only, and so prevented its oxidation.

It is for the purpose of bringing scientific education into closer contact with such manufacturing skill that colleges like the one projected at Newcastle are intended: we believe they are sure to exercise a lasting and beneficial influence upon the future of our country, and to repay well any cost that may be incurred in their establishment.

We trust that ere long no part of the country will be without such a college, and that in this way, among other advantages, opportunities may be provided for the acquisition of thorough scientific knowledge, which is so indispensable for the proper exercise of a pharmacist's daily business.

A LECTURE will be delivered "On National Health," by Dr. ACLAND, at the Royal College of Physicians, next Friday, the 2nd of June, at 5 P.M.; and at the same time on Wednesday, the 7th of June, a course of three lectures "On War in its Sanitary Aspects, with special reference to the period from 1793 to 1815," will be commenced by Dr. GUY, and continued on the following Friday and Wednesday.

ON Tuesday evening the House of Commons went into committee on the "Adulteration of Food and Drugs Bill," but progress was immediately reported, and the House resumed.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

May 17th, 1871.

MR. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

Present—Messrs. Atherton, Bottle, Bourdas, Brown, Carr, Deane, Dymond, Edwards, Evans, Groves, Hills, Mackay, Reynolds, Sandford, Stoddart, Sutton and Williams.

Mr. Bourdas was elected Vice-President, and took the chair accordingly.

The Secretary presented a list of members whose subscriptions had been tendered subsequently to the 30th April.

Resolved—That the said members be restored to their original status on payment respectively of a nominal fine of one shilling.

The following letter was read, and ordered to be entered on the minutes:—

"*Medical Department of the Privy Council*,
May 4th, 1871.

"Sir,—The Lords of Her Majesty's Council, observing that the Annual Meeting of the Pharmaceutical Society is to be held in the course of the present month, direct me to refer you to my letter of the 23rd December, 1870, and to say that they trust that such regulations will then be made (under the first section of the Pharmacy Act, 1868) in regard to the keeping, dispensing and selling of poisons, as will be sufficient to secure the safety of the public.

"Their Lordships think it right to apprise the Council of the Society that, should no such regulations be submitted for their approval after the approaching meeting, they will feel it their duty to endeavour to protect the public by proposing to Parliament further legislation.

"I am, Sir,
"Your obedient servant,
"JOHN SIMON.

"*The Secretary to the*
"*Pharmaceutical Society*,
"*Bloomsbury Square*."

Resolved—That the letter be read at the Annual General Meeting, and that copies be distributed among the members present.

The Council then adjourned to the Annual Meeting.

THE
THIRTIETH ANNUAL GENERAL MEETING OF THE PHARMACEUTICAL SOCIETY.

Wednesday, May 17th, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The SECRETARY having read the notice convening the meeting, the President delivered the following address:—

Gentlemen,—Two months ago I little expected that I should on this day have the honour and pleasure of addressing you from this chair. As there is no rose without a thorn, so the pleasure comes not unalloyed. You will readily understand the allusion, viz. the retirement of Mr. Sandford from the post I now fill. I feel assured that you will not only look for it from me, but strongly approve of my paying a passing tribute to the merits of that gentlemen, one of the best Presidents the Society ever had. I know his value well. You cannot estimate too fully the loss of so upright, so able, and last, but not least, so patient a chairman.

Thirty years ago a paper was read "On the Constitution of the Pharmaceutical Society of Great Britain," at the Introductory Pharmaceutical Meeting, held May 11th, 1841. For as many years have I, first as an associate, then as a member, watched the steady advancement of the Society. During that time I have observed many changes. I have seen the good ship threatened by storms from within and from without, surrounded ofttimes by shoals and quicksands, but ever buoyant, ever seaworthy, coming safe into harbour, avoiding Scylla and not falling into Charybdis. I call to mind now words spoken by one who has grown grey in your service, "that the Pharmaceutical Society would at some future day become a very great and influential Society." I endorsed his words then, I endorse them now; and why? Because it is based upon good sound principles; by educational means expanding, training and raising the mental qualities, striving by union for the good of each other, and conferring a corresponding advantage upon the general public by providing for it not merely an intelligent class of pharmaceutists, but also an educated intelligence, for natural talent and intellect lose nothing, but gain much, by cultivation. "The human mind, without education, is like marble in the quarry, which shows none of its inherent beauty until the skill of the polisher fetches out the colour."

Following the steps of those who have preceded me, I might remind you of novelties introduced and of the results of scientific research during the past year, but all these are now so freely published that they who run may read. Nevertheless, there is one preparation in particular which I cannot pass unnoticed, the hydrate of chloral; known before the past year, yet happily never before called so largely into requisition at home or abroad (during the war) for the relief of thousands of suffering fellow-creatures. In a lecture delivered in February last, Dr. Richardson stated that nearly fifty tons of the hydrate had been used in England during the previous eighteen months. He also stated—and this may be interesting to pharmaceutists, as showing the necessity of discretion in its employment—"that in professional hands, now that its action is better understood and the novelty of its application worn off, the employment of it is less than it was some months ago; while the practice of resorting to it by the public is on the increase, and a new class of cases is thereby becoming known, marked by particular symptoms, and assuming in some instances a serious character."

Among many other things which during the year have engaged the attention of correspondents in our Journal I have observed the question of *early closing*,—a question eminently interesting, and meriting earnest attention; but I have always felt, that whilst it is a matter in which each may do much by example and otherwise in his own immediate neighbourhood, it would be quite out of character for residents in one quarter of any large city to legislate for those in another. At some establishments in this metropolis closing commences at 8 o'clock P.M., an hour at which in others the main business of the day virtually begins, when an assistant so situated might exclaim, with Sterne's starling, "I can't get out—I can't get out!" The reason put forward not unfrequently in favour of early closing is, that apprentices and others may have time for study; and the reason, so far, is a good one. No one can well appreciate the value of opportunities for study more than those who have known and felt the want of such. Where were they thirty years ago? I trust that those who have opportunities will not only value them, but make much of them.

"To catch dame Fortune's golden smile,
Assiduous wait upon her;
And gather gear by ev'ry wile
That's justified by honour:
Not for to hide it in a hedge,
Nor for a train-attendant,
But for the glorious privilege
Of being independent."

This reminds me that I should make some remarks anent our Examinations. In so doing, I would invite your attention to that portion of the Annual Report which bears upon them. If a doubt ever existed in the minds of any respecting the nature and mode of conducting the Examinations, the passages extracted from Dr. Greenhow's communications thereon, published in the Twelfth Report on Public Health by the medical officer of the Privy Council will, I feel confident, at once dispel it, so far at least as the present Examiners are concerned. Personally (*ex officio*) I have taken great interest in the Examinations, and have been an earnest participator in all the duties of the Board, and I can say truly that I have never been associated with gentlemen more considerate and conscientious.

In continuation, a few words upon the Preliminary Examination may not be out of place, as many opinions have been expressed thereon. Some think it is too severe; others, that the Latin is more than should be expected; and again, that the questions are not always equal; that is, that they are more difficult upon one occasion than upon another. It may be so with some of the questions, but they are balanced by others equally easy; many, indeed, simply elementary. For my own part, I can scarcely see how the examination can be lighter, if, indeed, it is to be an examination at all; though candidates who have been some time from school may find Cæsar difficult to work up, the Pharmaceutical Latin required is only such as should be known by every one behind a chemist's counter; but in the face of this, some of the oldest candidates pass the best examination in Latin and arithmetic and some of the youngest the worst. Forty years ago, before this Society was established, a lad about to be apprenticed to a chemist was supposed, under any circumstances, to know something of Latin, for no prescriber in those days thought of putting any portion of his prescription in the mother-tongue; and now, after thirty years' existence of a Society, one of whose prominent features was and is an improved educational condition, can any say that he did not think Latin would be required? Any unbiassed person examining the written answers in the Preliminary Examinations, would be forcibly struck with what seems to indicate, in a large proportion of the cases, an utter absence of training in preparing for this examination; the work done represents the work of youths who have no one to guide, none to direct their studies and well-intentioned labour. I do not mean grinding or cramming. I hesitate to be more explicit. Gentlemen —like the author of a "Botanical Student's Dream" (*vide* PHARM. JOURN., March 18th, 1871, p. 745), and all those who take an interest in the young—will, I doubt not, comprehend to what I allude, for the young stand in need both of encouragement and guidance. Thus far I have said nothing of the Benevolent Fund, as it is pretty fully treated in the Report; but I may mention that the *first* legacy of £19. 19*s*. has been announced from the executors of the late Mr. C. Coles. Had Mr. Coles been spared to us, he would have been a valuable member. I am now fast approaching the end of that which I have desired to say, leaving to the last the most important question which will be brought before you for consideration to-day. The poison regulations have occupied the time not only of the Council, but more or less of all classes connected with pharmacy, the Council yielding,—when not to have done so might have been construed into unnecessary persistency,—determined, whether wisely or not I pretend not to say, to offer to this meeting certain recommendations to be observed in the keeping, storing and dispensing of poisons, for voluntary adoption. In considering this question when it comes before you, let me ask you, in all seriousness, to bestow upon it that quiet and calm consideration with which, on many previous occasions, you have been justly credited, and for which you had established a well-merited prestige. Before taking the final plunge, let me impress upon you this one word—Think.

"Facilis descensus Averni:
Sed revocare gradum, superasque evadere ad auras,
Hoc opus, hic labor est."

A word or two now upon my own account. This, gentlemen, is my first appearance, at a short notice, in this character; it may be the last; a few hours or a few days may send me amongst the rank and file. Be that as it may, I shall still labour in the cause of pharmacy and the Pharmaceutical Society; shall still respect the names of those Seniors who foreshadowed and established this our position; and as I have ever done, shall still take an interest, not only in this Society but in all those who follow the arduous and exacting occupation of a pharmaceutical chemist, or chemist and druggist.

The PRESIDENT called upon the Secretary to read the Report of the Council. It was resolved that the Report be taken as read.

REPORT OF THE COUNCIL.

In presenting the report of the proceedings of the past year, the Council commence as usual with some observations on the financial condition of the Society.

The Balance Sheet has been long enough in the hands of members of the Society to have been carefully read and considered, and doubtless has been compared by many with the statement of 1869, which exhibited a balance in the treasurer's hands at the close of the year considerably larger than the present, as well as larger investments made during the year in Government Securities. That year commenced with a much heavier balance, and another circumstance may be mentioned explaining the difference, namely,—an alteration in the time of receiving from the Publishers certain proceeds of the Journal, which at the end of 1870 amounted to £1586. 18*s*. 6*d*. due to the Society; had this been a receipt instead of an asset, it would have given the balance of the past year an advantage over its predecessor.

The true gauge, however, of prosperity must be looked for in the subscriptions and fees of the year, and under this head at first glance there seems to be a falling off; this must not, however, be taken as conclusive, because it arises from a decrease in the amount of registration fees of chemists and druggists in business before the passing of the Pharmacy Act, 1868: in those paid by assistants entitled to be registered on passing a Modified Examination; and also in the entrance fees of chemists and druggists. These items must lessen year by year, and ultimately disappear entirely from our financial statements. The subscriptions *proper* show an increase of nearly five hundred persons, who have become connected with the Society in the various grades since our last report.

On the debit side of the account a heavier amount than usual appears for apparatus; caused by the purchase of the large and valuable assortment collected from time to time by Dr. Redwood during his long connection with the Society. The Council before deciding on this purchase took advice from one of the most eminent philosophical instrument makers in London, and had the apparatus thoroughly examined by a Committee, both of whose reports were conclusive as to the desirability of the Society securing, under such favourable terms as Dr. Redwood had offered, this important collection.

The great increase in the business of the Society, and the greater number of clerks required for its performance, rendered it necessary in 1869 to remodel the office, involving a considerable outlay, part of which appears in the account of 1870.

The commission on laboratory fees paid to the Director and Demonstrator does not accurately give the expenditure of 1870, the commission on the fees of the previous year from October to Christmas being included in the £616 now debited. To accommodate additional pupils in the laboratory certain alterations, which were

mentioned in the report of last year, appear on this occasion as increasing the item of "Repairs and alterations."

The Council have been encouraged by the greater use made of the library to increase their outlay in the purchase of books. The selection has been carefully made from month to month by the Library Committee.

It will be observed that the cost entailed upon the Society by the publication of the Register, in conformity with the Act of 1868, has been reduced from £245 in 1869 to £68 in the past year, with the satisfactory prospect of a still further diminution of expense in future issues. In noticing the 'Register,' the Council would draw attention to the great difficulty experienced by the Registrar in keeping it correctly,—a difficulty mainly caused by unreported retirements, changes of residence and deaths. The Council would urge upon members the great assistance they may afford the Registrar, by sending timely information of changes which take place in their neighbourhoods.

The remarks on the Financial Statement cannot be closed without alluding to the pension granted to Dr. Redwood when the change in the editorship of the Journal occurred in July last. Dr. Redwood had been so long connected with that publication, and had devoted so many of the best years of his life to its service, that the Council felt it but an act of justice to give him such an acknowledgment of his labours.

It will be remembered that at the close of the meeting of 1870, a resolution, proposed by Mr. Schacht, was carried, expressive of the opinion that the means hitherto adopted by the Society for the advancement of Pharmaceutical Education were no longer adequate to the necessities of the times, and urging the in-coming Council to consider some scheme for enlarging the usefulness of the funds at their disposal.

The Council, mindful of the altered condition of the Pharmaceutical Society,—no longer a merely voluntary association, but one to which all intending chemists *must* apply for authority to exercise their calling, and, failing to possess a sufficient educational qualification, would fail to obtain that authority,—immediately after its first meeting issued inquiries to the various Provincial Associations, and founded on the answers thereto, a Report which was published in the Journal. Certain recommendations having been adopted, forms of application for aid were prepared; these, however, were found to require reconsideration, and some alterations were consequently made which it is hoped will render them more practicable. The subject is not an easy one, as the fund available for the purpose is small, yet the Council trust some aid may be afforded to those who are anxious to advance their professional education, but are residing in localities where chemists are not sufficiently numerous to maintain public schools for that purpose. One great advantage arising out of the purchase of Dr. Redwood's apparatus—an advantage which had due weight in deciding on the purchase—is, that some portions of it are adapted for the illustration of lectures, and may be lent on certain conditions to Provincial Associations.

The Council have great satisfaction in drawing attention to the following passages from the Reports on the Examinations of the Pharmaceutical Society of Great Britain by Dr. Greenhow, published in the Twelfth Report on Public Health by the medical officer of the Privy Council:—

"The technical examinations are made as practical as possible. The prescriptions submitted to the candidates are very various in character, and have all been actually written for patients and dispensed in chemists' shops. The ability to read prescriptions is obviously one of the most necessary qualifications for chemists and druggists, and a large proportion of marks has therefore been very properly allotted to this subject in both the Modified and Minor Examinations. When present I have observed that although most of the candidates can read ordinary prescriptions correctly enough to ensure their being able to dispense from them with safety, comparatively few are sufficiently conversant with Latin to read with accuracy prescriptions couched in somewhat unusual terms, or having appended to them minute directions for use in the Latin language. The already-recited regulations sufficiently show the scope of the several examinations in the other subjects, and I may add that the selection of specimens submitted to candidates for recognition is well calculated to test their practical knowledge.

"I have closely observed the mode of conducting the several technical examinations by the appointed examiners, and can bear testimony to the zealous and conscientious manner in which these gentlemen discharge their duty. On some occasions I have followed the same candidates through their examination in all the successive subjects, making my own estimate of the number of marks which they had earned in each subject, and then comparing this estimate with the number of marks assigned to them by the examiners, which has seldom shown any considerable discrepancy. On other occasions I have remained for a considerable time watching the examinations of successive candidates in the same subject, and have satisfied myself of their being conducted with perfect fairness and impartiality as between one candidate and another.

* * * * * *

"I have, in conclusion, only to repeat what has already been implied in my Report, that, in my opinion, the examinations of the Pharmaceutical Society are of such sort, and are conducted in such manner, as to constitute a sufficient guarantee to the public with regard to the qualifications of persons admitted to register under the Pharmacy Act, 1868."

The changes made last year in the publication of the Journal can scarcely be said to have had a sufficient trial. The largely increased expense caused by the weekly issue, the increase in the number of members, etc., have occasioned so much larger an expenditure than formerly, that sufficient advertisements have not been forthcoming to meet it.

At the last Annual Meeting, the following resolution, in reference to the regulations for the keeping, dispensing and selling of poisons, was adopted:—"That the subject be taken into consideration by the in-coming Council, and that a further report be made to the next Annual Meeting."

The consideration of this important question has occupied a considerable portion of the time of the Council during the past year. The various motions which have been brought forward and the result of the divisions thereon, have been published in the Journal. Yielding, however, to the opinions of a large number of pharmaceutical chemists and chemists and druggists throughout the kingdom, expressed at public meetings and in memorials, the Council have determined to submit to the meeting the regulations for adoption as *Recommendations.*

The Benevolent Fund has slowly but steadily advanced during the last few years. The dividends, however, arising from the invested capital being inadequate to meet the annual pensions,—the Council, in 1870, felt justified in transferring £500 from the ordinary Funds of the Society to this Fund. Twelve annuitants have been elected since Mr. Orridge (whose loss is greatly regretted) so strongly aided in establishing these grants and in generally furthering the objects of the Fund; occasional grants are also made where the Council consider them required and desirable.

All members of the trade are now eligible to receive aid from the Benevolent Fund, whether members of the Society or not; but it is a matter of regret that, while so many could well afford assistance, so few, comparatively, have come forward to help. It may be that men who are not members, and consequently are not called on for subscriptions to the Society, have not had the claims of the Fund brought immediately before them, but the Council believe that Local Secretaries might easily obtain their co-operation in so good an object.

During the past year Mr. Westwood, a very old member of the Society, and one who had for several years acted as an auditor of its accounts, has passed away, to the great regret of all who knew him.

The Council cannot conclude their Report without also expressing their sincere regret on account of the retirement of Mr. Sandford from the Presidential Chair; for, however opinions may occasionally have differed, they have uniformly admired the kind feeling, ability, patience and perseverance of their colleague.

The Registrar placed on the table the following:—

Register of Members, Associates and Apprentices of the Society.
Register of Pharmaceutical Chemists.
Register of Assistants.
Register of Apprentices or Students.
Under the Pharmacy Act, 1852.
Register of Chemists and Druggists.
Under the Pharmacy Act, 1868.

Mr. Wiggin (Ipswich): Gentlemen, I beg to move that the Report of the Council be received and adopted, and printed in the Journal and Transactions of the Society. I am very pleased indeed to have again the opportunity of addressing you, to come up again as I have done for many years, combining business with pleasure. As you have all, no doubt, read the Report, anything I could say would be quite a work of supererogation, particularly after the able manner with which our President, in his opening address, has commented upon everything connected with it. So far as regards the Finances, I must say I think the statements in the Report are hardly so good as usual; but I accept, as I feel myself bound to do, the explanations made by our governing body, those whom we have elected to serve us for the last year. I have nothing particular to say about that bone of contention amongst us, the Poison Regulations, because they will be the subject of remark hereafter; but I may say that I would rather we should manage our own work than let other people do it for us. There is one other matter which the Chairman mentioned, and upon which I feel very strongly, namely, the retirement of Mr. Sandford. We know the peculiar circumstances under which he retired, and I must say, that in electing to do so he did a very graceful act; one which, in my opinion, proved him to be a most honourable gentleman. I think he properly appreciated his position, and I hope and trust that by our votes to-day we shall show that the feeling of the majority of this Society goes with him.

A Member: May I ask whether, by adopting the Report, we also take the regulations as to the Poison Bill with it?

The Chairman: You do not. The regulations will be put to you afterwards as a separate question.

Mr. M. Carteighe: I beg to second the motion for the adoption of the Report.

Mr. Robbins: I should like to make a few observations with regard to the Benevolent Fund. In reading the Pharmaceutical Journal of last week, I was struck, upon looking over the list of subscriptions, with the smallness of the sums there enumerated. I searched the list for a great number of names which I fancied ought to be there, and found them only conspicuous by their absence. In looking over some of the large towns of great commercial importance, I found that the sums put down were really very insignificant, and there were other towns which I looked for in vain. I think it is a disgrace to such a body as the Pharmaceutical Society that this should be so; we are bound to look after the orphans and widows, the poor and the indigent of our own body. It is not only a duty which we ought to perform, but we should also look upon it as a privilege and a pleasure. I cannot fancy that chemists are less liberal and less charitable than other people. I think this must arise from the subject not having been placed prominently enough before the members generally. I am told that the donations, subscriptions and interest arising from funded property are not sufficient to meet the requirements of the annuitants, and when we see that the amount subscribed by the members does not amount to a shilling a head, I think it is time we took the matter into serious consideration. Our President has mentioned that we have recently had a legacy left us, and it is a remarkable fact that that is the first legacy left to the Benevolent Fund. We have not many Peabodys in our ranks, and therefore I shall not quarrel with the dead; but to the living I would urge that they take this matter into consideration and see whether, before the next meeting, we cannot put a more respectable list before the members.

Mr. Kent: Sir, my chief object in coming here to-day was to speak upon the subject which has been alluded to by the last speaker. I happen to know six large towns in the country from which you receive only £2. 7*s*., and there are above 100 respectable chemists doing a very large amount of business there. I do not think that those chemists are divested of feelings of sympathy for the poor in our class more than those chemists who do subscribe to our funds. I think it is due to the fact that their attention has not been drawn to the subject. I think if your local secretaries were specially directed to call attention to this matter, and make application to the different chemists of their localities, you would find a great improvement in the state of your Benevolent Fund. I hope that we have a good many of those local secretaries now present, and that their minds will be drawn to the subject; also that the incoming Council will encourage those gentlemen by sending a nice circular, so that it can be distributed amongst the chemists in their locality. I feel assured that we cannot exactly sleep comfortably in our beds if we neglect our widows and our orphans. I would further suggest that in the case of those chemists who are known to be well-to-do, and will not subscribe a farthing, if any of their friends should become dependent, it should be a question whether the Society should entertain any application from them. The various charitable institutions throughout the country, I believe, act upon that principle; and it again acts as a sort of stimulus on all parties during the time of prosperity, when they do possess the means to contribute something, to know that if the sorrows of life should come upon them, and their friends are left destitute, they will be cared for by the societies to which they have belonged, and to which they have subscribed. I am heartily pleased that attention has been drawn to this matter, and hope that after this day we shall have to congratulate ourselves upon the improved state of our Benevolent Fund.

Mr. Humpage: I should like to say a word, Sir, respecting this Benevolent Fund. I believe it is through apathy that many gentlemen have not come forward and assisted the Fund, and I think that generally they are not members of the Society. If they were, and had the Journal coming before them four times a month, they must see that the Benevolent Fund and its distribution does occupy a considerable portion of the Council's time and attention. When we bear in mind that three years ago there were about 2000 members of the Pharmaceutical Society, I did expect, when the doors of the Society were so widely, so kindly (I was going to say so lavishly) rolled open, a very large number would rush in. We asked them to come in and unite with us who had been working for thirty years. We had created the Society; we had in addition subscribed £10,000 for this Benevolent Fund—and all we asked them was, to come in and shake hands and help us. There could be no difference of opinion as to the desirableness of this fund. There might be a difference as to the proceedings at the Council table, but I repeat, there could be no difference as to the propriety of every member of the trade who can afford it giving an annual subscription to this fund, since all are eligible to receive its help. I hope and trust many country chemists will speedily join the Society, when their attention will be more completely called to its advantages; and depend upon it, if they have any prejudices, the more you can bring them in contact with the Society, those prejudices will be melted away. I have come in contact with many gentlemen who have prejudices. A short time ago a gentleman who lives in my neighbourhood, a man of standing, a man of influence, a man of character, and a man of position, launched a complaint to me to this effect,—I had no circular from the Council of the Pharmaceutical Society respecting these poison regulations, and I think I am as respectable a man as the 2000 who had the circulars. I am one of the 10,000 outside. I told him that he did not look at it in the proper light. I said, "Why have you not had a circular? Because you would not unite yourself with the Society. If I voluntarily keep myself back from joining a club, can I expect to have notice of the movements and doings of that club? Assuredly not."—"Sir," said he, "I never looked at it in that light; I see the justice of it; you are right."

Gentlemen, illuminate the trade generally, and you must have a very much larger income for distribution.

Mr. Vizer: Sir, I have one or two remarks I should be glad to make upon the Report. As touching the Benevolent Fund, I most fully concur with every word which has been uttered, and I would only add one suggestion respecting it; that is, in publishing the calendar, together with the members' names and residences, you should have a column stating the amount they subscribe to the Benevolent Fund. It would be very handy and convenient to those who were taking an interest in any case and canvassing for votes, because it would at once show the number of votes each member had; it would, at the same time, be a silent monitor to those against whose names a subscription was not found. Another matter is, that before the new issue of the Journal we used to have a report of the donations to that fund published monthly, which has recently been discontinued. I think that was a good plan, because it brought the matter prominently and frequently before the members. If that plan were readopted, it might stir up benevolence, and so help the fund. Another suggestion I would make is with regard to the library. I believe the rule at present is that the library shall be open up to six o'clock; might it not be extended, with advantage to many of the students and assistants in London, if it were open up to nine o'clock? Young men are out in the evening, and have an opportunity of reading in the library, but they cannot do so in consequence of the present regulations. Another point I would observe upon is the accuracy of the register. In last year's Report we were told that the register was very satisfactory. I am sorry to differ from that opinion. The experience I have had lately has told me it is anything but satisfactory. I believe, I may say, that in London there are from 150 to 200 addresses in the register which are wrong, and that in the whole of the country there are between 1000 and 2000 such wrong addresses. That is a very serious matter, because I believe if the register were taken into court, it would be no evidence whatever unless it were correct. The Act of Parliament, by clauses 9 and 10, provides against that difficulty, and gives the Registrar power to issue letters by which that register may be corrected. If the Council have the power, I think it would be well to exercise it; and before the publication of the register, every person should be required annually to notify his residence, and, in case of failing to do so, that his name should be left out, capable of being restored in after sheets up to a certain date upon payment of a trivial fine. I believe that a regulation of that kind is in force in the case of the Law Society, and that it would be a great improvement if it were judiciously carried out with the register of this Society.

Mr. Schacht (Clifton): Sir, the subject of the Benevolent Fund is one upon which I should be sorry to say one word that would seem like a damper upon the feelings which, I hope, more or less actuate us all. But however much the observations which have been made apply to us individually, I think they ought not to apply to us in our corporate capacity. It seems to me that benevolence should not be considered as the *first* duty, at any rate, of the Pharmaceutical Society. And moreover, whatever cause there may be for something like a lecture to us individually, I say I do not think it *does* apply to us in our corporate capacity; for, on the very balance-sheet we have in our hands, there is a sum of £500 which has been handed to the Benevolent Fund. The reason why I introduce the subject in this way is, that I wish at the same time to call attention to a statement in the Report in which I am very much interested, and with which my name is very politely again associated. I mean the subject I had the honour to introduce last year—provincial pharmaceutical education. I think, I may fairly say, that we owe the Council the expression of our gratitude for what has been done up to the present time. At any rate, the statements contained in the Report, and the action which they have taken, are as much, perhaps, as any of us, interested in the subject, had a right to expect at this stage of the history of the subject; but the admission made in the Report, and the action taken upon that admission, are, as yet, far from proportionate. And one of the arguments adduced for this poverty of action is the smallness of means available for the purpose. I rise not for the sake of complaining that more has not been done, but rather to express a hope that a great deal more will be done in this direction, which I consider to be one of such immense, I was going to say, paramount importance. You, Sir, in your opening address congratulated the whole profession of pharmacy upon the fact, that in the present day men who wanted to improve themselves had greatly better opportunities of doing so than in past times. I cannot help thinking that your attention has been rather limited to what you are accustomed to see in this institution, upon which have hitherto been concentrated all the resources of the Society. We complain that in the provinces scarcely anything has as yet been done, except by local effort; and it is a little galling to be told of the small amount that is at the disposal of the Council for this purpose. It may be so, but we think it a large sum. You have all noticed the fact that something like £2000 a year is spent on the education conducted in this institution. Something like £1200 are spent in the laboratory, and £630 in the lectures. Moreover, £500 are handed over to the Benevolent Fund, and thus education in the provinces is literally nowhere; and the only advance I can see is that a large purchase has been made of certain apparatus, valued at £300, which it is proposed shall be lent for lectures in the provinces. There are certain regulations, which seem to me to be intricate, in which I suppose money grants are hinted at, but their exact operation is made a little mysterious. Probably they are more generous than I think them to be. I am not in the least degree anxious to cavil, seeing that those regulations have first of all to stand the test of experience; but it is upon the spirit of the thing that I wish my observations to bear. We spare money for everything else, but seem to neglect that which, I think, is a paramount claim—the education of the mass of our young pharmacists. The accommodation at this school is only equal to about 100 pupils per annum, which is not more than a twentieth part of the number who require to be educated, and yet complaints are made that more do not pass the examination. I again say we have no opportunity other than in this establishment, nor any means of acquiring knowledge other than we had thirty years ago, which, instead of being matter for congratulation, is a disgrace.

Mr. Urwick: Sir, it would appear that there is some reason to suppose that some day or other we may fall short of funds if we give lectures in the country, but I think there is a way in which we may secure the requisite funds. It appears there are a large number of chemists and druggists who have all the privileges given them by the Act, but still not being members of this Society, we do not get their annual subscriptions. It would seem that there is a golden bar which prevents their entry, and that is the two-guinea bar. If that could be diminished, or even done away with altogether, I think the number of those men who stand outside would be greatly diminished, that they would come in, and that your annual subscriptions would greatly augment. Therefore, I would suggest that we should meet them in some way.

Mr. Radley (Sheffield): Sir, I feel very much gratified by the remarks which have just been made with reference to the educational question. I am connected with a local association which has endeavoured to establish a school and lectures for the benefit of the rising generation. Our difficulty is becoming rather serious in regard to funds for the maintenance of the lectures during the next few years. We can support our institution so far as the members are concerned as to finding rooms, library, chemical apparatus and a museum; but we are unable to get a sufficient number of pupils to meet the cost of the lectures. During the past winter we had twenty-four lectures on chemistry. To meet the expense of those lectures the association has had to pay £10. 10*s.* in addition to the pupils' fees; and if it is to be repeated in the various other branches of scientific knowledge it will be, as I have said, very difficult for us to maintain our position. We feel desirous to bring this matter before the Association generally; and, although the Council have done very well hitherto, we do hope in the coming year to succeed in getting help from them in this particular. A great number of our senior young men have taken advantage of the Modified Examination, and, therefore, do not go in for the lectures to the extent which all will have to do in the course of time. We feel it to be desirable that, at all events, for a few years we should have some monetary help to tide us over our difficulties. I am quite aware of the considerations that spring out of this from the number of schools there are in the country; but I think the thing might be met, and I trust it will be.

Mr. Slipper: Sir, there is an error in the casting of the Benevolent Fund, showing a deficiency of £10; and I should like to know whether it can be accounted for in any way.

Mr. Bremridge: There does appear to be an omission of £10; whether it be a clerical or printer's error I do not for the moment know. The money has, however, been expended, and the total is, I am sure, quite accurate.

At a later stage of the proceedings, Mr. Slipper announced to the meeting that Mr. Bremridge had shown him the auditors' account, in which the missing item was set out. It was, therefore, a printer's error.

The resolution for the adoption of the Report was then put and carried unanimously.

The Chairman: The next question before us, gentlemen, is that of the poison regulations. It is a very important one, and you will readily conceive my position in bringing the matter before you. At the last Annual Meeting it was remitted to the Council in this way,—that the subject be taken into consideration by the incoming Council, and that a further report be made to the next Annual Meeting. I shall not attempt to waste your time by using any arguments whatever, either in favour of or against the adoption of these regulations, as you know the Council a month ago decided upon presenting them to you as recommendations for your adoption. But it is quite right I should mention to you that it was considered by some that if they were adopted as voluntary regulations, the Privy Council could put their seal upon them, and the Act of Parliament would make them law, so that they would become compulsory. I also feel that I should read to you a letter received from Mr. Simon, medical officer to the Privy Council, about twelve days ago. The letter, which is addressed to the Secretary, is as follows:—

"Sir,—The Lords of Her Majesty's Council, observing that the Annual Meeting of the Pharmaceutical Society is to be held in the course of the present month, direct me to refer you to my letter of the 23rd December, 1870, and to say that they trust that such regulations will then be made (under the first section of the Pharmacy Act, 1868) in regard to the keeping, dispensing and selling of poisons, as will be sufficient to secure the safety of the public.

"Their Lordships think it right to apprise the Council of the Society that, should no such regulations be submitted for their approval after the approaching meeting, they will feel it their duty to endeavour to protect the public by proposing to Parliament further legislation.

"I am, Sir,

"Your obedient servant,

"John Simon."

I need scarcely tell you that this letter was very courteously acknowledged, but no further remark was made about it than that it would be presented to the Council at the earliest possible opportunity. With respect to the regulations or recommendations being made compulsory, supposing you adopt them to-day as voluntary, our Solicitor was instructed to draw up such a resolution as could not very well in common sense be made compulsory by merely adopting them as recommendations. These are the recommendations:—

"Recommendations by the Pharmaceutical Society of Great Britain for the keeping, dispensing and selling of poisons.

"1. That in the keeping of poisons each bottle, vessel, box, or package containing a poison be labelled with the name of the article, and also with some distinctive mark indicating that it contains poison.

"2. Also that in the keeping of poisons, each poison be kept on one or other of the following systems, viz.

"(*a*) In a bottle or vessel tied over, capped, locked, or otherwise secured in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop, or dispensary; or

"(*b*) In a bottle or vessel rendered distinguishable by touch from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop, or dispensary; or

"(*c*) In a bottle, vessel, box, or package kept in a room or cupboard set apart for dangerous articles.

"3. That in the dispensing and selling of poisons, all liniments, embrocations and lotions containing poison be sent out in bottles rendered distinguishable by touch from ordinary medicine bottles, and that there also be affixed to each such bottle (in addition to the name of the article, and to any particular instructions for its use) a label giving notice that the contents of the bottle are not to be taken internally."

It only remains now for me to put the resolution as drawn up by our Solicitor for your consideration, and it is this: "That this meeting having considered the recommendations as to the keeping, dispensing and selling of poisons, prepared by the Council, desires the Council to propose them for voluntary adoption, but does not desire and does not prescribe them as or to become Regulations within the meaning of the Pharmacy Act, 1868."

Mr. Burden: Can we have the first clause of the Pharmacy Act read?

Mr. Flux, the Society's Solicitor, then read the first clause, which is to the following effect:—"From and after the 31st day of December, 1868, it shall be unlawful for any person to sell or keep open shop for retailing, dispensing or compounding poisons, or to assume or use the title chemist and druggist, or chemist or druggist, or pharmacist, or dispensing chemist or druggist in any part of Great Britain, unless such person shall be a pharmaceutical chemist, or a chemist and druggist within the meaning of this Act, and be registered under this Act, and conform to such regulations as to the keeping, dispensing and selling of such poisons as may from time to time be prescribed by the Pharmaceutical Society, with the consent of the Privy Council."

Mr. Bourdas (Vice-President): I beg to second the resolution.

Mr. Giles: Sir, I think the occasions are few when any society, be it a society for scientific, social or commercial purposes, may differ on points of administration with its appointed governing body. But I do consider the present is such an occasion, not only on account of its vast importance, but also on account of the fact that the Council bring before us a matter which we know by their own previous information they do not in their hearts approve, but in obedience to an expression of opinion utterly informal, and which I consider they made a mistake in respecting to the extent they have done. I find it is necessary to deal with this question not simply upon the resolution, because the resolution does not raise, as it appears to me, the vital point which is at the bottom of the whole thing. I find it necessary therefore to move an amendment, and I will just state to you what that amendment is. It is in effect a repetition of the same motion applied to the present regulations, which motion was brought before you a year ago by the Council. But I will tell you why I desire to do so. It is, that we may decide now upon the *principle* which underlies the question of the imposition of these regulations; that is to say, whether we have contracted an obligation to Parliament which we are bound to fulfil in prescribing certain regulations, I care not now much what they are, because in considering the details of such regulations, we are led away from the point, whether it is our duty to prescribe them or not. There has been a great deal of very verbose discussion upon the matter, and there was a very lengthened meeting a year ago. Ever since that time there has been continual discussion of it in letters in the Journal and elsewhere. But I venture to assert that the main point of the question, the intrinsic essence of it, has been very much kept in the background, while questions of detail have been under consideration, which are only of secondary importance, or questions which do not concern us, as for example, the necessity for these regulations at all. Sir, *we* are not the conservators of the public safety. Parliament is the conservator of the public safety, and Parliament has said in terms, about which there has been no vagueness or uncertainty or dispute, that regulations *are* necessary. It is then a question for us whether we will fulfil the obligation imposed upon us by Parliament, or whether we intend to measure our feeble power against its omnipotence. I wish to call your attention to what the obligations are which we have undertaken, and I venture to say that no person who has read carefully, as I have done, the Act itself, the debates which occurred in the two houses of Parliament upon that Act, and the leaders in our own Journal at that time, can come to any other conclusion than that it was the intention of Parliament to impose upon us the obligation of prescribing *some* regulations, that we understood it so at the time, and that we accepted the Bill and the privileges which the Bill conferred, laden with that obligation. The first clause of the Act has been already read, all that is essential to us I will read again. That the persons privileged by this Act shall "conform to such regulations as to the keeping, dispensing and selling of such poisons as may from time to time be prescribed by the Pharmaceutical Society, with the consent of the Privy Council." I cannot conceive that you can rationally interpret that Act of Parliament, unless you suppose it contemplated that these regulations should be prescribed. But let us turn to the debates which took place upon the passing of that Bill through the House of Commons. Permit me, however, first of all, to turn to the leading article in our own Journal to show how that Act was interpreted at the time. "The provisions for preventing the improper use of poisonous substances will not be complete, notwithstanding the labours which the Legislature has devoted to the subject during this and previous sessions of Parliament, until some further arrangements and regulations have been made regarding dangerous medicines. Such regulations are contemplated in the Act which has just been passed, and they may be made from time to time by the Pharmaceutical Society, with the concurrence of the Privy Council. The subject is one of considerable importance, involving several points of detail, and it merits the serious attention, not only of pharmaceutists, but of members of every branch of the medical profession. Questions will naturally arise as to the best methods of arranging and labelling the bottles in which dangerous and other drugs are kept for use in dispensing, of distinguishing, when dispensed, such medicines as may be safely administered internally from those which are intended for external use, and of drawing attention to those medicines intended for internal administration which require great care or special precautions to be observed in using them." Then there are some other matters which I need not read. But then occurs this passage:—"Many of these regulations relate so exclusively to the internal arrangements of the shop or dispensary, that those only who have practical experience in dispensing can fully judge of the extent to which they are likely to realize the required object. Details of this description will therefore be most successfully devised and carried out by those who have the strongest and most direct interest in their operation." So far as to the way in which we interpreted the intention of the Act. Now let us see what the Legislature has thought and said upon that subject. I find that Mr. Lowe said when the Bill was about to be introduced into the House,—"The noble lord the Vice-President of the Committee of Council gave notice that he would move that the Bill should be referred to a Select Committee, but that notice has, I am sorry to see, been withdrawn, and some amendments have been put on the notice paper in substitution, but they do not seem to touch the main question, which is, whether powers of licensing persons to sell dangerous drugs shall be entrusted to persons who are in truth a mere voluntary association. I hope the Government will take care that an opportunity be given for discussing the principle of the Bill, and that the Bill be not allowed to pass through Committee between two and three in the morning without discussion. The Government ought to obtain some security from this voluntary association that the provisions of the Bill will be properly carried into effect." Again we find he says in reference to clause 1, "I move to leave out the words Pharmaceutical Society with the consent of;" the effect of that would be that it would have taken out of the hands of the Pharmaceutical Society any control, and would have vested the whole matter in the hands of the Privy Council. Mr. Headlam contended against that, and said, "The regulations as to the keeping and selling of poisons will be prescribed by the Pharmaceutical Society with the consent of the Privy Council. It seems perfectly clear that these two bodies, the Pharmaceutical Society, who will prepare these regulations which will relate to their own trading, and the Privy Council, will act together; for the latter will have to give their consent to the regulations. It cannot be objected that there ought to be some regulations relating to the sale of poisons; nor can it be objected, I think, that these regulations ought in the first instance to be framed by the Pharmaceutical Society." Mr. Headlam took charge of this Bill through the House, being in correspondence with our authorized representatives and negotiators, and he said, speaking in that capacity, "It cannot be objected there ought to be some regulations relating to the sale of poisons, or that the Pharmaceutical Society are the proper persons to frame them." I am trying to show the intention of Parliament with reference to this Bill which we accepted. Mr. Lowe further on says, "I think the clause as framed is nonsense. The idea is, that the persons referred to shall conform to certain regulations which, with the consent of the Privy Council, shall be prescribed by the Pharmaceutical Society, etc." So far as regards the House of Commons. Now in the House of Lords I find that Lord Redesdale was exceedingly pertinacious in an endeavour to introduce into the body of the Bill provisions as to the kind of bottles to be used in dispensing and sending out liniments, embrocations and poisons, which constitutes one of the provisions of these regulations. Lord Redesdale is chairman of committees in the House; he is a man of exceedingly great influence, and, at last, he very unwillingly yielded, upon the understanding that it would be done by the Pharmaceutical Society. But I want to read you the way in which his opposition was overcome by Lord Granville, who, also on behalf of the Society, was coaching the bill through the other House. He says,—"I think that the clause framed by the noble lord may be modified with advantage before it is submitted to the House. On this subject I have received a letter from a gentleman of much practical experience, and I will read it to the House. He says, 'I find that Lord Redesdale retains his faith in the poison-bottle, and intends to propose it again on the third reading of the Pharmacy Bill, adopting that which I certainly believe to be by far the most distinctive bottle ever used. But the more I consider his lordship's proposition, and the more I think of the value pertaining to special bottles of any shape when used according to the discretion of dispensers who understand their business, the more impressed I become with the impolicy of specific enactments concerning them. I have already told your lordship that most chemists in London use distinctive bottles for dangerous articles and external applications; they have done so for the last six or seven years, the practice gradually increasing. I have also said that the use of these bottles should be restricted to such articles. Now I presume the words "poison" and "poisonous" in the proposed clause must be construed according to clause 2. If so, we should be prohibited from using such bottles for every medicine not in the schedule; and I need scarcely say the schedule does not contain a sixth part of the dangerous preparations daily passing through our hands. I should not think now of selling laudanum in any other than a poison-bottle; laudanum is not in the schedule, consequently I must, if the amendment pass, discontinue that precaution. I know Lord Redesdale thinks it is the inconvenience of the compulsory enactment which actuates the Pharmaceutical Society in resisting his proposal, but I can assure you most honestly that they are anxious, both by example and recommendation, to promote his views, and really apprehensive that his amendment would prevent their doing so.'" The objection to that was, to a stiff, hard and fast rule for the adoption of a certain bottle at the will and pleasure of Parliament, without affording us an opportunity of considering how far it was applicable. I am not going to argue much in favour of the details of these regulations. What I want to contend for is, that we are under a bond of good faith to comply with the Act of Parliament, and pass such resolutions as we, with our knowledge of the business, know to be sufficient to carry out the intentions of Parliament and secure the public, whilst, at the same time, we do not impose any impediments to the carrying on of our business. I think I have shown it was the intention of Parliament to impose upon us the obligation to prescribe such regulations; that penalties were to be imposed on those who broke the regulations; and, if so, the language of the Act of Parliament would be perfect nonsense if they never were prescribed. I think I have shown you that that was so understood at the time throughout the country, and that it was so understood and accepted here as the signification of those clauses and the debates in Parliament. It is a question, therefore, as it seems to me, very much of good faith. As men of honour, as men of business, and as prudent men who are anxious to conserve that which we have been thirty years building up, the honour, the reputation and the influence of this Society, which has already checked much crude legislation that would have been of the greatest possible injury to us; in order that we may maintain that influence for the future as the protector of the trade, I say we must not now do that which would sacrifice our reputation, which would put us in the position of breakers of pledges, because I can conceive no consequences which would be more disastrous than the Nemesis which follows societies or individuals who do not keep good faith. I cannot see, Sir, how we, as men of honour, can depart from the negotiations which were conducted on our behalf by the Council and by those who more especially represented the Council. I do not see how we can repudiate the signification of that letter, which I take to be a guarantee that it would be safe to leave the carrying out of the intentions of Parliament to this Society. It is a very proud privilege, a great distinction, to have been associated with Parliament in making laws for our own government. As somebody has said, it is much better that we should have a hand in making our own laws, than that they should be framed by persons who do not understand our position. We have been told by our Council that they did give those pledges. It is evident that the Privy Council understood them to do so, and they now call upon us to fulfil our guarantees. But another thing is said, and that is, that if that pledge was given it was given in excess of authority. I profess to know something about Parliamentary business. There are few sessions in which I am not in Parliament, either promoting bills or opposing bills; and I confess that, I should be much astonished if those for whom I acted did not feel bound by pledges given in their behalf. Can a Society go up *en masse?* It is against the laws and liberties of England to do so. We are bound to depute our Council, and they depute their representatives; and what their representatives assent to, in obtaining privileges of great importance, is binding upon us. For goodness' sake do not let us begin, when we are thirty years old, to be breakers of pledges. I do not want to look at the consequences, for the fear of consequence is a low motive; but if it can be shown that we, with our eyes open, have undertaken this, then, I say, that whatever the consequences, *coûte que coûte*, let us carry out what we have undertaken to do. But I am content to rest upon consequences, and their advantageous or disadvantageous effect; and upon that point the only tangible thing I have heard is, that if we prescribe these regulations, it will inevitably lead to inspection, and all the inconveniences and annoyances which flow from it. I regard inspection as odious to Englishmen, and there is nothing on earth that I should be more anxious to contend for than my own independent action. But I have looked through this Act of Parliament, and I find that under it there *are no powers for inspection, and that it cannot be imposed upon us.* If we prescribe these regulations, I defy an inspector to come into my place, or I will guarantee to kick him out if he does. What are the provisions of clause 15 of the Act?—that whoever shall fail to conform with any regulation, and so on, "shall for every such offence be liable to pay a penalty," and so on. Let me ask how those penalties are to be recovered?—by the action of the Registrar only. But what are the consequences provided we do *not* pass these regulations? We exasperate the Privy Council. The Privy Council tell us in so many words that they will seek further legislation. It is no longer Mr. Lowe and Mr. Bruce: but the Chancellor of the Exchequer and the Home Secretary, who, throughout the passing of this Act, showed themselves most jealous of giving to a voluntary association any control. He was the man who said that Parliament ought to take security that we would fulfil our undertaking. But he said something more than that.

A Member: How long is he likely to be in office?

Mr. Giles: I do not care to attempt to answer that question. Mr. Lowe, with characteristic pertinacity, says, with reference to clause 2, "I shall move to leave out the words 'the Council of the Pharmaceutical Society of Great Britain (hereinafter referred to as the Pharmaceutical Society) may from time to time, by resolution, declare that any article in such resolution named ought to be deemed a poison within the meaning of this Act.' The object I have is this:—It is desirable that the public shall know the number and names of the poisons against which regulations have been made. The Arsenic Act is published and put in force, and you will want somebody to prosecute under this Act, and certainly the Pharmaceutical Society will be a most unfit body. *The Act ought to be placed under the care of the police and* in the hands of a department of the Government, and certainly not left in the hands of those who will live by the sale of poisons; if that be so, the restrictions imposed will be of little value." The Home Secretary says, "I shall support the amendment, for I desire to enlarge the powers of the Privy Council, who have already a medical department. The clause as it stands will restrict the powers of the Privy Council, and I see no advantage in doing that." What have we to expect if we wilfully let pass this opportunity of settling this question in a rational manner? I say these regulations are such as ought, apart from law or anything else, to be adopted by every conscientious man, by every wise man, who wishes to lay his head on his pillow with a feeling of satisfaction and security. I say what is likely to be the consequence if we lose the present opportunity? Why, we are told that we shall have application for further legislation. That application will be made to persons who will feel their sagacity and foresight complimented by our breakdown, and will be exceedingly glad to impose the strictest regulations upon those whom they regard as a recalcitrant and obstinate body of men, and they will come down with all the force of that hostility which we are so anxious to avoid. Sir, I beg to move as an amendment to the resolution, "That, by virtue and in exercise of all powers and authorities granted under the provisions of the Pharmacy Act. 1868, in this behalf, the Pharmaceutical Society of Great Britain do hereby prescribe the following regulations for the keeping, dispensing and selling of poisons, and resolve that the same be submitted to her Majesty's Privy Council for their consent." (The Regulations proposed were the same as the Recommendations proposed by the Council for voluntary adoption: see p. 949.)

Mr. Baldock (Norwood) said: Mr. President and Gentlemen,—I have much pleasure in seconding the amendment. I shall not say much on the subject, because I feel quite certain, from the ability with which Mr. Giles has dealt with the question, I should be very little able to add anything which will influence the meeting in favour of the amendment, but I fully agree in what he has said. Those gentlemen, however, who intend to oppose this, or propose any further amendment, should not forget what took place in 1868 and the two previous years, when Pharmacy Bills were brought in by Sir Fitzroy Kelly and by Sir John Shelley. On those occasions, we lost our Bill because we met with factious opposition from without,—the parties I refer to being, then as now, unwilling to be led in any way by the Council of the Pharmaceutical Society, which has done so much for the whole body during the last thirty years. The Bill which we might have had on that occasion, if it had not been for the opposition, was, I think, far more suited to our requirements than what we got in the following year, and we nearly lost that because there were no poison regulations in it. When Parliament gave us that Act, it was with the express understanding that it was to contain poison clauses, and much delay was caused on this account. Numerous meetings of the Society and of the Council took place, and ultimately the Bill was passed in its present shape. Coming, then, to the recommendations which have been proposed to us, it certainly seems to me, as I said in the letter which appeared in last week's Journal, that all opposition to them ought now to cease. No doubt it would be very objectionable in some cases to keep drug bottles under lock and key,—in the wholesale trade, for instance; but when we are simply asked to make the poison vessel distinguishable by the sense of touch,—whether it be anything which shall prick our fingers, or a spring upon the lid, or any other means,—I think the remedy is in our own hands, and could be easily applied by every one. The only fault I find with the poison schedule is, that it is so limited in its character. The poisons in the schedule are very few, and the more numerous they are the better for us, because, although to a certain extent it will increase the difficulties with which we have to deal, it would, on the other hand, confine the sale of poisonous articles to qualified men instead of leaving it so largely, as at present, in the hands of persons who are now not legally responsible for their acts in the same degree. The only objection made against these provisions is that they do not apply to medical men; but what have we to do with legislating for medical men? They, like us, are under the authority of the Privy Council, and are subject to all sorts of pains and penalties if they neglect their duties. We certainly fight under their banner, for they are a superior body to us, and, do what we can, we are not able to coerce them in any way any more than they can coerce us. We complain very justly that many of them dispense their own medicines, but that is totally beside the question now before the meeting, and has nothing whatever to do with it. If they choose to dispense their own medicines, and make a mistake and poison any one, they are quite as amenable to the law as we are. The question has been asked whether, if we pass these resolutions, they will become compulsory; and, if compulsory, whether they will involve a system of inspection. I take it they will not, and in both cases cannot. For who is to inspect us? Certainly not the police, as Mr. Giles said; we want a more intelligent body than they are. I take it, it will depend upon whether any accident occurs. If we pass these regulations, and make them compulsory, and any accident happen, we shall be then asked, "Have you or have you not complied with these regulations?" And if you have, that will be a sufficient answer to the charge; but, if not, you will incur the penalties mentioned in the Bill. I have great pleasure in seconding Mr. Giles's amendment.

Mr. Vizer: May I be allowed to ask a question, because I think it is very important that the meeting should understand clearly the position in which we stand? I came here this morning with the full determination that, as far as I was concerned, this discussion should be conducted in as calm and quiet a spirit as possible; but I want clearly to understand the nature of the amendment which is before the meeting, because it seems to me that it is a repetition of the resolution which was moved from the chair, with the addition simply that it be made compulsory. If such be the case, I cannot understand that that is an amendment unless the amendment consist in the fact of the regulations being made compulsory, which, I think, is a question we have already settled. The Council has settled it.

A Member: It is this meeting that has to settle it.

Mr. Vizer: The views of the whole meeting and of the trade are, I believe, against compulsion. We are not come here to-day to put a collar round our necks which last year we very distinctly refused to wear. If I understand the amendment aright, and we are asked to pass a vote for compulsory regulations, I do not think we need discuss it long. I shall be glad if the Chairman will tell us whether we are to divide upon the question whether these regulations are to be compulsory or not.

The Chairman: As I take it, this is an amendment by Mr. Giles on the original motion of the Council. It is quite competent to Mr. Giles to propose such an amendment, and it is also quite competent for any other member to propose a further amendment after that. If this amendment of Mr. Giles should pass, there can be no doubt, I think, that the recommendations or regulations will then become compulsory.

Mr. Brown (Manchester): I rise to a point of order. I shall certainly maintain that the amendment of Mr. Giles is no amendment at all. I should like to have the opinion of our solicitor upon that point, and I am sorry he is not present at this moment in order to answer it. But I appeal to any gentleman who has had experience of public meetings whether this is an amendment. I maintain it is an original motion, of which notice ought to have been given, and it ought to have been proposed as a substantive motion, and seconded in due form. Then it would have been in order.

Mr. Abraham (Liverpool): I am satisfied, Sir, that the amendment which has been moved is perfectly in order. It is upon the main question whether these regulations should be compulsory or not. I beg to say that there is not a member of the Society who would have been more glad than myself to have adopted them as recommendations only, provided we could honourably do so: but I think it has been shown clearly by Mr. Giles's statement, to every man in this room, that as members of the Pharmaceutical Society, we are bound to pass these regulations. Not because we like them, by any means, but because the Legislature has imposed upon us the duty of making regulations. And I beg to say that although I seconded Mr. Dymond's motion to bring this matter before you in the way in which it has now been done by the Council, it was simply to enable you to do the next best thing to doing the right thing. I believe it is our duty to pass these regulations in the sense in which they were contemplated by Parliament; and although as a member of the Council I seconded the motion that they should be framed so as to enable you to pass them as recommendations only, as I think that would be better than rejecting them altogether, yet standing here as a member of the whole body, who only have the authority to make these regulations, subject to the confirmation of the Privy Council, I cannot but raise my voice in favour of the amendment which has been moved by Mr. Giles. And I must remind you that it was the opinion of a large majority of the Council that they ought to be passed in the sense in which they were originally proposed. The proceedings of the Council are not now known to you only from the statement of the President, or from the resolution which has been laid before you. The proceedings of the Council have been published from month to month in the Journal, and you know that the Council think you ought to pass these as regulations. It is only a small minority of the Council who hold a different opinion, and I believe most or all of them were not members of Council at the time the Act passed. It is only with them that there is any difference of opinion as to our duty in the matter; and although I desire to make these regulations as little burdensome as possible,—and I do not think they ought to be adopted if they are at all burdensome, or if it could be shown that there would be any difficulty in observing them in any shop in the kingdom,—to refuse to pass any regulations at all is distinctly to set aside the vote of Parliament, and is, I am assured, perilling the interests of the Society and of every member of the body.

Mr. Brown: The question before the meeting is not whether the regulations should be compulsory or not, but whether this meeting will adopt certain recommendations which are submitted by the Council.

Mr. Vizer: In support of what Mr. Brown has just said, I maintain that if an amendment of this nature be laid before the meeting, it is one of the most unheard-of and unprincipled acts which can be conceived. I repeat it. It is an unheard-of and unjust act. This meeting has been called together in the ordinary way as an annual meeting; the recommendations have been issued to every member with the one distinct idea that they were to be brought forward by the Council as recommendations only. And I beg leave to say that if that view of the case is altered, it is most dishonourable on the part of the Council. This meeting has been called to decide the question whether we shall receive these as recommendations, and hundreds of members have absented themselves from this meeting on the distinct understanding that they were to be put forward simply as recommendations. I do assert most emphatically that if an amendment of this nature is allowed, it is a most discreditable act. The Council, as a body, ought to protest against it. But I sincerely trust that the meeting will not be detained over the argument on compulsory regulations, but that a division will be speedily come to, and I am convinced that 90 out of 100 will vote against it. It is an unheard-of thing to waste our time discussing such a question, and the sooner we come to a vote upon it the better.

Mr. Urwick: I wish to make a few observations on these recommendations, but in the first place I do feel that we should be committing a most dishonourable act if we are parties to any vote which is to be compulsory, when the notice sent to the country members and distributed throughout the kingdom had only recognized these as recommendations. It would be taking an advantage of the country members to entertain such a question, and I therefore protest against the amendment, and call upon the Chairman to enter my protest.

Mr. Edward Burden: May I ask if the Chairman has ruled that the amendment is in order, or not?

The Chairman: Yes, I have ruled that the amendment is in order. It is competent for any member to move an amendment to any motion that may be brought forward.

Mr. Humpage: It appears to me that it is no use my coming here and arguing, if I have sent up my paper pledging myself to a certain course. I conceive that these papers have been sent up believing that such-and-such a course would be adopted, and that these rules would be passed as recommendations. But I also ought to be aware that if at this annual meeting the members present should think otherwise, and any gentleman should choose to make an amendment, and a different view is afterwards taken, when argument has been gone into, it is perfectly regular to vote for such an amendment. We surely cannot tell our friends in the country what will take place at a meeting like this. If they are so much interested in it, let them come up, and then they will be ready to vote; but if we can do nothing, what is the use of coming here and discussing the question.

Mr. Urwick: Can we make rules binding the body of members, the body not having notice of those rules?

Mr. Hampson (Manchester): If it is thought desirable to deceive and disgust the whole trade, now is the time, by means of this amendment. You want the outsiders to come in, and by the course of action now proposed you thrust them out. The amendment may be in perfect order—I do not pass any opinion upon that—but the consequences of the amendment, if carried, will be to sow a whirlwind in the country that you will not see the last of for some time. I have had some means of judging of the spirit of opposition to compulsory regulations, and I can assure you that if you wish to advance the interests of pharmacy, or even to advance the interests of this Society, you will not vote in favour of the amendment. This amendment will plainly show the outsiders, many of whom I conceive are quite equal in capacity to ourselves, what they may expect from the unscrupulous adherents of compulsion, and you will likewise arouse a spirit amongst them that will not easily be set at rest. You will shut the doors against them, and sow discord throughout the country. I should like to say a few words on the general question. The word "honour" has been put forward in this discussion, and freely reiterated, and we are told that if we do not vote in a particular way we shall be dishonoured. I maintain that nothing of the sort follows as a consequence; that if certain gentlemen who were in high office at the time had the power through their fortuitous position to carry the Pharmacy Act through Parliament, they did not ask the opinion of the country about it, and you must also remember that we are not only legislating for the few in this room,—because, properly speaking, it is legislation we are about,—not merely for pharmaceutical chemists, but for the entire trade throughout the country, numbering many thousands.

Mr. Mackay: I desire to say one or two words upon this point. I have been listening very calmly to what has been going on, and have heard the word "honour" used repeatedly, and perhaps advisedly; but that word may in certain circumstances have two meanings. I am not prepared to say that the amendment is illegal, or to protest against its introduction, but this I do say, and I say it most emphatically, it would have been a much fairer course for the gentleman who has so ably and eloquently pleaded for this amendment, if due notice had been given of it. I make this remark, and, in doing so, speak strongly for the following reasons:—I know, and believe many gentlemen present know, that deputations had been organized in different parts of the country—I can speak positively as to Glasgow and some other places; that these gentlemen had been prepared to come here and represent the chemists and druggists in various towns, had the compulsory question not been understood to be at end; and therefore most of those deputations which had been organized would have been in this room to-day to oppose this amendment. It is not for me to enunciate what my views are, but at a recent meeting of the Council I joined in the almost unanimous vote that a certain course of procedure should be adopted. That course resulted in the recommendations which are before us, and, having emanated from the Council, they have been circulated broadcast throughout Great Britain, and I say it is specially unfair, and I use the word with due consideration, to many country gentlemen who are as deeply interested in this question as we are, to push the question of this amendment to a vote. So strongly do I feel upon this point, that if the amendment is pressed I may move the adjournment of the meeting.

Mr. Waugh: There has been a great deal of talk about honour, and so on, but my experience is this, that a man who knows and feels what personal honour is, will be very careful how he casts reflections upon the honour of other men. It is a very delicate thing, and to all rightly-constituted minds that which every man most highly prizes. I am perhaps the oldest member of the Council here, and whatever may be the abstract merits of this question, I say, do not press that amendment. When I came here to-day, a bit of paper was put into my hands, bearing date May 4th, and I must say I felt this was a most unusual step, and it looked very much like attempting to steal a march upon us. How was it that, the Journal having been published twice since that date, the document was not published? How was it you never published that little private note from your friend, Mr. Simon? It is a close thing, gentlemen, and, in my opinion, not a fair thing at all. I must sit down, but I beg you not to press that amendment.

A Member: Will not Mr. Giles withdraw the amendment, and make us all a happy family?

Mr. Randall (Southampton): I would heartily join in what has just been said, and beg that at all events in the shape it has taken, this amendment may be withdrawn. Not because I object to the amendment in itself, for I should support it most heartily at the proper time, and as it regards mere technicality I think it certainly is an amendment, and a reasonable one: but why I think it ought not to be taken now is, that it is more than an amendment, not less. It proposes that the common seal of the Society should be put to certain regulations which will give them the power of an Act of Parliament; but I say that after what has taken place, supposing we do this to-day, the Privy Council will not admit that it has been properly done, and will send it back to us to do again; for I am quite satisfied that the Privy Council on looking into the matter, would say,—We are very glad indeed that these regulations have been carried, but they certainly must be carried at a meeting at which due notice of their being brought forward has been given. I do not think it was necessary to speak quite so strongly about honour, and so on; I think we shall be all agreed that we cannot take them as regulations to-day, but I do hope that if Mr. Giles should see it right to withdraw them as such, he may still give some of us an opportunity of showing that we do feel that in our corporate capacity we ought to act exactly in the same way as we should as individuals. I say that if the members of this Society individually had done what we have done, as Mr. Giles pointed out to us, we should not one of us have drawn back from taking upon ourselves the burden of these regulations; I do not think, as a corporate body, we have any right to do anything less. Therefore, although it would not be proper to pass these now, seeing that no notice has been given of them, I quite agree that we ought to pass them some day. Now, gentlemen, it is only fair to look at the course which has been taken. It was not the Pharmaceutical Society's Bill that introduced poison regulations, but for some reason which I shall not criticize, our Bill was upset once, and nearly upset again by attempts to put poison regulations in. Then the Pharmaceutical Society said, that being the case, supposing Parliament will give us a Bill, not just for the promotion of our own interests, but a Bill that shall promote, as they think, the interests of the public, whereby, at the same time, our interests will be promoted,—we will put in the next Bill some poison regulations. They insisted on having not only regulations for selling, but also for keeping poisons. The Society has done its best to obtain a Bill; and having in vain attempted to do without poison regulations, now, as men of honour, as we have had the regulations forced upon us, I think we ought to carry them out straightforwardly. That I believe to be our position, and I think that we ought to pass these recommendations now, and also to pass a resolution that we shall be quite ready to make them regulations if called upon to do so.

Mr. Clark (Leicester): Would you kindly state, Mr. Chairman, if in your opinion the passing of this resolution will give satisfaction to the Lords of the Privy Council? If you think it will, or if you think it will save us from obnoxious legislation, I should at once ask this meeting to pass it unanimously, and would urge upon Mr. Giles to withdraw his amendment, upon condition that Mr. Vizer adopts the same course in regard to his resolution. If this plan should be adopted, I have no doubt a favourable impression would be made upon the Privy Council, and would have much more weight than if carried by only a small majority.

The Chairman: I am not in a position to say that the Privy Council would be satisfied with the recommendations. I have had no communication myself personally with the Privy Council or its officers in any way whatever. The letter which has been alluded to came to the Secretary, and, as has been stated, that letter was laid before the Council. I felt that was no more than I could do in my position. Certainly it appears to me that any gentleman may make an amendment, and any gentleman may make a further amendment. I am desirous of doing that which the meeting approves of; and if the meeting particularly desires that Mr. Giles's amendment should be withdrawn, and if Mr. Giles is willing to withdraw it, I am willing it should be so. But I cannot order Mr. Giles to withdraw it; and if he insists upon it being put, I must put it.

Mr. Squire: From the general spirit of this discussion on both sides, it does appear to me that the Privy Council must gather, from what has been said, that the thing requires more ventilation. These regulations consist of three parts, either of which may be adopted by chemists; and it does appear to me that they are still imperfect. I think if a law was imposed which we have to follow, it should implicitly state one rule of action. Here are three, and they appear to me to be very difficult for people to adhere to strictly. I do not think in any Act of Parliament this sort of ambiguity would be allowed. When I was in the House of Commons about this Bill, Mr. Sandford said to me, "What do you think of that clause?" which I afterwards learnt was a pet clause of a gentleman connected with the Privy Council, and it was to this effect, that no poison should be sent out except in single doses, and that upon the order of a medical man. When you consider that a man may be ordered a composing dose to be taken every two or three hours during the night, I think it would be rather awkward to require a doctor's order for each dose to be obtained. That shows you what may be expected from the Privy Council, and that without our assistance they could not frame such regulations as should be practicable; and it is no use making an Act of Parliament unless it is so, for it would never be followed. Upon the whole, therefore, I think that the question is not yet matured. When I was here last time, as a member of the Council, I said the same, and I still think so. I think the spirit of these meetings shows that there is an inclination to obey any laws that the Council like to make; and I think the tendency is to make such regulations, if they can, as shall, in every way, satisfy the Privy Council also. We are not a rebellious body, but we do not think these are the things which should be made compulsory; therefore, I hope that another year, if we shall live so long, we shall have an amendment of this which will be more acceptable to the body at large.

Mr. Hills: I wish to say shortly why I have changed my opinion, not since I have been in this room, but during the various meetings which we have had at the Council. I believe with many gentlemen who have spoken here to-day, that we must some day or other have regulations, and that they must be enforced—regulations framed by the Pharmaceutical Society and approved by the Privy Council. I originally was in the majority, thinking these regulations ought to be passed, and hoped that they would be confirmed by the meeting here and afterwards go to the Privy Council. But I changed my mind, because there seemed to be so great an objection out-of-doors. I therefore thought it would be better to pass them as recommendations to be tried, feeling sure that if once tried they would be voluntarily adopted as regulations; they are now brought forward as recommendations, and I hope my friend Mr. Giles will withdraw his amendment. By doing so we shall become, as has been said, a happy family; and the trial of these recommendations of the Council for twelve months will so far convince us of their usefulness and practicability, that we shall adopt them as regulations at the next annual meeting.

Mr. Sandford: Gentlemen, I have often been received here with the same good-feeling which now greets me, and though I fear I shall differ from many of you to-day, still I hope we shall be as good friends as ever. I am sure, Mr. President, you will quite appreciate the difficulty under which I rise,—I, who have always held that the Council should stick together, and that if there is a majority on any one point, the minority should succumb. I, being in the minority, a minority of one single individual, must now rise to oppose a majority. But in doing so, I act, as I ever have done, in the interests of the Pharmaceutical Society, because I believe most certainly that the course proposed by Mr. Giles is that which will secure for the Society the position which it has held hitherto, and which is now imperilled by the action, or rather want of action, proposed. It has been asked whether the Privy Council will be satisfied with these things as recommendations. I have had no communication with the Privy Council since, I think, January last, when the regulations in form were agreed to and submitted to this Council, and afterwards accepted by it. But I am perfectly satisfied that they would not be taken as of any value whatever. I think we must all of us have observed, gentlemen, that of late years the tendency of the Government has been to act in departments, and that certain subjects have been handed over to different departments. All matters connected with the public health have been handed over to the Privy Council, and I do not know that we should find fault with that because we want to have the Government of the country carried on as efficiently as possible. Formerly such questions were everybody's business; you might go to the Home Office, or the Board of Trade, or any other office; but now they are concentrated in the Privy Council Office, and there is a medical officer there who is one of the most active servants of the Government. We know perfectly well what the feeling of that medical officer is from what our friend Mr. Squire says, of a notice I pointed out to him on the paper, as our Bill went through, that no poison should be sold to any person except in medicinal doses, without the order in writing of a legally-qualified medical practitioner. That is the sort of thing which we may expect from the Privy Council. I hold here in my hand all the Poison Bills which have ever been introduced, there are no less than eight; and there is another very important one which was never introduced to Parliament. And what do I find are the provisions in these Poison Bills? I find that in the first, which was proposed by Lord Granville—I may say our friend Lord Granville, because it was through him we obtained our Bill,—that no poison should be sold except to persons of full age, that they should not be sold without witnesses, that they should not be sold without the certificate of a medical man, or a clergyman, or a magistrate. I find that every poison is to be sent out in four-sided bottles, and that on each of those sides there should be the word "poison" impressed. I find that there were inspectors to be appointed. Now the less we say about inspectors the better; but I find, as I go on, that in one of these Bills the inspectors were to be constables. Lord Granville's Bill in May, 1857, was No. 1. It went on to Mr. Walpole, so both sides of the House were engaged in this matter. Mr. Walpole was in power in 1859, when he proposed his Bill, and he put in a provision that the constables were to visit and see that we complied with the regulations. At that time Jacob Bell was living, and under his guidance we opposed all these Bills, but we did so on one special principle, viz. that they did not provide for the qualification of the vendor. I take up these Bills to show you that they were fairly considered in this Council, that they were considered as things which would go on, and they were amended by the Council. This Bill which I hold in my hand is covered over with erasures and alterations and interlineations made by way of amendment by your Council. Therefore it is not a new subject with the Council at all. And what happened then? Last of all, Jacob Bell himself drew a Bill. We have been told over and over again that had Jacob Bell been living, we should never have been threatened with such a Bill as this; that he would have led the trade and resisted it. But what did he do? He drew a Bill in which he introduced as examiners of the Pharmaceutical Society a foreign body; and he not only did that, but he proposed this particular clause appointing inspectors, which I must read to you, although I do not like to publish it. This Bill was never in Parliament; it was prepared with the endorsement, that it was a Bill containing in substance "all that is valuable or likely to be practically useful to the public in the sale of poisons." This, remember, was a Poison Bill, not a Pharmacy Bill. It provided who should be allowed to sell poisons, and that all poisons should be distinctly labelled with their names and so on, and then I find this clause, to which I want to call your attention. "The President and Censors of the College of Physicians of London shall have full power from time to time, at reasonable times in the day, to enter and search any shop or place where any drugs or medicine, simple or compounded, are sold by retail, to ascertain that the provisions of this Act concerning the keeping of poisons and the labelling of the same are duly observed." That is the Bill which was prepared by Jacob Bell himself to be submitted to Parliament. I just wished to show you that, to show in what a different position we now are. We have now the opportunity of making regulations without any inspection whatever. We cannot have an inspector sent into our shops without a fresh Act of Parliament, and we have every reason to believe that the Privy Council would be satisfied with the regulations we have proposed, which might be easily carried out. As Mr. Squire said, you may take one course or you may take all three courses; with that elasticity we should not interfere in any way with the easy carrying on of business. Here we have an opportunity of doing this, and now we say, no, we will not do it. If ever inspectors are appointed, we shall have to thank those who have drawn attention to the subject by their opposition. We do not say the regulations are bad, but it is a sentimental grievance that we should have them at all, therefore we throw it up entirely, and let the Privy Council go to Parliament. You know quite well what Parliament will do. There is a sample of what they would have done in 1857 and in later years. And I think that is evidence enough to show what Parliament will do now; because remember that with an active medical officer on the Privy Council, he will urge on his representatives in the House of Commons and the House of Lords, and the Government will go to him for advice on all these questions. He has before him all the details of poisoning cases and all the accidents that happen in business, and you cannot say that these things are unnecessary. If you say so, the answer is, we are told that in the best houses they are all adopted, therefore, how can you call them unnecessary? I heard a gentleman say this morning that he was utterly astonished at the opposition to these regulations; that he knew some twenty shops in the country where no precautions were taken, and where all the poisons and other drugs were huddled together indiscriminately. Now, remember it is not when a man is going to use strychnine that he wants to be reminded that he has strychnine in his hands, it is when he is going to use some innocent medicine such as James's powder, and he by accident gets hold of the strychnine bottle, it is then he wants to be reminded by some simple means that he has not got James's powder in his hand. And you are not bound to use the same precaution with every poison. I may tie strychnine over with a leather cap and be more careful with it than with a morphia bottle. I say nothing now about the honour of the thing, because I consider that is perfectly established. Mr. Giles has most correctly stated the feeling and the understanding there was at the time of the passing of our Act. I have heard it objected that it was a tacit understanding. Sir, there must be tacit understanding when you are on business like this. Mr. Giles tells you what happens always in getting Bills through Parliament. I was to a great extent authorized to treat with the members of Parliament and with the Government in the proceedings with regard to this Bill, and I am perfectly satisfied that I did not in any way neglect the interests of the Society. If any man battled with the medical officer of the Privy Council, I did, and in all but one thing I beat him, that one thing I always felt ashamed of, it was that he succeeded in bringing in poppies; that one thing I could not get over. It was the last thing, and I think Lord Granville went into the House rather in a hurry, or that might have been excluded also. I mention that to show you that I have not been the obsequious servant of Mr. Simon. He would never propose anything to me which would be derogatory to this Society. Mr. Giles alluded to the debates which took place, and I will not go further into this point. I will pass that over and confine myself to the question of policy. I say it is policy for us to adopt these regulations in the form in which Mr. Giles proposes. Some people speak of breach of faith in proposing this amendment. I say it is no such thing. Last year it was proposed that these recommendations should be adopted for twelve months; they have been on their trial for twelve months and more. They were submitted to you last year, and you have all had an opportunity of trying them since, and there has not been a valid objection to one. But if there were, it is quite open for this meeting to amend them in detail. If you do not like tying over, use some other means, you can amend them in any manner you like in detail; but just admit the principle that we are a part of the Government, that we are pledged, and that it is not only that we are pledged, but that it is our interest to act in accord with the Government and not in antagonism. I do therefore most sincerely trust that you will vote for the amendment of Mr. Giles.

