THE
ENCYCLOPÆDIA BRITANNICA

LATEST EDITION

A DICTIONARY OF ARTS, SCIENCES, AND GENERAL LITERATURE

NEW MAPS AND MANY ORIGINAL AMERICAN ARTICLES BY EMINENT AUTHORS
FULLY ILLUSTRATED, WITH OVER TEN THOUSAND PORTRAITS, PLATES, AND ENGRAVINGS

ORIGINAL NINTH EDITION IN TWENTY-FIVE VOLUMES EDITED BY
PROFS. SPENCER BAYNES, LL.D., AND W. ROBERTSON SMITH, LL.D.
ASSISTED BY OVER ONE THOUSAND CONTRIBUTORS

IN THIRTY VOLUMES WITH

NEW AMERICAN SUPPLEMENT

EDITED UNDER THE PERSONAL SUPERVISION OF
DAY OTIS KELLOGG, D.D.
Formerly Professor of English Literature and History, Kansas State University, etc., etc.
ASSISTED BY A CORPS OF EXPERIENCED WRITERS

TWENTIETH CENTURY EDITION
REVISED, WITH LARGE ADDITIONS, TO JANUARY 1, 1901

VOLUME VI

Encyclopædia Britannica.

VOL. VI.—(CLI–DAY).

Total number of Articles, 761.

PRINCIPAL CONTENTS.

CLIMATE. ALEX. BUCHAN, Secretary, Scottish Meteorological Society.
CLIVE. G. SMITH, LL.D., Editor of "Annals of Indian Administration, 1868–69."
CLOCKS. Right Hon. Lord GRIMSTHORPE, Q.C.
CLUB. Rev. CANON J. S. NORTHCOTE, and J. CLAUDE WEBSTER, Athenæum Club.
COAL. H. BAUERMAN, F.G.S., Royal School of Mines.
COBDEN. HENRY RICHARD, M.P.
COCHIN CHINA. C. MAUNOIR, Société de Geographie.
COFFEE. JAMES PATON, Corporation Galleries, Glasgow.
COFFER-DAMS. DAVID STEVENSON, C.E.
COLEOPTERA. JOHN GIBSON, Industrial Museum, Edin.
COLERIDGE. Rev. G. D. BOYLE, M.A.
COLOMBIA. H. A. WEBSTER.
COLOSSIANS. Rev. W. SAUMAREZ SMITH, Principal, St. Aidan's College, Birkenhead.
COMET. J. RUSSELL HIND, F.R.S., Superintendent of the "Nautical Almanac."
COMMERCE. ROBERT SOMERS, Author of "Trade Unions."
COMMUNISM. Mrs. FAWCETT.
COMPANY. EDMUND ROBERTSON, LL.D., M.P., Professor of Roman Law, University College, London.
COMPASS. F. H. BUTLER, M.A.
COMTE. JOHN MORLEY, M.P., Editor of the "Men of Letters" Series.
CONDILLAC. Rev. D. BALSILLIE, M.A.
CONDORCET. ROBERT FLINT, D.D., Professor of Divinity, University of Edinburgh.
CONFUCIUS. Rev. JAMES LEGGE, Professor of Chinese University of Oxford.
CONGRESS. HENRY REEVE, C.B.
CONGREVE. A. C. SWINBURNE.
CONIC SECTIONS. H. M. TAYLOR, Fellow of Trinity College, Cambridge.
CONNECTICUT. W. G. ABBOT, Hartford, Conn.
CONSTANTINE. W. BROWNING SMITH.
CONSTANTINOPLE. Rev. C. G. CURTIS, Chaplain to British Embassy, Pera.
CONSTITUTION OF BODIES. Prof. CLERK MAXWELL.
CONTRABAND. W. C. SMITH, LL.B., Advocate.
CONVOCATION. Sir TRAVERS TWISS, Q.C.
COOKERY. J. C. BUCKMASTER, South Kensington Museum, London.
COOLIE. R. WILSON.
CO-OPERATION. R. SOMERS.
COPPER. JAMES PATON.
COPTS. S. BIRCH, LL.D., D.C.L.
COPYRIGHT. Prof. ED. ROBERTSON, (AMERICAN) E. S. DRONE.
CORALS. Prof. H. A. NICHOLSON.
COREA. H. A. WEBSTER.
CORINTH. PERCY GARDNER, British Museum.
CORINTHIANS. Rev. W. SAUMAREZ SMITH.
CORK. R. CAULFIELD, LL.D.
CORN LAWS. R. SOMERS.
CORNEILLE. GEORGE SAINTSBURY.
CORNELIUS. W. CAVE THOMAS.
CORNWALL. R. J. KING.
CORONATION. Rev. S. H. REYNOLDS.
CORREGGIO. W. M. ROSSETTI.
COSMOGONY. Rev. Prof. CHEYNE.
COSTUME. A. STUART MURRAY and Rev. CHARLES BOUTELL.
COTTON. ISAAC WATTS, Chairman of Cotton Supply Association, Manchester.
COUNCIL. D. PATRICK.
COURT-MARTIAL. W. C. SMITH, LL.B.
COUSIN. JOHN VEITCH, LL.D., Professor of Logic and Rhetoric, University of Glasgow.
COWLEY. EDMUND W. GOSSE, Author of "New Poems."
COX. W. B. SCOTT.
CRANACH. J. A. CROWE, Author of "Painting in Italy."
CRANMER. W. BROWNING SMITH.
CREEDS. Very Rev. Principal TULLOCH.
CREMATION. W. C. SMITH, LL.B.
CRETE. E. H. BUNBURY, Author of "History of Ancient Geography."
CRIBBAGE. HENRY JONES.
CRICKET. H. F. WILKINSON.
CRIME. L. O. PIKE, Author of "History of Crime in England."
CRIMEA. Commander J. B. TELFER, R. N.
CRIMINAL LAW. Prof. ED. ROBERTSON.
CROMWELL, OLIVER. ALEX. NICOLSON, LL.D.
CROMWELL, THOMAS. T. M'K. WOOD.
CROQUET. HENRY JONES.
CROSS. Rev. CHARLES BOUTELL.
CROUP. Dr. J. O. AFFLECK.
CRUSADES. Rev. Sir GEO. W. COX, Bart.
CRUSTACEA. HENRY WOODWARD, F.R.S., British Museum.
CRYPT. Rev. Canon VENABLES.
CRYPTOGRAPHY. J. E. BAILEY.
CRYSTALLOGRAPHY. JAMES NICOL, late Professor of Natural History, University of Aberdeen.
CUBA. KEITH JOHNSTON.
CUCKOO. ALFRED NEWTON, Professor of Zoölogy, etc., University of Cambridge.
CUDWORTH. Prof. R. FLINT, D.D.
CUMBERLAND. H. I. JENKINSON and J. C. WARD.
CUMBERLAND (BISHOP). Prof. FLINT.
CUMBERLAND (DRAMATIST). A.W. WARD, Professor of English Literature, Owens College, Manchester.
CURVE. ARTHUR CAYLEY, LL.D., F.R.S., Sadlerian Professor of Mathematics, Cambridge.
CUTTLEFISH. Prof. H. A. NICHOLSON.
CUYP. J. A. CROWE, Author of "Painting in Italy."
CYPRUS. E. H. BUNBURY.
CYRUS. Rev. Prof. A. H. SAYCE, Queen's College, Oxford.
DACCA. Hon. W. W. HUNTER, LL.D., Director-General of Indian Statistics.
DAHOMEY. Col. W. K. ELLES, C.B.
DALHOUSIE. GEORGE SMITH, LL.D., Editor of "Annals of Indian Administration."
DALLING. CHARLES KENT.
DALTON. F. H. BUTLER.
DAMASCUS. J. L. PORTER, D.D., LL.D., Professor of Biblical Criticism, Belfast.
DANCE. W. C. SMITH, LL.B.
DANIEL. Rev. Prof. CHEYNE.
DANTE. OSCAR BROWNING, M.A., Fellow of King's College, Cambridge.
DANTON. JOHN MORLEY, M.P.
DARIUS. Rev. Prof. SAYCE.
DAVID. Prof. W. ROBERTSON SMITH, LL. D.

ENCYCLOPÆDIA BRITANNICA.

CLICHY, or Clichy la Garenne, a village or township of France, in the department of Seine, situated on the right bank of the river, immediately to the north of the ramparts of Paris, of which it may almost be said to be part. It is the seat of a number of extensive industrial establishments, engaged in the manufacture of steam engines, chemical stuffs, and glass. The village is of high antiquity, and was the residence of some of the early kings of France. Its church was built in the 17th century under the direction of the famous Saint Vincent de Paul, who at that time had charge of the cure. Population in 1872. 14,599.

CLIFTON, a watering-place and fashionable resort of England, in the county of Gloucestershire, forming practically a part of the city of Bristol. It is situated on the eastern heights above the gorge of the lower Avon, which divides it from the county of Somerset,—partly occupying a spacious table-land about 250 feet above the sea, and partly an abrupt declivity which sinks down to the once fashionable district of the Hotwells, on the same level as Bristol. Three ancient British earthworks bear witness to an early settlement on the spot, and a church was in existence as far back as the time of Henry II., when it was bestowed by William de Clyfton on the abbot of the Austin canons in Bristol; but, with the exception, perhaps, of Mardyke House, in Hotwells, there are no longer any architectural vestiges of an earlier date than the 18th century. Of the churches the most important are St Andrew's parish church, an ungainly structure rebuilt in 1819; All Saints, erected in 1863 at a cost of £32,000, after the designs of G. E. Street, and remarkable for the width of its nave and the narrowness of its aisles; and the Roman Catholic pro-cathedral church of the Holy Apostles, with a convent and schools attached. Among the other buildings of note may be mentioned the Victoria Rooms, which are used for concerts and other public assemblies, the Fine Arts Academy, dating from 1857, and Clifton College, a well-designed cluster of buildings in the Gothic style, founded in 1862 by a limited liability company, and giving education to 550 boys. The famous suspension bridge across the Avon, designed by Brunel and commenced in 1832, was completed in 1864. It has a span of 702 feet, and the roadway is 245 feet above high water; the total weight of the structure is 1500 tons, and it is calculated to stand a burden of 9 tons per square inch. Since it was opened a village called New Clifton has grown up on the opposite bank. The once famous hot springs of Clifton, to which, in fact, the town was indebted for its rise, are no longer frequented. They issue from an aperture at the foot of St Vincent's Rock, and the water has a temperature of about 76° Fahr. The population of Clifton in 1712, the date of the second edition of Sir Thomas Alleyne's work on Gloucester, was only 450; in 1841 it amounted to 14,177; in 1857 to 17,634; in 1861 to 21,375; and in 1871 to 26,364. In the last-mentioned year there were 10,319 males and 16,045 females. The average annual mortality is about 14 per 1000.

CLIMATE. The word Climate, or κλίμα, being derived from the verb κλίνειν, to incline, was applied by the ancients to signify that obliquity of the sphere with respect to the horizon from which results the inequality of day and night. The great astronomer and geographer Ptolemy divided the surface of the globe, from the equator to the arctic circle, into climates or parallel zones, corresponding to the successive increase of a quarter of an hour in the length of midsummer-day. Within the tropics these zones are nearly of equal breadth; but, in the higher latitudes, they contract so much that it was deemed enough to reckon them by their doubles, answering consequently to intervals of half an hour in the extension of the longest day. To compute them is an easy problem in spherical trigonometry. As the sine of the excess of the semidiurnal arc above a quadrant is to unity, so is the tangent of the obliquity of the ecliptic, or of 23° 28′, to the cotangent of the latitude. The semidiurnal arcs are assumed to be $91° 52\frac{1}{2}'$, $93° 45'$, $95° 37\frac{1}{2}'$, $97° 30'$, &c., and the following table, extracted from Ptolemy's great work, will give some general idea of his distribution of seasons over the surface of the globe. The numbers are calculated on the supposition that the obliquity of the ecliptic was 23° 51′ 20″, to which, according to the theory of Laplace, it must have actually approached in the time of Ptolemy. They seem to be affected by some small errors, especially in the parallels beyond the seventeenth, as the irregular breadth of the zone abundantly shows; but they are, on the whole, more accurate than those given by Varenius.

Climate in its modern acceptation signifies that peculiar state of the atmosphere in regard to heat and moisture which prevails in any given place, together with its meteorological conditions generally in so far as they exert an influence on animal and vegetable life. The infinitely diversified character which climate displays may be referred to the combined operation of different causes, which are chiefly reducible to these four—distance from the equator, height above the sea, distance from the sea, and prevailing winds, which may thus be regarded as forming the great bases of the law of climate.

Of these causes which determine climate incomparably the most potent is distance from the equator. The same sunbeam which, falling vertically, acts on a surface equal to its own sectional area is, when falling obliquely on the earth, spread over a surface which becomes larger in inverse proportion to the sine of the obliquity. Consequently less and less heat continues to be received from the sun by the same extent of surface in proceeding from the equator toward the poles; and this diminution of heat with the increase of obliquity of incidence of the solar rays is enhanced by the circumstance that the sun's heat, being partially absorbed in its passage through the atmosphere, the absorption is greatest where the obliquity is greatest, because there the mass of air to be penetrated is greatest. Hence arise the broad features of the distribution of temperature over the globe, from the great heat of equatorial regions, falling by easy gradations with increase of latitude, to the extreme cold of the poles. If the earth's surface were uniform, and its atmosphere motionless, these gradations would run everywhere parallel with the latitudes, and Ptolemy's classification of the climates of the earth would accord with fact. But the distribution of land and water over the earth's surface and the prevailing winds bring about the subversion of what Humboldt has termed the solar climate of the earth, and present us with one of the most difficult, as certainly it is one of the most important problems of physical science, viz., the determination of the real climates of its separate regions and localities, and the causes on which they depend.

The decrease of temperature with height is perceptibly felt in ascending mountains, and is still more evident in the snow-clad mountains, which may be seen even in the tropics. The snow-line marks the height below which all the snow that falls annually melts during summer. The height of this line above the sea is chiefly determined by the following causes—by distance from the equator; by the exposure to the sun's rays of the slope of the mountain, and hence, in northern latitudes, it is higher on the south than on the north slopes of mountains, other things being equal; by situation with reference to the rain-bringing winds; by the steepness of the slope; and by the dryness or wetness of the district. Since, then, no general rule can be laid down for the height of the snow-line, it can only be ascertained by observation. Speaking generally it sinks little from the equator to 20° N. and S. lat.; from 20° to 70° it continues to fall equably, but from 70° it falls rapidly to 78°, where it is at sea-level.