Mr. Wade: I think we may all take it for granted the Council are willing to adopt the views of the trade, and more especially of their own members. If such is the case, I would just take you back to the last annual meeting, when the resolution come to was, not that we did not require or would not take such regulations, but that which we distinctly stated, and which has since been endorsed, was, that these regulations that were put forward were not of a consistent character, and it was not desirable to have them compulsory. If such was the case, I would ask the Council whether they have learned from the trade during the past twelve months what is their opinion, and what is the opinion of their own members. I do not wish to mention intimidation, or to say a word about storms that may be created; but, having once expressed an opinion, I think, when that has been done in a calm and deliberate manner, the Council may be fully justified in altering the opinions they had formed, and studying the wants and desires of their constituents. I am not one to blame, but rather to honour and respect the course which has been taken by our late worthy President, and I shall, as long as I have the pleasure of knowing him, honour him for the course he has adopted. It is a great pleasure to me to acknowledge what he has done for the trade, although I have differed from him many times, but still it has always been my desire to hold him in high honour; and, although I differ from him now, still there is not an act which he ever committed which redounded more to his honour and credit than his resignation. Still, while I admit this, I must oppose Mr. Giles's amendment. At the same time, I cannot support the resolution of the Council. I say so for this reason. I consider it a most insidious amendment. I think it has been brought down after the sense of the whole trade and of all our members has been taken in every part of the country,—after that opinion has been expressed by deputation and memorial, and it has been virtually acknowledged. After that a letter comes to you on the 4th of May, which ought to have been published in the Journal. We ought to have been made acquainted with that, which may be called a threat, an intimidation sent from the Privy Council office. If there is anything dishonourable I consider it is Mr. Giles's amendment, because I do think that that which the Council have put forward was an act of honour. They attended to the wishes of their constituents; they saw that during the past year the trade had made up their minds upon the point, and, with commendable good sense, they attended to those wishes, and put forward these propositions in form of recommendations rather than regulations. I beg you not to go back from that course of action. If you do not wish to create distrust, but to make outsiders feel that this Society has but one interest, and that interest only the interest of its members, do not pass Mr. Giles's amendment. It comes in at the last hour when we are not prepared, the idea having gone abroad that we were not to have any opposition of this kind. The idea was, that we were to carry something which should meet the views of the Privy Council, and not be compulsory on ourselves. If the Council in their deliberations have come to the conclusion that these resolutions they have adopted are likely to be in accordance with the spirit of the Act, why do we hear so much about want of honour and breach of faith? Is it likely that your Council, composed of men of honour, would ever allow such resolutions as these to be put forward for your acceptance if they did not think they were carrying out the honour and spirit of the Act? Do you suppose they would allow their Solicitor to frame a resolution which would meet the wishes of the whole Society unless they felt they were carrying out honourably that which it was their duty to do? Therefore, upon every principle of honour, I think we ought to accept that which our Council have put forward rather than that insidious amendment of Mr. Giles. So much with regard to Mr. Giles; but with regard to the resolution of the Council, I must say I do not consider that these regulations have been sufficiently looked into since our last meeting. I consider they are almost equivalent to those which were then put forward. We then said we are prepared to accept certain recommendations, and if you will give us such recommendations not only which are beneficial to the public, but such as really can be carried out, that is what we want. We do not say we will not do it; we say, give us such regulations as we can practically and honourably carry out. Mr. Sandford has told us that in London every one adopts these resolutions. Of course they do, because there is no difficulty about it. But he says in the country you go into a shop, and find poisons of all kinds scattered about. Why is it? Because the characters of the business are so opposite, and what is easy in one place is difficult in another. Therefore we say that these resolutions are not practicable for the country. We say that in the great dispensing houses and others in cities, where you have nothing but small quantities to deal with, you may accept them, and think you are doing very right in carrying them out; but it is not so easy for our country friends; and therefore, unless you revise these resolutions,—and we asked you at the last meeting to take them back and revise them,—I do not think they are such as should meet with general acceptance. Let us have such a code of rules as can be carried out practically, and then we shall be ready to honourably fulfil our duties under the Act; we shall bring the whole trade into unity, and reflect credit on ourselves.

Mr. Sandford explained that the note from Mr. Simon had not been published earlier because, when a former one was published immediately on its receipt by the Secretary, a complaint was made that it ought not to have been done before it was laid before the Council.

Mr. Wade said he was glad to have that explanation, because the very fact of the former note having been published made him think it desirable that the one of May 4th should have made been known to the trade immediately.

Mr. Watts: Last year, during the noisy discussion which took place with regard to the Poison Bill, I made a remark to this effect, that we must not lose sight of this great fact, that if we did not make regulations for ourselves the Privy Council would make them for us, and that anything done on the part of the Government would be hardly so acceptable to the body generally as if it were done by ourselves. I think that same remark will apply on the present occasion. A great deal has been said about country members and outsiders, but my own opinion is that country members and outsiders know very little about the matter. What I mean is this, that there are a great many members in the country who desire to be led; and the proof of that is shown in what our friend Mr. Vizer has done, and he not only intends to lead the country members but the town members also, if possible. I must say I am rather surprised at the remark of Mr. Randall, that if these regulations were adopted the Privy Council would send them back and say they were irregular, or something to that effect. I conceive that Mr. Giles is in perfect order; and I am very much surprised that those who are in the habit of attending public meetings should express any opinion to the contrary. It is competent to any one to move an amendment, and I trust Mr. Giles will press his to a division.

Mr. Bell (Hull): The gentleman who has just sat down stated that Mr. Vizer was trying to lead the country members. This I consider a great slur upon those gentlemen, and I cannot submit to it. With regard to these regulations, we in Hull fully understood that they were withdrawn, and would come before us as recommendations only, otherwise I can assure you that two-thirds of the members of the Society in Hull would have been present here to oppose them.

Mr. Davison (Glasgow): I came here to represent Glasgow, and the feeling there is that the regulations would be presented to the meeting as recommendations simply. Since I came here I have seen this note of Mr. Simon's, but I am prepared to vote just the same. Mr. Simon speaks of the regulations being required for the safety of the public, but in Glasgow two-thirds of the dispensing is done by medical men who keep open shops. Some of them have three, and many have two; and I think if the Privy Council and Mr. Simon are going to legislate for the benefit of the public they ought to legislate for these surgeons. Not many weeks ago a man came into my shop, and asked for an ounce of tincture of cantharides, which I refused to supply him with unless he brought two witnesses with him, which he declined to do, but in the course of half an hour he came back again, and brought a bottle containing an ounce of tincture of cantharides without even a poison-label on it, which he had obtained at a surgeon's; and in many of these doctors' shops there is not a responsible person, but merely a girl or a boy sometimes to serve. I am quite prepared to attend before Mr. Simon any day to explain the matter.

Mr. R. O. Fitch (Hackney) said he had not intended to be present, as he understood the regulations had been withdrawn; but he had received a private intimation that it would be requisite for him to come. With regard to the Poison Bill, he could supplement what was said by the last speaker by parallel cases in London. It looked very well on paper to talk about the protection of the public, but there was a good deal of nonsense about it. Not long ago a Greenwich pensioner came into his shop, and asked if he wanted to buy any savin, as he had a large shrub of it for sale. On the other hand, a gentleman's coachman, who wanted some to give his horses at the spring of the year, came all the way from Acton to his shop at Hackney, where he had been accustomed to procure it, because the chemists at Acton would not supply him with it. If any regulations were required at all, he hoped they would include one that no person under sixteen should be served with any poison without written instructions, for mistakes were constantly happening with children.

Mr. Long: I must agree with Mr. Giles and Mr. Sandford, and all those gentlemen who have spoken on that side of the question. I think the opposition that we have is like the opposition which we get in every trade to everything in the nature of improvement. People talk about putting collars on their necks, and all that sort of thing; but, if they were to adopt every enlightened method of principle which was proposed, it would be much better for them. I cannot imagine men who, in such a dangerous business as ours, could be content to have these poisons strewn broadcast over their premises, to be taken hold of by anybody haphazard. The regulations are very good in themselves, and can easily be followed. Either of three principles which are laid down may be adopted; and the people in the country, of whom so much talk is made, if they have a cask of arsenic, can easily lock it up, and tie their other poison-bottles down with leather, or adopt some simple means of calling attention to them. I think, therefore, it is very absurd, and unnecessary, to object so to it. We shall have to have it, and therefore we may as well do it in our own way, as otherwise we shall have to accept regulations imposed upon us by Act of Parliament. If we were not to oppose so many difficulties, but to take advantage of every modern improvement,—like early closing, shutting up on Sundays, and so on,—we should be in a much better position than we are now. We have not any time to ourselves, not because we could not have it, but because we choose to impose this collar upon ourselves; and we allow the public to suppose that a chemist is at their beck and call any moment they like, instead of making them provide for their wants in our business the same as they would in any other case.

Mr. Dymond (Birmingham): I hope, Mr. Chairman, that whatever we do, we shall make up our minds to settle the matter now, without postponing it or adjourning the meeting. I have listened with the greatest interest to what has taken place, and the more I have listened the clearer has my mind come to the conclusion that the Council have done right in presenting the motion which they have. We have here opinions most ably stated by Mr. Giles, in which I may say I most cordially agree. We have other exactly opposite opinions, also ably stated by Mr. Vizer, and it seems to me that the recommendation of the Council exactly lies between them. If one side will give way a little, and the other will give way and meet at the point proposed by the Council, we may come to a unanimous conclusion. These recommendations I am sure, from my own experience of what has taken place in the Council, have been the result of long and anxious deliberation. We have, on the one hand, known all that Mr. Sandford has told us of what the Privy Council has done, of what has been attempted in previous Acts of Parliament, and indeed have become familiar with the whole history of the question, with opportunities which few others have possessed. Knowing this, a large majority of the Council felt that the regulations, in their compulsory form, were those which the country ought to accept. On the other hand, we have, since these first resolutions were arrived at, had manifestations of opinion throughout Great Britain, by means of meetings and memorials addressed to the Council, the meaning of which has been unmistakable, and which it would have been folly to ignore. The Council is but a representative body; it was bound to take notice of the opposition thus manifested, and it would not have been a fair representation of the opinion of our constituents to attempt to pass these resolutions compulsorily. We therefore went again into the matter with, speaking for myself, convictions still unshaken of the desirability of such regulations and of the obligations which the Society had incurred by the passing of the Pharmacy Act, but yet conscious that the chemists of the country were unprepared for such a measure. Convinced of that, I, as a member of the Council, say it was not our business to carry forward that measure in a compulsory form. Yielding to that which we see is the opinion of the trade, we have brought forward these measures in the form of recommendations; and I am convinced, in proposing that recommendatory form, we have done the only thing possible to do, and which I believe it is wise for this meeting to accept. I do ask you to settle the question now, by passing the moderate measure which we have proposed.

Mr. Linford: I perfectly agree with what Mr. Dymond has said, but what if the Privy Council will not accept that only as a recommendation? Are we any nearer to our end at all? Is it not possible that the only way in which it can be successfully presented would be that the recommendations should be adopted for a year on the distinct understanding that if they are found practicable, they, or some other recommendations which may be amendments of these, should be adopted as compulsory at the meeting this day twelvemonths. I think by that means we may arrive at a medium course, which may, to a certain extent, satisfy the Privy Council, and enable us to still hold in our own hands the regulations, which, if we once give them up to those who are not acquainted with the trade, will be imposed upon us in a very different shape. I have heard a great deal about objections to these regulations, but I myself have conducted business in the country and in London. I have dealt in paints, oils and colours, as well as drugs; and I have had the entire conduct of a large West-End business; but I have never yet heard any distinct and specific accusation against any one of the regulations as impossible to be carried out. I should like some country member to tell us what it is he cannot do. If he cannot lock up his cask, he can put some sandpaper on the lid, or put a rim of sandpaper round it; there are many things which will be strictly in conformity with these regulations, and which are perfectly easy of adoption. There is, perhaps, no business where it would be more difficult to carry them out than where I am at the present time, but I think even there I could manage to carry them out without any insuperable difficulty; and being able to carry them out without fear of inspection is an advantage which we ought not to lose sight of.

Mr. Squire: I think Mr. Linford's observation, if put in the form of an amendment, would be carried almost unanimously by the meeting,—that is, to adopt these regulations for a year.

Mr. Edwards: I will not go over the whole ground which has been gone over already to wearisomeness; but two things I will notice. We are charged with having unfairly published this letter, or rather with keeping it back as a threat. Now, when the first letter of Mr. Simon's came, it was published immediately; and we were charged with doing that which we had no business to do until the Council saw it. It was said that the Editor of the Journal had no business to publish that letter until it was laid before the Council; therefore, this letter was not published until the Council had seen it. One other remark I would make about the inspection. I shall not go at all deeply into that, except to state that the fear of inspection is a perfect fallacy in my mind, unless you refuse these regulations, and then, I believe, it looms in the distance, and is not very far off. But the Council have done what they could do. You know their opinion, and their opinion is unchanged still; but if you will not have these regulations, the Council have ceased to wish to force them upon you, and they throw the responsibility upon yourselves. But I, as a member of the Council, cannot help warning you that, if you wish for inspection with all your heart, you had better reject these resolutions. The Committee of the Privy Council, if they bring any bill into Parliament, will not omit inspection; and depend upon it you will have yourselves to thank for that which you might have avoided. We are not entitled to say that we know they are quite satisfied with them, but we have every reason to believe that, if you pass them, it is all they require. I remember a little time ago sitting at a board of health, and some Act of Parliament was mentioned. I said to the solicitor: "But supposing it is not done, how is it to be enforced?" "Enforced," said he, "like every other Act of Parliament. If a man breaks the law, and is found out, he will be punished." It was not that an inspector was needed. Where is there an inspector for gunpowder? Where is the inspector under the Arsenic Act? It rests on the same ground as every other law; if you do not obey it, you do it at your peril. You will find there is no inspection necessary; but I must tell you, whether you think it popular or unpopular, if you wish to have inspection, you cannot adopt a surer method to obtain it than by refusing to pass these resolutions.

Mr. Townsend: I think, with regard to the amendment of Mr. Giles, there is a very serious difficulty, from the fact of a circular having been sent to the whole trade which, by implication, led the country members to infer that the regulations would be adopted to-day as recommendations only. I think this difficulty might be solved, and the subject might be calmly considered, if some such resolution as this were passed, that in adopting the recommendations suggested by the Council, this Society is prepared to consider the desirability of confirming them as regulations at a future meeting.

Mr. Giles: I have been asked several times whether I will consent to withdraw my amendment. I shall be very willing to withdraw it on conditions. If I can be assured, to begin with, that by postponing action at the present time, we shall be secured against any action of an offensive nature in future. I regret exceedingly that it has been considered necessary—not by myself so much as by others with whom I have consulted—to mix up this question of compulsion and principle with these questions of detail. My last intention, after I had submitted the notice which I gave of this amendment, was to move a resolution to the effect that it is the duty of this meeting to comply with the provisions of the Pharmacy Act, by prescribing certain regulations, leaving altogether out of the question the nature of these special regulations, in order that they might be made the subject of further deliberation amongst gentlemen appointed by this meeting to confer with the Council. But I am satisfied it is no use to delay. We have delayed for twelve months, and I do not think we have fulfilled the kind of engagement we gave when we then postponed it. I do not think the chemists throughout the kingdom have given these regulations a trial. I would only just say one word more in justification of a slight imputation on my personal honour in bringing this matter forward at the last hour. To begin with, notice was given by Mr. Baldock of such a resolution in the Journal; and, in the second place, I have an abhorrence of anything like a packed meeting. I determined to bring this forward to such a meeting as happened to come, and I assure you, on my honour, I have not asked a single person to attend it. Granted the opportunity of packing the meeting, no matter what the question is, I will undertake to carry it, but do not let any one have the chance of packing it.

Mr. Urwick: I think Mr. Giles ought not to go into the question again. If there has been any question asked which he wishes to answer, and the meeting wishes to hear him, it might be allowed; but we ought not to go into a discussion again.

Mr. Edwards: Mr. Giles has an undoubted right to reply.

Mr. Giles: I understand that I am replying by the courtesy of the meeting. I assume I have cleared myself from the charge of bringing this forward in any dishonourable way. The question is, shall I withdraw this amendment? I am willing to meet any compromise which will not put us in the position of leaving this room to-day with the effect that we have passed over this opportunity, and have declined to do that which I hold to be our duty, to form regulations in accordance with the provisions of the Act of Parliament. If any gentleman can suggest any method, by which that can be done, I am willing to agree to it; but if it comes to this, that we withdraw this resolution, and let the thing go on as a denial of the obligation to impose some poison regulations, I do hold that it is of all things necessary that we should endeavour, at all events, to keep open a channel of communication between ourselves and the Privy Council. There, I think, is the fatal mistake made by our Council. I think you should have said we are bringing forward a thing which may not be agreeable to you, but still, as the representative organization of this Society, we think it our duty to keep faith. If we do not succeed in carrying this thing through, and we come into collision with Parliament, we shall at all events be clean-handed in the matter, and can go forward afterwards and make the best terms we can. That is of the greatest possible importance, and I do implore you not to be led aside. A gentleman near me said he did not think this question was understood in the country; and he is so far right, that it requires a great deal of reading up back evidence, in order to be quite in possession of the actual facts of the case. Do consider the question calmly, gentlemen, and not be rashly hurried into a decision which will land us in an unfortunate position, which we may hereafter have to regret. If any gentleman is prepared with a resolution which will have the effect of a compromise, I shall be glad to withdraw; but if not, I must still insist upon my amendment, in order to get a definite expression of the opinion of the meeting.

Mr. Vizer: If Mr. Giles will accede to the amendment which I was going to move, it will solve the difficulty.

Mr. Giles: I do not know what your amendment is.

The Chairman: I will read it. This is the amendment suggested by Mr. Vizer, "That whilst desirous of taking every reasonable means for the protection of the public, this meeting considers the recommendations of the Council unsatisfactory, and therefore refers the question for reconsideration to the new Council."

Mr. Stacey: I am very glad, Mr. Chairman, to notice from what has been said, the implicit confidence which the country members evidently have in the Council in London. They say that so fully was it understood that the Council were going to bring forward these recommendations, that hundreds of members felt there was no need for them to attend. I am glad to see that there is such confidence in the Council; but I will call their attention to one fact, that having that confidence and the Council having given most unusual exertions to this matter, they must remember that the Council have expressed their full confidence in the views of Mr. Giles and Mr. Sandford. Almost every one, certainly every one that has spoken has done so. Now the difference in the whole discussion lies between those two words "recommendations" and "regulations." The views are the same in every other respect. I have been attending to this discussion with very great care, and I wish further to call attention to one very important principle that was a little interfered with in one part of the discussion, namely, that this meeting is not a corporate body, that is to say, it is not a complete representation of the Pharmaceutical Society of Great Britain. Now if you once allow that principle to creep in, we get into very dangerous considerations with respect to previous meetings. You must take this meeting as a meeting of the Society, and its actions as such; and I would ask this meeting to consider whether they cannot accept these regulations as the express act of the Council, and not merely take them as recommendations, which will place this Society in very great difficulties with the Government. To say nothing else, it will place them in great difficulty with the Privy Council, and they are already in a sufficiently difficult position. Our position will be rather anomalous, seeing that as a voluntary Society we have to carry out an Act of Parliament which refers to the whole body of chemists in the country. Therefore, I think the Council may ask the support of the meeting, and I hope the meeting will give them that support in passing these as regulations.

The Chairman: I will now, gentlemen, put the amendment, but you must bear with me one moment, whilst I say that if anything has been done which has proved not quite so open as you might have expected, it has been simply an error in judgment, not from any desire to mislead. But when I see an amendment in print which was intended to be brought forward without having been made known to the Council or the Society at large, I cannot see how you could complain of another gentleman bringing forward an amendment which had not been in print. I simply say that, because some of our friends have used the word "honour" once or twice, and I think we ought to do, not only that which is honorable, but if possible something more. The letter from the Privy Council has been in the hands of every member of the Council for some days, and, therefore, it was quite competent for those gentlemen who reside in the country, and who felt so strongly that their friends would be kept away from this annual meeting, on the supposition that the resolutions would be passed as recommendations, to have informed their constituents that they had received such a letter, and that possibly something more than was anticipated might be brought forward. I need not again read Mr. Giles's amendment; but I will ask Mr. Giles and Mr. Vizer to be tellers on one side, and Mr. Baldock and Mr. Betty on the other.

The meeting then divided, and upon Mr. Vizer being requested to announce the numbers, he reported that there were 104 against the amendment, 85 for it.

The CHAIRMAN then declared the amendment lost by 19 votes.

The CHAIRMAN being about to put the original resolution—

Mr. VIZER said: I now beg leave to move my amendment, Sir. I will not detain the meeting long, because I hope they will agree to it. The amendment is as follows:—"That whilst desirous of taking every reasonable means for the protection of the public, this meeting considers the recommendations of the Council unsatisfactory, and therefore refers the question for reconsideration to the new Council." I hope the meeting will clearly understand that we do not by this amendment turn aside the idea of the need of recommendations. We, on the contrary, acknowledge and receive that fact as an axiom of pharmacy, but at the same time we hold that these recommendations which are now put forth by the Council are capable of material improvement; and on that ground we think this meeting should return them. But, further, these recommendations are virtually the same as those put forward last year. I have this morning carefully compared them, and can see no difference whatever in them, with the exception of a word or two here and there, and the transposition of clauses in second division, the spirit and essence being essentially the same. We believe that if the Council, instead of returning on our hands the same regulations which we last year so unmistakably declared to be unsatisfactory, were to take them back, and invite help from gentlemen outside to a general committee appointed to reconsider the whole question, a far better code of recommendations might then be issued. I think, therefore, that if the Council would now take them back, and in twelve months' time submit them again for our acceptance at the next annual meeting (so far as I can learn the feelings of those gentlemen with whom I have been in contact), the meeting would not then object to adopt a really good code of regulations. It is, therefore, in my opinion, most desirable that these should be reconsidered, and that we should have a more thoroughly digested code. I want it to be clearly understood that we do not object to recommendations, but we do say that these are crude and unsatisfactory.

Mr. HAMPSON: I will not detain the meeting, but I simply second the resolution.

Mr. URWICK: I beg leave to support the amendment, and for one reason I may say, that at the very beginning of the recommendations we find the word "selling;" but the Act itself has provided for the selling of poisons, and there is nothing said in the following clauses about it; therefore, that word is uncalled for, and shows the necessity for revision. When I commenced business some years ago, I adopted a poison cupboard, and every precaution which I could in dispensing; but there are still things here which, I think, may be changed, so as to place the dispenser, and one who has to deal with drugs, in a more comfortable position than these regulations would entail. For instance, we are told all poisons; but it did not say that this refers to the schedule of the Act. Seeing the meeting is impatient, I will only make an observation on the words "not to be taken internally." In the case of an acid lotion being sent out, the words "not" or "internally" may become obliterated, and the words "to be taken" or "to be taken internally" remain on the bottle; I therefore suggest the words "for outward" or "external" use would be better.

Mr. SANDFORD asked whether Mr. Vizer meant recommendations or compulsory regulations.

Mr. VIZER: Certainly not compulsory regulations,—recommendations only.

The CHAIRMAN then put the amendment, which, upon a show of hands, he declared lost.

Mr. LINFORD: I have already given notice of one amendment which I proposed to move, which was simply to the effect that we adopt these recommendations for a year, with a distinct understanding that the Council will propose these, or some amended form, in which the regulations may become compulsory at the next general meeting.

Mr. GILES: I second Mr. Linford's amendment.

The CHAIRMAN said this was not an amendment, but would come as a substantive resolution.

The original resolution as moved by the President and seconded by Mr. Bourdas was then put and carried.

The SECRETARY said that Mr. Linford was preparing a resolution which he intended to submit; but, in the meantime, he should like to secure a sufficient number of gentlemen willing to act as scrutineers, and the following gentlemen were nominated:—

Messrs. Andrews, Baldock, Constance, Froom, Hopkin, Horncastle, Humpage, Kettle, Moss, Palmer, Pound, Robbins, Vizer and Young.

Mr. E. BURDEN asked what was the meaning of two items in the invested property of the Society, one of which was denominated Hills' Prize Fund (£200), and the other the Secretary's Casual Relief Fund (£105). Did that mean relief given occasionally to the Secretary?

The CHAIRMAN said that Mr. Hills, who was always very desirous to assist in promoting the education of young men, had established a prize of books to be distributed every month to those who passed the best Minor examination. It was not necessary to say how that fund was established, but Mr. Hills himself had found the largest portion of the money, the remainder being derived from the sale of the portrait of the late Mr. Jacob Bell. With respect to the Secretary's Casual Fund, it arose in this way. Upon one occasion an honorarium of £100 was given to the Secretary for his extraordinary services in connection with the passing of the Pharmacy Bill, which he invested at once, in order that he might have a sum of money to apply to in the case of persons who asked for casual relief, not being eligible for the Benevolent Fund.

Mr. E. BURDEN said he was very glad to hear this explanation, and he begged leave to propose a vote of thanks to both those gentlemen.

The motion, being seconded, was carried with acclamation.

Mr. HILLS said he was very glad the Society had been pleased to accept his small donation, the object being to assist those who passed the Minor examination with books to prepare them for the Major one. As a young man he had felt the want of books himself, and, therefore, he thought it desirable to help those who might be in the same position.

The SECRETARY said, whoever happened to fill his office after him would always find a great many calls for casual relief; and, therefore, if any gentleman liked to add to the fund he should be very happy to receive such donations.

Mr. LINFORD: Mr. Chairman, I shall be as brief as possible in proposing this resolution, and my object in doing so is, that the Society may not land themselves in a hole. The Privy Council will not accept simply recommendations as a reason for staying other proceedings, and, therefore, I have framed the resolution in such terms as to acknowledge our liability at all events. I therefore propose, "That this Meeting is of opinion that it is the duty of the Pharmaceutical Society to propose at an early opportunity regulations for the keeping, dispensing and sale of poisons, in accordance with the provisions of the Pharmacy Act, 1868.

Mr. GILES: I beg leave to second that resolution.

Mr. REYNOLDS (Leeds): After the most impressive way in which Mr. Mackay has spoken of the duty of this meeting towards those members who are absent to-day upon the faith of an understanding, and his illustration of the intended deputation from Glasgow, I feel it difficult to add anything upon the point. Mr. Randall has represented the same view from the south of England; and it is my duty, on behalf of my fellow-members in Leeds, to protest against the principle of compulsion being voted in their absence, which is due to their faith in the late vote of the Council. If a matter has undergone free discussion, and it is put to the vote, after every member has had the privilege of expressing his opinion, I will bow to the opinion of the majority as readily as any man, but I am quite sure that what has been said by the Council, the acceptation of the resolution already passed by it, with only one dissentient, and the statement by the Journal that this question was practically settled, have induced gentlemen to stay away; and after the resolution which has been passed, I can see no reason why we should commit ourselves for the future, as this resolution would do. If notice is given I do not object to any motion whatever, only let us act fairly towards those who are not here. I will add one word as to the recommendations themselves. I believe the great mischief in connection with them as they now stand is that they adopt the poison schedule A, which was drawn up for a totally different purpose, and, I think, we should start on a simpler basis.

Mr. GILES: I rise to second the resolution, because I believe it has not yet been done. And I must protest at people coming here and saying that because their friends are not here, it is not competent for the meeting to transact the ordinary business of the Society. Such a thing I never heard of in all my life, and I have been a good deal accustomed to public meetings. I never did hear such a ridiculous proposition as that. If that were the principle to be acted on, why should we come here at all? why not transact our business through the post by means of postal cards? We are met here to discuss anything and everything connected with the business of the Society which may have arisen during the year, and if the Council, or governing body, choose to bring forward any subject, that subject being on the *tapis* is sufficient to justify anybody in bringing forward his own views upon it, and carrying them if he can. Do not, then, let us make such children of ourselves as to talk such stuff as that. I am ashamed of being a member of a meeting which fills this room, and to hear it seriously argued that we are not competent to deal with any question that is brought before us. This resolution is not the same as the one which was proposed before, but it is one which has my assent and approval, rather more even than the amendment I myself moved, because it leaves entirely open what the nature of the regulations shall be, and contemplates their being thoroughly ventilated, and that if thought desirable, as has been suggested, you may call in the assistance of persons from without. Persons may be appointed at this meeting, or there is no reason why any person should not write to the Council; in fact, I do not know that the Council have not already been inundated with suggestions. Some persons say that these suggestions are not satisfactory, but no one has said why, except one gentleman who said so under a mistake. And although we have heard, over and over again, that many firms adopt superior precautions to those recommended here, I defy anybody to indicate a possible precaution which is not contained within the four corners of this paper. I admit the elasticity of that paper. Our excellent and generally sagacious friend, Mr. Squire, rather complained of their not being sufficiently matured, and wanted a hard-and-fast system of regulations. But that is exactly the thing we do not want. We want something that shall comprehend everything necessary, and not bind us to anything in particular. I do think, therefore that we are justified in passing this resolution, and that it is not pressing the old question in a new form. The old question was whether we should, on this present occasion, prescribe for ourselves certain specific regulations, and now the new question is, that this Society should acknowledge the duty which lies upon it of prescribing regulations at a convenient time. Those are totally distinct things. If not, gentlemen, I am a donkey, and do not understand the English language. That is my misfortune, and I am very sorry it should be inflicted on the meeting. I do think we ought now to give a distinct indication to the Privy Council that we are not going to evade the obligations which they think lie upon us. If, on the other hand, we do mean to evade them let us say so in downright terms, so that there may be no mistake about it.

Mr. RANDALL (Southampton): In the first place, Mr. Chairman, let me say that I do not bring to this meeting any authority, save and except such as I bring in my own person, and I do not pretend to represent anybody. We have had no meetings, but I believe, as far as I know, the majority of those near me would be quite satisfied to have compulsory regulations passed. I think so, but I am not quite sure. In the next place, I look at this resolution as a perfectly different matter from the former one. I feel that it would be dishonourable in us to do anything to bind the Society to-day, after it has been understood that no such thing would be brought forward. If the first resolution had passed, it would have bound the whole body, but this will simply bind the present meeting.

Mr. EDWARD BURDEN: We have committed ourselves to certain recommendations which are to be forwarded to the Privy Council. I was going to ask, suppose the Privy Council set their seal to them, and render them compulsory. How should we be placed then?

Mr. SQUIRE: I think the Council are placed in this position. They will have to give some answer to the Privy Council, but we do not commit ourselves under this resolution to do anything immediately, but simply that regulations should be made for the storing, keeping and dispensing poisons, according to the provisions of the Act; and we on the Council may frame, with the advice of others, such regulations as should not be so obnoxious as these, and present them to the Privy Council. It simply says, we do propose to make some regulations. We are not compelled to make them as stringent as these, and I do not, therefore, see any reason why the meeting should not adopt Mr. Linford's resolution. There is nothing in it which commits us to any particular line,—it only says the regulations are to be framed; and surely it is not such a very hard case to frame such as should be satisfactory to the Society by another year.

The CHAIRMAN: This motion says nothing about time, and therefore I apprehend it really implies that we are to set to work at once. I cannot say how soon we may be called upon.

Mr. SCHACHT: It strikes me that there is a very important principle involved in this resolution. We have voted once, I thought, on the principle,—we have argued on the principle; and now this is a modification of the old principle again. It says this meeting is of opinion that it is the duty of the Council to do so-and-so; but it was upon that very consideration, whether it was a duty or not, that I went into one lobby instead of the other. I am of opinion that there is no obligation on the Pharmaceutical Society to do anything of the kind. I am quite aware that there is an awkward legal phrase in the Pharmacy Act, which may be interpreted in two ways. There is a word there written "may," which some individuals choose to read "shall." In my opinion the latter reading is incorrect; and on that interpretation I held my objection to the original proposition of the Council last year, and, consequently, I approve of what they have done in the interval, in changing their regulations into recommendations. We are now told that if these recommendations do not satisfy the Privy Council, we shall have some dreadful system of inspection forced upon us in exchange, and we are taunted with the fact that it will serve us right. I disbelieve it altogether. My opinion is that any application to Parliament for compulsory powers, such as would be imperatively necessary in order to make any such regulations compulsory and effectual, would be met with such a storm of opposition from all sections of the medical and pharmaceutical bodies, that it would have to be withdrawn; that, in fact, it would receive precisely the same treatment with which the recent attempt in Parliament was received to place the regulations of railways under the inspection of the Board of Trade. I dare say gentlemen will remember that only a few weeks ago an attempt was made to introduce a system of regulation and management of railways, but it was rejected almost tumultuously; and the grounds upon which one member of the Government opposed it were precisely the same as those upon which, as I understand, the chemists and druggists of England rest their objections to these compulsory regulations, viz. that in the first place it would involve the recognition of something like a handing over of a portion of the responsibility which each individual feels he is under if left to himself; and, on the other hand, that in order to make it in the smallest degree efficient you must have a system of inspection. "However good the regulations may be," said Mr. Chichester Fortescue, "it is no good pressing them upon the railway interest, unless you establish a system of inspection to see they are carried out." And precisely the same here. The sole legal power to enforce these regulations, should they become law, rests with Mr. Bremridge. There is no one else who has power to prosecute any individual who infringes that Act. Upon Mr. Bremridge alone rests the responsibility of doing so, and I ask what can he do? He can do simply nothing. I may obey the regulations, and my next-door neighbour may leave them alone. Not a creature will know anything about it, and unless he poisons some one, every one may do precisely as he likes. Then, what is the use of them? A law already exists which deals with any one who commits an offence. If any one by mistake, accident or default poisons another he is amenable to the law, and has to pay a heavy penalty. This Bill makes it possible that he may have to pay an additional £5 fine, after, perhaps, having to pay £2000 as compensation. What is the good of that? Simply nothing at all. If these things mean anything, they mean that care should be taken that men exercise those precautions which should prevent accidents; and, in order that they may answer their purpose, there must be a system of inspection. That I rebel against vehemently and strongly. I would not allow the smallest end of the wedge to intrude itself between me and the conduct of my own business. I should not vote for any regulations at all, for it seems to me that they would become merely a dead letter. I believe we are not necessarily compelled as a body to frame these regulations at all. I am aware that that is a moot question; but I never held the opinion that it was obligatory. It is a matter referred to the future, evidently for consultation by the members of the Pharmaceutical Society, and if the Society, in its entire and corporate capacity, chooses to determine that compulsory regulations are unwise, there is no obligation in that Bill to make it a point of honour in the smallest degree to introduce them.

Mr. M. Carteighe: Gentlemen, I hope you will support this resolution. There is one question raised now by Mr. Schacht on which I cannot remain silent. He says he believes that if such regulations as are contemplated were ever brought before the Legislature, they would be scouted and laughed at. Let me tell him that in the lobby of the House of Commons four members of the Parliamentary Committee of this Society watched every stage of the Bill, and every alteration suggested by the medical officer of the Privy Council; that they were in telegraphic communication with every local secretary throughout the country; that Mr. Brady, Mr. Reynolds, and many others were working with all their might to get members up; but in the face of all that we could not, on a vital principle of the Bill, get forty members in the House when there was a division. In fact, the Council resisted every alteration as much as they possibly could, and endeavoured to do without these regulations, but it was simply a question of a bargain: we were told, either you must have these regulations, or you shall not have a monopoly without. You may not think it was a right thing to do; it may have been a wrong thing, but the Act is now law, and it would be found very difficult to *undo* the law. If you pass this resolution, you may save the Council from immediate action on the part of the Privy Council, and I do adjure you, therefore, to pass it. As Mr. Randall has told you, it does not impose any regulations; it simply asserts a principle, and therefore many who could not vote for Mr. Giles's amendment can go with us on this point. By so doing, I am sure you will save the Council from considerable difficulty. Where will you find men who would have done more for you with the Privy Council than they have? It was said that these regulations were not what was required, and that they ought to be referred back again to the new Council. Why the same thing was done last year; and Mr. Vizer and his friends did all they could to send new men to the Council, and from that very new Council we get recommendations practically the same as we had last year.

Mr. Vizer: I had nothing whatever to do with influencing the elections last year.

Mr. Carteighe: I only go by what you said last year. You said send fresh men to the Council—I am speaking from memory—and these fresh members have brought before us to-day in substance the same recommendations as were brought forward last year. It is really a question of your power of resisting the Government. If you are sure that you can resist a Government measure if it is introduced, then do nothing; because recommendations are utterly worthless to the Privy Council. Once admit the principle that you ought to do this, and they will, I think, give you time to consider what regulations you will adopt, and to make them as lenient as you think desirable. But do acknowledge the principle, or else say deliberately that you reject it. If you do so by so narrow a majority as you have had to-day, you may guess what will happen if any unfortunate chemist should happen by accident to poison a bishop. Contemplate the smallest thing of the kind occurring, and what will be the result, with the energy which the medical officer of the Privy Council possesses. You all know what immense power he has, and that he is not a man to be balked. I do not sympathize with the regulations, I only look at it as a matter of policy, of prudence and of wisdom. Where do you find pharmacy without restrictions, that is, on a professional basis? Go to the United States; you find restrictions there. Go anywhere on the Continent, and you find restrictions on the sale of poisons much greater than these would be. You cannot blow hot and cold. You cannot be both free-traders and monopolizers.

A Member: We are not monopolists.

Mr. Carteighe: You have a monopoly of examination. I do not say we should not have secured it unrestricted if we could, but we tried and failed. As for the notion that the words do not mean it, all I can say is, as a member of the Council at the time and as a member of the Committee—and there are several other members here who, I think, will agree with me—that was not only the distinct understanding, but the understanding in writing, and the clause was drawn up in concert with the Medical Officer of the Privy Council. We tell you that, and you say it does not bind you, but that I cannot agree to. You lost a great deal by not passing this last year. At that time, as Mr. Schacht has said, regulations might have become a dead letter; in fact, he has told you how excellent they would be for practically carrying *nothing* out, and he astonishes me by not having voted for Mr. Giles's amendment. It appears that he is really waiting for inspection, and giving the notion of its necessity to the Government for the time being. And really the discussion in the Journal keeps the idea in the minds of the Government and of the medical officer, who no doubt reads our Journal regularly. You may depend upon it if he thinks the public will not be sufficiently protected without inspection he will ask for it. As Mr. Randall has very fairly expressed it, there may be differences of opinion whether these are the best possible regulations, but we are now simply enunciating the principle that at some time or other we will impose regulations of some kind. If we do not, I am sure the Council will be in a great difficulty, and I fear you will not get men on the Council who will be willing to give up the necessary time to fight the Government on a question of this sort when it may arise.

Mr. Wade: I desire to move an amendment in order to test this question, and it is to this effect,—"That this meeting having already expressed its opinion on the question of poison regulations, desires to leave it in the hands of the Council to deal with as they shall see fit." I move this because I apprehend that the Council, both the outgoing and incoming Council, will be perfectly competent to know what to do as to carrying out the provisions of the Act. It will be for the incoming Council, taking the wishes of the meeting as expressed to-day, to carry out these recommendations as they may see fit. I think, therefore, that such a resolution as Mr. Linford's is altogether superfluous and unnecessary.

Mr. Vizer: I beg to second the amendment of Mr. Wade. Mr. Carteighe says he does not blow hot and cold. This powerfully illustrates the evil of the continued absence of reporters from our Council meetings. If those proceedings were reported, we should really know what was done by the Council, which now we know nothing about further than on which side each gentleman votes. I do sincerely hope that the new Council will take this matter into their early consideration. One word about the amendment. Mr. Carteighe says we are not able to balk Mr. Simon; my opinion happens to be just the reverse: I think if that gentleman were to bring forward an Act of Parliament for compelling us to accede to compulsory regulations, he would not be able to carry it without including also medical men, surgeons, dispensers at hospitals and everybody else connected with the dispensing of medicines. I have far too high an opinion of the character of our Legislature to believe that the British House of Parliament would pass any Act to bind a fractional part of a large and intelligent body of men, leaving the greater majority unshackled with any restriction whatever. I think in that way we may fairly meet Mr. Simon. If he wishes to make the regulations compulsory let him go to Parliament to do so, and then we shall have to fight the battle out. The motion is in my opinion merely an attempt by a side wind to catch a few votes on the principle of Mr. Giles's amendment, which has been already lost.

Mr. Squire: I think the amendment is a very judicious one. Let us leave the matter in the hands of the Council, and see what course of action they take.

Mr. Sandford: I feel perfectly convinced that you will not satisfy the Privy Council in this way; and when I think how much more power Mr. Simon has now than he had in 1868, I do implore you to vote for the resolution.

Mr. Abraham: You may remit it to the Council, but they have no power to do anything. Nothing but this meeting can exercise the legal authority of the Pharmaceutical Society, unless you choose to adjourn it or call a special meeting.

Mr. E. Burden: I do hope the Council will have the wisdom to leave the question where it is and do no more. I hear the words Privy Council, Government, Parliament, used by one and another, and at the same time we are told that these recommendations are not going before the Privy Council at all. I believe if they are submitted to the Privy Council or the Government, the question will be directly asked, how do you propose to enforce them? and they will require some system of inspection or some other regulations which may prove obnoxious. Under these circumstances I should be for leaving the matter where it is, and let it rest until the Government raises the question. Mr. Giles has remarked that no one had brought forward any objection to these regulations, but the fact is he gave us no opportunity for doing so, by shutting us up to the question of compulsion or not. Otherwise I should have been prepared to propose the omission of No. 2 altogether.

The amendment was then put by the Chairman and declared to be carried on a show of hands. It was then put as a substantive motion and carried.

Mr. Urwick proposed a vote of thanks to the President for his able conduct in the chair, which was carried unanimously, and the meeting was then adjourned until Friday the 19th instant at eleven o'clock.

ADJOURNED MEETING,

Friday, May 19th, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The Scrutineers brought up their report as follows:—

SCRUTINEERS' REPORT.

We, the undersigned Scrutineers, appointed at the Thirtieth Annual General Meeting of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting-papers committed to us and report the following:—

Voting-papers received		1478
Disallowed as follows:—		
Informal (having more than 14 names left)	13	
Received by the Secretary, per post, after the 15th inst.	124	
Enclosed in envelopes not signed by Voters	14	
Sent direct to the Secretary	3

BENJAMIN HUMPAGE, *Chairman.*

FREDERICK ANDREWS, JOHN MOSS,
JOHN H. BALDOCK, ROBERT PALMER,
EDWARD CONSTANCE, MATTHEW POUND,
WM. HENRY FROOM, JOHN ROBBINS,
WM. KING HOPKIN, EDWIN B. VIZER,
JOHN HORNCASTLE, ROBT. FISHER YOUNG.
JOSEPH KETTLE,

May 18th, 1871.

The Chairman then declared the Council and Auditors for the ensuing twelve months to consist of the following Members:—

COUNCIL.

ATHERTON, JOHN HENRY, Long Row, Nottingham.
BETTY, SAMUEL CHAPMAN, 6, Park Street, Camden Town, London.
BOTTLE, ALEXANDER, 37, Townwall Street, Dover.
BROWN, WILLIAM SCOTT, 113, Market Street, Manchester.
CARR, JOHN, 171, High Holborn, London.
EDWARDS, GEORGE, Dartford.
FRAZER, DANIEL, 113, Buchanan Street, Glasgow.
GREENISH, THOMAS, 20, New Street, Dorset Square, London.
GROVES, THOMAS BENNETT, Weymouth.
HASELDEN, ADOLPHUS FREDERICK, 18, Conduit Street, Regent Street, London.
HILLS, THOMAS HYDE, 338, Oxford Street, London.
MACKAY, JOHN, 119, George Street, Edinburgh.
REYNOLDS, RICHARD, 13, Briggate, Leeds.
SANDFORD, GEORGE WEBB, 47, Piccadilly, London.
SAVAGE, WILLIAM DAWSON, 30, Upper Bedford Street, Brighton.
SHAW, JOHN, 24, Great George Place, Liverpool.
SMITH, EDWARD, 8, The Strand, Torquay.
STODDART, WILLIAM WALTER, 9, North Street, Bristol.
SUTTON, FRANCIS, 9, Bank Plain, Norwich.
WILLIAMS, JOHN, 5, New Cavendish Street, London.
WOOLLEY, GEORGE STEPHEN, 69, Market Street, Manchester.

AUDITORS.

BARRON, FREDERICK, 2, Bush Lane, London.
BOWER, WILLIAM, 96, Tottenham Court Road, London.
HODGKINSON, WILLIAM, 127, Aldersgate Street, London.
MACKEY, JOHN BRUNT, 2, Bouverie Street, London.
SQUIRE, WILLIAM, 5, Coleman Street, London.

The Scrutineers also handed to the President their report of the returns for the election of Local Secretaries.

Votes of thanks were given to the Scrutineers and the Chairman, and the meeting separated.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE BENEVOLENT FUND.

Sir,—As one of the Local Secretaries, whose conduct Mr. Vizer seemed by implication to censure, I should like to ask that gentleman on what authority he made the statement on Wednesday last, that there were at least 1050 errors in the country Register.

I feel sure he cannot find any in this district; and I question the extent of his allegation in others. I can easily understand that in London 150 errors may creep in, because there are difficulties in obtaining information which do not exist in the country. Here, those on the Register often inquire of me the position of others in respect to it. Besides this I am periodically stirred up to make the necessary inquiries by a circular from our active Registrar.

Ipswich, May 20th, 1871. J. WIGGIN.

Sir,—In looking over the list of subscribers to the Benevolent Fund, I was struck with the poor figure the wholesale houses cut in the list. I should have thought gentlemen making their thousands a year could have at least subscribed their ten guineas yearly. The mistake has doubtless arisen more from want of thought than want of heart; I hope next year will see an amendment. Some, I am sorry to say, are conspicuous by their absence.

Many of us are very poor, but there is not one of us, even if it cost a day's fast, who could not subscribe at least a shilling a year. Out of 10,000 chemists you have, at a rough calculation, not above a thousand subscribers. I would suggest that the 9000 should be canvassed for at least a shilling subscription, and as much more as they are able to give. I would suggest, moreover, that the publication of the names should not be compulsory, as many men do not like to confess they are poor. The Secretary of the Fund should appoint a chemist in every parish in London, and in every town and village in the country, with authority to make the collection. He should have a printed card given him, and the necessary safeguards taken against peculation.

A hundred years hence, it is possible, a Benevolent Fund, through better social arrangements, will be almost superfluous, but till that "good time" arrives each must give his mite.

May 16th, 1871. "LEFT HAND."

THE RECOMMENDATIONS FOR THE KEEPING, DISPENSING AND SELLING OF POISONS.

Sir,—I should be obliged by your allowing me space in the Journal for the following statement, which I intended to have laid before the Meeting on the 17th, but into which, owing to the length to which the discussion had already extended when I rose to move my amendment, I abstained from going, as also many other arguments, with which I was prepared to prove the unsatisfactory nature of the "recommendations" submitted to the trade for adoption; but this statement is such conclusive evidence of the absence of any grounds calling for compulsory enforcement of regulations, that I hope you will excuse my troubling you with it.

Having carefully gone through the Pharmaceutical Journals of the last ten years, the following is the summary of deaths from accidental poisoning as reported therein:—

Errors in dispensing by chemists	5
" " surgeons	6
Errors in retail	7
Errors by nurses, etc., mistaking bottles	3

Omitting those by surgeons, the total deaths per annum would be one and a half.

When we take into consideration the tens of thousands of prescriptions annually dispensed, and the innumerable sales of poisons, would any regulations, however carefully they might be framed, and however stringently enforced, apart from absolute perfection, reduce this infinitesimally small percentage? Could any Government with reason go to Parliament for power to bind a large and intelligent body of men upon such grounds? EDWIN B. VIZER.

63, *Lupus Street, Belgravia South, S.W.*

Sir,—In the course of the discussion upon the poison regulations, I have been somewhat amused to find that many members of the Council, through the opposition manifested throughout the country, have withdrawn their support from Mr. Sandford, although their opinions still agreed with his. Now, I maintain that when we members vote for gentlemen to represent us upon the Council, we expect them, after proper consideration, to vote always in the way they themselves shall at the time being judge to be for the best interests of the Pharmaceutical Society, quite irrespective of the opinions of those outside or around them. Were our representatives to do this, we should always respect them, if we could not agree with them. I think Mr. Sandford alone in this affair has acted altogether consistently. The actions of some of the others would almost indicate their wish for office (did I not know the honourable character of those I am alluding to). I can only suppose, therefore, that they have been influenced by the idea that their duty is to carry out the wishes of the majority of those who send them there instead of being free to exercise their own judgment.

May 20th, 1871. M. P. S.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. F. Vincer, Mr. R. Sheppard, Mr. J. Wiggin, Mr. J. Schweitzer, Mr. J. H. Gostling, Mr. S. Maskery, Mr. Paton, Mr. W. W. Jones, Mr. Harry Leach, Mr. J. W. Williams, Mr. J. R. Jackson, the Secretary of the Liverpool Chemists' Association, the Secretary of the Norwich Chemists' Assistants' Association, M. P. S., R. G. H., X. Y. Z., J. H., T. H., H. B., "Lover of Truth," "Capsicum," "Henricus," "A Country Chemist," "Give and Take," "Obrera," "Quæro," "Aquila."

In consequence of the great pressure upon our space caused by the report of the proceedings at the Annual Meeting, we are compelled to defer the publication of several communications.

CHLORAL HYDRATE.

BY DR. F. VERSMANN.

Some time ago I proposed sulphuric acid for testing chloral hydrate, and I now wish to give the numerical results of a few comparative experiments made with sulphuric acid and ammonia. The objections to the last reagent are twofold, the results obtained are not very accurate and the analysis requires longer time than is desirable.

In my previous paper I have drawn attention to the fact that the solubility of chloroform in water is the true cause of the inaccuracy, and not the further decomposition of chloroform by ammonia, and I arrived at the result in the following manner. In testing chloral hydrate I always take 10 grammes instead of the large quantity hitherto proposed. 10 grammes, if pure, should yield 4·82 c. c. of chloroform. I therefore placed 5 c. c. of chloroform in a long and narrow well-stoppered tube, graduated in 0·1 c. c., and after having added some water and briskly shaking the tube, I heated it in like manner as in the analysis of the hydrate and allowed it to stand for twelve hours. The loss was exactly 0·2 c. c. with repeated experiments; and as exactly the same loss was found in experiments with strong ammonia, it is evident not only that it is owing to the solubility of chloroform in water, but also that it must be taken into account in testing the hydrate. It is a constant loss, and whenever the ammonia test should be preferred, 0·2 c. c. must be added to the quantity of chloroform actually observed. I have adopted this plan, which I may call the ammonia test corrected. The results thus corrected correspond exactly with the sulphuric acid test, but I still prefer the latter, because the decomposition of the hydrate into chloral and water is completed in a few minutes.

I have described the *modus operandi* before and I therefore need not repeat it, but I will at once give the results of a few experiments made with samples from different manufacturers. The specific gravity of chloroform has been taken by Mr. Umney and others at 1497. I think this is too high; I prefer to take it as 1490 at 15·5 C. (60° F.). The specific gravity of pure chloral I take as 1505 at the same temperature.

AMMONIA TEST.
Ten Grammes of Chloral Hydrate.

Cubic centim. of Chloroform.		Percentage of Chloroform.	Percentage of Hydrate.

THE OCHRO AND THE MUSK MALLOW.

BY JOHN R. JACKSON, A.L.S.,

Curator of Museums, Royal Gardens, Kew.

Perhaps there is no one family of plants having so many species, with such a decided characteristic property running through the whole, as the *Malvaceæ*. Almost all are mucilaginous, and though none of them are now officinal in this country, the marsh mallow (*Althæa officinalis*, L.) and the common mallow (*Malva sylvestris*, L.) are sometimes used by the peasantry in rural districts, a decoction of the leaves of the first being applied for fomentations, and the mucilage with which both this and the common mallow abound being employed as a soothing or softening drink in coughs and bronchial affections. It is, however, chiefly in France that the roots are used to produce a demulcent drink known there as Guimauve.

In tropical or temperate regions, where the species of this Order are found most abundantly, the mucilage and seeds of the several species are used by the natives for various medicinal purposes. Two of the most interesting plants are the ochro (*Hibiscus esculentus*, L.) and the musk mallow (*H. Abelmoschus*, L.), the first interesting on account of its esculent and medicinal properties and uses, and the second principally on account of its seeds being used, to a certain extent, as a substitute for animal musk.

The Ochro, or edible hibiscus, is an annual herbaceous plant, with hairy stems and alternate cordate leaves strongly toothed, and from three to five-lobed. The petals are pale yellow, with a deep crimson base. The capsules or fruits appear to vary much in size according to the country where they are produced. Those we have seen from the East Indies are usually from four to six inches in length and about one inch in diameter at the base, tapering upwards to the apex, while those grown in Venezuela and some other parts of South America, as well as those from South Africa, are not more than two or two and a half inches long and one and a half inches diameter across the centre. They are marked with from five to eight ridges, running longitudinally from the base upwards and corresponding with the number of cells, each ridge forming a valve and partially dehiscing when the fruit is ripe and dry; the small round seeds also becoming loose and shaking in the capsule like a rattle. The plant is a native of the West Indies, but is cultivated extensively in all tropical countries, as well as in the south of France, principally for the sake of its fruit. This is gathered before it is fully ripe and is used as a vegetable, but chiefly for imparting a mucilaginous thickening to soups; it is also used when very young for pickling, like capers. The plant is officinal in India, being considered a valuable emollient and demulcent; the capsules are employed in a decoction, and the Indian Pharmacopœia gives the following instructions for its preparation:—

"Take of the fresh immature capsules, sliced transversely, three ounces; water, a pint and a half. Boil to a pint and strain; sweeten to taste.

"Dose.—From three to six ounces, or *ad libitum*, as an ordinary drink."

The inhalation of the vapour of the hot decoction has been found very serviceable in allaying cough, hoarseness, irritation of the glottis and other affections of the throat and fauces. The dried capsules may be employed when they are not procurable in a fresh state.

According to the testimony of Dr. Gibson and others, the fresh capsules bruised form an efficient emollient poultice.

The seeds are used in native practice in the preparation of a demulcent drink, corresponding to our use of barley, and the leaves are used for poultices.

The musk mallow (*H. Abelmoschus*, L. = *Abelmoschus moschatus*, Mœnch) is also an annual herbaceous plant with irregularly-toothed hastate leaves. The flowers, like those of the former species, are yellow with a crimson base, and are succeeded by an oblong-lanceolate hairy capsule. The plant is a native of the East Indies, but has become naturalized in the West, and is also cultivated in most tropical countries.

Both in the East and West Indies the bruised seeds are used internally and externally as a supposed remedy for snake-bites; they have a very strong musky odour, and possess cordial and stomachic properties, and the Arabs mix them with their coffee to give it a perfume. They are also used by perfumers in this country, chiefly, we believe, in the form of powder for sachets, being imported from the West Indies for this purpose.

Both of the above-named plants abound in a strong silky fibre.

ORIENTAL SPICES.

BY JAMES PATON,

Assistant-Keeper in the Museum of Science and Art, Edinburgh.

(*Continued from page* 923.)

International commerce in the earlier ages of the world was very different in all its relations and surroundings from the conditions under which the trafficking of the world is conducted. Commercial treaties are modern, and free trade is yet only an idea; geographical knowledge was cultivated among the ancients only to the extent of knowing the strength and weakness of neighbouring estates; a foreigner all over the world was a natural enemy, a highway through the nations there was therefore none, and he was indeed a brave man who trusted himself to the sea in the frail vessels which, creeping along the coasts, courted destruction at the first blast of a summer gale:—

> "Ille robur et æs triplex,
> Circa pectus erat, qui fragilem truci
> Commisit pelago ratem."

In these circumstances each people had to find within its own borders the necessities of life; to bring them from abroad was out of the question, and when home supplies became insufficient the people had to spread themselves outward over unoccupied lands. International commerce consisted in passing onward from State to State a very few of the rarest luxuries and indispensable medicines, which the very wealthy and most civilized demanded; and these in their progress through each nation were made a source of revenue to the communities that commanded the route. Thus spices and odorous gums, the rich products of the Eastern tropics, of which no single grain has ever been raised on the less genial shores of Europe, along with precious stones and pearls, from the earliest ages, formed the sole basis of the commerce of the West with the East.

The earliest glimpse we have of the spice trade gives us a most characteristic and vivid impress of the traffic of the early world. As the sons of Jacob had just completed the execution of their plot against their envied brother Joseph, on the horizon appeared "a company of Ishmaelites from Gilead, bearing spicery, balm, and myrrh, going to carry it down to Egypt." Thus 1700 years before the Christian era we find the Arabs possessed of the spice-trade, which their country, as a principal *entrepôt*, continued to hold down to the sixteenth century, when the whole system was overthrown by the discovery of the Cape passage. At this period Egypt was the capital of civilization, learning and luxury; and myrrh, cassia and other odoriferous substances, we are informed by Herodotus, were used for embalming the dead and in religious ceremonies.

The southern portion of Arabia, called Sabæa or Sheba, was peculiarly well situated for commanding the great trade in spices (hence the name Arabia Felix or Araby the Blest), lying in the direct route from the east to the west, commanding the great caravan route by the valley of the Euphrates to the shores of the Mediterranean, and just opposite the Regio Cinnamomifera or Aromata, the north-east promontory of Africa, from which, and not from India, the main supply of the spices then used was drawn. The Sabeans had the necessary skill and enterprise for conducting this trade, and cunning did not fail them. They overclouded the mysteries of the prized commodities with fables, such as that cinnamon was gathered from the nests of the phœnix, which bird procured it in some miraculous way; that it was found in the land of the birth of Bacchus, in marshes guarded by winged serpents; that terrible bats flew at the eyes of those engaged in gathering cassia, and other such tales, all of which we presume served to keep up both the interest in and price of these spices, and to deter the much believing inhabitants of the early world from prosecuting such dangerous enterprises on their own account.

The wealth and glory of Arabia Felix, acquired through this spice trade, was the wonder of ancient times, and the writers revel in descriptions of the grandeur of its cities, and the magnificence of its merchants' houses. Vessels of silver and gold, pillars of houses of pure silver, furniture inlaid and overlaid with pure silver, gold and precious stones are spoken of as common furnishings in the houses of the merchants; and our own Milton, in imaging the gorgeous state of the prince of the power of darkness, uses the comparison:—

> "High on a throne of royal state which far
> Outshone the wealth of Ormuz or of Ind."

Further, the fame of spices from Araby, and the poetical fallacy of winds laden with the spicy odours he alludes to in one of his magnificent images—

> "North-west winds blow
> Sabean odours from the spicy shores
> Of Araby the blest."

Civilization and the trade in spices, from the earliest ages of which we have any records, marched steadily from East to West, hand in hand, till in the end of the fifteenth century, having reached the great ocean, this very spice trade carried civilization across this mighty obstacle, and added a new and hitherto unknown world to the dominions of culture. Sidon, and afterwards Tyre, the mighty cities of the Phœnicians, situated on the east of Palestine, first commanded the waters of the Mediterranean, and by the way of the Persian Gulf and the valley of the Euphrates received the spiceries of the East, in which they traded with Egypt and the western countries.

Alexander the Great, on his triumphal return from his conquering march over Asia, brought back with him to Europe the first knowledge and use of common pepper. His contemporary, Theophrastus, in his 'History of Plants,' thus describes it: "Pepper, indeed, is a fruit, and there are two kinds of it; the one is round, like a vetch, having a husk, and rather red in colour, but the other is oblong, black, and full of seeds, like poppy seeds. Both kinds are heating, on which account they are used as remedies for, and antidotes against poisoning." Thus apparently both common pepper and capsicums were known as pepper from the earliest times.

Arabia Felix, being out of the line of Alexander's progress through Asia, he left in the quiet possession of its most lucrative trade; but in founding the city of Alexandria, he established what was, to some extent, a rival to the commercial cities of South Arabia, and an additional link in the long chain that stretched from the gates of Rome away into the absolutely unknown East.

In a work entitled the 'Periplus of the Erythrean Sea,' written in the early years of the Christian era, most minute details regarding the commerce of that period are given. As showing the estimation in which spices were held in Rome, about the time the Apostle Paul lay there a prisoner, and when Rome was in its zenith of wealth, luxury and dissipation, we may quote the prices paid for spiceries:—

	£.	s.	d.	
Cinnamon (then chiefly brought from the Regio Cinnamomifera or the modern Guardafui) .	*0	17	3	per lb.
Cinnamon Oil	60	0	0	,,
Black Pepper	0	3	3	,,
White ,, ...	0	5	9	,,
Long ,, ...	0	12	2	,,
Cardamoms	0	9	8	,,
Ginger	0	4	9	,,

It is remarkable that in this list neither nutmegs nor cloves, two of the most esteemed luxuries of later times, appear. These the Romans had not for another 100 years; it is not till about A.D. 160 that they are first spoken of. On two or three of the most insignificant islands in the Indian Archipelago, heaved up, and still constantly tossed by violent volcanic energy, these precious trees had hitherto grown and flourished unheeded by the inoffensive savages that peopled the isles. It had been well for the innocent people had they rooted out and cast into the sea the last stump of these trees, for they brought on their heads unspeakable sufferings, and on the Western nations a load of crime and cruel infamy unparalleled among the cruel deeds of mankind.

Growing upon these very remote islands, and not at all cared for by any inhabitants of the Archipelago, it is not to be wondered that these most delicate substances were so late in being discovered, when intercommunication was limited and perilous, and among people of sluggish and unadventurous habits. The discovery of the virtues of nutmegs and cloves is presumed to have been accomplished by the Telingas of the east or Coromandel coast of India about the time of Christ, when by religious persecution they were driven in large numbers to the islands of the Archipelago. In connection with this, Mr. John Crawford, in his 'History of the Indian Archipelago,' remarks, "It is a curious and interesting fact that every important change in the mode of conducting the commerce of India has been the result of, or has followed a religious revolution or convulsion. The trade of the Hindoos extended in no direction but towards Arabia until a religious schism propelled their enterprise to the hitherto unknown countries which yielded spices. The Arabian traders went no further east than the coast of Malabar, until they acquired enthusiasm and energy from the religion of Mahomed, when they crossed the Bay of Bengal, colonized in the India islands, and pushed their commerce and their settlements to China. Even the last great revolution in the commerce of the East, effected by the European race, is distinctly connected with the great changes in religious, as well as other opinions which characterized the commencement of the sixteenth century."

(To be continued.)

* These figures, of course, represent very much less value at the present day.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, B.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

HYDRARGYRI OXIDUM RUBRUM.

Some mercury is divided into two equal portions; one is dissolved in nitric acid, and the solution evaporated to dryness.

$$3Hg+8HNO_3=3[Hg2NO_3]+2NO+4H_2O.$$

The other is then triturated with the dry residue, and the whole heated till black, and nitrous vapours cease to be evolved; on cooling it becomes red.

$$Hg2NO_3 + Hg = 2HgO + 2NO + O_2.$$

The official product is an orange-red powder. The scaly variety commonly seen is made by heating the crystallized nitrate. They are identical in composition and properties, but the yellow oxide precipitated in the Lotio Hydr. Flava, or by adding potash or soda to solution of mercuric chloride is a distinct variety which possesses decidedly greater chemical activity. Red oxide of mercury is sufficiently soluble in water to give an alkaline reaction with litmus paper. [§ Entirely volatilized by a heat under redness, being at the same time decomposed into mercury and oxygen. If this be done in a test-tube, no orange vapours are perceived.] Complete volatilization ensures freedom from such things as brick-dust, red lead, etc. which would be left behind. The presence of undecomposed nitrate, a most dangerous contamination, would be shown by the production of orange nitrous vapours.

Red oxide of mercury dissolves in hydrochloric acid, forming the perchloride.

Unguentum Hydr. Oxidi Rubri is frequently apt to become slate-coloured. This arises from a reduction or deoxidation of the red oxide with formation of the black mercurous oxide. This is not so liable to occur when, as in the present Pharmacopœia, *yellow* wax is employed. In the last edition the ointment was prepared from *white* wax, prepared lard and almond oil. So made, it rapidly becomes grey, and, if a careless operator has used unwashed lard, it even becomes white from the reaction of the salt upon the mercuric oxide to form corrosive sublimate.

Hydrargyri Perchloridum.

A mixture of mercuric sulphate, common salt and a little black oxide of manganese is heated in a dry flask, or any suitable subliming apparatus. The perchloride condenses in distinct brilliant prismatic crystals or in masses. The change which occurs is a double decomposition.

$$HgSO_4 + 2NaCl = HgCl_2 + Na_2SO_4.$$

But since the sulphate of mercury is apt sometimes to contain small quantities of mercurous sulphate, which by reacting upon the salt would give rise to calomel, the oxide of manganese is added to prevent this.

[§ Perchloride of mercury is more soluble in alcohol, and still more so in ether than in water.] When dissolved in much water and exposed to light, a partial decomposition of the salt ensues, and a little calomel is deposited. In the Liquor Hydrarg. Bichlor. B. P., a small quantity of sal-ammoniac is added, with the view of preventing this change by forming with the perchloride a more stable double salt.

The aqueous solution is acid to test-paper.

[§ Its aqueous solution gives a yellow precipitate with caustic potash (HgO), a white precipitate ($HgNH_2Cl$) with ammonia, and a curdy white precipitate ($AgCl$) with nitrate of silver. When heated it sublimes without decomposing or leaving any residue.]

Specific gravity of vapour

$$\frac{200 + 2(35\cdot5)}{2} \times \cdot0693 = 9\cdot39.$$

The antidote to corrosive sublimate is albumen, which combines with it to form an insoluble compound. The white of egg should be given in moderate quantities, or the insoluble compound is redissolved.

ECONOMIC ENTOMOLOGY.

In the collection of economic entomology exhibited at South Kensington Museum, the life history of the insects is given, not only by specimens showing them in their various stages of development, but also by exhibiting specimens of the material subject to attack, with the insect belonging to it fixed in the natural position, as observed either when carrying on its work or undergoing its transformations.

Thus, in the case of our timber beetles, specimens are given showing the injured wood with the beetles at work on it as when alive, and in the case of some of our insects which carry on their work or transformations in the earth, specimens are given of the earth structures, so preserved as to present them, if not in their full freshness, at least sufficiently clearly for purposes of instruction.

For the method of preparation of the earth-cells we may take those of the *Balaninus glandium* as an example. The cells should be laid on a smooth surface, such as wood or china, and a rather thin solution of gum arabic, carefully dropped from a camel's-hair pencil, on all the parts that can be reached, and the moisture allowed to soak in; the drops of gum-water may be gently drawn in any direction required with the point of the brush, but the earth should not on any account be touched with the brush during the process, or it will be reduced to mud, and the characteristic markings destroyed. When dry the specimen should be turned, and the gum-water applied as before to the parts previously untouched, and the process repeated till the specimen is firmly set. If the operation has been carefully performed, the glaze on the surface will give little more than the appearance of wet earth; but if this is objectionable a little dry earth of the same kind, powdered over the surface whilst still damp, will restore the natural appearance.

Such specimens as ants' nests may be preserved by taking up a section of a few inches in thickness very carefully with a sharp spade, or, better still, with a long kitchen-knife, and laying it at once on a board, with the face, afterwards to be exhibited, downwards; and, having trimmed the specimen neatly, so as to be square at the sides, enclosing it in a strong cardboard or thin wooden frame (like a box without top or bottom), filling in what is then the upper side with very liquid plaster of Paris up to the edge of the enclosing frame. The liquid mixture will run into the holes, and, setting almost immediately, will keep the earth from falling away when the specimen is restored to its proper position, and the surface to be exhibited may then, if necessary, be treated as above described, with gum-water to secure the safe preservation of the earth galleries.

Beetles injurious to timber may be well displayed by choosing a piece of wood with characteristic specimens of the injuries caused by the kind of beetle to be exhibited, and drilling two small holes beneath the spot where it is to be placed, then passing a fine wire horizontally through the thorax of the insect, drawing the two ends through the drilled holes, and tying them securely at the back of the wood. If a pin is also passed through the beetle in the usual way, it will help to secure the insect in the desired position; and the head of the pin may be cut off or concealed by a touch of paint, so as not to spoil the life-like appearance of the specimen. Beetles, or other insects too small or soft in their texture to be treated in this manner, may be fixed by gum, glue or marine glue, or a single pin may be driven through so deeply into the wood that the head of the pin rests on the insect, and sometimes by carefully lifting one of the elytra of a beetle the pin may be passed through beneath it, and the wing-cover returning to its place will entirely conceal the artificial support.