The following are a few of the more noteworthy of the exceptions. On the north side of the Himalayas it is about 4000 feet higher than on the south side, owing to the greater depth of snow falling on the south side and the greater dryness of the climate of Tibet, resulting in a more active evaporation from the snows and stronger sun-heat on the north side, to which is to be added the comparative want of vegetation on the north side, thus favouring a more rapid melting of the snows. The snow-line is higher in the interior of continents than near their coasts, the rainfall there being less and the heat of summer greater; and similarly, owing to the greater prevalence of westerly over easterly winds in many regions of the globe, it is higher on the east than on the west sides of continents. In South America the snow-line rises very considerably from the equator to 18° S. lat. and more so, markedly, on the west than on the east slopes of the Cordilleras, because of the smaller amount of precipitation of the west side of this mountain range. It is as high in 33° as in 18° S. lat., but south of 33° it rapidly sinks owing to the heavy rains brought by the westerly winds which begin to prevail there. In the south of Chili it is 6000 feet lower than among the Rocky Mountains at the same distance from the equator, and 3000 feet lower than in the same latitudes in Western Europe. It is impossible to overestimate the importance of the snow-line as one of the factors of climate in its relations to the distribution of animal and vegetable life.

Glaisher, in his balloon ascents, made observations of temperature at different heights, the results of which may be thus summarized. Within the first 1000 feet the average space passed through for 1° was 223 feet with a cloudy sky and 162 feet with a clear sky; at 10,000 feet the space passed through for 1° was 455 feet for the former and 417 feet for the latter; and above 20,000 feet the space with both states of the sky was 1000 feet nearly for a decline of 1°. It must be noted, however, that these rates of decrease refer to the temperature of the atmosphere at different heights *above the ground*, which are in all probability altogether different from the rates of decrease for places *on the earth's surface* at these heights above the level of the sea—the problem with which climatologists have to deal.

Observation shows, as might have been expected, that the rate at which the temperature falls with the height is a very variable quantity,—varying with latitude, situation, the state of the air as regards moisture or dryness, and calm or windy weather, and particularly with the hour of the day and the season of the year. In reducing temperature observations for height, 1° for every 300 feet is generally adopted. In the present state of our knowledge this or any other estimation is at best no more than a rough approximation, since the law of decrease through its variations requires yet to be stated, being in truth one of the most intricate and difficult problems of climatology awaiting investigation at the hands of meteorologists. Among the most important climatic results to be determined in working out this problem are the heights at which in different seasons the following critical mean temperatures, which have important relations to animal and vegetable life, are met with in ascending from low-lying plains in different regions of the world, viz., 80°, 75°, 70°, 65°, 63°, 60°, 58°, 55°, 50°, 45°, 39° (the maximum density of fresh water), 32° (its freezing point), and 20°.

These results, which only affect the mean daily temperature in different seasons, and which are due exclusively to differences of absolute height, though of the greatest possible practical importance, yet leave untouched a whole field of climatological research—a field embracing the mean temperature of different hours of the day at different heights, for an explanation of which we must look to the physical configuration of the earth's surface and to the nature of that surface, whether rock, sand, black soil, or covered with vegetation.

Under this head by far the most important class of conditions are those which result in extraordinary modifications, amounting frequently to subversions, of the law of the decrease of temperature with the height. This will perhaps be best explained by supposing an extent of country diversified by plains, valleys, hills, and table-lands to be under atmospheric conditions favourable to rapid cooling by nocturnal radiation. Each part being under the same meteorological conditions, it is evident that terrestrial radiation will proceed over all at the same rate, but the effects of radiation will be felt in different degrees and intensities in different places. As the air in contact with the declivities of hills and rising grounds becomes cooled by contact with the cooled surface, it acquires greater density, and consequently flows down the slopes and accumulates on the low-lying ground at their base. It follows, therefore, that places on rising ground are never exposed to the full intensity of frosts at night; and the higher they are situated relatively to the immediately surrounding district the less are they exposed, since their relative elevation provides a ready escape downwards for the cold air almost as speedily as it is produced. On the other hand valleys surrounded by hills and high grounds not only retain their own cold of radiation, but also serve as reservoirs for the cold heavy air which pours down upon them from the neighbouring heights. Hence mist is frequently formed in low situations whilst adjoining eminences are clear. Along low-lying situations in the valleys of the Tweed and other rivers of Great Britain laurels, araucarias, and other trees and shrubs were destroyed during the great frost of Christmas 1860, whereas the same species growing on relatively higher grounds escaped, thus showing by incontestible proof the great and rapid increase of temperature with height at places rising above the lower parts of the valleys.

This highly interesting subject has been admirably elucidated by the numerous meteorological stations of Switzerland. It is there observed in calm weather in winter, when the ground becomes colder than the air above it, that systems of descending currents of air set in over the whole face of the country. The direction and force of these descending currents follow the irregularities of the surface, and like currents of water they tend to converge and unite in the valleys and gorges, down which they flow like rivers in their beds. Since the place of these air-currents must be taken by others, it follows that on such occasions the temperature of the tops of mountains and high grounds is relatively high because the counter-currents come from a great height and are therefore warmer. Swiss villages are generally built on eminences rising out of the sides of the mountains with ravines on both sides. They are thus admirably protected from the extremes of cold in winter, because the descending cold air-currents are diverted aside into the ravines, and the counter-currents are constantly supplying warmer air from the higher regions of the atmosphere.

Though the space filled by the down-flowing current of cold air in the bottom of a valley is of greater extent than the bed of a river, it is yet only a difference of degree, the space being in all cases limited and well defined, so that in rising above it in ascending the slope the increased warmth is readily felt, and, as we have seen, in extreme frosts the destruction to trees and shrubs is seen rapidly to diminish. The gradual narrowing of a valley tends to a more rapid lowering of the temperature for the obvious reason that the valley thereby resembles a basin almost closed, being thus a receptacle for the cold air-currents which descend from all sides. The bitterly cold furious gusts of wind which are often encountered in mountainous regions during night are simply the out-rush of cold air from such basins.

The two chief causes which tend to counteract these effects of terrestrial radiation are forests and sheets of water. If a deep lake fills the basin, the cold air which is poured down on its surface having cooled the surface water, the cooled water sinks to a greater depth, and thus the air resting over the lakes is little if at all lowered in temperature. Hence deep lakes may be regarded as sources of heat during winter, and places situated near their outlet are little exposed to cold gusts of wind, while places on their shores are free from the severe frosts which are peculiar to other low-lying situations. The frosts of winter are most severely felt in those localities where the slopes above them are destitute of vegetation, and consist only of bare rock and soil, or of snow. If, however, the slopes be covered with trees, the temperature is warmer at the base and up the sides of the mountain,—the beneficial influence of forests consisting in the obstacle they offer to the descending currents of cold air, and in distributing the cold produced by terrestrial radiation through a stratum of the atmosphere equalling in thickness the height of the trees.

Hence as regards strictly local climates, an intelligent knowledge of which is of great practical value, it follows that the best security against the severity of cold in winter is afforded where the dwellings are situated on a gentle acclivity a little above the plain or valley from which it rises with an exposure to the south, and where the ground above is planted with trees. When it is borne in mind that in temperate climates, such as that of Great Britain, the majority of the deaths which occur in the winter months are occasioned or at least hastened by low temperatures, it will be recognized as of the most vital importance, especially to invalids, to know what are the local situations which afford the best protection against great cold. In truth, mere local situations may during periods of intense cold have the effect of maintaining a temperature many degrees above that which prevails close at hand—a difference which must mitigate suffering and not unfrequently prolong life.

In addition to mere elevation and relative configuration of surface, the land of the globe brings about important modifications of climate in the degree in which its surface is covered with vegetation or is a desert waste. Of all surfaces that the earth presents to the influences of solar and terrestrial radiation an extent of sand is accompanied with the most extreme fluctuations of climate, as these are dependent on the temperature and moisture of the air; whilst on the other hand, extensive forests tend to mitigate the extremes of temperature and distribute its daily changes more equably over the twenty-four hours.

As regards the influence of the sun's heat on the temperature of the air, attention is to be given almost exclusively to the temperature of the extreme upper surface of the earth heated by the sun with which the air is in immediate contact. Badly conducting surfaces, such as sand, will evidently have the greatest influence in raising the temperature of the air, for the simple reason that the heat produced by the sun's rays being conveyed downwards into the soil with extreme slowness must necessarily remain longer on the surface, in other words, remain in immediate contact with the atmosphere. Similarly at night, the cooling effects of terrestrial radiation being greatest on sandy surfaces, the climate of sandy deserts is characterized by nights of comparatively great cold. These daily alternations of heat and cold are still further intensified by the great dryness of the air over extensive tracts of sand. In warm countries the surface temperature of sandy deserts often rises to 120°, 140°, or even to 200°, and the shade temperature has been observed as high as 125°. It is this hot air, loaded with particles of sand still hotter, and driven onwards by furious whirlwinds, which forms the dreaded simoon of the desert; and the irritating and enervating sirocco of the regions bordering the Mediterranean is to be traced to the same cause. It is in the deserts of Africa, Arabia, Persia, and the Punjab that the highest temperature on the globe occurs, the mean summer temperature of these regions rising to and exceeding 95°. The extreme surface of loam and clay soils is not heated during day nor cooled during night in so high a degree as that of sandy soils, because, the former being better conductors, the heat or the cold is more quickly conveyed downward, and therefore not allowed to accumulate on the surface.

When the ground is covered with vegetation the whole of the sun's heat falls on the vegetable covering, and as none of it falls directly on the soil its temperature does not rise so high as that of land with no vegetable covering. The temperature of plants exposed to the sun does not rise so high as that of soil, because a portion of the sun's heat is lost in evaporation, and the heat cannot accumulate on the surface of the leaves as it does on the soil. Hence the essential difference between the climates of two countries, the one well covered with vegetation, the other not, lies in this, that the heat of the day is more equally distributed over the twenty-four hours in the former case, and therefore less intense during the warmest part of the day.

But the effect of vegetation on the distribution of the temperature during the day is most markedly shown in the case of forests. Trees, like other bodies, are heated and cooled by radiation, but owing to their slow conducting power the times of the daily maximum and minimum temperature do not occur till some hours after the same phases of the temperature of the air. Again, the effects of radiation are in the case of trees not chiefly confined to a surface stratum of air a very few feet in thickness, but as already remarked, are to a very large extent diffused through a stratum of air equalling, in thickness at least, the height of the trees. Hence the conserving influence of forests on climate, making the nights warmer and the days cooler, imparting, in short, to the climates of districts clad with trees something of the character of insular climates. Evaporation proceeds slowly from the damp soil usually found beneath trees, since it is more or less screened from the sun. Since, however, the air under the trees is little agitated or put in circulation by the wind, the vapour arising from the soil is mostly left to accumulate among the trees, and hence it is probable that forests diminish the evaporation, but increase the humidity, of climates within their influence. The humidity of forests is further increased by the circumstance that when rain falls less of it passes immediately along the surface into streams and rivers; a considerable portion is at once taken up by the leaves of the trees and percolates the soil, owing to its greater friability in woods, to the roots of the trees, whence it is drawn up to the leaves and there evaporated, thus adding to the humidity of the atmosphere.

Much has been done by Dr Marsh and others in elucidation of the influence on climate of forests and the denudation of trees, in so far as that can be done by the varying depths of lakes and rivers and other non-instrumental observations. Little comparatively has been done anywhere in the examination of the great practical question of the influence of forests on climate, by means of carefully devised and conducted observations made with thermometers, the evaporating dish, or the rain gauge. The most extensive inquiry on the subject yet set on foot has been for some years conducted in the forests of Bavaria under the direction of Professor Ebermeyer, and a like inquiry was begun in Germany in 1875,—the more important results being that during the day, particularly in the warm months, the temperature in the forest is considerably lower than outside in the open country, there being at the same time a slow but steady outflow of air from the forest; and that during the night the temperature in the forest is higher, while there is an inflow of air from the open country into the forest. The mean annual temperature in the forest increases from the surface of the ground to the tops of the trees (where it is observed to approximate to what is observed in the open country), a result evidently due to the facility of descent to the surface of the cold air produced by terrestrial radiation, and to the obstruction offered by the trees to the solar influence at the surface. The mean annual temperature of the woodland soil from the surface to a depth of 4 feet is from 2° to 3° lower than that of the open country. A series of observations was begun at Carnwath, Lanarkshire, in 1873, at two stations, one outside a wood, and the other inside the wood in a small grass plot of about 50 feet diameter clear of trees. From these valuable results have been obtained relative to the differences in the daily march of temperature and the different rates of humidity, the most important being the substantial agreement of the mean annual temperature of the two places. The establishment of a station, with underground thermometers, which it is proposed to erect under the shade of the trees close to the station in the cleared space, will furnish data which will not only throw new light on the questions raised in this inquiry, but also on the movements and viscosity of the air and solar and terrestrial radiation.

When the sun's rays fall on water they are not as in the case of land arrested at the surface, but penetrate to a considerable depth, which, judging from observations made by Sir Robert Christison on Loch Lomond, and from those made on board the "Challenger," is probably in clear water about 600 feet. Of all known substances water has the greatest specific heat, this being, as compared with that of the soil and rocks composing the earth's crust, in the proportion of about 4 to 1. Hence water is heated much more slowly by the sun's rays and cooled more slowly by nocturnal radiation than the land. It is owing to these two essential differences between land and water with respect to heat that climates come to be grouped into the three great classes of oceanic, insular, and continental climates.

The maximum densities of fresh and salt water, which are respectively 39°·1 and 26°·2 (when the sea-water is the average degree of saltness), mark an essential distinction between the effects of sheets of fresh and salt water on climate. The surface temperature of sea-water falls very slowly from 39°·1 to 28°·4, its freezing point, because as it falls the temperature of the whole water through its depths must fall; whilst from 39°·1 to 32° the surface temperature of fresh water falls rapidly because it is only the portion floating on the surface which requires to be cooled. If the bottom temperature of fresh water exceed 39°·1 the cooling takes place also very slowly, since in this case the water through all its depth must be cooled down to 39°·1 as well as that of the surface.