Pupæ may be fixed with glue and concealed pins, and the larger larvæ, such as those of the goat-moth, may be well represented by plaster models from life, fixed in the injured timber from which the original was taken: but in all these matters the characteristic position and colouring of the insect should be well studied before any attempt is made to represent it, and all artificial attachments or supports should show as little as possible. If it is quite unavoidable that they should appear, a little earth or wood-dust applied to the surface of the glue or gum, and a few touches of paint on the wires will usually deaden them, so as to attract little notice.

Besides the substances mentioned, there are others still more perishable, such as fruit, leaves or roots, which it is necessary should be represented, in order to give perfect illustration of the destructive powers of many of our insects. In some cases these can be shown by accurate drawings; in others, models in wax or plaster give a satisfactory representation, and in the Entomological Collection of the Horticultural Society at South Kensington are many specimens of models in plaster of Paris, representing vegetable substances injured by insects, the insects themselves in their larval form, and other subjects connected with economic entomology. The process of making these is as follows:—

The object to be modelled should first be coated thickly and strongly with wax; this may be done by placing it on a smooth board which has been slightly damped to prevent adhesion, and then brushing the melted wax rapidly over it with a camel's-hair pencil. The wax should at first be almost boiling hot, so that it may flow from the brush like water, and leave no marks where the successive applications join each other, and when a thin coating of wax has been secured over the entire surface of the object (or such parts as it is desired to model), the mould should be gradually thickened by the application of successive brushfuls of the rapidly cooling wax till it is of the required strength.

If the object to be modelled is a leaf, it is best to remove it from the mould before the wax is perfectly cool. In this state it can be gently lifted and drawn from the mould without injuring the most delicate folds. If it is a fruit or root, the wax should be left untouched till it is thoroughly cold and hard, and the object may then be cut away carefully with a knife or curved chisel, the central part being first gradually removed till a mere film remain of the rind or bark of the object immediately touching the wax mould. This may be broken away or withdrawn by a pair of forceps, and removed through the opening which has been left where the object was placed on the modelling-board.

The cavity is then to be filled with plaster of Paris, mixed smoothly with water to about the consistency of cream, and laid into the mould in successive brushfuls with the kind of paint-brush known as a hog-tool. Much of the beauty of the model depends on the care exercised in this part of the work. If the plaster is sufficiently liquid, and worked well into all parts of the mould with the brush, all is well; but if the plaster is too thick, or allowed to run at once in a mass into the mould, air-bubbles and other defects are most likely to appear, and the model to be totally useless.

It is necessary to procure the best plaster of Paris, such as may be procured from the London dealers, as what is procured in country towns seldom sets properly, and consequently causes much disappointment. When the plaster has set firmly, the wax should be removed by pouring scalding water over it; and the model, after having been properly dried, either by warmth or by setting it aside on blotting-paper for some days, should be carefully examined, and all superfluous plaster and imperfections removed, and it will then be ready for colouring.

In colouring, the great object is to give the natural tints without injuring the perfect representation of texture of surface already obtained; unless the colouring materials are used with great care, the fine markings which, through their truth of representation, give the life-like appearance to the model, will be lost sight of, and its value much deteriorated.

To meet this point, we should be careful to avoid the application of paint in layers, which are liable to leave the projecting parts bare and the fine depressions clogged, and to render evident the markings of the brush and the junctions of the various tints of paint. If the model is prepared by being soaked on the surface with drying oil, and, after being slightly warmed, the paint (which should be the ordinary good oil-paint used by artists) is, so to say, floated with the brush over the surface, allowing the tints to blend and run into each other in some places, the superfluous matter being carefully removed from the hollows with a fine brush,—this method will usually, with care and patience, succeed, so that the object may be satisfactorily tinted in a very short time, and will only require the addition of a few characteristic touches (or possibly corrective washes of transparent tint), applied where requisite, after the first coat has dried.

The minutiæ of work, such as kinds of varnish and different methods of manipulation, would be too long in detail to enter on here, but it may be added that the natural appearance of the model may often be much enhanced by the addition of such parts of the original as are durable. For example, the dry scales of the pseudo-bulbs of orchids, or the outer coats of some bulbs, may be carefully removed from the object to be modelled before the mould is taken, and, being replaced on the model in their proper position after it has been tinted, will give a truthfulness and beauty to the work which could be obtained in no other manner.—*Gardeners' Chronicle.*

THE USE OF WAX, TALLOW, ETC. IN SUPPOSITORIES.*

BY CHARLES L. EBERLE.

Pure cacao-butter may be asserted to be but rarely if ever met with in the drug market. The samples for sale vary sensibly in colour and consistency, and no positive rule for judging of a pure article by cursory examination can be offered. A candid admission by several prominent manufacturers of the article, reveals the fact of its frequent adulteration, and since the extended demand and sale of this production for cosmetic and suppository application, a greater variety of mixtures known as butter of cacao is to be found than formerly.

The pharmacist, however, but seldom applies it to uses other than in the preparation of suppositories, the successful use of which depends upon a base, whose point of fusion will correspond to animal heat, which can be handled readily when in form, and which, upon exposure to the natural heat of the body, will promptly liquefy not melt slowly, thus depositing quickly the medicating ingredient upon the surface to which it has been exhibited.

The butter of cacao most satisfactory for pharmaceutical use is of a dirty white, inclined to yellow in appearance, firm under pressure, yet disposed to yield its surface when held in the hand by the warmth thus imparted, fusing readily at or about 98°, which sets rapidly after fusion when exposed to cold, and which, after such exposure, maintains its original character at ordinary temperatures.

Such cacao-butter may be had, and under proper manipulation it needs no addition of a hardening ingredient to adapt it to suppository use.

Cacao-butter at 98° F. liquefies. This is more apparent in the rectum or vagina than by merely holding in the hand. The mixtures, I mean the mixtures made by the pharmacist with the cacao-butter of the market, vary in their behaviour in proportion to the quantity and character of the hardening ingredient used in connection with it.

A considerable proportion of cetaceum may be added without materially affecting the value of a suppository; at least ten per cent., if combined with the butter, will produce a suppository which will not be likely to be complained of by the medical profession, but the slowness with which this alloy, so to speak, fuses, makes this or the addition of any hardening substance a serious objection. We need promptness of action in the application of medicines by suppository, which can be best secured by rapid liquefaction of the excipient, and no mixture or single substance combines the essential requisites so completely as a good sample of so-called cacao-butter.

The addition of wax to cacao-butter is to be reprehended. While, under restriction, a mixture may be formed which will harden more quickly and bear more handling than the butter alone, the reflecting pharmacist will bear in mind the slowness of its fusion at anim

---

* Paper read at the meeting of the American Pharmaceutical Association.

heat, and the consequent suspension of the medicine, which should be diffused and deposited over as large a surface as possible.

Content with the simple fusion of such mixtures, the ease with which they may be manipulated, and the temptation to dispense quickly, the more important fact has been overlooked by many, who will, doubtless, correct the error in their future operations. I have invariably found that when the additions were not large enough to render the use of the moulded cones inadmissible, there was no advantage gained by a combination of base or excipient.

With regard to the effect upon the animal tissues of such applications of hardened suppositories, I can only say that where they are of such a character as to produce local irritation, the uneasiness induced requires their removal; this objection is now but seldom met with. Within the past two years the education of the pharmacist has materially advanced in this direction, so that none of repute dispense cones that will not at least fuse at animal temperature, however slowly this fusion may occur, or however imperfectly they may medicate from the suspension of the medicine until its ejection by the action of the parts. Those having but occasional prescriptions for them, are now in the habit of depending on the larger retail establishments, who furnish the trade with a great variety.

There need be no apprehension of a local irritation arising from the use of wax, if not carried beyond the proper fusing-point. As much as fourteen per cent. is used by pharmacists of good repute, without complaint in this respect. The mixture fuses quite slowly at animal temperature, but there is no apparent dissection of the cone, whereby the wax is separated from the butter *during fusion*, however much this may be the case when the melted substances are allowed to cool *ad libitum*. There is a uniformity of constitution so long as the heat is present.

Slow manipulation with a mixture of wax and cacao-butter before hardening, we can readily understand, would cause a granulation of the wax, and produce a cone in which the heat to which it is to be subjected would act only upon the cacao-butter, to the exclusion of the wax, which would then remain unchanged, causing irritation and difficulty; but we are only supposed to be dealing with mixtures which have been well stirred at the time of their introduction into the mould, which mould has been thoroughly chilled, and the suppository likewise. Under such circumstances the mixture is uniform and perfect, and shows no disposition to separate on fusion, if the heat be maintained at that point.

The difficulties in a proper understanding of the preparation of suppositories without the addition of a hardening ingredient in connection with cacao-butter have been solely those of manipulation.

Experience is leading many to prepare the excipient with a smaller proportion of wax, spermaceti, etc., than they at first thought necessary, until the quantity used by some is so trifling as to practically amount to little or no use.

Of the various mixtures, those of one-eighth spermaceti or one-fourteenth or less of wax are least objectionable. Tallow suet or paraffine produced no results not secured by the first-mentioned, while there were some objections to be attached to their use not present in the others.

Now while some have discovered points of manipulation to make these suppositories of *cacao-butter alone*, rapidly and well, (and how much often hangs upon a very slight thread in this respect!) far exceeding in value those I am about to offer to you, I will simply state the mode which gives me the most satisfactory result.

The mould is of brass; a clamp hinged at one extremity and handled at the other, held firmly in place by a ring slipped over said handles; the cones are turned from the interior face of the clamps, as in an ordinary bullet-mould. It should mould at least one dozen, and be improved by the addition of a loose clamp, to be attached firmly in the centre and at the bottom of so long a tool, to prevent the loss of the fused mass before congealing, by running from between the plates.

This mould should, so far as possible, be thoroughly chilled and ready for use. To place the fused butter in the mould while it is warm, and cool both by the same operation, almost invariably results in the contraction of the metal upon the cool cone to a degree that upon the attempted separation of the matrix every cone will be split in two. When the mould is thoroughly cooled, the butter sets rapidly, and in fifteen or twenty minutes the suppositories will drop from the matrices by their own gravity.

The deductions I draw from a close observance of this subject for the past two years are, that the addition of a substance such as wax, spermaceti, etc. to cacao-butter produces a mixture requiring a higher point of heat for its fusion, and in proportion to the amount of such addition; and that when such addition is made, if it should not be sufficient to prevent the fusing of a suppository at animal temperature, no irritating or harmful effect is produced either upon the vagina or urethra. Where a larger quantity than that mentioned above is added, the annoyance produced requires the removal or ejection of the suppository before any harm may be done.—*Proc. Amer. Pharm. Assoc.* 1870.

PROCESS FOR PREPARING LIQ. FERRI TERSULPHATIS AND LIQ. FERRI SUBSULPHATIS, U.S.P., WITHOUT THE FORMATION OF NOXIOUS GASES.

BY J. CREUSE.

The best method for preparing the persulphates of iron perfectly pure is, undoubtedly, to run a stream of chlorine gas through a solution of the protosulphate previously acidulated with the proper quantity of sulphuric acid. But this is obviously impracticable to most pharmaceutists. The Pharmacopœia of the United States prescribes to oxidize the protosulphate of iron by means of nitric acid, a certain proportion of sulphuric acid being added. This is more practicable, and yields a good product, but is liable still to several objections. Expensive vessels are required for boiling a mixture of sulphuric and nitric acids; a good draught is also necessary for the escape of the nitrous fumes, and very often during the operation the vessels are broken, or the operator is annoyed by the poisonous gases escaping into the room. For these reasons, many pharmaceutists prefer to buy the articles ready made; they have to pay a high price for it, and to depend on the manufacturer for its strength and purity.

I propose this new method, by which any pharmaceutist may prepare his own liq. ferri tersulphatis or his liq. ferri subsulphatis on his very prescription-desk, if need be, and with the usual implements found in all drug-stores.

℞. Sulphate iron in coarse powder, 12 troy ounces.
Sulphuric acid, 2 troy ounces and 60 grains.
Chlorate of potash, 348 grains.
Boiling water, 12 fluid ounces.

Dissolve the sulphate of iron, in the boiling water, in a glass matrass, or any convenient bottle. Add the sulphuric acid gradually, and, while the liquid is hot, add the chlorate of potash by small portions. When all is dissolved, filter and complete 24 fluid ounces. The whole operation need not take more than fifteen minutes.

The following equation explains the reaction:—

$$12FeO,SO_3 + 6SO_3 + KO,ClO_5 = 6Fe_2O_3,3SO_3 + KCl.$$

This process has the advantage of giving out no fumes or smell of any kind; the product is free from any acidity but what belongs to the salt itself.

It is true the persulphate of iron thus obtained contains a small quantity of chloride of potassium, but this does not interfere with any of the uses for which it is wanted by the pharmaceutist. I think that the nitric acid always present in the preparation of U. S. P. is much more objectionable. Besides, any one who has followed the U. S. P. process knows that it is always when one tries to get rid of the last traces of nitric acid that the porcelain or enamelled dishes are broken.

A slight modification of the formula will give the liquor ferri subsulphatis U. S. P.:—

℞. Sulphate of iron, coarse powder, 12 troy ounces.
Sulphuric acid, 1 troy ounce and 30 grains.
Chlorate of potash, 340 grains.
Boiling water, 10 fluid ounces.

Operate as above, and evaporate to 12 fluid ounces. Filter.—*The Physician and Pharmacist, Feb.* 1871.

AMERICAN SUMAC.

Since the war, and in the reversal of fortune consequent thereto, many of the people of the South have turned their attention to other sources of revenue than the former staples of tobacco, corn and cotton, and this necessity has developed new and heretofore neglected sources of revenue. For instance, it is said that one county alone of the State of North Carolina shipped North last winter about $100,000 worth of quails (called partridges there), not to speak of the new industry of "*truck farming*," in which men are now making fortunes, who a few years ago would have thought it almost a disgrace to sell so apparently insignificant a thing as a strawberry.

Among these new industries, and rising rapidly into importance, are the gathering and manufacturing for market of sumac. This article is used as a dyestuff and for tanning morocco. Formerly all used was brought from Europe; now the Southern States supply a large quantity, already supplanting the low grades of the foreign article, and it is hoped ere long also to take the place of the finer grade.

The difference between American and foreign, or, rather, American and Sicilian first grades, is probably due to the fact that the latter is cultivated; the former is as yet a wild product growing on those vast fields of so-called worn-out land abundant through the South from their former wasteful system of farming. However, one of the largest dye-manufacturers says that the tannin in the Southern sumac seems to be in a different form from the Sicilian, and hence the latter is still preferred by dyers, especially for fine work. Still this may be due merely to cultivation, as all know the changes that have been made from time immemorial in various grains, grasses and fruits by culture and care.

Tanners of morocco say that the Southern sumac, when carefully gathered, free from sticks and dirt, the leaves and leaf-stem only, is equal in tannin strength to the best Sicilian; that with Sicilian at $175 per ton such sumac finely ground should bring $125 per ton. The usual price is $50 to $90, and it has sold at $110. It is like everything else; it pays to put it on the market in the best order possible.

In treating of the operation of gathering and preparing for market, we shall first state something of the different varieties of sumac. There are six botanically different varieties of sumac in the United States; of these, three are of value, one is of little or no use, and two are poisonous. The first three resemble each other very much in leaf and size, growing from four to ten and fifteen feet high, chiefly on dry uplands, in old fields. Of these three, two have hairy berries and one has a hairy down on the branch, like that on a deer's horn in summer; the third has a perfectly smooth berry and branch. The leaves of all these are valuable, though probably, if care were taken to keep them separate, the hairy or stag-horn sumac would be found most valuable for dyeing.

Of the other three the dwarf sumac, one or two feet high, is valueless; another grows only in swampy places, and while its juice is said to make a fine varnish, used largely in Japan, yet it is so poisonous to many persons that it is best let alone; the third is the well-known poison oak.

In gathering the sumac, leaves and leaf-stems should be carefully picked without any of the woody stem, then dried under cover on lattice-work shelves to give free access to air, frequently stirring or turning to prevent heating. When thoroughly dried, at the end of two or three weeks, it is sent to New York or to the nearest mill for sale. In this state it is worth from $1.25 to $1.75 per hundred lbs., but woody stems and dirt detract from its value very much. The buyer in the interior of Virginia, North Carolina, South Carolina and Georgia can seldom afford to pay more than $1 per hundred.

At the mill it is ground very fine and screened. The mill is of the usual drug-mill form: an upright wheel revolving on its edge in a circular trough, as the old-fashioned mill for grinding clay. It should be tightly enclosed; if not, a large quantity of the light, fine powdered sumac will escape and be lost. On care and economy in this operation depends the miller's profit. After grinding, it is screened and packed in bags, 162 lbs. to the bag, and thus sent to market. The bags to hold this quantity should be cut out 40 × 60 inches. Fourteen such bags will hold a ton. This is exactly the style and weight that Sicilian sumac is packed as sent to the United States. To sell well, it should be of a light green colour.

The time of gathering is from July 1st to just before first frost, not later; in some parts it may commence earlier. It should be done when the flower is in full bloom, not before.

It is stated that the consumption of sumac in Great Britain is over 20,000 tons per annum, and that it is yearly increasing. In the United States 3500 tons of native, and perhaps 3000, or over, of foreign are used; probably 500 tons of native growth are exported. As the demand and uses for leather never grow less, it is not at all probable that all which the South can produce, if properly prepared, will ever fill the needed supply; and if it should create a plethora on the market, it would only cause new uses to be found for it, or engender the production of a finer article.

There is no reason why at least 5000 tons should not be exported to Europe, besides supplying home demands. The mill machinery is said to cost $2500 without power. With the crude article at $1.50 per hundred even, $12 to $15 per ton for grinding and bags, $10 for loss, and $10 for freight to New York, there is certainly a fair margin of profit at $90 per ton, at least, which price a good article will certainly always bring in New York. These figures of cost, also, are rather high. There is plenty of room for at least ten more mills in the now unoccupied field of North Carolina, South Carolina and Georgia. Any good business place in the upper or middle sections of these States will do as a site.

We have stated that sumac is used for tanning and dyeing. For these purposes the user generally makes his own decoctions, and uses them when fresh and warm. It is stated that the liquor injuries by standing. For tanning it is valued, as it does not discolour the leather. It is used in the same manner as a decoction of bark. Best Sicilian contains, according to Muspratt, sixteen per cent. of tannin and Virginia ten per cent. We have no doubt the vastly improved mode of gathering and preparing the American sumac will now increase its quantity of tannin.

In dyeing it is used to produce a fawn and a rich yellow, a black, a peculiar shade of green, and a red. The mordants are usually tin or aluminous substances.

With Brazil wood and tin solution it produces a red; with copperas and logwood a rich permanent black. With a solution of chloride of tin alone, a rich yellow, and this with Prussian blue, shades of green. It is used chiefly as a base, and has the quality of giving great permanency to the colours dyed with it. The leaves of the hairy species called staghorn are considered best to dye yellow.

The sumac berries are of very little value, though we think in the progress of science a use will be found for them. They are said to contain large quantities of malic acid. They are now used in small quantities by the druggists, and when ripe make a very refreshing and cooling beverage. They should by all means be kept out of the gathered leaves, as they contain a red dye, hence would injure the quality of the sumac.—*Scientific American*.

POPPY FARMING IN QUEENSLAND.

A successful attempt at poppy farming is reported from Queensland. A specimen of opium, grown by Mr. Tatnel in the Toowoomba district last season, has been exhibited, consisting of five cakes weighing one pound each, which was part of the produce of a quarter of an acre of poppies. The quality was so superior that the whole exhibit was purchased by a medical gentleman in Toowoomba at £3. 10*s*. per pound. The net proceeds of the crop will amount to £28 or £30.

We extract the following particulars as to the cultivation from the *Brisbane Courier*:—

"The first advice given by Mr. Tatnel is to be exceedingly careful in selecting the seed (*Papaver somniferum*). This appears to be the main point, as on this hinges ultimate success. There are some kinds of poppies very similar, in many respects, to the true Turkey, but which are not adapted to this climate. The East Indian seeds germinate quite as freely, but the Turkish plant will blossom nearly three weeks before it. The former, also, has but one capsule, and upon incising it only a small quantity of gum will exude, and subsequent incisions will not produce further discharges.

"The white poppy plant is also very similar to the East Indian, but equally unprolific. Opium can be obtained in greater or less quantity from all the poppy species, but the main object is to select those sorts which will yield the greatest profit to the grower.

"The poppy must have rich ground, either naturally so, or through the application of manure. Land which has been worked previously for a root-crop, and brought into fine tilth by the cultivator and horseshoe, is better than new land for this plant, for as it has a tap-root any interference with the downward course of the latter will prevent the flow of opium. It ought to be sown in drills, from eighteen inches to two feet apart. The objections to the broadcast system of sowing are:—First. That when making incisions it is very difficult to distinguish between those plants which are cut, and those uncut. Secondly. When gathering it is impossible to avoid coming in contact with the liquid gum, thus causing a great waste. Sow the seed in the drills in the first instance, as transplanting is so difficult and uncertain, with such delicately tap-rooted plants. The tap-root resembles a piece of cotton thread, and it is almost impossible to remove it without injury. The time for sowing in this district is from the middle of May to the end of June, but it would be well to get as much of the sowing completed as soon as possible before the end of May. Frosts will not affect the poppy plant, nor will watering too freely benefit them, warm dry weather being the most favourable season for a large return of gum. The plant may be made to grow very rank, through the application of liquid manure, but the extra quantity of produce will prove a thin milky substance, which, when dry, is not worth the trouble of collecting. The system of gathering is very simple, and may be performed by careful children. The yield per acre has been estimated at from 35 to 40 lb., and the price for the raw and unadulterated produce would range from about £3 to £3. 10*s*. per lb."

The following practically explains the gathering process:—

"The time to cut the capsule is from two to three days after the flower-leaves have fallen off, when it will be about the size of a walnut. There are two methods of doing this, which have been found to answer; the first is by making several longitudinal cuts from the base to the crown; the second to make two horizontal incisions one above the other half-round the capsule, the cuts to be made with a sharp knife, and made in such a way that they should have an upward slope, by which means—should the knife penetrate through the shell of the capsule—inward bleeding and consequent loss of gum will be prevented.

"The latter plan was found to be the best. The knife used should be one having two blades one-sixth of an inch apart, with a guard upon the blades to prevent them cutting too deeply. The cutting process should take place during the evening, as the gum exudes in greater quantities during the cool hours of the night than in the day, and will be found in a fit state to gather when the sun has been on it for an hour or two in the morning.

"Those who are to collect the gum should be furnished with a blunt knife, with which to scrape the heads, and have a sharp-edged tin fastened by a strap round the waist in which to collect the opium. The tin must have a sharp edge, as the opium adheres very firmly to the knife, from which some force is required to remove it.

"Towards the evening, hands can be set to work to cut the heads a second time, making the cuts on that side of the capsule left uncut the previous day. The process, as described, may be continued each day until the heads cease to yield sufficient gum to make it payable.

"In conclusion, the opium collected should be dried in shallow plates to a proper consistency to work into flat cakes weighing about half a pound each, and let this be done as early as possible, for it soon becomes musty if not properly dried. When it is worked into the required shape, cover it with poppy leaves and keep it in a dry place.

"The plant may be grown with profitable results for capsules alone, and with very little risk to the cultivators. The capsules are worth 35*s*. per thousand in Melbourne, and the yield per acre is from thirty-five to forty thousand, according to season.

"We understand that, independently of the yield of opium, Mr. Tatnel has also obtained a fair crop of seed, a portion of which he will no doubt distribute among his friends and neighbours before the planting-season, which is now rapidly approaching."

In connection with the subject of the entomological prizes offered by the Royal Horticultural Society,* we have great pleasure in reproducing in another part of this Journal an article from the *Gardeners' Chronicle*, containing some valuable advice on the preparation of specimens.

NOTICE.—In answer to several inquiries we are enabled to state that Ashworth's Patent Looped Binder Folios, made to hold six, thirteen or twenty-six numbers of the PHARMACEUTICAL JOURNAL, are now ready, and may be had of Messrs. Taylor and Co., Printers, 10, Little Queen Street, London, W.C., price 1*s*. 6*d*. Binders, 6*d*. per gross.

* See *ante*, p. 931.

The Pharmaceutical Journal.

SATURDAY, JUNE 3, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

LIME AND LEMON-JUICE.

IT is well known among those chiefly interested in the subject that one of the main objects of the Merchant Shipping Act of 1867 (commonly called the DUKE OF RICHMOND'S Act) was to ensure a supply of genuine lime and lemon-juice to the crews of merchant ships. Past experiences went to prove that a large proportion of so-called lime-juice, put on board ships bound to distant parts, consisted of solutions of citric, sulphuric or other acids, entirely inert, and sometimes harmful. Scurvy continued to prevail, and hence it was enacted that all lime and lemon-juice shipped for the use of sailors shall be examined by a competent officer, mixed with a certain amount of spirit, and bottled under the direction of customs' officers. There can be no reasonable doubt that this system has succeeded remarkably well, as it has secured a proper supply of good juice to the mercantile marine, and as scurvy has in consequence diminished by from 60 to 70 per cent. But there are two unsettled and very important questions in connection with this subject which pharmaceutists should be specially able to aid in deciding. (1.) The exact analytical standard of lime and lemon-juice. (2.) Does genuine lime and lemon-juice require the addition of alcohol for its proper conservation? As to (1) we would remark that the Marine Department of the Board of Trade have delegated the official examination of lime and lemon-juice in connection with the working of the Merchant Shipping Act of 1867 to the Laboratory Department of the Inland Revenue, and that no very delicate analysis is required to determine the genuineness of the juice. But inasmuch as the antiscorbutic value of lime and lemon-juice does not appear to depend upon a single ingredient, but upon the combination, it is eminently useful and necessary to know exactly the proportions of the constituents and the particular way in which they are combined. The late MASTER OF THE MINT separated, with great care, the colloid and crystalline principles of the juice, and submitted them for practical experiment to the officers of the Seamen's Hospital, with a view to aid in determining whether the therapeutic value of the juice existed in the former or the latter principle.

There is no doubt that the second point should immediately engage the serious attention of chemists, inasmuch as whenever the Merchant Shipping Code is discussed in Committee of the House of Commons, an energetic attempt will be made to do away altogether with the "fortifying" section of the Act of 1867, and to send the juice aboard ship "unadulterated" with spirit of any sort or kind. The positive therapeutical effects of lime and lemon-juice can be best determined by medical men, but pharmaceutists may render very valuable aid in assisting to determine accurately the points above mentioned. And a rider may be added to the investigation, indicating the comparative differences between the juice of the lime and the lemon, so as to aid the physician in determining, if possible, which of the two may be recommended as the more valuable prophylactic against scurvy.

RECOGNITION OF BLOOD-STAINS.

DR. LETHEBY'S recent reference to the use of the spectroscope for this purpose in medico-legal inquiries has called forth from a writer in the *Lancet* the following remarks:—

"The spectroscope, as many of our readers will know, came into use as an instrument of chemical analysis thirteen years ago, and was originally employed for the detection of the alkali-metals and a number of other metals, the substances to be analysed being heated strongly in a colourless flame, and made to yield incandescent vapours, the light from which, passing through a prism, furnished characteristic spectra. These spectra consist of narrow bands of light, quite sharp and distinctly defined, and having much the aspect of bands of narrow China ribbon. They have *fixed colours* and *fixed position* in the spectrum. The value of this kind of analysis was most strikingly exemplified by Bunsen, its discoverer, who by means of it discovered two new alkali-metals, cæsium and rubidium. Later, Mr. Crookes discovered the metal thallium by means of spectroscopic observation; and still later a fourth new metal, indium, was recognized in the same manner. In each of these examples chemists operated upon incandescent vapours, and it was the presence of a *narrow bright line* of peculiar colour, and occupying a *perfectly fixed* and *definite position* in the spectrum, which led to these important discoveries. A second kind of spectroscopic observation naturally suggested itself to chemists, viz. observations of spectra given by passing colourless light through coloured solutions; instead of light from incandescent vapour, light from a coloured liquid was sent through the prism.

"This second kind of spectroscopic observation is, however, not so satisfactory as the first. There are no sharp and brilliant bands of light, standing out like China ribbon, and perfectly unmistakable by all eyes. Instead of striking appearances of this kind, all that is to be observed is a little *dimness* here and there in the spectrum. The dim spaces which are not sharply bounded have been dignified with the name of *absorption bands*, and many of them are so little conspicuous as to be invisible to all but the highly educated eye.

"No discovery has as yet been made by means of these spectra; and but for the great success which attended the first kind of spectrum-analysis very little weight and importance would be allowed to the indications of the second.

"In the spectra of incandescent vapours there are, as we mentioned, narrow bright lines of light. There are also bright tracts in these metallic spectra. Now, if there were only these illuminated tracts, and not the lines of light, the spectrum of an incandescent vapour would degenerate, for analytical purposes, into the condition of the spectrum furnished by light after transmission through a coloured liquid. The spectrum-analysis of blood does not deserve the highest degree of confidence."

This conclusion is likely to be zealously controverted by the admirers of spectroscopy, though the late supposed discovery of a new element through its aid, and by two philosophers simultaneously, is perhaps calculated to raise some doubt as to the spectroscope being a safe guide in such important cases.

INDIAN QUININE.

The Indian papers give a very unsatisfactory account of the results obtained in the manufacture of bark alkaloids lately attempted by the Government. The subject is of such importance that we extract the following documents from the *Calcutta Observer* and the *Englishman*. We believe the statements made are in the main correct. There seems to be some little discrepancy as regards the issue of the impure product, but we have been promised further information on the matter from Professor De Vrij, which will no doubt put it in a proper light.

"Does the Government of India eat pickles? We know that a late member of that Government, who is now obtaining a considerable amount of public attention, devoted much of his time to the study of that important condiment. We see no internal evidence of its still finding a place in the dictary scale of the members, at all events of the Legislative Council; and we, therefore, venture to request the serious attention of Government to the humane caution which Messrs. Crosse and Blackwell are in the habit of affixing by labels to their bottles, warning the public against being unduly attracted by the beautiful green of the preparations of other vendors into poisoning themselves with copper. We must, then, ask them if they are aware that they are issuing under their sanction a preparation by the side of which the dangers of green pickles sink into insignificance. We understand that the officer in charge of the Government cinchona gardens has produced, with immense satisfaction to himself and the Government, a preparation which he is pleased to call 'amorphous quinine'; if this preparation has one quality of which he is more proud than another, it is its beautiful green colour, so soothing to the eye of a fevered patient, so suggestive of the luxuriant growth of the Government gardens, and, we are afraid we must add, of the skill of its manufacturing agents. This pleasant-looking drug has been largely issued to the heads of departments for experiments in the public hospitals and dispensaries. If some fortunate accident had not prevented its actual use, there is reason to fear that the result of the experiment would have shown itself in a large increase in the death-rates of our hospitals, which would no doubt in due course, and according to well-established precedent, have been attributed to inappropriate buildings or insufficient ventilation. But, happily, Government has been saved from being placed in the position of a druggist ignorantly compounding and dispensing poison by the discovery made by Dr. Simpson, who is now sitting on the cinchona committee, that this green drug is little more than a cunningly-devised mixture of copper stewpan and bark, displaying, it must at all events be admitted, considerable skill in the dissolving of the stewpans. We trust that the escape will teach the Government that it is not real economy to entrust the more delicate chemical operations to a European gardener assisted by Booteah coolies. If a private manufacturer have a business of this sort in hand, his first endeavour will be to secure the best available skill for its superintendence; but the financial policy of the present day takes an opposite view, and thinks control of expenditure, without the slightest regard for future profit or loss or consequences in any form, is all that it has to look to."—*Calcutta Observer.*

"It is stated that the new product of the cinchona bark, lately furnished by the Superintendent of the Darjeeling plantations for distribution to medical officers, is largely contaminated with poisonous quantities of copper. This gentleman had prepared a substance which he believed to contain the whole of the cinchona alkaloids jumbled up together, and forwarded it with a view to its febrifuge and anti-periodic powers being subjected to crucial trial in some of the large hospitals. He supposed that this compound contained all the febrifuge principles of bark; and the reason assigned for stopping short of isolating the various alkaloids, such as quinine, quinidine, cinchonidine and cinchonine, is economy of manufacture. Hence the attempt to introduce this substance of unknown chemical composition and strength. Such an attempt is essentially a retrograde step in science, and could only have been initiated by ignorance of the modern tendency and principles of therapeutics, the whole scope of which has been to procure the separation of the active principles of drugs in a manageable form, so that their doses may be fixed with certainty, and the powers of those doses ascertained with the greatest attainable exactitude. This has already been done with reference to elaterium and morphia, and also with reference to quinine, quinidine, cinchonidine, and cinchonine; yet Mr. Clarke now asks medical men to go back to the old system, in defiance of the teachings of organic chemistry and therapeutics, and to substitute imperfection for perfection, uncertainty for certainty, in a matter, concerning the welfare and lives of thousands of human beings.

"If there cannot be found in India scientific talent sufficient for the isolation of the cinchona alkaloids in a pure form—and we believe that such is available—by all means let the process of manufacture be stopped at a stage when all the alkaloids are believed to have been concentrated in a small compass. But let the substance thus obtained be sent to Europe for sale to the manufacturers, who know how to properly work the mixed mass. In the name of humanity we protest against this raw compound being foisted upon the hospitals of this country,—a proposal as unscientific and unsound as it would be to substitute opium or the squirting cucumber for morphia or elaterium, on the ground that a saving would be effected thereby in the manufacture. The gentleman from whom the idea emanates, although holding a quasi-medical appointment, is not a medical man, or he would have shrunk from the risks to human life which would inevitably follow the practical adoption of his scheme. The powder has been used in Madras, where the fevers are of a very mild type, and, as was to be expected, a fair number of recoveries are noted. So it was with the "Jesuits' Bark" in the seventeenth century. But just as the latter had to be abandoned for quinine, so it would be folly and cruelty now to return from the pure form of the medicine to Mr. Clarke's raw material. The dangers of such a course are increased by the medical ignorance of the present superintendent. The substance which he has supplied for hospital use is found upon analysis to contain 20 per cent. of the poisonous carbonate of copper, or $10\frac{1}{2}$ per cent. of the metallic copper! The presence of dangerous adulteration in such quantities indicates either gross incapacity, or almost criminal carelessness in the preparation of the drug. Fortunately, the timely discovery of the poisonous admixture had been made, we believe, by a member of the Cinchona Commission before the powder was issued from the medical stores for trial. Had this discovery not been made in time, a large quantity would have been distributed, and disastrous consequences must have resulted from large doses of a poison cumulative in its operation, and deadly in its effects.

"The announcement of this fact, we hope, will make the Government pause before they commit the extraction of the cinchona alkaloids to persons unacquainted with the delicate chemical processes requisite for their successful isolation and purification.—*The Calcutta Englishman.*"

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

May 24th, 1871.

Present—Messrs. Allchin, Bourdas, Carteighe, Cracknell, Davenport, Deane, Edwards, Gale, Hanbury, Haselden, Ince and Southall.

Dr. Greenhow was also present on behalf of the Privy Council.

Thirty-four Candidates presented themselves, viz. six Major and twenty-eight Minor; the following twenty-four passed, and were declared to be duly qualified to be registered:—

MAJOR (as Pharmaceutical Chemists).

*Freeman, Ernest	Stourbridge.
*Catterns, Heneage Parker	London.
Troake, Marler Hamilton	Kingsbridge.
Sambrook, William	Cardigan.

MINOR (as Chemists and Druggists).

	*Selley, John	Aylesbury.
	*Wilkes, John Sanders	Stafford.
	*Dolman, William	Cheltenham.
	*Barnes, Francis Joshua	Preston.
	*Hill, Walter	Cheltenham.
	*Threlfall, Hugh	London.
	*Barclay, John	London.
	Webb, Herbert Charles	London.
	Ellwood, Francis Henry	Norwich.
	Cooper, Anthony Vincett	Birmingham.
	Stansby, Charles John	Derby.
	Smith, Arthur John	London.
	Brown, Richard Fearon	London.
	Wilson, Thomas	Blackheath.
	Forsbrook, William Henry	Birmingham.
Equal.	Carr, George	Sheffield.
Equal.	Cordley, William Bains	London.
	Smyth, Arthur William	Diss.
	Tonks, Joseph	Wolverhampton.
	Parker, William	London.

The above names are arranged in order of merit.

The certificate presented by the undermentioned was received in lieu of the First or Preliminary Examination:—

Sergeant, William R. .... Boston.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Thirteenth and concluding General Meeting of this Association (Twenty-second Session) was held at the Royal Institution on Thursday evening, the 11th inst.; the President, Mr. John Abraham, in the chair.

Mr. S. G. Hilditch made the following communications:—

Liq. Myrrhæ Co.—A convenient method for the easy preparation of mistura ferri composita, according to the following formula—

℞ Ferri Sulphas gr. xxv
Aq. Rosæ ℥viij
Liq. Myrrhæ Co. ℥ij } = ℥x Mist. Ferri Co. B. Ph.

Tinctura Ferri Acetatis.—The instructions given in Squire's 'Companion to the British Pharmacopœia' would not produce the preparation in accordance with the Pharmacopœia. Mr. Squire recommended the acetate of potash to be dissolved in 20 oz. of water; the Pharmacopœia ordered rectified spirit.

The President said that this was one of the most unsatisfactory preparations in the Pharmacopœia; he had made several experiments, but could not succeed in making a tincture which would keep an indefinite time.

Mr. Edward Davies, F.C.S., considered an alcoholic solution of acetate of iron an impossibility.

Tinctura Hyoscyami.—Large quantities of hyoscyamus leaves of first year's growth were used in making this preparation. It was necessary that it should be prepared from leaves of second year's growth. A tincture prepared from the former, when put into water, would remain perfectly bright, whilst the officinal tincture would become milky.* This was a simple test; the matter was of great importance, as it had been proved that the therapeutic effects of the two tinctures differed very materially.

Carbo Animalis Purificatus.—The result of his experiments was the production of 8 per cent. of animal charcoal from ordinary bone black.

Mr. Davies thought a good sample of bone black should yield at least 10 per cent.

An interesting discussion followed these communications, in which several members took part.

The President thanked Mr. Hilditch for his valuable information, and then delivered the following valedictory address:—

President's Valedictory Address.

This being the last meeting of the Session, I am expected to address to you a few parting words.

First, let me express my sense of our obligations to those gentlemen who have contributed to our instruction by interesting communications. One of the first of these was a valuable paper on ozone, by our Vice-President, Mr. Davies. Another was by Mr. Keith, on some of the newest processes connected with photography. I had not the pleasure of hearing it, but I was told by those qualified to judge that it was unusually excellent. There were also two able papers, well illustrated, on the chemistry of calico printing by Mr. Blair. We have been much indebted to our Hon. Secretary for his diligent attention to the duties of his office, and also for bringing before us the subject of chloral.

This new sedative has hardly maintained the place which was first assigned to it. Experience has shown that its use is not unattended with danger, and that for its beneficial application care and experience are required.

A thoughtful paper on the nomenclature of the natural sciences was contributed by Dr. Syme; but until we get a new science of geometry, I fear that we cannot abandon the use of arbitrary terms in the descriptions of most natural objects.

Our most interesting evening was unquestionably that on which our talented townsman, Professor Roscoe, favoured us with his lecture on solar chemistry; on which occasion experiments connected with spectrum analysis were shown in a manner more brilliant and effective than had been before seen in Liverpool. During the same evening many of our friends contributed to our entertainment and instruction, amongst whom I should particularly mention members of the Microscopical Society with their instruments. Mr. Albert Samuel exhibited very successfully an interesting experiment to illustrate Tyndall's theory of the cause of the blue colour of the sky; and we were indebted to Mr. Davies for experimental illustrations of the properties of explosive compounds.

The additions to the Library are deserving of special mention. First, a book of autograph prescriptions, compiled by Mr. Mee; secondly, fourteen volumes presented by the Pharmaceutical Conference from the fund sup-

* Passed with Honours.

* This communication was made before the publication of M. Donovan's paper on "Tincture of Hyoscyamus" in the Pharmaceutical Journal of the 13th inst., of the existence of which Mr. Hilditch was unaware.—A. H. Mason, *Hon. Sec.*

plied by Mr. Thomas Hyde Hills. For the selection we were indebted to Professor Attfield; for I am glad to say that our library is so well supplied with useful and valuable books that we had some difficulty in determining what we could advantageously add to it.

I am sorry that I cannot congratulate you on the numbers which have attended the classes of our school of pharmacy. But wherever the blame may rest—if there be blame anywhere—it must not fall on our teachers of chemistry, botany and materia medica, Mr. Davies and Dr. Carter, whose qualifications can hardly be excelled. The shoe does not yet pinch our young men very much, by-and-by it will be felt.

Our attention has no doubt often been called to the consideration of the causes of the unhealthiness of Liverpool, or rather—as I believe it would be more correct to say—of *parts* of Liverpool. To chemistry our town authorities are now looking for a remedy, and we shall wait with much interest for the report of the able chemists, Doctors Parkes and Sanderson, to whom the inquiry has been intrusted. In the meantime, I will venture to express my belief that a very large part of the unhealthiness of certain classes of the population arises from their sleeping in large numbers in very small rooms, with all access of air shut off. There is a popular idea that night air is bad, I believe that it is a pernicious error, and that we should take every means in our power for correcting it. Night air is at any rate far better than the exhausted air which has been breathed by any of our fellows.

Our kindred societies in Edinburgh and Bath have published price-lists, which I would recommend you to procure, particularly the more recent one published at Bath. It is very desirable that we should know what others think on this matter, and that we should do what is just and fair to ourselves and the public.

I am sorry to observe the death of our townsman, Mr. James Yates, F.R.S., who has taken so active a part for many years in promoting the adoption of the metrical system, and of the advocacy of which he was one of the principal and most munificent supporters.

Mr. Abraham concluded with a few other remarks, including an expression of thanks to Mr. Charles Sharp for his services in teaching an elementary botanical class.

Mr. E. Davies, F.C.S., in moving a vote of thanks to the President for his address and his conduct in the chair during the year, agreed with Mr. Abraham that among the causes of the unhealthy state of Liverpool, the one he had referred to was one of the greatest. He gave his experience of a visit he paid to a house in a court off a small street, in which he said the smell was something frightful. Overcrowding and want of ventilation, and that pernicious system of building houses back to back, and in courts with one end stopped up and the other end nearly so, were the great causes of the high death-rate in Liverpool. He admitted many other causes. The bad habits of the people, drunkenness and other things had their effects; but his own private opinion was that these others were the great root of the evil, and until they could do something in the way of providing dwellings for the poor outside the town, and razing to the ground a great number of these courts, and opening up some more complete channels for the air to go up from the river right through the town, they would not bring down the mortality of Liverpool to anything like a normal figure.

Mr. J. Shaw seconded the motion, which was supported by Mr. A. H. Mason, F.C.S., who drew attention to the injurious practice of householders allowing walls to be papered without having the previous paper removed, instancing cases where five or six were to be seen on one wall, thereby fostering disease and impure air.

The vote having been carried unanimously, the Chairman acknowledged the compliment, and the proceedings terminated.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

On Monday, May 15th, Mr. F. Sutton, F.C.S., gave a highly interesting lecture on Carbon, at the rooms of the above Association.

The lecturer began by remarking how difficult it was to make an isolated lecture really instructive, as the limited time at their disposal forbade more than a passing allusion to the most prominent characters of the subject under consideration, but he trusted that he should be able to interest them in some of the facts connected with carbon, and if this only led them to take up chemistry as an amusement, his purpose would be answered.

The lecturer then advocated the cause of "hobbies," and after reminding his hearers of the saying that "The man of one book was a dangerous opponent," he advised all present to make a "hobby" of either chemistry or some branch of natural history, assuring them that they would find such a course advantageous in every respect.

After noticing the various forms of carbon, and its universal presence in organic bodies, the lecturer proceeded to consider its use in the animal and vegetable economies, its importance in ordinary methods of illumination and heating, and, finally, the explosive compounds into which it enters.

The subject was well illustrated with striking experiments, and elicited repeated applause.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The Second Annual Meeting of the above Association was held at the Temperance Hall, Birmingham, on May 26th. In the unavoidable absence of the President, the chair was taken by Mr. H. Whittles. We regret to say there was but a small attendance of members.

The Honorary Secretary read the Report of the Council, and the Chairman the statement of accounts.

Report.

"Following the precedent set at their first annual meeting, the Council beg to submit a simple statement of their proceedings during the past year.

"It will be in the recollection of some here present that at our last annual meeting a letter addressed to the Home Secretary respecting the Petroleum Act of 1868 was ordered to be forwarded. It was to the effect that great injustice was done to the retailers of petroleum in this town from the excessive charge made by the Town Council for licences for selling the same, it being two guineas in Birmingham, and only from 2*s.* 6*d.* to 5*s.* in most large towns.

"His attention was also drawn to the promised introduction of a supplementary bill for amending that Act, and exempting benzine collas, benzine, etc., from its operation.

"A reply was received that it was under the consideration of Government, but nothing more has been heard of it. It was, however, stated in one of our daily papers a few days ago that a Bill was to be introduced into the House of Lords to exempt these articles.

"The Council were also directed to arrange for a course of lectures on pharmacy to the assistants and apprentices of members during the summer months.

"In accordance with these directions, a circular was addressed to the members of the Association, inquiring as to the number that would take advantage of the same. The replies being tolerably satisfactory, arrangements were made with Dr. Hill for a course of lectures, and thirty attended the first course. A second was arranged for, but from some cause or other this was not so well attended, only eleven entering their names, resulting in a considerable loss to the Association.

"The failure of these attempts to afford practical instructions on pharmacy to our rising members is such as will, we think, prevent, at any rate for the present, a fresh movement for a like purpose.

"In December a communication was received from the Warden of Queen's College on the practicability of establishing a course of lectures on botany, pharmacy, etc., and wishing to know if any support might be expected from the Pharmaceutical Society. Some letters passed between the Council and the Pharmaceutical Society; but it being found that the Pharmaceutical Society did not intend at present to propose to subsidize any local arrangements by money grants, the proposal dropped through, mainly on the ground of the high fees named by the Queen's College.

"In January arrangements were made for the Annual Supper, but the responses to the invitations sent out were so few that it was thought advisable to postpone it. A very pleasant evening having been spent on a former occasion, it was thought that it might be a means of uniting the members of the Association more closely together, and by being oftener brought into contact with each other, of doing away with the petty jealousies that so often are the greatest bane in any profession or trade.

"Some further correspondence has taken place on the Petroleum Bill with the Pharmaceutical Society. Mr. Bremridge states that no charge is made in London for licences, and he questions if the authorities have any legal right of making any charge whatever.

"The new-elected Hon. Sec. having written to ask the favour of the Journal being sent for the use of the members of this Association, the Council of the Pharmaceutical Society kindly consented, and the Secretary has supplied all the numbers of the present series, which, when complete and bound, will make the first volume the property of the Association, and be a useful work of reference. And the weekly issue, which will continue to be sent to one of the new Hon. Secs., if it is thought practicable, could be circulated among the members.

"The general expenditure of the Association seems to have been well guarded, and, but for the large item of £23. 2*s*. 0*d*. paid to Dr. Hill, would have been very small; as it is, there remains a balance in its favour of £19. 15*s*. 2*d*.

"In conclusion, the Council submit to this meeting their second revised edition of the 'Price List,' which they believe is now pretty generally adopted in the Midland Counties; and, at the same time, they must express their regret that the efforts they have made for the establishment of classes on Pharmacy, etc. for the assistants and apprentices have not been more highly appreciated."

The election of officers for the ensuing year having taken place, a vote of thanks to the Chairman brought the proceedings to a close.

ABERDEEN ASSOCIATION OF ASSISTANT CHEMISTS AND DRUGGISTS.

At the half-yearly General Meeting of the Aberdeen Association of Assistant Chemists and Druggists, held in St. Nicholas Lane Hall, on Thursday, 25th May, the following were elected office-bearers for the next six months:—President, Mr. John Tocher; Vice-President, Mr. L. Maitland; Secretary, Mr. John Gordon; Treasurer, Mr. John Hosil; Committee, Messrs. Cassil, Farquhar, Broomhead, Fraser and Spence.

During the past session a long and varied programme has been gone through, the essays on some of the subjects showing no small ability and talent in their writers; and in addition to what the members have contributed for their mutual improvement, Mr. Ross, chemist, Castle Street, kindly added a share, by a magnificent exhibition of photographic transparencies by means of the lime light.

On the whole, in spite of manifold drawbacks, the Society still bravely fights its way onward, and strives with a steady purpose to fulfil its mission, viz. to blend in the nicest proportions the useful with the entertaining.

Proceedings of Scientific Societies.

ROYAL INSTITUTION OF GREAT BRITAIN.

The Revived Theory of Phlogiston.*

BY WILLIAM ODLING, M.B., F.R.S.,

Fullerian Professor of Chemistry, Royal Institution.

"Observationem, quam produco, bono jure mihi vindico. . . . Materia hæc ignescens, in omnibus tribus regnis, una eademque existit. Unde, ut e vegetabili in animale, abundantissime transmigrat, ita ex utrolibet horum, in mineralia et ipsa metalla, promptissime omnium transfertur."—*Stahlii Experimenta, Observationes, Animadversiones, CCC Numero.*

In 1781–83 Cavendish showed that when inflammable air, or hydrogen, and dephlogisticated air, or oxygen, are exploded together in certain proportions, "almost the whole of the inflammable and dephlogisticated air is converted into pure water," or as he elsewhere expresses it, "is turned into water."

On June 24, 1783, the experiment of Cavendish was repeated on a larger scale and in a somewhat different form by Lavoisier, who not only confirmed the synthesis of the English chemist, but drew from it the conclusion —at first strongly contested, then rapidly acknowledged, and since never called into question—"that water consists of inflammable air united to dephlogisticated air," or that it is a compound of hydrogen and oxygen.

This conclusion, so opposite to his own preconception on the matter, Lavoisier subsequently confirmed by an analysis of water. He found that iron, heated to redness and exposed to the action of water-vapour, became changed by an abstraction of oxygen from the water, into the selfsame oxide of iron procurable by burning the metal in oxygen gas,—the other constituent of the water, namely, its hydrogen, being freely liberated.

With the demonstration by Lavoisier of the composition of water began the triumph of that antiphlogistic theory, which he had conceived, in a necessarily imperfect form, so far back as 1772, or before the discovery of oxygen, and had brought to completion by the aid of every successive step in pneumatic chemistry, achieved by himself or by others.

In 1785, the relationship to one another of hydrogen and water being then conclusively established, Berthollet declared himself a convert to the new theory of combustion put forward by his countryman. Fourcroy next gave in his adhesion; and soon afterwards De Morveau, invited to Paris expressly to be reasoned with by Lavoisier, succumbed to the reasons set before him. The four chemists then associated themselves together, and in spite of a strong though short-lived opposition both in England and Germany, succeeded in obtaining for 'La Chimie Française' an all but universal recognition.

The principal articles of the new or antiphlogistic theory of combustion propounded by Lavoisier are as follows:—That combustible bodies in burning yield products of various kinds; solid in the case of phosphorus and the metals, liquid in the case of hydrogen, gaseous in the case of carbon and sulphur. That in every case the weight of the products formed by the burning is greater than the weight of the combustible burnt. That the increase of weight is due to an addition of matter furnished to the combustible by the air in which its burning takes place. That bodies of which the weights are made up of the weights of two or more distinct kinds of matter are of necessity compound; whereas bodies of which the weights cannot be shown to be made up of the weights of two or more distinct kinds of matter are in effect simple or elementary. That inas-

* Notes of a Lecture delivered at the Weekly Evening Meeting, Friday, April 28, 1871; Sir Henry Holland, Bart., M.D., D.C.L., F.R.S., President, in the chair.

much as the weights of the products furnished by the burning of different combustibles are made up of the weights of the combustible burnt and of the oxygen consumed in the burning, these products are compound bodies—oxides, in fact, of the substances burnt. That inasmuch as given weights of many combustibles, as of hydrogen, sulphur, phosphorus, carbon and the metals, are not apparently made up of the weights of two or more distinct kinds of matter, these particular combustibles are in effect elementary; as for the same reason is the oxygen with which, in the act of burning, they enter into combination. And lastly, that combustion or burning consists in nothing else than in the union of combustible matter, simple or compound, with the empyreal matter, oxygen—the act of union being somehow attended by an evolution of light and heat. And except that it would be necessary nowadays to explain how, in certain cases of combustion, the combustible enters into union, not with oxygen, but with some analogue of oxygen, the above precise statement might equally well have been made by Lavoisier in 1785 or be made by one of ourselves at the present day.

Lavoisier's theory of combustion being known as the antiphlogistic theory, the question arises, What was the phlogistic theory to which it was opposed and which it succeeded so completely in displacing? This phlogistic theory was founded and elaborated at the close of the seventeenth century by two German physicians, Beecher and Stahl. Having exercised a scarcely disputed authority over men's minds until the notorious defection in 1785, it preserved for some years longer a resolute though tortuous existence, and was to the last defended and approved by our own Priestley and Cavendish, who died, the former in 1804 and the latter in 1810.

The importance attached to the refutation of this theory may be judged of from the circumstance that after the early experiments of Lavoisier on the composition and decomposition of water had been successfully repeated by a committee of the French Academy in 1790, a congratulatory meeting was held in Paris, at which Madame Lavoisier, attired as a priestess, burned on an altar Stahl's celebrated 'Fundamenta Chemiæ Dogmaticæ et Experimentalis,' solemn music playing a requiem the while. And the sort of estimation in which the Stahlian doctrines have since been held by chemists is fairly illustrated by a criticism of Sir J. Herschel, who, speaking of the phlogistic theory of chemistry, says that it "impeded the progress of the science, as far as a science of experiment can be impeded by a false theory, ... by involving the subject in a mist of visionary and hypothetical causes in place of the true acting principles." Possibly, however, this much-abused theory may yet prove to contain an element of permanent vitality and truth; anyhow the study of this earliest and most enduring of chemical theories can never be wholly devoid of interest to chemists.

To appreciate the merit of the phlogistic theory it is necessary to bear in mind the period of its announcement. Its originator, Beecher, was born in 1625, and died a middle-aged but worn-out man in 1682, a few years before the publication of the 'Principia.' His more fortunate disciple, Stahl, who was born in 1660 and died in 1734, in his seventy-fifth year, though afforded a possibility of knowing, seems equally with Beecher to have remained throughout his long career indifferent to the Newtonian principle that the weight of a body is proportionate to its quantity of matter,—that loss of weight implies of necessity abstraction of matter, and increase of weight addition of matter. Whether or not the founders of the phlogistic theory conceived that change of matter in the way of kind, might equally with its change in point of quantity, be associated with an alteration in weight—and it must not be forgotten what pains Newton thought it necessary to take in order to show the contrary—certain it is they attached very little importance to the changes of weight manifested by bodies undergoing the metamorphoses of combustion. It might be that when combustible charcoal was burned the weight of incombustible residue was less than the original weight of charcoal,—it might be that when combustible lead was burned the weight of incombustible residue was greater than the original weight of metal; this was far too trifling an unlikeness to stand in the way of the paramount likeness presented by the two bodies. For the lead and charcoal had the common property of manifesting the wonderful energy of fire; they could alike suffer a loss of light and heat—that is, of phlogiston—by the deprivation of which they were alike changed into greater or less weights of inert incombustible residue.

And not only were these primitive students of the philosophy of combustion unconscious of the fact and meaning of the relationship in weight subsisting between the consuming and the consumed body, but they were altogether ignorant of the part played by the air in the phenomena which they so boldly and successfully attempted to explain. Torricelli's invention of the barometer and Guericke's invention of the air-pump were both indeed made during Beecher's early boyhood; but years had to elapse before the consequent idea of the materiality of air could be domiciled, as it were, in human understandings. And not until more than a century after Torricelli's discovery of the weight of air, —not, indeed, until the time of the great pneumatic chemists Black and Cavendish, and Priestley and Scheele, was it ever imagined that the aerial state, like the solid or liquid state, was a state common to many distinct kinds of matter; and that the weight or substance of a rigid solid might be largely contributed to by the weight or substance of some constituent having its independent existence in the aerial or gaseous form. The notion that 100 lbs. of smithy-scales might consist of 73 lbs. of iron and 27 lbs. of a particular kind of air, and that 100 lbs. of marble might consist of 56 lbs. of lime and 44 lbs. of another kind of air, was a notion utterly foreign to the older philosophy. Air, it was allowed, might be rendered mephitic by one kind of contamination and sulphurous by another, and inflammable by a third; it might even be absorbed in, and so add to the weight of a porous solid, as water is absorbable by sand; but still air was ever indisputably air, essentially alike and unalterable in its mechanical and chemical oneness. This familiar conception had to be overcome, and the utterly strange notion of the largely aerial constitution of solid matter to be established in its stead, by the early pneumatic chemists, Black and Cavendish and Bergmann, before the deficiencies rather than positive errors of the phlogistic theory could be perceived.

But long ere the foundation of modern chemistry had thus been laid, in 1756, by Black's discovery of fixed air or carbonic acid as a constituent of mild alkalis and limestone, those old German doctors, Beecher and Stahl, though ignorant of the nature of air and neglectful of the import of gravity, had yet found something to say about the chemistry of combustion worthy of being defended a century afterwards by men like Priestley and Cavendish,—worthy, it is believed, of being recognized nearly two centuries afterwards as the expression of a fundamental doctrine in chemical and cosmical philosophy. They pointed out, for example, that the different and seemingly unlike processes of burning, smouldering, calcining, rusting, and decaying, by which combustible is changed into incombustible matter, have a community of character; that combustible bodies possess in common a power or energy capable of being elicited and used, whereas incombustible bodies are devoid of any such energy or power; and lastly, that the energy pertaining to combustible bodies is the same in all of them, and capable of being transferred from the combustible body which has it to an incombustible body which has it not, rendering the body that was energetic and combustible inert and incombustible, and the body that was inert and incombustible energetic and combustible,—and further rendering some particular body combustible over and over again. That this is a fair representation of the views held by phlogistic chemists is readily recognizable by a study of chemical works written before the outbreak of the antiphlogistic revolution. After Lavoisier's challenge, the advocates of phlogiston, striving to make it account for a novel order of facts with which it had little or nothing to do, were driven to the most incongruous of positions; for while Priestley wrote of inert nitrogen as phlogisticated air, Kirwan and others regarded inflammable hydrogen as being phlogiston itself in the isolated state. Very different is the view of phlogiston to be gathered from the writings of Dr. Watson, for example, who was appointed Professor of Chemistry at Cambridge in 1764, became Regius Professor of Divinity in 1771, and Bishop of Llandaff in 1782. This cultivated divine, indifferent it is true to the novel questions by which in less placid regions men's minds were so deeply stirred, amused the leisure of his dignified university life by writing scholarly accounts of the chemistry it had formerly been his province to teach; and in the first volume of his well-known 'Chemical Essays,' published in 1781, the following excellent account of phlogiston is to be found:—

"Notwithstanding all that perhaps can be said upon this subject, I am sensible the reader will still be ready to ask, *What is phlogiston?* You do not surely expect that chemistry should be able to present you with a handful of phlogiston, separated from an inflammable body; you may just as reasonably demand a handful of magnetism, gravity, or electricity to be extracted from a magnetic, weighty, or electric body. There are powers in nature which cannot otherwise become the objects of sense, than by the effects they produce; and of this kind is phlogiston. But the following experiments will tend to render this perplexed subject somewhat more clear.

"If you take a piece of *sulphur* and set it on fire, it will burn entirely away, without leaving any ashes or yielding any soot. During the burning of the sulphur, a copious vapour, powerfully affecting the organs of sight and smell, is dispersed. Means have been invented for collecting this vapour, and it is found to be a very strong acid. The acid thus procured from the burning of sulphur, is incapable of being either burned by itself, or of contributing towards the support of fire in other bodies: the sulphur, from which it was procured was capable of both: there is a remarkable difference, then, between the acid procured from the sulphur and the sulphur itself. The acid cannot be the only constituent part of sulphur; it is evident that *something* else must have entered into its composition, by which it was rendered capable of combustion. This something is, from its most remarkable property, that of rendering a body combustible, properly enough denominated the food of fire, the *inflammable principle, the phlogiston*. . . . . This inflammable principle, or phlogiston, is not one thing in animals, another in vegetables, another in minerals; it is absolutely the same in them all. . . . . This identity of phlogiston may be proved from a variety of decisive experiments; I will select a few, which may at the same time confirm what has been advanced concerning the constituent parts of sulphur.

"From the analysis or decomposition of sulphur effected by burning, we have concluded that the constituent parts of sulphur are two—an *acid* which may be collected, and an *inflammable principle* which is dispersed. If the reader has yet acquired any real taste for chemical truths, he will wish to see this analysis confirmed by synthesis; that is, in common language, he will wish to see sulphur actually made by combining its acid with an inflammable principle. It seldom happens that chemists can reproduce the original bodies, though they combine together all the principles into which they have analysed them; . . . . . in the instance, however, before us, the reproduction of the original substance will be found complete.

"As the inflammable principle cannot be obtained in a palpable form separate from all other bodies, the only method by which we can attempt to unite it with the acid of sulphur must be by presenting to that acid some substance in which it is contained. Charcoal is such a substance; and by distilling powdered charcoal and the acid of sulphur together, we can procure a true yellow sulphur, in nowise to be distinguished from common sulphur. This sulphur is formed from the union of the acid with the phlogiston of the charcoal; and the charcoal may by this means be so entirely robbed of its phlogiston, that it will be reduced to ashes, as if it had been burned. . . . .

"I will in this place, by way of further illustration of the term phlogiston, add a word or two concerning the necessity of its union with a metallic earth, in order to constitute a metal. Lead, it has been observed, when melted in a strong fire, burns away like rotten wood; all its properties as a metal are destroyed, and it is reduced to ashes. If you expose the ashes of lead to a strong fire, they will melt; but the melted substance will not be a *metal*, it will be a yellow or orange-coloured *glass*. If you pound the glass, and mix it with charcoal dust, or if you mix the ashes of the lead with charcoal dust, and expose either mixture to a melting heat, you will obtain, not a *glass*, but a *metal*, in weight, colour, consistency and every other property the same as lead. The ashes of lead melted *without* charcoal become *glass;* the ashes of lead melted *with* charcoal become a *metal*. The charcoal, then, must have communicated *something* to the ashes of lead, by which they are changed from a glass to a metal. Charcoal consists of but two things—of ashes and of phlogiston; the ashes of charcoal, though united with the ashes of lead, would only produce glass; it must therefore be the other constituent part of charcoal, or phlogiston, which is communicated to the ashes of lead, and by an union with which the ashes are restored to their metallic form. The ashes of lead can never be restored to their metallic form without their being united with *some* matter containing phlogiston, and they may be reduced to their metallic form by being united with *any* substance containing phlogiston in a proper state, whether that substance be derived from the animal, vegetable, or mineral kingdom; and thence we conclude not only that phlogiston is a necessary part of a metal, but that phlogiston has an identity belonging to it, from whatever substance in nature it be extracted. And this assertion still becomes more general, if we may believe that metallic ashes have been reduced to their metallic form, both by the solar rays and the electrical fire."

The foregoing account by Dr. Watson is almost a translation from Stahl's 'Zymotechnica Fundamentalis, simulque experimentum novum sulphur verum arte producendi,' in which he establishes what may be called the permanency of chemical substance,—that metallic lead is reproducible from the ashes of lead, *sulphur verum* from the acid of sulphur. And, whether or not taking note of the oxidations and deoxidations effected, how little differently, even at the present day, would the actions referred to be described and explained! Is it not our habit to say that charcoal and sulphur and lead are bodies possessing potential chemical energy, that is phlogiston; that in the act of burning, their energy which was potential becomes kinetic or dynamical, and is dissipated in the form of light and heat; that the products of their burning (including the gaseous product now known to be furnished by the burning of charcoal) are substances devoid of chemical energy, that is, of phlogiston; that when the acid substance furnished by burning sulphur is heated with charcoal, some energy of the unburnt charcoal is transferred to the burnt sulphur, just as some energy of a raised weight may be transferred to a fallen one, whereby the burnt sulphur is unburnt, provided with energy, and enabled to burn again, and the fallen weight is lifted up, provided with energy, and enabled to fall again; that the potential chemical energy of metallic lead did not originate in the lead, but is energy or phlogiston transferred thereto from the charcoal by which it was smelted; and, lastly, that the chemical energy of the charcoal itself, its capability of burning, its power of doing work,—in one word, its phlogiston is merely a portion of energy appropriated directly from the solar rays?

If this be a correct interpretation of the phlogistic doctrine, it is evident that the Stahlians, though ignorant of much that has since become known, were nevertheless cognizant of much that became afterwards forgotten. For most of what has since become known, mankind are indebted to the surpassing genius of Lavoisier; but the truth which he established, alike with that which he subverted, is now recognizable as a partial truth only; and the merit of his generalization is now perceived to consist in its addition to—its demerit to consist in its supersession of—the not less grand generalization established by his scarcely remembered predecessors. This being so, the relationship to one another of the Stahlian and Lavoisierian theories of combustion furnishes an apt illustration of the general truth set forth by a great modern writer, that "in the human mind one-sidedness has always been the rule, and many-sidedness the exception. Hence, even in revolutions of opinion, one part of the truth usually sets while another rises. Even progress, which ought to superadd, for the most part only substitutes one partial and incomplete truth for another; improvement consisting chiefly in this, that the new fragment of truth is more wanted, more adapted to the needs of the time, than that which it displaces."

The partial truth contributed by Lavoisier was indeed more wanted, more adapted to the needs of the time, than the partial truth which it displaced. To him chemists are indebted for their present conception of material *elements*; and especially for their knowledge of the part played by the air in the phenomena of combustion, whereby oxygenated *compounds* are produced. The phlogistians, indeed, were not unaware of the necessity of air to combustion, but, being ignorant of the nature of air, were necessarily ignorant of the function which it fulfilled. To burn and to throw off phlogiston being with them synonymous expressions, the air was conceived to act by somehow or other enabling the combustible to throw its phlogiston off; and a current of air was conceived to promote combustion by enabling the combustible to throw its phlogiston off more easily. Moreover, contact of air was not essential to combustion, provided there was present instead some substance, such as nitre, which equally with, or even more effectively than air, could enable the combustible to discharge itself of phlogiston. But while the phlogistians, on the one hand, were unaware that the burnt product differed from the original combustible otherwise than as ice differs from water, by loss of energy; Lavoisier, on the other hand, disregarded the notion of energy, and showed that the burnt product included not only the stuff of the combustible, but also the stuff of the oxygen it had absorbed in the burning. But, as well observed by Dr. Crum-Brown, we now know "that no compound contains the substances from which it was produced, but that it contains them *minus* something. We now know what this something is, and can give it the more appropriate name of potential energy; but there can be no doubt that this is what the chemists of the seventeenth century meant when they spoke of phlogiston."

Accordingly, the phlogistic and antiphlogistic views are in reality complementary, and not, as suggested by their names and usually maintained, antagonistic to one another. It has been said, for example, that, according to Stahl, the product of combustion is simple, and the combustible a compound of the product with imaginary phlogiston, which is false; whereas, according to Lavoisier, the combustible is simple, and the product a compound of the combustible with actual oxygen, which is true. But in this case, as in so many others, everything turns upon the use of the same word in a different sense at different periods of time. When Lavoisier spoke of red lead as being metallic lead combined with oxygen, he meant that the matter or stuff of the red lead consisted of the matter or stuff of lead *plus* the matter or stuff of oxygen. But when the Stahlians spoke of metallic lead being burnt lead combined with phlogiston, they had the same sort of idea of combination in this instance as others have expressed by saying that the weight of a body is compounded of its matter and its gravity; or that steam is a compound of water and heat; or, to use a yet more Lavoisierian expression, that oxygen gas itself is a compound of the basis of oxygen with caloric. It is not, then, that the one statement, Stahlian or Lavoisierian, is false and the other true, but that both of them are distorted, because incomplete. Chemists nowadays are both Stahlian and Lavoisierian in their notions; or have regard both to energy and matter. But Lavoisierian ideas still interfere very little with our use of the Stahlian language. While we acknowledge that in the act of burning the combustible and the oxygen take equal part, just as in the act of falling the weight and the earth take equal part, yet in our common language we alike disregard the abundant atmosphere and abundant earth as being necessarily understood, and speak only of the energy of the combustible and of the weight, which burn and fall respectively. Whatever may be the fault of language, however, chemists do not omit to superpose the Lavoisierian on the Stahlian notion. They recognize fully that it is by the union of the combustible with oxygen that phlogiston is dissipated in the form of heat; and further, that phlogiston can only be restored to the burnt combustible on condition of separating the combustible from the oxygen with which it has united; just as energy of position can only be restored to a fallen weight on condition of separating it to a distance from the surface on which it has fallen.

That Stahl and his followers regarded phlogiston as a material substance, if they did so regard it, should interfere no more with our recognition of the merit due to their doctrine, than the circumstance of Black and Lavoisier regarding caloric as a material substance, if they did so regard it, should interfere with our recognition of the merit due to the doctrine of latent heat. But though defining phlogiston as the principle or matter of fire, it is not at all clear that the phlogistians considered this matter of fire as constituting a real body or ponderable substance; but rather that they thought and spoke of it as many philosophers nowadays think and speak of the electric fluid and luminiferous ether. The nondescript character, properly ascribable to phlogiston, is indicated by the following quotation taken from Macquer's 'Elémens de Chymie Théorique,' 1749. It must not, of course, be forgotten that the popular impression as to phlogiston having been conceived by its advocates as a material substance having a negative weight or levity, is erroneous; and is based on an innovation that was introduced during the struggling decadence of the phlogistic theory, and advocated more particularly by Lavoisier's subsequent colleague, Guyton de Morveau, in his 'Dissertation sur le Phlogistique, considéré comme Corps grave, et par rapport aux changemens de pesanteur qu'il produit dans les corps auxquels il est uni,' 1762. Macquer writes as follows:—

"La matière du soleil, ou de la lumière, le phlogistique, le feu, le soufre principe, la matière inflammable, sont tous les noms par lesquels on a coutume de désigner l'élément du Feu. Mais il paroît qu'on n'a pas fait une distinction assez exacte . . . . du nom qu'il mérite véritablement lorsqu'il entre effectivement comme principe dans la composition d'un corps, ou bien lorsqu'il est seul et dans son état naturel. Si on l'envisage sous cette dernière vue, le nom de Feu, de matière du soleil, de la lumière et de la chaleur, lui convient particulièrement. Pour lors, c'est une substance que l'on peut considérer comme composée de particules infiniment petites, qui sont agitées par un mouvement très-rapide et continuel, par conséquent essentiellement fluide. Cette substance, dont le soleil est comme le réservoir général, s'en émane perpétuellement, et est répandue universellement dans tous les corps que nous connoissons; mais non pas comme principe ou essentielle à leur mixtion, puisqu'on peut les en priver, du moins en grande partie, sans qu'ils souffrent pour cela la moindre décomposition. . . . Cependant les phénomènes que présentent les matières inflammables lorsqu'elles brûlent, nous indiquent qu'elles contiennent réellement la matière du Feu comme un de leurs principes. . . . Examinons donc les propriétés de ce feu fixé, et devenu principe des corps. C'est lui auquel nous donnerons particulièrement le nom de matière inflammable, du soufre principe, ou de Phlogistique, pour le distinguer du Feu pur."