The temperature at the greatest depths of Loch Lomond, which is practically constant at all seasons, is not 47°·8, the mean annual temperature of that part of Scotland, but 42°, which happens to be the mean temperature of the cold half of the year, or that half of the year when terrestrial radiation is the ruling element of the temperature. Thus, then, there is an immense volume of water at the bottom of this lake at a constant temperature 5°·8 below that of the mean annual temperature of the locality. From this follow two important consequences, viz.—(1) during each winter no inconsiderable portion of the cold produced by terrestrial radiation is conveyed away from the surface to the depths of the lake, where it therefore no longer exercises any influence whatever on the atmosphere or on the climate of the district in lowering the temperature; and (2) this annual accession of cold at these depths is wholly counteracted by the internal heat of the earth. In corroboration of this view it may be pointed out that the water of the Rhone as it issues from Lake Geneva is 3°·7 higher than that of the air at Geneva. Thus, the influence of lakes which do not freeze over is to mitigate in some degree the cold of winter over the district where they are situated. This is well illustrated on a large scale by the winter temperature of the lake region of North America. The influence of the sea is exactly akin to that of lakes. Over the surface of the ground slanting to the sea-shore the cold currents generated by radiation flow down to the sea, and the surface-water being thereby cooled sinks to lower depths. In the same manner no inconsiderable portion of the cold produced by radiation in all latitudes over the surface of the ocean and land adjoining is conveyed from the surface to greater depths. The enormous extent to which this transference goes on is evinced by the great physical fact disclosed to us in recent years by deep sea observations of temperature, viz., that the whole of the depths of the sea is filled with water at or closely approaching to the freezing point of fresh water, which in the tropical regions is from 40° to 50° lower than the temperature of the surface. The withdrawal from the earth's surface in high latitudes of such an enormous accumulation of ice-cold water to the depths of the sea of tropical and subtropical regions, rendered possible by the present disposition of land and water over the globe, doubtless results in an amelioration to some extent of the climate of the whole globe, so far as that may be brought about by a higher surface temperature in polar and temperate regions.

Oceanic climates are the most equable of all climates, showing for the same latitudes the least differences between the mean temperatures of the different hours of the day and the different months of the year, and being at all times the least subject to violent changes of temperature. So far as man is concerned, oceanic climates are only to be met with on board ship. The hygienic value of these climates in the treatment of certain classes of chest and other complaints is very great, and doubtless when better understood in their curative effects they will be more largely taken advantage of. It is, for instance, believed by many well qualified to form an opinion that they afford absolute, or all but absolute, immunity from colds, which are so often the precursors of serious complicated disorders.

The nearest approach to such climates on land is on very small islands such as Monach, which is situated about seven miles to westward of the Hebrides, in the full sweep of the westerly winds of the Atlantic which there prevail. The mean January temperature of this island, which is nearly in the latitude of Inverness, is 43°·4, being 1°·8 higher than the mean of January at Ventnor, Isle of Wight, 0°·8 higher than that of Jersey and Guernsey, and almost as high as that of Truro. Again, Stornoway, being situated on the east coast of Lewis on the Minch, an inland arm of the Atlantic, has thus a less truly insular position than Monach. Its climate is therefore much less insular, and accordingly its mean temperature in January is 38°·7, or 4°·7 lower than that of Monach. From its position near the Moray Firth, on the east of Scotland, Culloden occupies a position still less insular; hence its January temperature is only 37°·1, being 1°·6 less than that of Stornoway, and 6°·3 less than that of Monach.

On the other hand, the mean temperature of July is 55°·0 at Monach, 57°·8 at Culloden, 61°·0 at Guernsey, and 62°·6 at Ventnor. Thus the conditions of temperature at these stations are completely reversed in summer, for while in January Monach is 1°·8 warmer than Ventnor, in summer it is 7°·6 colder. Since the prevailing winds in the British Isles are westerly, places on the east coast are less truly insular than are places similarly situated on the west, whence it follows that the winter and summer climates of the east coast approach more nearly the character of inland climates than do those of the west.

The facts of the temperature at such places as Monach in Scotland and Valentia in Ireland disclose the existence of an all but purely oceanic climate along the coasts, particularly of the west, so distinct and decided, and extending inland so short a distance, that it would be impossible to represent it on any map of land isothermals of ordinary size. The only way in which it can be graphically represented is by drawing on the same map the isothermals of the sea for the same months, as Petermann has done on his chart of the North Atlantic and continents adjoining. Such maps best lead to a knowledge of the true character of our seaside climates.

Though it is impossible to overestimate the climatological importance of seaside climates, as evinced by their curative effects on man, and their extraordinary influence on the distribution of animal and vegetable life, it must be confessed that we are yet only on the threshold of a rational inquiry into their true character. Undoubtedly the first step in this large inquiry is the establishing of a string of about six stations at various distances from a point close to high-water mark to about two miles inland, at which observations at different hours of the day would be made, particularly at 9 A.M. and 3 and 9 P.M., of the pressure, temperature, humidity, movements, and chemistry of the air.

Our large towns have climates of a peculiar character, which may be said to consist chiefly in certain disturbances in the diurnal and seasonal distribution of the temperature, an excess of carbonic acid, a deficiency of ozone, and the presence of noxious impurities. Systematic inquiries into the condition and composition of the air of our large towns have been instituted this year (1876) in Paris and Glasgow, in which the ozone, ammonia, nitric acid, and germs present in different districts of these cities are regularly observed. There yet remain to be devised some means of making truly comparable thermometric and hygrometric observations in different localities, including the more densely-peopled districts, for the investigation of what we may call the artificial climates peculiar to each district. While such an inquiry, at least in its earlier stages, must necessarily be regarded as a purely scientific one, it may fairly be expected to lead sooner or later to a knowledge of the causes which determine the course of many epidemics—why, for instance, diphtheria is more frequent and more fatal in the new than in the old town of Edinburgh, and why in some parts of Leicester diarrhœa is unknown as a fatal disease, while in other parts of the same town it rages every summer as a terrible pestilence among infants—and ultimately suggest the means by which they may be stamped out when they make their appearance.

It has been already pointed out (see ATMOSPHERE) that prevailing winds are the simple result of the relative distribution of atmospheric pressure, their direction and force being the flow of the air from a region of higher towards a region of lower pressure, or from where there is a surplus to where there is a deficiency of air. Since climate is practically determined by the temperature and moisture of the air, and since these are dependent on the prevailing winds which come charged with the temperature and moisture of the regions they have traversed, it is evident that isobaric charts, showing the mean pressure of the atmosphere, form the key to the climates of the different regions of the globe, particularly those different climates which are found to prevail in different regions having practically the same latitude and elevation. This principle is all the more important when it is considered that the prevailing winds determine in a very great degree the currents of the ocean which exercise so powerful an influence on climate.

Since winds bring with them the temperature of the regions they have traversed, southerly currents of air are warm winds, and northerly currents cold winds. Also since the temperature of the ocean is more uniform than that of the land, winds coming from the ocean do not cause such variations of temperature as winds from a continent. As air loaded with vapour obstructs both solar and terrestrial radiation, when clear as well as when clouded, moist ocean winds are accompanied by a mild temperature in winter and a cool temperature in summer, and dry winds coming from continents by cold winters and hot summers. Lastly, equatorial currents of air, losing heat as they proceed in their course, are thereby brought nearer the point of saturation, and consequently become moister winds; whereas northerly currents acquiring greater heat in their progress become drier winds.

It follows from these relations of the wind to temperature and moisture that the S.W. wind in the British Isles is a very moist wind, being both an oceanic and equatorial current; whereas the N.E. wind, on the other hand, is peculiarly dry and parching, because it is both a northerly and continental current. Owing to the circumstance of atmospheric pressure diminishing from the south of Europe northwards to Iceland, it follows that S.W. winds are the most prevalent in Great Britain; and since this diminution of pressure reaches its maximum amount and persistency during the winter months, S.W. winds are in the greatest preponderance at this season; hence the abnormally high winter temperature of these islands above what is due to mere latitude. The mean winter temperature of Lerwick, Shetland, in respect of latitude alone would be 3°, and of London 17°, but owing to the heat conveyed from the warm waters of the Atlantic across these islands by the winds, the temperature of Shetland is 39° and of London 38°. In Iceland and Norway the abnormal increase of temperature in winter is still greater. This influence of the Atlantic through the agency of the winds is so preponderating that the winter isothermals of Great Britain lie north and south, instead of the normal east and west direction.

This peculiar distribution of the winter temperature of the British Isles has important bearings on the treatment of diseases. Since the temperature of the whole of the eastern slope of Great Britain is the same, it is clear that to those for whom a milder winter climate is required a journey southward is attended with no practical advantage, unless directed to the west coast. As the temperature on the west is uniform from Shetland to Wales, Scotland is as favourable to weak constitutions during winter as any part of England, except the south-west, the highest winter temperatures being found from the Isle of Wight westward round the Cornish peninsula to the Bristol Channel; and from Carnsore Point in Ireland to Galway Bay the temperature is also high.

The height and direction of mountain ranges form an important factor in determining the climatic characteristics of prevailing winds. If the range be perpendicular to the winds, the effect is to drain the winds which cross them of their moisture, thus rendering the winters colder and the summers hotter at all places to leeward, as compared with places to windward, by partially removing the protecting screen of vapour and thus exposing them more effectually to solar and terrestrial radiation. To this cause much of the observed difference between the west and east climates of Great Britain is due. In Ireland, on the other hand, where the mountains are not grouped in ranges running north and south, but in isolated masses, the difference between the climates of the east and west is very much less. In the east of the United States the prevailing winds in summer are S.W., and as the Alleghanies lie in the same direction the temperature is little affected by these mountains, and the rainfall is pretty evenly distributed on both sides of the range.

In its climatological relations the distribution of rain over the globe presents us with a body of facts which lead, when intelligently interpreted, to a knowledge of the laws regulating the distribution of plants more quickly and certainly than do the facts of temperature. It is to the prevailing winds we must look for an explanation of the rainfall, the broad principles of the connection being these:—1, The rainfall is moderately large when the wind has traversed a considerable extent of ocean; 2, if the winds advance into colder regions the rainfall is largely increased, and if a range of mountains lie across their path, the amount precipitated on the side facing the winds is greatly augmented, but diminished over regions on the other side of the range; 3, if the winds, though coming from the ocean, have not traversed a considerable extent of it, the rainfall is not large; and 4, if the winds, even though having traversed a considerable part of the ocean, yet on arriving on the land proceed into lower latitudes, or regions markedly warmer, the rainfall is small or nil. It is this last consideration which accounts for the rainless character of the summer climates of California, of Southern Europe, and of Northern Africa.

The region extending from Alaska to Lower California presents more sudden transitions of climate, and climates more sharply contrasted with each other, than any other portion of the globe, this arising from the contour of its surface and the prevailing winds. A direct contrast to this is offered by the United States to the east of the Mississippi, a region characterized by a remarkable uniformity in the distribution of its rainfall in all seasons, which, taken in connection with its temperature, affords climatic conditions admirably adapted for a vigorous growth of trees and for the great staple products of agriculture. India and the region of the Caspian Sea and the Caucasus Mountains also present extraordinary contrasts of climate in all seasons, due to the prevailing winds, upper as well as lower winds, the relative distribution of land and water, and the physical configuration of the surface of the land.

In the above remarks the only question dealt with has been the average climate of localities and regions. There are, however, it need scarcely be added, vital elements of climate of which such a discussion can take no cognizance. These are the deviations which occur from the seasonal averages of climate, such as periods of extreme cold and heat, or of extreme humidity and dryness of air, liability to storms of wind, thunderstorms, fogs, and extraordinary downfalls of rain, hail, or snow. An illustration will show the climatic difference here insisted on. The mean winter temperature of the Southern States of America is almost the same as that of Lower Egypt. Lower Egypt is singularly free from violent alternations of temperature as well as frost, whereas these are marked features of the winter climate of the States bordering on the Gulf of Mexico. Robert Russell, in his *Climate of America*, gives an instance of the temperature falling in Southern Texas with a norther from 81° to 18° in 41 hours, the norther blowing at the same time with great violence. A temperature of 18° accompanying a violent wind may be regarded as unknown in Great Britain.

It is to the cyclone and anticyclone (see ATMOSPHERE) we must look for an explanation of these violent weather changes. Climatically, the significance of the anticyclone or area of high pressure consists in the space covered for the time by it being on account of its dryness and clearness more fully under the influence of solar and terrestrial radiation, and consequently exposed to great cold in winter and great heat in summer; and of the cyclone or area of low pressure, in a moist warm atmosphere occupying its front and southern half, and a cold dry atmosphere its rear and northern half.

The low areas of the American cyclones, as they proceed eastward along the north shores of the Gulf of Mexico, are often immediately followed to west and north-westward by areas of very high pressure, the necessary consequence of which is the setting in of a violent norther over the Southern States. Since similar barometric conditions do not occur in the region of Lower Egypt, its climate is free from these sudden changes which are so injurious to the health even of the robust. Since many of the centres of the cyclones of North America follow the track of the lakes and advance on the Atlantic by the New England States and Newfoundland, these States and a large portion of Canada frequently experience cold raw easterly and northerly winds. The great majority of European storms travel eastward with their centres to northward of Farö, and hence the general mildness of the winter climate of the British Isles. When it happens, however, that cyclonic centres pass eastwards along the English Channel or through Belgium and North Germany, while high pressure prevails in the north, the winter is characterized by frosts and snows. The worst summer weather in Great Britain is when low pressures prevail over the North Sea, and the hottest and most brilliant weather when anticyclones lie over Great Britain and extend away to south and eastward.

Low pressures in the Mediterranean, along with high pressures to northward, are the conditions of the worst winter weather in the south of Europe. A cyclone in the Gulf of Lyons or of Genoa, and an anticyclone over Germany and Russia, have the mistral as their unfailing attendant, blowing with terrible force and dryness on the Mediterranean coasts of Spain, France, and North Italy, being alike in its origin and in its climatic qualities the exact counterpart of the norther of the Gulf of Mexico. It follows from the courses taken by the cyclones of the Mediterranean, and the anticyclones which attend on them, that also Algeria, Malta, and Greece are liable to violent alternations of temperature during the cold months.

The investigation of this phase of climate, which can only be carried out by the examination of many thousands of daily weather charts, is as important as it is difficult, since till it be done the advantages and hazards offered by different sanataria cannot be compared and valued. It may in the meantime be enough to say that no place anywhere in Europe or even in Algeria offers an immunity from the risks arising from the occurrence of cold weather in winter at all comparable to that afforded by the climates of Egypt and Madeira. See ATMOSPHERE, METEOROLOGY, and PHYSICAL GEOGRAPHY. (A. B.)

CLINTON, a city of the United States, in Clinton County, Iowa, about 42 miles higher up than Davenport, on the Mississippi, which is crossed at this point by an iron drawbridge upwards of 4000 feet long. It is a thriving place, with workshops for the Chicago and North-Western Railway, and an extensive trade in timber. Several newspapers are published weekly. Population in 1870, 6129.

CLINTON, a town of the United States, in Worcester county, Massachusetts, on the Nashua River, about 32 miles west of Boston, at the junction of several railway lines. It is the seat of extensive manufacturing activity, chiefly expended in the production of cotton cloths, woollen carpets, boots and shoes, combs, and machinery. The Lancaster mills rank as perhaps the best in the United States; and the wire cloth company has the credit of being the first to weave wire by the power-loom. Population in 1870, 5429.