Again, much the same thing is to be found in Baumé's 'Manuel de Chymie,' 1765: as for example:—

"Nous considérons le feu sous deux états différens. Lorsqu'il est pur, isolé, et qu'il ne fait partie d'aucun composé . . . . Lorsqu'il est combiné avec d'autres substances, et qu'il fait un des principes constituans des corps composés . . . . On n'est pas certain si le feu est pesant. Il y a des expériences pour et contre. . . .

"Pendant la combustion des substances, le feu combiné se réduit en feu élémentaire, et se dissipe à mesure. Le célèbre Boerhaave n'est cependant pas de ce sentiment; il dit que si cela étoit, la quantité de feu élémentaire devroit augmenter à l'infini dans la nature. . . . Mais il est facile de répondre à cette objection, en disant comme on est en droit de le présumer, que le feu élémentaire, dégagé des corps, se combine à mesure avec d'autres substances, et qu'il perd toutes ses propriétés de feu libre, en devenant principe constituant des corps, dans la composition desquels il entre. . . . Le principe dont nous entendons parler ici, est celui que Stahl a nommé *phlogistique*."

In interpreting the above and other phlogistic writings by the light of modern doctrine, it is not meant to attribute to their several authors the precise notion of energy that now prevails. It is contended only that the phlogistians had, in their time, possession of a real truth in nature which, altogether lost sight of in the intermediate period, has since crystallized out in a definite form. "I trust," said Beecher, "that I have got hold of my pitcher by the right handle." And what he and his followers got hold of and retained so tenaciously, though it may be shiftingly and ignorantly, we now hold to knowingly, definitely and quantitatively, as part and parcel of the grandest generalization in science that has ever yet been established.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of Executive Committee at 17, Bloomsbury Square.

May 16*th*, 1871.

Present—Messrs. Williams (in the chair), Brady, Carteighe, Groves, Mackay, Martindale, Matthews, Schacht, Attfield and Reynolds (Secretaries), and Collins (Assistant-Secretary).

'*Year Book of Pharmacy for* 1871.'—Arrangements were made for printing and publishing the second annual volume in the autumn of the present year.

Distribution of the 'Year Book.'—After due deliberation, and the consideration of opinions expressed by several local secretaries, the Committee resolved to distribute the next 'Year Book' by post only. The Secretaries were instructed, in collecting the annual subscription of five shillings, to ask for an additional sixpence to cover cost of delivery of the volume, and to request all members to accept this rule in order to avoid the expense of salaries to clerks and messengers. The Committee considered that by thus devoting nearly the whole of the funds to the production of the 'Year Book,' a complete, efficient and inexpensive manual would be obtained, which would always be found to be indispensable as a desk companion for the year, and an invaluable permanent work of reference for every chemist and druggist.

Presentation Copies of the 'Year Book.'—The Secretaries reported that sixteen books had been sent to the leading libraries and journals of pharmacy in Europe and America. Resolved, that a copy be forwarded to every English provincial Pharmaceutical Association possessing a library.

The "Bell and Hills" Fund.—The Secretaries stated that ten guineas' worth of books had been presented to the library of the Chemists' Association at Liverpool, and had been duly acknowledged.

New Members.—In view of the continuous annual publication of the 'Year Book,' the Secretaries were ordered to issue a circular, requesting every member to obtain one or more new members, and otherwise to endeavour to increase the numerical strength of the Conference.

Candidates for Membership.—The following were elected members of the Conference:—

Anderson, J., Edinburgh; Babtie, J., Dumbarton; Baker, A. P., London; Baker, F. B., London; Barratt, J., London; Berry, W., Bristol; Birch, H. C., London; Brearey, W. A., Isle of Man; Brodie, R., Glasgow; Buchanan, D., Greenock; Buchanan, Dr. J. D., Glasgow; Button, J., Rangoon; Clarke, A. H., London; Colclough, W., London; Collett, C. B., Exeter; Cowan, Professor, Glasgow.; Cuff, R. C., Bristol; Dunn, J., Selkirk; Evans, D. O., Halstead; Evans, W., Liverpool; Fairgrieve, T., Edinburgh; Fowler, W. R., Spilsby; Fraser, J., Inverness; Gilmour, W., Edinburgh; Griffith, R., Slough; Hammond, C. T., Hull; Hart, J., Manchester; Hart, W., Bolton; Hartley, W., St. Andrews; Henderson, W. P., Dundee; Hewitt, G., Kidderminster; Hodgkinson, W., London; Hothersall, J., Bolton; Hughes, J. T., Altrincham; Hurst, J. B., Louth; Jackson, A. H., Manchester; Jackson, J. P., London; Johnson, A., Rotherham; Jones, M., Flint; Laird, G. H., Edinburgh; Leigh, J. J., Bishop Auckland; Longley, G., Stockport; Mackenzie, —, Glasgow; Mackenzie, J., Edinburgh; Mackey, —, London; Mackill, R. C., Hamilton; Macpherson, A., Stornoway; Maitland, J. E., London; Maxwell, G. N., Northampton; Mitchin, F., London; Moffatt, Dr. R. C., Glasgow; Napier, A., Edinburgh; New, T. C., Manchester; Niven, W., Edinburgh; Paine, C., Wrexham; Palmer, A. N., Bury St. Edmunds; Parkin, C., Doncaster; Pasmore, G., Portsmouth; Peake, H. F., Twickenham; Peters, J., London; Pond, B. C., London; Porrett, G. W., Scarborough; Pote, S. R., Exeter; Prince, A. G., Longton; Procter, Dr. W., York; Sang, E., Edinburgh; Selkirk, J., Edinburgh; Slater, W. H., Romsey; Smith, A., Edinburgh; Stewart, J., Hamilton; Swift, F., Spalding; Symons, W., Barnstaple; Taylor, C., Liverpool; Taylor, W., Heywood; Taylor, W. G., Nuneaton; Vennall, G., Cranleigh; Warrior, H., Northallerton; Williams, R., Manchester; Woodburn, Dr. J. C., Glasgow; Woolley, G., Nottingham; Wynne, E. P., Stratford-on-Avon; Young, P., Dundee.

CHEMICAL SOCIETY.

May 18*th.*—Professor Frankland, F.R.S., President, in the chair. Messrs. T. Greenish and J. E. Mayall were elected Fellows. The following papers were read:— "On a New Double Salt of Thallium," by R. J. Friswell. The author, wishing to prepare platinocyanide, mixed hot solutions of thallic carbonate and potassic platinocyanide, and obtained, on leaving the mixture to cool, masses of splendid crystals, which appeared by transmitted light of a magnificent crimson-red, whilst their reflected colour was a bronzy green of strong metallic lustre. Analysis showed that they are a compound of thallic carbonate with thallic platinocyanide $Tl_2PtCy_4, COTlo_2$. On treating this salt with acids, carbonic acid is set free, and a pale pink residue left, which, on examination, was found to be thallic platinocyanide. The next paper read was "On the Action of Nitric Acid on Dichlorophenolsulphuric Acid," by Dr. Armstrong.

MEETINGS FOR THE ENSUING WEEK.

WEDNESDAY ...*London Institution*, at 2 P.M.—Distribution June 7. of Prizes and Certificates by the President, Thomas Baring, Esq., M.P.

FRIDAY ....*Quekett Club*, at 8 P.M.

June 9. *Royal Botanic Society*, at 4 P.M.—"Economic Botany." By Professor Bentley.

SATURDAY ......*Royal Botanic Society*, at 3.45 P.M.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

APPOINTMENT.

Mr. Edwin Foy has been appointed Dispenser at her Majesty's Prison at Dartmouth.

Parliamentary and Law Proceedings.

POISONING BY PRUSSIC ACID.

On Tuesday, an inquiry was held at St. George's Hospital respecting the death of Mr. Russell Goldie, the secretary and superintendent of the institution. It appeared from the evidence adduced that the deceased had been in the habit of taking prussic acid to allay a certain pain from which he was suffering. On Sunday morning he went up to his room in the hospital. He said he was unwell, and complained of a pain in the side. After drinking a cup of tea, he lay down on the couch and said he did not wish to be disturbed. About two o'clock in the afternoon the assistant secretary found him lying on the couch quite cold and dead. On the table was a bottle which had contained prussic acid and camphor. Mr. John F. Boyes, Gloucester Crescent, Regent's Park, said he had known deceased for many years. When he had been with him he had often thought his breath smelt of prussic acid or laudanum. Witness had charged him, as a friend, with taking prussic acid, and deceased on one occasion said, "My dear friend, if you suffered the pain I do, you would be glad enough to take anything to allay it." Mr. Thomas Jones, resident medical officer of the hospital, said he saw the deceased alive on Saturday. He then appeared very nervous and excited, and said to witness the cause of his condition was through certain annoyance and the hospital work. He died from the effects of prussic acid. The coroner having summed up, the jury returned a verdict that the deceased was accidentally poisoned by taking an overdose of prussic acid.

The following journals have been received:—The 'British Medical Journal,' May 27; the 'Medical Times and Gazette,' May 27; the 'Lancet,' May 27; the 'Medical Press and Circular,' May 31; 'Nature,' May 27; the 'Chemical News,' May 26; 'Gardeners' Chronicle,' May 27; 'Journal of the Society of Arts,' May 27; the 'Grocer,' May 27; 'Produce Markets Review,' May 27; the 'English Mechanic,' May 27; 'Journal of the Chemical Society' for May; the 'Canadian Pharmaceutical Journal' for May; the 'Chicago Pharmacist' for May; the 'Leavenworth Medical Herald and Journal of Pharmacy' for May; the 'British Journal of Dental Science' for June.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

BORAX AND BLACKBEETLES.—We have received a considerable amount of correspondence upon the question whether the use of borax as a beetle-powder is followed by the extirpation of those household pests. Most of our correspondents deny its efficacy. Professor Tomlinson, to whose letter, under the signature of "*T.*," we in a recent number appended a note pointing out that there was diversity of opinion upon the subject, informs us that he tried the recommendation of *H. C. B.*, and sprinkled powdered borax in the haunts of the beetles, but without success. He therefore resolved to decide the matter by experiment upon a captured blackbeetle, particulars of which he has kindly forwarded to us. The conclusions at which he arrived were—"(1) that powdered borax is not a poison to the blackbeetle; (2) that it does not act by any supposed odour on the beetle,—the beetle, on the contrary, gives a powerful odour to the borax and to his prison-house; (3) the pounded borax does seem to annoy the beetle by its mechanical action, clinging to his limbs and making him uncomfortable; (4) the beetle is under no permanent delusions as to the powdered borax—he tasted it and did not like it, he got it about his person and cleaned it off, and avoided it as far as his narrow prison would allow. In conclusion, I must express my opinion that powdered borax is quite useless in getting rid of blackbeetles."

Another correspondent ("*Obrera*"), who has experimented with borax and found it inefficacious, has also tried red lead, flour and sugar without result, in consequence, he thinks, of the beetles declining to eat the mixture. He says that a mixture of strong ammonia with two or three times its bulk of hot water has a very quick effect. He has known a large beetle to be killed by receiving two or three drops of it on the head. He suggests that the solution should be injected late at night through the crannies which the beetles are known to traverse. He has not found liquid carbolic acid to have much effect upon them; but the carbolic acid powder seems to clog their feet, and permit the vapour to reach their brain organism before they can escape from it.

On the other hand, "*A Country Chemist*" writes:—"A grocer in this city about two years since, having great numbers of these pests about his premises, tried various articles which we were then selling as 'beetle poisons,' but with little beneficial result. Upon the recommendation of a wholesale biscuit manufacturer, who assured him that powdered borax kept their place quite clear of these vermin, he purchased an ounce of me, which he found to be a certain cure. We, therefore, tried it on our own premises, and, finding it to answer, have ever since sold it as 'beetle powder' without a single complaint against its efficacy."

"*Give and Take*," whose query has brought forth such differences of opinion, suggests that the question of the best way to exterminate these and similar household pests is worthy of more attention than it has hitherto received, especially from those who are students in the science of entomology. Our correspondent seems to complain that, by the use of the word "borax" instead of "sodæ biboras," in our 'Notes and Queries' column, we have enabled other journals to publish what, if it had been what it professed to be, ought to have been regarded somewhat in the light of a trade secret. Even if we were prepared to endorse such an opinion,—which would be equivalent to supposing that none but chemists know that the terms are synonymous,—we could not plead guilty to the charge, as the paragraph which has been going the round of the papers was taken from an American source, and generally acknowledged as such.

[231.]—BEETLE POWDER.—I have found that common red wafers, such as are used for letters, placed in the haunts of beetles, are very useful in getting rid of these troublesome pests. I have also successfully used a mixture of plaster of Paris and oatmeal, equal parts, and about one-fourth of sugar.—J. N. M.

Correspondence.

The Benevolent Fund.

Sir,—I was much surprised to see that a suggestion had been made at the annual meeting that "it would be advantageous to add a separate column to the Calendar, showing the subscription, or lack of subscription, of each of the members" to the Benevolent Fund. It is a fertile idea, and might be worked by promoters of local charities and sectarian leaders until all spontaneity were eliminated from our charity and our giving became a mere matter of coercion. Surely the asterisks of the Calendar are all that—if not somewhat more than—could be desired. To me it is questionable what moral right any person has to advertise my not subscribing to any particular charity. Whence the authority of the censors?

To the utmost I would support the proposition that it is the duty of every man to devote a liberal portion of his income to charitable purposes; but I would equally oppose the interference of any one in the manner of its allocation. No man should be branded for electing to be the almoner of his own bounty.

Charity is such an evident outflow of Christianity that it is difficult to discuss any branch of it without recalling the admonition of its Founder that "alms should be in secret." In this spirit the suggestion might, perhaps, be tolerated that, while it is highly desirable that subscribers should increase their subscriptions, and that every member should become a subscriber, it is not advisable that any names should be published.

Is there so little of principle and so much of policy in our giving that a half-crown subscription must be published all over the country? In modern times we have so improved upon the ancient sect that we "sound the trumpet" of our promises before us and advertise our subscriptions afterwards. We no longer "do good by stealth," nor "blush to find it fame." Henricus.

May 22nd, 1871.

Poison Regulations.

Sir,—When the Council agreed to submit the poison regulations as a code for voluntary adoption, a "tacit understanding" arose that they would not be submitted to the vote of the meeting as a compulsory code. I need not say more, for those who have read your last number know all the rest.

Barnard S. Proctor.

Sir,—I was apprenticed in the country, the business a mixed wholesale and retail. I have lived in situations both in country and town I have been in my present house thirty years, and have been connected with the Pharmaceutical Society from the year of its formation, but cannot recollect a single case of poisoning that would not have been prevented by the most simple precaution.

Education will give knowledge of drugs and doses, but will not prevent absence of mind. It is reported of one of our greatest men that, instead of applying his lady's hand to his lips, he once used the little finger of it as a tobacco-stopper. The best, because the most simple, precaution that I have read of, is a band of colour, equally applicable to the most carefully conducted dispensing establishment or the most carelessly kept country warehouse; in the one case by a solution of sealing-wax in spirit round the neck and under the lip of the bottle, and in the other by a paint brush round the top of the arsenic cask. We should not again hear of arsenic being substituted for gypsum in lozenges, or strychnia for salicin in powders. I voted yesterday for the "recommendations" of the Council being made "regulations," but I fear if they become law this plan becomes illegal, as the bottles, etc., are neither tied over, capped or locked, rendered distinguishable by touch or necessarily kept apart. I should regret this, and therefore make my remonstrance while it is still open to the Council to consider it.

J. M. Hucklebridge.

116, *Ebury Street, Eaton Square, S.W.*,
May 18th, 1871.

The Register of Chemists and Druggists.

Sir,—As Mr. Wiggin, who addresses a question to me in this week's Journal, was present at the meeting when I made the statement the accuracy of which he doubts, I regret he did not save his own as well as my time by putting the query then; had he done so, I should have felt great pleasure, with the kind permission of our "active Registrar," in giving him ocular demonstration that I had not made an assertion I was unable to substantiate. If Mr. Wiggin will, on his next visit to Bloomsbury Square, ask our mutual friend the "active Registrar" for a view of returned circulars, his incredulity will, I think, at once be put to flight.

As Mr. Wiggin is evidently anxious that, so far as Ipswich at least is concerned, all matters should be found correct, I venture to draw his attention to one oversight on his part, which doubtless he will take an early opportunity of rectifying. I refer to the utmost entire absence of Ipswich from the list of contributors to the Benevolent Fund. Should the Council think well to adopt my suggestion of publishing the subscriptions against each name in the Calendar, I regret to say Mr. Wiggin and his charge would be found wanting.

As Mr. W. may be anxious to know my authority for stating this fact, I refer him to the Calendar of the Pharmaceutical Society for 1871, and to the Pharmaceutical Journal of the 13th instant. Edwin B. Vizer.

63, *Lupus Street, Belgravia South*,
May 27th, 1871.

The late Election of Council.

Sir,—Will you permit me, through your columns, very sincerely to thank the 719 members who recorded their votes in my favour at the Annual Meeting on the 17th inst. The result is highly satisfactory to me, being only three votes below Mr. Sandford, the late President. I should have been exceedingly sorry to have displaced that gentleman, and thereby deprive the Society of his valuable services. I trust, however, at some future time, to have a seat on the Council, when I shall have more time and leisure to attend to its important duties.

In the meantime, let me urge on the great body of chemists to secure at least the return of two or three of their number to represent them on the Council.

John Owen.

234, *Upper Street, Islington, London, N.*

Pharmaceutical Examinations.

Sir,—Your correspondent, Mr. P. H. Mason, asks some one to inform him what advantage is gained by passing the Major Examination besides the honour of the thing? I will attempt to answer him. In the first place, Mr. M. allows that the title Fellow would be compensation enough, thus proving that it is no direct monetary advantage that he alludes to. With this premise, by stating my own case, I think I shall effect my proof. Having lately passed the Examination alluded to with honours, although in studying for it I have only learnt enough to teach me my ignorance of the great field of knowledge beyond, yet I have gained the title of Pharmaceutical Chemist, with a diploma stating to the public that it was obtained by examination, which title will yearly be of more value, as those who have obtained it otherwise are passing away. Also, I obtained the privilege of becoming a member of the Society, giving me the power of voting at the General Meeting, etc., which privilege I have recently availed myself of; and, thirdly, when I set up in business, I expect to prosper beyond what I should have done with only my Minor qualification. Believing, Sir, that these inducements are quite sufficient to urge young men to push on to the Major, I see no need for the title of Fellow, which would but add another to the long list that already confuses the public mind. If we who have lately passed it do not obtain from the public all the respect we would have them give to it, yet the day is coming when the young pharmacist will enjoy a very superior position to the chemist and druggist.

M. P. S.

Sir,—I fully agree with "B. S." that the man who has passed the Modified Examination should be eligible for the Minor. I myself, knowing I must pass the Modified before January, 1870, or be shut out from the Society altogether, hastened to do so, fully intending, at a future time, to present myself for the Minor, and lastly the Major; but finding by the bye-laws I am debarred this opportunity, I, with many others, shall remain a Modified man, unless the Council shall alter the bye-laws, and allow the man who has passed the Modified to present himself for the Minor Examination. Should they do so, it would not only greatly increase the number of Pharmaceutical Chemists and interests of the Society, but meet the requirements of the many and not the few of the Modified men.

FORWARD.

THE DRUGS SUPPLIED BY SURGEONS.

Sir,—In reading the account of the inquest on the body of the child Bruce Logan, at Steeple Claydon, Bucks, I was surprised at the following part of the evidence:—

It was stated that a day or two before the murder the accused woman Muir obtained some "laudanum" at a surgeon's, which was served in his absence by his "wife," and was not labelled "poison." Afterwards, however, that lady called and stated that as the laudanum was stronger than was usually sold by druggists her husband wished to have it labelled.

Now, although surgeons are not subject to the same pains and penalties that we druggists are for selling poisons without a label, I think it hardly fair for them to cover their assistants' carelessness by a reflection upon the strength of our drugs. That this statement was, on the part of the surgeon, a palpable misrepresentation seems evident; and I certainly do not think that the experience of druggists will tend to establish the fact that the drugs used by surgeons are of superior quality to our own. For my own part, I have seen too frequently to the contrary. In bringing this matter before the notice of your correspondents, I am anxious to know their views upon the subject.

May 20th, 1871. A LOVER OF TRUTH.

THE EARLY CLOSING QUESTION.

Sir,—You were kind enough to find space in your valuable Journal for a letter written by me some months ago proposing the establishment in Brighton of a school of pharmacy. I am sorry to say that out of the many chemists we have here, not one would second my proposal. So much for their public spirit. My present purpose, however, is to request you to be kind enough to grant me space for a few remarks on 'early closing.' I quite sympathize with my brother assistants as to the long hours we day by day endure. Why cannot the servants who receive their orders from their mistresses early in the morning deliver them to the chemist within reasonable hours? Instead of this they lay prescription and bottle on the dresser-shelf, and there they let them remain until they go out dressed, at seven or eight o'clock (and even later) in the evening. Thus their pleasure becomes our pain. They leave their orders at this late hour and coolly request that they may be made up and sent home immediately. It may be that it is Missis' night draught and she can't go to bed without it, and so on; such messages are quite an every-day affair here. Sometimes I employ a little gentle remonstrance, but am frequently told (in anything but polite terms), "Do you think I was going to come up with it on purpose, when Missis doesn't want it till she goes to bed?"

Some evenings I have counted from fifteen to twenty prescriptions delivered by servants after eight o'clock to be dispensed that same night, nearly all of which might have been brought in earlier in the day. During my experience in Brighton I cannot remember one instance where a lady has brought a prescription after dusk, unless it be a newly-written one. But as long as servants know our shops are kept open till ten or eleven o'clock at night for general retail, we shall be martyrs to long hours. The proprietors do not suffer, only the assistants. The proprietors have no more examinations to pass, nor do they wish to. They are already registered and in business. The assistant, on the other hand, before he can call himself a chemist and druggist and go into business, must pass an examination. How can he study? What time has he? He is mixing up scammony and jalap from 7.30 A.M. till 10.30 P.M. Can he be expected to study Attfield's 'Chemistry,' Bentley's 'Botany' and his Latin 'Delectus' after these late hours?

After all, Sir, I think you will agree with me that there is a great deal of human nature in the chemist's assistant, and that he ought not to be expected to do so very much above and beyond other men. Let our hours be from eight to eight, and then we shall be able to find time for two hours' study, night and morning. No one, of course, will ever grumble to dispense a prescription for any emergency or accident after the prescribed hours. When the public know the time for closing, they will purchase their ounce of salts or pennyworth of hair-oil before eight, as they now do before ten o'clock.

A. H. A., JUN.

Cliftonville, Brighton, May 16th, 1871.

DRUGGISTS' PRICES.

Sir,—The "prices" question is ever again and again cropping up in the Journal; but agitate as we will, the end at which we aim will be delayed indefinitely so long as we have members of the trade meeting in committee and drawing up "price lists," in which the prices of ℥i, ℥iss and ℥ij mixtures are appraised at 4*d.* 6*d.* and 8*d.* respectively. These prices actually appear in a list drawn up by our friends north of the Tweed, in which, by the way, though there is some flourish about "your committee," etc., everything that might indicate its origin is suppressed,—printer's name and address included.

Fourpence for eight doses of medicine! How much is left for the "skilled labour," after deducting 2½*d.* for bottle, cork, labels, paper, etc. On whatever sum can one "live and keep up appearances" in the "land of cakes"?

Bradford, May 20th, 1871. R. G. H.

Sir,—There has been a great deal said lately in the PHARMACEUTICAL JOURNAL about various prices in different towns. A week or two since, when visiting Bristol, I found there was a chemist in that town advertising articles at such very low prices, that I should have almost thought incredible had I not read it myself; for instance, carbonate of soda 4*d.* per lb., citrate of magnesia 1*s.* 6*d.* per lb., seidlitz powders 9*d.* per doz., and boasts in his advertisement of selling articles in the trade cheaper than any other man. I hear, too, that he dispenses prescriptions and charges only as much as the articles come to, and sells 13½*d.* patent medicines at 10½*d.* each. I think, with the difficult examinations that have to be passed, there might be more uniformity in prices, without such foolhardy competition. T. H.

J. N. M.—The examination is a written one, and may be conducted by a local secretary, if notice be given to the Registrar.

A. Z.—The method proposed by Dr. Attfield in the article referred to, for obtaining a solution of quinine in cod-liver oil, was to produce an oleate of quinine by digesting the alkaloid, well dried, with twice its weight of oleic acid at the temperature of boiling water for an hour or two. Oleate of quinine has the consistence of a soft resin, is perfectly stable, and may be regarded as a concentrated solution of quinine, to be diluted whenever necessary, and to any required extent. The paper is too long to be extracted entire, but copies of the number containing it may be had on application to the publishers.

C. G. Bunn.—(1.) Yes. (2.) The Latin examination includes the translation into English of a paragraph from the first book of Cæsar, *or* a passage from each of the following works:—Pereira, 'Selecta e Præscriptis,' and the last edition (Latin) of the *London* Pharmacopœia.

Arum.—(1.) The different directions as to the pronunciation of the words mentioned result from the different rules of orthoepy followed by the lexicographers. We cannot undertake to decide which is right. (2.) We should recommend you to follow Professor Bentley's arrangement.

Guaco.—We do not know the substance inquired about, but believe the name to be that given to one of the alleged remedies which are supplied by benevolent advertisers in return for a certain number of stamps.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. F. Liley, Mr. M. C. Cooke, Mr. J. R. Jackson, Mr. D. Hanbury, X. Y. Z., J. A. M., F. P. C., A. P. S., "Cyathus," "Unguentum," "Bo-Peep."

BEEF EXTRACT IN COMBINATION.

BY PROFESSOR EDWARD PARRISH.

The greatly increased reliance by practitioners of medicine on the use of proper nutriment, not only as an aid to convalescence, but also to sustain the forces of life in the incipient stages, and, indeed, throughout the course of some very prevalent diseases, has called for a variety of beef extracts for the ready preparation of essence of beef and beef-tea. The large sale of these attests the value placed on them, not only by physicians but by the public at large, and yet the idea of making articles of diet from something bought at the drug store, and having some of the characters of a medicine, is so repulsive to the keen sensibilities of many invalids, that often resort is had to the tedious extemporaneous methods of extracting the juice directly from fresh beef.

Moreover, it is often observed that, however nicely made, essence of beef and beef-tea soon lose their relish when given constantly, under medical advice, or as a part of the treatment—a distaste which is sometimes due to the disease, but perhaps oftener to the fact, that variety constitutes one of the chief attractions in matters dietetic.

In giving medicines, the importance of consulting the taste of the patient is less recognized; they are taken as a disagreeable necessity, and are not expected to possess the attractions which usually pertain to articles of diet.

These considerations seem to favour the idea of combining beef extract into pharmaceutical preparations, and thus giving it at stated intervals, *nolens volens*.

The composition of such preparations being unknown to the patient, and the taste being disguised by admixture with suitable adjuvants, that feeling of disgust created by the idea of animal food in an undefined state, intermediate between medicine and diet, is avoided.

Of the several proprietary beef compounds recently introduced I have little knowledge, and have no doubt that they are useful. The object of this paper is not to supersede these, but to point out a method of varying the composition of nutritive medicinal compounds, and to put it within the reach of all to meet the requirements of the medical practitioner, by furnishing any of these extemporaneously, as required.

Beef stock, as sold in tin cans, soldered, has been cheap since the war, and by solution in glycerine, diluted with water, may be brought to a tolerably permanent fluid, miscible with pharmaceutical preparations. The proportion may be six parts of beef stock to three or four of water, and one of glycerine. In time this becomes gelatinous, probably by the glycerine combining with gelatine, always present in the stock.

Experiments tried by exposing this fluid to a temperature and other circumstances favourable to putrefaction, indicate that in midsummer it would be necessary to keep it in a cool place, yet probably no further difficulty would be experienced with this than with many other preparations which during the intense heat of our summers require special precautions to prevent decomposition.

In the absence of beef stock, resort may be had to either of the solid extracts of beef. I have dissolved Tourtellot's extract in eight parts of water, and added half a part of glycerine, but the solution, like the foregoing, is very inelegant. A good addition to either of these is caramel, which improves the colour and gives a flavour of bitterness.

Gelatine is the ingredient which interferes with the eligible appearance and physical properties of these solutions, and hence to remove this without materially impairing their nutritive qualities is a desideratum. Solutions of tannin added in small portions, after largely diluting with water, causes a white flocculent to separate, which may be removed on a filter or Canton flannel strainer, and then, on evaporation to about the consistence of syrup, we have what may be termed a clarified solution of beef extract, preserved by glycerine. The tannin should be added with care, not to have an excess, and the filtration should be resorted to before the solution is inspissated, and yet after heat has been applied.*

The beef basis being at hand, it is easy to make suitable extemporaneous mixtures with iron, quinine, the phosphates, and other tonics, dissolved either in very dilute alcoholic, or in saccharine menstrua. Some judgment is required in the selection of these. As a rule, sweet syrups are best adapted to children; molasses is used in one of the popular proprietary nutritive tonics; but, on the other hand, great care is required not to cloy the stomach of an adult with sweets constantly administered.

Fluid extract of liquorice is one of the best excipients for disguising the meat flavour; that made from the root by the use of diluted alcohol gives a strong liquorice flavour and taste without much body. Diluted phosphoric acid, or the compound syrup of phosphates, is a good addition. Strong alcoholic liquids would be incompatible with it, but wines mix well, increasing fluidity and producing but slight precipitation. Wine of iron or bitter wine of iron may be advantageously added in the proportion of one part of the wine to three of the extractum carnis fluidum.—*American Journal of Pharmacy.*

BRISTOL PHARMACOLOGY.

BY W. W. STODDART, F.C.S., F.G.S.

(*Continued from page* 922.)

Nat. Ord. URTICACEÆ.

This, though not a very extensive Order, yet is one containing plants of great utility, some supplying edible fruits, some valuable textile fibres and others caoutchouc. From others, also, is procured the terrible upas poison, the intoxicating churrus, the fig and the mulberry.

Humulus Lupulus (Linn.).

This well-known climber is often seen on the hedges near Stapleton, Flax Bourton, Crew's Hole, Saltford and Bishopsworth. Near the last locality it has been seen growing with the *Cuscuta Europæa.*

The Hop plant was introduced into England from Flanders in the reign of Henry VIII.:—

> "Hops, reformation, bays and beer,
> Came into England all in one year."

Some naturalists have hesitated to consider the Hop

* Liebig's beef extract is free from the objection arising from the presence of gelatine, and, as it is desirable to dispense with the tannin treatment, and to be able to prepare an eligible fluid by an easy and quick process, resort may be had to this elegant though costly product.

as other than naturalized, but Babington says it is truly a native. It is the female plant that is so much employed as a brewing ingredient, the strobiles being the part used. These are composed of scales, each of which has at its base two minute seeds. On the scales and seeds are found yellow, granular, resinous glands, which, as the strobile ripens, become loose and drop off. These minute bodies are used in pharmacy under the name of lupulin, and in them resides the flavour so highly prized. The strobiles yield from 8 to 18 per cent. of these lupulinic grains. They are most interesting microscopic objects; from $\frac{1}{200}$ to $\frac{1}{140}$ of an inch in diameter, and are shaped like flattened, subovate little saucers, and covered over with cell markings. They are attached by a short pedicel. As they get older, the central portion expands, and instead of the former concave shape, swell out and become convex.

According to the analyses of MM. Pelletier and Payen, the so-called lupulin consists of volatile oil, 2 per cent.; bitter extract, 10 per cent.; resin, 50 per cent.; and tannic acid, 5 per cent.,—the remainder being gum, calcium and potassium malates, etc. When distilled with water, about 1 per cent. of valerianic acid ($C_5H_{10}O_2$) passes over, with an oil consisting of a hydrocarbon ($C_{10}H_{16}$) and valerol ($C_6H_{10}O$). The latter, by keeping, becomes converted into valerianic acid. Hence the peculiar cheesy flavour of old hops.

$$\underset{\text{Valerol.}}{C_6H_{10}O} + H_2O = \underset{\text{Valerianic acid.}}{C_5H_{10}O_2} + 2\,H.$$

One hundredweight of hops will yield about forty pounds of extract as ordered by the Pharmacopœia.

Nat. Ord. Ulmaceæ.

The plants forming this Order differ from the last by never having the flowers in the form of catkins, but in clusters of flat, membranous, leaf-like expansions, with a notch at the top, and one seed fixed in the centre.

Ulmus campestris (Linn.).

This noble tree occurs very generally throughout the neighbourhood. Fine examples may be examined in the grove leading to Redland Court, and in some of the city squares. The finest specimens are found where the soil is rich, friable and sandy.

Elm bark is a tonic and astringent, and is much prized in Norway for tanning leather used for glove-making. Ulmin, so familiar to the agricultural student as one of the constituents of mould, peat, etc., derives its name from the substance found in the black excrescences so often observed on the trunks of old elms.

Elm bark contains about 20 per cent. of a kind of mucilaginous substance, 3 of tannin, 6 of resin and 10 of inorganic salts.

Nat. Ord. Amentaceæ.

This valuable Order of trees is distinguished by the flowers being arranged in catkins (amenta). Only one is mentioned in the Pharmacopœia.

Quercus pedunculata (Willd.).

Perhaps no natural object has been so frequently mentioned by writers of every age and clime as the Oak. It is frequently mentioned in the Bible, although probably in many passages the evergreen oak (*Q. Ilex*) is the species meant. It was held sacred by the Greeks, Romans, Gauls and Britons. Horace speaks of

> "Quercus et ilex
> Multa fruge pecus, multâ dominum juvet umbrâ."

and in many of his beautiful descriptions of rural scenes alludes to the groves of oak-trees:—

> "Querceta Gargani laborant."

In his 'Bucolics,' 'Georgics' and 'Æneid,' Virgil over and over again mentions the monarch of the forest as one of the principal objects of a sylvan landscape:—

> "The monarch oak, the patriarch of the trees,
> Shoots rising up, and spreads by slow degrees;
> Three centuries he grows, and three he stays
> Supreme in state, and in three more decays."

The chief value of the plant resides in the bark, which is celebrated for the large quantity of tannic acid it contains. The barks are gathered in the spring, because they contain a larger percentage and are more easily separated from the wood. The bark of young stems is most highly prized. Besides tannic acid, oak-bark contains gallic and quercitannic acids, and about 2 per cent. of ash.

The following example of the percentage of tannic acid from oak-barks, at different periods of the year, are taken from the author's laboratory journal:—

Entire bark in	May	= 6·05	per cent.
,,	August	= 4·39	,,
Inner bark only	May	= 21·13	,,
,,	August	= 15·34	,,

Tannic acid ($C_{27}H_{22}O_{17}$) from oak is that kind which gives a bluish-black colour with ferric salts. It is glucoside, for when boiled with diluted acid it becomes converted into glucose and gallic acid ($C_7H_6O_5$).

$$\underset{\text{Tannic acid.}}{C_{27}H_{22}O_{17}} + 4\,H_2O = \underset{\text{Glucose.}}{C_6H_{12}O_6} + \underset{\text{Gallic acid.}}{3\,C_7H_6O_5}.$$

Gallic acid differs from tannic by producing no precipitate with gelatine. It is, however, a singular circumstance that, when mixed with gum it has that property.

When tannic acid is heated, it becomes decomposed into pyrogallic acid ($C_6H_6O_3$), so well known as an article of great use in photography, and a singular dark-coloured insoluble substance termed metagallic acid ($C_6H_4O_2$).

$$\underset{\text{Tannin.}}{C_{27}H_{22}O_{17}} = \underset{\text{Pyrogallic acid.}}{3\,C_6H_6O_3} + \underset{\text{Metagallic acid.}}{C_6H_4O_2} + 3\,CO_2.$$

The tannic acid procured from catechu, cinchona, etc. differs from that contained in oak-bark, by giving, with ferric salts, a greenish instead of a bluish-black precipitate, and by not yielding glucose or pyrogallic acid. Quercitannic acid present in oak-bark differs from the usual tannic acid of the galls by being non-convertible into gallic acid or pyrogallic acid, and from the tannic acid of catechu by giving a bluish-black precipitate with ferric salts.

During the last few years the oaks in the West of England have been infested by galls. A great number have been analysed by the author, but have proved useless for commercial purposes, from the small percentage of tannic acid present. This may be owing to being allowed to remain on the tree till the insect escapes, for nearly all were perforated.

NOTICE ON THE DECOLORIZATION AND DEODORIZATION OF TINCTURE OF IODINE.

BY JAMES LAKER MACMILLAN.

Within the last year or two an unusual degree of attention has been devoted to methods for decolorizing tincture of iodine. The agent commonly resorted to for this purpose is ammonia; a practice which cannot be too highly censured, inasmuch as a change takes place which is highly detrimental to its medicinal properties. By the addition of ammonia to this tincture, one or more compounds of iodine and nitrogen are formed, which are thrown down in the state of a black precipitate, which is redissolved after standing for a number of hours, or by the addition of carbolic acid.

The reaction is as follows:—

$$6I + 4NH_3 = NI_3 + 3NH_4I.$$

Thus, it will be seen that the use of ammonia for this purpose is detrimental to the medicinal efficacy of the iodine; and that when such so-called tinctures prepared by this process are substituted for the tincture proper, the physician unwittingly uses a solution of the above compound. To rectify this error is the object of this notice; to which I append the following simple, though none the less noteworthy processes, for the consideration of the pharmaceutical body at large.

Process No. 1.—Potassium acetate ($KC_2H_3O_2$) 2·59 gram, with 7·7 gram solution of KHO, having a specific gravity of 1·06, at 15·55° C., are capable of decolorizing 2·592 decagrams of tincture of iodine, B. P.

Process No. 2.—A similar reaction is manifest if treated with a solution of $NaHO$, having a specific gravity of 1·07 at 15·55° C., in the proportions of 5·3 decigrams of the sodium solution to 3·6 gram of the tincture.

[We believe these preparations (introduced by the late Sir James Simpson) should not be decolorized, since that cannot be done without interference with the medicinal efficacy of the iodine.—Ed. Pharm. Journ.]

ORIENTAL SPICES.

BY JAMES PATON,

Assistant-Keeper in the Museum of Science and Art, Edinburgh.

(*Concluded from page* 967.)

With the discovery and introduction into commerce of the clove and nutmeg, the last link in the series of Oriental spices was supplied. In the early and rude state of the traffic, the steps by which spices reached the European markets were numerous, and their progress slow. The Javanese brought the Moluccas spices to the western ports of the Archipelago. The Klings or Telingas next carried them to the eastern shores of India. Thence the third journey was to Calicut, or other port on the Malabar coast, where were collected the pepper and other spices of India and Ceylon. Fourthly, the Arabs conveyed them to their ports on the Red Sea, or the Persian Gulf, and from these, by many stages, they reached the Mediterranean and Black Sea ports. These four voyages were, as already remarked, reduced to one by the Arabs in the seventh century, under the impulse given to their energies by the doctrine of Mahomed, and in this condition the Asiatic portion of the journey continued till the discovery of the Cape passage struck it a fatal blow.

On the European side many important cities arose, flourished and attained great power during what we call the dark Middle Ages, through their hold on this most lucrative commerce. Smyrna caught the caravans that toiled along the Euphrates Valley, and across the Desert, and forwarded the precious products to the Black Sea ports and Constantinople. To a few mud-flats at the head of the Adriatic the miserable remnant of a Roman province were, in the sixth century, hunted by the hordes of the Goths and Huns, and in miserable huts, they caught a few fish, and dried a little salt, in which they began a humble commerce. From that beginning the proud republic of Venice arose, the commercial influence and political power of which overshadowed the civilized world. The records of the Middle Ages are principally made up of the wars and commercial rivalries, the endeavours to outwit and overreach each other in the great eastern trade of the Venetians and their great compeers the Genoese, till the Portuguese involved both in inevitable ruin by opening up the Cape passage.

Towards the beginning of the fifteenth century the civilization and commercial instincts which had been marching steadily westward reached what appeared to be the outer limit of the world. The ocean-bounded kingdoms cast greedy, longing eyes at the glories of Venice derived from the costly aromatics of the East. The restless spirit of enterprise chafed at the seemingly impassable barrier. Then at the courts of these Western nations appeared two brothers, Genoese sailors, of the name of Colon or Columbus, with a proposal to reach the land of spices by what appeared to them a short voyage due west. Ultimately the one, by name Christopher, succeeded with the king of Spain, and found, not the little spice islands, but the great continent of America. At the same time, the Portuguese had sent two emissaries to the East to explore the countries where the pepper, cinnamon and spices that enriched Venice were produced. One went to India, where he saw pepper and ginger actually growing, and learned that cloves and nutmegs were produced in very distant eastern countries. On his return to Cairo, he sent to his government much information regarding eastern commerce, and departed to Abyssinia, the land of Prester John, where his companion had died. Here he was detained twenty years,—the Abyssinians even at that time had a fancy for Europeans;—then he was allowed to return home, without his release costing his country ten millions of pounds.

Meantime, the restless Portuguese had likewise been feeling their way along the African coast, and Bartholomew Diaz had actually doubled the Cape, which, from its stormy waters, he called Cabo Tormentosa; but the king, seeing better omen in it, changed it to Cabo de Boa Esperança. Thereafter, in 1498, Vasco de Gama, with the first European vessel which had ploughed the eastern seas, dropped his anchor in the harbour of Calicut. The stream of merchandise, which for twenty centuries had poured its torrents of wealth through the Red Sea and the Persian Gulf was immediately dried up, and the States which had flourished by it withered like plants from which the nourishing roots were cut off.

The success of the Portuguese discoveries stimulated the enterprise of other maritime nations; and to the endeavours to find a route to the Spice Islands are distinctly traceable our own early efforts to establish a north-west passage which have now such tragic interest for us, and of which we have not even yet heard the last. To the same impulse is also owing the first circumnavigation of the globe by the brave but unfortunate Spaniard Magellan, who, by sailing westward, reached, in 1521, the northern islands of the Archipelago, known and yet possessed by the Spanish as the Philippine Islands.

Such were some of the great ends attained for the world by the agency of this commerce. But with these the benefits to humanity ceased. It is true that for a time wealth, power and prosperity flowed into Portugal. The enhancement in price which naturally accrued on these luxuries, from tedious, difficult and dangerous journeys, and which had averaged at lowest twenty times the original price, the Portuguese unjustly continued to demand, and Europe was no gainer in this respect by the opening up of the ocean path to the East.

Thus we find that pepper, when it came to England by the tedious and costly journeying already described, cost 3*s.* 6*d.* per pound, or about sixteen times its cost in the Malabar market. Under the Portuguese it rose to 4*s.*, or eighteen times its prime cost. Cloves continued to cost about 10*s.* 6*d.* per pound, thirty times their price in the Moluccas, and the Venetian merchants for some time even continued to compete with their western rivals. Nutmegs and mace by way of the Mediterranean, which at one time could be bought in the Moluccas for ½*d.* and 1*d.* per pound respectively, cost 4*s.* 6*d.* and 9*s.* Under the close monopoly of the Dutch, they rose—nutmegs to 10*s.* 3½*d.* per pound, and mace to £1. 10*s.* 5*d.* Thus mace cost in England 730 times what was once regarded as its fair value in its native islands! With such enormous sources of profit, the spirit of avarice and greed was effectually stirred up, and all sense of moderation, uprightness or even decency in dealing was forgotten among the western trading Powers. The claims of the possessors of the soil were never for a minute considered, except in so far as they were tools for production of wealthy cargoes, or obstructions to the rapacity of the traders, which should be treated as men treat noxious weeds in their gardens. The history of the three centuries which follow the discovery of the Cape passage is made up of sickening details, intrigue, meanness and bloodshed; the Portuguese by such means established themselves, by like means the Dutch sought to supplant them, and we are bound to confess, by the same unholy method, our nation also founded our great eastern empire. Honourable trading was never thought of. The Pope first divided nearly the whole world, known and unknown, between the Spaniards and the Portuguese. The Portuguese seized their eastern possessions as quickly as distance and their limited navy would allow. Their first work was to overawe the people by strongly-fortified trading posts; then the triple work of commerce, conversion and extermination went on hand in hand. Next the Dutch appeared, and dexterously used the cowed and terrified people against their original oppressors. Codlin, they said, was the friend. Then the appearance of the British completed the triangular duel; and, with varying fortunes, they fought, separately or any two against any one, till the Portuguese were first in effect driven from the field. The Dutch were ultimately driven from Ceylon towards the end of the last century, but their hold upon the eastern archipelago was never fairly shaken. There, through persevering monopoly and other narrow-spirited restrictions, they ultimately succeeded in killing the goose that laid the golden eggs; and the trade which made the glories of Venice and Genoa, and first established the great trading communities of the West, is now carried on at a loss to the Dutch government. In Ceylon we have the same tale to tell; the settlers there also were too late in being removed, and the cinnamon trade has become insignificant and unheeded.

Yet we must acknowledge that more powerful agencies have been at work than the spirit of monopoly. A trade has sprung up with the East which, in extent and value, is a hundredfold that of the spices. Tea and coffee have supplied a new stimulant in a much more manageable form; they have effected a social revolution, and spice, the former king of commerce,—a name that lured men even more than the charm of gold,—would now little more than occupy the capital of one of our great merchants; and the trees which were guarded with inhuman jealousy, and the roots of which Roman conquerors placed with divine honours in the temples of their gods, may now grow, drop their fruit, and wither unheeded in the tangle of tropical forests.

UVA URSI.

BY JULIUS JUNGMANN.

[The author gives a good botanical description of the plant and its habitat; he describes the drug, refers to its introduction in medicine, and reviews the analyses made since 1809 to the present time, then he proceeds to his own experiments.]

A quantity of coarsely powdered *Uva ursi* leaves was exhausted with cold water by percolation, the infusion heated to the boiling-point, strained, a greenish flocculent coagulum of albumen was left on the strainer; the infusion, after having been more concentrated, was treated with freshly prepared hydrated oxide of lead, until it would no longer produce a precipitate; this was separated by a filter. The filtrate, still more concentrated by evaporation, was divided into two parts; the first was set aside in a warm place to evaporate spontaneously, the second was treated with strong alcohol; this produced a bulky precipitate of gummy matter, which was removed by filtration; the alcoholic filtrate was again divided into two portions, the first set aside to evaporate spontaneously, the second evaporated to a syrup and then treated with ether; the different ethereal solutions were mixed and evaporated at common temperature. The residue consisted of a mass of nearly colourless prismatic crystals of considerable size, of a bitter slightly acrid taste, with a small quantity of resinous matter of peculiarly disagreeable odour adhering—ericolin.

They could be easily purified by either washing them with ether, which would dissolve out the resin, or else by dissolving them in a small quantity of boiling water, filtering and recrystallizing; thus purified from water they were inodorous, not near as large, but small needles having a silky lustre.

The alcoholic solution yielded a dark coloured extract nearly black; this was redissolved in alcohol and treated with animal charcoal, filtered and again evaporated spontaneously; yielded, after being pressed and dried, yellowish-white crystals of a flocculent character having no odour.

The aqueous solution, which had been set aside in a warm place, was found, after about two weeks standing, to consist of a soft extractive mass, covered all over the surface with small white crystals, very difficult to remove, on account of the large amount of black, gummy extractive adhering to it. The crystals contained in this mass could only be obtained after long and repeated treatment with animal charcoal; to remove colouring matter and other impurities, it might be purified by precipitating the colouring matter by a solution of *alum;* but this mode of proceeding can only be recommended when *arbutin* is the only object in view, otherwise it is objectionable, as it complicates the process. A quicker way, however, to obtain the crystals, I found to be by treating the extractive mixture with a mixture of alcohol and ether, in which they readily dissolve, leaving behind nearly all the impurities; as thus obtained, the crystals have, in their moist condition, a yellowish colour, becoming nearly white when dried; they possessed the same properties as those obtained previously.

All the crystals obtained by these different processes proved to be *arbutin*, the discovery of which was first announced by Kawalier in 1852.

A second quantity of leaves was reduced to a coarse powder, decocted with water, the decoction strained and precipitated with neutral acetate of lead, the precipitated lead salt was filtered off and the filtrate was treated with basic acetate of lead, until a precipitate was no longer produced, this being filtered out. Sulphuretted hydrogen gas was passed in the filtrate until all the lead was precipitated; the sulphuret of lead was then removed by a filter, and the excess of hydrosulphuric acid by heating the filtrate; this was evaporated to a soft extract, redissolved in water, treated with animal charcoal, then again filtered and evaporated, and, while hot, set aside. After about twenty-four hours' standing, the bottom of the vessel was covered with bunches of small crystalline needles of arbutin; these were pressed and dried between filtering-paper, and purified by redissolving them in a small quantity of boiling water and again allowing the crystals to separate; these, when pressed and dried, consisted of small prismatic needles having a silvery lustre. This second process for obtaining the arbutin is, in the main points, the original one of Kawalier, except that he does not precipitate with *basic* acetate of lead, which, however, removes nearly all the gum and colouring matter, and thereby facilitates the crystallization to some extent.

Arbutin generally crystallizes from ether in prismatic needles of considerable size and perfectly colourless, from an alcoholic solution in small acicular crystals of a white colour, and in small bunches of needles from water; it is neutral in its behaviour, very soluble in warm or hot water, less in cold water or alcohol, more in hot alcohol, very sparingly in ether; a concentrated solution of arbutin is precipitated by strong alcohol or ether added to it, but the precipitate rapidly disappears on shaking. Concentrated sulphuric acid or hydrochloric acid, added to the crystals on a small plate, gradually dissolves them without change of colour. With nitric acid the crystals first turned black and then slowly dissolved, the acid assuming a yellow colour and giving off fumes of nitrous acid. Arbutin in aqueous solution does not affect an alkaline solution of sulphate of copper, the salts of lead, acetate and subacetate do not precipitate it, salts of iron have no effect upon it; other reagents for organic bodies as tannic and gallic acid, bichloride of mercury, nitrate of silver, iodide of potassium and bichloride of platinum were tried without any results.

While experimenting with these reagents, I accidentally found a very characteristic and remarkable test for arbutin. When a solution of arbutin in water is rendered alkaline by ammonia, or any other caustic or carbonated alkali, and then phosphomolybdic acid is added, a blue colour is produced; in strong solutions the coloration is of a deep azure blue, but the bluish hue can be observed even in very dilute solutions. One grain of arbutin was distinctly indicated in twenty pints of water (1 in 140,000); this reaction does not occur with molybdate of ammonia, nor does it take place when phosphoric or phosphomolybdic acid is acted upon by an alkali alone.

A solution of arbutin may be perfectly colourless but still impure; when to an impure solution of arbutin ammonia or any caustic or carbonated alkali is added, a deeper, sometimes orange, colour is produced, while a solution of pure arbutin is not affected in this way.

[The author next describes the composition and glucoside nature of arbutin and the mode of obtaining hydrokinone, the literature on the subject being reviewed and compared with his experiments.]

E. C. Hughes, in an essay on *Uva ursi*, published in the *American Journal of Pharmacy*, 1847, describes a crystalline principle which he obtained from the leaves and to which he gave the name "Ursin." This ursin, although it has not been noticed in European literature, has received some attention, and has generally been regarded as a distinct principle in American works. As this was obtained before the known existence of arbutin, and as its mode of preparation is similar to that of arbutin, I was led to suppose that the two might, perhaps, be identical; to satisfy myself, I prepared some ursin according to Hughes' method, which consists in maceration and percolation of the leaves with cold water, precipitating the tannin by a solution of gelatine, filtering and evaporating to dryness, treating the remaining extract by strong alcohol, the alcoholic solution with animal charcoal, filtering and evaporating spontaneously. By this process an acicular crystalline mass, to which a small quantity of resin adhered, was obtained, having nearly all the properties of arbutin; the solution, rendered alkaline, produced a blue colour with phosphomolybdic acid, and it yielded, when boiled with dilute sulphuric acid, the same product of decomposition, hydrokinone, besides separating ericolin.

Hughes states, however, that his ursin was precipitated by carbonate of potash and by the solution of subacetate of lead, while it was not affected by the *tincture* of chloride of iron; but as he uses a solution of gelatine to precipitate the infusion of the leaves, he only gets rid of the tannic acid while the gallic acid remains in solution, and is afterwards obtained together with the arbutin (his ursin). A solution of this mixture, then, of course, precipitates with basic acetate of lead, but then it ought to be affected by the salts of iron; but the tincture which he used is a very uncertain test, owing to the free acid it contains, which does not indicate small quantities, as in this case, while the solution of subacetate of lead precipitates even the smallest trace of gallic acid. Carbonate of potash would produce a slight change in the colour, but an actual precipitation did not take place. The ursin of Hughes must, therefore, be considered as an impure arbutin.

[The author then minutely describes the action of nitric acid on arbutin and the production of binitro-arbutin, discovered by Strecker; also, the decomposition of this compound into sugar and binitro-hydrokinone, after which the effect of chlorine upon arbutin is considered.]

Arbutin has also been found abundantly in *Chimaphila umbellata*, and it probably exists in a number of ericaceous plants. Its medical properties have never been practically applied; it was at one time believed to represent the diuretic properties of *Uva ursi*, and Hughes states that one grain of his ursin proved a powerful diuretic. The celebrated pharmacologist, Dr. Schroff of Vienna, who experimented with pure arbutin, states, however, that it possesses no diuretic properties at all: he gave it in doses as high as 8 grains, and could not detect it in the urine.

When the mother-liquor from arbutin is heated with a dilute acid (sulphuric or muriatic) a resinous body separates, which has received the name of ericolin; this, again, is a glucoside, which, when treated with a dilute acid, splits into grape sugar, and an odorous substance having the character of a volatile oil, ericinol; both have been noticed already by Kawalier in his investigation. In preparing ericolin from the mother-liquor of arbutin, I found that a portion of ericolin is decomposed as soon as it forms into ericinol, giving rise to the strong disagreeable odour of the latter. Ericolin is a dark brown resin, becoming somewhat lighter when dried and rubbed to powder; its chemical composition is $C_{68}H_{56}O_{42}$. Its decomposition into ericinol is shown by the following:—

Ericolin.		Ericinol.		Grape Sugar.
$C_{68}H_{56}O_{42} + 8HO$	=	$C_{20}H_{16}O_2$	+	$4C_{12}H_{12}O_{12}$.

[The literature on ericinol and ericolin is now reviewed, and their occurrence in different plants spoken of. The precipitate obtained with hydrated oxide of lead was found to contain tannin, gallic and malic acids, but to be free from tartaric and citric acids. The precipitate obtained by adding alcohol in a concentrated infusion of the leaves, contained gum, glucose and a lime salt. The leaves, previously exhausted with water, were treated with ether, and Trommsdorff's urson was prepared from the ethereal tincture (see Am. Journ. Ph., 1854).]

Trommsdorff's process directs the ethereal extract to be washed by ether before treating with alcohol; this removes, besides the colouring matter, some fatty matter; but when operating upon larger quantities, I believe that animal charcoal will answer the same purpose. Another way to prepare urson is to percolate the leaves, previously exhausted by water, with strong alcohol; the dark-green tincture deposits already on standing a large quantity of nearly white urson, which only needs recrystallizing; the remainder of the tincture is evaporated, treated with water, and then washed with ether and recrystallized from alcohol. Urson, when pure, possesses neither odour nor taste; it is insoluble in water, sparingly soluble in alcohol and ether. It is not affected by alkalies or dilute acids.

Concentrated sulphuric acid turns it black and gradually carbonizes it, the acid assuming a red colour. Concentrated nitric acid turns it yellow, gradually dissolving it, giving off nitrous acid. When heated, urson melts into an amorphous transparent mass; at a still higher temperature it boils and sublimes in a test-tube unchanged. Its medical properties have as yet not been ascertained, at least no physiological experiments have been made with it, and very probably it is entirely inert. A small quantity of *volatile oil* was found in the aqueous solution of the ethereal extract, besides some tannic and gallic acids.

The organic constituents of uva ursi as obtained by this investigation, therefore, are:—

Arbutin, and its product of decomposition, hydrokinone; ericolin, ericinol, urson; (ursin, the diuretic principle of Hughes, was found to be impure arbutin;) tannic, gallic and malic acids, then a small quantity of volatile oil, fatty matter, wax, gum, sugar, albumen, colouring matter, etc.

The test for arbutin may, perhaps, serve for finding this principle in plants, without isolating it, for an infusion of uva ursi, when diluted with sufficient water to make it perfectly colourless and then rendered alkaline, produces, on the addition of phosphomolybdic acid, the blue reaction due to arbutin; when the alkali (ammonia) is added to the diluted colourless infusion, a colour (orange) again appears, owing to the astringent acids present; this colour must also be removed by again diluting it with water, before the final addition of the phosphomolybdic acid.

This test cannot be applied to a strong infusion, because phosphomolybdic acid reacts with tannic and gallic acids green, and the blue colour cannot then be observed. —*Amer. Journ. of Pharmacy.*

ERYTHROCENTAURIN IN AMERICAN CENTAURY.

BY JOHN F. HUNEKER.

This principle was discovered in European centaury (*Erythræa Centaurium*), a few years ago, by Méhu, a French chemist, who obtained it in the minute quantity of one grain in three thousand grains of the herb. The question very naturally arose, whether American centaury (*Sabbatia angularis*) also contained this principle; the experimenter will prove that it may be obtained.

The flowers and leaves of *Sabbatia angularis* to the amount of two pounds were exhausted with one gallon of water, a portion of which was evaporated by a water bath, and allowed to stand to deposit the apotheme. This was separated by filtration, and strong alcohol added to the filtrate, which precipitated gum. On again filtering, the infusion was evaporated to the consistence of a syrup, and, on cooling, washed with strong ether, which took up erythrocentaurin and deposited it on spontaneous evaporation. Erythrocentaurin, as thus obtained, is a non-nitrogenous principle, in small acicular crystals, which are transparent, but in this case were contaminated with yellow colouring matter, and, being in such a small quantity, the experimenter feared losing them in decolorizing.

The crystals have a sharp acrid taste, reminding one of tobacco, and are soluble in alcohol, ether, water, alkalies in solution and acids, but insoluble in fixed and volatile oils, being also slightly volatilized by heat.

The only proofs that they are similar to erythrocentaurin of the European centaury are:—first, that they exist in the same minute quantity; second, that they are *reddened* by solar light, but if dissolved and recrystallized, regain their original colour. Therefore there is not a doubt but that these principles are similar in composition and character.

[The author made a series of experiments to determine the proximate composition of American centaury, and found, besides erythrocentaurin, resin, chlorophyll, fatty matter, gum, albumen, pectin, bitter extractive, trace of volatile oil, an organic acid, red colouring matter and salts. He was unsuccessful in his attempts to isolate and crystallize the bitter principle.

The author regards the aqueous extract as the most concentrated pharmaceutical preparation; he gave ten grains of it to a half-grown cat, which in a short time appeared to be under the influence of a narcotic sedative; after sleep, lasting for two hours, violent purgation set in, causing death in twenty-four hours.—Ed. *Amer. Journ. Pharm.*]

THE CHEMISTRY OF CALICO PRINTING.*

BY JAMES BLAIR.

The art of producing coloured figures or patterns on cotton cloth has been known and practised for many years in this country, and for centuries in India and China. Within the last quarter of a century this industry has made great progress, due to the use of improved appliances, and the more accurate knowledge of colouring matters and their various compounds, besides the discovery of many new colouring matters, the result of unwearied chemical investigation and research. This result has been greatly attained by calico printers themselves, among whom are to be found many able chemists.

The old plan of printing with blocks by hand has been almost entirely superseded by the cylinder printing machine, and in every department more perfect machinery has been introduced, with a corresponding decrease of manual labour. The result of this is, that

* Paper read before the Liverpool Chemists' Association, on March 16th and April 13th, 1871.

while the production of printed goods is yearly increasing, the number of operatives employed is nearly stationary; the number of print-works is also smaller than previously, the small works having been gradually supplanted by a few large ones. Some of these are very extensive, employing over 1000 operatives, and producing nearly 1,500,000 pieces of printed cloth per annum.

Of the very many colouring matters known, comparatively few are now employed by the calico printer in producing all the combinations of colours he requires; and these vary greatly, both in the manner of application and in the value of the effects produced; and as chemistry has furnished us with a host of new colouring matters,—aniline, phenol, naphthaline, and anthracine colours,—and as these are commercially valuable just in so far as they can be employed by the dyer and printer, I have thought that a brief sketch of the various operations, and the chemical changes involved, might possess some little interest.

Fibres may be generally divided into two classes, animal fibre and vegetable fibre,—the former represented by silk and wool, the latter by flax and cotton, which entirely differ, both in their formation and in the manner in which they retain colouring matters. Animal fibre, such as wool, presents under the microscope the appearance of a solid cylinder of a soft spongy matter, has considerable elasticity, and absorbs and retains readily most colouring matters. It contains a fatty matter, from which it has to be freed by scouring with very weak alkali, to prepare it for dyeing. Wool, also, is strongly acted on, indeed dissolved by alkalies, and it is turned yellow by immersion in nitric or sulphuric acids. Cotton, on the other hand, is unchanged in colour by NO_5 or SO_3, but first swells up, and by lengthened immersion dissolves in these acids, while it is nearly unaffected by treatment with alkaline solutions, and it contains no oil in the fibre. Wool not only absorbs colouring matters from their solutions, but many metallic salts (as $Al_2O_3SO_3$), which cannot be removed by washing with cold water, and only by large volumes of boiling water. Cotton, on the other hand, has a very weak affinity for metallic salts and colour. When viewed under the microscope, a cotton fibre presents the appearance of a hollow cylindrical tube, sometimes slightly oval, the walls of the tube being coated with a fine down. Some chemists, as Persoz, have maintained that the union of fibres with metallic salts and colouring matters was purely chemical, and that the difference between wool and cotton in this respect was simply one of degree. However, Mr. Crum has shown that dyed cotton cloth retains the colour simply mechanically; in other words, the dyeing of cotton consists in introducing the colouring matter in a soluble form into the hollow tube, and then solidifying it by forming an insoluble lake with some metallic salt or other mordant, when the insoluble compound so produced is unable to escape by the narrow openings of the fibre.

In unripe or not fully-developed cotton the tube is nearly flat, and too narrow to admit of solution; consequently, this cotton will not dye. The printer receives the grey cloth direct from the loom, and turns it out ready to be made up into dresses, which involves several operations preparatory to, and succeeding, the impression of the coloured pattern on the cloth. Preparatory to the printing, the cloth is singed and bleached.

Singeing is a purely mechanical operation, and has for its object the removal of the soft down coating the exterior of the fibres. The appliance consists of a small furnace about 10 ft. long by 6 ft. high and 5 ft. broad; in the middle of the roof of the furnace, and running its entire length, is a semicircular bar of copper, which is kept red-hot by the fire underneath. The cloth is drawn over, and, by pressing in its passage the red-hot copper bar, the down on the cloth is burnt off; but the spark on the cloth is extinguished before the cloth can be materially injured by passing immediately through a trough of cold water. This operation, if properly conducted, does not injure the strength of the fibre, which should sustain the same strain after as before singeing. The next operation is bleaching.

Bleaching has for its object purification of the fabric from all coloured or other impurities, whether naturally associated with the tissues or added to serve some purpose, and which, communicating more or less colour to the cloth, thereby destroy its beauty. These are a resinous matter, a yellowish colour, soluble in alkalies; the dressing employed in the manufacture of the cloth, and the coloration produced by singeing. This process is conducted in the following manner:—

The grey cloth is first damped (by passing through a cistern filled with cold water, and is then drawn through squeezers, by which the damping is made uniform and the excess of water removed) to make it less bulky in the kier, to which it is transferred from the squeezers by a winch.

During the filling of the kier the valves at the bottom are kept open to allow of the escape of any moisture which may fall to the bottom.

In a pot or small boiler, 60 lb. of burnt lime shell are slaked and boiled with 100 lb. of soda ash dissolved in water, until the carbonate of soda is converted into caustic soda.

The solution is allowed to clarify by resting till the sediment ($CaOCO_2$) has fallen to the bottom, and the clear solution is drawn off by a valve situated a few inches above the bottom of the pot, and run into the kier where the grey cloth has been arranged. The charge is made up with water to 900 gallons, or till the cloth is covered with the alkaline solution. This is the charge for 4000 lb. of grey muslins or calicoes, and is boiled for four hours under 35 lb. pressure steam.

The solution is then drawn off from the kier into a cistern, where it is kept for further use, and the goods are cooled by running cold water on them, which is allowed to drain off by the bottom of the kier.

The cloth is then run from the kier through a machine, fed with 200 lb. burnt lime shell slaked and made into a cream with water, and back to the kier, where it is boiled (with the liquor of the first boil and the 200 lb. of lime which it took up in passing through the machine) for ten hours with open kiers.

The exhausted liquor is of no further use and is thrown away; the goods are then cooled, passed through a washing machine with cold water, and then through a souring machine, fed with sulphuric acid, at 4° Tw., and allowed to lie in the sour taken up, on a drainer for four hours.

The cloth is then washed by passing through a machine with water, twice if the water be not very pure, but if quite pure, the washing may be effected by pouring water upon the goods till the sour is washed out.

The goods are then run back to the kier and boiled with a charge consisting of 250 lb. of soda ash, 60 lb. of rosin and 900 gallons of water (which has been previously prepared in the following manner), for ten hours, under 35 lb. pressure of steam. The 250 lb. soda ash are dissolved in 150 gallons of water and added to the 60 lb. rosin. This solution of rosin soap is then run into the kier and water added up to 900 gallons, with the 4000 lb. of cloth, and boiled, as before stated, for ten hours under 35 lb. pressure of steam.

The liquor is then run off and the goods cooled as before. The goods are then washed in a machine and passed through squeezers. The cloth is then passed through a machine, fed with bleaching liquor, at 1° to 2° on the chlorine test, and allowed to lie on a drainer four hours. It is then sweetened by passing through a machine with water, soured as before, and the sour washed out by twice washing with cold water.

It is then dried on steam-heated cylinders.

Previous to printing, the cloth is shaved, or freed from loose fibres, by passing over a spiral knife, dusted, and then beamed on a roller free from all creases. It is then ready for printing.

The colours of printed goods may be divided into three classes, viz. 1. Pigment Colours; 2. Steam Colours; 3. Mordanted Colours.

Pigment Colours are those which require no treatment subsequent to printing to develope them, and which remain in great measure unchanged in colour by printing, and where the operation consists simply in fixing them in or on the cloth. They are of two kinds—1st, soluble pigments, which can be introduced into the interior of the fibres, such as the aniline colours; 2nd, insoluble pigments, which can only be fastened on the exterior, as ultramarine, chrome green, ochres, lakes, etc.

Steam Colours are those in which chemical and colouring matters are so mixed that, when printed, they enter the fibre in solution; but, on being submitted to the action of steam, chemical combination takes place, so as to produce an insoluble colour in the fibre.

Mordanted Colours are those where a metallic salt or other fixing agent is printed on the cloth, which, when subsequently immersed in a bath containing the colouring matter in solution, becomes dyed, the mordant forming with the colour an insoluble lake or coloured compound, as garancine and madder work.

In describing the operation of printing, it is necessary to describe the apparatus employed; secondly, the preparation of the colours, and the mode of procedure.

The printing machine consists of a massive iron roller, accurately turned, supported at each end by a strong iron support or cheek furnished with arms, through each of which works a screw; at the ends of the screws are the rests in which the ends of the copper rollers are placed, and by these screws the rollers can be tightly screwed up against the iron cylinder. There is also an arrangement of screws to fix the rollers more or less aside, so as to enable the printer to fit the pattern that is to make the engravings on the various rollers exactly coincide. Above the central roller of the machine is a light iron roller, and around these two rollers passes an endless blanket of india-rubber. The cloth to be printed is fastened behind the machine on two light projecting arms. The rollers having been properly fastened in the machine, a colour trough of wood or copper is fastened beneath each copper roller; in each trough is a light wooden roller, sometimes a brush, brought nearly in contact with the copper roller; this is to transfer the supply of colour from the trough to the copper roller. Into each trough is then placed the colour to be printed on the cloth by that part of the pattern engraved on the corresponding copper roller. When the machine is set in motion, the cloth is passed between the copper rollers and the iron cylinder of the machine, and in its passage it gets the coloured pattern impressed upon it. Each copper roller is furnished with two knives, one resting along the top, the other along its base; the one is to remove all colour from the surface of the roller, except that in the engraving, before coming in contact with the cloth, the other to take up any loose fibres or down before the roller gets a second supply of colour. Simultaneously with the passage of the white cloth through the machine, two plies of grey cloth are passed through the machine with it, and between the endless blanket of the machine and the white cloth; this is to serve as a blotter and to absorb any excess of colour printed on, and so prevent any spreading of the colours beyond the limits of the pattern.

(*To be continued.*)

FERRATED ELIXIR OF CINCHONA.

BY PROFESSOR MAISCH.

At my request, Mr. William M'Intyre, of Philadelphia, has furnished me with the following formula for elixir of calisaya with pyrophosphate of iron, in which calisaya bark is employed:—

Take of Calisaya ℥iv
Sweet Orange Peel, recently dried ℥iii
Coriander ʒvi
Ceylon Cinnamon ʒiv
Cardamom
Anise, ana ʒij.

Prepare these for percolation, and displace with a mixture of one quart stronger alcohol and three quarts of water.

To this tincture add—
Oil of Orange (fresh) 40 ♏
Lemon (fresh) 16 ♏
Almonds (fresh, essential) 4 ♏, dissolved in Alcohol, four fl. drs.

Agitate this mixture with moist freshly precipitated hydrated sesquioxide of iron (well washed), prepared from an aqueous solution of the sesquichloride, for three or four days, or until a portion filtered off shows no reaction with the tincture of chloride of iron. Filter, and dissolve in it, without heat, two and a half pounds (av.) sugar. Add 1024 grs. pyrophosphate of iron, previously dissolved in a small portion of water, and make up the measure of one gallon, if necessary, by the addition of water. If a more reddish colour is wanted, use a few grains of soluble citrate of iron.

The elixir thus prepared will keep well in colour, and has a resemblance to the article extensively advertised under the same name.

If the cinchona bark contains 3 per cent. of alkaloids, and supposing the bark to be entirely exhausted, one gallon of elixir prepared according to the above formula would contain about 60 grains of alkaloids, or nearly half a grain to the fluid ounce. Cinchona bark, however, cannot be completely exhausted by weak alcohol, and after the treatment of the resulting tincture with hydrated sesquioxide of iron, the natural combination of the cinchona alkaloids is broken up, and nothing of medicinal value is retained by the liquid except the alkaloids. The aromatics used in most of the formulas, I believe, add comparatively little to the medicinal virtues of this preparation, which aims, ostensibly, to unite the tonic properties of cinchona and iron. These considerations induced me to take advantage of the excellent combination of aromatics with calisaya bark, which was suggested by Dr. Squibb, and has met with great favour by the medical corps of the United States army. Accordingly, I have dispensed, for the last five years, a ferrated elixir of calisaya made by the following formula, and manipulated as follows:—

1. Triturate magnes. carbon. ℥ss first with the following volatile oils:—Ol. aurantii ♏ xx, ol. anisi ♏ xv, ol. coriandri and cinnam. ana ♏ 10, ol. carvi ♏ v; then, with a mixture of 2 oz. alcohol and 14 oz. water, throw upon a filter and wash with water until the filtrate measures $3\frac{1}{2}$ pints.

2. Mix tinct. cardam. (simpl.) f℥ij, tinct. zingib. and calami ana f℥i, alcohol Oj, and add syrup. simpl. Oj.

3. Dissolve unbleached quinia ʒiss, with acid. citr. ʒijss, in alcoh. dilut. f℥iv.

4. Dissolve ferri pyrophosph. ʒxx, in aq. ferv. f℥viij.

Add solution No. 3 to No. 2; then add No. 4, then No 1, and finally add $1\frac{1}{2}$ pint simple syrup and $\frac{1}{2}$ pint alcohol. The whole measures $8\frac{1}{2}$ pints, and may be coloured by caramel to suit; each fluid ounce contains about $9\frac{1}{2}$ grs. pyrophosphate, $\frac{3}{8}$ gr. alkaloids, and 1 gr. each of ginger, calamus, and cardamom. It has a very pleasant, warm, aromatic, but, at the same time, a decidedly bitter taste. The unbleached quinia may be prepared from the infusion of calisaya bark, made with acidulated water, by precipitating with an alkali. I have come into possession of a chinoidin containing a large percentage of quinia and quinidia, which has been used with advantage.

The two formulas published above represent the two views held by our pharmacists, namely, that cinchona bark, as such, and the isolated alkaloids alone should be combined with salts of iron.—*Amer. Journal of Pharmacy.*

The Pharmaceutical Journal.

SATURDAY, JUNE 10, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed* "*Pharm. Journ.*"

THE REGULATION OF PHARMACY FROM A MEDICAL POINT OF VIEW.

OUR esteemed contemporary, the *British Medical Journal*, has undertaken to censure with vehemence the action lately taken in reference to poison regulations. Though an entire column is occupied with hard words of condemnation, the real facts of the case are evidently so little understood by the writer that we are filled with wonder to find a journal so likely to be well informed on this subject should have perpetrated such an absurdity as to charge the Council with breaking faith with the Government. It is equally absurd to blame the Council of this Society with having avoided a responsibility that never rested with it, and never was imposed upon it by the Government or the Pharmacy Act, or anything save our contemporary's imagination; for though the public at large, or the general press, might well be excused for ignorance of the fact, we little expected to find a medical journal even forgetting that the power of prescribing poison regulations does not rest with the Council at all, but that it is the Society alone, in its corporate capacity, which has that power under the Pharmacy Act; yet this cardinal fact is overlooked by the *British Medical Journal;* and since its censure of the Council has no other foundation, we have no need to defend that body against the charge of having committed "a flagrant abandonment of public duty."

But, apart from this strange error, we will not affect to be unconscious that our contemporary's strictures were intended to have a wider application. No doubt the writer of the article shares the opinion of those who advocate the adoption of poison regulations in a compulsory form,—they are a numerous and a goodly party, comprising some of the foremost men of British Pharmacy,—but we must not forget that they constitute a minority of the Society which has the power of acting in the matter. Even Mr. SANDFORD, the most strenuous advocate of compulsory regulation, recognizes the propriety of united action in which the minority should succumb to the majority, and we have always contended that this question must be decided by vote. It has been so decided, and whether the decision be right or wrong, whether it be a conclusive settlement of the question or not, those who hold the opinion of the minority have no right to assume that the majority has been unmindful of those duties and obligations which are imposed upon the Society by the Pharmacy Act, or that the opposition to compulsory regulations has been instigated by selfish disregard of what is necessary for the public safety. Without taking side with either of the opinions held on the question of poison regulations, we do not hesitate to say that such an assumption would be monstrous. However obligatory the provisions of the Act may be in regard to poison regulations, it surely cannot be contended that the Society is under the obligation to prescribe regulations unless they were necessary, and it has been decided by the Society that compulsory regulations are not needed.

The Society has done what it deemed necessary, after consideration of the question by those most competent to judge. It has, in fact, adopted the recommendation of its Council (though the *British Medical Journal* does not appear to be aware of this); and until the measures decided upon have proved inadequate to secure the public against danger arising from the keeping and dispensing of poisons, there does not seem to be any rational ground for urging that further steps be taken. Whenever that proof can be furnished, we have little doubt that the members of this Society will duly fulfil their obligations and exercise their privilege of providing a remedy at once protective of the public and conducive to their own interests as a class. Meanwhile, we would suggest to our contemporary that his zeal in the matter of poison regulations may be fitly exercised in reforming the practices of medical dispensers, and with great prospect of benefit to the public. The opportunity for this has been pointed out repeatedly in this Journal, and it is again referred to in this number by a correspondent.

THE PRELIMINARY EXAMINATION.

To undergo an examination, it will be admitted, is not generally one of the most agreeable ordeals; and if the person examined be inexperienced and the surrounding circumstances be strange, the resulting embarrassment doubtless sometimes prevents the candidate from doing full justice to his attainments. This would be very likely to occur in such an examination as the Preliminary Examination of the Pharmaceutical Society, where a large proportion of the persons examined are young, and comparatively unaccustomed to judge and act for themselves. To assist such in economizing the time at their disposal by proceeding methodically to their work, the following plain suggestions for avoiding the errors which the candidates most frequently fall into, have been prepared. We hope that they will be of service and prove the truth of the adage,—

"A word spoken in due season, how good is it!"

1. Do the work in the order set down, not beginning with English, running confusedly into arithmetic and Latin, and then finishing with English.

2. Do not throw away time by writing out the questions before the answers; put the numbers only, distinctly and carefully, leaving a small space between each answer.

3. Translate all the Latin, if it can be done readily, without taking up too much time, or such passages only as can be done.

4. Read the questions carefully, and do not give a gender when asked for a case.

5. When particular case-endings of certain nouns are required, do not decline one noun entirely.

6. When Latin examples are asked for, give them in that language, and not in English.

7. Do not say objective case in Latin, or accusative in English.

8. In arithmetic endeavour to let the working of the sums appear, keep them well apart; when the answers only are put down, let them be clear and separate; let the scribbling-papers, showing the working, accompany the answers, and do not lose time by carrying decimals *ad infinitum.*

9. In the English let the composition be written, if possible, fairly off at first, so as not to spend time in writing the same twice; attend to the orthography; select *one* subject and keep to it, not doing five or six lines upon two subjects.

10. All the previous questions being published, work them out, and ask some kind friend to examine, and, if necessary, correct the answers.

11. Each candidate should state his age as indicated.

12. By endeavouring to carry out these simple directions, candidates will not so frequently finish with "no more time."

DR. ACLAND ON THE NATIONAL HEALTH.

A NUMEROUS and influential audience assembled in the theatre of the Royal College of Physicians on Friday, the 2nd instant, to hear Dr. ACLAND's lecture on the "National Health." Few men have established a better right to be heard on this subject than the Regius Professor of Medicine in the University of Oxford. His monograph on the outbreak of cholera there in 1854; his numerous lectures and reports on drainage, on fever, on the sanitary condition of various localities, take rank among the best contributions to the science of hygiene; while their classic elegance of style has made their subject attractive in quarters rarely reached by the pure *savant.* His lecture of Friday last will very shortly be made *publici juris,* so that it will suffice for us merely to draw attention to one or two of its salient features.

Dr. ACLAND placed in a very clear light what is meant by National Health, which he defined to be, "that condition of the individuals of the nation which enables those individuals to discharge rightly their respective functions in the State, 'to do their duty in the state of life to which they are called': the statesman to be in training for exercising the complex intellectual operations of his high office; the artisan, the soldier, the abstract thinker, each for his; and if we regard the philosophic teaching of the great author of the 'Republic,' parents of either sex for the raising of the future citizens of the State." Combating the objection that "National Health" is a fiction of the mind,—that no such collective physical condition exists,—he proceeded to show that DARWIN's doctrine confirms the conviction that acquired habits, whether of body or mind, may be very permanent in a race—so permanent as to require a corresponding persistency of sanitary amelioration to eradicate them.

He drew an interesting sketch of the noble controversy which some forty years ago arose in Scotland between Dr. CHALMERS and Dr. PULTENEY ALISON as to whether the care of the sick poor and of the destitute should be left to the voluntary efforts of the benevolent, or be placed under the strict eye of the law. The latter solution of the difficulty was ALISON's, who showed, once for all, that whatever might have been the evils engendered in England under the Poor Law, the evils of destitution left to charity were greater, both to the nation and to the individual. In logical sequence on the doctrine of ALISON, we are fast reaching a further social conception that prevention of sickness is a yet more rational course than its cure; that, in fact, prevention of all disease which is not surgical, and of much disease that is surgical, is as strictly a department of medicine as treatment.

The great conditions of a nation's health were next passed in review, and the causes by which they are perverted were clearly and exhaustively set forth.

The distinguished lecturer concluded by enforcing the necessity for a sanitary State service, and congratulated his audience on the fact that Trinity College, Dublin, had just followed the example of University and of King's College, London, in adding a Professorship of State Medicine to its curriculum. Scotland will be untrue to her traditions as a promoter of medical science, if she fail to follow the example of the sister kingdom. Whatever excuse she may have had for postponing the establishment of a sanitary chair becomes every day weaker and weaker with the diffusion of such enlightened views on national health as those of their latest and most eloquent expositor, Dr. ACLAND.

THE Adulteration of Food, Drugs, etc., Bill is not to be proceeded with further this session. On the 1st instant the order for committee was discharged and the Bill withdrawn.

The Local Executive Committee of the British Association have announced that the meeting at Edinburgh will commence on Wednesday, August 2nd, under the Presidency of Sir William Thomson, M.A., LL.D., D.C.L., F.R.S.L. & E., Professor of Natural Philosophy in the University of Glasgow.

We have been favoured with a copy of the first number of a new journal of pharmacy from America. The conductors of the *Leavenworth (Kansas) Medical Herald*, considering "the intimate relations existing between medicine and its close and natural ally, the art of pharmacy," and believing that "the judgment and opinions of the educated pharmacologist must be of interest to the ambitious physician," have thought it advisable to supplement the *Medical Herald* with a department to be entitled the *Journal of Pharmacy*. We cannot say much for the originality of the articles in the first number, but doubtless when it becomes known to the Kansas pharmacists that such a journal exists, it will not be long before original communications are forthcoming. The editorship of the new journal has been entrusted to Mr. R. J. Brown, who, in his "salutatory" address, thus announces his intentions and opinions:—

"My aim shall be to make this Journal of practical use to every druggist in this section of country, and to deal in questions of special interest pertaining to the science; make such selections as will be of service to our readers, and supply the best information on all new preparations, chemicals, etc., at my command.

"I believe in the onward march of pharmacy, its growth and prosperity. The Great West throbs in sympathy with its progress, and moves forward with its schools of pharmacy in solid column.

"I shall bear the standard that shall be for the elevation and advancement of this science, encouraging a spirit of research and study, and working in harmony with all who are assisting in its progress; advocating a thorough pharmaceutical education for the young men of our country, the establishment of schools of pharmacy, where they can receive such instruction as will fit them for the responsible duties of their profession."

A project for framing a Universal Pharmacopœia for the whole of the German Empire is reported. According to the *Lancet*, a Committee is to be formed for the purpose, consisting of twelve members, of whom Prussia is to send three, Saxony, Mecklenburg and Bavaria each two, and Würtemberg, Baden and Hesse each one. The Committee will be empowered to call to their assistance men whose special knowledge may prove useful. It is anticipated that the work will be ready by the 1st of January, 1872.

We notice that the Montreal Chemists' Association has succeeded in obtaining an Act of Incorporation. This, although not of so great importance as the Act recently passed in Ontario, is a step in the right direction. About two years since an effort was made to secure an Act for the better regulation of pharmacy in the province of Quebec; but, in consequence of the great opposition offered by the medical men who, in some parts, monopolize both the prescribing and the dispensing of medicines, it was unsuccessful. At present, a person wishing to enter the business must submit to an examination by a board of examiners, consisting entirely of doctors; and the sole power of granting a licence to carry on the business is vested in the physicians. It is hoped that the educational organization in connection with the newly incorporated Society will gradually win for its members an influence that will ensure success in a future attempt at legislation.

The prosecution of the Toronto druggists for the illegal sale of poisons, to which we have referred on former occasions,* has finally resulted in the dismissal of all the cases through the absence of the informer's witness. Under the new law, which has been passed since the institution of the proceedings, such a prosecution will not be possible.

A Bill has been brought before the New York Legislature proposing to forbid the renewal of a prescription without the special order of the prescriber, but there does not appear much probability of its passing. The subject was to come on for discussion before the American Medical Association at its annual meeting in May at San Francisco. In reference to this subject, the *American Journal of Pharmacy* states that in Philadelphia several physicians have tested it practically by having on their prescription-blanks a notice that the apothecary is to retain the prescription, but not to renew it without a special order. This plan has, however, been found to be impracticable, and it is believed that the physicians have discontinued the use of these forms.

Nature reports that among other South American districts on the point of being re-worked are the Cinnabar mines of Santa Barbara in Huancavolico, in Peru, gold and silver mines in Cauca, and copper mines in Doepar, in Colombia or New Granada.

We learn from the *Journal of the Society of Arts* that a new fibre, obtained from the bark of the mulberry tree, has been produced by Mr. G. B. Marasi. It is expected that the new material will answer almost all the purposes for which hemp and flax are employed.

We read in the *Athenæum*, that a native amorphous sulphide of mercury has recently been collected in Lake County, California. Its composition is—sulphur, 13·82; mercury, 85·79. It is proposed to call this new mineral metacinnabarite.

Transactions of the Pharmaceutical Society.

EXAMINATION IN EDINBURGH.

May 30th, 1871.

Present—Messrs. Ainslie, Aitken, Baildon, Brown, Buchanan, Kemp, Young and Mackay (Secretary).

Fourteen Candidates were examined, viz. four Minor, four Modified, and six Preliminary; the following ten passed, and were declared to be duly qualified to be registered:—

MINOR (as Chemists and Druggists).

*Fingland, William, jun.	Thornhill.
Black, James	Markinch.
Beaton, William	Fraserburgh.

MODIFIED (as Chemists and Druggists).

Gavin, John	Manchester.
Ramsden, William	Fallowfield.
Richardson, Thomas James	Carlisle.

FIRST, or PRELIMINARY (as Apprentices or Students).

Chalmers, George	Edinburgh.
Gowans, James	Edinburgh.
Equal { Brown, James Macdonald	Dunfermline.
Equal { Paterson, Alexander Clarkson	Edinburgh.

The above names are arranged in order of merit.

LOCAL SECRETARIES, 1871–72.†

Aberdare	Evans, Thomas Whitty.
Aberdeen	Davidson, Charles.
Abingdon	Smith, William.
Altrincham	Holt, William Henry.
Andover	Madgwick, William B.
Ashby-de-la-Zouch	Johnson, Samuel E.
Ashton-under-Lyne	Bostock, William.
Aylesbury	Turner, John.
Banbury	Beesley, Thomas.
Banff	Ellis, Bartlet.
Barnet	Huggins, George Thomas.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The Monthly General Meeting was held on Friday, May 12th; Mr. TOWNSEND in the chair.

The HON. SEC. reported the receipt from Joseph Ince, Esq., of two additional batches of prescriptions collected and forwarded by him for the purpose of rendering more complete the 'Book of Prescriptions' already presented to the Association.

The following letter was then read from the President, Mr. STODDART:—

"Dear Mr. Schacht,—I am sorry to say that I am prevented joining you this evening. I have sent a specimen of that curious substance metachloral, which has been mentioned by Dr. Richardson as a new hypnotic. Although isomeric with soluble chloral, it is perfectly insoluble in ether, water, and alcohol. Like common chloral, it is convertible into trichloracetic acid; and when treated with an alkali is also converted into chloroform and an alkaline formeate. It, however, differs by not being altered by hydrochloric acid and chlorate of potash.

"When common chloral is kept for some time, it changes spontaneously into the insoluble metachloral. It is more easily prepared by adding sulphuric acid to chloral hydrate, when, after standing for seven or eight hours, the metachloral separates, and may be washed with water and alcohol. The chloral becomes converted into metachloral and chloralide:—

$$\underset{\text{Chloral.}}{3\,C_2HCl_3O} = \underset{\text{Chloralide.}}{C_5H_2Cl_6O_3} + \underset{\text{Chloroform.}}{CHCl_3}.$$

the remaining chloral becoming metachloral, but unchanged as to its chemical composition.

"I have sent the specimen in water, to show its complete insolubility. On drying it and heating it to 180° C., it immediately becomes ordinary soluble chloral.

"Yours very truly,

"W. WALTER STODDART."

Mr. SCHACHT then introduced the subject of the Liquor Ferri Perchloridi Fortior and the Tincture of the British Pharmacopœia. He detailed a series of experiments, made with a view to explain the cause of the occasional change which occurs in the latter, and showed it was due to a want of sufficient chlorine in the mixture. He explained the liability to this deficiency by pointing out that the quantity of nitric acid ordered in the Pharmacopœia preparation was more than sufficient for the conversion of the iron into the condition of perchloride, and that exactly to that extent was the liability of failure, inasmuch as all excess of nitric acid went to the production of aqua regia with the free hydrochloric acid in the preparation, and thus necessarily the chlorine was lost during the subsequent evaporation. He recommended that the nitric acid be added gradually to the hot acid solution of the ferrous chloride, and only in sufficient quantity to bring about its conversion into *per*chloride, a change that is very distinctly indicated by the sudden evolution of red fumes. He believed that, attention being paid to this point in the manufacture of the liquor, the Tinctura Ferri Perchloridi of the B. P. was a better preparation than the old Tr. Ferri Sesquichlor., inasmuch as pure iron wire was more easily procured than pure peroxide of iron. This opinion was founded upon the examination of samples of the two preparations made both by himself and by other pharmacists.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

A Meeting of this Society was held on Tuesday, April 18; Professor PROCTER presided.

Professor PARRISH read a paper on Beef Extracts in Combination,* and exhibited specimens of several fluid preparations made with and without treatment for the separation of gelatine, all containing glycerine as an antiseptic ingredient. He also showed some bottles of Fleisch Extract Syrup, imported several years ago from Frankfort-on-the-Main, the contents of which had become completely solidified.

In view of the suggestion to precipitate the gelatine by means of tannin from the beef extracts of commerce, Professor Procter queried whether the animal alkaloids might not also be precipitated by tannin.

Professor MAISCH said that the Liebig Company's Extract of Meat, and some other kinds made by Liebig's formula, were free from gelatine, and would furnish fluid extracts without the necessity of resorting to the process of clarifying.

Professor PARRISH remarked that he had intended to prepare some of a similar preparation from Liebig's Extract, and would do so, and embody the result in his paper. On motion, the paper was referred for publication.

Professor PARRISH exhibited specimens of several farinaceous materials prepared by the Nutrio Manufacturing Company for domestic use and for infants' food. These were all made from wheat which had been heated to nearly 300° F., by which it loses from 10 to nearly 20 per cent. of moisture, and the starch is partially converted into dextrine and sugar. The Company is working under patents which apply in part to the apparatus for the application and regulation of the temperature. One of the chief advantages to be obtained by the extension of this branch of manufacture will be the cheapening of infants' food, now so extensively imported.

A general discussion followed on the process for making Ferrated Elixir of Bark, and the practicability of separating the tannin by hydrated peroxide of iron, the experience of members differing in regard to this.

Mr. M'INTYRE stated that if Calisaya bark is treated with a very dilute alcoholic menstruum, and the tincture then mixed with the hydrated oxide, it would cease to blacken with soluble salts of iron. He stated that he used pyrophosphate of iron as the principal salt in the elixir, and overcame the green tint by a small addition of solution of citrate of iron. He had also diluted the officinal fluid extract of cinchona with good success, instead of starting with the bark itself. He had found the solution of chloride of iron convenient for precipitating the hydrated oxide with ammonia, on account of the great facility of washing out the very soluble muriate of ammonia from the magma.

Professor MAISCH expressed his preference for the Cinchona alkaloids in making this elixir, and stated his conviction that few, if any, of the principal manufacturers used the bark itself, or even the alkaloids, in sufficient proportion to impart much of the tonic property of Cinchona. He stated the proportion of his elixir as follows, using a chinoidin, which contains much quinia and quinidia, 90 grains to O viiiss, $9\frac{1}{2}$ grains of pyrophosphate are contained in each fluid ounce.

A general discussion followed as to the propriety of preparing elixirs to meet the popular demand, or to fill the prescriptions of physicians. Professor Maisch's custom is to make all such as are required in the course of his business, and to decline prescriptions which call for special proprietary preparations. Professor Procter prefers sending to the physician for the formula in all cases in which there is uncertainty as to the composition designed, and dispensing such as are well known. Professor Parrish's practice is to originate a formula in any

* See p. 985.

case in which there is none published, taking into account the proper doses and pharmaceutical requirements of the ingredients, but in no case selling one of his own where another is evidently intended to be prescribed.

Mr. GAILARD exhibited a specimen of Whitman's Cacao Butter, of fine quality, used by him in making suppositories.

Professor MAISCH called attention to the fact that the fusing-point of this oil is generally stated to be at about 90° F.,* while common experience shows that suppositories made with it, without admixture, will retain their shape reasonably well throughout the hot summers of the United States.

The preparation of suppositories being under discussion, the method of preparing them without fusion was adverted to.

Professor PROCTER stated that he had practised that method on their first introduction, but noticed a difference in the facility of manipulating them according to the temperature of the hands of different persons; while some could form a suppository without inconvenient fusion, others would have the mass become too soft to handle.

Professor Procter exhibited the remains of the retort, the explosion of which killed the late Ferris Bringhurst, together with the curved piece of iron taken from his brain, measuring about $1\frac{1}{2}$ inches in length by about 1 inch in width by $\frac{1}{2}$ inch in thickness.

Professor MAISCH gave the result of his analysis of several samples of assafœtida taken by the drug inspector of the port from different cases and from different parts of the mass, with the following result:—

	No. 1.	No. 2.	No. 11.	No. 18.	No. 20.
Oleoresin	34·25	41·47	61·80	37·86	28·88
Alcoholic resin	2·23	2·42	1·13	1·62	1·20
Total resin and vol. oil	36·48	43·89	62·93	39·48	30·08
Impurities	57·50	44·01	15·20	51·70	62·09
Gum moisture and loss	6·02	12·10	21·87	8·82	7·83
	100·00	100·00	100·00	100·00	100·00

These were samples of amygdaloid assafœtida which a year ago was rejected by the purchaser as adulterated, he claiming that good assafœtida should be entirely free from sulphate of lime. The impurities in the above instance consist of gypsum and vegetable fragments, as always met with in the resinous matter agglutinating the tears.

MASSACHUSETTS COLLEGE OF PHARMACY.

The Third Annual "Commencement" of the Massachusetts College of Pharmacy was held in Boston, on May 18th. The President, Mr. S. C. COLCORD, in his opening address, said that the students were from thirty to forty in number, with three professors. The Institution suffered from the want of suitable rooms, and at present he thought apothecaries did not take sufficient interest in it, but he hoped the time would come when the College would compare well with that at Philadelphia.

Professor J. BABCOCK then read a portion of two selected theses by members of the graduating class, on "Citrate of Iron and Quinine," by Mr. Beale, and "Capsicum, with Assays of its Commercial Powder," by Mr. Drury. The reading of the theses was supplemented by some remarks upon the importance of assays in discovering adulterations in drugs. A valuable hydrometer was then presented to Mr. Drury for proficiency in his studies.

A valedictory address was delivered by Professor G. F. H. MARKOE. He spoke of the new and enlarged field of action upon which, in the enjoyment of their professional rights, the students were about to enter. As pharmaceutists, he said, they must still continue students, especially of chemistry and botany. By devoting their leisure hours to the study of science, they would ennoble their characters and elevate their profession. They should look well to the details of their art, bearing in mind that what was worth doing at all was worth doing well. The pharmacist should carefully avoid invading the domain of medicine. The professions should be kept carefully distinct. Either one affords scope for the best abilities, and there is no excuse for the practice of both by the same person. He exhorted the graduates to remember the importance of their duties and acquit themselves like men.

The Rev. J. M. MANNING then delivered an address. The subject of pharmacy, he said, was one in which all people were interested, and there were some considerations in respect to it which clergymen, although not familiar with the science, might enforce. As Shylock said of the Jews, so it is with clergymen, if you poisoned them they died. The quality and preparation of medicines were of the utmost importance, as blunders and mistakes by apothecaries could not be risked. Lawyers might sometimes, after a case had been lost, seek redress for their clients in a higher court, and clergymen could restate their doctrines if in one Sunday's sermon they had been a little top-heavy, but there was no chance for a second experiment with the apothecary. He ought also to know how to stock his shelves and to stand between the public and the importers of drugs. Adulterations in articles of food might be endured occasionally, but it was necessary that the pharmacist should be ever ready and able to protect the public against harmful mixtures. Such knowledge and skill being required, the next question was how to prepare men for the profession. He did not think that men who were preoccupied or were enthusiasts on any subject were fit to be pharmacists. Keenness of touch, delicate eyesight, a nice sense of smell, and an exquisite perception by taste were necessary for the skilful performance of his duties. No one should be allowed to attempt practising until he was acquainted with every detail and item of his duties; therefore, the College of Pharmacy was indispensable, and he was surprised that no one had yet thought of endowing such an institution in Boston. As to the question whether pharmacy should be regarded as a trade or a profession, the point he made was that it did not make so much difference what it was called, provided the work was honestly and well done. Just in proportion as they maintained their integrity the calling would be elevated. He also thought that the pharmacist could not be too careful in entering the inviting field of dealing in patent medicines.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY .. ...*Royal Medical and Chirurgical Society*, at
June 13. 8.30 P.M.
Photographic Society, at 8 P.M.

WEDNESDAY ...*Microscopical Society*, at 8 P.M.

THURSDAY ......*Royal Society*, at 8.30 P.M.
June 15. *Chemical Society*, at 8 P.M. — "An Experimental Inquiry as to the Action of Electricity on Oxygen." By Sir B. C. Brodie.
Linnean Society, at 8 P.M.

FRIDAY ....*Society of Arts*, at 8 P.M.—Annual Conversazione at the South Kensington Museum.
June 16. *Royal Botanic Society*, at 4 P.M.—"Economic Botany." By Professor Bentley.

The following journals have been received:—The 'British Medical Journal,' June 3; the 'Medical Times and Gazette,' June 3; the 'Lancet,' June 3; the 'Medical Press and Circular,' June 7; 'Nature,' June 1; the 'Chemical News,' June 3; 'Gardeners' Chronicle,' June 3; 'Journal of the Society of Arts,' June 3; the 'Grocer,' June 3; 'Produce Markets Review,' June 3; the 'English Mechanic,' June 3; 'Proceedings of the Royal Institution;' 'Journal of Materia Medica' for May.

* Watts' 'Dictionary of Chemistry' gives 30° C. (86° F.)

Parliamentary and Law Proceedings.

Court of Queen's Bench, Westminster, *5th June.*

Ex parte Whisken.

This was an application on the part of a chemist and druggist, at Welshpool, for a *mandamus* to compel the Pharmaceutical Society to restore his name to the Register. It was alleged that he had a right to be registered, and the applicant made affidavit that previous to, and at the time of the passing of the Pharmacy Act, 1868, he kept an open shop for the making up of medicines.

The Court granted a rule *nisi.*

The applicant in this case had been sued for penalties, and the case was to come on for trial in the Welshpool County Court on Thursday, June 8.

In due course the whole case will be submitted to the Court.

Central Criminal Court, *6th June.*

Robbery of Saffron.

William Hall, warehouseman; John Adams, labourer; and George Robinson, chemist, were charged with feloniously breaking and entering the warehouse of Charles Brumleu, and stealing 200 lb. weight of saffron, value £250, his property.

The prosecutor is a drug merchant. On the night of the 17th April, a warehouse in Billiter Street, belonging to him, was broken into, and a large quantity of saffron stolen. When the prisoners were taken into custody, it was found that they had been dealing with the stolen property immediately after the robbery, and offering it for sale at prices far below its real value.

The jury returned a verdict of feloniously receiving against Hale, and acquitted the other two prisoners, believing that they had acted innocently under the direction of Hale. The Recorder sentenced Hale to eighteen months' imprisonment with hard labour.

Alfred Hughes, who carried on the business of a chemist in the Hackney Road, was also charged with being implicated in the transaction, but while in custody at the police station he attempted to commit suicide by cutting his throat, and has since died.

Attempted Suicide by Vermin Killer.

On Wednesday, May 17, the wife of a pensioner living at Freston, in Suffolk, made a determined attempt to commit suicide, having, while taking her tea, swallowed a large quantity of Battle's Vermin Killer. The woman became very ill, and symptoms of poison being very evident, medical assistance was obtained. She is likely to recover.

Suicide by Arsenic.

An inquest was held at Bethnal Green on Tuesday, June 6, on the body of William Perry, who had died from the effects of arsenical poisoning. Deceased was a carman out of work, and had lately been in a very desponding state. He had been selling arsenic to chance customers recently, and his wife believed he had stolen it. He told her that he was afraid the police would take him up, and the same night he poisoned himself with some of it. A card, with an address in the City Road, was found, and on inquiries being instituted, the deceased was stated to be an agent to a shop engaged to sell arsenic and other drugs. Mrs. Jackson, the owner of the shop, said that she had in her possession 28 lb. of arsenic from the time of the death of her husband seventeen years ago. She expressed great surprise when told that she was liable to pay a fine. The jury returned a verdict of "Suicide while of unsound mind," and the coroner ordered the police to take the case in hand.—*Standard.*

HOUSE OF COMMONS.

Adulteration of Food, Drugs, etc., Bill.—*Thursday, June 1st.*—The order for committing the Adulteration of Food, Drugs, etc., Bill was read and discharged, and the Bill withdrawn.

In answer to a question concerning the adulteration of tea, put by Lord E. Cecil on Friday, the Chancellor of the Exchequer said no regulations could be made to require custom-house officers to detain tea suspected of adulteration under the present law, neither would he take upon himself to recommend the enactment of a law to provide for making such regulations, because such a course would render the customs more unpopular than they were, and would not prevent adulteration by the retailer.

Weights and Measures.—*Friday, 2nd June.*—In answer to Mr. Read, Mr. Chichester Fortescue said he had hoped to bring in a Bill dealing with the whole subject of weights and measures this session, but in the present state of public business he did not see a prospect of securing the attention of the House to so complicated a subject. He added, that neither the Select Committee of 1862, nor the Royal Standards Commission, recommended the compulsory introduction of the metric system; the Royal Commission, however, recommended its permissive introduction.

Obituary.

DR. JAMES WATSON.

Medicine has lost an able practitioner, and Glasgow a valuable citizen, in Dr. James Watson, who died on the 30th ult. The deceased gentleman, after an unusually thorough curriculum of study, was admitted a Fellow of the Faculty of Physicians and Surgeons in 1810. In 1842, he was appointed one of the physicians to the Royal Infirmary and to the Fever Hospital in Clyde Street. He was three times elected President of the Faculty of Physicians and Surgeons, by whom he was fondly termed the "Father of the Faculty," on the ground, not only of his seniority, but of the paternal interest he took in the welfare of the Corporation. The Faculty, as a further mark of the esteem in which they held him, hung his portrait in their Hall, and founded the prize which bears his name. No department of medicine, whether in its diagnostic or in its pharmaceutical aspect, escaped his intelligent recognition; and in his capacity as member of the General Medical Council of the United Kingdom he did valuable service in elevating the standard of preliminary education for all aspirants to professional practice.

BOOKS RECEIVED.

Companion to the Last Edition of the British Pharmacopœia, comparing the Strength of its various Preparations with those of the London, Edinburgh, Dublin, United States and other Foreign Pharmacopœias, with Practical Hints on Prescribing. By Peter Squire, F.L.S. Eighth Edition. London: J. and A. Churchill. 1871.

Contributions towards the Materia Medica and Natural History of China, for the Use of Medical Missionaries and Native Medical Students. By Frederick Porter Smith, M.B. London, Medical Missionary in Central China. Shanghai: American Presbyterian Mission Press. London: Trübner and Co., 60, Paternoster Row. 1871.

On the Curability of Cancer and its Medical Treatment without Surgical Operation. By Dr. G. von Schmitt. London: Wyman and Sons. 1871.

Notes and Queries.

**** In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[228.]—SYRUPUS TONICUS.—It was not till I read in a recent Journal Mr. Woolley's reply to query 228 that I was aware the name "tonic syrup" (originated by myself some five or six years since) had passed the limits of this town. As, however, it appears to have done so, I will trespass on your space with a brief explanation of its origin and the formula for the same.

About the time indicated above, a physician suggested to me that the formula for syr. ferri et quinæ et strychniæ phosph. might probably be altered with advantage, some of his patients having complained of its acidity or extreme bitterness, others of its tendency to change before they had taken the quantity prescribed. With this view I made several experiments, resulting in the adoption of the following formula:—

℞. Ferri Sulph. ʒv
Sodæ Phosph. ʒv
Sodæ Acetat. ʒj
Quinæ Sulph. gr. 192
Liq. Ammoniæ q. s.
Acid. Sulph. Dil. q. s.
Aquæ Dest. q. s.
Strychniæ gr. vj
Acid. Phosph. Dil. ℥x
Sacch. Alb. ℥xx
Aq. Aurantii ℥iv.

Manipulate as in the original formula.

The points of difference are, the use of sodæ acet. with the phosph. in precipitating the iron, diminution in the quantity of acid. phosph. and increase of sugar and addition of aq. aurantii. The proportions of iron, quinine and strychnine are the same as in Easton's syrup. But it became desirable to distinguish between the two (many medical men adhering to the old form). The name tonic syrup seemed suitable and short, in the same way that "chemical food" is used to indicate Parrish's syrup. This syrup is more pleasant to take, and its keeping qualities enhanced, but I still find it desirable to preserve it in small bottles (2 or 4 oz.), well stoppered, quite full and in the dark.—CHARLES SYMES, *York Place, Birkenhead.*

[236.]—BROMIDE OF POTASSIUM.—I am quite disposed to agree with the remarks made by ED. PHARM. JOURN. I have known cases of ʒss to ʒiss ordered for a dose.—W. C. H.

BORAX AND BLACKBEETLES.—Two closets in different rooms in my business premises were infested with this pest. Every likely remedy had been tried, including brushing over their haunts with a strong solution of corrosive sublimate, but in vain. I accidentally saw from an American source that borax was a cure. I tried it by sprinkling it freely in these closets, and where formerly scores could have been seen at any time, not one can now be found, and I concluded they were poisoned. A few days since, however, finding some in a cask, I had them caught and put into a box with some borax. It did not kill them; but, for my part, I am quite contented that, whether dead or alive, they have quite disappeared.—H. C. B.

[256.]—LIQUID COCHINEAL.—I should feel obliged by your asking for a recipe for liquid cochineal?—TOL PEDN PENWITH.

[*** Several formulæ have been given in the Journal, though it appears there is still a want of one for a preparation that will keep well.—ED. PHARM. JOURN.]

[257.]—GINGER BEER POWDER.—*H. B.* would be glad of a formula for making ginger beer powder, sufficient for two gallons in a packet.

[258.]—ESSENTIAL OILS OF MYRRH AND WAX.—Can any of your readers inform me, where in London or elsewhere, I can meet with the essential oils of myrrh and wax? I have tried everywhere, but without success.—A. S.

[*** We are informed that Messrs. Trepte and Ferko, of Leipzig, in their long list of essential oils, offer "myrrhenöl ächt." By oil of wax, it is presumed that the empyreumatic oil of wax, the preparation of which is described in many old books (as Ph. Lond. 1721), is intended, but it is not a thing to be found in the shops.—ED. PHARM. JOURN.].

[259.]—DRYING SALVE.—Can any one give me a good form for a drying salve for cows?—UNGUENTUM.

[*** Probably the information would be found in a work on veterinary pharmacy.—ED. PHARM. JOURN.]

[260.]—PASTILLES GUIMAUVES.—*Z. and Y.* is desirous of obtaining a formula for preparing pastilles guimauves.

LOCAL APPLICATIONS IN SMALL-POX.—At a recent meeting of the Société de Thérapeutique, M. Deliou stated that the plan which he had found to succeed best was the application of a mixture of collodion and castor oil, with the addition of 1-100th of bichloride of mercury.—*Practitioner.*

GANTEINE FOR CLEANING KID GLOVES.—
White Soap 250 parts
Water 155 parts.
Dissolve with heat, cool, and add—
Eau de Jarelle, 165 parts
Solution of Ammonia 10 parts.
The whole to be ground together until a smooth paste is formed. A little of this is rubbed over the glove with a piece of flannel.—*New York Druggists' Circular.*

VANILLA FLAVOUR.—A correspondent of the *New York Druggists' Circular* says that, having tried various methods of extracting all the virtue of the vanilla, he has found none to answer so well as the following:—
Take Vanilla Beans 1 oz.
White Sugar 1 oz.
Triturate in an iron mortar until reduced to a pulpy mass, then pack in a conical glass percolator, and pour on it 8 oz. of neutral sweet spirits, heated by a water-bath in a lightly stoppered bottle to the temperature of 125° F. When this has passed, change the receptacle, and repeat the process with the same quantity of sweet spirits; lastly, mix the percolates.

DUTCH DROPS OR HAARLEM DROPS.—There is a considerable difference in the ingredients and quality of these long-celebrated drops, but the most common preparation, perhaps, is according to the following formula:—
Take Balsam of Turpentine 2 oz.
Oil of Turpentine 10 oz.
Mix. The genuine drops are the residuum of the rectification of oil of turpentine.—*New York Druggists' Circular.*

PRESERVATION OF ERGOT.—Ergot is injured from being eaten by a minute insect of the *Acarus* genus, which appears to have a liking for damaged rye, among, perhaps, many other things to it not less palatable. As it has an aversion, however, to many pungent things, it may be kept away by putting in the vessel that contans the ergot a few drops of the oil of cloves, or a few cloves themselves, or cardamom seeds or camphor. If well dried before corking up, ergot may in this manner be preserved for several years.—*New York Druggists' Circular.*

UTILIZATION OF RESIDUE IN MAKING TINCTURE OF MYRRH.—Mr. E. B. Shuttleworth, the editor of the *Canadian Pharmaceutical Journal*, having noticed the large amount of residue in making tincture of myrrh according to the British Pharmacopœia, was induced to attempt to utilize it. From fifty-two pounds of the residue of percolation, dissolved in boiling water, strained, and allowed to deposit, he obtained twelve gallons of mucilage, forming an excellent substitute for paste, and possessing unlimited keeping qualities. Although scarcely so adhesive as mucilage of gum arabic, this latter property may be obtained by the addition of a little molasses.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Poison Regulations.

Sir,—I beg the favour of your inserting copy of the accompanying correspondence in relation to a letter published in the Journal of June 3rd.

Clifton, June 6th, 1871. Richard W. Giles.

(Copy.)

Clifton, June 3rd, 1871.

Sir,—Permit me to ask what you wish to be understood from your letter in the current No. of the Pharmaceutical Journal, headed "Poison Regulations." Allow me also to direct your attention to a letter in the Journal of May 13th, signed by Mr. Baldock, who seconded the amendment proposed by myself at the Annual Meeting, to which amendment your letter appears to point.

Your reply is requested for the purpose of inserting it in the next No. of the Journal, and I shall therefore feel obliged if you will favour me with it as early as possible.

Your obedient servant,

Barnard S. Proctor, Esq. Richard W. Giles.
Newcastle-on-Tyne.

(Copy.)

Grey Street Newcastle-on-Tyne.

Dear Sir,—I have just received your note, and in reply, all I wish to be understood by my few lines in last No. of Journal is that it is dangerous to have any "tacit understandings;" they are as slippery as ghosts and about as indefinite.

Yours truly,

R. W. Giles, Esq. Barnard S. Proctor.

Sir,—In your last number Mr. Hucklebridge advocates the use of a red band of colour as the simplest and most efficient check against mistakes.

Now as I decidedly differ from him on this point (whilst agreeing with the rest of the letter), it will not perhaps be unfair to endeavour to turn his own illustration against him.

Let me ask now if the lady whose finger had been so very rudely used for a tobacco stopper, had been anxious to guard against the repetition of such a mistake, would she have been more likely to effect this by colouring the top of her finger red, or by wearing two or three rings with sharp points or roughened edges properly placed?

Having written so recently on poison regulations, I should not have troubled you again, only I think the distinction drawn is worthy of consideration.

W. C. H.

Sir,—I have a strong feeling against the "Poison Bottle." I fear that such a bottle becoming familiar in households will be used for general purposes. There is a general reluctance to smashing a bottle of whatever kind, and when the sign of danger becomes familiar it loses its caution. The Poison-Bottle may be used for an innocent medicine (or other contents), and this practice may lead to awful mistakes, because the sign of poison being associated thus with an innocent medicine may lead to the swallowing of poison instead of the innocent medicine, as both may be in the same kind of bottle.

To pay for a bottle or phial, so long as one has a bottle or phial fit for the purpose in hand, is "against the grain," and there is a too common trust in mere remembrance as the reconciliation for departure from strict propriety.

Common beer-bottles are used for furniture oil, and ink (and I know of a mistake of a serious nature caused thereby), and even vitriol, and I have seen a castor-oil bottle used for ardent spirits. I have seen blacking-bottles hardly distinguishable from stone ginger-beer bottles, and, so far as I know, the one bottle was used for both purposes, from the reluctance to pay for the proper bottle.

Suppose a "stingy" man, or a "hard up" man, or an *economical* (!) man, wants something in a bottle, for which bottle he must pay if he have not one. Suppose he has a "poison-bottle," and gets that filled with non-poisonous contents, what is the harm? It is this, that trusting to the familiar use of such a bottle, he may be some day off his guard and use a "poison-bottle," *with poison in it*, believing he is using the innocent stuff.

I believe in a poison-bottle only if it can change its character when the poison is no longer in it, and is so decidedly alarming in appearance, while the poison is in it, that even in the dark its characteristic warning will be FELT.

The nearest approach to such a thing, that I now conceive, is a broad black tape tied round the neck of every bottle containing poison (whether as stock in the shop, or dispensed), and that such tape shall have two long ends hanging down over the bottle. When such a poison-bottle is no longer used for poison the tape can be removed, and the bottle looked upon as a safe bottle. The deliberate removal of the tape will be the surety that the poison also is removed (unless criminality is involved), and the familiar idea of poison also removed, leaving such a symbol with its full terrors when seen.

The accidentally removable "Poison" *label* would not only be there (subject to obliteration), but there would tenaciously remain a peculiar symbol of poison, which only deliberation or design could remove, while, for convenience, when no poison existed, the removal of the tape (impossible by ordinary accident) would restore the washed bottle to a common purpose.

I hold that the symbol of poison should vanish with the poison.

Alfred W. P. Smith.

Edinburgh, May 31st, 1871.

Poisons in Surgeries.

Sir,—Just now as there is a deal of agitation respecting the manner in which chemists store their poisonous preparations, it may not be out of place to say a few words respecting the way in which surgeons keep their preparations.

As a traveller for a provincial wholesale drug house, I have good opportunity for observing the manner in which their preparations are stored in their surgeries.

In the first place, I frequently find the bottles, pots, etc. labelled very illegibly and imperfectly; and as regards their juxtaposition, you will find ext. belladon. and ext. anthem. embracing each other; whilst on the other hand, tinct. opii, liq. ammoniæ and sp. æther. nit. are close companions with lin. belladon., lin. aconit. and tinct. rhei. co., in fact they are jumbled together in hopeless confusion; and when this is coupled with the bits of scribbled paper stuck on by way of apology for a label, I am surprised that fatal mistakes do not occur more frequently than they appear to do.

I do not wish to say one word against our surgeons which they do not deserve, but we know that sometimes "very unfavourable symptoms set in," or perhaps "the fever is increased with wonderful rapidity," or something of that sort.

Lycopodium.

The Benevolent Fund.

Sir,—Much has been written on this subject lately, some of it in a spirit likely to do good, and some with a very different tendency, for I cannot think that the cynical, conceited, dogmatic tone adopted by some correspondents, whose chief aim appears to be to make themselves very prominent in everything,—if not by popularity, then by notoriety,—can elicit any good result.

I fully agree with the sentiments of "*Henricus.*" There are some people who, in these matters, not only "let their right hand know what their left hand doeth," but they seem little pleased if everybody else does not know it too. I am quite willing that they should be gratified, even by having their names embalmed in printer's ink with heavier type than those of their less magnanimous neighbours, if that can be conveniently carried out; but let them be satisfied with their own distinction, and concern themselves less about others. When they ask that the names of others shall be printed in a manner to show that they do not subscribe as much as Mr. Biglittle, I think they are asking what they have no right to ask, and what they would not like others to ask if they were differently concerned. There are many who have not yet subscribed to the Benevolent Fund, and others who have contributed only small sums, simply because they cannot afford to do more, but who are not a whit less generous or well-disposed towards it than some who give a little more, and accompany it with so much ostentation. Few of us can afford to help others much, whatever may be our desires, and therefore let the more prosperous ask their less fortunate brethren for subscriptions with some consideration for their feelings, or they will annoy and disgust many more than they will win to subscribe.

After thus freely expressing my opinion, I will venture to suggest for consideration one small way of increasing the Fund; which is, that instead of free admission to the annual conversazione, a small charge should be made for the tickets —not less than a shilling, and not more than half-a-crown— the money so obtained to be given unreduced to the said fund.

I believe everybody would pay it, not only without grumbling, but with pleasure, knowing the purpose to which it would be applied.

Whether I may be able to attend or not, I will pledge myself always to pay for one if not for two.

If this suggestion is objectionable, possibly it may prompt others to think of some way more acceptable.

I will just add that, notwithstanding the twitting manner in which the words "our active Registrar" are quoted, after some little personal experience of him, I do not think the adjective misapplied, but think it would be well if we all were as "active" in our own business, and as little "active" in that of other people as "our active Registrar." SALT.

Sir,—I am surprised to see a process of intimidation suggested as a means of getting subscribers. This will never do, it must be left to every man's conscience what he can or will give in any work of charity. And as far as my experience goes, I do not believe there are many who can be frightened into liberality.

On the other hand, the Fund certainly has a claim upon every chemist and druggist throughout the land. Let circulars be sent to the local secretaries throughout the country, for distribution. In these circulars let the attention of the trade be solicited to the benefits and requirements of this Institution. Let those who are not members of the Pharmaceutical Society be requested to become so. I do not think the entrance fee unjust or unreasonable (certainly I paid it myself without any scruple). The annual subscription is moderate enough for the advantages conferred in return; especially if exemption from jury service be added, which in all reason and equity ought to be the case.

Some who would not become members, might be induced to be subscribers to the Benevolent.

I am firmly convinced that a great deal might be done in this way, from personal experience during the time I was connected with the United Society.

And another part of my experience is this, that there are few occupations in life where there is a greater likelihood of pecuniary assistance being required by deserving members than in that of a chemist and druggist.

ONE WHO HAS KNOWN THE DRUG TRADE MORE THAN THIRTY YEARS.

PHARMACEUTICAL EXAMINATIONS.

Sir,—In answer to your correspondent of the 20th inst., though I cannot point out the advantages I will endeavour to give him a few of the disadvantages of those who have passed the Major Examination, and also been some few months in the Laboratory studying practical chemistry.

If my memory does not fail me, some few years since, at a special General Meeting of the Society, it was stated that the Council had no intention of again opening the door of admission except by examination. Now, Sir, I and many others took the Council at their word, and after going through the due course of training at Bloomsbury Square, passed the examinations; and how has the Society rewarded us for our simple faith? Our best means of explanation will be to take two fellow-apprentices just free from their bonds, both with £500: the one goes forth as an assistant, and by that means adds a little to his store, whereas the other thirsting after a knowledge of the articles that daily pass through his hands, wends his way towards Bloomsbury Square, where we find him, day after day, ruminating over Fownes, Bentley, Royle, Bowman, etc., and, after months of careful training, passes the Major, and receives a certificate.

We again find our two friends brought face to face, when they wish to commence business; granting them to be both of equal business tact and perseverance, the one who turned his back on the Society is able to buy a very much better business than the Major Associate, but of this he did not complain, and only asked to be left with his knowledge and title to fight the battle for himself; but here steps across his path the foster-mother to whom he had been taught to look up, and who he had fondly hoped would prove the lever that would raise him some little above his non-examined neighbour. She not only folds her arms round his opponent, but gives him a title quite equal to his own, and from which the public cannot distinguish the difference. What we, who have been led to part with our money, ask, or rather demand is, that all who have passed the Major shall have some title which will distinguish them from those who have passed into the Society through another gate, and I would suggest Fellows of the Pharmaceutical College—F.P.C.

Perhaps some may think this picture overdrawn, but I can only tell them I am writing from practical experience.

May 31st, 1871. F. P. C.

Sir,—I cannot agree with your correspondent "*Forward*," that he, having passed the Modified Examination, should be allowed to skip the Preliminary.

I suppose I may infer, that the Modified men are alarmed at the number of examinations they have to undergo. I would suggest, the Council might make the path easier for them in this way, viz. when they have passed the Preliminary, to allow them to go on for the Major.

I do not think that any one should or could attain the title of pharmacist without having knowledge of the kind necessary to pass the Preliminary, so that it would be no hardship, but the reverse to require him to undergo the test previously.

If the Council were to make the Modified an equivalent to the Minor, when the Preliminary is passed, it would remove any cause for grumbling.

There would be no injustice done to those who have passed the Minor, as the Modified men are placed on the same footing with them in other respects already, for which I think the latter gentlemen have cause to be thankful.

Birkenhead, June 5th, 1871. J. H. K.

DRUGGISTS' PRICES.

Sir,—A week or ten days ago I was offered 1*s*. 3*d*. for a ℥xij effervescing mixture and xij carb. soda powder and bottle, but declined; it was an old prescription, but no chemist's name appeared on it. I was informed that it had been dispensed scores of times for 1*s*. in the North.

Peterborough. STEPHEN WILLSON.

Sir,—I know of a retail doctor at the east of London who doles out a child's powder for the low charge of 1*d*. where chemists charge 1½*d*. each, and whose equipage would not disgrace a West-End M.D., with a pair of handsome grey horses and three fine spotted carriage dogs to follow in the rear; and this very same doctor, moreover, is principal agent—"the London depot"—of the wonderful "Elixir of strength."—"it gives strength to the weak and makes the aged forget their infirmities, and restores manhood to the most shattered constitution"—"nervousness more speedily cured by the elixir than by any agency yet discovered."—"N.B. This renowned medicine will keep in all climates; no vessel should proceed to sea without having a supply on board"—"The glory of man is strength"—"Agents: all registered chemists throughout the civilized world"—"Copyright entr. Sta. Hall, April 21, 1865." Trade mark, or words elixir of strength." What medical man of sensibility and education would not say Bosh to this glaring trash? This is a specimen of the degrading trade done by a doctor even in London, as well as Glasgow.

I have troubled you with rather a long "ditty," with hope against hope that it may put shame in the conscience of the accused and teach them to desist from so encroaching and low a scale of trading; which will fully reward your obedient servant with others of his brethren. BO-PEEP.

May 30th, 1871.

Druggists' Prices North of the Tweed.

Sir,—Your correspondent "*R. G. H.*" makes reference in last Saturday's Journal to a retail price list, which, he states, has been drawn up on this side of "the border." I consider it my duty as Secretary to the Glasgow Association to state that so far as that body is concerned, they have had no hand in its compilation; they have not countenanced in any way the dispensing of a one-ounce mixture for fourpence, nor have they suppressed the origin of the list issued by their authority.

James M. Fairlie,
Hon. Sec. Glasgow Chemists' Association.
St. George's Cross, Glasgow, 5th June, 1871.

Sir,—"*R. G. H.*" (Bradford) is quite entitled to sneer at our prices, but we cannot allow him to misrepresent them. He quotes ℥i, ℥iss ℥ij mixtures 4*d.*, 6*d.* and 8*d.* respectively (it should be ℥i, 4*d.* to 6*d.*), and afterwards deducts 2½*d.* for bottles, etc., to estimate how much is left for skilled labour. Will it be believed that immediately above the line he quotes, there stands "all prices exclusive of bottles"? and that ℥i, ℥iss, ℥ij phials are priced 2*d.* each in the same price list.

Edinburgh. A. N.

The Chemists' Club.

Sir,—I was extremely pleased with the suggestion of "*Subscriber*" on the above subject in the Journal, and as he invites the opinions of those interested, I with much pleasure volunteer mine.

I think that if a club were established under the control of our Council, possessing the necessary accommodation for country members visiting the metropolis, for students coming up for examinations or attending the laboratories, or for assistants seeking situations, also to be used as a resort for London members and assistants, it would be an advantage, the necessity of which has long been felt, and which would be much appreciated, and would do much, I am sure, to further a feeling of fraternity and good-fellowship among our brother members.

I think a nominal annual subscription, together with a moderate charge for accommodation, would be quite a success, and that few indeed of our members, in town or country, would withhold from subscribing to so useful an institution. I hope to hear the opinions of other gentlemen, and that it may be well considered and discussed.

One who would gladly Subscribe.

Inspection of Weights and Measures.

Sir,—It has often occurred to my mind whether chemists and druggists are really liable to be visited by inspectors of weights and measures, and I now beg leave to put forth this question through your valuable Journal, if you will kindly allow me so to do. It does appear by the enclosed old list that there are copies of the imperial standard weights in 8-dram, 4-dram, 2-dram, 1-dram and ½-dram; consequently all using these weights in way of trading are subject to be called upon by these officials; even all dispensing chemists, as well as doctors and surgeons who retail. M. P. S.

A Medley.

℞. Potass. Bicarb. ʒij
Ammon. Carb. ʒss
Liq. Ammon. Acet. ℥j
Sp. Etheris Nitr. ʒiss

M. Capt. partm. 6tam c. ℥ss succ. limon. ter die in statu effervescentia.

The above is the prescriber's usual remedy for coughs and colds, sometimes omitting liq. cinchon., and in one case omitting it, but adding—

Sp. Ammon. Co. ʒiij
Liq. Taraxaci ʒvj.

Highgate. Alf. Marshall.

C. A. Threadgale.—The answer to the question "if the calling of a chemist and druggist is a profession" will depend mainly upon the way in which that calling is pursued. Our correspondent will see some pertinent remarks on the question at page 999.

F. H. W.—(1.) We believe that the rule would be to use the Pharmacopœia preparation. (2.) We are not aware that Mr. Wilson has a preference for any particular aqua mellis.

"*Hydrargyrum.*"—The stain may be removed by heating the button carefully in a glass-tube until the mercury is volatilized.

M. M. L.—You are quite correct in your supposition.

J. Hooge.—One of the best books for preparing for the Minor Examination in the subject mentioned is Garrod's 'Essentials of Materia Medica.' There are also a good work by Scoresby-Jackson, a new edition of which has been published recently, and Farre's Abridgment of Pereira's Materia Medica.

"*Ferment.*"—Pasteur's papers on Fermentation were published in the 'Comptes-Rendus des Séances de l'Académie des Sciences.'

F. Liley.—The temperature would be about 180° F.

"*Cyathus.*"—We have already given, at p. 878, a few receipes similar to those you ask for, but it requires only a small amount of pharmaceutical ingenuity to produce any of the flavouring syrups used for aerated drinks.

C. S.—A precipitate must be produced if the medicine be dispensed according to the prescription, and if there be the proper amount of quinine in the ferro-citrate.

"*Aquila*" had better write to the editor of the *Hairdressers' Chronicle.*

"*Dubitas.*"—If the preparation be kept, it is liable to explode.

A. P. S. (Liverpool).—(1.) We do not know of any authority for preferring one kind to another. There is a considerable difference in the price. (2.) The results obtained appear to be of sufficient interest and importance to justify their being made the subject of a paper, and we shall be glad to open the inquiry by publishing them in the Journal in that form.

"*Amygdala.*"—A solution containing one scruple in one ounce of water will keep at ordinary temperatures.

W. Morgan.—We are obliged for the information, and will place it at the disposal of future inquirers.

A. P. S.—The question has already been asked, but has not yet been answered.

"*Capsicum.*"—Probably because rectified spirit of wine is the better solvent of the active principles.

A. Barron.—(1.) The most trustworthy test for chloral hydrate is the production of chloroform by the action of alkalies upon it, but the method of using the test would depend upon circumstances. (2.) We have noticed the coloration spoken of, but are not aware of the cause. Probably it is due to some slight impurity in the preparation.

S. Maskery.—If the pills were put up in boxes containing more than a dose, we think that the label would be liable.

"*Stucco.*"—The action is due to oxidation of the spirit vapour induced by the spongy platinum and generating sufficient heat to keep the platinum red-hot and evaporate the perfume.

"*Gulielmus.*"—We think the label is liable as referring to a remedy for a disorder, and giving directions for use.

G. W.—Mix seven parts of water with one part of the acid referred to.

H. W. H.—The article mentioned is a proprietary one, and we are therefore unable to give the formula for its preparation.

"*Inquirer.*"—We know of no authorized formula.

"*Alpha.*"—You would probably find the information in a work on perfumery.

G. H. Strickland.—The amount is very small and variable.

Erratum.—In last week's Journal, p. 983, col. 29, line 17 from top, *for* "utmost entire absence" *read* "almost entire absence."

Communications, Letters, etc., have been received from Mr. S. Wilson, Mr. J. H. Kay, Mr. J. Edwards, Mr. E. H. Strickland, Mr. D. Hanbury, Mr. R. Manlove, Report of the Nottingham and Notts Chemists' Association, H., "Spes," "Investigatio," "Minor," "Associate."

NOTE ON HYDROCYANATE OF MORPHIA.

BY PROFESSOR J. M. MAISCH.

Among the descriptions of morphia salts, as furnished by various chemists, the hydrocyanate is not enumerated. In Gmelin's 'Chemistry' some double hydrocyanates are mentioned, but not the simple morphia salt; and, as far as I know, nothing is known of its formation or its properties.

A prescription having been received, calling for 1 grain each of acetate of morphia and cyanide of potassium in a 3-oz. mixture, the separation of needles was observed before the medicine was handed out; they were removed by straining, and found to be a salt of morphia. Although granulated cyanide of potassium was used, it was still possible that this salt might have been impure, and the formation of the crystals due to some impurity.

Pure hydrocyanic acid was therefore neutralized with ammonia, and the aqueous liquid diluted, so that it contained in each fluid drachm 1 grain of pure cyanide of ammonium. This solution was experimented with like the solution of cyanide of potassium. The following contains the results of the experiments thus far obtained:—

1. A neutral solution of a morphia salt, even if diluted to the proportion of 1 : 1500 (1 grain in 3½ oz.), yields with a neutral cyanide a crystalline precipitate consisting of hydrocyanate of morphia.

2. After the crystals have separated, the filtrate, acidulated with nitric acid, yields no precipitate with iodohydrargyrate of potassium; the morphia hydrocyanate, therefore, if soluble at all, dissolves but very sparingly in water.

3. The solubility of the morphia hydrocyanate appears not to be increased by an excess of the precipitant.

4. The precipitate is readily dissolved if the liquid is slightly acidulated by a mineral acid; it is likewise soluble in acetic acid, and for this reason does not appear in a mixture containing syrup of squill.

5. Hydrocyanic acid does not precipitate a neutral solution of morphia.

It is obvious from the foregoing that morphia salts ought not to be prescribed simultaneously with neutral cyanides, except enough acid be added to retain the hydrocyanate of morphia in solution.—*Amer. Journ. Pharmacy.*

LIQUOR PLUMBI SUBACETATIS.

BY STEWART KELLAM, OF GALVESTON, TEXAS.*

As it is of considerable interest to the pharmaceutist to know the strength of the basic acetate of lead of the different Pharmacopœias, I have, in the laboratory of Dr. F. A. Genth, carefully prepared the different samples, and have examined them with reference to their specific gravity, and the amount of oxide of lead which they contain. The materials used for such preparations were first examined qualitatively. The acetate of lead was in thick, stout crystalline masses; the interior brilliant, and only the outside slightly coated with a more basic acetate; it was free from copper, and contained no other impurities.

The litharge, on the contrary, was of far less purity. I have examined six samples from different sources; they all contained carbonic acid and minute traces of silver; two of them also metallic lead, and red oxide of lead; two were contaminated with oxides of iron and copper, with alumina and lime; and the other two showed, besides the impurities mentioned, silicic acid and teroxide of antimony. As it is so very easy to obtain the pure oxide of lead by the calcination of the pure carbonate, it is advisable to prepare always the pure oxide for pharmaceutical preparations. I have prepared my solutions of the subacetate, both with the purest of the examined samples of commercial litharge, and with chemically pure oxide of lead.

1. Prepared according to the Pharmacopœia Badensis:—190 parts of sugar of lead are digested with 222 parts of oxide. I have tried the process by digesting, in a close flask, 12 grms. of acetate of lead with 14 grms. of litharge and 60 c. c. of distilled water for two days. The mixture, after a short time, had assumed a thick, pasty consistence, from the formation of a large percentage of the so-called $\frac{1}{6}$ acetate, and yielded such a small proportion of liquid that further experiments were not made.

2. According to the Prussian Pharmacopœia:—3 parts of acetate of lead are digested in a close flask for one or two days, with one part of litharge and 10 parts of water, and filtering the product after cooling, which then should have a specific gravity of 1·235 to 1·240.

An experiment made with 18 grms. acetate of lead, 6 grms. of litharge and 60 c. c. of water (distilled) gave, after digestion and filtration of the small quantity of undissolved basic acetate, a clear liquid, which, however, after several days, deposited a slight precipitate. The specific gravity was found to be 1·238, and 19·3255 grms. of the liquid gave, when precipitated with sulphuric acid, and after the expulsion of the liberated acetic acid by evaporation, 5·0258 grms. sulphate lead, equal to 19·14 per cent. of oxide of lead.

3. The Bavarian Pharmacopœia takes, for three parts of acetate of lead, one part of litharge and eight parts of water, and boils down the mixture till the liquid has acquired a specific gravity of 1·360. According to Wittstein ('Chemisch-Pharmaceutische Praeparate'), it is easier and better, and yielding the same result, to take only one-half the quantity of water. My experiment was made according to Wittstein, and 18 grms. of acetate of lead, with 6 grms. of oxide of lead, were digested with 33 grms. of water, and, after filtration, gave a clear liquid of 1·376 specific gravity. 12·5856 grms. gave 4·8464 grms. sulphate of lead, equal to 28·34 per cent. of oxide of lead.

4. The Pharmacopœia Gallica uses the same proportions of acetate and oxide of lead as the Bavarian; hence I did not deem it necessary to repeat my experiments with these proportions.

5. The Pharmacopœia Britannica prepares the liquor plumbi subacetatis by taking 5 oz. (avoird.) of acetate of lead, 3½ ounces of litharge, and one imperial pint of distilled water; boils for half an hour, constantly stirring the mixture; filters after cooling, and adds water to make the product 20 ounces. The specific gravity is 1·260.

In my experiment I have taken 20 grms. of acetate of lead, 14 grms. of litharge and 60 grms. of water, and added to the product the required quantity of water to produce 60 grms. of liquid. The specific gravity in my experiment was considerably higher, and found to be 1·353. 18·0218 grms. gave

* An Inaugural Essay upon passing the examination for the degree of Graduate in Pharmacy of the Philadelphia College of Pharmacy.

6·5408 grms. sulphate lead, equal to 26·71 per cent. of oxide of lead.

6. Several experiments were made with the process recommended in the U. S. Pharmacopœia, with commercial litharge as well as with chemically pure oxide of lead, and, for comparison with these, others by using the cold process recommended by M. Nerning.*

1. *Hot process.*—The required specific gravity of the product is 1·267.

A. I boiled for half an hour 16 grms. of acetate of lead with 9·5 grms. of litharge and 64 grms. of distilled water. The product was a clear liquid of 1·265 specific gravity. 9·5588 grms. gave 2·9403 grms. of sulphate of lead, or 22·64 per cent. of oxide of lead.

B. The same proportions of ingredients were used, but c. p. oxide of lead in the place of litharge. The specific gravity of the product was 1·234. 14·2815 grms. gave 3·7053 grms. of sulphate of lead, equal to 19·09 per cent. of oxide of lead.

C. A repetition of the last experiment with a sample of acetate of lead from another source, gave a liquid of 1·230 specific gravity, 11·4528 grms. of which gave 2·9068 grms. sulphate of lead, equal to 18·68 per cent. of oxide of lead.

II. *Cold process.*—The same proportions of the requisite substances were allowed to remain, with frequent agitation, in contact for twenty-four hours, and in experiment *a*, made with litharge, gave a liquid of 1·243 specific gravity, of which 19·3736 grms. gave 5·2476 grms. sulphate of lead, which is equal to 19·93 per cent. of oxide of lead.

B. repeated with c. p. oxide of lead, I obtained a liquid of 1·242 specific gravity, of which 15·2463 grms. gave 4·1196 grms. of sulphate of lead, or 19·88 per cent. of oxide of lead.

C. A third experiment, which was made with acetate of lead from another source, yielded a liquid of 1·220 specific gravity. 13·14 grms. of the same gave 3·23 grms. of sulphate of lead, which represents 18·09 per cent. of oxide of lead.

From these experiments it will be seen that the liquores plumbi subacetatis obtained by the different Pharmacopœias yield very different products, but also that the same process gave products of not exactly the same composition; and as always the same care has been used in each case, I cannot account for differences of nearly 2 per cent. in the amount of oxide of lead (as has been found between No. 6, II A. and C.), otherwise than that the very low temperature at the time of the preparation of *C.* is the cause of this and other discrepancies.

As a general observation I will add, that the preparations made in the cold appear to keep better than those obtained by boiling, the latter more readily depositing basic salts.—*Amer. Journ. Pharmacy.*

* Pharm. Journ. July 9th, 1870, from *Journ. de Pharmacie et de Chimie.*

NOTES ON BIRD OILS.

BY P. L. SIMMONDS.

Among the animal oils or fats, that of birds has been the least investigated, probably because it is so seldom met with in commerce, and yet there are some quarters where various kinds have economic and medicinal uses. Goose grease is perhaps the only one which with us has a domestic reputation as an emollient for chapped hands, etc. As Mr. Stanford has recently drawn attention to the fulmar oil in the Journal, a few notes as to the uses and commerce in other oils or fats from birds may probably lead to further investigations and a careful examination of any useful properties they may possess.

The Penguin (*Diomedia chilensis*) in the Falkland Islands is chiefly sought after for its oil, deriving its name from its pinguidity or excessive fatness. On the islands of the Falkland group these birds are found in millions, and schooners, with a gang of twelve or fifteen men, go there solely for boiling down the oil of the birds. The fat of eleven birds skimmed gives about one gallon of oil, and each schooner or gang of men will return to Stanley, after a month or six weeks' campaign, with from 25,000 to 30,000 gallons of oil. This oil, which comes chiefly to London, is used, I believe, for currying leather only. I have sent Mr. Stanford and the museum of the Society specimens of this oil. It varies in colour according to the time it has been boiled.

Another bird oil largely sought for in the islands of Bass's Straits and New Zealand, is from what is called locally the mutton bird (*Procellaria obscura*). Large quantities of oil are obtained from the young birds. The body is pressed and the oil runs from the mouth, each bird yielding about half a gill. The oil is reputed to possess considerable virtue as a liniment in cases of rheumatism. The fat, when clean, is pure white and looks like goose fat, but the taste is rather oily; however, it may be used for a good many purposes other than for food. It burns very well in small, shallow tin lamps, which get warmed by the light and melt the fat.

Father Labat (Nouv. Voy. tome vi. p. 395) speaks of the virtues of the grease or fat of the frigate bird. It is said to be an admirable specific in the sciatica, and in numbness of the limbs and other ailments arising from a want of circulation. The grease is to be heated, and while it is on the fire, the parts affected are to be well rubbed and chafed in order to open the pores, and some good brandy or spirits of wine are to be mixed with the fat immediately before it is applied. A piece of blotting-paper steeped in this mixture may be laid on the part, with compresses and a bandage to keep it in its place.

Mother Carey's chickens (*Procellaria pelagica*) are killed in quantities at the Western Islands for their oil. They are so plump that the islanders merely draw a candle-wick through the body, and it becomes so saturated with the liquid fat as to form a lamp without further process.

Ostrich fat has much local repute. The first care of the sportsman after securing his bird, is to remove the skin, so as to preserve the feathers uninjured; the next is to melt down the fat and pour it into bags formed out of the skin of the thigh and leg, strongly tied at the lower end. The grease of an ostrich in good condition fills both its legs, and as it brings three times the price of common butter, it is considered no despicable part of the game. It is not only eaten with bread and used in the preparation of kooskoos and other articles of food, but the Arabs reckon it a valuable remedy in various maladies. In rheumatic attacks, for instance, they rub it on the part affected till it penetrates thoroughly; then lay the patient in the burning sand, with his head carefully protected. A profuse perspiration comes on, and the cure is complete. In bilious disorders, the grease is slightly warmed, mixed with salt and administered as a potion. It acts thus as a powerful aperient, and causes great emaciation for the time; but, according to the Arabs, the patient, having thus been relieved from all the bad humours in his body, afterwards acquires robust health and his sight becomes singularly good.

The grease of the emu, or Australian ostrich (*Dromaius Novæ-Hollandiæ*) is held in great esteem by both colonists and natives as a cure of bruises and rheumatism. The skin of the bird produces six or seven quarts of a clear, beautiful, bright yellow inodorous oil. The method of obtaining the oil is to pluck the feathers, cut the skin into pieces and boil it.

At one of the Madras Industrial Exhibitions, oil from peacocks' fat in Tinnevelly was shown, but it was not stated to what use it was applied.

In South America, in the immense cavern of Guacharo, in the government of Cumana, Humboldt describes an extensive pursuit carried on of a bird for its fat by the Indians. This cave is peopled by millions of nocturnal birds (*Steatornis caripensis*), a new species of the *Caprimulgis* of Linnæus. About midsummer the young birds are slaughtered by thousands. The peritonæum is found loaded with fat, and a layer of the same substance reaches from the abdomen to the vent, forming a kind of cushion between the hind legs. Humboldt remarks that this quantity of fat in frugivorous animals not exposed to the light, and exerting but little muscular motion, brings to mind what has been long observed in the fattening of geese and oxen. It is well known, he adds, how favourable darkness and repose are to this process. The fat of the young birds is melted in clay pots over a brushwood fire. It is half liquid, transparent, inodorous, and so pure that it will keep above a year without turning rancid.*

The passenger pigeons (*Columba migratoria*) of North America are another source of oil. They migrate at certain seasons in millions, and the Indians, watching their roosting-places in the forests, knock them on the head in the night and bring them away by thousands. The Indians preserve the oil or fat, which they use instead of butter. There was formerly scarcely any little Indian village in the interior where a hundred gallons of this oil might not at any time be purchased. The squabs, or young pigeons, when taken in quantity, are also melted down by the settlers as a substitute for butter or lard.