CLINTON, DE WITT (1769–1829), an American statesman, born at Little Britain, in the State of New York, was the son of a gentleman of English extraction who served as brigadier-general in the war of independence, and of a lady belonging to the famous Dutch family of De Witts. He was educated at Colombia College; and in 1788 he was admitted to the bar. He at once joined the republican party, among the leaders of which was his uncle, George Clinton, governor of New York, whose secretary he became. At the same time he held the office of secretary to the board of regents of the university, and to the commissioners of fortifications. In 1797 he was elected member of the Assembly, in 1798 member of the Senate of the State of New York, and in 1801 member of the Senate of the United States. For twelve years, with two short breaks, which amounted only to three years, he occupied the position of mayor of New York. He was also again member of the Senate of New York from 1803 to 1811, and lieutenant-governor of the State from 1811 to 1813. In 1812 he became a candidate for the presidency; but he was defeated by Madison, and lost even his lieutenant-governorship. Throughout his whole career Clinton had been distinguished by his intelligent support of all schemes of improvement, and he now devoted himself to carrying out the proposal for the construction of canals from Lakes Erie and Champlain to the River Hudson. The Federal Government refused to undertake the work; but some time after, in 1815, the year in which he finally lost the mayoralty, he presented a memorial on the subject to the Legislature of New York, and the Legislature appointed a commission, of which he was made a member, to make surveys and draw up estimates. Having thus recovered his popularity, in 1816 Clinton was once more chosen governor of the State; in 1819 he was re-elected, and again in 1824 and 1826. In 1825 the Erie Canal was completed; and he afterwards saw the work which owed so much to him carried on by the construction of important branch canals.

De Witt Clinton published a *Memoir on the Antiquities of Western New York* (1818), *Letters on the Natural History and Internal Resources of New York* (1822), and *Speeches to the Legislature* (1823). His life was written by Hosack (1829) and Renwick (1840); and in 1849 appeared Campbell's *Life and Writings of De Witt Clinton*.

CLINTON, HENRY FYNES (1781–1852), an English classical scholar, was born at Gamston, in Nottinghamshire. He was descended from the second earl of Lincoln; for some generations the name of his family was Fynes, but his father resumed the older family name of Clinton. Educated at Southwell school in his native county, at Westminster school, and at Christ Church College, Oxford, he devoted himself to the minute and almost uninterrupted study of classical literature and history. From 1806 to 1826 he was M.P. for Aldborough.

His chief works are—*Fasti Hellenici, a Civil and Literary Chronology of Greece*, which also contains dissertations on points of Grecian history and Scriptural chronology (4 vols., 1824, 1827, 1830, 1834); and *Fasti Romani, a Civil and Literary Chronology of Rome and Constantinople from the Death of Augustus to the Death of Heraclius* (2 vols., 1845 and 1851). In 1851 he published an epitome of the former, and an epitome of the latter appeared in 1853. *The Literary Remains of H. F. Clinton* were published by C. J. F. Clinton in 1854.

CLITHEROE, a manufacturing town and a municipal and parliamentary borough of England, in the county of

Lancashire, situated not far from the Ribble, at the foot of Pendle Hills, about 28 miles by railway north of Manchester. It has several suburbs, known as Waterloo, Salford, and Bawdlands, and at the side of the river is the little village of Low Moor. Its principal buildings are the parish church of St Michael's, a grammar school founded in 1554, the moothall, and the county court erected in 1864; and its industrial establishments comprise cotton-mills, extensive print-works, paper-mills, foundries, and brick and lime works. The cotton manufacture alone employed upwards of 2000 people in 1871. Clitheroe was a borough by prescription as early as the 11th century, and in 1138 it is mentioned as the scene of a battle between the Scotch and English. Its castle, probably built not long after, was a fortress of the Lacy family, and continued a defensible position till 1649, when it was dismantled by the Parliamentary forces. The Honor of Clitheroe, for a long time a part of the duchy of Lancaster, and bestowed by Charles II. on General Monk, is now in the possession of the Buccleuch family. Population of the municipal borough in 1871, 8208; of the parliamentary, 11,786.

CLITOMACHUS, a leader of the New Academy, was a Carthaginian originally named Hasdrubal, who came to Athens about the middle of the 2d century B.C. He made himself well acquainted with Stoical and Peripatetic philosophy; but he principally studied under Carneades, whose views he adopted, and whom he succeeded as chief representative of the New Academy in 129 B.C. His works were some 400 in number; but we possess scarcely anything but a few titles, among which are *De sustinendis offensionibus*, περὶ ἐποχῆς (on suspension of judgment), and περὶ αἱρέσεων (an account of various philosophical sects). In 146 he wrote a philosophical treatise to console his countrymen after the ruin of their city. One of his works was dedicated to the Latin poet Lucilius, another to L. Censorinus, who was consul in 149 B.C.

CLITOR, a town of ancient Greece, in that part of Arcadia which corresponds to the modern eparchy of Kalavryta. It stood in a fertile plain to the south of Mount Chelmos, the highest peak of the Aroanian Mountains, and not far from a stream of its own name, which joined the Aroanius, or Katzana. In the neighbourhood was a fountain, the waters of which were said to deprive those who drunk them of the taste for wine. The town was a place of considerable importance in Arcadia, and its inhabitants were noted for their love of liberty. It extended its territory over several neighbouring towns, and in the Theban war fought against Orchomenos. As a member of the Achæan league it suffered siege at the hands of the Ætolians, and was on several occasions the seat of the federal assemblies. The ruins, which bear the common name of Paleopoli, or Old City, are still to be seen about three miles from a village that preserves the ancient designation. The greater part of the walls and several of the circular towers with which they were strengthened can be clearly made out; and there are also remains of a small Doric temple, the columns of which were adorned with strange capitals.

CLIVE, ROBERT (1725-1774), Baron Clive of Plassy, in the peerage of Ireland, was the statesman and general who founded the empire of British India before he was forty years of age. He is now represented by the Powis family, his son having been made earl of Powis in the peerage of the United Kingdom. Clive was born on the 29th September 1725 at Styche, the family estate in the parish of Moreton-Say, Market-Drayton, Shropshire. We learn from himself, in his second speech in the House of Commons in 1773, that as the estate yielded only £500 a year, his father followed the profession of the law also. The Clives, or Clyves, formed one of the oldest families in the county of Shropshire, having held the manor of that name in the reign of Henry II. One Clive was Irish Chancellor of the Exchequer under Henry VIII.; another was a member of the Long Parliament; Robert's father sat for many years for Montgomeryshire. His mother, to whom throughout life he was tenderly attached, and who had a powerful influence on his career, was a daughter, and with her sister Lady Sempill co-heir, of Nathaniel Gaskell of Manchester. Robert was their eldest son. With his five sisters, all of whom were married in due time, he ever maintained the most affectionate relations. His only brother survived to 1825. Young Clive was the despair of his teachers. Sent from school to school, and for only a short time at the Merchant Taylors' school, which had then a high reputation, he neglected his books for boyish adventures, often of the most dangerous kind. But he was not so ignorant as it is the fashion of his biographers to represent. He could translate Horace in after life, at the opening of the book; and he must have laid in his youth the foundation of that clear and vigorous English style which marked all his despatches, and made Lord Chatham declare of one of his speeches in the House of Commons that it was the most eloquent he had ever heard. From his earliest years, however, his ambition was to lead his fellows; but he never sacrificed honour, as the word was then understood, even to the fear of death. At eighteen he was sent out to Madras as a "factor" or "writer" in the civil service of the East India Company. The detention of the ship at Brazil for nine months enabled him to acquire the Portuguese language, which, at a time when few or none of the Company's servants learned the vernaculars of India, he often found of use during his service there. For the first two years of his residence he was miserable. He felt keenly the separation from home; he was always breaking through the restraints imposed on young "writers;" and he was rarely out of trouble with his fellows, with one of whom he fought a duel. Thus early, too, the effect of the climate on his health began to show itself in those fits of depression during one of which he afterwards prematurely ended his life. The story is told of him by his companions, though he himself never spoke of it, that he twice snapped a pistol at his head in vain. His one solace was found in the Governor's library, where he sought to make up for past carelessness, not only by much reading, but by a course of study. He was just of age, when in 1746 Madras was forced to capitulate to Labourdonnais, during the war of the Austrian Succession. The breach of that capitulation by Dupleix, then at the head of the French settlements in India, led Clive, with others, to escape from the town to the subordinate Fort St David, some twenty miles to the south. There, disgusted with the state of affairs and the purely commercial duties of an East Indian civilian, as they then were, Clive obtained an ensign's commission.

At this time India was ready to become the prize of the first conqueror who to the dash of the soldier added the skill of the administrator. For the forty years since the death of the Emperor Aurungzebe, the power of the Great Mogul had gradually fallen into the hands of his provincial viceroys or soubadars. The three greatest of these were the nawab of the Deccan, or South and Central India, who ruled from Hyderabad, the nawab of Bengal, whose capital was Moorshedabad, and the nawab or vizier of Oudh. The prize lay between Dupleix, who had the genius of an administrator, or rather intriguer, but was no soldier, and Clive, the first of a century's brilliant succession of those "soldier-politicals," as they are called in the East, to whom, ending with Sir Henry Lawrence, Great Britain owes the conquest and consolidation of its greatest dependency. Clive successively established British ascendency against French influence in the three great provinces under these nawabs. But his merit lies especially in the ability and foresight with which he secured for his country, and for the good of the natives, the richest of the three, Bengal. First, as to Madras and the Deccan, Clive had hardly been able to commend himself to Major Stringer Lawrence, the commander of the British troops, by his courage and skill in several small engagements, when the peace of Aix-la-Chapelle forced him to return to his civil duties for a short time. An attack of the malady which so severely affected his spirits led him to visit Bengal, where he was soon to distinguish himself. On his return he found a contest going on between two sets of rival claimants for the position of viceroy of the Deccan, and for that of nawab of the Carnatic, the greatest of the subordinate states under the Deccan. Dupleix, who took the part of the pretenders to power in both places, was carrying all before him. The British had been weakened by the withdrawal of a large force under Admiral Boscawen, and by the return home, on leave, of Major Lawrence. But that officer had appointed Clive commissary for the supply of the troops with provisions, with the rank of captain. More than one disaster had taken place on a small scale, when Clive drew up a plan for dividing the enemy's forces, and offered to carry it out himself. The pretender, Chunda Sahib, had been made nawab of the Carnatic with Dupleix's assistance, while the British had taken up the cause of the more legitimate successor, Mahomed Ali. Chunda Sahib had left Arcot, the capital of the Carnatic, to reduce Trichinopoly, then held by a weak English battalion. Clive offered to attack Arcot that he might force Chunda Sahib to raise the siege of Trichinopoly. But Madras and Fort St David could supply him with only 200 Europeans and 300 sepoys. Of the eight officers who led them, four were civilians like Clive himself, and six had never been in action. His force had but three field-pieces. The circumstance that Clive, at the head of this handful, had been seen marching during a storm of thunder and lightning, led the enemy to evacuate the fort, which the British at once began to strengthen against a siege. Clive treated the great population of the city with so much consideration that they helped him, not only to fortify his position, but to make successful sallies against the enemy. As the days passed on, Chunda Sahib sent a large army under his son and his French supporters, who entered Arcot and closely besieged Clive in the citadel. An attempt to relieve him from Madras was defeated. Meanwhile the news of the marvellous defence of the English reached the Mahratta allies of Mahomed Ali, who advanced to Clive's rescue. This led the enemy to redouble their exertions, but in vain. After for fifty days besieging the fort, and offering large sums to Clive to capitulate, they retired from Arcot. The brave garrison had been so reduced by the gradual failure of provisions that the sepoys offered to be content with the thin gruel which resulted from the boiling of the rice, leaving the grain to their European comrades. Of the 200 Europeans 45 had been killed, and of the 300 sepoys 30 had fallen, while few of the survivors had escaped wounds. In India, we might say in all history, there is no parallel to this exploit of 1751 till we come to the siege of Lucknow in 1857. Clive, now reinforced, followed up his advantage, and Major Lawrence returned in time to carry the war to a successful issue. In 1754 the first of our Carnatic treaties was made provisionally, between Mr T. Saunders, the Company's resident at Madras, and M. Godcheu, the French commander, in which the English protegé, Mahomed Ali, was virtually recognized as nawab, and both nations agreed to equalize their possessions. When war again broke out in 1756, and the French, during Clive's absence in Bengal, obtained successes in the northern districts, his efforts helped to drive them from their settlements. The Treaty of Paris in 1763 formally confirmed Mahomed Ali in the position which Clive had won for him. Two years after, the Madras work of Clive was completed by a firmaun from the emperor of Delhi, recognizing the British possessions in Southern India.

The siege of Arcot at once gave Clive a European reputation. Pitt pronounced the youth of twenty-seven who had done such deeds a "heaven-born general," thus endorsing the generous appreciation of his early commander, Major Lawrence. When the Court of Directors voted him a sword worth £700, he refused to receive it unless Lawrence was similarly honoured. He left Madras for home, after ten years absence, early in 1753, but not before marrying Miss Margaret Maskelyne, the sister of a friend, and of one who was afterwards well known as astronomer royal. All his correspondence proves him to have been a good husband and father, at a time when society was far from pure, and scandal made havoc of the highest reputations. In after days, when Clive's uprightness and stern reform of the Company's civil and military services made him many enemies, a biography of him appeared under the assumed name of *Charles Carracioli, Gent.* All the evidence is against the probability of its scandalous stories being true. Clive's early life seems occasionally to have led him to yield to one of the vices of his time, loose or free talk among intimate friends, but beyond this nothing has been proved to his detriment. After he had been two years at home the state of affairs in India made the directors anxious for his return. He was sent out, in 1756, as governor of Fort St David, with the reversion of the government of Madras, and he received the commission of lieutenant-colonel in the king's army. He took Bombay on his way, and there commanded the land force which captured Gheriah, the stronghold of the Mahratta pirate, Angria. In the distribution of prize money which followed this expedition he showed no little self-denial. He took his seat as governor of Fort St David on the day on which the nawab of Bengal captured Calcutta. Thither the Madras Government at once sent him, along with Admiral Watson. He entered on the second period of his career.