AJWAN OR OMUM.

(*Ptychotis ajowan.*)

BY M. C. COOKE, M.A.

One of the drugs included in the new Indian Pharmacopœia, which is unknown in European practice but has doubtless intrinsic merit to recommend it, is the one which heads this notice. The seeds, or more accurately the fruits, of several umbelliferous plants are well known and appreciated, but the Omum has, somehow, escaped regard. It may be that it has no virtues which are not possessed in an equal degree by others, yet a notice and a few observations on its uses will not be altogether out of place.

The vernacular names collected and verified by Mr. Moodeen Sheriff are—*Kamúne-muluki*, Arabic; *Nankhah* and *Zinyan*, Persian; *Ajvayan*, Hindustani; *Ajvan*, Dukhni; *Omam*, Tamul; *Omamu* or *Vamamu*, Telegu; *Ayamodakam* and *Homam*, Malayalim; *Voma*, Canarese; *Ajvain* or *Ajvan*, Bengali; *Vova-sada* and *Vova*, Mahratta; *Ajwan*, Gujerati; *Assamodagun* or *Omam*, Cinghalese; and *Samhum*, Burmese.

The fruits are smaller than caraways or any umbelliferous fruits employed in Europe, and there

Fruits of Ajwan (*Ptychotis ajowan*).

is no record of their ever having been offered for sale in our markets. The plant itself is thus described:—

"Stem erect, dichotomous; leaves few, cut into numerous linear or filiform segments, the uppermost simply pinnate; umbel with 7–9 rays; involucre few-leaved; leaflets linear, entire; fruit strongly ribbed, covered with small blunt tubercles." Figured in the second volume of Wight's 'Icones,' plate 566. Roxburgh says, "This is one of the most useful and at the same time grateful of the umbelliferous tribe. It is much cultivated in Bengal during the cold season. I never saw it wild. The seeds, like those of caraway, have an aromatic smell and warm pungent taste; they are much used by both natives and Europeans for culinary and medicinal uses; they are amongst the smallest of the umbelliferous order, and are to be met with in every market in India."*

Mr. Wood says, in his remarks on this drug,† "I have good reason, indeed, to remember the effects of the omum, for on one occasion, when a boy, I was attacked at midnight with a severe fit of colic (the only severe one I recollect to have ever suffered from), brought on by indulging in fruit. No medical aid was at hand, and the only remedy given me was the omum seed, which I was directed to chew and wash down with water, which was not only followed by speedy but complete relief." And in another part of the same communication he adds, "While at Vizagapatam some few years ago, I remember to have seen, during a pretty sharp outbreak of cholera, the richer classes of the people purchasing the omum water and distributing it wherever required."

By the natives of India, the omum or ajowan is constantly used in all sudden derangements of the *primæ viæ*, such as vomiting, diarrhœa, colic, flatulence, etc.; in the premonitory diarrhœa of cholera, and often in the unmistakable cholera itself; and testimony is not wanting to show that it is sometimes at least as useful a medicine in the earlier

* Roxburgh: 'Flora Indica,' vol. ii. p. 91.

† The 'Madras Quarterly Journal of Medical Science,' Oct. 1862, p. 294.

stages of the last-mentioned disease as many other more costly ones.

In some forms of dyspepsia, in the vomiting, griping, or diarrhœa from errors in diet, in simple flatulence and even tympanites, in faintness and exhaustion, in choleraic diarrhœa, in certain cases of colic and in hysteria, it has been found, even when given alone, pre-eminently useful.

From all that is known of this medicine it appears to combine the stimulant quality of capsicum or mustard, the bitter property of kreata, and the anti-spasmodic virtues of asafœtida.

The seed, or fruit, is one of the forms of administration by the natives; another is in decoction with sundry other aromatics, namely, ginger, sweet flag, galanga, etc., but it is evident this is not a good form. A distilled water, under the names of 'Sison Cordial' and 'Omum Water,' is sold at many of the dispensaries and shops about the country. Another preparation called "Sugar of Omum" is to be had in Madras. It has the appearance of candy, and though probably a little more expensive, is much more efficacious and agreeable than the water. Mr. Lynsdale gives the following directions as to quantity for distillation:—"To one viss (or 3 lb.) of the bruised seed, add six bottles of water and distil over four. In the necks of these bottles will be found the oil, amounting to about ℥ss." The Bengal Pharmacopœia directs two gallons of water to one of the Ajwan, distilling over one gallon.

The Pharmacopœia of India gives the following,—"Take of Ajwain fruit, bruised, twenty ounces, water two gallons; distil a gallon. Dose, from one to two fluid ounces." There is not probably, in the city of Madras and its suburbs, a single Eurasian family who, if they have not some of the omum water at home (and numbers have), have not used it at some time or other, or at least heard of its virtues. And it is not in Madras alone that it is so extensively used by the middle classes of society, but in many of the larger cantonments up-country it is pretty well known. Further, with very few exceptions indeed, the so-called seed of the omum is to be found among the domestic medicines of both Mahomedan and Hindoo families, and is looked upon as the *sine quâ non* of remedies in many affections.

The "sugar of omum" alluded to above is evidently the same as in the Pharmacopœia of India is called *Ajwain-ka-phul*, said to be sold in the bazaars of the Deccan, Scinde, etc., and is prepared in Central India during the cold season. It is also stated to form spontaneously on the surface of the distilled water of Ajwan. Dr. Stenhouse examined and found it to be a Stearopten (see PHARM. JOURN. 1855, Vol. XIV. p. 272).

ON THE PREPARATION OF SUPPOSITORIES.

BY WILLIAM G. EWING.

I have read most of the articles that have appeared in the *Amer. Journ. Pharmacy* for several years upon the subject of suppositories, and have gained many valuable suggestions from Messrs. J. B. Moore, Charles L. Eberle and others; but I have fallen upon a process not alluded to by any of them, that greatly facilitates this tedious, and sometimes very difficult and troublesome class of prescriptions. The plan I have adopted is as follows:—

First, procure a large, coarse tin grater,—such as may be had of any tinner,—and with it grate the cacao butter into a coarse powder, pass through sieve No. 20, and put it into a wide-mouthed bottle ready for use; next, take some pure white wax, grate, sift, bottle, and set it aside in the same manner as above. The fragments that will not pass through the sieve can be melted and grated again after cooling. With these two substances on hand, the prescriptionist is prepared for any formula in the suppository line.

The management of the melting-point of suppositories has been a matter of great difficulty, annoyance and delay, varying as it does with the seasons; but with this grated material we have a ready means of regulating it at will; for if the mass should be too hard,—as in winter,—the addition of a little olive oil will be found advantageous; or, if too soft,—as in summer,—the addition of the grated wax will bring it to the right consistence. In addition to the above ready means of controlling the melting-point, it has the advantage of being much more easily manipulated. For instance, take the following suppository from the U. S. Dispensatory, 13th edition, viz.:—

℞	Tannic Acid	grs.	36
	Benzoated Lard	„	44
	White Wax	„	10
	Oil of Theobroma. . . .	„	90

The directions are to melt the wax and oil of theobroma with a gentle heat and add the tannic acid and benzoated lard, previously rubbed together in a mortar, and mix all the ingredients thoroughly; pour the mixture, while it is still fluid, into suitable moulds of the capacity of 15 grains, or the fluid mixture may be allowed to cool, and then divided into twelve equal parts, each of which shall be made into a conical or other convenient form for a suppository.

The above formula is easily expressed, but not so easily complied with in all cases, owing to the variable nature of the oil of theobroma, and also to the temperature of the season; but, accepting it as it stands, the advantage of the grated wax and cacao butter is very perceptible, since, instead of melting one portion together, and rubbing the other portion in a mortar as prescribed, the whole may be at once mixed and rubbed together in a mortar, forming a plastic mass as easily rolled into lengths and divided as an ordinary pill mass; and each piece formed by the fingers into a conical shape, or, if desirable, pressed into suitable moulds previously dusted with lycopodium, as suggested by Mr. J. B. Moore. The following is a copy of a far more difficult prescription that was brought to me by a patient to be filled one very warm night:—

℞	Carbolic Acid	grs. xxx
	Cacao Butter	℥iss.

Mix and make suppositories No. 10.

Here the prescriptionist is in a dilemma. If the carbolic acid and cacao butter are melted together, they will not solidify on cooling; if wax be melted with the mixture, considerable time is occupied in adjusting the proportions, as it is necessary to test it by allowing portions to cool from time to time, and adding wax by degrees until the proper consistence is attained; meanwhile the carbolic acid is evaporating and the efficacy of the suppositories being impaired. Having the grated materials at hand, and no other resource but to add a sufficiency of wax, it was immediately and easily done by rubbing it in until the proper consistence was attained, the amount of wax required being 70 grains; the prescription was much more quickly dispensed than by any of the usual methods, and as there was no heat employed in the process there could have been no evaporation of the carbolic acid. In the above case, the grated wax and carbolic acid were first well rubbed together and the cacao butter added last.

As no allowance was made for the addition of wax, the size of each suppository was slightly increased (though not materially) and, as each contained the exact proportion of its active ingredient, the design of the prescription was executed. The weight of each suppository might have been left unchanged by omitting enough cacao butter to balance the wax that was added.

It is needless to repeat examples, though many difficult ones might be given from actual experience; it is sufficient to state a few general principles.

When dry substances are prescribed, they should be reduced to fine powders (if not already so), then thoroughly incorporated with the grated cacao butter, and rubbed in a mortar until the mixture becomes a plastic mass easily rolled into lengths, divided and formed into suppositories. Should moist substances, such as extracts or any articles not dry, be prescribed, they may be rubbed first with about an equal bulk of the grated cacao butter, and afterwards readily combined with the remaining ingredients.

As a general rule, all substances used in medicating suppositories must be either in the state of a fine powder or a uniform paste; the prescriptionist must decide upon the more easily attainable state.

The advantages of using the cacao butter in the grated state are numerous. It furnishes the means of easy manipulation, of readily adjusting the melting-point, of avoiding the delay of melting and cooling, and the use of ice which is not always procurable, of thorough and perfect incorporation of its ingredients, of exactness with which the mass may be divided; besides the satisfaction it gives the prescriptionist of *knowing* that no separation nor subsidence of any of its ingredients can possibly take place, which certainly cannot be felt when the substance is *melted* and moulded.—*American Journal of Pharmacy.*

THE CRYSTALLIZATION OF CAMPHOR.

BY R. ROTHER.

The peculiar predilection of camphor for the crystalline form, is one of the petty annoyances inherent to the dispensing department. Insignificant as the objection may seem, it is nevertheless one for which the dispensing pharmaceutist is but too willing to accept a remedy. This difficulty is chiefly experienced with powdered camphor, but the objection, likewise, though in a less obvious degree, applies to the aqueous solution. The most perfect means of pulverizing camphor, although not the most practicable, is undoubtedly the method by precipitation. The trituration with small quantities of chloroform, ether, benzine, and naphtha, has been proposed; but none of these substances possess any advantages over alcohol, which even still is preferable to all. There is no difficulty whatever in pulverizing camphor, the object is to retain it so.

For this purpose it has been suggested to triturate the camphor with small quantities of magnesium carbonate. If this management ensured the pulverulent state indefinitely, the magnesium would often be objectionable. The writer has not tested the process, but was informed by good authority that it is not satisfactory; a similar result is experienced by precipitating the camphor with water from an alcoholic solution, holding the magnesium carbonate in suspension. Other dry substances, as starch, for instance, have been used with equally indifferent success. The writer, feeling the necessity of some alternative, and basing his theory of this crystallization upon the volatility of camphor, applied an ethereal solution of resin with a view of coating the particles with a deposit of resin. The experiment, however, yielded a negative result. The writer, assuming then that a non-volatile solvent might retard the crystallization, employed a small proportion of fixed oil—preferably castor oil. This addition is entirely unobjectionable, and although it does not strictly meet the most sanguine expectation of preventing crystallization, it yet modifies this tendency to such a degree that after a long trial the writer is so thoroughly satisfied with its peculiar advantages that the complete success of the experiment would have been scarcely hailed with more delight. The proportion of castor oil employed is about one part in thirty of camphor, or even less. It is added, together with the alcohol, to the camphor, and the whole triturated to the proper degree of fineness. The great advantage rests in the fact that the crystals of camphor subsequently formed are exceedingly minute, and that the oil entirely removes the very disagreeable adhesiveness and tenacity of the camphor, which becomes so troublesome during the trituration of pure camphor. Camphor containing the oil can be triturated in large or small quantities, without in the least clogging the mortar or pestle. The powder, after keeping even a long time, mixes perfectly and with facility with all the ordinary ingredients with which it is usually combined in prescriptions. The peculiar gumminess has been perfectly removed by the intervention of the oil.

The aqueous solution of camphor is another point at issue. It has been supposed that during cold weather camphor water drops part of its camphor. However, this phenomenon is only apparent. The writer has often been struck by the extraordinary solvent power of very cold water upon camphor, so that during the coldest winter weather the cold water drawn fresh from the hydrant, and having a very low temperature, always yielded the strongest camphor-water, which, when subjected to the warm temperature of the room, deposited camphor abundantly and in weighable quantities, not upon the glass above the liquid, but floating in beautiful crystals in the liquid itself; so much so, that the water was often filtered again before use.

To verify the above conclusion, the writer employed lukewarm water. The camphor was first finely triturated with the aid of alcohol, then with the magnesium carbonate, first rubbed through a coarse sieve, then with a portion of the water, and poured into a capacious bottle; the remainder of the water was then gradually added, and the mixture violently shaken during the intervals, and finally filtered. (This is essentially the writer's manipulation for the aromatic waters.) The bottle containing the filtrate was securely corked and allowed to cool. After six hours a very thin film of crystalline camphor had deposited on the walls of the bottle above the liquid, the latter containing no visible trace, not even floating upon the surface. The liquid was again filtered and exposed to intense cold for a long time, but no more camphor separated, although the liquid possessed the taste of camphor in a marked degree. Therefore, to make camphor-water, free from separated camphor, use lukewarm water, or use water of the ordinary temperature, let it become equalized to the temperature of the room, and, after a repose of twenty-four hours, filter. But to make a supersaturated camphor-water, employ water having a very low temperature.—*The Pharmacist.*

THE CHEMISTRY OF CALICO PRINTING.

BY JAMES BLAIR.

(*Continued from page* 992.)

Pigment Colours.—These consist essentially, first, of the colouring-matter to be printed; secondly, of the fixing material; and thirdly, of the thickening necessary to give the colour consistence, and to prevent the running or spreading of the colour, and so the spoiling of the figure to be printed.

Insoluble Colours.—The principal insoluble colours are—ultramarine, Guignot's green, chromate of lead, prussian blue, brown earths, aniline black and lakes, of the colouring principles of Persian berries, logwood, cochineal, etc. with iron, alumina and oxide of tin.

Soluble Paint Colours.—These are chiefly the Aniline colours, viz. magentas, blues, mauves, violets, green, orange, scarlet and brown.

The Phenol Colours.—Azuline blue, rosolic acid and peonine; these separately, or mixed, furnish most of the required shades.

Aniline black is produced by the action of a salt of copper (the sulphide is generally used) on hydrochlorate of aniline. It is a very intense and fast colour.

Lampblack, digested in strong sulphuric acid and then washed free from acid by cold water, has also been used as a black pigment. A black pigment is also obtained by precipitating a slightly ammoniacal decoction of logwood by a salt of iron, such as the nitrate of iron, and washing the resulting precipitate of hemateate of iron with cold water until free from impurities.

Guignot's green (sesquioxide of chromium) is prepared by heating to dull redness a mixture of three parts of boracic acid and one part of bichromate of potash. The mixture swells and becomes of a very fine green colour. The mass is then lixiviated with water to remove the borate of potash, and the sesquioxide of chromium finely pulverized is ready for use. In the preparation of this colour, too high a pressure, causing fusing of the mass, must be guarded against, as the colour is thereby entirely destroyed, an olive-green gloss being obtained in its place.

Mauve colours are produced by the action of bichromate of potash, hypochlorite of lime and chloride of tin on solutions of salts of aniline.

Magenta.—This name is applied to several of the salts of rosaniline,—the acetate and the hydrochlorate of rosaniline.

Rosaniline $C_{20}H_{19}N_3$ is produced by the action of various oxidizing agents on a mixture of aniline and toluidine. The best result is obtained by heating a mixture of 70 per cent. of toluidine and 30 per cent. of aniline at a temperature of 190° F., until the production of colour is complete. The resulting product is impure arseniate of rosaniline, from solutions of which the rosaniline may be obtained by precipitation by an alkali. Arseniate, acetate and hydrochlorate of rosaniline are soluble in water and alcohol and yield very fine pink colours.

Blue and violet are obtained by heating salts of rosaniline with aniline, and with many of the alcohol radicals, as phenyl, ethyl, methyl, etc., the alcohol radical taking the place of hydrogen.

Amine, or rosolic acid, is produced by heating at 140° 6 parts of carbolic acid, 4 parts of oxalic acid and 3 parts of sulphuric acid. It is soluble in alcohol and yields golden-yellow and orange shades.

Peonine is produced by prolonged heating of aurine with a large excess of ammonia. This colour yields shades of crimson.

These colours, by themselves or mixed, yield most shades required.

For example:—

Pt. Lavender.—Mauve + indigo extract.

„ Drab.—Logwood pulp + $\left(\text{Brown} \left\{ \begin{matrix} \text{yellow pulp} \\ \text{magenta} \end{matrix} \right\} \right)$ buff liquor $\left\{ \begin{matrix} FeOSO_3 \\ PbOA \end{matrix} \right\}$

„ Stone.—The above + ultramarine.

„ Brown.—Berry pulp, magenta, pt. purple.

„ Slate.—Indigo extract, magenta, black pulp.

Thickenings.—Wheat starch, or gum tragacanth.

Fixing Agents.—Blood or egg albumen, dissolved in water at 3 to 6 lb. per gallon, and used = 1 to 2 lb. albumen per gallon of colour; caseine and gluten are also used as fixing agents.

Steam Colours.—In these colours the ingredients are mixed in such a manner that they are soluble when printed, and so penetrate the fibre, but, on being submitted to steam, chemical action takes place and an insoluble colour is formed on the fibre. It is sometimes very difficult to meet this condition, but it is sometimes effected by leaving out an essential ingredient from the colour and preparing the cloth with it previous to printing; indeed, as this preparation is found beneficial to most colours of this class, it is usually adopted, and is called steam prepare.

Steam Prepare.—The goods are padded in a solution of stannate of soda, at $\left\{ \begin{matrix} 11° \\ 5° \\ 3° \end{matrix} \right\}$ Tw., according to the kind of cloth and the colours likely to be printed on it. The cloth is then dried and beamed, after passing through weak acid and washing.

Black.—Logwood liquor, 4½ gallons at 12° + iron liquor, 2 gallons at 12°; starch, 12 lb.; boil and cool, then add iron liquor, 1¼ gallons, at 32°; Fe Cl, 1 quart, at 80°.

Chocolate.—Logwood liquor, 6¾ gallons + starch, 13 lb. + 4 B. B. gum $\left\{ \begin{matrix} \text{3 quarts berry liquor, at 80°} \\ \text{8 lb. alum} \end{matrix} \right\}$ $\left\{ \begin{matrix} \text{8 lb. red prussiate of potash} \\ \text{1½ gallons water.} \end{matrix} \right\}$

U. Red.—Sapan, wood liquor, nitrate of alum, $KOClO_5$, alum, bark liquor, water starch.

R. Blue.— $\left\{ \begin{matrix} \text{Water} \\ \text{Gum} \\ \text{Starch} \end{matrix} \right\}$ $\left\{ \begin{matrix} \text{Tartaric} \\ \text{Oxalic} \end{matrix} \right\}$ $\left\{ \begin{matrix} NH_3Cl \\ \text{Blue pulp} \end{matrix} \right\}$ $\left\{ \begin{matrix} \text{Yellow and red pulp} \\ \text{Concentrated } SO_3. \end{matrix} \right\}$

Green.—Blue + berry liquor + $SnCl_2$, or else + bark liquor.

Lavender.—Logwood, boiled in red liquor + oxalic acid or + red prussiate = purple.

Amber.—Berry liquor with oxide of tin.

Brown.—Catechu, 4 lb.; acetic acid, 2½ pints + $NaOCO_2$, 2 lb., in 1 gallon water; when used, add 1 pint $CuONO_5$, at 102° Tw.

The colours are printed and dried in the same manner as paint colours; and as the after treatment of these two kinds of colours differs much from that of the mordanted colours, we will follow them to completion. The printed goods, whether paints or steams, are loosely reeled, wrapped in a stout blanket and hung up in a strong iron chamber, where they are subjected to a pressure of steam for one hour, which in the case of paints fixes the colour by coagulating the albumen; and, in the case of steams, developes as well as fixes the colours. The goods are then opened out and exposed to the air to cool, washed with water, sometimes slightly soaped and dried. They are then cleared.

CONVERSAZIONE OF THE ROYAL COLLEGE OF PHYSICIANS.

The Royal College of Physicians held a Conversazione on Wednesday evening. The attendance was numerous enough to be almost oppressive; the libraries and the dining room, where refreshments were served, being at one time so full that there was barely standing space. The objects of interest were judiciously selected from a great variety of quarters. Mr. Graves contributed the portraits of the Marquess of Lorne and the Princess Louise, by Mr. Holyoake; Mr. Brudenell Carter, a very fine Japanese cloisonnée enamel; Professor Tennant, a selection of fossils, with diamonds from South Africa, and gold from New Zealand; Dr. Rae, a number of curiosities of the Esquimaux and North Pacific Islanders; while the Autotype Company, Messrs. Salviati and Co., the London Stereoscopic Company, Messrs. Murray and Heath (of Jermyn Street), and Messrs. Power and Lealand were each represented by numerous specimens of their respective arts. In the small library, Mr. Anderson Rose's choice collection of engraved portraits deservedly attracted much attention from those of the company who appreciated art in its application to history; and Mr. Seymour Haden's very fine etchings also received special commendation.

In consequence of the pressure upon our space caused by the legal reports, we are compelled this week to withhold the Correspondence and Reports of Societies.

The Pharmaceutical Journal.

SATURDAY, JUNE 17, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACEUTICAL LEGISLATION.

THE official report of the proceedings of the Council* and our Parliamentary report,† will, this week, be found to contain matter of especial interest and importance. At the Council meeting held on the 7th instant, it was resolved, in furtherance of the decision arrived at by the Society at its Annual Meeting, that the regulations for the keeping, dispensing and selling of poisons, which we have already published,‡ should be forwarded to every Pharmaceutical Chemist and Chemist and Druggist on the register, with the urgent request of the Council for their universal adoption. At the same time a letter of inquiry from Mr. SIMON was answered, informing him that this was to be done at once.

But it has since then become apparent that a Bill to amend the Pharmacy Act of 1868 had already been introduced into the House of Lords, by the LORD PRESIDENT OF THE COUNCIL, acting on behalf of the Privy Council. The purport of this Bill, which will be found printed at p. 1015, is to transfer the power of action in the matter of poison regulations from the Society to the Council, and also to give the Privy Council the power of acting under certain conditions. This Bill was ordered to be printed on the 6th instant. On Monday it was read a second time. On Tuesday it passed through Committee. On Thursday it was read a third time, and passed.

Consequent upon this action of the Privy Council, a special meeting of the Council of the Pharmaceutical Society was summoned on Wednesday, resulting in a resolution—That a Committee be appointed to watch the progress in Parliament of the Bill, and prevent the passing of obnoxious clauses.

It now remains to be seen what ground there may be for the opinion which has been pretty freely expressed to the effect that the pharmacists of this country have not as a class either the power or the influence to command representation in Parliament. It is not now necessary to consider the grounds on which this opinion is based, but there is no question as to the present occasion being an opportunity for showing whether there can be any efficient opposition brought to bear, or whether there may not be good reason for the taunt that the agitation against poison regulations is merely "tall talk" about a "sentimental grievance."

In reference to our article last week, in which we expressed a hope that the action taken by the Society would have been deemed sufficient by the Privy Council, at least for the present, we may just mention that one of the obscurer medical journals endeavours to ridicule our remarks on the subject; but while betraying ignorance of the fact that the Council had acted for the Society, and had acted as its representative, it merely exposes the deficiency of its information, and illustrates the maxim, "*ex nihilo nil fit.*"

* See p. 1013. † See p. 1015. ‡ See p. 949.

RECENT EVENTS AND THE "OUTSIDE" ORGAN.

THE *Chemist and Druggist* for June, while naturally devoting to the "pecuniary principle" the first place, furnishes its readers with a somewhat out of date *résumé* of the election for fourteen members of the Pharmaceutical Council, in the shape of a column of propositions, which are generally so far truisms as to be above criticism. In another place our contemporary deals largely in retrospective potentialities concerning those who "stayed away" from the Annual Meeting; but at the same time shrewdly assumes an air of warning as to the possible consequences of staying away on such an occasion. In a spirit of fairness we abstain from any comment on the prophecy as to the action of Parliament in the matter of Poison Regulations, for it is evident the article was written before any knowledge of the Pharmacy Bill of 1871 had been obtained, and the validity of the prediction hazarded yet remains uncertain.

But the most interesting portion of the *Chemist and Druggist* this month is the Supplement containing an account of the Pharmacy Bill now in the House of Lords, and there the *Chemist and Druggist*, so far does justice to the remarks we have elsewhere made, as to express belief in the passage of the Bill through Parliament, and in the need for active measures if it is to be opposed successfully. We quite agree with this view, and feel equally sure that as the matter now stands, something will be needed much more efficient than editorial buttering of Mr. GLADSTONE.

MULTIPLE VISION.

IN the columns of a scientific contemporary there recently appeared a discussion as to how many different objects it is possible to include in an instantaneous glance of the eye. The performance of any considerable number of experiments to decide this question would possibly result in a certain amount of bewilderment and inability for the time to discriminate between a larger and a smaller quantity.

We would charitably suggest some such condition to account for the propensity shown by the *Lancet*, when referring to some topics, to reverse the generally received axiom that the lesser is included in the greater. We would only just allude to the fact that whenever it refers to the poison question it speaks as if the number of deaths proved to have occurred through the carelessness of pharmacists was a very large one; this might be a matter of opinion depending upon what constitutes a large number.

But some of our contemporary's statements are not open to this explanation. A short time ago it gravely announced in leader type, in reference to infant mortality in France, that "out of every thousand children under a year old, 288, according to Dr. BERTHILLON, perish in the Marne, 295 in the Oise, 307 in Seine-et-Marne, 313 in Yonne, 318 in Seine Inférieure, 319 in Eure, and in the department Eure-et-Loire (dedicated 'aux petits Parisiens'), 370!" And then it naïvely asks, "Is not this an appalling return?" Well, we rather think it is.

As a fitting corollary we add another extract from the *Lancet* last week. "A chemist and druggist at Welshpool, because of some alleged misstatement on his part, had his name removed this year from the Society's Register, with the result of his being repeatedly sued in the Welshpool County Court for penalties as an unregistered vendor of drugs." Now as the "chemist and druggist" with whom the *Lancet* seems to sympathize has only been sued once by the Pharmaceutical Society, and the result of that case was hardly known in London at the time when it is presumed our contemporary went to press, we are compelled to fall back upon some such theory as we have suggested, unless indeed the *Lancet* intends to try its hand with the sporting papers in the prophetic line. But then, will not the fact that the Court of Queen's Bench has since decided that the person in question is not a "chemist and druggist" at all, have some slight effect upon the vaticination?

Mr. BENTHAM, in his recent Presidential Address at the Anniversary Meeting of the Linnean Society, said that the mismatching of specimens had been in botany a fertile cause of the production of false genera and species. The most careful collectors have in good faith transmitted flowers and fruits belonging to different plants as those of one species: the fruits perhaps picked up under a tree from which they were believed to have fallen, or under two trees in the same forest with similar leaves, one in flower, the other in fruit, are supposed to be identical, but in fact not even congeners. Mismatching in the subsequent stages of drying, sorting and distributing of specimens is also very frequent. Another cause is that collectors instead of noting down any memoranda at the time, and attaching them immediately to the specimens, or identifying them by numbers, too often trust to their memory when finally packing up their specimens. So long as a hasty glance at a specimen and the memoranda attached to it is substituted for reasoning by analogy, these errors are not discovered. Till recently the genus *Magallana*, of CAVANILLES, was allowed seriously to invalidate the character of Tropæoleæ, the strong internal evidence that it was founded upon the fruit of one Natural Order carefully attached to a poor flowering specimen of another, being overlooked.

MUCH has been done of late years in introducing medicinal plants of other climes into Indian soil for cultivation for commercial purposes. The cinchonas have been a grand success, and other experiments, we hope, will be equally successful. Though we are naturally more interested in plants connected with our own branch of science, we can nevertheless rejoice at the success of other useful plants; and though the following extract of a letter of a correspondent in Southern India bears more immediately upon agriculture, it is, we think, a good indication of what we may expect of India at no very distant date. Our correspondent says,—"Agricultural topics have of late received much more attention out here than they ever did before. Arrangements are pending at Calcutta for a new department of agriculture and commerce for India. Model farms are also being established in different parts of the country, to show the native farmers the advantages of the European system. The authorities are at last beginning to perceive that the native style of cultivation is, after all, faulty, and are getting alarmed about the land revenue, crops not being so good as they used to be. Fuel is getting scarcer every year, and the manure is taken as a substitute, thereby impoverishing the soil, while artificial manures are still unknown to the natives generally."

THE first of a series of articles, by Dr. B. W. RICHARDSON, F.R.S., entitled "Some Further Additions to Therapeutics," appears in the current number of the *Practitioner*. In this paper the author treats of the organic bromides, viz. bromide of quinine, bromide of morphine, and bromide of strychnine, their combinations and administration, and hydrobromic ether and bromide of methyl. The substance of the article has already appeared in the Journal, *ante*, p. 854.

WE are this week indebted to a correspondent for a copy of the *Beverley Guardian*, containing a full account of a recent case of poisoning by arsenic at Beverley; we take the opportunity of communicating to our readers that we shall always be glad to receive from them any similar information on matters of interest to pharmaceutists.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

June 7th, 1871.

Present—Messrs. Atherton, Betty, Bottle, Brown, Carr, Edwards, Greenish, Groves, Haselden, Hills, Sandford, Savage, Shaw, Smith, Stoddart, Sutton, Williams and Woolley.

Mr. A. F. Haselden was called to the chair, and took the same accordingly.

The minutes of Council on the 3rd and 17th ult. were read and confirmed.

This being the first meeting of the Council after the Anniversary, the election of Officers for the ensuing year was proceeded with by ballot.

Mr. A. F. Haselden was unanimously elected President.

Ballot was then taken for the election of Vice-President with the following result:—

Edwards	9
Williams	7

Mr. Edwards was then declared Vice-President.

Mr. Hills was unanimously elected Treasurer.

Elias Bremridge was reappointed Secretary and Registrar.

Richard Bremridge was reappointed Assistant-Secretary and Deputy-Registrar.

Moved by Mr. Brown, seconded by Mr. Carr,

Resolved—That the following be the Standing Orders of the Council for the ensuing year:—

1.—That at all meetings of the Council the chair shall be taken at eleven o'clock in the forenoon, and business immediately proceeded with, provided a quorum be present.

2.—That all notices of motion shall be given in writing to the Secretary, and shall distinctly state the nature or substance of the resolution intended to be submitted to the Council; and all such notices shall be dated and numbered as received, and entered in a book to be kept for that purpose at the Secretary's office, which book shall be open to the inspection of every member of the Council.

3.—That motions for which such notice shall be given shall have precedence over other motions, and be entered by the Secretary upon the notice paper in the order in which they are received,—routine business and other matters brought specially before the Council by the President only excepted.

4.—That the Secretary shall insert in the summonses for any meeting of the Council, in addition to such matters as may be ordered by the President, all subjects for which notice of motion shall have been given before five o'clock in the afternoon of the day preceding the day for summoning the Council.

5.—That at every meeting of the Council all motions, whether original motions or amendments, shall be reduced into writing, signed by the mover, and delivered to the Secretary immediately upon being seconded.

6.—That whenever amendments are made upon original motions, no second amendment shall be taken into consideration until the first amendment be disposed of.

7.—That if a first amendment be carried, it displaces the original question, and becomes itself the question, whereupon any further amendment may be moved.

8.—That if the first amendment be negatived, then a second may be moved to the original question under consideration; but only one amendment shall be submitted to the Council for discussion at one time.

9.—That the mover of every original motion, but not of any amendment, shall have a right to reply, immediately after which the question shall be put from the chair; but that no other member be allowed to speak more than once on the same question, unless permission be given to explain, or the attention of the chair be called to a point of order.

Resolved—That the best thanks of this Council are due, and are hereby tendered, to their Lordships the Committee of Council on Education for the use of the South Kensington Museum on the 17th May for the purpose of holding the Society's Conversazione.

Resolved—That the Secretary be requested to convey to the official staff of the South Kensington Museum the best thanks of this Council for the prompt and energetic manner in which the arrangements for the Society's Conversazione on the 17th May were carried out.

The following Committees were appointed:—

General Purposes—The whole of the Council; to meet on the day preceding the meeting of Council, at 7.30 P.M.

Finance—Messrs. Betty, Carr, Greenish, Sutton and Woolley; at 11 A.M. on the day preceding the meeting of Council.

Library, Museum and Laboratory—Messrs. Brown, Greenish, Hills, Sandford, Stoddart and Williams; at 11 A.M. on the second Wednesday of each month.

House—Messrs. Brown, Greenish, Hills, Sandford, Stoddart and Williams.

Benevolent Fund—Messrs. Betty, Carr, Greenish, Sutton and Woolley.

Parliamentary—Messrs. Atherton, Bottle, Brown, Hills, Sandford, Savage, Shaw and Williams, with power to add to their number.

Publication of Council Minutes—The President, Vice-President and Mr. Sandford; the first Tuesday after the meeting of Council.

Provincial Education—Messrs. Atherton, Betty, Carr, Greenish, Groves, Mackay, Reynolds, Sandford, Shaw, Stoddart, Sutton, Williams and Woolley; to meet, when required, on the day preceding the meeting of Council, at 4 P.M.

On the motion of Mr. Hills, seconded by Mr. Savage, the following twelve Pharmaceutical Chemists were elected and appointed Examiners for England and Wales for the ensuing year, subject to the approval of the Privy Council:—

Allchin, Alfred	London.
Barnes, James Benjamin	London.
Bird, Augustus	London.
Carteighe, Michael	London.
Cracknell, Charles	London.
Davenport, John T.	London.
Gale, Samuel	London.
Garle, John	Bickley, Kent.
Hanbury, Daniel	London.
Ince, Joseph	London.
Linford, John Samuel	London.
Southall, William	Birmingham.

The following seven Pharmaceutical Chemists were appointed Examiners for Scotland for the ensuing year, subject to the approval of the Privy Council:—

Ainslie, William	Edinburgh.
Aitken, William	Edinburgh.
Brown, David Rennie	Edinburgh.
Buchanan, James	Edinburgh.
Gilmour, William	Edinburgh.
Kemp, David	Portobello.
Young, James R.	Edinburgh.

The President and Vice-President are on all Committees *ex officio*, and on the respective Boards of Examiners in London and Edinburgh.

LOCAL SECRETARIES.

The Council elected Local Secretaries for the ensuing year (a list of whom was published in last week's Journal).

The Report of (Messrs. Carr, Haselden and Williams, who acted as) the Finance Committee in auditing the accounts for the past month was presented, showing on the General Fund account a balance in the Treasurer's hands of £2983. 14*s.* 2*d.*, and submitting for payment accounts amounting to £773. 9*s.* 11*d.*; and on the Benevolent Fund account a balance of £569. 10*s.* 1*d.*

Resolved—That the Report be received and adopted, and payments made.

Resolved—That the Treasurer be requested to purchase Stock on the following accounts:—

General Fund . .	New Three per cents.	£1000
Life Members' Fund	do.	£110
Benevolent Fund .	Consols	£500

Resolved—That the Report of the Library, Museum and Laboratory Committee be received, and that the question of warming the Laboratory be referred back to the Committee.

Resolved—That it is expedient to elect two Annuitants on the Benevolent Fund in October next, and that the Secretary be requested to announce in the usual channels that such election will take place.

REPORT OF THE BOARD OF EXAMINERS.

England and Wales.

The following letter from the Medical Department of the Privy Council was read:—

[Copy.]

"*Medical Department of the Privy Council,*
"*June* 1*st*, 1871.

"Sir,—Adverting to my letter of the 4th ult.,* the Lords of Her Majesty's Council, believing that the Annual Meeting, therein referred to, of the Pharmaceutical Society has now been held, direct me to inquire what steps the Society has taken with regard to the matters to which that letter has reference.

"I am, Sir,
"Your obedient servant,
"John Simon.

"*The Secretary to the*
"*Pharmaceutical Society,*
"*Bloomsbury Square,* w.c."

Moved by Mr. Brown, seconded by Mr. Woolley,—
Resolved—That the following letter be adopted by this Council, and the Secretary be instructed to forward the same to the Medical Department of the Privy Council:—

* See Pharm. Journ. May 27th, 1871, p. 942.

[Copy.]

"*Pharmaceutical Society of Great Britain,*
"17, *Bloomsbury Square, W.C.,*
"*June 7th*, 1871.

"Sir,—In reference to your letter of May 4th, drawing attention on behalf of the Lords of Her Majesty's Council to the approaching Annual Meeting of the Pharmaceutical Society, trusting that regulations would then be made in regard to the keeping, dispensing and selling of poisons (as will be sufficient to secure the safety of the public), and of June 1st, inquiring what steps the Society had taken with regard to the matters referred to in the previous letter, I am instructed by the Council of the Pharmaceutical Society this day assembled (being the first meeting after the Annual Meeting), to inform you that at the meeting of the Council of the Pharmaceutical Society, held on the 5th April, it was resolved that Regulations for the keeping, selling and dispensing of poisons should be issued as Recommendations.

"In this form they were submitted to and adopted by the Annual Meeting of the Pharmaceutical Society, held on the 17th May last, and copies will at once be distributed by the Council to Pharmaceutical Chemists and registered Chemists and Druggists throughout the country. The Council beg to submit to the Lords of her Majesty's Privy Council a copy of the Recommendations and the resolution of the Annual Meeting thereon.

"I have the honour to be, Sir,
"Your obedient servant,
"Elias Bremridge,
"*Secretary and Registrar.*

"John Simon, Esq."

Resolved—That a printed copy of the recommendations for the keeping, dispensing and selling of poisons,* passed at the Annual Meeting, be forwarded to every Pharmaceutical Chemist and Chemist and Druggist on the Register, with the urgent request of this Council for their universal adoption.

A memorial which had been handed in by Mr. Vizer from chemists and druggists, not being Members of the Society, deprecating the enactment of compulsory regulations as to the storing and dispensing of poisons, was presented to the Council.

Moved by Mr. Atherton, seconded by Mr. Brown,—
Resolved—That the various applications for assistance which had been received from Provincial Societies be referred to the Provincial Education Committee for their consideration.

Resolved—That Dr. J. L. Soubeiran, of Paris, be elected an Honorary and Corresponding Member of this Society.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be severally granted a Certificate stamped with the seal of the Society:—

Bannard, Henry	London.
Catterns, Heneage Parker	London.
Deane, James	Clapham.
Fowler, William Ratcliffe	Ipswich.
Freeman, Ernest	Stourbridge.
Linton, Ralph Tait	Edinburgh.
Sambrook, William	Cardigan.
Troake, Marler Hamilton	Kingsbridge.

Resolved—That the following Pharmaceutical Chemists be, and are hereby elected Members of the Society:—

Agnew, Ernest James Tween	London.
Clarke, Josiah	Croydon.
Deane, James	Clapham.
Fowler, William Ratcliffe	East Kirkby.

* See Pharm. Journ. May 27th, 1871, p. 949.

Fryer, Charles ....London.
Horsley, Thomas Wood ......London.
Procter, Samuel James ......London.
Scott, Walter ....Elgin.
Sherburn, Thomas ....Howden.
Watts, John ....London.
Williams, George Henry......London.

Resolved—That the following registered Chemists and Druggists be elected Members of the Society:—

Bainbridge, Robert Robinson..Stockton-on-Tees.
Bellamy, John ....Birmingham.
Dudgeon, Charles ....Bristol.
Dutton, Francis ....Bolton.
Holmes, Joseph ....Leeds.
Hunt, Samuel ....Sudbury.
Jones, Alfred Maddox.........Brynmawr.
Kaye, Hamor ....Huddersfield.
Linnett, Samuel Soden ....59, Southgate Road.
Scott, David Wolsey ....Barmouth.
Short, Edward Henry ....Acton.
Walker, Joseph ....Tewkesbury.
Wells, Thomas ....91, Charlwood St.

Resolved—That the following having passed their respective examinations be elected Associates in business:—

MINOR.

Edey, George ....Christchurch.
Gittings, Alfred ....Oldbury.
Glazier, Walter Henry ....London.
Grindell, John ....Hull.
Hay, Thomas Alexander .....Wavertree.
Hodgkinson, George A........London.
Richardson, Richard Thomas..Liverpool.
Riggall, Francis Henry ....Louth.
Sumner, Benjamin Tindale ..Grantham.
Waterworth, Alfred ....Preston.

MODIFIED.

Burn, Thomas ....Sunderland.
Fudgé, Charles William .....Shepton Mallet.

Resolved—That the following having passed their respective examinations be elected Associates:—

MINOR.

Ballard, Frank Perry.........Ludlow.
Barclay, John ....London.
Barnes, Francis Joshua ....Preston.
Black, James ....Markinch.
Carr, George ....Sheffield.
Cooper, Anthony Vincett .....Birmingham.
Davies, Robert Higgins.......Dartford.
Ellwood, Francis Henry .....Norwich.
Forsbrook, William Henry ..Birmingham.
Hill, Walter...................Cheltenham.
Kemp, John ....Inverness.
Maddison, Henry Gildon .....London.
Parker, William ....London.
Saunders, Charles Price......Haverfordwest.
Selley, John...................Aylesbury.
Shenstone, William Ashwell..Colchester.
Smyth, Arthur William.......Diss.
Stansby, Charles John ....Derby.
Tonks, Joseph ....Wolverhampton.
Wilkes, John Sanders ....Stafford.
Woolley, Harold..............Manchester.

MODIFIED.

Archer, James ....Lechlade.
Bowen, Joseph William.......Holyhead.
Burton, Joseph ....Sheffield.
Coates, Henry ....York.
Ramsden, William ....Fallowfield.
Richardson, Thomas James ..Carlisle.
Spratt, George Uriah ....Boston.
Woodcock, Arthur ....London.

The Secretary presented a list of Members and "Associates in Business," who had paid their subscriptions since the 30th April last, and it was

Resolved—That they be severally restored to their former status on payment respectively of a nominal fine of 1*s*.

SPECIAL MEETING OF COUNCIL, *June 14th*,

To consider the provisions of the Bill now before the House of Lords, intituled "An Act to Amend the Pharmacy Act, 1868."

MR. A. F. HASELDEN, PRESIDENT, IN THE CHAIR.
MR. EDWARDS, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Brown, Carr, Greenish, Groves, Hills, Sandford, Savage, Shaw, Smith, Williams and Woolley.

Moved by Mr. Brown, seconded by Mr. Greenish,

That the passing of the Biil as now worded, intituled an "An Act to Amend the Pharmacy Act, 1868," be opposed by the Council.

Amendment—Moved by Mr. Groves, seconded by Mr. Smith,

That a committee of this Council be appointed to watch the progress in Parliament of the Bill "to Amend the Pharmacy Act, 1868," and prevent the passing of obnoxious clauses.

For the Amendment—
Messrs. Carr, Edwards, Groves, Haselden, Hills, Sandford, Smith and Williams.

Against—
Messrs. Atherton, Betty, Bottle, Brown, Greenish, Savage, Shaw and Woolley.

The numbers being equal, the Chairman gave the casting vote in favour of the Amendment.

The Amendment was then put as a substantive motion and carried.

Moved by Mr. Groves, seconded by Mr. Smith, and

Resolved—That the Parliamentary Committee be instructed to watch the Bill referred to in the last Resolution, and that Mr. Betty be added to that Committee.

Moved by Mr. Woolley, seconded by Mr. Brown, and

Resolved—That the proceedings of this day's Council be inserted in the current week's Journal.

At the termination of the Council meeting the Parliamentary Committee met and determined on sending a deputation to the medical officer of the Privy Council on the following day (Thursday) for the purpose of introducing certain amendments into the Bill.

Parliamentary and Law Proceedings.

A BILL INTITULED AN ACT TO AMEND THE PHARMACY ACT, 1868.

Whereas under the Pharmacy Act, 1868, persons selling or keeping open shop for retailing, dispensing or compounding poisons are required to conform to such regulations as to the keeping, dispensing and selling of poisons as may from time to time be prescribed by the Pharmaceutical Society, with the consent of the Privy Council:

And whereas the Pharmaceutical Society have failed to submit for the consent of the Privy Council any regulations for the above purposes, and it is expedient to make further provision for the making of such regulations:

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in the present Parliament assembled, and by the authority of the same, as follows:

1. This Act shall be construed as one with the Phar-

macy Act, 1868 (in this Act referred to as the principal Act), and with the Act of the session of the thirty-second and thirty-third years of the reign of her present Majesty, chapter one hundred and seventeen, intituled "An Act to amend the Pharmacy Act, 1868," and those Acts and this Act may be cited together as the Pharmacy Acts, 1868 to 1871, and each of the above-mentioned Acts and this Act may be cited as the Pharmacy Act of the year in which it was passed.

2. The recited powers of the Pharmaceutical Society of Great Britain under the principal Act shall cease, and the Council of the said Society may from time to time submit to the Privy Council regulations as to the keeping, dispensing and selling of poisons within the meaning of the principal Act, and as to revoking or amending any such regulations previously made, and the Privy Council may, if they think fit, by order approve of such regulations.

If at any time it appear to the Privy Council that there are no regulations for the time being in force under the principal Act as to the keeping, dispensing and selling of poisons within the meaning of the principal Act, the Privy Council may serve a notice on the Council of the Pharmaceutical Society requiring them to frame and submit for the approval of the Privy Council regulations as to the matters aforesaid, and if the Council of the Pharmaceutical Society, within the time limited by such notice, not being less than two months from the date of the service of the notice, make default in framing such regulations, or obtaining the approval of the Privy Council thereto, the Privy Council may themselves frame regulations as to the matters aforesaid.

All regulations approved or framed by the Privy Council in pursuance of this section shall have the same effect as regulations prescribed in manner specified in the principal Act.

HOUSE OF LORDS.

PHARMACY BILL, *June* 6.—The Pharmacy Bill was introduced by the Lord President of the Council. It was read a first time and ordered to be printed. The second reading was appointed for June 12.

June 12.—The Pharmacy Bill was read a second time. Committee fixed for June 13.

June 13.—The Pharmacy Bill passed through Committee. To be read a third time on Thursday, June 15.

June 15.—The Pharmacy Bill was read a third time and passed.

HOUSE OF COMMONS.

MEDICAL ACT (1858) AMENDMENT BILL.—*June* 14.—The second reading of this Bill was moved by Dr. Lush. He said it was brought forward in consequence of Mr. Foster's Bill of last session having failed to satisfy the profession, and the Government being too busy this session to deal with the question. It proposed to substitute the present Council of twenty-four members by one of twelve, four members to be nominated by the nineteen examining bodies at present in existence, four by the Crown, and four by the whole body of the profession. It provided also that before a man was allowed to practise he should be compelled to pass one examination, which examination should indicate the minimum standard of professional education in this country.

Mr. Jessel said this Bill would give a monopoly of examination into the hands of the Medical Council, by giving it a right to appoint the Board of Examiners, in which it differed from the Government Bill of last year. It also defined what the examiners were to do, without having regard to the natural progress of science and learning. Under the present system there had been a race to diminish the qualification required, in order to attract a large number of fee-paying persons to the examinations. The examiners must be made honest by preventing them from having a pecuniary interest in the result of the examinations. It would not be right to have the Examination Board and the Controlling Board composed of the same persons.

Dr. Brewer supported the Bill.

Dr. Playfair said that whereas the present Bill extinguished the old corporation, which he thought was a mistake, another Bill that was before the House recognized, and left them nearly alone. It was a disadvantage to have nineteen examining bodies having a tendency to compete with each other, thus securing only a minimum qualification; but it did not follow that they should be reduced to one. It would be better that there should be an examining body for England, another for Scotland, and another for Ireland. He hoped both Bills would be withdrawn, and that the Government would deal with the question next Session.

Mr. W. Forster said that the Government were aware of the great practical evils that resulted from there being nineteen accredited bodies for certifying medical practitioners, but they had been unable to deal with the question this year. So many subjects pressed for legislation, that he could not pledge the Government to bring in a Bill next session, but if they did not, and a private member took up the subject, no opposition would be offered to the fullest consideration of the subject.

After a few words from Dr. Brady, who stated that his own Bill, the "Medical Act (1858) Amendment (No. 2) Bill," had been carefully prepared, and gave satisfaction to the profession, both Bills were withdrawn.

WELSHPOOL COUNTY COURT, *Thursday, June 8th*, 1871.

(*Before* J. W. SMITH, Esq., *Judge.*)

Pharmaceutical Society of Great Britain *v.* E. C. Whisken, of Welshpool.

This was an action brought to recover £5, upon particulars as follows:—"To amount of penalty incurred by the defendant in selling or keeping open shop for retailing, dispensing or compounding poisons or a poison, and in taking, using or exhibiting the name or title of chemist and druggist, contrary to the provisions of the Pharmacy Act, 1868 (31 & 32 Vict. cap. 121)."

Mr. Flux (of London) appeared for the Pharmaceutical Society; Mr. Chandler (of Shrewsbury) appeared for the defendant.

Mr. Chandler.—Your Honour will allow me to apply that this case shall stand over to a future day. I can only assure you that the case came before the Court of Queen's Bench this week, and that a rule was granted *nisi* for a *mandamus*. The case will be tried in all its details on Saturday, and the very fact of this plaint being issued is mentioned in the application to the Judges. I am not prepared to go on with the case to-day; my documents are in London, and I do not think it is fair to yourself or to the defendant that the case should be proceeded with. I am prepared to pay the amount of the penalty sued for into Court, but I do not think it fair that the case should be heard here to-day.

Mr. Chandler then handed to the Judge the *Times* of Tuesday, June 6th.

Mr. Flux.—I have no objection to your Honour looking at the *Times*. I have no doubt that it contains a correct report of what took place in the Court of Queen's Bench, but the application to that Court was an *ex parte* one. Of course the application of my friend is opposed by me. That this application would be made was intimated to me, and my reply, which I will hand to your Honour, is dated the 27th May. The case of the Society which I have the honour to represent is this:—They are charged in the public interests to protect the public in the matter of the selling of poisons, and, having satisfied themselves that the defendant is not a qualified person, and is deliberately violating the law, they have thought it a duty to commence this action (which by the law must be tried in the locality where the defendant resides and is known) for the protection of the public; and, representing the Society, I cannot take the responsibility of consenting to, or even of failing to the utmost of my ability to oppose, any delay in this matter, because so long as this case is undecided the defendant is holding himself out to the world as possessing a statutory qualification to sell poisons; and if by any accident any subject of her Majesty were to be seriously prejudiced through the sale of poisons by the defendant, I being charged with these proceedings, could not feel that I was free from blame in the matter. As to the case in the Court of Queen's Bench being disposed of on Saturday or Monday, seeing that the term ends on Monday, I can hardly hope that, in the existing state of business, the rule can be argued before November. So far as I am aware, there will not be any sittings after term at which a rule of this kind can be argued, and I have no hope of getting the matter disposed of before Michaelmas Term unless it be accomplished on Monday. If it be not disposed of on Monday, the defendant will have an excuse for continuing to sell poisons to her Majesty's subjects between this date and November.

The Judge.—Is it limited to the case of selling poisons?

Mr. Flux.—Certainly; he can sell anything else, but he cannot call himself chemist and druggist, and he cannot sell certain poisons if he be not a duly qualified person. The issue as to whether he is a duly qualified person or not is one which I can approach with the utmost confidence. I put it to your Honour that I may proceed with it at once. This question will hardly be disposed of by the Court of Queen's Bench, because if the defendant be restored to the register he will none the less have been in open violation to the law during the period covered by this plaint. He knows that he is not on the register, and my case is plain that he is violating the law at this moment. Whether he can obtain the restoration of his name to the register is a matter which the Court of Queen's Bench may deal with; but that he will get his name restored I, as the adviser of the Society, cannot for a moment imagine. Your Honour will see that the gist of the defendant's case in the Court of Queen's Bench is, that before a given day in 1868 he carried on the business of a chemist and druggist in open shop, in New Street, in this town. The place is within a few minutes' walk of this, and although it is perhaps too much for me to suggest that your Honour should see the place yourself, I may venture to say that if some one deputed by your Honour were to go, he would be shocked at the appearance of the place.

The Judge.—Was there no open shop?

Mr. Flux.—No, your Honour.

Mr. Chandler.—These are facts which have to be decided on solemn affidavits in London. The defendant's witnesses are not here now, and will not be here. The question which is now being tried is a sort of preliminary one, and may be used by us on Monday. Whisken was certainly at one time on the register, and during that time no harm occurred to any one; and to ask your Honour to put a stop to a business—

The Judge.—Is he the farrier?

Mr. Flux.—Yes, your Honour, and never was anything else.

Mr. Chandler.—I am in no position to fight the case to-day. My agents gave the other side notice of my intention to apply for this postponement, and it has not been consented to.

Mr. Flux.—My reply was, that if the defendant would cease to use the title "chemist and druggist," and would otherwise cease to violate the law during the interval, we would consent.

The Judge (to Mr. Chandler).—One would have thought that you would have been willing to have foregone the selling of poisons.

Mr. Chandler.—We have not violated the law, and why should a large society ride rough-shod over us? Acting under the advice of counsel, I would not give such an undertaking. Besides, there is in the defendant's shop a member of the Pharmaceutical Society acting as his assistant; and no danger can therefore arise, and, even if it did, the Pharmaceutical Society would not be liable for it. Therefore, that argument is, I think, a somewhat far-fetched one. The case is before your Honour, but I repeat that I am not prepared to proceed with it now.

Mr. Flux.—I know nothing about there being any member of the Society in the defendant's employ.

The Judge.—I will turn the matter over in my mind.

Mr. Flux.—Respecting my friend's statement as to this gentleman's name having been on the register, I should like your Honour to note that it was placed on the register on the strength of a certificate granted by a gentleman who is at present High Sheriff of the county; and that, upon a letter being addressed to that gentleman by the Registrar of the Society (a most courteous letter, as your Honour will see), directing his attention to that which he had signed, as well as to the words of the statute,—that gentleman wrote a most courteous reply, expressing his prior ignorance of the words of the statute, and withdrawing his certificate; and thereupon the Council of the Society erased the defendant's name from the register.

Mr. Chandler.—Although they had received further certificates.

Mr. Flux.—No, they had not.

The Judge.—What I have to do is to make up my mind whether I shall direct this case to be adjourned or not, and I will consider the matter.

At a later period of the day, the Judge, addressing the defendant's attorney, said: The facts are admitted which render the defendant liable to the penalty, and you seek an adjournment only in consequence of the proceedings in town?

Mr. Chandler.—Yes, because we say that he ought to be on the register.

The Judge.—I do not conceive that I have any power to abrogate any section of the Act of Parliament, or to add any words to it. Even admitting that it had been already decided that the Pharmaceutical Society were wrong in excluding the name of the defendant from the register, he would still, according to the Act of Parliament, be liable to this penalty, and I should have no power, so far as I can at present see, to relieve him from it. I sit here to administer the law as I find it.

Mr. Chandler.—Supposing that the Court of Queen's Bench decides that the defendant is entitled to have his name upon the register, we shall obtain a judge's order directing the Society to reinstate the name.

The Judge.—That would not relieve him from the penalty; he was not on the register at the time when the act complained of was committed.

Mr. Chandler.—Very true; but if the judges order his name to be replaced, the Society will be obliged to comply with the order, and then they would not be able to sue him for a penalty.

The Judge.—Still he would not have been on the register during the past time, in respect of which this action is brought.

Mr. Chandler.—Your Honour will see that the judges might find that it was wrong to remove his name.

The Judge.—I do not know that they would have the power to do so. They might grant a rule against me in enforcing the penalty against him under those circumstances; that, however, is not the case before me. According to the Act of Parliament he is within the penal clause, and I do not think that I have any power to relieve him; but what I can do is this, to say to the representative of the Society; if it be decided against you in the Court of Queen's Bench, I would suggest that you should undertake not to enforce the penalty.

---

* We are informed by the Registrar that the assistant is not a member of the Pharmaceutical Society, nor is he on the Register of Chemists and Druggists.—ED. PHARM. JOURN.

Mr. Flux.—Your Honour may be sure that I will not enforce this penalty until the decision of the Court of Queen's Bench upon the rule is obtained, and that if the decision be in favour of this defendant I will not seek to enforce the penalty at all; but I wish the defendant to understand this, that by continuing the business so long as his name is not on the register, he is holding himself out to the public in a capacity which I cannot recognize, and which I am bound, by all means, to discourage; and that if he continues the offence, I shall deem it a duty to renew my applications for a penalty.

Mr. Chandler.—But not until after a decision.

Mr. Flux.—I shall indeed.

The Judge.—I quite expected Mr. Flux to say that; but he will not enforce them.

Mr. Flux.—No.

The Judge.—Until the contrary be proved, it must be assumed that the decision of the Council as to the erasure of the defendant's name from the register was a just one; otherwise, we should be continually having these defences raised, and we might, during an indefinite period of time, have these persons carrying on their trade, and endangering the lives of her Majesty's subjects, whilst it was being tried in a Superior Court whether they ought to have been on the register or not. I think it would be an unfortunate state of things if that were so. At any rate, I sit here to administer the law as I find it, and not to relieve from the effects of the law by importing provisions which I do not find in the Act of Parliament itself. I think it would be an idle waste of the public time to do more than submit that if the decision in the Court of Queen's Bench be adverse to the Society the penalty shall not be enforced. As to any future penalties which might be sued for, "sufficient unto the day is the evil thereof."

Mr. Chandler.—My friend has put it fairly enough, but I believe that this case will be tried on Saturday; my friend, however, thinks differently, and I quite bow to his superior judgment. All that I say is, that if we do our best to try this on Saturday we lose no time, and it would be unjust to make a man liable from day to day.

The Judge.—I think they will have vindicated the public interests by these proceedings, and that they will not feel obliged themselves to sue for any further penalty, as Mr. Chandler says his real intention is to pursue this in the Superior Court with the utmost possible diligence, and I should think the sooner he can get the question decided, the better pleased he will be.

Mr. Flux.—Everything is being done on my part to facilitate the hearing of the case in the Queen's Bench before the end of the term; and I venture to say that there can be no doubt as to the great weight which will attach to your Honour's remarks with my clients; and I shall feel it a duty to communicate them, and act upon them, so far as possible, although I do not feel at liberty to give an undertaking on their part not to sue.

The Judge.—You can represent my views to them.

Mr. Chandler.—This has been going on for some time, and the proceedings should have been taken long ago.

Mr. Flux.—That remark recoils upon my friend; he should have applied for his mandamus before.

The Judge.—It certainly strikes me as remarkable, that Mr. Chandler's client should have waited so long as he has and should not have taken proceedings at once.

Mr. Chandler.—His waiting caused him no injury, and he thought he might be affording amusement to the Society.

Mr. Flux then tendered formal evidence.

Mr. Chandler.—I admit that my client's name was not on the register, that he used the title chemist and druggist, and that the action is duly brought in point of form.

The Judge.—I give judgment for the plaintiff with costs.

Mr. Flux then applied for the cost of the Registrar's attendance as a witness.

The Judge.—I do not see that there was any necessity for the Registrar's personal attendance.

COURT OF QUEEN'S BENCH, WESTMINSTER.

TRINITY TERM.

Monday, June 12th, 1871.

Present—LORD CHIEF JUSTICE COCKBURN, MR. JUSTICE LUSH, and MR. JUSTICE HANNEN.

The Queen *v.* the Council of the Pharmaceutical Society of Great Britain.

Mr. Quain (Mr. Bullock with him).—My Lords, in the case of the Queen against the Council of the Pharmaceutical Society of Great Britain, I have to show your Lordships cause against a rule which has been obtained by my learned friend Mr. Bullen upon the 5th of this month, calling upon that Society to show cause "why a writ of mandamus should not issue directed to them commanding them to direct the Registrar of the said Society to restore the name of the said Edward Charles Whisken to the Register of Chemists and Druggists." The question is, whether this gentleman is entitled to be restored to that register? My Lords, the Act of Parliament under which this question arises is the 31st and 32nd Victoria, chapter 121, and that is "An Act to regulate the Sale of Poisons, and Alter and Amend the Pharmacy Act, 1852." Now this Act of Parliament provides for persons entitled to be registered; and I believe I may state shortly the fact, that nobody is entitled to call himself a "chemist and druggist," or to sell poisons (I believe he may sell anything else), unless he brings himself within the authority of this Act. Those are the only two things which the Legislature have interfered with. In order to do that, the statute defines what persons shall be entitled to be registered, and the only question we have to discuss is this, whether the applicant for the writ of mandamus in this case was a chemist and druggist carrying on that business in an open shop dispensing prescriptions of duly qualified medical practitioners before July, 1868, it being in July, 1868, that this Act came into operation; because it entitled all persons who were actually in business before that date to be registered, as a matter of course, after delivering to the Registrar their certificates. Now, the third section says, and this is the section upon which it turns, "chemists and druggists within the meaning of this Act shall consist of all persons who at any time before the passing of this Act, have carried on in Great Britain the business of a chemist and druggist in the keeping of open shop for the compounding of the prescriptions of duly qualified medical practitioners." It turns out to be entirely a question of fact, upon one part of the case, which is as to whether Mr. Whisken, who makes this application, can bring himself within that definition, and can show that he was a chemist and druggist carrying on business in an open shop, dispensing prescriptions of duly qualified medical practitioners, before the date of July, 1868? Now, my Lords, I will tell you what the facts are as disclosed upon the affidavits.

Mr. Bullen.—My Lords, if my friend is going into the facts, I must ask that the case may be postponed, in order that we may answer the affidavits that have been filed, as the affidavits, of which there are no less than twenty-six sheets, have only been delivered to me late on Saturday night last.

Mr. Quain.—It was only moved on the 5th of June.

Mr. Bullen.—But the affidavits consist of all sorts of imputations upon my client.

Mr. Quain.—I apprehend, my Lords, the question is this: we say—and that, in fact, explains the whole case—that we were induced to place upon the register the name of this applicant in consequence of incorrect information furnished to us. That so far from being a chemist and druggist (at least, that is what we say) within the meaning of the provision that I have just read to your Lordship, this person was nothing else but a cow or cattle doctor—a farrier, in fact—at Welshpool; that he was not a chemist and druggist in the ordinary sense of the word, and did not make up prescriptions, except so far as they were for cattle and horses, and that he was not a person who came within the status which he ought to have occupied at the time he made the application. This is the question of fact, so far as that is concerned. I have a large number of affidavits, of course, upon the subject.

The Lord Chief Justice.—It is a difficult inquiry, and this is an unsatisfactory mode of disposing of it, if it depends upon the affidavits.

Mr. Quain.—I was going to say, my Lord, if it were a mere question of fact, no doubt, as there are conflicting affidavits, your Lordships would not go into them.

The Lord Chief Justice.—What I was thinking was that we might refer it to the Master.

Mr. Quain.—I am ready to take any course your Lordship wishes; but, before your Lordship does that, I would wish to draw your attention to this. My learned friend, Mr. Bullock, who is with me, and myself, have looked at the matter in consultation, and, as I have just observed, if it rested entirely upon conflicting affidavits upon matters of fact, I could not expect your Lordships at this moment to go into them and to decide upon them; but I would submit (and I throw this out for the consideration of my friend Mr. Bullen) that this is a matter resting entirely upon points of law, and I would ask your Lordships to decide it upon them without going into the facts, and upon them, I say, this is not a case for a mandamus at all.

The Lord Chief Justice.—We had a similar application to this some time ago.

Mr. Bullen.—That was upon another Act, my Lord.

Mr. Quain.—My friend is quite right; that, was upon another Act. This is the first time your Lordships have been called upon to put a construction upon this Act. The point I am going to take is, that this is a matter of discretion; that is to say, that there is a judicial discretion in the Council of the Pharmaceutical Society, and, that if they have decided it, your Lordships will not interfere. This is not an application upon the ground that they have been asked for a hearing and have declined it, because, here, they have heard and have decided; and I submit that the matter having been so heard and so decided by the Council of the Society under the Statute, it then comes within the ordinary case where the Legislature having vested these functions in the Council of a Society, and they having exercised them, the question cannot be retried upon affidavits. That is the real point. Now, having referred your Lordships to the third section, I will call your Lordship's attention to the fifth: "The persons who at the time of the passing of this Act shall have been duly admitted pharmaceutical chemists, or shall be chemists and druggists within the meaning of the Act, shall be entitled to be registered under the Act without paying any fee for such registration: provided, however, as regards any such chemist and druggist, that his claim to be registered must be by notice in writing, signed by him, and given to the Registrar, with certificates according to the schedules C and D." And, accordingly, the applicant in this case sent up to the Registrar the certificates C and D, within the meaning of that clause; and, having done that, he was thereupon placed on the register, and his name was printed in the Register of the year 1870. Information after that reached the Council of the Society that he was not really what he professed to be, and thereupon an investigation took place. The certificate under schedule C is one that comes from himself, that being one that is sent from the person in business as a chemist; but the certificate under schedule D is to be in these words, and is to be from a medical practitioner or magistrate: "I declare that I am a duly qualified medical practitioner (or magistrate), and that to my knowledge [blank], residing at [blank], in the county of [blank], was in business as a chemist and druggist, in the keeping of an open shop for the compounding of the prescriptions of duly qualified medical practitioners before the [blank] day of [blank]." That he complied with, undoubtedly, in the first instance; but as soon as the information reached the Society that he was not what he professed to be, they communicated with him, and they also wrote to the gentleman, the magistrate, who had signed that certificate. He happened to be a gentleman named Jones, and a most respectable gentleman, no doubt, he being, at the present time, the High Sheriff of Montgomeryshire. The matter having been brought to his attention, he was asked whether he adhered to the declaration he had made according to the terms of the statute, a copy of the Act of Parliament being sent to him, showing that he must state, within his knowledge, that the person was a person who compounded medicines. As soon as that matter was called to Mr. Jones's attention, and he saw the nature of the certificate which he was expected to give, he wrote a letter, in which he withdrew the certificate, saying that he could not allow his name to be attached to a document upon which a shadow of doubt existed. After that withdrawal, I apprehend this gentleman was not entitled to remain on the register.

After that, a certificate of a gentleman named Brock was sent in, but that was after the name had been erased in the way in which I am going to tell your Lordships.

Then comes the 8th section, which refers to the Registrar: "The Registrar appointed, or to be appointed, under or by virtue of the Pharmacy Act, shall be Registrar for the purposes of the Act."

Then the 9th section says:—"The Council of the Pharmaceutical Society shall, with all convenient speed after the passing of this Act, and from time to time as occasion may require, make orders or regulations for regulating the register to be kept under this Act as nearly as conveniently may be in accordance with the form set forth in the schedule (B) to this Act or to the like effect."

Then comes the 10th section, which is with reference to the Registrar:—"It shall be the duty of the Registrar to make and keep a correct register in accordance with the provisions of this Act of all persons who shall be entitled to be registered under this Act, and to erase the names"—your Lordships see he has power to erase the names—"of all registered persons who shall have died, and from time to time to make the necessary alterations in the addresses of the persons registered under this Act. To enable the Registrar duly to fulfil the duties imposed upon him, it shall be lawful for the Registrar to write a letter to any registered person, addressed to him according to his address on the register, to inquire whether he had ceased to carry on business or has changed his residence," and so on.

Then there is the important section, section 12, of the Act, and the words are these:—"No name shall be entered in the register except of persons authorized by this Act to be registered, nor unless the Registrar be satisfied by the proper evidence that the person claiming is entitled to be registered; and any appeal from the decision of the Registrar may be decided by the Council of the Pharmaceutical Society, and any entry which shall be proved to the satisfaction of such Council to have been fraudulently or incorrectly made may be erased from or amended in the register by order in writing of such Council."

Then there is a penalty put upon the Registrar by section 14:—"Any Registrar who shall wilfully make or cause to be made any falsification in any matter relating to the said registers, and any person who shall wilfully procure, or attempt to procure, himself to be registered under the Pharmacy Act or under this Act, by making or producing, or causing to be made or produced, any false or fraudulent representation or declaration, either verbally or in writing, and any person aiding or assisting him therein, shall be deemed guilty of a misdemeanour." Then there are certain rights reserved under the 16th section. Now, what happened was this: As soon as this magistrate, Mr. Jones, withdrew his certificate, the matter was brought before the Council of the Society, and a correspondence took place.

Mr. Justice Lush.—Was Mr. Jones himself the person who gave the certificate?

Mr. Quain.—Yes.

Mr. Justice Lush.—That he withdrew?

Mr. Quain.—Yes.

Mr. Justice Lush.—At that time there was no proper evidence.

Mr. Quain.—I suppose so. His name had been on.

Mr. Bullen.—It was actually on at that time.

Mr. Quain.—He was on at the time Mr. Jones withdrew his certificate. On receiving the certificates C. and D., and the application, it was put on as a matter of course. Then being on, and being published in the list, he was on the regular register for 1870, and then this information reaches the Council that he has not been properly put on.

Mr. Justice Lush.—Then you say that it was proved to the satisfaction of the Council that his name had been incorrectly put on?

Mr. Quain.—Yes, my Lord.

Mr. Justice Lush.—And therefore they authorized the erasing it?

Mr. Quain.—Yes.

Mr. Bullen.—I should like to have the letter read which was written by Mr. Jones, if my friend comments on this, at the time he withdrew it.

Mr. Quain.—By all means.

Mr. Bullen.—Your Lordships will see he does not go into the merits at all.

Mr. Quain.—Whether he goes into the merits or not, he withdrew his letter. The correspondence is set out on the affidavit. Mr. Whisken most improperly says that Mr. Jones was threatened. There was no threat or anything of the kind to Mr. Jones. The letter is written to Mr. Jones on the 16th July, and he answers it in this way:—"I thank you very much for your courteous communication respecting Mr. Whisken, veterinary surgeon, Welshpool. On the receipt of your letter I sent to Mr. Whisken, requesting his immediate presence to give a satisfactory explanation. My declaration was founded entirely upon his statement of the facts that he had fully and faithfully complied with the requirements of the Pharmacy Act. I had never seen the Act until you kindly favoured me with a copy. I understand the point is whether Mr. Whisken keeps an open shop or not? I have requested Mr. Whisken, with whom I have had an interview to-day, to write to you full particulars in reply to your inquiries, and shall feel obliged if you will oblige me with a line saying that his explanations are satisfactory."

Mr. Justice Lush.—If that is true, his certificate was contrary to the statute.

Mr. Quain.—Yes.

Mr. Justice Lush.—It requires it to be within the knowledge of the party.

Mr. Quain.—By an oversight he overlooked the point; it was accordingly pointed out to him in the next letter.

Mr. Jones is then written to by the Registrar in these words, "Dear Sir,—I am in receipt of yours of the 16th instant, and also of a letter from Mr. Whisken. The chief point is not as you apprehend, whether or not he kept an open shop, although that is important. The question is this: did Mr. Whisken keep an open chemist's shop to your knowledge for the compounding of the prescriptions of duly qualified medical practitioners? His letter is so illiterate that my informant's statement, that 'he could not read a prescription if any one were rash enough to trust him with one,' would seem to be correct."

We have a *facsimile* of one of his letters, if your Lordships would like to see it.

"As to his having a shop, we must, I suppose, accept his own statement, which is, that he 'had a place sit a part as a shop,' but as to the prescriptions, I should be glad to hear from you further. If you do not feel satisfied that Mr. Whisken is entitled to registration, and you made the declaration, on the faith of which his name was placed on the register, without having at the time a full knowledge of the conditions on which such registration could be effected, I presume you will withdraw your name from the matter altogether; if not, please confirm your adherence to your declaration."

Then the Act of Parliament is sent to that gentleman, and he answers it on the 19th July in these words, "Dear Sir,—Since I was favoured by you with the Pharmacy Act of 1868, I have considered its provisions, and wish to withdraw my declaration relating to Mr. Whisken, of Welshpool, as I cannot allow my name to be attached to a document upon which a shadow of doubt exists."

(*Their Lordships consulted.*)

Mr. Justice Lush.—Does it appear that the Council had decided?

Mr. Quain.—Yes; the resolution of the Council is set out in the affidavit.

The Lord Chief Justice.—I cannot help thinking, Mr. Bullen, that unless you are prepared to show that there has been something altogether exceptional, or something arbitrary in the decision of the Council in the course of the case, we cannot take upon ourselves to review their exercise of the jurisdiction and authority, which is clearly vested in them. They are the proper persons to decide it, and it is within their competency.

Mr. Quain.—I should say that we have offered him a rehearing if he likes, and he has declined it; I can read the letter.

Mr. Bullen.—I am told that is not so.

Mr. Quain.—Don't say that, because I will read, from the affidavit, what we have offered. As the Council was most anxious that justice should be done, this letter was written by Mr. Bremridge, "I am in receipt this morning of a letter from Messrs. Howell, Jones and Howell;" they are his attorneys. "If you like to make an appeal to the Council yourself,"—that is, a second appeal, after the first case has been decided,—"I will lay the matter before them again, in this case. Please let me have your appeal this week, so that it may be presented next Council day. In the meanwhile, as your name does not now appear on the register; if you continue to carry on business, it will be the duty of this Society at once to institute proceedings against you." After that we get an answer from Messrs. Howell, Jones and Howell, the attorneys: "Our client has handed to us your letter of yesterday to reply to. He declines to make any appeal to the Council, and, notwithstanding your communication, intends to continue his business."

Mr. Bullen.—Your Lordships will find from our affidavit, that so late as the 10th February, 1871, in this year, Mr. Whisken went before the President of the Council and had an interview with him about the matter. That letter was written by Messrs. Howell and Jones. How it came to be written I don't know; but he has been before them since.

Mr. Justice Lush.—What did the President say? He is not the Council.

Mr. Bullen.—He is President of the Council. That appears upon my affidavit, on which I moved.

Mr. Justice Lush.—How does that appear?

Mr. Bullen.—I will read it. "On or about the 10th day of February, 1871, I had an interview with Mr. G. W. Sandford, the President of the said Society, who advised me to lay a full statement before the Council by way of appeal, promising that it should be laid before the Council's monthly meeting, held the 1st day of March, 1871, and that I should hear the result of their decision, immediately after, and that all proceedings were stayed against me for the present." If your Lordship remembers, we were being sued in the County Court for penalties. And, "I accordingly, on the 27th of the same month of February, sent a full account of the facts, as also copies of the letters or certificates now produced and shown to me, marked respectively C, D, E, F and G, enclosed in a letter to the said Mr. Sandford, copy whereof is as follows:—'Welshpool, 27th February, 1871. Dear Sir, —I have sent you a copy of statement, also copy of some of the letters that I am in possession of, shall be greatly obliged if you will lay the same before the Council. I think you will see by the enclosed that I have been subjected to the greatest insults, and the conduct of your local secretary here has been most disgraceful; a part of which has been in this place disposed of before the magistrates.'" Now, in one of my affidavits we show that the local secretary and himself had been summoning one another before the magistrate, and were at daggers drawn, and that the whole proceeding has arisen from jealousy. 'I also think it my duty to inform you that every time my name has been appended in the Journal it has been publicly exhibited by your local secretary. Thanking you for the kindness and courtesy shown towards me when last in London. I am,'" etc. Then the affidavit goes on:—"Not having heard either from the said Mr. Sandford or the Registrar, Mr. Elias Bremridge, I, on the 20th day of March, 1871, sent the following letter to the said Mr. Sandford, which I caused to be registered: —'Welshpool, 26th March, 1871. Dear Sir,—I delivered my statement to you before March 1st, 1871, as registered, and this being the 20th, I think I ought to have heard something from you respecting the decision of the Council in my case before now. Will you kindly inform me by return what decision the Council came to, and oblige,' etc.; and on the 24th of the same month of March, received a reply as follows:—'March 22nd, 1871. Dear Sir,—Your statement was laid before the Council at its last sitting, and, as we only meet on the first Wednesday of each month, may be said to be still under consideration. After Wednesday, April 5th, you will, doubtless, hear definitely from the Registrar. In the meantime you know all the proceedings against you are stopped. Faithfully yours, G. W. Sandford.' I then heard nothing more of the matter until the 15th day of May instant, when I was served with the County Court summons now produced and shown to me marked H; and on the 17th day of may instant, I wrote the said Mr. Elias Bremridge as follows:—'Welshpool, 17th of May, 1871. Sir,—Not having heard in reply to the statement forwarded to your President on the 26th February last, to be laid before the Council, and having been served with a County Court summons for the recovery of a penalty of £5, I beg to apply to the Pharmaceutical Society to insert my name on the Register of Chemists and Druggists for the present year, and that on default thereof, I intend to apply for a *mandamus* to the Court of Queen's Bench to compel the insertion of my name, and I have to request an immediate reply to this application. Yours, etc., E. C. Whisken.' And, on the 24th day of the same month of May, I received a reply from Messrs. Flux and Co., Solicitors to the Pharmaceutical Society." So that the answer after we had been sued, only came from Messrs Flux and Co.:—"Sir,—Your letter of the 17th instant, addressed to E. Bremridge, Esq., Registrar, 17, Bloomsbury Square, has been handed, by that gentleman, to us. On reference to the Pharmacy Act, you will find that the action brought against you is by the Registrar of the Pharmaceutical Society with the authority of the Council. You may be sure that the Council did not give authority until after full consideration of your case. We may mention that one of the members of the Council was deputed to visit Welshpool, and made inquiries, and that the Council are fully satisfied that the action brought is proper in all respects."

Mr. Quain.—Now allow me to interpose for a moment. So far from that being the case, as my learned friend has just stated, I have an affidavit in my hand of the President, in which I have got this statement: that they took the trouble of sending one of their own Council to Welshpool, to investigate the matter again. I have the affidavit of the gentleman who went down to Welshpool, and, so far from there being no communication with Mr. Whisken, I have his letters, in the affidavit to the President, on the subject after the statement was sent in. It is in Mr. Sandford's affidavit. He says, "Mr. Whisken called on me on the 10th day of February last. I listened to what he had to say, and told him that his best course was to lay a full statement (by which I meant an accurate statement) before the Council by way of appeal, promising that it should be laid before the Council's monthly meeting to be held on the then next first of March, and that he should hear the result of their decision afterwards, and that I would request the solicitors to hold their hands until further instructed, and I did afterwards accordingly so request the said solicitors. The said E. C. Whisken having sent to me the letter of the 27th February, 1871, set out in his affidavit, together with the documents therein referred to, I laid them before the meeting of the Council which was held on Wednesday, the 1st day of March, and they were considered, and proceedings then took place as expressed in minutes of that meeting in the words following:—'Registration of E. C. Whisken, of Welshpool. An appeal and affidavits in support of Mr. Whisken's claim to registration having been read, it was resolved, That Mr. Abraham be authorized to visit Welshpool, and to make personal inquiry as to the claim of Mr. Whisken to be restored to the register of chemists and druggists, and report to the next Council meeting.' I subsequently received from the said E. C. Whisken his letter of the 20th March, 1871, and replied by mine of March 22nd, 1871, set out in his affidavit. The statement in the said affidavit which immediately follows the copy of my letter dated 22nd March, 1871, and which is in the words following—'I then heard nothing more of the matter until the 15th day of May instant, when I was served with the County Court summons'—is absolutely untrue, so far as it is inconsistent with the following facts, for I say that the said Mr. Abraham did discharge the duty undertaken by him at the Council, and go from Liverpool to Welshpool and investigate the matter, and have an interview with the said E. C. Whisken; and that on March 28th, 1871, the said E. C. Whisken wrote and sent to me a letter which contained clauses as follows:—'I received your letter on the 24th inst., and on the 25th a person called upon me from Liverpool, stating himself to be one of the Council, and giving his name as John Abraham. He said he was in possession of my statement, and also copies of letters, and wished to see the original letters, which I allowed him to do. He then asked me a series of what I thought were impertinent questions, adding insult to injury; he also wished me to read some prescriptions which he had brought with him, but, taking into consideration the facts of the case, I declined to comply with his request. . . . I shall therefore be glad to know whether the Council had authorized Mr. Abraham to call and catechise me in the way he has done, and to hear the result of its meeting on the 5th proximo.' I also received from the said E. C. Whisken another letter, dated April 3rd, 1871, also referring to the said call of Mr. Abraham. Mr. Abraham attended the meeting of the Council on the first Wednesday in April last, and proceedings took place thereat, and produced a report which was considered by the Council, and appeared to be conclusive against the claims of the said E. C. Whisken, and the Council accordingly rejected and referred the documents and evidence in reference to the case to Mr. Flux, with instructions to take such further action in conjunction with the Registrar as might be desirable or necessary. In all the minutes aforesaid the Council of the said Society acted *bonâ fide* and in the exercise of the best of their judgment; they have been anxious to discharge the duty committed to them for the protection of the public in the matter of the sale of poisons, and at the same time most desirous not to act unjustly to the said E. C. Whisken."

The whole thing has been thoroughly investigated.

The Lord Chief Justice.—If we had known all this we should not have granted the rule.

Mr. Bullen.—That is an affidavit that I have not got a copy of. My Lords, what we say is this, that opposition has been got up by Mr. Williams, who is the local secretary to the Society down there.

The Lord Chief Justice.—Whose duty it is to make any communication to them if any one is carrying on business as a chemist and druggist who is not qualified.

Mr. Bullen.—But we say the information that was given to the Society has not been true information.

The Lord Chief Justice.—They were willing to give you an opportunity of being reheard, which I do not know that they are now bound to do, as you have allowed the time to pass. Still they are willing to give you an opportunity of going before the Council again.

Mr. Bullen.—I should have said that your Lordships had power to have this matter inquired into.

The Lord Chief Justice.—So we have, if we see any abuse of the authority of the Council. *The powers given to them are so salutary, and the exercise of them so desirable for the protection of the public, that unless we see a case of manifest injustice and oppression we do not interfere.* So far from seeing anything of that kind here, as far as I can judge, it appears that what has been done by the Council has been properly done. I do not wish to say anything more.

Mr. Bullen.—What I wish to submit to the Court is this, that I have sufficient evidence before the Court, in the shape of affidavits from medical practitioners in the place, for it to be said that the Council has been misinformed.

The Lord Chief Justice.—If they have been misinformed, they can correct anything they have done; that is to say, if you would be so good as to condescend to go to the proper tribunal, that is, the Council, and satisfy the Council that they have acted improvidently in the case.

Mr. Bullen.—I should submit it is rather late in the day for them to say they are ready to hear it again.

Mr. Justice Lush.—A man who declines to satisfy them that he can read a prescription, surely is not entitled to come here for a mandamus.

Mr. Bullen.—We have satisfied them.

Mr. Quain.—On the contrary.

Mr. Justice Lush.—On the contrary, you have not.

Mr. Bullen.—We have the affidavits of several medical practitioners who have examined this man. But there is this difficulty, my Lords, they have put us in the County Court.

Mr. Justice Lush.—You deserve to be there if you have been practising without a qualification. This is an indirect mode of preventing that action being tried.

Mr. Bullen.—No, my Lord, we say "you wrongfully refused to qualify us, and therefore we go to the Court of Queen's Bench to make you do it. We are prepared to say to the Court of Queen's Bench we have satisfied the Act in all respects." That is what I ask your Lordships to do, and to hear the affidavits, and say whether you are not satisfied that we are properly qualified to be put on the register.

The Lord Chief Justice.—What for? However, if you have anything to say we will hear you.

Mr. Bullen.—I do not wish to keep the case up if your Lordships have made up your minds; but I should ask your Lordships to impose, so to say, the rehearing of our case before the Council itself.

The Lord Chief Justice.—They offer that.

Mr. Quain.—We have done that twice.

Mr. Bullen.—Are you ready to do it again? that is the question.

The Lord Chief Justice.—Up to the present time you have declined to avail yourself of that offer. It is not for us, under those circumstances, to impose any condition. The Council will do what they think to be right. If they have thought it right to say they will give you a further hearing, I have no doubt they will continue to say it, without our interfering. I think there is no alternative but to discharge the rule, and to discharge it with costs. If a man will be obstinate, and not submit himself to the proper authority which has been authorized by the Act of Parliament to consider whether he is entitled to practise or not, and will come here, he must pay the expenses.

Poisoning by Arsenic.

An inquiry into the deaths of Mrs. Matilda Harper, wife of Mr. William Harper, farmer, of Linley Hill, near Beverley, and of Lily Marian Taylor, their grandchild, was held on Friday last. On the 25th ult., Mrs. Harper, Miss Harper and the child Taylor, in the absence of the male members of the family, partook of tea, and during the meal the child was taken ill. Mrs. Harper, who for some time previously had been in delicate health, soon afterwards became indisposed, and as they grew worse assistance was sent for. Dr. Calvert, of Brandesburton, ascertained that they were suffering from the effects of poison. Everything possible was done to alleviate their agonies, but medical aid was of no avail, and both Mrs. Harper and her granddaughter died next day. Miss Harper and Hannah Bromby were also taken ill after tea, as was also Henry Dunn, a bricklayer, working at the house, but they were ultimately restored. An inquest was opened on the bodies on the 20th ult., evidence was given to show that red lead had been used by the family during cleaning time, and the hypothesis was entertained that the water used for the tea might have become impregnated with the poison. A pump, which had been for a time disused, was repaired the same day, and the water for the tea was taken from this pump. Other persons, however, who were not affected, drank from the pump spout shortly after it was mended, and this fact tended to show that poison must have been contained in some of the vessels in which the water had been placed from the time of its extraction from the pump to coming on to the table. The kettle, teapot, etc., were carefully taken care of by the police, and the inquest was adjourned in order that the viscera of the child and the contents of the vessels might be analysed.

Miss Mary Anna Harper said: Red lead was used on Thursday. Hannah Bromby filled the kettle on the day of the accident from the pump. No one told her to put the kettle on the first time. She put it on the kitchen fire on her own account. It was her duty to do so. The kettle boiled some time between four and five o'clock. When it boiled, I told her to take it off and refill it from the river. When it boiled over, I saw some stuff of a slate colour come from the kettle, and I told her to fill it from the river. She took it out of the kitchen into the back kitchen, and I suppose into the yard. I had not noticed the kettle boil over in that way before. She was just going out of the kitchen where I was, when I told her to refill it from the river. She could not help hearing me. During the time the pump was disused, about three weeks, we used the water from the river for drinking purposes. We have not lately used soda in the tea, not for three or four months perhaps. Do not remember using it since Hannah Bromby came to us. Did not observe anything the second time the kettle boiled. Do not remember looking. My mother filled the teapot as soon as the kettle boiled a second time. I gave Marian Taylor about a quarter of a mug full of tea first, and about as much milk. It was not a large mug. She did not drink above half of it. She complained of being sick, and mother gave her a drink of her tea in a saucer. She drank about a quarter of a saucer full. She had not been sick before, but only complained. As soon as she got the tea out of the saucer she was sick before she could get out of her chair. I then got some tea and also began to be sick. Bromby at that time was in the back kitchen, and also looking out of the front kitchen door. That morning there had been a disagreement between my mother and the under-girl. There had also been one once before. On the Thursday morning (the day of the occurrence) mother told her to sweep up the back kitchen. I did not hear her say anything in reply. When I came down, the other girl told me that Bromby had been saucy to my mother. I spoke to her and told her I should not have my mother insulted. She did not say anything to me and I told her she should leave. I believe I said she should go at once. My mother was first sick on the lawn.

By Dr. Procter: The substance that boiled up out of the kettle was not like red sand.

Mr. William Procter, of York, deposed: I am a doctor of medicine and Fellow of the Chemical Society, London. I received on Sunday, the 21st of May, from Dr. Calvert, the following articles, viz. No. 1 jar, containing a liver and portion of intestine. In both I found a small quantity of arsenic. Another jar contained a stomach and its contents. That I found, on examination, to be considerably inflamed, and contain a small quantity of stringy mucus, with matter like white of egg, which chemically I found it to be. In this, also, I detected arsenic. No. 3 was a pint bottle, labelled water from the pump. On standing, that deposited a brown matter, which I separated by filtration, and found to consist only of organic matter. In neither the water nor the deposit could I detect any trace of arsenic or lead. No. 4 was a bottle containing about four ounces of water said to be obtained from the kettle. On standing, it deposited a reddish-brown powder. This I separated by filtration. In the first instance I distilled the clear water filtered from the powder. I found nothing in the distillate. I then examined the water, and from the quantity of water given to me, about four ounces, I separated 12 grains of sulphide, or yellow arsenic, which is equivalent to 9½ grains of white arsenic. I then examined the brown powder which I had separated by filtration. That contained very slight traces of arsenic, and I found it to be composed of carbonate of lime and oxide, or rust of iron. (Witness explained that he did not expect to find arsenic in quantities in the powder; it was soluble, and would be found in the water.) No. 5 was a bottle containing Mrs. Harper's last vomit. That contained a large quantity of greenish deposit, which the microscope showed to consist of mucus containing partly digested food, and a few muscular fibres and fat globules. I found, by examination, that the green tinge was due to bile. I detected no mineral poison. No. 6 was Mrs. Harper's fæces. In that I detected no mineral poison. No. 7 was given to me as the under-servant's vomit. It contained some whitish particles floating in it, which the microscope showed to be partly digested food and fat mixed with mucus. This I verified chemically. I detected no arsenic, lead, or other mineral poison in it. No. 8 was given me as the upper-servant's vomit. I found it contained a very large quantity of flaky matter, which was evidently food. I detected no poisonous matter at all. No. 9 was a bottle which contained water, and a reddish powder adhering to the sides and to the bottom of the bottle. This I found to be a mixture of litharge and red lead with some oily matter. I found no arsenic in it. On Tuesday, the 23rd of May, I received from Mr. Calvert the following articles, namely, No. 10, an iron kettle. At the time he brought it to my house it contained about a tea-cup full of water. In his presence, in that water, I showed the presence of arsenic. The kettle is very much furred with oxide of iron. (This, witness said, was only the ordinary fur.) No. 11 was a caddy, containing about a teaspoonful of tea. That contained no poisonous substance. Several other packages I received, but I found no arsenic in them. No. 19 was a red powder, but it contained no arsenic. The packages, from No. 15 to 19, I received from Superintendent Wright, on the 29th of May. The others I received from Dr. Calvert. I received others up to No. 25, which were of no importance. No. 26 was a tin case in which was a sod, on which had been vomited matter. I examined it carefully. It gave no indication of any poisonous matter, except arsenic, which I found in it. No. 27 was a portion of soil, but it contained no arsenic. It has been stated that some soils contained arsenic, but this did not.

In reply to Lieut-Col. Layard, Dr. Procter said he had received communications from large manufacturers of colours, and found that the practice to mix red lead with arsenic to adulterate it was unknown. Since this occurrence he had analysed red lead from nearly all the retail dealers in York, and found no arsenic. With regard to the existence of arsenic in water he might say that cold water would take up a grain or a grain and a half, whilst water which has been boiled and allowed to cool would take up perhaps 12 grains.

Dr. Calvert, of Brandesburton, deposed: On Thursday, the 18th May, about a quarter to eight o'clock p.m., I received a note from Mrs. Harper stating that Megson, from Leven, had been repairing their pump, after which the girl had filled the teakettle. Tea having been made, the family had partaken of it, and were immediately taken ill. The writer requested that I should send them something to do them good. I considered the matter well over, and considered it my duty to proceed to the house, as I suspected it was a case of poisoning. My suspicions were more confirmed on meeting a young man named Watson Dunn, jun., coming for me to visit his brother, who had just arrived from the Harpers, and who was suffering from violent vomiting and other symptoms. His residence being in the way to the Harpers, I first visited him and found him suffering from violent vomiting, attended with pains at the stomach, with heat and burning at the back of the throat, headache, great thirst, drowsiness and general collapse. The skin was cold and clammy and the countenance pale; the pulse small and scarcely perceptible. He had vomited freely on his way home, and had had an emetic administered. I gave him certain directions in the way of treatment, and then proceeded to the Harpers. On my arrival I found Miss Harper and the child reclining on a couch. I at once inquired what was the matter, and Miss Harper told me that after partaking of tea the child, her mother and herself had commenced to vomit. I proceeded to examine Miss Harper and the child, and found them suffering from similar symptoms to those from which Henry Dunn was suffering. I then inquired for Mrs. Harper and found her in bed. She got up and came down to see me. In the meantime Mrs. Harper referred me to the under-girl, Hannah Bromby, who she said was suffering the same way as the rest of the family. I proceeded to the kitchen and found Bromby suffering, as far as I was able to judge at the time, from the same symptoms as the rest of the family. I administered the usual remedies in cases of irritant poison, and, after a space of about three hours and a half, found my patients to a certain extent rallied. I returned to Leven, and finding Dunn somewhat better I went home and forwarded medicine to each patient. About half-past three next morning I was again summoned, and arrived soon after four. I found that the child had died in the meantime. Mrs. Harper was suffering from a great amount of collapse, and I requested Mr. Harper to send for Dr. Boulton. In the meantime I administered stimulants, and had the satisfaction of finding Mrs. Harper gradually rallying. About seven o'clock I was summoned to Leven to a case, and, considering that Mrs. Harper had, to some extent rallied, and expecting the presence of Dr. Boulton shortly, I left. On returning, about eleven, which was as early as I could get, I met Dr. Boulton coming to Leven from Linley Hill. On asking him how Mrs. Harper was, his answer confirmed the opinion I had formed at seven o'clock that she was rallying. He returned with me to Linley Hill, but unfortunately our favourable prognostics was doomed to be fallacious, we found Mrs. Harper gradually dying, and she expired a little before one. We administered stimulants and other remedies applicable to the case. On Saturday morning, by the coroner's orders I proceeded to make a post-mortem examination on the body of the child Marian Taylor. I found oozing from the nostrils a thick brownish matter, and on proceeding to open the abdomen I found the peritoneum in a highly congested state. I exposed the stomach and intestines. I did not open the stomach, but removed it for the purpose of analysing the contents. I also removed the liver and a portion of the smaller intestines, which, with the stomach, I placed in jars. The contents of the abdomen were in a congested condition throughout. I did not examine any other organ. On the Friday morning, early, I inquired for the kettle in which the water had been boiled from which the tea had been made, and of which Mrs. and Miss Harper and Marian Taylor had partaken. It was brought to me by Elizabeth Ash, the upper-girl. I found it to contain a small quantity of water, which I poured into a clean bottle. The kettle and bottle were given over to Superintendent Wright. I procured the fæces and last vomit of Mrs. Harper and locked them up. I took to Dr. Procter, of York, on Sunday, the 21st, in jars, the liver, stomach and portion of small intestines of Lily Marian Taylor, a little bottle containing water from the pump, a bottle containing water taken from the kettle, Mrs. Harper's last vomit, Mrs. Harper's fæces, the under-servant's vomit, the upper-girl's vomit, and a jar containing red lead in suspension. On Tuesday, the 23rd of May, I took to York, to Dr. Procter, the iron kettle, which I received from Superintendent Knight, a teacaddy containing a small portion of tea, a bottle containing water from the foldyard pump, some anti-smut powder, white crystalline powder, and another packet of powder from the bacon-house.

As soon as I arrived at Dr. Procter's, on the Tuesday, he proceeded to show me certain tests applied to about a teaspoonful of water, which was in the kettle, on my delivering it to him. The tests applied indicated fully the presence of arsenic.

Mr. James Douglas Wright, Superintendent of Police at Leven, deposed: On the morning of Friday, the 19th of May, from information I received, I came to Mr. Harper's, where I was shown the dead body of Lily Marian Taylor. It would be between eight and nine o'clock in the morning. I made inquiries, and received from Mr. William Harper a bottle containing water, numbered 4. On a shelf in the front kitchen was a basin containing the vomit of the under-girl, Bromby. In the servants' bedroom I found the vomit of the upper-girl, Elizabeth Ash. A puncheon, containing water and a mixture of red lead, was handed to me by the charwoman, Mrs. Newman. A teakettle was handed to me by Mr. John Harper the same morning. A teacaddy I found on a sideboard in the room. On the 22nd I took a bottle full of water from the foldyard pump. I took possession of a packet of smut powder from the saddle-room on the 19th, also a packet of alum powder from the saddle-room, and some powder taken from the bakehouse. These articles were locked up by me in a closet in the house as well as some ducks. On the 20th I delivered up to Dr. Calvert, by the directions of the coroner, several of those articles, and on the 28th I delivered up others. On the 23rd I made a further search here, and found in a closet, in the front kitchen, a paper containing powder, numbered 16, and a tin canister containing some other powder. I also found a packet of anti-smut powder and other powders, a paper of horse-balls, a bottle containing liquid, a bottle containing consistency like paste, and a teapot containing sundry bottles. The latter I found in a bureau in the room. These I locked up in the kitchen closet, the key of which I have yet. On the 24th, I was shown by Miss Harper the first and second vomits of Mrs. Harper on the lawn. I took up the sods, and placed them in a tin canister. I also, at a distance of eight or ten paces from these vomits, took up some of the sods and earth on the lawn, which I also placed in a tin. On Monday, the 29th May, I handed to Dr. Procter, of York, several of these articles. On Friday morning, the 19th, I searched the female servants' boxes, but found no packages in powder of any description there. I have since made inquiries at Beverley, Driffield, Leven and the neighbourhood of all chemists relative to the sale of any arsenic, but cannot hear that any has been sold at any of these places recently that was likely to have been got by any of the servants about here.

Mr. John Robert Harper stated that on Friday morning, the 19th ult., he gave the kettle, from which the water had been taken for tea, to Superintendent Wright. Witness got it from the boiler top in the front kitchen. He got his tea in the kitchen, on his return with his father from Beverley fair, about eight o'clock on the previous night. He took tea alone, and the water used was from a small kettle. The other kettle was near the fireplace then, and was in the same position the next morning.

Henry Dunn, of Leven, bricklayer, deposed that on Thursday, the 18th of May, he was working at Linley Hill. About a quarter to six o'clock he came from upstairs, where he had been working, into the kitchen, and sat down to tea. The child was sick then. He drank from half to three-quarters of a cup out of a basin, and as it was nasty he did not sup any more. He had not got above two or three hundred yards from the house when he was taken sick, and vomited three or four times before he got to the Hall Garth, where he got a drink of water. He then went to Leven and got two emetics at the druggist's shop. He went home with them and took them both, one about an hour after the other. He vomited until about one o'clock in the morning, when he felt somewhat better, and by the leave of Dr. Calvert, who had attended him twice, went to bed.

By Mr. Harper: Before I started to go home the upper-girl, Ash, asked me when I was near the pump, if I had drunk any tea. I said yes. She then asked me if I thought it was pump water that made it nasty. I said I did not know, but if I had got more I should have been sick then. She appeared to think I was more frightened than hurt.

Thomas Matthew Gilbert deposed that he was shepherd to Mr. Harper. On Thursday night, the 18th ult., he went through the yard to see the sheep, about a quarter to seven o'clock, and saw the under-girl, Bromby, vomiting at the swine tub. Witness asked her what was the matter, and she said she was sick, but she did not know what with. She had only had cold water from the pump. He went into the back kitchen, and the groom said to him that they were all sick, but did not know what with. Witness then went and sat down to his supper in the front kitchen. Miss Harper sat by the fireside, and the charwoman had the little girl on her knee. He asked them what the matter was, and one of them said they were all sick with the tea. Witness told them that if they thought there was any poison in it, they had better send for the doctor. Miss Harper wrote a note, and sent the groom for the doctor.

This concluded the evidence, and the jury, after a short deliberation, returned a verdict of "Wilful Murder" against some person or persons unknown, the deceased having been in their opinion feloniously and with malice aforethought poisoned by the administration of arsenic, but by whom administered there was no evidence to show.

NEW READING OF THE PETROLEUM ACTS.

BY BOVERTON REDWOOD, F.C.S.

Secretary and Consulting Chemist to the Petroleum Association.

Considerable misapprehension appears to prevail in reference to the Judgment recently delivered in the Court of Queen's Bench in an appeal against a conviction under the Petroleum Acts. The judgment in question involves a new reading of the Acts of a somewhat unexpected nature; and a very general impression exists that, whereas a licence has only hitherto been needed for such petroleum as gives off inflammable vapour below 100° F., it is now, in consequence of this judgment, unlawful to keep any description of petroleum, except in pursuance of a licence. This opinion is in fact embodied in the following notice, which has been circulated in the town of Cambridge:—

"Borough of Cambridge. The Court of Queen's Bench having decided that all persons dealing (without a licence) in petroleum or any product thereof, whether it gives off an inflammable vapour at a temperature of less than 100 degrees Fahrenheit or not, are liable to the penalties imposed by the Petroleum Acts. Notice is hereby given, that proceedings will be taken against all persons found dealing therein, contrary to the provisions of the Petroleum Acts, on and after the 15th day of June instant.

"By order, EDMOND FOSTER, Town Clerk.

"*Guildhall, 5th June*, 1871."

It will, however, be evident from a consideration of the facts of the case that such a view is not in accordance with the decision of the Court.

The appellant, an oil merchant, was charged before the Surrey magistrates, under the Petroleum Acts, with keeping, otherwise than for private use, within fifty yards of a dwelling-house, a quantity of petroleum without being licensed in accordance with the said Acts. On the hearing of the information it was admitted by both parties that the petroleum in question did not give off inflammable vapour at a temperature of less than 100° F.; nevertheless, the magistrates convicted the appellant and adjudged him to pay a fine of ten shillings and costs, a case being granted for the Court of Queen's Bench. The case was argued before Mr. Justice Blackburn and Mr. Justice Mellor; Mr. Grantham appearing for the appellant and Mr. Lord for the respondent. Mr. Grantham contended that as the petroleum in question did not give off inflammable vapour below 100° F., it did not come within the following definitions contained in the Acts of 1862 and 1868:—

1862. "'Petroleum,' for the purposes of this Act, shall include any product thereof that gives off an inflammable vapour at a temperature of less than one hundred degrees of Fahrenheit's thermometer."

1868. "For the purposes of the Petroleum Acts, 1862, 1868, including all local acts and bye-laws relating to petroleum or the produce thereof; 'petroleum' shall include all such rock-oil, Rangoon oil, Burmah oil, any product of them, and any oil made from petroleum, coal, schist, shale, peat, or other bituminous substance, and any product of them, as gives off an inflammable vapour at a temperature of less than one hundred degrees of Fahrenheit's thermometer."

The Court, however, held that it was not sufficient to show that the petroleum in question did not give off inflammable vapour below 100° F. in order to prove that it was not "petroleum" within the meaning of the Acts; since the Legislature, by the use of the words "shall include," evidently intended that "petroleum" (legally used) should mean, not only all such products of petroleum and the other substances mentioned in the Act as give off inflammable vapour under 100° F., but also petroleum itself (as distinguished from the products of petroleum) unconditionally. Mr. Grantham argued that the words "shall include" had always been construed in the sense of "shall be confined to," and that, although it was possible that a wrong word might have been used, yet that the intention of the Legislature was in accordance with what he contended for. In this sentiment the Court could not concur, Mr. Justice Blackburn remarking:*—"It is very common in the interpretation clause of an Act of Parliament to say that a parish shall include a township, but it never could be contended with success that a parish is confined to a township." Mr. Grantham was unprepared for this distinction being drawn between petroleum and the products of petroleum, and therefore found himself in a difficulty. The liquid in question had, as is usual in such cases, been spoken of by both sides as petroleum; the term petroleum being, of course, used in its ordinary commercial sense; in fact, it had been admitted by the appellant to be petroleum commercially speaking, though it was denied that it was "petroleum" within the meaning of the Acts. Now, however, it was clear that, according to the definition of the Court, the liquid should have been termed a product of petroleum which, scientifically, it undoubtedly was. This Mr. Grantham explained, and the following argument ensued:—

Mr. Justice Blackburn: "I thought the case had found that it was what is called petroleum."

Mr. Grantham: "The term, as used in the trade, is applied to that which you go into a shop and buy, and at once put in your lamp and burn."

Mr. Justice Blackburn: "I should have inferred that that was a product of petroleum, not petroleum itself."

Mr. Grantham: "It is assumed that that which is the subject of the argument is what is commonly called petroleum."

Mr. Justice Blackburn: "If there has been a mistake, and that this was not petroleum, but the product of petroleum, he has lost his ten shillings; the penalty is nothing; it is the principle."

Mr. Grantham: "If there be any doubt as to that, I should ask that the case may be re-stated."

Mr. Justice Blackburn: "It would cost twenty times as much as it is worth. Assuming this to be petroleum, and not a mere product, it is required that it should be licensed, although it does not throw off this vapour."

The case therefore proceeded on the assumption that the liquid in question was petroleum as distinguished from the products of petroleum, or, in other words, was crude petroleum, Mr. Justice Blackburn remarking: "The only question in this case is, whether that [the interpretation clause] does not include crude petroleum, or natural petroleum, which gives off this vapour or not." The decision of the Court will be evident from the following extracts from the judgment:—

Mr. Justice Blackburn: "I think the object and intention of the Legislature was, that petroleum, as im-

* This quotation and similar ones are from a transcript of the shorthand writer's notes, which Mr. Grantham has assured the writer are substantially correct.

ported in its natural state, should not be stored without a licence." . . . "I have, therefore, come to the conclusion" . . . "that the petroleum, not being a manufactured petroleum but petroleum proper, may not be kept and stored without a licence."

The new reading of the Acts as embodied in this judgment, therefore, amounts to this, that "petroleum" (legally speaking) has a double meaning; it means:—

1. Any product of petroleum or other substance mentioned in the Act of 1868, provided it give off inflammable vapour below 100° F.
2. Petroleum proper (as distinguished from the products of petroleum), or, in other words, crude petroleum, unconditionally.

This new reading, though doubtless at variance with the intention of the Legislature, is, as will be seen, of no practical importance, if it be understood, as crude petroleum is not now imported; it is however a hardship that dealers should be subjected to the unjustifiable annoyance, arising from those in authority being unacquainted with the real meaning of the judgment.

It should be distinctly comprehended that the oil imported from America, known in the wholesale trade as "refined petroleum," and sold in the shops under the names "petroleum," "rock oil," "crystal oil," etc., is, not only scientifically, but also in the eye of the law, "a product of petroleum," and that, as such, no licence is needed for storing it, provided it does not give off inflammable vapour below 100° F. when tested in accordance with the Act.

Note.—Since the above was forwarded to the Editor, a Petroleum Bill, now before the House of Lords, has been printed. This Bill contains a new interpretation clause, which is a great improvement on those of the existing Acts; and although the term "include," which has caused so much trouble, again makes its appearance, there can be no doubt that, should the Bill become law (in which case the Acts of 1862 and 1868 would be repealed), much of the ambiguity which at present attaches to the word "petroleum" would be removed.—B. CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Hydrargyri Subchloridum.—Mercuric sulphate is first triturated with a quantity of metallic mercury equal to that which it already contains, the combination being assisted by moistening with a few drops of water. A grey powder is thus obtained which is practically mercur*ous* sulphate.

$$HgSO_4 + Hg = Hg_2SO_4.$$

From this equation $HgSO_4$, or 296 parts of the sulphate, require Hg or 200 parts of the metal, forming 496 parts of the mercurous sulphate.

Chloride of sodium is then added and the mixture sublimed with the aid of a pretty strong heat.

$$Hg_2SO_4 + 2NaCl = 2HgCl + Na_2SO_4.$$

If the sublimation is conducted in a small flask or pot, so that the vapour condenses upon a warm surface and but slowly, crystalline masses are obtained, a form which would be unsuitable for administration in medicine. The vapour is therefore driven from the subliming pot into a pretty large brick chamber, in which, in consequence of the sudden cooling effected, the calomel condenses in the form of a fine dust. This is washed with boiling water, to remove from it the traces of corrosive sublimate that are invariably produced.

Calomel, in the pulverulent state, as produced by sublimation, is not a white powder, but has a yellowish tint, which is increased by trituration in a mortar.

[§ Digested with solution of potash, it becomes black; and the clear solution, acidulated with nitric acid, gives a copious white precipitate with nitrate of silver.] The black compound is of course mercurous oxide, chloride of potassium being left in solution.

[§ Contact with hydrocyanic acid also darkens its colour.] The result, however, is not a definite mercurous cyanide, but a mixture of metallic mercury, calomel and a cyanide, or probably a chlorocyanide. [Warm ether, which has been shaken with it in a bottle, leaves, on evaporation, no residue.] This shows the absence of corrosive sublimate.

Calomel may be prepared according to other methods; one which was at one time employed consists in precipitating a solution of mercurous nitrate with common salt.

In undergoing volatilization, there can be no doubt that calomel undergoes decomposition into free mercury and mercuric chloride, recombination ensuing when it again condenses. In consequence of this, the specific gravity of the vapour connot, in this case, be taken as any evidence of molecular weight.

Hydrargyri Sulphas.—Mercury is boiled with strong sulphuric acid, the heat being continued until the metal has disappeared and a dry, white, crystalline powder remains:—

$$Hg + \underbrace{H_2O_2SO_2}_{\text{Sulphuric acid.}} + H_2SO_4$$

$$= \underbrace{HgSO_4}_{\text{Mercuric sulphate.}} + \underbrace{H_2O}_{\text{Water.}} + H_2O + \underbrace{SO_2}_{\text{Sulphurous acid gas.}}.$$

Mercuric sulphate is decomposed by water with formation of "turpeth mineral," a mercuric oxysulphate:—

$$3HgSO_4 + 2H_2O = Hg_3SO_4O_2 + 2H_2SO_4.$$

Hydrargyrum.—This important metal is obtained almost exclusively from the native sulphide, HgS or cinnabar, by one of two processes. Either the mineral is roasted in a current of air, which oxidizes the sulphur into the permanently gaseous SO_2, the mercury being simultaneously carried in the state of vapour through a series of earthen pipes, where it condenses to the liquid state and runs into a reservoir; or the powdered mineral is distilled with lime, when a mixture of sulphide and sulphate of calcium remains behind with the excess of lime and the gangue, and metallic mercury distils over.

The impurities contained in the mercury of commerce are principally traces of lead, zinc, tin and bismuth. Mercury so contaminated does not form bright spheroidal globules, but each one leaves a trail behind it. These impurities are best removed by redistillation, but the mercury may also be rendered sufficiently pure for ordinary purposes by agitation with a small quantity of nitrate of mercury and subsequent straining. Pure mercury is entirely volatilized by heat and leaves no residue. It boils at 680° F. Specific gravity, 13·596.

HYDRARGYRUM AMMONIATUM.—A solution of perchloride of mercury in water is poured into solution of ammonia, and the precipitate collected, washed free from sal-ammoniac and dried at 212°:—

$$HgCl_2 + \underset{\text{Ammonia.}}{NH_2H} + \underset{\text{Ammonia.}}{NH_3}$$

$$= \underset{\text{Amido-chloride of mercury.}}{HgNH_2Cl} + \underset{\text{Sal-ammoniac.}}{NH_3HCl.}$$

Ammoniated mercury is an opaque white powder, which often has a slight yellowish tinge, which is increased by prolonged washing.

[§ Digested with caustic potash, it evolves ammonia, acquiring a pale yellow colour, and the fluid filtered and acidulated with nitric acid gives a white precipitate with nitrate of silver.]

$$Hg''NH_2Cl + \underset{\text{Potash.}}{KHO}$$

$$= \underset{\text{Yellow mercuric oxide.}}{HgO} + \underset{\text{Ammonia.}}{NH_3} + \underset{\text{Chloride of potassium.}}{KCl.}$$

[§ Boiled with a solution of chloride of tin, it becomes grey and affords globules of metallic mercury.]

$$HgNH_2Cl + \underset{\text{Stannous chloride.}}{Sn''Cl_2} + \underset{\text{Hydrochloric acid.}}{2HCl}$$

$$= \underset{\text{Metallic mercury.}}{Hg} + \underset{\text{Sal-ammoniac.}}{NH_4Cl} + \underset{\text{Stannic chloride.}}{Sn^{iv}Cl_4.}$$

[§ Entirely volatilized by a heat under redness.] To this should be added the words "*without fusing.*"

Much of the white precipitate of commerce melts before volatilizing, in consequence either of consisting of "fusible white precipitate,"

$$HgH_2NCl, NH_4Cl,$$

which contains a smaller proportion of mercury; or in consequence of deficient washing whereby it retains some sal-ammoniac. (See PHARM. JOURN. s. s. Vol. X. p. 515.)

White precipitate is represented by most chemists as a compound formed from sal-ammoniac by the replacement of two atoms of hydrogen by one atom of mercury.

$$\underset{\text{Sal-ammoniac.}}{H_4NCl.} \qquad \underset{\text{White precipitate.}}{HgH_2NCl.}$$

By others it is regarded as an amido-chloride or chlor-amide of mercury; that is to say, as a compound in which the bivalent atom mercury is united to the two univalent atoms Cl and amidogen NH_2. In reality, however, these two views are identical, as an examination of the formulæ will show:—

First view. Second view.

$$\left.\begin{matrix}Hg''\\H_2\end{matrix}\right\}NCl \qquad Hg\left\{\begin{matrix}NH_2\\Cl\end{matrix}\right.$$

$$\text{or } HgH_2NCl. \qquad \text{or } HgNH_2Cl.$$

The univalent radicle NH_2 results from the removal of one atom of H from ammonia NH_3, just as the univalent radicle Cl is left on the removal of H from HCl:—

$$NH_3 - H = (NH_2)'.$$
$$ClH - H = Cl'.$$

HYDRARGYRUM CUM CRETA.—Grey powder, when kept for a long time, is apt to contain traces of mercuric oxide, formed by gradual oxidation of the mercury by contact, in a finely divided state, with the air. To detect this, the test is given in the Pharmacopœia. [§ The solution formed with hydrochloric acid is not precipitated by the addition of chloride of tin.]

DETECTION OF TURMERIC IN POWDERED RHUBARB AND YELLOW MUSTARD.

BY J. M. MAISCH.

Rhubarb root which has been attacked by insects or deteriorated in consequence of dampness and heat, is by some dealers sent to the mills and ground together with some sound rhubarb, or, if the colour is not sufficiently bright, turmeric is added, and the powdered rhubarb finds its way afterwards into the hands of the unsuspicious as a prime article. The fraud may be detected in a few minutes in the following manner:—

A small quantity of the suspected rhubarb is agitated for a minute or two with strong alcohol and then filtered. Chrysophanic acid being sparingly soluble in this menstruum, the brown yellow colour of the filtrate is due to the resinous principles of rhubarb mainly; if adulterated with turmeric, the tincture will be of a brighter yellow shade. A strong solution of borax produces in both tinctures a deep red-brown colour. If now pure muriatic acid be added in large excess, the tincture of pure rhubarb will instantly assume a light yellow colour, while the tincture of the adulterated powder will change merely to a lighter shade of brown red. The test is a very delicate one, and is based on the liberation of boracic acid, which imparts to curcumin a colour similar to that produced by alkalies, while all the soluble principles of rhubarb yield pale yellow solutions in acid liquids.

The same test, applied in the same manner, is also applicable to ground mustard seed. The seeds of *Sinapis alba* yield a powder of a yellow-grey colour, entirely distinct from the colour of yellow mustard met with in the market. Agitated with alcohol and filtered, a turbid solution is obtained, which assumes a bright yellow on the addition of the borax solution, and becomes colourless or whitish again on being supersaturated with muriatic acid. If the mustard be coloured with turmeric, the filtrate has a yellow tint, becomes brown-red by borax and retains the colour on the addition of muriatic acid. All the so-called yellow mustard of our commerce which I have had occasion to examine, whether ground in England or in the United States, contains turmeric. This practice ought to be discountenanced; for, under the yellow colour imparted by curcuma, adulteration of mustard may be carried on to an almost indefinite extent, if *strength* be supplied by the addition of a little capsicum.—*Amer. Journ. of Pharmacy.*

GLYCEROLE OF LUPULIN.

BY EMMET KANNAL.

Take of Lupulin, one troy ounce
Alcohol, six fluid ounces
Glycerin, nine fluid ounces
Curaçao cordial, one fluid ounce.

Mix the alcohol with two fluid ounces of glycerine, moisten the lupulin with the mixture, pack into a cylindrical percolator, and continue to add this mixture until eight fluid ounces of the percolate has passed; to this add the remainder of glycerine, previously mixed with the curaçao, and thoroughly mix the whole together. This will afford, by careful manipulation, a very fine preparation, miscible with any of the officinal syrups or tinctures, and possessing all the medicinal properties of lupulin. Dose, for an adult, one teaspoonful, representing $7\frac{1}{2}$ grains of lupulin.—*Amer. Journ. of Pharmacy.*

THE CHEMISTRY OF CALICO PRINTING.

BY JAMES BLAIR.

(*Continued from page* 1010.)

Clearing has for its object the removing of any taint or soiling contracted in the former operations, and also has a brightening action on some colours. It consists in padding the goods in a solution of bleaching powder at $\frac{1}{8}°$ to $\frac{3}{4}°$ Tw. (the less whites the stronger the liquor), then passing the goods through blue liquor, *i. e.* ultramarine and HO. The ultramarine may be mixed with the bleaching liquor. The goods on passing from the bleaching and bluing liquor are dried by passing over steam cylinders, then starched with solution of fine wheat starch and dried (if muslins tentered), calendered, folded, pressed.

Mordanted or Dyed Colours.—In these colours various metallic salts are printed on the cloth, and means adopted for rendering their base permanently fixed. This being accomplished, the goods are immersed in a bath containing the colouring principle, which in the operation of dyeing combines with the mordant in the cloth, forming a lake or other chemical compound with it. The principal styles of this class are:—1, Chrome oranges and yellows. 2, Logwood blacks. 3, Madder work. 4, Garancine work.

The first are, of course, produced by a lead salt and a soluble chromate. The other styles involve the use of madder, logwood, garancine, alizarine, Lima wood, bark, sumac, quercitron, galls, flavine, Persian berries, in the dye bath; salts of iron, alumina and tin, individually or mixed, constituting the mordants.

Chrome Orange.—The cloth is padded with solution of $MgOSO_3$ at 12 oz. per gallon and dried. The orange mordant, the basis of which is acetate of lead, is printed on, and by the $MgOSO_3$ converted into the insoluble sulphate of lead in the fibre of the cloth.

The cloth is then passed through a *cold* bath of 35 lbs. bichrome + 112 lbs. salt + HO till 26° Tw., which produces the yellow and insoluble chromate of lead.

The cloth is then worked in a vat of bichrome at 40° Tw. and CaO, boiling, which changes the yellow chromate into the orange chromate of lead; then cooled by rinsing in cold water, and then rinsed in lime water, rinsed in water, and dried.

Chrome Yellows are produced in the same way as the orange, but the treatment in the hot chrome and lime vat and the washing in lime water is omitted.

The operations of printing and dyeing madder, garancine and logwood are in some degree analogous, so may be conveniently described together. The mordants required for this style are acetate of iron and alumina, and chloride of tin, catechu, nitrate of copper, chloride of iron; the dyes—logwood, Lima wood, bark, sumac, quercitron, galls, flavine and Persian berries.

Mordants.—Acetate of iron, supplied to the printer in concentrated solution at 32° Tw., is made by passing the crude pyroligneous acid obtained from wood distillation direct from the still over iron turnings in the condenser. It invariably contains tarry impurities, which, however, in no way interfere with its usefulness; diluted less or more with HO it furnishes all the shades of black, purple and lilac produced by dyeing with madder, logwood, garancine, alizarine or mixtures of these dyes; thus black—1 volume FeOA and 1 volume HO = FeOA at 16°, thickened by boiling with flour + 2 oz. ASO_3; purple, weaker according to shade wanted; purple standard, FeOA, at 12° F., from 1 of purple standard to 8 of gum water to 1 to 36; covers 1 to 6 to 1 to 22; pads 1 to 24 to 1 to 54, figure thick with black gum; covers and pads boiled with flour. The solutions of acetate of iron are thickened for printing by flour or British gum.

Acetate of alumina is made by neutralizing sulphate of alumina solution with solution of acetate of lime, and is used neutral, or with a trace of free alum. Acetate of lime is made by saturating slaked lime with the crude acetic acid from wood distillation; it always contains tarry matters, which, for most work, are harmless. Cake alum supplied in slabs is nearly pure $Al_2O_3SO_3$, and must be free from iron.

This mordant, more or less diluted, furnishes all shades of red and pink with madder, garancine or alizarine. Where a very bright red is wanted, chloride of tin is mixed with the alumina mordant.

For pinks, the tin is sometimes omitted. The mordants are prepared for printing by thickening with starch or British gum.

Mixtures of alumina mord. and iron mord. give all shades of chocolate from madder, garancine and alizarine.

Catechu.—The valuable colouring principle of this substance is catechin, $C_7H_6O_3$, which bears a resemblance to tannin.

This substance furnishes, with small proportions of $CuONO_5$ and acetate of alumina, the various shades of brown.

A standard solution is made of catechu in HO, with NH_3Cl and acetic acid; this is thickened with gum gedda, and $CuONO_5 + Al_2O_3SO_3$ added just before printing.

The same colours, with FeCl substituted for Al_2O_3 acetate, furnish shades of drab.

Dyes.

Logwood contains hematoxyline $C_{15}H_{14}O_6$; it is soluble in HO and alcohol, and crystallizes with three atoms of water in colourless crystals. Air or oxygen do not act upon it, but *in presence* of NH_3 it is converted into hematein, $C_{16}H_{10}O_5$, which combines with the NH_3, forming hemateate of ammonia, thus $C_{16}H_{14}O_6 + O + NH_3 = C_{16}H_9(NH_4)O_5 + 2H_2O$; hematein, the actual colour is soluble in HO. It is an amorphous brown-red body, and forms crystallized salts with the alkalies and insoluble lakes with many metallic salts, thus, the lead lake is blue, the copper violet, tin violet, iron black,—these lakes have considerable stability.

Madder (*Rubia tinctoria*).—The valuable constituents of madder-roots are—rubian, $C_{28}H_{34}O_{15}$; alizarine, $C_{10}H_6O_3$; purpurine, $C_{30}H_{20}O_{10}$; and erythrosyme, a nitrogenous body.

Rubian, $C_{28}H_{34}O_{15}$, is regarded as the primary source of the valuable colouring-matters in the madder root. It is soluble in cold water and in alcohol, yielding yellow-coloured solutions having a bitter taste. By fermentation produced by the action of erythrosyme, and also by sulphuric acid, rubian is converted into alizarine and purpurine, glucose and resinous matters being also formed at the same time.

Alizarine, $C_{10}H_6O_3$.—This is the valuable colouring-principle of madder. It does not exist to any great extent in the root, but is a product resulting from the decomposition of the rubian by fermentation. Alizarine is insoluble in cold water, but soluble in boiling water, bisulphide of carbon, naphtha, etc. It sublimes at 228° F., and is obtained in golden-yellow needles. It forms stable compounds with alumina, iron and tin, and these lakes are insoluble in water and even in solutions of soap.

Purpurine, $C_{30}H_{20}O_{10}$, is another colouring-matter resulting from the decomposition of rubian. It forms definite compounds with alumina, iron and tin. These lakes are redder in shade than the corresponding alizarine compounds. They are insoluble in water, but are distinguished from the alizarine lakes by their solubility in solutions of soap and also in hot solutions of alum.

Garancine.—This is prepared by boiling ground madder roots with sulphuric acid and water. The acid is then removed by washing with water. By this treatment the rubian of the madder is converted into alizarine and purpurine, while the pecten and resinous matters are in great measure destroyed.

Bark, Sumac, Galls.—The valuable constituent of these substances is the tannin which they contain.

Persian Berries, Quercitron, Flavin.—The colouring principle of these substances is quercitrine, $C_{23}H_{10}O_{10}$, which forms lakes with several metallic bases. Its combinations with alumina and oxide of tin are yellow.

Lima Wood contains a colouring principle called braziline, $C_{20}H_{20}O_7$, which also forms lakes with many metallic salts.

The dye-stuffs are mostly used in conjunction with garancine, for the production of various shades of chocolate, red, orange, brown and drab.

The style of goods dyed direct from madder roots are black, purple, lilacs, red and pinks, and sometimes orange.

The goods are printed in the same manner as pigment or steam colours, but instead of colouring-matter, the ferrous or alumina mordants, already described, are printed on and the goods are dried. Simple figures are printed once, covers twice, and pads three times.

Ageing.—The dried goods are then aged. This operation is conducted in a building called a stove. This building is open from ceiling to floor; on the floor is an iron frame with light tin rollers about 9 feet long, and near the top of the building is a similar frame, but to every six tin rollers is a massive wooden roller (covered with flannel), propelled by gearing, and forming the traction-power for drawing the cloth through the machine. The cloth is passed in a continual line through this machine, entering at the bottom, ascending to the top, and descending again, after passing over each roller; and as the rollers are closely set, a great length of cloth may be in the machine at a time; and although moving rapidly, the time it is in the building is considerable. The stove is usually made so wide as to have two frames in the width; parallel with each frame is a 6-inch steam-pipe, along the entire length of which are many openings, expanding into wide tin funnels, hooded in such a way as not to project the steam which issues from them against the cloth. During the passing of the goods through the stove, volumes of steam are being thrown from the tin funnels into the chamber, and this steam is rapidly absorbed by the dry goods. The object is to keep the atmosphere as nearly saturated as possible without condensing into water. If the supply of steam is inadequate, the ageing will be ineffective; if too much steam, the dew-point will be reached, and water-drops falling on the goods will cause stains or blanks in the dyeing. The temperature is kept at about 80° F., the degree of saturation is regulated by observation of a wet and dry bulb hygrometer; dry bulb, 80°, wet 76°. The goods are then further aged by being loosely piled in a warm and moist room for 48 hours. In the ageing the action that takes place is as follows:—The greater part (but never the whole) of the acetic acid is volatilized, leaving behind the oxides of iron and alumina; in the case of the former, it is partly changed into sesquioxide, the result being partly ferrous and partly ferric oxide.

After ageing, the goods are submitted to the operation of *Dunging*, or *Cleansing*.—This has for its object the removal of the thickening and sightenings and from the excess of mordant used in the printing, secondly, from the excess of acid, and it has also been found to make the colours brighter and faster than they would otherwise be; it also has a remarkable influence in permanently fixing the mordants, and bringing them into the condition most favourable for the dyeing. For many years this process consisted in passing the goods through a bath of cow-dung in warm water, the insoluble and fibrous matters of it removing the excess of mordant and thickening, thereby preventing the staining of the whites, whilst its alkalinity neutralized the excess of acid in the mordant. The peculiar green colouring principle has also been thought to be efficacious in producing brighter and faster shades, either by combining with the mordant or by deoxidizing it. But perhaps the most valuable constituent of the dung was its phosphates, which rendered the mordants more permanent. Since the value of the phosphates has been ascertained, several chemical compounds have been substituted for the cow-dung; the principal of these are phosphates, silicates, arsenites and arseniates of soda and lime, or mixtures of these substances.

Dunging of Pink Pads.—The vat is charged with 2000 gallons of HO and 4 gallons of arseniate of soda at 74° Tw., and heated to 150° F., and the goods are passed through this solution. The strength of the liquor is maintained by addition of AsO_5NaO. The goods are then thoroughly washed in a washing machine.

Pink Plates.—Same as for pads, but a mixture of silicate of soda with $NaO\,AsO_5$.

Purple Pads.—These are run successively through three baths, all consisting of water and $CaO\,SiO_3$ in suspension, the first bath being strongest, the second weaker, and the third weakest; temperature 180° F.

Purple Plates.—Same bath as for pads, but heated only to 140°.

Chocolate Pads and Acid Garancines.—Three baths; first, with cow-dung and chalk; the others with cow-dung alone (chocolate, temp. 80°; acid garancine, 150°), all well washed afterwards.

Garancines.—Three baths, $NaO\,AsO_5 + NaO\,AsO_3$. Heat 150°.

Logwood Blacks.—Same dunging as garancines.

The goods having been dunged, and then thoroughly well washed, are ready for the next process.

Dyeing.—The dye-bath is usually made of iron, sometimes of wood, and is a rectangular cistern from 10 to 15 feet long by 4 to 5 feet wide and 4 to 7 feet deep; sometimes it is narrower towards the bottom. It is heated by a perforated steam pipe, which is placed along the bottom of the bath. There is usually a diaphragm in the middle of the bath, but which does not extend the full depth. This is to prevent the goods getting entwined, while at the same time it allows of their passing below the bottom of the diaphragm. Along the top of the bath is a winch or reel, which during the dyeing is kept revolving. The bath having been filled with the proper quantity of cold water, the goods are then entered; one end of each piece being passed over the reel, down the back of the diaphragm, below it, and then brought up in the front of it, is sewn to the other end. In this way twenty-five to fifty pieces may be placed in the bath. The proper quantity of ground madder-root is then thrown in, and if necessary a little $CaO\,CO_2$. The winch is then set in motion, and when the dye-stuff is thoroughly mixed in the bath, steam is turned on, and the temperature gradually and steadily raised to 200° or 180° F. in three hours. The chemical changes in the bath have already been described in speaking of alizarine. The rubian is converted into alizarine and purpurine, and these combine with the mordants; the pecten combines with the lime.

Garancines are dyed in a similar manner, but, owing to the colour all existing as alizarine and purpurine, the temperature can be raised more rapidly, and the dyeing is usually completed in two hours.

After dyeing madder, the cloth, besides alizarate of iron, Al_2O_3, and tin, contains purpurates of these bases, also sometimes pectates of the colouring matter and resinous matters, mechanically adhering to the surface of the cloth. These latter have all to be removed; and to effect this the goods are first washed in boiling water, then in cold water, and are then soaped. Black and purples are cleansed best in a bath of soap, and boiling HO, the treatment lasting one hour. Pinks one hour; commence cold, raised gradually to 212°; from 4 oz. to 10 oz. of soap are required for each piece, according to cloth and colours. The soaping dissolves the purpurates, but any impurities still remaining are removed by clearing. This consists in passing the goods through a vat at 190° F. of weak $NaOCO_2$ and bleaching powder. If pinks are of a bluish hue, it is removed by a weak bath of SnCl and sulphuric acid cold, washing, and then cleansing as above. Garancines are not regarded as so fast as madder work, arising from the fact that garancine usually contains a larger proportion of purpurine; and as this class of work is usually done at a cheaper rate than madder or alizarine, they are only very slightly soaped, so as to get the full advantage of the coloured purpurates. The combinations alizarine and purpurates form with the catechu mordants (producing brown and drab colours) are less stable than their combinations with FeO and Al_2O_3, and therefore brown and drab work is not soaped, but after dyeing is simply well washed in boiling and cold water, then dried, and cleared in the same way as steam colours, *i. e.* by padding with weak bleaching liquor and ultramarine blue. They are next dried, then finished. This consists in starching, calendering, folding and pressing.

I have thus endeavoured very briefly to give you the general outline of the operations involved in calico printing, an industry which must always be peculiarly interesting to chemists, as its rapid progress and present high degree of perfection arises, in no small degree, from the study and intelligent application of the science of chemistry. Nor can it be doubted that a clearer knowledge of the nature and properties of the various colouring matters will be accompanied by corresponding progress of this industry.

UNGUENTUM ACIDI CARBOLICI, LIQUOR SEDATIVUS AND EXTRACTUM FABÆ CALABARIENSIS.

The following formulæ for the preparation of Unguentum Acidi Carbolici, Liquor Sedativus and Extractum Fabæ Calabariensis have been furnished to the Chicago *Pharmacist* by Mr. C. Eredigke:—

Unguentum Acidi Carbolici.

Simple Ointment, benzoated, 4 pounds troy.
Carbolic Acid, crystallized, 3 ounces 96 grains.

Liquefy the acid by immersing the vessel containing it in hot water, and when the ointment is about congealing, add the acid, stirring well with a strong wooden spatula.

Each drachm contains three grains.

This ointment has been of excellent service in treating large superficial wounds, and ulcerating surfaces caused by burns, and in cutaneous eruptions of a parasitic nature.

Liquor Sedativus.

Tinct. Opii Camphor.
Spts. Æth. Nit. dulc.
Spts. Mindereri.
Syr. Simpl.
Aq. Camphoræ, ana part. æq.
M. et ft. solutio. Dose: A teaspoonful.

To increase the therapeutic effect of this mixture, 2 fl. ʒ of tinct. gelsemini, or 1 fl. ʒ of tinct. verat. vir. are often added to four ounces, to meet particular indications. This is a combination often prescribed in diseases complicated with febrile symptoms.

Extractum Fabæ Calabariensis.

Calabar Beans, 1000 grammes.
Alcohol of 0·864, 5000 grammes.

Reduce the beans to a fine powder, digest with a litre of alcohol over a water-bath, which must be maintained at a gentle heat for two hours. Then introduce the mixture into a displacement cylinder, and when the liquor, which results from this digestion, ceases to run, pour over the powder a second litre of boiling alcohol, and continue in this manner till the liquor passes off colourless. Mix the solutions, distil off the greater portion of the alcohol, and evaporate over a water-bath to the consistence of an extract. It is necessary to stir constantly towards the close of the operation, in order to render the product homogeneous.

1000 grammes of Calabar beans furnish from 25 to 30 grammes of extract, having a pilular consistence.

The above is the process for the preparation of this extract adopted by the French Pharmacopœia.

THE PHARMACY BILL.

MEETING OF MEMBERS OF THE PHARMACEUTICAL SOCIETY AT LIVERPOOL.

At a Meeting of the local members of the Pharmaceutical Society of Great Britain, held at the Royal Institution, Liverpool, on the 19th June, 1871, convened to consider the Bill before Parliament for amending the Pharmacy Act; Mr. John Abraham in the chair,—

It was moved by Mr. SHAW, and seconded by Mr. HORTON—

"That this meeting oppose the Bill now before the House of Commons, entitled an Act to Amend the Pharmacy Act of 1868."

It was moved as an amendment by Mr. ALPASS, seconded by Mr. PARKINSON—

"That this meeting is of opinion that the exemption of medical men, keeping open shops for the retailing, dispensing and compounding of medicines, from any regulations approved by the Privy Council, should be abrogated."

After a discussion, the amendment was withdrawn, and the motion having been put was negatived.

It was moved by Mr. ALPASS, and seconded by Mr. BARBER, "That this meeting approve of the action of the Council of the Pharmaceutical Society in the appointment of a Committee to watch the progress of the Bill, with a view to prevent the introduction of obnoxious clauses."

The motion was carried unanimously.

MEETING OF CHEMISTS AND DRUGGISTS AT LEEDS.

A Meeting of the Registered Pharmaceutical Chemists and Chemists and Druggists of Leeds was held at the Philosophical Hall on Monday, June 19; Mr. WILLIAM SMEETON, President of the Leeds Chemists' Association, in the chair.

Nearly forty chemists carrying on business in Leeds were present, and representatives from Bradford and Wakefield.

The following resolutions were carried unanimously:—

Moved by Mr. Edward Thompson, seconded by Mr. Edward Brown,—

1st. That this meeting, having carefully considered what would be the effect of the passing of a Bill now before Parliament, intituled "A Bill to Amend the Pharmacy Act, 1868," expresses its strong disapproval of the Bill, and indignation at the attempt being made to force it hastily through Parliament.

Moved by Mr. J. B. Stead, seconded by Mr. E. Yewdall,—

2nd. That a petition be presented to the House of Commons against the passing of the Pharmacy Bill and forwarded to Mr. Baines for presentation, and that the other Members for the borough, as well as those for the West Riding, be requested to support the prayer of the petition.

Moved by Mr. S. Taylor, seconded by Mr. P. Jefferson,—

3rd. That the following be appointed a delegation from this meeting to join a deputation to the Right Hon. W. E. Forster, in order to represent to him the strong reasons existing why this unnecessary, oppressive and unfair measure should not be passed,—

Delegation—Messrs. Smeeton, Brown, Thompson, Reynolds and Yewdall.

The meeting was unanimous in feeling, and on no previous occasion has any subject excited so much interest among the chemists of the town. Numerous speakers denounced the injustice and impolicy of the Bill, and deprecated the position brought about by those leaders of the Pharmaceutical Society who had misrepresented to the Government the views of their constituents.

A vote of thanks to the Chairman closed the proceedings.

MEETING AT GLASGOW.

At a Special Meeting of Chemists of Glasgow and surrounding towns (convened by circular), held in Anderson's University, 204, George Street, Glasgow, on Tuesday the 20th inst., the "Pharmacy Act Amendment Bill" was discussed, and the following resolutions unanimously agreed to:—

Proposed by Mr. T. Davison, seconded by Mr. John Jaap—

1. In the opinion of this Meeting, the conduct of Dr. Simon, Medical Officer of the Privy Council, towards the Pharmaceutical Society and the trade generally, has been marked by an arbitrariness and want of courtesy, which deserves our severest censure, in so far as Dr. Simon assumes that the Pharmaceutical Society is bound by the Act, 1868, to make regulations for the keeping, etc., of poisons,—an assumption which is not warranted by the fact, and also for the unseemly haste with which his Amended Act was forced through the House of Lords,—it having passed the third reading before the trade were made aware of its nature.

Proposed by Mr. H. Hart, seconded by Mr. A. Kinninmont—

2. That this measure, placing as it does, the interests of an entire trade at the mercy, virtually, of a single individual, from whose decision there is no appeal, is unjust, oppressive, and unworthy of the legislation of this country.

Proposed by Mr. Harvie, Airdrie, seconded by Mr Sinclair—

3. That the safety of the public is best secured by the proper education of the dispenser, and that this is ensured by the provision of the Pharmacy Act, 1868, —the only amendment necessary being an explanation or interpretation that its clauses, as to the sale and dispensing of poisons, extends alike to all shops, whether kept by surgeons or registered chemists.

Proposed by Mr. Black, seconded by Mr. Greig—

4. That a deputation be appointed by this meeting to wait upon the Vice-President of the Privy Council, in conjunction with other deputations from various parts of the country; and also, on account of the absence of Mr. Frazer, a deputy wait on Mr. Mackay before he leaves to attend the Council Meeting in London on Thursday.

Proposed by Mr. Carr, seconded by Mr. Fairlie—.

5. That an earnest appeal be made to the chemists throughout Glasgow and West of Scotland, to raise funds sufficient to carry out a thorough opposition to the Bill about to be brought before the House of Commons, and to defray the expenses of a deputation to London to explain and express the true opinions of the trade; and that the Secretary and Treasurer be appointed to carry out the same.

Proposed by Mr. James White, seconded by Mr. Lockhart (Maryhill)—

6. That the following petition be signed by all chemists in Glasgow and surrounding towns, and sent to Mr. Graham, M.P., for presentation to Parliament.

To the Honourable the Commons of Great Britain and Ireland in Parliament assembled.

The humble petition of the undersigned pharmaceutical chemists, chemists and druggists and others, inhabitants of Glasgow and surrounding towns, Scotland, carrying on business and duly registered under the provisions of the Pharmacy Act, 1868,

Sheweth:

That, whereas a Bill, intituled "An Act to Amend the Pharmacy Act, 1868," has been introduced into the House of Lords, has been rapidly passed through the various stages, and is now before your honourable House, that the said Act contains provisions which will inflict grievous annoyance and injury on your petitioners and others, and that such provisions are in nowise necessary, either for the safety of the public, or for the due carrying out of the provisions of the Pharmacy Act, 1868.

Your petitioners, therefore, humbly pray that your honourable House will refuse its sanction to the said amended Act, or postpone, for a reasonable time, its consideration, to enable evidence to be presented by which your petitioners will be able to satisfy your honourable House that the said amended Act is unnecessary and unjust.

And your petitioners will ever pray.

MEETING AT NEWCASTLE.

Copy of resolutions passed at a meeting of the Chemists and Druggists of Newcastle and Gateshead, held at the College of Medicine, Newcastle-upon-Tyne, June 20th, 1871; Jos. W. Swan, Esq., in the chair.

Moved by Mr. Buckett, seconded by Mr. Owen, and resolved—

That this meeting, having carefully considered a Bill now before Parliament, entitled "An Act to Amend the Pharmacy Act of 1868," protests against its provisions on the following grounds:—

1st. That the Bill, if passed, would, without reason, deprive the Pharmaceutical Society of rights carefully reserved to it in the Pharmacy Act of 1868.

2nd. That it would place in the hands of the Privy Council the power of making petty regulations for the storage of poisons, which, to be of any practical value, must be devised by those who know by daily experience the requirements of the case.

3rd. That as by far the largest proportion of the dispensing of poisons in England and Scotland—and in many parts of the kingdom a considerable portion of their retail sale—is undertaken in the surgeries of medical practitioners whom this Act would not affect, its provisions, whilst they would afford no material protection to the public, would involve a manifest injustice to the whole body of chemists and druggists.

4th. That the Pharmacy Acts now in force afford a better guarantee to the public that only really useful regulations respecting the keeping, dispensing and selling of poisons will be sanctioned than if the existing Acts were amended in the manner proposed by the said Bill.

Moved by Mr. Dobson, seconded by Mr. Alfred Brady, and resolved—

That this meeting adopt a petition to the House of Commons against the Bill, the same to be forwarded to the Right Hon. T. E. Headlam, with a request that he will present it and support its prayer, and that this meeting at the same time expresses its grateful acknowledgment to the Right Hon. T. E. Headlam for his services in promoting useful Pharmaceutical legislation.

Moved by Mr. H. B. Brady, seconded by Mr. Owen, and resolved—

That the Chairman (Mr. Swan) and the Secretary (Mr. B. S. Proctor) be requested to join the deputations from Leeds and other places in representing to Mr. Forster and such Members of Parliament as it may seem desirable to communicate with *personally* the views of the chemists of this district respecting the measure.