Since, in August 1690, Job Charnock had landed at the village of Chuttanutti with a guard of one officer and 30 men, the infant capital of Calcutta had become a rich centre of trade. The successive nawabs or viceroys of Bengal had been friendly to it, till, in 1756, Suraj-ud-Dowlah succeeded his uncle at Moorshedabad. His predecessor's financial minister had fled to Calcutta to escape the extortion of the new nawab, and the English governor refused to deliver up the refugee. Enraged at this, Suraj-ud-Dowlah captured the old fort of Calcutta on the 5th August, and plundered it of more than two millions sterling. Many of the English fled to the ships and dropped down the river. The 146 who remained, were forced into "the Black Hole" in the stifling heat of the sultriest period of the year. Only 23 came out alive. The fleet was as strong, for those days, as the land force was weak. Disembarking his troops some miles below the city, Clive marched through the jungles, where he lost his way owing to the treachery of his guides, but soon invested Fort William, while the fire of the ships reduced it, on the 2d January 1757. On the 4th February he defeated the whole army of the nawab, which had taken up a strong position just beyond what is now the most northerly suburb of Calcutta. The nawab hastened to conclude a treaty, under which favourable terms were conceded to the Company's trade, the factories and plundered property were restored, and an English mint was established. In the accompanying agreement, offensive and defensive, Clive appears under the name by which he was always known to the natives of India, Sabut Jung, or the daring in war. The hero of Arcot had, at Angria's stronghold, and now again under the walls of Calcutta, established his reputation as the first captain of the time. With 600 British soldiers, 800 sepoys, 7 field-pieces and 500 sailors to draw them, he had routed a force of 34,000 men with 40 pieces of heavy cannon, 50 elephants, and a camp that extended upwards of four miles in length. His own account, in a letter to the archbishop of Canterbury, gives a modest but vivid description of the battle, the importance of which has been overshadowed by Plassy. In spite of his double defeat and the treaty which followed it, the madness of the nawab burst forth again. As England and France were once more at war, Clive sent the fleet up the river against Chandernagore, while he besieged it by land. After consenting to the siege, the nawab sought to assist the French, but in vain. The capture of their principal settlement in India, next to Pondicherry, which had fallen in the previous war, gave the combined forces prize to the value of £130,000. The rule of Suraj-ud-Dowlah became as intolerable to his own people as to the English. They formed a confederacy to depose him, at the head of which was Jaffier Ali Khan, his commander-in-chief. Associating with himself Admiral Watson, Governor Drake, and Mr Watts, Clive made a treaty in which it was agreed to give the office of souba, or viceroy of Bengal, Behar, and Orissa, to Jaffier, who was to pay a million sterling to the Company for its losses in Calcutta and the cost of its troops, half a million to the English inhabitants of Calcutta, £200,000 to the native inhabitants, and £70,000 to its Armenian merchants. Up to this point all is clear. Suraj-ud-Dowlah was hopeless as a ruler. His relations alike to his master, the merely titular emperor of Delhi, and to the people left the province open to the strongest. After "the Black Hole," the battle of Calcutta, and the treachery at Chandernagore in spite of the treaty which followed that battle, the East India Company could treat the nawab only as an enemy. Clive, it is true, might have disregarded all native intrigue, marched on Moorshedabad, and at once held the delta of the Ganges in the Company's name. But the time was not ripe for this, and the consequences, with so small a force, might have been fatal. The idea of acting directly as rulers, or save under native charters and names, was not developed by events for half a century. The political morality of the time in Europe, as well as the comparative weakness of the Company in India, led Clive not only to meet the dishonesty of his native associate by equal dishonesty, but to justify his conduct by the declaration, years after, in Parliament, that he would do the same again. It became necessary to employ the richest Bengalee trader, Omichund, as an agent between Jaffier Ali and the English officials. Master of the secret of the confederacy against Suraj-ud-Dowlah, the Bengalee threatened to betray it unless he was guaranteed, in the treaty itself, £300,000. To dupe the villain, who was really paid by both sides, a second, or fictitious treaty, was shown him with a clause to this effect. This Admiral Watson refused to sign; "but," Clive deponed to the House of Commons, "to the best of his remembrance, he gave the gentleman who carried it leave to sign his name upon it; his lordship never made any secret of it; he thinks it warrantable in such a case, and would do it again a hundred times; he had no interested motive in doing it, and did it with a design of disappointing the expectations of a rapacious man." Such is Clive's own defence of the one act which, in a long career of abounding temptations, stains his public life.

The whole hot season of 1757 was spent in these negotiations, till the middle of June, when Clive began his march from Chandernagore, the British in boats, and the sepoys along the right bank of the Hooghly. That river, above Calcutta is, during the rainy season, fed by the overflow of the Ganges to the north through three streams, which in the hot months are nearly dry. On the left bank of the Bhagarutti, the most westerly of these, 100 miles above Chandernagore, stands Moorshedabad, the capital of the Mogul viceroys of Bengal, and then so vast that Clive compared it to the London of his day. Some miles farther down is the field of Plassy, then an extensive grove of mango trees, of which enough yet remains, in spite of the changing course of the stream, to enable the visitor to realize the scene. On the 21st June Clive arrived on the bank opposite Plassy, in the midst of that outburst of rain which ushers in the south-west monsoon of India. His whole army amounted to 1100 Europeans and 2100 native troops, with 10 field-pieces. The nawab had drawn up 18,000 horse, 50,000 foot, and 53 pieces of heavy ordnance, served by French artillerymen. For once in his career Clive hesitated, and called a council of sixteen officers to decide, as he put it, "whether in our present situation, without assistance, and on our own bottom, it would be prudent to attack the nawab, or whether we should wait till joined by some country power?" Clive himself headed the nine who voted for delay; Major (afterwards Sir) Eyre Coote, led the seven who counselled immediate attack. But, either because his daring asserted itself, or because, also, of a letter that he received from Jaffier Ali, as has been said, Clive was the first to change his mind and to communicate with Major Eyre Coote. One tradition, followed by Macaulay, represents him as spending an hour in thought under the shade of some trees, while he resolved the issues of what was to prove one of the decisive battles of the world. Another, turned into verse by an Anglo-Indian poet, pictures his resolution as the result of a dream. However that may be, he did well as a soldier to trust to the dash and even rashness that had gained Arcot and triumphed at Calcutta, and as a statesman, since retreat, or even delay, would have put back the civilization of India for years. When, after the heavy rain, the sun rose brightly on the 22d, the 3200 men and the six guns crossed the river and took possession of the grove and its tanks of water, while Clive established his headquarters in a hunting lodge. On the 23d the engagement took place and lasted the whole day. Except the 40 Frenchmen and the guns which they worked, the enemy did little to reply to the British cannonade which, with the 39th Regiment, scattered the host, inflicting on it a loss of 500 men. Clive restrained the ardour of Major Kirkpatrick, for he trusted to Jaffier Ali's abstinence, if not desertion to his ranks, and knew the importance of sparing his own small force. He lost hardly a white soldier; in all 22 sepoys were killed and 50 wounded. His own account, written a month after the battle to the secret committee of the court of directors, is not less unaffected than that in which he had announced the defeat of the nawab at Calcutta. Suraj-ud-Dowlah fled from the field on a camel, secured what wealth he could, and came to an untimely end. Clive entered Moorshedabad, and established Jaffier Ali in the position which his descendants have ever since enjoyed, as pensioners, but have not unfrequently abused. When taken through the treasury, amid a million and a half sterling's worth of rupees, gold and silver plate, jewels, and rich goods, and besought to ask what he would, Clive was content with £160,000, while half a million was distributed among the army and navy, both in addition to gifts of £24,000 to each member of the Company's committee, and besides the public compensation stipulated for in the treaty. It was to this occasion that he referred in his defence before the House of Commons, when he declared that he marvelled at his moderation. He sought rather to increase the shares of the fleet and the troops at his own expense, as he had done at Gheriah, and did more than once afterwards, with prize of war. What he did take from the grateful nawab for himself was less than the circumstances justified from an Oriental point of view, was far less than was pressed upon him, not only by Jaffier Ali, but by the hundreds of the native nobles whose gifts Clive steadily refused, and was openly acknowledged from the first. He followed a usage fully recognized by the Company, although the fruitful source of future evils which he himself was again sent out to correct. The Company itself acquired a revenue of £100,000 a year, and a contribution towards its losses and military expenditure of a million and a half sterling. Such was Jaffier Ali's gratitude to Clive that he afterwards presented him with the quit-rent of the Company's lands in and around Calcutta, amounting to an annuity of £27,000 for life, and left him by will the sum of £70,000, which Clive devoted to the army.

While busy with the civil administration, the conqueror of Plassy continued to follow up his military success. He sent Major Coote in pursuit of the French almost as far as Benares. He despatched Colonel Forde to Vizagapatam and the northern districts of Madras, where that officer gained the battle of Condore, pronounced by Broome "one of the most brilliant actions on military record." He came into direct contact, for the first time, with the Great Mogul himself, an event which resulted in the most important consequences during the third period of his career. Shah Aalum, when Shahzada, or heir-apparent, quarrelled with his father Aalum Geer II., the emperor, and united with the viceroys of Oudh and Allahabad for the conquest of Bengal. He advanced as far as Patna, which he besieged with 40,000 men. Jaffier Ali, in terror, sent his son to its relief, and implored the aid of Clive. Major Caillaud defeated the prince's army at the battle of Sirpore, and dispersed it. Finally, at this period, Clive repelled the aggression of the Dutch, and avenged the massacre of Amboyna, on that occasion when he wrote his famous letter, "Dear Forde, fight them immediately; I will send you the order of council to-morrow." Meanwhile he never ceased to improve the organization and drill of the sepoy army, after a European model, and enlisted into it many Mahometans of fine physique from Upper India. He re-fortified Calcutta. In 1760, after four years of labour so incessant and results so glorious, his health gave way and he returned to England. "It appeared," wrote a contemporary on the spot, "as if the soul was departing from the government of Bengal." He had been formally made governor of Bengal by the court of directors at a time when his nominal superiors in Madras sought to recall him to their help there. But he had discerned the importance of the province even during his first visit to its rich delta, mighty rivers, and teeming population. It should be noticed, also, that he had the kingly gift of selecting the ablest subordinates, for even thus early he had discovered the ability of young Warren Hastings, destined to be his great successor, and, a year after Plassy, made him "resident" at the nawab's court.

In 1760, at thirty-five years of age, Clive returned to England with a fortune of at least £300,000 and the quit-rent of £27,000 a year, after caring for the comfort of his parents and sisters, and giving Major Lawrence, his old commanding officer, who had early encouraged his military genius, £500 a year. The money had been honourably and publicly acquired, with the approval of the Company. The amount might have been four times what it was, had Clive been either greedy after wealth or ungenerous to the colleagues and the troops whom he led to victory. In the five years of his conquests and administration in Bengal, the young man had crowded together a succession of exploits which led Lord Macaulay, in what that historian termed his "flashy" essay on the subject, to compare him to Napoleon Bonaparte. But there was this difference in Clive's favour, due not more to the circumstances of the time than to the object of his policy—he gave peace, security, prosperity, and such liberty as the case allowed of to a people now reckoned at 240 millions, who had for centuries been the prey of oppression, while Napoleon warred only for personal ambition, and the absolutism he established has left not a wreck behind. During the three years that Clive remained in England he sought a political position, chiefly that he might influence the course of events in India, which he had left full of promise. He had been well received at court, had been made Baron Clive of Plassy, in the peerage of Ireland, had bought estates, and had got not only himself but his friends returned to the House of Commons after the fashion of the time. Then it was that he set himself to reform the home system of the East India Company, and commenced a bitter warfare with Mr Sulivan, chairman of the court of directors, whom finally he defeated. In this he was aided by the news of reverses in Bengal. Vansittart, his successor, having no great influence over Jaffier Ali Khan, had put Kossim Ali Khan, the son-in-law, in his place in consideration of certain payments to the English officials. After a brief tenure Kossim Ali had fled, had ordered Summers, or Sumroo, a Swiss mercenary of his, to butcher the garrison of 150 English at Patna, and had disappeared under the protection of his brother viceroy of Oudh. The whole Company's service, civil and military, had become demoralized by such gifts, and by the monopoly of the inland as well as export trade, to such an extent that the natives were pauperized, and the Company was plundered of the revenues which Clive had acquired for them. The court of proprietors, accordingly, who elected the directors, forced them, in spite of Sulivan, to hurry out Lord Clive to Bengal with the double powers of governor and commander-in-chief.

What he had done for Madras, what he had accomplished for Bengal proper, and what he had effected in reforming the Company itself, he was now to complete in less than two years, in this the third period of his career, by putting his country politically in the place of the emperor of Delhi, and preventing for ever the possibility of the corruption to which the English in India had been driven by an evil system. On the 3d May 1765, he landed at Calcutta to learn that Jaffier Ali Khan had died, leaving him personally £70,000, and had been succeeded by his son, though not before the Government had been further demoralized by taking £100,000 as a gift from the new nawab; while Kossim Ali had induced not only the viceroy of Oudh, but the emperor of Delhi himself, to invade Behar. After the first mutiny in the Bengal army, which was suppressed by blowing the sepoy ringleader from the guns, Major Munro, "the Napier of those times," scattered the united armies on the hard-fought field of Buxar. The emperor, Shah Aalum, detached himself from the league, while the Oudh viceroy threw himself on the mercy of the English. Clive had now an opportunity of repeating in Hindustan, or Upper India, what he had accomplished for the good of Bengal. He might have secured what are now called the North-Western Provinces and Oudh, and have rendered unnecessary the campaigns of Wellesley and Lake. But he had other work in the consolidation of rich Bengal itself, making it a base from which the mighty fabric of British India could afterwards steadily and proportionally grow. Hence he returned to the Oudh viceroy all his territory save the provinces of Allahabad and Corah, which he made over to the weak emperor. But from that emperor he secured the most important document in the whole of our Indian history up to that time, which appears in the records as "firmaund from the King Shah Aalum, granting the dewany of Bengal, Behar, and Orissa to the Company, 1765." The date was the 12th August, the place Benares, the throne an English dining-table covered with embroidered cloth and surmounted by a chair in Clive's tent. It is all pictured by a Mahometan contemporary, who indignantly exclaims that so great a "transaction was done and finished in less time than would have been taken up in the sale of a jackass." By this deed the Company became the real sovereign rulers of thirty millions of people, yielding a revenue of four millions sterling. All this had been accomplished by Clive in the few brief years since he had avenged "the Black Hole" of Calcutta. This would be a small matter, or might even be a cause of reproach, were it not that the Company's, now the Queen's, undisputed sovereignty proved, after a sore period of transition, the salvation of these millions. The lieutenant-governorship of Bengal, with some additions since Clive's time, now contains sixty millions of people, and yields an annual revenue of twelve millions sterling, of which eight goes every year to assist in the good government of the rest of India. But Clive, though thus moderate and even generous to an extent which called forth the astonishment of the natives, had all a statesman's foresight. On the same date, he obtained not only an imperial charter for the Company's possessions in the Carnatic also, thus completing the work he began at Arcot, but a third firmaun for the highest of all the lieutenancies or soubaships of the empire, that of the Deccan itself. The fact has only recently been discovered, by distinct allusion to it in a letter from the secret committee of the court of directors to the Madras Government, dated 27th April 1768. Still so disproportionate seemed the British force, not only to the number and strength of the princes and people of India, but to the claims and ambition of French, Dutch, and Danish rivals, that Clive's last advice to the directors, as he finally left India in 1777, was this, given in a remarkable state paper but little known: "We are sensible that, since the acquisition of the dewany, the power formerly belonging to the soubah of those provinces is totally, in fact, vested in the East India Company. Nothing remains to him but the name and shadow of authority. This name, however, this shadow, it is indispensably necessary we should seem to venerate." On a wider arena, even that of the Great Mogul himself, the shadow was kept up till it obliterated itself in the massacre of English people in the Delhi palace in 1857; and the Queen was proclaimed, first, direct ruler on the 1st November 1858, and then empress of India on the 1st January 1877

Having thus founded the empire of British India, Clive's painful duty was to create a pure and strong administration, such as alone would justify its possession by foreigners. The civil service was de-orientalized by raising the miserable salaries which had tempted its members to be corrupt, by forbidding the acceptance of gifts from natives, and by exacting covenants under which participation in the inland trade was stopped. Not less important were his military reforms. With his usual tact and nerve he put down a mutiny of the English officers, who chose to resent the veto against receiving presents and the reduction of batta at a time when two Mahratta armies were marching on Bengal. His reorganization of the army, on the lines of that which he had begun after Plassy, and which was neglected during his second visit to England, has since attracted the admiration of the ablest Indian officers. He divided the whole into three brigades, so as to make each a complete force, in itself equal to any single native army that could be brought against it. His one fault was that of his age and his position, with so small a number of men. He lacked a sufficient number of British artillerymen, and would not commit the mistake of his successors, who trained natives to work the guns, which were turned against us with such effect in 1857. It is sufficient to say that Government has returned to his policy, for not a native gunner is now to be found save in a few unhealthy and isolated frontier posts.

Clive's final return to England, a poorer man than he went out, in spite of still more tremendous temptations, was the signal for an outburst of his personal enemies, exceeded only by that which the malice of Sir Philip Francis afterwards excited against Warren Hastings. Every civilian, whose illicit gains he had cut off, every officer whose conspiracy he had foiled, every proprietor or director, like Sulivan, whose selfish schemes he had thwarted, now sought their opportunity. He had, with consistent generosity, at once made over the legacy of £70,000 from the grateful Jaffier Ali, as the capital of what has since been known as "the Clive Fund," for the support of invalided European soldiers, as well as officers, and their widows, and the Company had allowed 8 per cent. on the sum for an object which it was otherwise bound to meet. Burgoyne, of Saratoga memory, did his best to induce the House of Commons, in which Lord Clive was now member for Shrewsbury, to impeach the man who gave his country an empire, and the people of that empire peace and justice, and that, as we have seen, without blot on the gift, save in the matter of Omichund. The result, after the brilliant and honourable defences of his career which will be found in Almon's *Debates* for 1773, was a compromise that saved England this time from the dishonour which, when Warren Hastings had to run the gauntlet, put it in the same category with France in the treatment of its public benefactors abroad. On a division the House, by 155 to 95, carried the motion that Lord Clive "did obtain and possess himself" of £234,000 during his first administration of Bengal; but, refusing to express an opinion on the fact, it passed unanimously the second motion, at five in the morning, "that Robert, Lord Clive, did at the same time render great and meritorious services to his country." The one moral question, the one stain of all that brilliant and tempted life—the Omichund treaty—was not touched.

Only one who can personally understand what Clive's power and services were will rightly realize the effect on him, though in the prime of life, of the discussions through which he had been dragged. We have referred to Warren Hastings's impeachment, but there is a more recent parallel. The marquis of Dalhousie did almost as much to complete the territorial area and civilized administration of British India in his eight years' term of office as Lord Clive to found the empire in a similar period. As Clive's accusers sought a new weapon in the great famine of 1770, for which he was in no sense responsible, so there were critics who accused Dalhousie of having caused that mutiny which, in truth, he would have prevented had the British Government listened to his counsel not to reduce the small English army in the country. Clive tells us his own feelings in a passage of first importance when we seek to form an opinion on the fatal act by which he ended his life. In the greatest of his speeches, in reply to Lord North, he said,—"My situation, sir, has not been an easy one for these twelve months past, and though my conscience could never accuse me, yet I felt for my friends who were involved in the same censure as myself. . . . . I have been examined by the select committee more like a sheep-stealer than a member of this House." Fully accepting that statement, and believing him to have been purer than his accusers in spite of temptations unknown to them, we see in Clive's end the result merely of physical suffering, of chronic disease which opium failed to abate, while the worry and chagrin caused by his enemies gave it full scope. This great man, who fell short only of the highest form of moral greatness on one supreme occasion, but who did more for his country than any soldier till Wellington, and more for the people and princes of India than any statesman in history, ceased to exist on the 22d November 1774, in his fiftieth year.

The portrait of Clive, by Dance, in the Council Chamber of Government House, Calcutta, faithfully represents him. He was slightly above middle-size, with a countenance rendered heavy and almost sad by a natural fulness above the eyes. Reserved to the many, he was beloved by his own family and friends. His encouragement of scientific undertakings like Major Rennell's surveys, and of philological researches like Mr Gladwin's, was marked by the two honorary distinctions of F.R.S. and LL.D.

The best authorities for his life, which has yet to be worthily written, are—article "Clive," in the second or Kippis's edition of the *Biographia Britannica*, from materials supplied by his brother, Archdeacon Clive, by Henry Beaufoy, M.P.; Broome's *History of the Bengal Army*; Aitchison's *Treaties*, second edition, 1876; Orme's *History*; and Malcolm's *Life*. (G. SM.)

CLOCKS

THE origin of clock work is involved in great obscurity. Notwithstanding the statements by many writers that clocks, *horologia*, were in use so early as the 9th century, and that they were then invented by an archdeacon of Verona, named Pacificus, there appears to be no clear evidence that they were machines at all resembling those which have been in use for the last five or six centuries. But it may be inferred from various allusions to *horologia*, and to their striking spontaneously, in the 12th century, that genuine clocks existed then, though there is no surviving description of any one until the 13th century, when it appears that a horologium was sent by the sultan of Egypt in 1232 to the Emperor Frederick II. "It resembled a celestial globe, in which the sun, moon, and planets moved, being impelled by weights and wheels, so that they pointed out the hour, day, and night with certainty." A clock was put up in a former clock tower at Westminster with some great bells in 1288, out of a fine imposed on a corrupt chief-justice, and the motto *Discite*

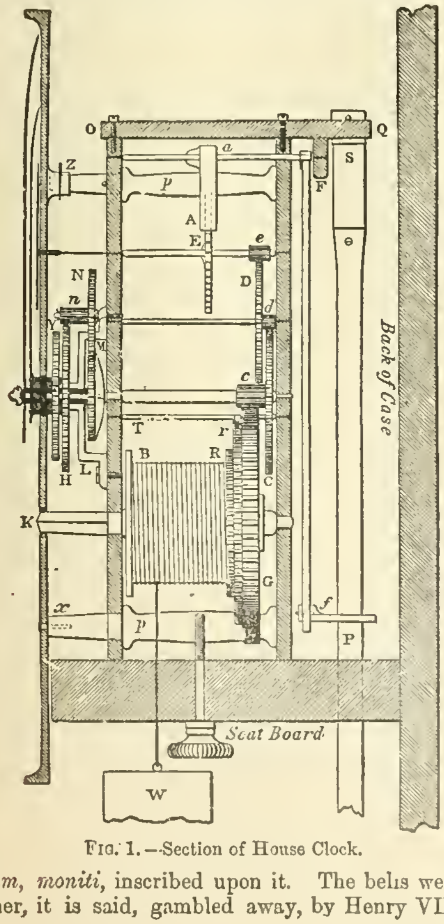

FIG. 1.—Section of House Clock.

justitiam, moniti, inscribed upon it. The bells were sold or rather, it is said, gambled away, by Henry VIII. In 1292 one is mentioned in Canterbury Cathedral as costing £30. And another at St Albans, by R. Wallingford the abbot in 1326, is said to have been such as there was not in all Europe, showing various astronomical phenomena. A description of one in Dover Castle with the date 1348 on it was published by the late Admiral Smyth, P.R.A.S., in 1851, and the clock itself was exhibited going, in the Scientific Exhibition of 1876. In the early editions of this *Encyclopædia* there was a picture of a very similar one, made by De Vick for the French king Charles V. about the same time, much like our common clocks of the last century, except that it had a vibrating balance, but no spring, instead of a pendulum, for pendulums were not invented till three centuries after that.

The general construction of the going part of all clocks, except large or turret clocks, which we shall treat separately, is substantially the same, and fig. 1 is a section of any ordinary house clock. B is the barrel with the rope coiled round it, generally 16 times for the 8 days; the barrel is fixed to its arbor K, which is prolonged into the winding square coming up to the face or dial of the clock; the dial is here shown as fixed either by small screws x, or by a socket and pin z, to the prolonged pillars p, p, which (4 or 5 in number) connect the plates or frame of the clock together, though the dial is commonly, but for no good reason, set on to the front plate by another set of pillars of its own. The great wheel G rides on the arbor, and is connected with the barrel by the ratchet R, the action of which is shown more fully in fig 14. The intermediate wheel r in this drawing is for a purpose which will be described hereafter, and for the present it may be considered as omitted, and the click of the ratchet R as fixed to the great wheel. The great wheel drives the pinion c which is called the centre pinion, on the arbor of the *centre wheel* C, which goes through to the dial, and carries the long, or minute-hand; this wheel always turns in an hour, and the great wheel generally in 12 hours, by having 12 times as many teeth as the centre pinion. The centre wheel drives the "second wheel" D by its pinion d, and that again drives the scape-wheel E by its pinion e. If the pinions d and e have each 8 teeth or *leaves* (as the teeth of pinions are usually called), C will have 64 teeth and D 60, in a clock of which the scape-wheel turns in a minute, so that the seconds hand may be set on its arbor prolonged to the dial. A represents the pallets of the escapement, which will be described presently, and their arbor a goes through a large hole in the back plate near F, and its back pivot turns in a cock OFQ screwed on to the back plate. From the pallet arbor at F descends the *crutch* Ff, ending in the *fork* f, which embraces the pendulum P, so that as the pendulum vibrates, the crutch and the pallets necessarily vibrate with it. The pendulum is hung by a thin spring S from the cock Q, so that the bending point of the spring may be just opposite the end of the pallet arbor, and the edge of the spring as close to the end of that arbor as possible—a point too frequently neglected.

We may now go to the front (or left hand) of the clock, and describe the dial or "motion-work." The minute hand fits on to a squared end of a brass socket, which is fixed to the wheel M, and fits close, but not tight, on the prolonged arbor of the centre wheel. Behind this wheel is a bent spring which is (or ought to be) set on the same arbor with a square hole (not a round one as it sometimes is) in the middle, so that it must turn with the arbor; the wheel is pressed up against this spring, and kept there, by a cap and a small pin through the end of the arbor. The consequence is, that there is friction enough between the spring and the wheel to carry the hand round, but not enough to resist a moderate push with the finger for the purpose of altering the time indicated. This wheel M, which is sometimes called the minute-wheel, but is better called the *hour-wheel* as it turns in an hour, drives another wheel N, of the same number of teeth, which has a pinion attached to it; and that pinion drives the *twelve-hour wheel* H, which is also attached to a large socket or pipe carrying the hour hand, and riding on the former socket, or rather (in order to relieve the centre arbor of that extra weight) on an intermediate socket fixed to the *bridge* L, which is screwed to the front plate over the hour-wheel M. The weight W, which drives the train and gives the impulse to the pendulum through the escapement, is generally hung by a catgut line passing through a pulley attached to the weight, the other end of the cord being tied to some convenient place in the clock frame or *seat-board*, to which it is fixed by screws through the lower pillars. It has usually been the practice to make the case of house clocks and astronomical clocks not less than 6 feet high; but that is a very unnecessary waste of space and materials; for by either diminishing the size of the barrel, or the number of its turns, by increasing the size of the great wheel by one-half, or hanging the weights by a treble instead of a double line, a case just long enough for the pendulum will also be long enough for the fall of the weights in 7½ or 8 days. Of course the weights have to be increased in the same ratio, and indeed rather more, to overcome the increased friction; but that is of no consequence.

PENDULUM.

The claim to the invention of the pendulum, like the claim to most inventions, is disputed; and we have no intention of trying to settle it. It was, like many other discoveries and inventions, probably made by various persons independently, and almost simultaneously, when the state of science had become ripe for it. The discovery of that peculiarly valuable property of the pendulum called *isochronism*, or the disposition to vibrate different arcs in very nearly the same time (provided the arcs are none of them large), is commonly attributed to Galileo, in the well-known story of his being struck with the isochronism of a chandelier hung by a long chain from the roof of the church at Florence. And Galileo's son appears as a rival of Avicenna, Huyghens, Dr Hooke, and a London clockmaker named Harris, for the honour of having first applied the pendulum to regulate the motion of a clock train, all in the early part of the 17th century. Be this as it may, there seems little doubt that Huyghens was the first who mathematically investigated, and therefore really knew, the true nature of those properties of the pendulum which may now be found explained in any mathematical book on mechanics. He discovered that if a *simple* pendulum (*i.e.*, a weight or *bob* consisting of a single point, and hung by a rod or string of no weight) can be made to describe, not a circle, but a cycloid of which the string would be the radius of curvature at the lowest point, all its vibrations, however large, will be performed in the same time. For a little distance near the bottom, the circle very nearly coincides with the cycloid; and hence it is that, for small arcs, a pendulum vibrating as usual in a circle is nearly enough isochronous for the purposes of horology; more especially when contrivances are introduced either to compensate for the variations of the arc, or, better still, to destroy them altogether, by making the force on the pendulum so constant that its arc may never sensibly vary.

The difference between the time of any *small* arc of the circle and *any* arc of the cycloid varies nearly as the square of the circular arc; and again, the difference between the times of any two small and nearly equal circular arcs of the same pendulum, varies nearly as the arc itself. If a, the arc, is increased by a small amount da, the pendulum will lose $10800ada$ seconds a day, which is rather more than 1 second, if a is 2° (from zero) and da is 10′, since the numerical value of 2° is ·035. If the increase of arc is considerable, it will not do to reckon thus by differentials, but we must take the difference of time for the day as $5400\ (a_{,}^2 - a^2)$, which will be just 8 seconds if $a = 2°$ and $a_{,} = 3°$. For many years it was thought of great importance to obtain cycloidal vibrations of clock pendulums, and it was done by making the suspension string or spring vibrate between *cycloidal cheeks*, as they were called. But it was in time discovered that all this is a delusion,—first, because there is and can be no such thing in reality as a simple pendulum, and cycloidal cheeks will only make a simple pendulum vibrate isochronously; secondly, because a very slight error in the form of the cheeks (as Huyghens himself discovered) would do more harm than the *circular error* uncorrected, even for an arc of 10°, which is much larger than the common pendulum arc; thirdly, because there was always some friction or adhesion between the cheeks and the string; and fourthly (a reason which applies equally to all the isochronous contrivances since invented), because a common clock escapement itself generally tends to produce an error exactly opposite to the circular error, or to make the pendulum vibrate quicker the farther it swings; and therefore the circular error is actually useful for the purpose of helping to counteract the error due to the escapement, and the clock goes better than it would with a simple pendulum, describing the most perfect cycloid. At the same time, the thin spring by which pendulums are always suspended, except in some French clocks where a silk string is used (a very inferior plan), causes the pendulum to deviate a little from circular and to approximate to cycloidal motion, because the bend does not take place at one point, but is spread over some length of the spring.