MEETING AT NOTTINGHAM.

At a large Meeting of chemists, held on Tuesday, June 20th, at the rooms of the Nottingham and Nottinghamshire Chemists' Association, the following resolutions were proposed and unanimously carried:—

That this meeting entirely disapproves of the Bill now before Parliament, entitled, "An Act to Amend the Pharmacy Act, 1868," and resolves that a petition be forwarded to the local representatives to be presented to Parliament, and would respectfully urge them to support the prayer thereof.

That this meeting, recognizing the necessity, at the present crisis, of united action in opposing the Pharmacy Bill, 1871, now before Parliament, would respectfully urge the Council of the Pharmaceutical Society to ask for delay, in order that its provisions may be fully considered.

That three delegates—Mr. Atherton, Mr. Rayner and Mr. W. Smith—from this meeting be appointed to attend the deputation to the Right Hon. W. E. Forster, at the House of Commons, on Thursday next.

MEETING OF THE HALIFAX CHEMISTS' ASSOCIATION.*

Mr. Stott, President, in the chair.

The meeting was called to consider the amended Pharmacy Bill of the Government. The Secretary stated that immediately on receipt of the Act he had entered into correspondence with the Manchester Defence Association and also with the borough members. Replies were read from both, stating that ample time would be allowed for chemists to become acquainted with the Bill.

The President stated that during the Annual Meeting he learned a good deal on the poison question, and found that the medical officer of the Privy Council was a most indefatigable servant, and had fully determined that something should be done; still he did not see what we could do otherwise than offer a strenuous opposition to the Bill. He doubted if the Council, being so divided, would pass any compulsory regulations, and then the sole power would be vested in Dr. Simon.

Messrs. Dyer, Farr, Jessop, Hebden, all spoke against the measure; and on the motion of Mr. Brook, seconded by Mr. Dyer, a petition against the Bill as read was adopted by the meeting, and ordered to be sent to the Right Hon. James Stansfeld for presentation to the House of Commons, and that Col. Akroyd be requested to support its prayer.

It was thought highly important that each individual chemist should correspond with the borough and county members, asking them to oppose the Bill, and that a deputation should join the Manchester one, to confer with Mr. Forster, the Vice-President of the Council.

* The report of this meeting was received without any date affixed.

DEPUTATION TO THE PRIVY COUNCIL.

A Deputation of Pharmaceutical Chemists and Chemists and Druggists from various parts of the kingdom had an interview with the Right Hon. W. E. Forster, Vice-President of the Council, at his official residence in Downing Street, on Thursday last. The Medical Officer of the Privy Council was present. Mr. Jacob Bright introduced the deputation. The following members of Parliament were present on behalf of the deputation:—Mr. Jacob Bright, the Right Hon. T. E. Headlam, Mr. Edward Baines, Mr. James Clay, Mr. S. A. Beaumont, Mr. Christopher Sykes, Mr. T. W. Mellor, Mr. Graham, Mr. A. O. Ewing, Mr. Pease and Mr. W. St. J. Wheelhouse. There were also present six members of the Council of the Pharmaceutical Society, the Secretary and the Solicitor to the Society.

Mr. Schacht, of Bristol, stated the object of the deputation, and the objections of the chemists and druggists throughout the kingdom to the proposed amendment of the Pharmacy Act were urged by Mr. Kinninmont, of Glasgow, Mr. Vizer, of London, and Mr. Brown, of Manchester, who spoke at considerable length.

Mr. Flux (Solicitor) then read a resolution which had been passed by the Council of the Pharmaceutical Society.*

Mr. Forster, in reference to the remarks of Mr. Schacht, pointed out that the figures produced showed that, exclusive of medical practitioners, only one-fourth of the persons keeping open shop as chemists and druggists were members of the Pharmaceutical Society, and it might be presumed that the remaining three-fourths comprised many who did not possess the educational qualifications which had been relied upon by the speaker as being all that were required for the protection of the public. Also that the remarks of a member of the Government quoted in favour of leaving railway companies and others free of restraint—while, perhaps, well founded as general rules for conduct—were subject to exceptions, and that the restraints imposed on railway companies respecting the carriage of gunpowder and other especially dangerous articles were a precedent for restraints on dealings in especially dangerous poisons.

In reference to the remarks of Mr. Vizer and Mr. Brown respecting the feeling of the trade and the absence of public opinion on the subject of compulsory regulations, he said that Parliament had already considered the matter and passed the existing Act, which, according to his reading of it, required that regulations should be framed and become compulsory; that the course pursued by the Society had been brought under his notice, and he thought it a duty, as a member of the Government, to see that, so long as the Act remained unrepealed, it should be carried out; that the Government had not been hasty either in framing the Bill now before the House of Commons or in passing it through the House of Lords,—that, in fact, the course of the Bill in the upper house was usual; and with regard to the future, he was quite prepared to afford every opportunity for discussion, and should be happy to give his most careful consideration to any suggestions which may be made for improvement of the Bill, but that he could not encourage the idea that the Bill would be withdrawn or postponed until next session; and then, with especial reference to remarks by Mr. Kinninmont, said that he individually thought that a *primâ facie* case existed for placing all persons keeping open shop for the retailing of poisons on an equal footing with respect to formalities, and he should be glad to consider any clause which might be framed with that object.

The deputation then thanked the Right Honourable gentleman for his courteous reception, and withdrew.

* See p. 1035.

The Pharmaceutical Journal.

SATURDAY, JUNE 24, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

METHYLATED FINISH.

WE have frequently called attention to the difficulties experienced by chemists and others keeping methylated finish for sale, in obtaining *legal* finish from the makers, and not methylated spirit containing a small proportion of gum, and which legally is nothing but methylated spirit. The fact may not be known to many in the trade, but it is nevertheless a fact, that nearly all the so-called finish now sold contains in solution not more than one-tenth the required amount of gum resin. In proof of this we may state that of ten samples of finish recently examined, one only contained the proper proportion of gum, viz. three ounces in the gallon. The consequence is, that those persons who have no licence for the sale of methylated spirit, but who sell this spurious finish, are liable to a penalty of £50.

Why the makers of finish are so chary of adding the full proportion of gum, it is not difficult to explain. In the first place gum, though very cheap, adds to the price of methylated spirit, and its presence also prevents the dilution with water of spirit below a certain strength, and in the second place, as finish can be kept on any premises and sold in any quantity without being accompanied by certificate, the maker is not subject to the restrictions upon him as in the case of methylated spirit. It is well known to the makers that the so-called finish would be liable to seizure if kept by them in any place except in rooms allowed for storing methylated spirits.

They therefore are careful to keep the finish and methylated spirit together, and thus the excise authorities are compelled to recognize all as methylated spirit so long as it is on the trader's premises. As soon, however, as such finish comes into the possession of a person not licensed to keep methylated spirit, he is liable to a penalty for keeping methylated spirit without licence, and thus it is we constantly hear of chemists and others being prosecuted, whilst the makers, who are the actual offenders, escape punishment.

Even in a good cause there is always a certain amount of obloquy attaching to a man prosecuted in a police-court, and in cases like those now under review, the annoyance of so appearing is increased by the fact that though legally guilty, the defendant is morally innocent. Only recently a case of this kind was heard at Bow Street,* but Messrs. TAYLOR and CULVER, the defendants, were bold enough to go into court, in order to be able to take proceedings against the person who supplied them with this illegal finish. The magistrate, while compelled to convict, could not refrain from expressing his opinion that the defendants had been imposed upon. Now while one man may be found to have sufficient courage to go into court, there are scores, especially in country towns, where publicity of this kind is ruinous, who would pay any moderate sum rather than defend such a case, and this is a main reason why the manufacture of finish is carried on in such a loose manner.

To propose a remedy for this state of things which would be completely effectual, would be difficult indeed, but we venture to suggest that the excise authorities might, at certain fixed periods, have examinations made of the finish made by all the different manufacturers, and also more frequently cause the so-called finish to be examined after it has left the premises of the maker. By these two simple precautions the Board of Inland Revenue would become acquainted with those who did not comply with the law, and also be able to detect the maker sending out this spurious finish without certificates. This increased vigilance would, we are sure, do much to put a stop to the present practice, by causing manufacturers to exercise more care in complying with the excise regulations. The expense incurred in such supervision would be merely nominal, as there are less than a dozen makers of methylated spirit in the United Kingdom, and although there is no record in the official reports of the number of finish makers, we are strongly of opinion that the number does not exceed twenty.

Whilst suggesting increased vigilance on the part of the Excise, it is only fair to say that every needful precaution should be taken by the purchasers of finish, that they get the proper article supplied to them. The finish they buy should therefore be tested, and a simple mode of examination is based on the fact that gum resin is insoluble in water, although soluble in spirit. Thus, if to a small quantity of finish in a test-tube there be added about three times its bulk of water, it will be found that if the finish be properly made, the mixture becomes milky, and a curdy precipitate falls; but if the mixture remains transparent, or only slightly turbid, it does not contain the proper proportion of gum.

In cases like the present, great advantages would be obtained if those interested would combine to suppress such an illegal trade as that we have endeavoured to expose; and if the pharmaceutical chemists of the United Kingdom would take the trouble to turn their chemical knowledge to account for the protection of their own interests, prosecutions like

* See p. 1040.

those we have named would be few indeed; and wholesale houses would in this case, as in others, find very speedily, that the only satisfactory mode of doing business is to supply legitimate and proper articles to their customers.

THE HARVEIAN ORATION.

On Wednesday, in the Royal College of Physicians, Dr. Thomas King Chambers delivered the Harveian oration on the "Progress of Therapeutics," a subject on which few men have a better right to speak than the author of 'Digestion and its Derangements,' the 'Renewal of Life,' and of 'Indigestion Functionally Treated.' The accomplished lecturer gave a rapid survey of the history of medicine, showing the gradual liberation of medical practice from the doctrine that disease is something external to the body — something to be expelled from it by various kinds of treatment. Disease, he said, was now regarded as a condition,—a lowered one, indeed, but still a condition—of vitality. Towards the restoration of life to its normal standard, therapeutic aid was now directed; and the profession was becoming more successful in this undertaking from the teachings of "designed experiment" on the lower animals, and from the aid supplied by such instruments as the sphygmograph. With the multiplication of those aids, the lecturer anticipated a much more certain and satisfactory means of diagnosis, suggesting much more successful plans and treatment than had hitherto been adopted. Dr. Chambers brought his oration, amid loud applause, to an effective close; after which the President, in the name of himself and the Council, proceeded to award the "Baly medal" to the most distinguished cultivator of physiological science within the year. After a few appropriate observations in compliment to its late founder, and in reference to the encouragement it was calculated to give to scientific medicine, the medal, twenty guineas in value, was awarded to Dr. Lionel Beale.

AMERICAN REGULATION OF TRADE.

Now that "regulations" affecting trade are a matter of so much interest, the following account, given by Mr. T. Hughes, M.P., of the regulations in reference to the sale of alcoholic liquors in Massachusetts is worth notice:—

"As regards the 'liquor laws,' he did not stop to discuss the question of absolute prohibition, but spoke favourably of the stringent laws of Massachusetts, where a strict and direct legal supervision over the sale of liquor was exercised. A State Commissioner, appointed every year, controlled the sale of alcoholic liquors, which were vended by a small number of authorized agents—only four for the city of Boston. The agents could only obtain their supplies from the State Commissioner, and they were bound to record all their sales. All liquor had to be tested and certified by the public assayer. Persons known as confirmed drinkers might be reported by their friends or guardians, and it was a penal offence for the agents to sell to them, damages being also, in addition, recoverable from them by action. The practical result of these stringent laws was that a drunken man was nowhere to be seen, and that a thirsty one might have to travel through many streets before he came to a liquor shop."

SPECTROSCOPIC TEST FOR BLOOD.

We call our readers' attention to the letter on this subject by Mr. Stoddart, of Bristol, for, as an experienced observer, his opinion carries much weight with it, more especially since his remarks are free from any exaggeration.

The Managers of the London Institution, in accordance with the recommendation of the Annual Meeting of Proprietors, have resolved to afford opportunities during the ensuing season for the reading and discussion of communications on subjects of special interest in science, literature, commerce and the arts, provided they receive such offers as will ensure an adequate succession of suitable papers. It is believed that this proposed extension of the use of the commodious lecture theatre in Finsbury Circus will produce a series of attractive meetings, similar in character to those of the Society of Arts, but representing directly the business and thought of the City. It is not intended to restrict the reading and discussion of papers to the proprietors of the Institution, or to limit the range of subjects otherwise than by the provisions of the Royal Charter, which preclude theology and politics.

The Newark (New Jersey) Pharmaceutical Association has published a formulary of elixirs and unofficinal preparations, and issued it to the medical profession of that city, together with a circular in which they deprecate the prescribing of such fancy preparations of particular manufacturers, since many of them cannot contain the constituents they profess to contain. The members of the Association propose in all cases to dispense those made according to the formulæ agreed upon, unless a special preparation is indicated.

Mr. Robert Howard, whose death we chronicle this week, was the head of the well-known firm of Howard and Sons. He was a son of the celebrated meteorologist Luke Howard. Mr. Robert Howard had been in delicate health for some time, and died at his estate in Dorsetshire. He was buried in Abney Park Cemetery on the 8th instant.

We much regret to learn that Mr. Francis Sutton, of Norwich, has been suffering from a severe attack of pleurisy, which has left him in a very weak state.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

June 22nd, 1871.

MR. A. F. HASELDEN, PRESIDENT, IN THE CHAIR.

Present—Messrs. Atherton, Betty, Bottle, Brown, Carr, Greenish, Groves, Haselden, Hills, Mackay, Reynolds, Sandford, Savage, Shaw, Stoddart, Williams and Woolley:—

Deputations in reference to the proposed Pharmacy Bill from various parts of the country and London were received:—

A deputation of delegates to the Pharmaceutical Council upon their action with regard to the Amended Pharmacy Act, consisting of Messrs. Edwin B. Vizer, Pimlico; John Owen, Islington; Jas. Baynes, Hull; Atkinson Pickering, Hull; Chas. B. Bell, Hull; John Unthank, Wakefield; John Wade, London; Joseph W. Swan, Newcastle-on-Tyne; Robert Hampson, Manchester; Barnard S. Proctor, Newcastle; Thos. S. Johnson, Manchester; Thomas D'Aubney, London; Jabez Waterhouse, Ashton-under-Lyne; G. F. Schacht, Clifton; John Pitman, Bristol; W. W. Urwick, London; W. H. Waterhouse, Ashton; Job Preston, Sheffield; Edward Taylor, Rochdale.

Also a deputation from Glasgow, consisting of Mr. Alexander Kinninmont, Mr. Davison and Mr. Fairlie.

A Memorial from Pharmaceutical Chemists and Chemists and Druggists, requesting a Special General Meeting to be convened, was received, but, being informal, the request could not be complied with.

Moved by Mr. Reynolds, seconded by Mr. Greenish—

That the result of the interview of the Parliamentary Committee with the Right Hon. W. E. Forster is not satisfactory, and that considering the widely-felt objection to the proposed amended Pharmacy Bill, this Council determines to oppose the passing of such a measure in the House of Commons.

Amendment, moved by Mr. Sandford, seconded by Mr. Groves,—

That it is undesirable that this Council should commit itself to such decided opposition to the Bill; and that the course, proposed at the last special meeting of Council, of watching the progress of the measure and preventing the passing of obnoxious clauses, should be continued, the more especially as this course affords an opportunity of obtaining advantages for chemists generally.

For the Amendment—

Messrs. Groves, Haselden, Hills, Mackay, Sandford, Stoddart and Williams.

Against—

Messrs. Atherton, Betty, Bottle, Brown, Greenish, Reynolds, Savage, Shaw and Woolley.

The Amendment was therefore lost.

Mr. Carr was not present at the division.

On the original motion being again put, the following Amendment was moved by Mr. Groves, seconded by Mr. Hills:—

That any decided opposition to the Bill is unadvisable at the present time, as the appointment with Mr. Forster on Saturday might furnish reasons for viewing the Bill in a more favourable light.

For the Amendment—

Messrs. Groves, Haselden, Hills, Sandford, Stoddart and Williams.

Against—

Messrs. Atherton, Betty, Bottle, Brown, Greenish, Reynolds, Savage, Shaw and Woolley.

The Amendment was therefore lost.

Mr. Mackay did not vote and Mr. Carr was not present at the division.

On the original motion being again put, it was moved by Mr. Brown and seconded by Mr. Bottle:—

Resolved—That the words "during this Session of Parliament" be added to the original motion.

The original motion, with the addition of those words, was then put.

For the Motion—

Messrs. Atherton, Betty, Bottle, Brown, Greenish, Mackay, Reynolds, Savage, Shaw and Woolley.

Against—

Messrs. Groves, Haselden and Sandford.

The motion was therefore carried.

Messrs. Hills, Stoddart and Williams were present, but did not vote. Mr. Carr was not present at the division.

Moved by Mr. Savage, seconded by Mr. Bottle, and

Resolved—That the Secretary of this Society do attend with the deputation of chemists appointed to wait upon the Right Hon. W. E. Forster, at three o'clock to-day, and take with him a copy of the Resolution of this Meeting of Council and leave the same with Mr. Forster; and that the Society's Solicitor do also attend.

The Council then adjourned until five o'clock.

On the reassembling of the Council—

Moved by Mr. Brown, seconded by Mr. Shaw—

Resolved—That a memorial be drawn up by the Council of the Pharmaceutical Society and forwarded to the Vice-President of the Privy Council, urging the withdrawal or postponement of the Amended Pharmacy Bill.

It was then proposed by Mr. Woolley, and seconded by Mr. Betty,—

That this Council do petition the House of Commons not to pass the Bill now before it, intituled "An Act to Amend the Pharmacy Act, 1868," the seal of the Society being attached to the petition.

For—

Messrs. Betty, Brown, Greenish, Mackay, Reynolds, Shaw and Woolley.

Against—

Messrs. Haselden and Sandford. Messrs. Hills and Williams did not vote.

Moved by Mr. Shaw, seconded by Mr. Woolley,—

Resolved—That Messrs. Betty, Brown, Greenish and Reynolds be appointed a Committee to direct the operations of the Society in communicating with the Local Secretaries and members upon the subject of opposing the Bill.

The Council then adjourned till Saturday at 10.30 P.M.

Provincial Transactions.

NOTTINGHAM AND NOTTINGHAMSHIRE CHEMISTS' ASSOCIATION.

The Second Annual Meeting of this Society was held at the rooms, Britannia Chambers, Pelham Street, on Tuesday, the 30th of May.

The President, Mr. J. H. ATHERTON, who occupied the chair, alluded, in the course of a short address, to the satisfactory position of the Society, and complimented the members on the importance of the work of the past session, more especially in its educational efforts. The classes on chemistry, materia medica and pharmacy had been well attended by the associates, and with encouraging results. The increase in the number of members during the past year, and the unanimity of their meetings, were a source of congratulation to the Council. The President then mentioned the progress made in the formation of the museum, and expressed a belief that, at the commencement of the next session, a very fair number of specimens would be classified and arranged. After referring to the poison regulations proposed by the Pharmaceutical Society at the request of the Privy Council, the assistance to provincial associations by the parent society and other matters of special interest to the profession, he concluded by thanking the members for the invariable courtesy and kindness he had always received at their hands during the three years he had held the position as president of their society.

The Annual Report of the Council was then read and adopted.

A special vote of thanks was accorded to the lecturers, more especially to Mr. Mayfield, who conducted the class on materia medica and pharmacy.

The following officers were elected for the ensuing year:—*President:* Mr. J. H. Atherton, F.C.S. *Vice-President:* Mr. W. H. Parker. *Treasurer:* Mr. John Rayner. *Hon. Secretary:* Mr. R. Fitzhugh, F.C.S. *Council:* Messrs. Woodward, Jackson, Mayfield, W. Smith, Whitworth, F. White, Lewis and J. Jenkins.

Parliamentary and Law Proceedings.

A BILL INTITULED AN ACT FOR THE SAFE KEEPING OF PETROLEUM AND OTHER SUBSTANCES OF A LIKE NATURE.

Whereas it is expedient to consolidate and amend the law relating to the safe keeping of petroleum and other substances of a like nature:

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. This Act may be cited as "The Petroleum Act, 1871."

2. In this Act, if not inconsistent with the context, the following terms have the meanings hereinafter assigned to them; that is to say,

The term "borough" means—

In England any place for the time being subject to the provisions of the Act of the session of the fifth and sixth years of the reign of King William the Fourth, chapter seventy-six, "to provide for the regulation of municipal corporations in England and Wales," and the Acts amending the same;

In Scotland any royal burgh and any burgh or town returning or contributing to return a member or members to serve in Parliament;

In Ireland any place for the time being subject to the provisions of the Act of the session of the third and fourth years of the reign of her present Majesty, chapter one hundred and eight, "for the regulation of municipal corporations in Ireland, and the Acts amending the same;"

The term "person" includes a body corporate:

The term "Secretary of State" means one of her Majesty's Principal Secretaries of State:

The term "Lord Lieutenant" means the Lord Lieutenant of Ireland or the lords justices or other chief governors or governor of Ireland for the time being:

The term "harbour" means any harbour properly so called, whether natural or artificial, and any port, haven, estuary, navigable river, dock, pier, jetty, or other works in or at which ships do or can ship or unship goods or passengers:

The term "harbour authority" includes any persons or person being or claiming to be proprietors or proprietor of or intrusted with the duty or invested with the power of improving, maintaining, or managing any harbour:

The term "ship" includes every description of vessel used in navigation, whether propelled by oars or otherwise:

The term "Summary Jurisdiction Acts" means, as follows:

As to England, the Act of the session of the eleventh and twelfth years of the reign of her present Majesty, chapter forty-three, intituled "An Act to facilitate the performance of the duties of justices of the peace out of sessions within England and Wales with respect to summary convictions and orders," and any Acts amending the same:

As to Scotland, "The Summary Procedure Act, 1864:"

As to Ireland, within the police district of Dublin metropolis, the Acts regulating the powers and duties of justices of the peace for such district, or of the police of such district; and elsewhere in Ireland, "The Petty Sessions (Ireland) Act, 1851," and any Act amending the same:

The term "Court of Summary Jurisdiction" means and includes any justice or justices of the peace, sheriff or sheriff substitute, metropolitan police magistrate, stipendiary or other magistrate, or officer, by whatever name called, to whom jurisdiction is given by The Summary Jurisdiction Acts or any Acts therein referred to, or to proceedings before whom the provisions of the Summary Jurisdiction Acts are or may be made applicable:

The term "county rate" means as regards Scotland the county general assessment leviable in pursuance of "The County General Assessment (Scotland) Act, 1868."

3. For the purposes of this Act the term "petroleum" includes any rock oil, Rangoon oil, Burmah oil, oil made from petroleum, coal, schist, shale, peat, or other bituminous substance, and any products of petroleum, or any of the above-mentioned oils; and the term "petroleum, to which this Act applies," means such of the petroleum so defined, as, when tested in manner set forth in schedule one to this Act, gives off an inflammable vapour at a temperature of less than eighty-five degrees of Fahrenheit's thermometer.

4. Every harbour authority shall frame and submit for confirmation to the Board of Trade bye-laws for regulating the place or places at which ships carrying petroleum to which this Act applies are to be moored in the harbour over which such authority has jurisdiction, and are to land their cargo, and for regulating the time and mode of, and the precautions to be taken on, such landing. The harbour authority shall publish the bye-laws so framed with a notice of the intention of such authority to apply for the confirmation thereof. The Board of Trade may confirm such bye-laws with or without any omission, addition or alteration, or may disallow the same.

Every such bye-law when confirmed shall be published by the harbour authority, and may be from time to time altered or repealed by a bye-law made in like manner. Bye-laws under this section shall be published in such manner as the Board of Trade may from time to time direct.

If at any time it appears to the Board of Trade that there is no bye-law for the time being in force under this section in any harbour the Board of Trade may, by notice, require the harbour authority of such harbour to frame and submit to them a bye-law for the purposes of this section, and if such harbour authority make default in framing a bye-law and obtaining the confirmation thereof within the time limited by such notice, the Board of Trade may make a bye-law for the purposes of this section, and such bye-law shall have the same effect as if it had been framed by the harbour authority and confirmed by the Board of Trade.

Where any ship or cargo is moored, landed or otherwise dealt with in contravention of any bye-law for the time being in force under this Act in any harbour, the owner and master of such ship, or the owner of such cargo, as the case may be, shall each incur a penalty not exceeding fifty pounds for each day during which such contravention continues, and it shall be lawful for the harbour master or any other person acting under the orders of the harbour authority of such harbour to cause such ship or cargo to be removed, at the expense of the owner thereof, to such place as may be in conformity with the said bye-law, and all expenses incurred in such removal may be recovered in the same manner in which penalties are by this Act made recoverable.

5. The owner or master of every ship carrying a cargo consisting wholly or in part of petroleum to which this Act applies, on entering any harbour within the United Kingdom, shall give notice of the nature of such cargo to the harbour authority having jurisdiction over such harbour.

If such notice is not given, the owner and master of such ship shall each incur a penalty not exceeding the value of such ship and cargo.

6. Where any petroleum to which this Act applies—

(a) Is kept at any place except during the seven days next after it has been imported; or

(b) Is sent or conveyed by land or water between any two places in the United Kingdom; or

(c) Is sold or exposed for sale;

the vessel containing such petroleum shall have attached thereto a label in conspicuous characters, stating the description of the petroleum, with the addition of the words "dangerously inflammable," and with the addition,—

(a) In the case of a vessel kept, of the name and address of the consignee or owner:

(b) In the case of a vessel sent or conveyed, of the name and address of the sender:

(c) In the case of a vessel sold or exposed for sale, of the name and address of the vendor.

All petroleum to which this Act applies which is kept, sent, conveyed, sold or exposed for sale, in contravention of this section, shall, together with the vessel containing the same, be forfeited, and in addition thereto, the person keeping, sending, selling or exposing for sale the same, shall for each offence be liable to a penalty not exceeding five pounds.

7. Save as hereinafter mentioned, after the passing of this Act petroleum to which this Act applies shall not be kept, except in pursuance of a licence given by such local authority as is in this Act mentioned.

All petroleum kept in contravention of this section shall, together with the vessel containing the same, be forfeited, and in addition thereto, the occupier of the place in which such petroleum is so kept shall be liable to a penalty not exceeding twenty pounds a day for each day during which such petroleum is so kept.

This section shall not apply to any petroleum kept either for private use or for sale, provided the following conditions are complied with:—

(1) *That it is kept in separate glass, earthenware, or metal vessels, each of which contains not more than half a pint, and is securely stopped:*

(2) *That the aggregate amount kept, supposing the whole contents of the vessels to be in bulk, does not exceed three gallons.*

8. The following bodies shall respectively be the local authority to grant licences under this Act in the districts hereinafter mentioned; (this is to say,)

(1) In the city of London, except as hereafter in this section mentioned, the Court of the Lord Mayor and aldermen of the said city:

(2) In the metropolis (that is in places for the time being within the jurisdiction of the Metropolitan Board of Works under "The Metropolis Management Act, 1855"), except the City of London, and except as hereafter in this section mentioned, the Metropolitan Board of Works:

(3) In any borough in England or Ireland, except as hereafter in this section mentioned, the mayor, aldermen, and burgesses acting by the Council:

(4) In any place in England or Ireland, except as hereafter in this section mentioned, within the jurisdiction of any trustees or improvement commissioners appointed under the provisions of any local or general Act of Parliament, and not being a borough or comprising any part of a borough, the trustees or commissioners:

(5) In any borough in Scotland, except as hereafter in this section mentioned, the town council;

(6) In any place in Scotland, except as hereafter in this section mentioned, within the jurisdiction of police commissioners or trustees exercising the functions of police commissioners under any general or local Act, and not being a borough or comprising any part of a borough, the police commissioners or trustees:

(7) In any harbour within the jurisdiction of a harbour authority, whether situate or not within the jurisdiction of any local authority before in this section mentioned, the harbour authority, to the exclusion of any other local authority:

(8) In any place in which there is no local authority as before in this section defined, in England or Ireland, the justices in petty sessions assembled, and in Scotland any two or more justices of the peace for the county sitting as judges in the justice of peace court.

9. Licences in pursuance of this Act shall be valid if signed by two or more of the persons constituting the local authority, or executed in any other way in which other licences, if any, granted by such authority are executed. Licences may be granted for a limited time, and may be subject to renewal or not in such manner as the local authority think necessary.

There may be annexed to any such licence such conditions as to the mode of storage, the nature and situation of the premises in which, and the nature of the goods with which petroleum to which this Act applies is to be stored, the facilities for the testing of such petroleum from time to time, the mode of carrying such petroleum within the district of the licensing authority, and generally as to the safe keeping of such petroleum as may seem expedient to the local authority.

Any licensee violating any of the conditions of his licence shall be deemed to be an unlicensed person. There may be charged in respect of each licence granted in pursuance of this Act such sum, not exceeding five shillings, as the local authority may think fit to charge.

10. If on any application for a licence under this Act the local authority refuse the licence, or grant the same only on conditions with which the applicant is dissatisfied, the local authority shall, if required by the applicant, deliver to him in writing under the hand or hands of one or more of the persons constituting the local authority, a certificate of the grounds on which they refused the licence or annexed conditions to the grant thereof.

The applicant within ten days from the time of the delivery of the certificate may transmit the same to a Secretary of State if the application is for a licence in England or Scotland, and to the Lord Lieutenant if the application is for a licence in Ireland, together with a memorial, praying that notwithstanding such refusal the licence may be granted, or that the conditions may not be imposed, or may be altered or modified in such manner and to such extent as may be set forth in such memorial.

It shall be lawful for the Secretary of State, or the Lord Lieutenant, if he think fit, on consideration of such memorial and certificate, and, if he think it necessary or desirable, after due inquiry and a report by such person as he may appoint for that purpose, to grant the licence prayed for, either absolutely or with such conditions as he thinks fit, or to alter or modify the conditions imposed by the local authority; and the licence so granted, or altered and modified, as the case may be, when certified under the hand of a Secretary of State, or the Lord Lieutenant, shall be to all intents as valid as if granted by the local authority.

11. Any officer authorized by the local authority may purchase any petroleum from any dealer in it, or may, on producing a copy of his appointment, purporting to be certified by the clerk or some member of the local authority, or producing some other sufficient authority, require the dealer to show him every or any place, and all or any of the vessels in which any petroleum in his possession is kept, and to give him samples of such petroleum on payment of the value of such samples.

When the officer has by either of the means aforesaid taken samples of petroleum, he may declare in writing to the dealer that he is about to test the same, or cause the same to be tested, in manner provided by this Act, and it shall be lawful for him to test the same or cause the same to be tested, at any convenient place at such reasonable time as he may appoint, and the dealer or any person appointed by him may be present at the testing, and if it appear to the officer or other person so testing that the petroleum from which such samples have been taken is petroleum to which this Act applies, such officer or other person may certify such fact, and the certificate so given shall be receivable as evidence in any proceedings that may be taken against a dealer in petroleum in pursuance of this Act; but it shall be lawful for a dealer proceeded against to give evidence in proof that such certificate is incorrect, and thereupon the court before which any such proceedings may be taken may, if such court think fit, appoint some person skilled in testing petroleum to examine the samples to which such certificate relates, and to declare whether such certificate is correct or incorrect.

Any expenses incurred in testing any petroleum of such dealer in pursuance of this section shall, if such dealer be convicted of keeping, sending, conveying, selling, or exposing for sale, petroleum in contravention of this Act, be deemed to be a portion of the costs of the proceedings against him, and shall be paid by him accordingly. In any other event such expenses shall be paid by the local authority out of any funds for the time being in their hands, and in case the local authority are the justices out of the county rate as part of the expenses of such justices.

12. Any dealer who refuses to show to any officer authorized by the local authority every or any place or all or any of the vessels in which petroleum in his possession is kept, or to give him such assistance as he may require for examining the same, or to give to such officer samples of such petroleum on payment of the value of such samples, or who wilfully obstructs the local authority, or any officer of the local authority, in the execution of this Act, shall incur a penalty not exceeding twenty pounds.

13. Where any court of summary jurisdiction is satisfied by information on oath that there is reasonable ground to believe that any petroleum to which this Act applies is being kept, sent, conveyed, or exposed for sale within the jurisdiction of such court in contravention of this Act, at any place, whether a building or not, or in any ship or vehicle, such court shall grant a warrant by virtue whereof it shall be lawful for any person named in such warrant to enter the place, ship, or vehicle named in such warrant, and every part thereof, and examine the same and search for petroleum therein, and take samples of any petroleum found therein, and if any petroleum to which this Act applies be found therein, which is kept, sent, conveyed, or exposed for sale, in contravention of this Act, to seize and remove such petroleum and the vessel containing the same, and to detain such petroleum and vessel until some court of summary jurisdiction has determined whether the same are or not forfeited, the proceedings for which forfeiture shall be commenced forthwith after the seizure.

Any person seizing any petroleum to which this Act applies in pursuance of this section shall not be liable to any suit for detaining the same, or for any loss or damage incurred in respect of such petroleum, otherwise than by any wilful act or neglect while the same is so detained.

If any petroleum to which this Act applies is seized in pursuance of this section in any ship or vehicle, the person seizing the same may use for the purposes of the removal thereof, during twenty-four hours after the seizure, the said ship or vehicle, with the tackle, beasts, and accoutrements belonging thereto, and, if he do so, shall pay to tho owner thereof a reasonable recompense for the use thereof, and the amount of such recompense shall, in case of dispute, be settled by the court of summary jurisdiction before whom proceedings for the forfeiture are taken, and may be recovered in like manner as penalties under this Act may be recovered.

Any person who, by himself or by any one in his employ or acting by his direction or with his consent, refuses or fails to admit into any place occupied by or under the control of such person, any person demanding to enter in pursuance of this section, or in any way obstructs or prevents any person in or from making any such search, examination, or seizure, or taking any such samples as authorized by this section, shall be liable to pay a penalty not exceeding twenty pounds, and to forfeit all petroleum to which this Act applies which is found in his possession or under his control.

14. Her Majesty may from time to time make, revoke and vary Orders in Council directing this Act or any part thereof to apply to any substance, and this Act, or the part thereof specified in the Order shall, during the continuance of the Order, apply to such substance, and shall be construed and have effect as if throughout it such substance had been included in the definition of petroleum to which this Act applies, subject to the following qualifications:

(1) The quantity of any substance to which this Act is directed by Order in Council to apply, which may be kept without a licence, shall be such quantity only as is specified in that behalf in such order, or if no such quantity is specified no quantity may be kept without a licence;

(2) The label on the vessel containing such substance shall be such as may be specified in that behalf in the order.

15. All offences and penalties under this Act, and all money and expenses by this Act directed to be recovered as penalties, shall be prosecuted and recovered under the provisions of the Summary Jurisdiction Acts before a court of summary jurisdiction, and all necessary powers and jurisdictions are hereby conferred on such court in Scotland.

Provided as follows:

1. A court of summary jurisdiction shall not impose a penalty exceeding fifty pounds, but any such court may impose that or any less penalty for any one offence, notwithstanding the offence involves a penalty of higher amount.
2. The "Court of Summary Jurisdiction," when hearing and determining an information or complaint, shall be constituted in some one of the following manners; that is to say,—

(*a*) In England, either of two or more justices of the peace in petty sessions sitting at a place appointed for holding petty sessions, or of one of the magistrates hereinafter mentioned, sitting alone or with others at some court or other place appointed for the administration of justice; that is to say, the Lord Mayor or any alderman of the city of London, a metropolitan police magistrate, a stipendiary magistrate, or some other officer or officers for the time being empowered by law to do alone or with others any act authorized to be done by more than one justice of the peace:

(*b*) In Scotland, of two or more justices of the peace sitting as judges in a justice of the peace court, or of one of the magistrates hereinafter mentioned sitting alone or with others at some court or other place appointed for the administration of justice; that is to say, the sheriff of the county or his substitute, or the provost or other magistrate of a royal burgh, or some other officer or officers for the time being empowered by law to do alone or with others any act authorized to be done by more than one justice of the peace:

(c) In Ireland, within the police district of Dublin metropolis, one of the divisional justices of the police district of Dublin metropolis, and elsewhere of two or more justices of the peace in petty sessions, sitting at a place appointed for holding petty sessions.

3. The description of any offence under this Act in the words of such Act shall be sufficient in law.

4. Any exception, exemption, proviso, excuse or qualification, whether it does or not accompany the description of the offence in this Act, may be proved by the defendant, but need not be specified or negatived in the information; and if so specified or negatived, no proof in relation to the matters so specified or negatived shall be required on the part of the informant or prosecutor.

5. No conviction or order made in pursuance of this Act shall be quashed for want of form or be removed by certiorari or otherwise, either at the instance of the crown or of any private party, into any superior court. Moreover, no warrant of commitment shall be held void by reason of any defect therein, provided that there is a valid conviction to maintain such warrant, and it is alleged in the warrant that the party has been convicted.

6. All forfeitures may be sold or otherwise disposed of in such manner as the court may direct.

16. All powers given by this Act shall be deemed to be in addition to and not in derogation of any other powers conferred on any local or harbour authority by Act of Parliament, law, or custom, and every local authority and harbour authority may exercise such other powers in the same manner as if this Act had not passed; and nothing in this Act contained shall be deemed to exempt any person from any penalty to which he would otherwise be subject in respect of a nuisance.

17. The Acts mentioned in schedule two to this Act are hereby repealed to the extent in that schedule mentioned.

Provided that such repeal shall not affect any Order in Council made, or any licence granted, under any Act hereby repealed or any liability or penalty incurred in respect of any offence committed before the passing of this Act, or any remedy or proceeding for enforcing such liability or penalty, and every such order, so far as relates to the matters provided for by this Act, and every such licence shall have effect as if it had been made or granted under this Act.

SCHEDULES.

SCHEDULE ONE.

Directions for Testing Petroleum to Ascertain the Temperature at which it Gives Off Inflammable Vapour.

The apparatus to be employed in this test shall consist of:—

(*a*) An outer vessel of metal to contain water, about four inches in diameter and four inches deep, so contrived that some source of heat, such as a spirit-lamp or gas-burner, can be applied to it to heat the water which it contains:—

(*b*) An inner vessel of thin metal to contain the petroleum to be tested, about two inches in diameter and two inches deep, provided with an external rim or flange, above which the edge of the vessel shall rise about one-fourth of an inch, and by which it may be supported in the outer vessel so that its contents may be heated through the medium of the water.

The inner vessel for the petroleum shall be provided with a cover of thin metal fitting to the edge which rises above the rim or flange already described. This cover shall be about half an inch deep, so that its top may be half an inch above the surface of the petroleum to be tested. In the cover there must be fitted a Fahrenheit thermometer with a spherical bulb, in the scale of which ten degrees shall occupy at least half an inch in length; the thermometer must be placed in such a position that the bulb shall be just covered by the petroleum.

Near the front edge of the cover there shall be a circular opening, and through this the petroleum is to be tested. This opening is to be provided with a small moveable cover.

In making the experiment with this apparatus, the water in the outer vessel shall in every case be heated to eighty degrees Fahrenheit before the petroleum is put into the inner vessel. When the temperature of the water has reached eighty degrees, the source of heat must be withdrawn, the inner vessel must then be filled with the petroleum to be tested up to the level of the outer rim or flange, which must be indicated by a mark on the inside, and the cover with the thermometer must be put in its place. The source of heat must now be again placed beneath the vessel containing the water, and when the temperature of the petroleum in the inner vessel has reached eighty degrees, a small light should be applied to the circular opening in the cover; if the vapour be not ignited, that is if no pale blue flash or flicker of light be produced, the application of the light should be repeated at about every two degrees of increase of temperature until the flash of the ignited vapour be observed, and the temperature at which the first flash takes place is the temperature at which that sample of petroleum gives off an inflammable vapour.

In every case a second experiment shall be made to check the results obtained in the first.

A model of the apparatus described above is deposited with the warden of the standards, and reference shall be made to it in case of any difficulty or dispute as to the meaning of the terms employed in this description.

SCHEDULE TWO.

Year and Chapter.	Title.	Extent of Repeal.
25 & 26 Vict. c. 66.	An Act for the Safe Keeping of Petroleum.	The whole Act.
29 & 30 Vict. c. 69.	The Carriage and Deposit of Dangerous Goods Act, 1866.	Sections eight and nine.
31 & 32 Vict. c. 56.	The Petroleum Act, 1868.	The whole Act.

HOUSE OF LORDS.

Petroleum Bill.—*June* 16.—A Bill for the safe keeping of petroleum and other substances of a like nature was presented by the Earl of Morley, and read a first time.

June 20.—The Earl of Morley, in moving the second reading of the Petroleum Bill, explained that it consolidated the former Acts on the subject, and the existing regulations as to the landing, storage, etc.

HOUSE OF COMMONS.

Pharmacy Bill.—*June* 19.—The Pharmacy Bill, having passed the House of Lords, was brought in and read a first time. Ordered to be read a second time on Monday, June 26.

Weights and Measures (Metric System) Bill.—*June* 21.—The second reading of this Bill was deferred till Wednesday, July 26.

Illegal Sale of Methylated Spirit.

On the 8th instant, Messrs. Taylor and Culver, 173 and 175, High Street, St. Pancras, were prosecuted at Bow Street, before Mr. Vaughan, for selling methylated spirit without licence. They pleaded "Guilty," but wished the case to be heard on its merits, for the purpose of giving them power to take legal proceedings against the firm who supplied them with the article. It was proved in evidence that the sample sold to the Inland Revenue officer was part of a gallon of what had been purchased by the defendants as "Finish." The stone bottle containing the so-called "Finish" was produced, and a large gummed label having on it "Methylated Finish" was pasted on the bottle.

It was proved by Mr. Bannister, of the Inland Revenue Laboratory, that the sample purchased contained only 57 grains of gum in the gallon, instead of 1312½ grains. The magistrate said, that from the invoice handed in, and from the bottle produced, labelled as it was, he was of opinion the defendants had been imposed upon, but his duty was to fine the defendants in the mitigated penalty of £12. 10*s*., as the offence, had been fully proved. Mr. Dwelly, the Crown Solicitor, informed the magistrate he hoped to be able to prosecute the person who had supplied the illegal article, but at present there were certain difficulties in the way which he would not then name, but which, however, he hoped to remove in order to bring the proper person to punishment.

Sheffield County Court.—*Thursday, June 15th*, 1871.

(*Before* T. Ellison, Esq., *Judge.*)

Claim against a Chemist.

Thomas Ingall, saw carpenter, Oak Street, Heeley, sought to recover from Joseph John Riding, chemist and druggist, Devonshire Street, the sum of £50, damages alleged to have been sustained through the administration of improper medicine. Mr. Sugg appeared for the plaintiff, and Mr. Whitfield for the defendant, the case being tried before a jury.

In opening the case, Mr. Sugg said that the defendant had a branch establishment at Heeley, near to where the plaintiff resided. On December 17th, the plaintiff was passing along the street when the defendant, who was near his shop door, asked him how he was. Plaintiff replied that he was not very well, upon which the defendant recommended him to have a pennyworth of his pills. He took the pills as advised, but received no benefit from them, and he informed the defendant of this as he passed his shop the day but one afterwards. The defendant thereupon said that plaintiff's liver was out of order, and told him he had better take some of his liver pills, supplying him with a box containing twenty, and instructing him to take six per day. This he did for three days, and on the fourth morning he took the remaining two. After commencing work on the fourth day he was taken very ill while at work; he became very weak, his tongue was swollen, his teeth loose, and salivation set in. Up to that time he had been strong and healthy, and had never before required the aid of a medical man. So ill, however, did he become on that occasion, that he fell down and had to be taken home. Mr. Harrison, surgeon, who was sent for, attended him at his home for nearly a fortnight, and gave it as his opinion that his illness was the effect of extreme salivation. He then went into the Sheffield Hospital, where he was under the care of Mr. Taylor. For sixteen weeks the plaintiff was unable to work, and his health was not yet quite restored. Mr. Sugg contended that the defendant, if he represented himself as skilled in diseases such as he said the plaintiff was suffering from, ought to have given him proper directions in reference to the medicine, and in a case where salivation was deemed necessary, he should have called to see the plaintiff to ascertain how he was progressing. Instead of doing this, however, he sold him twenty mercurial pills, and never visited him, the result being the fearful illness to which he had referred.

The plaintiff was then called, and in his evidence bore out Mr. Sugg's opening statement. He said that during his illness he went to the Buxton Hospital, where his expenses were £1 per week; but in cross-examination by Mr. Whitfield, he admitted that he was a free patient at that institution, and explained that but for this fact he would have had to pay the amount named. On the fourth day of taking the pills he saw the defendant, who, on observing his state, said, "Oh dear! You must not take any more." He would not take any more for £100,000. He had lost twenty-six pounds of flesh in a month and four or five days. His earnings were £1. 11*s*. 7½*d*. per week.

Mr. Harrison, surgeon, said that when he was called in to attend the plaintiff he found him suffering from general debility and mercurial salivation. It was dangerous to take cold while salivation was going on. Medical men seldom administered mercury to salivation, but when they did so they looked carefully after the patient.

Mr. A. Taylor, house surgeon, Sheffield Public Hospital, said that when he first saw the plaintiff he was suffering from salivation, but rheumatism subsequently set in. Taking cold while under salivation would very likely lead to rheumatism.

Evidence was also given proving the plaintiff's absence from work and his previous good health.

Mr. Whitfield submitted that there was no case to go to the jury. The defendant did not hold himself out as capable of curing these diseases, but simply said, "Try my pills."

His Honour said that the law now was that every person who held himself out as following any skilful employment was bound to bring to the exercise of it a reasonable amount of skill. This applied to medical men, but not to chemists and druggists, who were simply sellers of drugs. There was a case in which a person went to a blacksmith to have a tooth drawn, and the latter broke his jaw. He sued for damages, and the Court held that there was no cause of action, because the man should not have gone to a blacksmith under such circumstances.

Mr. Sugg contended that in the present case the defendant had voluntarily placed himself in the position of a skilful practitioner.

His Honour said that a chemist and druggist could not administer medicines for profit. *If a man would be so great a fool as to go to a chemist* and take any pills that he might give him, it was his own fault. The matter having been argued at some length, his Honour decided that there was no case for the jury. If it had been a case in which a surgeon or qualified practitioner had done an injury to any one through not bringing to the performance of his duties that amount of reasonable skill which the law required, the action would have lain; but the defendant was merely a chemist and druggist, and held himself out to the world as simply a seller of drugs. *The ordinary practice of mankind was not to go to chemists and druggists as if they were medical men, but to go to a medical man first, obtain his advice, and then go to the chemist and druggist for the drugs that had been prescribed.* In the present case the plaintiff first went to the chemist and druggist, and took the pills which he recommended. It might be that the plaintiff had been injured by the pills, but in his opinion that made no case for the jury. *There was no skill required by a chemist and druggist*, who did not hold himself out as a possessor of skill. It was the same as if the plaintiff had taken pills which he (the Judge) had recommended as very valuable for his complaint. He (the Judge) would not be liable under such circumstances. He should therefore hold that there was no case to go to a jury, so that unless the plaintiff elected to be nonsuited, he should direct the jury to find a verdict for the defendant.

Mr. Sugg preferred a verdict for the defendant, in order that he might be in a position to appeal.

A verdict for the defendant was then entered.

LAMBETH POLICE COURT, *June* 16.

CHARGE AGAINST A "MEDICAL BOTANIST."

Charles de Badderley, 41, of Exeter Villas, Kennington Oval, described as a medical botanist, and Sarah de Badderley, 37, said to be his wife, were charged before Mr. Ellison on a warrant with having supplied ergot of rye with intent to cause the miscarriage of a woman. Mr. Poland appeared on the part of the Government to prosecute; Mr. Fullager was for the prisoners.

Counsel, in opening the case, said the attention of the police authorities had been directed to the parties, and their notice was called to the following advertisement in a publication called the *Medium*:—"Clairvoyance.—Madame de Badderley, the celebrated clairvoyante, at home for consultation from 2 to 7 daily. Communications by letter, stating age, etc. Morning consultations by appointment. Address 4, Exeter Villas, Kennington Oval, London, S.E."

Mrs. Hansard, a widow, who had acted under the direction of Mr. Inspector Clark, of the detective department of Scotland Yard, said that according to instructions she went on the 16th of March to 4, Exeter Villas, with the letter produced and a sovereign he gave her. She told the servant who opened the door that she wanted to see Madame de Badderley privately. The male prisoner came forward and said he was "Mr. de Badderley." The woman came, and he left for a time. Witness told the female prisoner that she was in great trouble through a niece, who was pregnant, and was in a situation in the country. The prisoner said she could do nothing until put into a state of clairvoyance; and the male prisoner, who came in, said he would perform the operation. He stared at her and made passes, and when she nodded that she was in a proper state of clairvoyance, he blindfolded her, and told witness to hold her hand while asking her any question, or her power would be gone. Witness took her hand and held it the whole time. She read the letter to her which had been given by Inspector Clark, and which was written as if it came from the niece to the aunt. Witness asked the female prisoner if she could do anything, and she said she would, when out of the clairvoyant state, give her some herbs to procure abortion. Witness rang the bell, and the male prisoner came into the room, took off the bandage from the eyes of the woman, who appeared to wake up. Witness then told her what she had said, and the woman requested the man to give her two bundles of herbs and also a box of the strongest pills. He went out of the room and shortly came back with a bundle of herbs. The female prisoner said the fee was usually a guinea, but as the girl was a servant it would be 10*s*. Witness handed to her the sovereign she had from Inspector Clark, and she gave it to the male prisoner, and he gave witness 10*s*. in change. The woman said that in case what she had given her did not act she was to call on the 21st of March, and then she would give her something stronger. Witness took the articles to the Horns Tavern, where she had appointed to meet the inspector, and gave them to him. On the 21st of March she met Sergeant Freeman at Kennington, and from him received a second letter and another sovereign. She went to the house of the prisoners. She again saw both prisoners together. She told the woman that the medicine had not acted. The woman was again put in a state of clairvoyance. Witness read a second letter, and asked her if she could give her the powders promised. She said she would, and they were to be taken in warm bitter beer before going to bed. The powders would be very strong, and she described what they could perform. She said, if required, she would make up a mixture, and her fee would be £5. Witness said the price was high, and the woman said she had great difficulty in getting the herbs. She afterwards told witness not to come before three weeks, as it was a critical case. Witness was also to write a note a day before she came, without giving any name, which was to be addressed to her as Madame de Badderley, as Mr. de Badderley had nothing to do with such cases, and she made up the medicine herself. When she had asked her all questions on her state she rang the bell, and the male prisoner brought her out of her state of clairvoyance, and after going out of the room he returned with four powders. Witness handed her the sovereign given to her and received 10*s*. in change. She gave, on leaving, the powder to Sergeant Freeman. On the 19th of April witness wrote a letter as directed, addressed to "Madame de Badderley," and on the next day called. Inspector Clark gave her a £5 note, of which he took the number, and the male prisoner told her a letter had been received, and madame would be ready in a few minutes. The female prisoner came in, and at her own request was put into a state of clairvoyance. While in that supposed state the woman startled her, and said a gentleman was passing her vision who frequently consulted her. She added that she did not know what she had to do with the witness's young friend who then came up before her. There was, she continued to say, life in the child, and it was a very critical case. She would give her the mixture, and advised that the girl should get away from her place, as it would make her cry out, and that would cause the domestics to become alarmed; a doctor would be sent for, and they would all be in a pretty plight. She said how powerful the mixture was, and what was left must at once be destroyed. The girl, she said, was to have every comfort, and to be careful not to take cold. Witness produced the £5 note, and she said to witness, "You stupid; why didn't you bring gold?" The other prisoner got change, and the woman put one guinea aside, she said, for his consultation fee.

Inspector Clark was called to confirm the last witness. He had planned the interview, and took the prisoners on Thursday morning into custody at the house.

Mr. Fullager reserved his cross-examination, and Mr. Poland asked for an adjournment. Mr. Ellison said there must be a remand.

Mr. Fullager asked that bail might be accepted, and produced a letter, he said, from a member of Parliament. Mr. Ellison said the case was far too serious for him to take bail. Mr. Poland said he should complete the case on the next occasion.

Review.

DR. DOBELL'S REPORTS ON THE PROGRESS OF PRACTICAL AND SCIENTIFIC MEDICINE IN DIFFERENT PARTS OF THE WORLD. Contributed by numerous and distinguished Coadjutors. Vol. II. London: 1871.

In spite of his somewhat unprofessional title-page, (if coadjutors are "distinguished'," there is surely no necessity for publishing the fact!) Dr. Dobell has carried out a good idea so satisfactorily as to make us regret that this, his second, volume will also be his last. As medicine advances, it becomes more and more requisite to record the net results of each successive year's observation and experience; otherwise, the fellow-workers in the same mighty field will be kept in ignorance of each other's achievements, and much time will be wasted in the solution of problems already solved.

As might have been expected, the report of the contributions made to medical knowledge in the United Kingdom is fuller and more satisfactory than those transmitted from other parts of the globe; Dr. Dobell having laboured under disadvantages similar to those of the compilers of our Army and Navy Blue-books, which are generally a year or two behindhand, owing to the distance of the several stations from headquarters. Among the most interesting papers in this section are those of Dr. W. W. Ireland (of Fisher Row, near Edinburgh), on the "Prevention of Disease;" the author being very instructive in the matter of disinfectants; of Dr. Adolphus Wahltuch (of Manchester), on "Materia Medica and Therapeutics," in which a good account is given of chloral hydrate; and of Mr. R. Brudenell Carter (Ophthalmic Surgeon to St. George's Hospital) on "Ophthalmology," in which he enounces Mr. Jonathan Hutchinson's doctrine that the hurtful effects of tobacco upon the optic nerves are most frequently seen in persons who abstain from alcohol; Mr. Hutchinson being "decidedly of opinion that the injurious influence of tobacco is, to some extent, counteracted by alcohol."

Of the contributions from abroad, undoubtedly the best, as well as most interesting, is that of Professor Villemin, of the Val-de-Grâce Hospital (translated by Dr. Ireland), on the progress of medical science in France. Surrounded by wounded, and beset by every kind of distraction during the latter part of 1870, Dr. Villemin has succeeded in composing a very instructive picture of what France has achieved in medicine during that eventful year. Germany is well represented by Dr. Julius Althaus; and Italy by Dr. Sammut, of Naples. Of the colonies, perhaps Australia, in spite of the fragmentary nature of its reports, appears in the most entertaining, if not instructive, light; a considerable portion of its contribution being occupied by a vindication of Professor Halford's mythical (and slightly dangerous) "cure for snake-bite." There is also a paper on the prevalence of consumption in Australia,—a subject on which there is no better authority than the writer, Dr. William Thomson, of Melbourne.

This volume is a great improvement on its predecessor. Dr. Dobell, indeed, as often happens, seems to have abandoned his undertaking just when he was acquiring that familiarity with its subject-matter and *modus operandi* which makes after-success not only certain but progressive.

Obituary.

On the 2nd of June, Mr. Robert Howard, F.C.S., Pharmaceutical Chemist, of Tottenham. Aged 70.

On the 4th of June, Dr. Frederic Holst, Ex-Professor of Medicine in the University of Christiania, and Honorary Member of the Pharmaceutical Society of Great Britain. Aged 79¾ years.

On the 9th of June, at his residence, Sloane Street, Chelsea, Charles Rowett Quiller, Pharmaceutical Chemist. Aged 42 years.

MEETINGS FOR THE ENSUING WEEK.

Tuesday ......*Royal Medical and Chirurgical Society*, at June 27. 8.30 p.m.

Wednesday ...*Society of Arts*, at 4 p.m.—Anniversary.

Friday ....*Royal Botanic Society*, at 4 p.m.—"Economic June 30. Botany." By Professor Bentley.

The following journals have been received:—The 'British Medical Journal,' June 17; the 'Medical Times and Gazette,' June 17; the 'Lancet,' June 17; the 'Medical Press and Circular,' June 21; 'Nature,' June 15; the 'Chemical News,' June 17; 'Gardeners' Chronicle,' June 17; 'Journal of the Society of Arts,' June 17; the 'Grocer,' June 17; 'Produce Markets Review,' June 17; the 'English Mechanic,' June 17; the 'Chicago Pharmacist' for May; the 'American Journal of Pharmacy' for June; the 'New York Druggists' Circular' for June; the 'Florist and Pomologist,' the 'Brewer's Guardian,' June 19; 'Bulletin de la Société Botanique de France,' vol. xviii. part 2; 'Neues Repertorium für Pharmacie,' vol. xx. part 5.

Notes and Queries.

Liq. Potassæ ʒij
Syrupi ad ℥vj

Misce. C. S. S.

[259.]—DRYING SALVE.

R. Alum. Pulv.
Adipis Ppt. aa ℥iv
Ol. Origani ʒss
Ft. Ung.

[260.]—"PATE DE GUIMAUVE.

Take of Decorticated Marshmallow Root ℥iss
Distilled Water Oiss.

Macerate for twenty-four hours and strain. To this, add
Picked Gum Arabic, and
Finest White Sugar, of each ℥xv

Dissolve, and stirring constantly, evaporate to the consistency of thick syrup, add gradually the whites of 5 eggs well beaten up with
Orange Flower Water ℥iss

Evaporate (with constant stirring) until the "paste" is firm enough to be cut into tablets of the required shape.—J. T. C.

[261.]—"EXTRACT OF MALACCA BEAN."—Would any reader kindly oblige me with some information respecting the above extract? I was asked for it a few days ago, and my customer said that he had got it before. Would it be the St. Ignatius bean he meant?—G. S. Highmoor.

[262.]—TINCT. FERRI PERCHLORIDI.—I wish to elicit an opinion from some of your readers as to the advisability of substituting liq. ferri perchlor. for the tincture of the same, in dispensing, as during warm weather the latter will not keep without undergoing decomposition. In nine prescriptions out of ten the liquors may be used without causing the slightest difference from what would be the case were tincture used, and it has the advantage of being a stable preparation under all ordinary circumstances. I am convinced that medical men order the tincture solely as a matter of habit, and not from any superior therapeutical effect it may have.—H.

[263.]—DISPENSING PRICES.—A prescription was lately brought to me as follows:—

R. Tr. Veratriæ Virid. ʒij
Sumat guttæ iij ter die ex aqua.

Will some of your correspondents kindly favour me with their opinion as to what would be a reasonable price for the same?—H.

ORANGE FLOWER WATER.—It is a matter of daily experience that this water frequently becomes unsightly from the formation in it of flocculent vegetable matter, and sometimes this turbidity is accompanied by an unpleasant odour. I recently tried the experiment of adding to such a sample a crystal or two of permanganate of potassium, and was much gratified by the result. After standing for a few hours, the confervoid matter and the precipitated manganic oxide were easily removed by filtration, leaving the water colourless, bright and of faultless odour. The alkaline reaction produced in it was very slight, and would not, I think, interfere with the uses to which this water is applied.—J. F. BROWN, *Dover.*

NEW FIBRE FROM THE BARK OF THE MULBERRY TREE.—In reference to the paragraph on the above subject, on p. 995, a correspondent sends us an extract from a little biographical work by Alphonse Karr, in which the discovery is said to have been made by Serres more than three centuries ago, and asks whether it has lain dormant ever since. The authority for our statement, as mentioned at the time, was the *Journal of the Society of Arts*, but we shall be glad to receive any further information on the subject. The extract is as follows;—"Serres (naquit près Viviers en 1539) est le premier qui ait introduit en France la culture de cet arbre utile et annonça qu'on pouvait faire de belles étoffes avec l'écorce des arbres qu'on en retranche à la taille."

SAUCES.—As we have received several inquiries from correspondents concerning sauces, we extract the following formulæ from the *New York Druggists' Circular*, though we are unaware upon what authority they are given:—

No. 1.

White Vinegar 15 gallons
Walnut Catsup 10 gallons
Madeira Wine 5 gallons
Mushroom Catsup 10 gallons
Table Salt 25 pounds
Canton Soy 4 gallons
Powdered Capsicum 2 pounds
Allspice, powdered,
Coriander, powdered, aa 1 pound
Cloves,
Mace,
Cinnamon, aa ½ pound
Assafœtida ¼ pound, dissolved in Brandy 1 gallon.

20 pounds of hogs' liver is boiled for twelve hours with 10 gallons of water, renewing the water from time to time. Take out the liver, chop it, mix with water, and work it through a sieve; mix with the sauce.

No. 2.

White Vinegar 240 gallons
Canton Soy 36 gallons
Sugarhouse Syrup 30 gallons
Walnut Catsup 50 gallons
Mushroom Catsup 50 gallons
Table Salt, 120 pounds
Powdered Capsicum 15 pounds
Allspice,
Coriander, of each 7 pounds
Cloves,
Mace,
Cinnamon, of each, 4 pounds
Assafœtida 2½ pounds, dissolved in St. Croix Rum 1 gallon.

No. 3.

White Vinegar 1 gallon
Canton Soy,
Molasses, of each 1 pint
Walnut Catsup 1½ pint
Table Salt 4 ounces
Powdered Capsicum,
Allspice, of each 1 ounce
Coriander ½ ounce
Cloves,
Mace, of each ½ ounce
Cinnamon 6 drachms
Assafœtida ¼ ounce, in 4 ounces Rum.

M.

PINEAPPLE ESSENCE.

Chloroform 1 part (by volume)
Aldehyde 1 part
Butyrate of Ethyl 5 parts
Butyrate of Amyl 10 parts
Glycerine 3 parts
Alcohol 100 parts.

RASPBERRY ESSENCE.

Nitric Ether 1 part
Aldehyde 1 part
Acetate of Ethyl 5 parts
Formiate of Ethyl 1 part
Butyrate of Ethyl 1 part
Benzoate of Ethyl 1 part
Enanthylate of Ethyl 1 part
Sebacic Ether 1 part
Salicylate of Methyl 1 part
Acetate of Amyl 1 part
Butyrate of Amyl 1 part
Tartaric Acid 5 parts
Succinic Acid 1 part
Glycerine 4 parts
Alcohol 100 parts.

STRAWBERRY ESSENCE.

Nitric Ether 1 part
Acetate of Ethyl 5 parts
Formiate of Ethyl 1 part
Butyrate of Ethyl 5 parts
Salicylate of Methyl 1 part
Acetate of Amyl 3 parts
Butyrate of Amyl 2 parts
Glycerine 2 parts
Alcohol 100 parts.

AROMATIC ESSENCE OF GINGER.—Mr. W. R. Jones recommends the following as yielding a very agreeable form of tincture of ginger:—

℞. Ginger . . . . ℥xij
Cinnamon . . . . ℥j
Cardamoms . . . . ℥ss
Cloves . . . . ʒiij
Capsicum . . . . ʒij
All in moderately-coarse powder.
Alcohol . . . . Oiv.

Moisten the powder with a small portion of the alcohol, pack firmly into a percolator, and gradually pour on the remainder of the alcohol.—*American Journal of Pharmacy.*

ADULTERATION OF LARD.—A case of adulteration of lard, for the sake of obtaining a good colour, is reported in the *Canadian Pharmaceutical Journal* by Mr. E. B. Shuttleworth. Having purchased some beautifully white lard, he proceeded to use it for the preparation of ointment of nitrate of mercury. Upon adding the mercurial solution, instead of a citrine a decidedly saturnine colour was produced, developing in a short time to a full slate colour. The lard was consequently examined, and found to contain a large proportion of lime. Mr. Shuttleworth was afterwards told by a lard renderer that it was a common practice among lard dealers to mix from 2 to 5 per cent. of milk of lime with the melted lard. A saponaceous compound is thus formed that is not only pearly white, but will allow of the stirring in, during cooling, of 25 per cent. of water.

TINCTURA OPII CAMPHORATA (U.S.).—The following formula for the extemporaneous preparation of tinctura opii camphorata is published by Mr. W. Bamstead Jones, of Mount Airy, Philadelphia, in the *American Journal of Pharmacy*:—

Take of Tinct. Opii . . . . . . ℥iij ʒijss
Sp. Camphoræ . . . . . ℥j ʒiij
Ol. Anisi . . . . ʒij
Acid. Benzoic. . . . . . ʒij
Alcoholis, q. s. ft. . . . . Oij.
Mix.
Mel. Despumat. . . . . . ℥iv (troy)
Aquæ, q. s. ft. . . . . . Oij.

Mix the two solutions together, and filter through paper.

Correspondence.

The Lancet and the Spectroscope.

Sir,—All who are in the habit of reading the *Lancet* must have remarked the article in a recent number, containing some rather caustic reflections on the value of part of Dr. Letheby's evidence, in which he refers to the valuable aid afforded by the micro-spectroscope. Either the author of that article must have been misled, or not much accustomed to the use of that instrument.

The bands produced by the blood-spectrum are by no means "dim," but, on the contrary, well defined when observed by a properly-constructed instrument. The micro-spectroscopes generally sold differ greatly; most of them give rectangular fields, but all are not equally adapted for observing the spectra of coloured solutions. The prisms of one kind are so arranged that the colours run parallel to the short side, and are much diffused. The others are so arranged that the colours run parallel to the long side of the rectangle. The former arrangement is the best for observing the spectra of incandescent metals, and showing what the Editor of the *Lancet* terms "the China ribbon" lines. It will, however, give very inferior results with the absorption bands of coloured liquids. The latter arrangement, or that with the colours running parallel with the longest side of the field, will show them well defined, even when a very diluted solution of blood is used.

Moreover, this is not the chief point to be observed in micro-spectroscopy. It is not so much whether the bands are well defined, but their position in the spectrum. It must have constantly occurred to every observer that there are numerous examples that, when placed on the stage of the microscope one after another, appear identical even to the most practised eye and the closest scrutiny. But when two spectra are placed side by side by means of the auxiliary prism, the question of their identity is instantly decided. If the spectra be from the same substance, they will fit exactly one on the other; but if not, there would be what the geologist would term "a fault." Mr. Sorby and Dr. Letheby are quite correct when they say that no other known spectrum is like that of blood. If the spectrum of blood be observed by the terminal prism of the spectroscope, the spectrum of no other known substance, placed in juxtaposition by means of the side prism, will exactly match it.

The jargonium fallacy has nothing whatever to do with the question; and, before taunting Mr. Sorby, the Editor of the *Lancet* would do great service in the cause of medical jurisprudence if he would name any substance that would give a spectrum coincident with that of blood.

W. W. Stoddart.

"Orders" in Council.

Sir,—What have the Council been doing to Mr. Brown, that Mr. Brown should so rebuke the Council? Has it proved such a bear-garden since he joined it, that his rooted aversion to "regulations" has been forced to give way to the necessity of prescribing standing orders for its better government?

I can assure Mr. Brown that before he enjoyed the distinction of a seat at the Council, business was conducted there with the decorum and regularity to be expected from gentlemen and men of business. There was in those days no necessity to codify the very A B C of public affairs.

But "nous avons changé tout cela." The Council is now distracted by party feeling, its unity of action sadly impaired, its influence abated; and these new "standing orders" give token of still further disorganization.

As we read clauses 6, 7 and 8, we wonder if the object be to impeach the late President or to affront his successor, and a horrible apprehension takes hold of us that the next clause will follow—

"9. To prevent confusion, no two members will in future be allowed to speak at once, without express permission from the chair."

But seriously these exhibitions are calculated to bring the Council and the Society into contempt. How could the President have accepted a proposition imputing to him total incompetence for the duties of his office?

It is time that the better sense of the Society rose against the factious proceedings by which elections of Council have recently been dominated, and that our members should recollect that the Council which they appoint is not a parliament but a government.

Ex-Councillor.

Poison Regulations.

Sir,—I am surprised to find so much opposition to the "Poison Regulations;" however inconvenient and unpleasant it may be to submit to those regulations, my belief is that the more we have of Government inspection the better it will be for the *bonâ fide* chemist. The Pharmaceutical Council deserves the thanks of the community for swelling the tide of that progress which, in my belief, is gradually carrying us to the adoption of the continental system of Government appointment and supervision. That system, while making the number of pharmacists less, would place those left in a position to do without debasing the trade by dealing in farthing dips and methylated tincture of rhubarb.

A Country Chemist.

The Preliminary Examination.

Sir,—If "*B. S.*" intended his letter of the 13th ult. to be a reply to mine of the 29th April, I fail to see that he has answered one point in it. I urged two objections to the Modified men being admitted to the Minor.

1st. In justice to those who were not of age at the time of the passing of the Pharmacy Act, many of whom had been longer in the trade than some of those eligible for the Modified.

2nd. That no advantage would be gained by being admitted to the Minor without the Preliminary, as to a considerable extent the same knowledge requisite in the Preliminary is requisite in the Minor, in the translation of prescriptions.

"*B. S.*" is perfectly correct in saying that the Modified does "test the practical capabilities of the candidate," so far as it goes, but as to its being a "delusion and snare," it can neither be the one nor the other, as all who avail themselves of the Modified know, or ought to know what to expect.

To take the Modified with all its privileges (which "*B. S.*" admits to be as great as those enjoyed by pharmaceutical chemists), and then to cry out because they cannot skip the Preliminary, seems to me selfish in the extreme.

If in the words of "*Another Associate*" men desire pharmaceutical honours, they ought not to shrink from the conditions under which they are conferred.

June 7th, 1871. Minor Associate.

"*Live and Let Live.*"—The evils of the system are obvious, but at present it seems as if it must be left to work its own cure. If our correspondent can suggest any method of advantageously dealing with the subject, we should be glad to receive such communication from him.

"*Ice Cream Soda.*"—One of the ingredients in your mixture might raise the question whether you would not require to take out a spirit licence.

"*Kappa.*"—Articles on the subject of the removal of hydrocyanic acid from oil of bitter almonds will be found in the Pharm. Journ. 1st Ser. Vol. XIII. p. 277, and 2nd Ser. Vol. VI. p. 407.

F. W. Steel.—Our attention has been drawn to the same practice before, but it is one that we do not see that there is any possibility of interfering with.

"*Spes.*"—Boiled linseed oil is generally used for the purpose.

"*Country Druggist.*"—(1.) The mixture should be sent out in an ℥viij bottle, not filled up. (2.) We believe a perfumed carbolic acid has been advertised by several manufacturers.

[*** Carbolic acid readily dissolves essential oils, and it may be made aromatic in this way at discretion.—Ed. Pharm. Journ.]

Communications, Letters, etc., have been received from Mr. R. Palmer, Mr. E. Agnew, Mr. T. Perkins, Mr. Pardoe, Mr. W. Grey, Mr. R. Owen, Mr. Pollard, Mr. Procter, Messrs. Schoetensack, Mr. J. M'Innes, Mr. W. Wilkinson, Mr. J. Smith, Mr. H. B. Brady, Mr. Woolley, Mr. Coles, Mr. W. Hills, Mr. H. B. Poland, N. E. L. K., J. T. C., R. G. H., S. R., A. P. S., A. B. C., R. H. C. M., W. J. S., "Phyto," "Chemicus," "Ignotus," "Chemist."

INDEX TO VOL. I.

(THIRD SERIES.)

All Letters to the Editor will be found arranged under the head of "Correspondence;" Leading Articles, etc., under the head of "Editorial Articles and Notes."