The accurate performance of a clock depends so essentially on the pendulum, that we shall go somewhat into detail respecting it. First then, the time of vibration depends entirely on the length of the pendulum, the effect of the spring being too small for consideration until we come to differences of a higher order. But the time does not vary as the length, but only as the square root of the length; *i.e.*, a pendulum to vibrate two seconds must be four times as long as a seconds pendulum. The relation between the time of vibration and the length of a pendulum is expressed thus:—

$t = \pi\sqrt{\frac{l}{g}}$, where t is the time in seconds, π the well-known symbol for 3·14159, the ratio of the circumference of a circle to its diameter, l the length of the pendulum, and g the force of gravity at the latitude where it is intended to vibrate. This letter g, in the latitude of London, is the symbol for 32·2 feet, that being the velocity (or number of feet per second) at which a body is found by experiment to be moving at the end of the first second of its fall, being necessarily equal to twice the actual number of feet it has fallen in that second. Consequently, the length of a pendulum to beat seconds in London is 39·14 inches. But the same pendulum carried to the equator, where the force of gravity is less, would lose 2¼ minutes a day.

The seconds we are here speaking of are the seconds of a common clock indicating *mean solar time*. But as clocks are also required for sidereal time, it may be as well to mention the proportions between a mean and a sidereal pendulum. A sidereal day is the interval between two successive transits over the meridian of a place by that imaginary point in the heavens called ♈, the first point of Aries, at the intersection of the equator and the ecliptic; and there is one more sidereal day than there are solar days in a year, since the earth has to turn more than once round in space before the sun can come a second time to the meridian, on account of the earth's own motion in its orbit during the day. A sidereal day or hour is shorter than a mean solar one in the ratio of ·99727, and consequently a sidereal pendulum must be shorter than a mean time pendulum in the square of that ratio, or in the latitude of London the sidereal seconds pendulum is 38·87 inches. As we have mentioned what is 0 or 24 o'clock by sidereal time, we may as well add, that the mean day is also reckoned in astronomy by 24 hours, and not from midnight as in civil reckoning, but from the following noon; thus, what we call 11 A.M. May 1 in common life is 23 h. April 30 with astronomers.

It must be remembered that the pendulums whose lengths we have been speaking of are simple pendulums; and as that is a thing which can only exist in theory, the reader may ask how the length of a real pendulum to vibrate in any required time is ascertained. In every pendulum, that is to say, in every body hung so as to be capable of vibrating freely, there is a certain point, always somewhere below the centre of gravity, which possesses these remarkable properties—that if the pendulum were turned upside down, and set vibrating about this point, it would vibrate in the same time as before, and moreover, that the distance of this point from the point of suspension is exactly the length of that imaginary simple pendulum which would vibrate in the same time. This point is therefore called the *centre of oscillation*. The rules for finding it by calculation are too complicated for ordinary use, except in bodies of certain simple and regular forms; but they are fortunately not requisite in practice, because in all clock pendulums the centre of oscillation is only a short distance below the centre of gravity of the whole pendulum, and generally so near to the centre of gravity of the bob—in fact a little above it—that there is no difficulty in making a pendulum for any given time of vibration near enough to the proper length at once, and then adjusting it by screwing the bob up or down until it is found to vibrate in the proper time.

Revolving or Conical Pendulum.

Thus far we have been speaking of vibrating pendulums; but the notice of pendulums would be incomplete without some allusion to revolving or *conical* pendulums, as they are called, because they describe a cone in revolving. Such pendulums are used where a continuous instead of an intermittent motion of the clock train is required, as in the clocks for keeping an equatorial telescope directed to a star, by driving it the opposite way to the motion of the earth, to whose axis the axis on which the telescope turns is made parallel. Clocks with such pendulums may also be used in bedrooms by persons who cannot bear the ticking of a common clock. The pendulum, instead of being hung by a flat spring, is hung by a thin piece of piano-forte wire; and it should be understood that it has no tendency to twist on its own axis, and so to twist off the wire, as may be apprehended; in fact, it would require some extra force to make it twist, if it were wanted to do so. The time of revolution of such a pendulum may be easily ascertained as follows:—Let l be its length; α the angle which it makes with the vertical axis of the cone which it describes; ω the angular velocity; then the centrifugal force $=\omega^2 l \sin. \alpha$; and as this is the force which keeps the pendulum away from the vertical, it must balance the force which draws it to the vertical, which is $g \tan. \alpha$; and therefore $\sqrt{\frac{g}{l \cos. \theta}}=$ the angular velocity, or the angle described in a second of time; and the time of complete revolution through the angle 360° or 2π is $\frac{2\pi}{\omega}=2\pi\sqrt{\frac{l \cos. \alpha}{g}}$; that is to say, the time of revolution of a pendulum of any given length is less than the time of a double oscillation of the same pendulum, in the proportion of the cosine of the angle which it makes with the axis of revolution to unity.

A rotary pendulum is kept in motion by the train of the clock ending in a horizontal wheel with a vertical axis, from which projects an arm pressing against a spike at the bottom of the pendulum; and it has this disadvantage that any inequality in the force of the train, arising from variations of friction or any other cause, is immediately transmitted to the pendulum; whereas it will be seen that in several kinds of escapements which can be applied to a vibrating pendulum, the variations of force can be rendered nearly or quite insensible. And it is a mistake to imagine that there is any self-correcting power in a conical pendulum analogous to that of the governor of a steam-engine; for that apparatus, though it is a couple of conical pendulums, has also a communication by a system of levers with the valve which supplies the steam. The governor apparatus has itself been applied to telescope-driving clocks, with a lever ending in a spring which acts by friction on some revolving plate in the clock, increasing the friction, and so diminishing the force as the balls of the governor fly out farther under any increase in the force. And with the addition of some connection with the hand of the observer, by which the action can be farther moderated the motion can be made sufficiently uniform for that purpose.

Various other contrivances have been invented for producing a continuous clock-motion. The great equatorial telescope at Greenwich is kept in motion by a kind of water clock called in books on hydrostatics Barker's Mill, in which two horizontal pipes branching out from a vertical tubular axis have each a hole near their ends on opposite sides, from which water flows, being poured constantly into the tubular axis, which revolves on a pivot. The resistance of the air to the water issuing from the holes drives the mill round, and there are means of regulating it. Another plan is to connect a clock train having a vibrating pendulum with another clock having a conical pendulum by one of the lower wheels in the train, with a spring connection; the telescope is driven by the revolving clock train, and the other pendulum keeps it sufficiently in order, though allowing it to expatiate enough for each beat of the pendulum. The more complicated plan of Wagner of Paris described in Sir E. Beckett's *Rudimentary Treatise on Clocks and Watches and Bells* does not appear to have ever come into use, and therefore it is now omitted.

Pendulum Suspension.

The suspension of the pendulum on what are called *knife-edges*, like those of a scale-beam, has often been advocated. But though it may do well enough for short experiments, in which the effects of the elasticity of the spring are wanted to be eliminated, it fails altogether in use, even if the knife-edges and the plates which carry them are made of the hardest stones. The suspension which is now used universally, in all but some inferior foreign clocks, which have strings instead, is a thin and short spring, with one end let into the top of the pendulum, and the other screwed between two *chops* of metal with a pin through them, which rests firmly in a nick in the cock which carries the pendulum as shown in fig. 2 a little farther on; and the steadiness of this cock, and its firm fixing to a wall, are essential to the accurate performance of the clock. The thinner the spring the better; provided, of course, it is strong enough to carry the pendulum without being bent beyond its elasticity, or bent short; not that there is much risk of that in practice. Pendulum springs are much oftener too thick than too thin; and it is worth notice that, independently of their greater effect on the natural time of vibration of the pendulum, thick and narrow springs are more liable to break than thin and broad ones of the same strength. It is of great importance that the spring should be of uniform thickness throughout its breadth; and the bottom of the chops which carry it should be exactly horizontal; otherwise the pendulum will swing with a twist, as they may be often seen to do in ill-made clocks. If the bottom of the chops is left sharp, where they clip the spring, it is very likely to break there; and therefore the sharp edges should be taken off.

The bob of the pendulum used to be generally made in the shape of a lens, with a view to its passing through the air with the least resistance. But after the importance of making the bob heavy was discovered, it became almost necessary to adopt a form of more solid content in proportion to its surface. A sphere has been occasionally used, but it is not a good shape, because a slight error in the place of the hole for the rod may make a serious difference in the amount of weight on each side, and give the pendulum a tendency to twist in motion. The mercurial jar pendulum suggested the cylindrical form, which is now generally adopted for astronomical clocks, and in the best turret clocks, with a round top to prevent any bits of mortar or dirt falling and resting upon it, which would alter the time; it also looks better than a flat-topped cylinder. There is no rule to be given for the weight of pendulums. It will be shown hereafter that, whatever escapement may be used, the errors due to any variation of force are expressed in fractions which invariably have the weight and the length of the pendulum in the denominator, though some kind of escapements require a heavy pendulum to correct their errors much less than others. And as a heavy pendulum requires very little more force to keep it in motion than a light one, being less affected by the resistance of the air, we may almost say that the heavier and longer a pendulum can be made the better; at any rate, the only limit is one of convenience; for instance, it would obviously be inconvenient to put a large pendulum of 100 ℔ weight in the case of an astronomical or common house clock. It may perhaps be laid down as a rule, that no astronomical clock or *regulator* (as they are also called) will go as well as is now expected of such clocks with a pendulum of less than 28 ℔ weight, and no turret clock with less than 1 cwt. Long pendulums are generally made with heavier bobs than short ones; and such a clock as that of the Houses of Parliament, with a two-seconds pendulum of 6 cwt., ought to go 4½ times as well as a small turret clock with a one-second pendulum of 60 ℔. Pendulums longer than 14 feet (2 seconds) are inconvenient, liable to be disturbed by wind, and expensive to compensate, and they are now quite disused, and most or all of the old ones removed, with their clocks, for better ones.

Pendulum Regulation.

The regulation of pendulums, or their exact adjustment to the proper length, is primarily effected by a nut on the end of the rod, by which the bob can be screwed up or down. In the best clocks the rim of this nut is divided, with an index over it; so the exact quantity of rise or fall, or the exact acceleration or retardation, may be known, the amount due to one turn of the nut being previously ascertained. By the calculation used below for compensation of pendulums, it may be seen that if the length of the pendulum rod is l, and the breadth of one thread of the screw is called dl, then one turn of the nut will alter the rate of the clock by $43200\frac{dl}{l}$ seconds a day; which would be just 30 seconds, if the pendulum rod is 45 inches long, and the screw has 32 threads in the inch. To accelerate the clock the nut has always to be turned to the right, as it is called, and *vice versa*. But in astronomical and in large turret clocks, it is desirable to avoid stopping, or in any way disturbing the pendulum; and for the finer adjustments other methods of regulation are adopted. The best is that of fixing a collar, as shown in fig 2, capable of having very small weights laid upon it, half-way down the pendulum, this being the place where the addition of any small weight produces the greatest effect, and where, it may be added, any moving of that weight up or down on the rod produces the least effect. If M is the weight of the pendulum and l its length (down to the centre of oscillation), and m a small weight added at the distance d below the centre of suspension or above the c.o. (since they are reciprocal), t the time of vibration, and $-dt$ the acceleration due to adding m; then

$$\frac{-dt}{t} = \frac{m}{2M}\left(\frac{d}{l} - \frac{d^2}{l^2}\right):$$

from which it is evident that if $d = \frac{l}{2}$, then $-d$T the daily acceleration $= \frac{10800\, m}{M}$; or if m is the 10800th of the weight of the pendulum it will accelerate the clock a second a day, or 10 grains will do that on a pendulum of 15 lb. weight (7000 gr. being = 1 lb.), or an ounce on a pendulum of 6 cwt. In like manner if $d = \frac{l}{3}$ from either top or bottom, m must $= \frac{M}{7200}$ to accelerate the clock a second a day. The higher up the collar is the less risk there is of disturbing the pendulum in putting on or taking off the regulating weights. The weights should be made in a series, and marked ¼, ½, 1, 2, according to the number of seconds a day by which they will accelerate; and the pendulum adjusted at first to lose a little, perhaps a second a day, when there are no weights on the collar, so that it may always have some weight on, which can be diminished or increased from time to time with certainty, as the rate may vary.

Compensation of Pendulums.

Soon after pendulums began to be generally used in clocks, it was discovered that they contained within themselves a source of error independent of the action of the clock upon them, and that they lost time in the hot weather and gained in cold, in consequence of all the substances of which they could be made expanding as the temperature increases. If l is the length of a pendulum, and dl the small increase of it from increased heat, t time of the pendulum l, and $t+dt$ that of the pendulum $l+dl$; then

$$\frac{t+dt}{t} = \frac{\sqrt{l+dl}}{\sqrt{l}} = 1 + \frac{dl}{2l}$$

since $\left(\frac{dl}{l}\right)^2$ may be neglected as very small; or $dt = \frac{tdl}{2l}$; and the daily loss of the clock will be $43200\frac{dl}{l}$ seconds. The following is a table of the values of $\frac{dl}{l}$ for 1000° Fahr. of heat in different substances, and also the weight of a cubic inch of each:

		lb
White deal	·0024	·036
Flint glass	·0048	·116
Steel rod	·0064	·28
Iron rod	·007	·26
Brass	·010	·30
Lead	·016	·41
Zinc	·017	·25
Mercury (in bulk, not in length)	·100	·49

Thus a common pendulum with an iron wire rod would lose 43200 × ·00007 = 3 seconds a day for 10° of heat; and if adjusted for the winter temperature it would lose about a minute a week in summer, unless something in the clock happened to produce a counteracting effect, as we shall see may be the case when we come to escapements. We want therefore some contrivance which will always keep that point of the pendulum on which its time depends, viz., the *centre of oscillation*, at the same distance from the point of suspension. A vast number of such contrivances have been made, but there are only three which can be said to be at all in common use; and the old *gridiron pendulum*, made of 9 alternate bars of brass and steel is not one of them, having been superseded by one of zinc and iron, exactly on the same principle, but requiring much fewer bars on account of the greater expansion of zinc than brass. The centre of oscillation so nearly coincides in most clock pendulums with the centre of the *bob* that we may practically say that the object of compensation is to keep the bob always at the same height. For this purpose we must hang the bob from the top of a column of some metal which has so much more expansion than the rod that its expansion upwards will neutralize that of the rod, and of the wires or tube by which the bob is hung, downwards. The complete calculation, taking into account the weight of all the rods and tubes is too long and complicated to be worth going through, especially as it must always be finally adjusted by trial either of that very pendulum or of one exactly similar. For practical purposes it is found sufficient to treat the expansion of zinc as being ·016 to steel ·0064, instead of ·017 as it is really; and for large pendulums with very heavy tubes even the ·016 is a little too much. Moreover the c.o. is higher above the c.g. of the bob in such large pendulums than in small ones with light rods and tubes.

But neglecting these minutiæ for the first approximation, and supposing the bob either to be of iron, in which case it may be considered fixed anywhere to the iron tube which hangs from the top of the zinc tube, or a lead bob attached at its own centre, which obviates the slowness of the transmission of a change of temperature through it, the following calculation will hold. Let r be the length of the steel rod and spring, z that of the zinc tube, b half the height of the bob; the length of the iron tube down the centre of the bob is $z-b$. If the iron tube is of steel for simplicity of calculation, we must evidently have $·064(r+z-b) = 16z \therefore z = \frac{2}{3}(r-b)$. It is practically found that for a seconds pendulum with a lead cylindrical bob 9 in. × 3 hung by its middle r has to be about 44 inches, and z nearly 27. At any rate it is safest to make it 27 at first, especially if the second tube is iron, which expands a little more than steel; and the tube can be shortened after trial but not lengthened. The rod of the standard sidereal pendulum at Greenwich (down to the bottom of the bob, which is such as has been described and weighs 26 lb), is 43¾ and z is 26 inches, the descending wires being steel. A solar time pendulum is about ¼ inch longer, as stated above. If the bob were fixed at its bottom to the steel tube the zinc would have to be 4·88 longer. Fig. 2 is a section of the great Westminster pendulum. The iron rod which runs from top to bottom, ends in a screw, with a nut N, for adjusting the length of the pendulum after it was made by calculation as near the right length as possible. On this nut rests a collar M, which can slide up the rod a little, but is prevented from turning by a pin through the rod. On a groove or annular channel in the top of this collar stands a zinc tube 10 feet 6 inches long, and nearly half an inch thick, made of three tubes all drawn together, so as to become like one (for it should be observed that *cast* zinc cannot be depended on; it must be drawn). On the top of this tube or hollow column fits another collar with an annular groove much like the bottom one M. The object of these grooves is to keep the zinc column in its place, not touching the rod within it, as contact might produce friction, which would interfere with their relative motion under expansion and contraction. Round the collar C is screwed a large iron tube, also not touching the zinc, and its lower end fits loosely on the collar M; and round its outside it has another collar D of its own fixed to it, on which the bob rests. The iron tube has a number of large holes in it down each side, to let the air get to the zinc tube; before that was done, it was found that the compensation lagged a day or two behind the changes of temperature, in consequence of the iron rod and tube being exposed, while the zinc tube was enclosed without touching the iron. The bottom of the bob is 14 feet 11 inches from the top of the spring A, and the bob itself is 18 inches high, with a dome-shaped top, and twelve inches in diameter. As it is a 2-seconds pendulum, its centre of oscillation is 13 feet from the top A, which is higher than usual above the centre of gravity of the bob, on account of the great weight of the compensation tubes. The whole weighs very nearly 700 lb, and is probably the heaviest pendulum in the world.

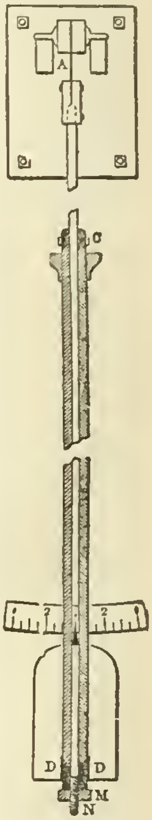

Fig. 2.—Section of Great Westminster Pendulum.

The second kind of compensation pendulum in use is still more simple, but not so effective or certain in its action; and that is merely a wooden rod with a long lead bob resting on a nut at the bottom. According to the above table, it would appear that this bob ought to be 14 inches high in a 1-second pendulum; but the expansion of wood is so uncertain that this proportion is not found capable of being depended on, and a somewhat shorter bob is said to be generally more correct in point of compensation. All persons who have tried wooden pendulums severely have come to the same conclusion, that they are capricious in their action, and consequently unfit for the highest class of clocks.

The best of all the compensations was long thought to be the mercurial, which was invented by Graham, a London clockmaker, above a century ago, who also invented the well-known dead escapement for clocks, which will be hereafter explained, and the horizontal or cylinder escapement for watches. And the best form of the mercurial pendulum is that which was introduced by the late E. J. Dent, in which the mercury is enclosed in a cast iron jar or cylinder, into the top of which the steel rod is screwed, with its end plunged into the mercury itself. For by this means the mercury, the rod, and the jar all acquire the new temperature at any change more simultaneously than when the mercury is in a glass jar hung by a *stirrup* (as it is called) at the bottom of the rod; and moreover the pendulum is safe to carry about, and the jar can be made perfectly cylindrical by turning, and also air-tight, so as protect the mercury from oxidation; and, if necessary, it can be heated in the jar so as to drive off any moisture, without the risk of breaking. The height of mercury required in a cast-iron jar, 2 inches in diameter, is about 6·8 inches; for it must be remembered, in calculating the rise of the mercury, that the jar itself expands laterally, and that expansion has to be deducted from that of the mercury in bulk.

The success of the Westminster clock pendulum, however, and of smaller zinc and steel pendulums at Greenwich and elsewhere, has established the conclusion that it is unnecessary to incur the expense of a heavy mercurial pendulum, which has become more serious from the great rise in the price of mercury and the admitted necessity for much heavier bobs than were once thought sufficient for astronomical clocks. The complete calculation for a compensated pendulum in which the rods and tubes form any considerable proportion of the whole weight, as they must in a zinc pendulum, is too complicated to be worth undertaking generally, especially as it is always necessary to adjust them finally by trial, and for that purpose the tubes should be made at first a little longer than they ought to be by calculation, except where one is exactly copying pendulums previously tried.

Barometrical Error.

It has long been known that pendulums are affected by variations of density of the air as well as of temperature, though in a much less degree,—in fact, so little as to be immaterial, except in the best clocks, where all the other errors are reduced to a minimum. An increase of density of the air is equivalent to a diminution of the specific gravity of the pendulum, and that is equivalent to diminution of the force of gravity while the inertia remains the same. And as the velocity of the pendulum varies directly as the force of gravity and inversely as the inertia, an increase of density must diminish the velocity or increase the time. The late Francis Baily, P.R.A.S., also found from some elaborate experiments (See *Phil. Trans.* of 1832) that swinging pendulums carry so much air with them as to affect their specific gravity much beyond that due to the mere difference of stationary weight, and that this also varies with their shape,—a rod with a flat elliptical section dragging more air with it than a thicker round one (which is not what one would expect), though a lens-shaped bob was less affected than a spherical one of the same diameter, which of course is much heavier. The frictional effect of the air is necessarily greater with its increased density, and that diminishes the arc. In the *R.A.S. Memoirs* of 1853 Mr Bloxam remarked also that the current produced in the descent of the pendulum goes along with it in ascending, and therefore does not retard the ascent as much as it did the descent, and therefore the two effects do not counteract each other as Baily assumed that they did. He also found the circular error always less than its theoretical value, and considered that this was due to the resistance of the air. The conclusions which were arrived at by several eminent clockmakers as to the effect of the pendulum spring on the circular error about 40 years ago were evidently erroneous, and the effect due to other causes.

It appears from further investigation of the subject in several papers in the *R.A.S. Notices* of 1872 and 1873, that the barometrical error also varies with the nature of the escapement, and (as Baily had before concluded from calculation) with the arc of the pendulum, so that it can hardly be determined for any particular clock *a priori*, except by inference from a similar one. The barometrical error of an ordinary astronomical clock with a dead escapement was said to be a loss of nearly a second a day for an inch rise of barometer, but with a gravity escapement and a very heavy pendulum not more than ·3 second. Dr Robinson of Armagh (see *R.A.S. Mem.*, vol. v.) suggested the addition of a pair of barometer tubes to the sides of the pendulum, with a bulb at the bottom, and such a diameter of tube as would allow a sufficient quantity of mercury to be transposed to the top by the expansion under heat, to balance the direct effect of the heat upon the pendulum. But it is not necessary to have two tubes. In a paper in the *R.A.S. Notices* of January 1873 Mr. Denison (now Sir E. Beckett) gave the calculations requisite for the barometrical compensation of pendulums of various lengths and weights, the principle of which is just the same as that above given for regulating a pendulum by adding small weights near the middle of its length. The formula is also given at p. 69 of the sixth edition of his *Rudimentary Treatise on Clocks.* A barometrical correction of a different kind has been applied to the standard clock at Greenwich. An independent barometer is made to raise or lower a magnet so as to bring it into more or less action on the pendulum and so to accelerate or retard it. But we do not see why that should be better than the barometer tube attached to the pendulum. The necessity for this correction seems to be obviated altogether by giving the pendulum a sufficient arc of vibration. Baily calculated that if the arc (reckoned from 0) is about 2° 45′ the barometrical error will be self-corrected. And it is remarkable that the Westminster clock pendulum, to which that large arc was given for other reasons, appears to be free from any barometric error, after trying the results of the daily rate as automatically recorded at Greenwich for the whole of the year 1872. We shall see presently that all the escapement errors of clocks are represented by fractions which have the square or the cube of the arc in the denominator, and therefore if the arc can be increased and kept constant without any objectionable increase of force and friction, this is an additional reason for preferring a large arc to a small one, though that is contrary to the usual practice in astronomical clocks.

Escapements.

The escapement is that part of the clock in which the rotary motion of the wheels is converted into the vibratory motion of the balance or pendulum, which by some contrivance or other is made to let one tooth of the quickest wheel in the train escape at each vibration; and hence that wheel is called the "scape-wheel." Fig. 3 shows the form of the earliest clock escapement, if it is held sideways, so that the arms on which the two balls are set may vibrate on a horizontal plane. In that case the arms and weights form a balance, and the farther out the weights are set, the slower would be the vibrations. If we now turn it as it stands here, and consider the upper weight left out, it becomes the earliest form of the pendulum clock, with the *crown-wheel* or *vertical* escapement. CA and CB are two flat pieces of steel, called *pallets*, projecting from the axis about at right angles to each other, one of them over the front of the wheel as it stands, and the other over the back. The tooth D is just escaping from the front pallet CA, and at the same time the tooth at the back of the wheel falls on the other pallet CB, a little above its edge. But the pendulum which is now moving to the right does not stop immediately, but swings a little further (otherwise the least failure in the force of the train would stop the clock, as the escape would not take place), and in so doing it is evident that the pallet B will drive the wheel back a little, and produce what is called the *recoil*; which is visible enough in any common clock with a seconds-hand, either with this escapement or the one which will be next described.

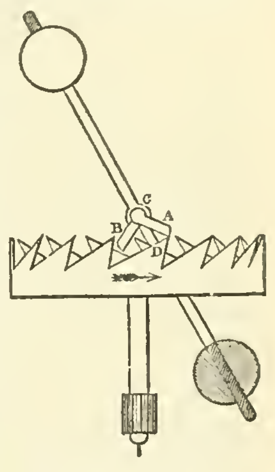

Fig. 3.—Recoil Escapement.

It will be seen, on looking at figure 3, that the pallet B must turn through a considerable angle before the tooth can escape; in other words, the crown-wheel escapement requires a long vibration of the pendulum. This is objectionable on several accounts,—first, because it requires a great force in the clock train, and a great pressure, and therefore friction, on the pallets; and besides that, any variation in a large arc, as was explained before, produces a much greater variation of time due to the circular error than an equal variation of a small arc. The crown-wheel escapement may indeed be made so as to allow a more moderate arc of the pendulum, though not so small as the 2°, usually adopted in the best clocks, by putting the pallet arbor a good deal higher above the scape-wheel, and giving a small number of teeth to the wheel; and that also diminishes the length of the run of the teeth, and consequently the friction, on the pallets, though it makes the recoil very great and sudden; but, oddly enough, it never appears to have been resorted to until long after the escapement had become superseded by the "anchor" escapement, which we shall now

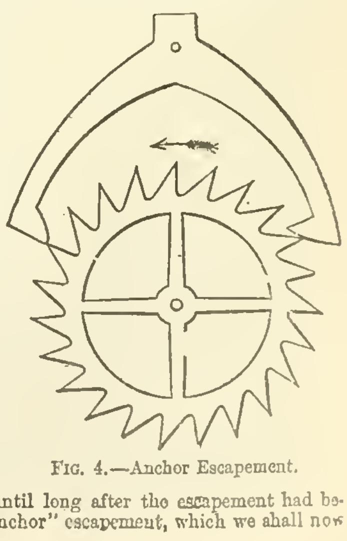

Fig. 4.—Anchor Escapement.

describe, and which appears to have been invented by the celebrated Dr Hooke as early as the year 1656, very soon after the invention of pendulums.

In fig. 4 a tooth of the scape-wheel is just escaping from the left pallet, and another tooth at the same time falls upon the right hand pallet at some distance from its point. As the pendulum moves on in the same direction, the tooth slides farther up the pallet, thus producing a recoil, as in the crown-wheel escapement. The acting faces of the pallets should be convex, and not flat, as they are generally made, much less concave, as they have sometimes been made, with a view of checking the motion of the pendulum, which is more likely to injure the rate of the clock than to improve it. But when they are flat, and of course still more when they are concave, the points of the teeth always wear a hole in the pallets at the extremity of their usual swing, and the motion is obviously easier and therefore better when the pallets are made convex; in fact they then approach more nearly to the "dead" escapement, which will be described presently. We have already alluded to the effect of some escapements in not only counteracting the circular error, or the natural increase of the time of a pendulum as the arc increases, but overbalancing it by an error of the contrary kind. The recoil escapement does so; for it is almost invariably found that whatever may be the shape of these pallets, the clock loses as the arc of the pendulum falls off, and *vice versa*. It is unfortunately impossible so to arrange the pallets that the circular error may be thus exactly neutralized, because the escapement error depends, in a manner reducible to no law, upon variations in friction of the pallets themselves and of the clock train, which produce different effects; and the result is that it is impossible to obtain very accurate time-keeping from any clock of this construction.

But before we pass on to the dead escapement, it may be proper to notice an escapement of the recoiling class, which was invented for the purpose of doing without oil, by the famous Harrison, who was at first a carpenter in Lincolnshire, but afterwards obtained the first Government reward for the improvement of chronometers. We shall not however stop to describe it, since it never came into general use, and it is said that nobody but Harrison himself could make it go at all. It was also objectionable on account of its being directly affected by all variations in the force of the clock. It had the peculiarity of being very nearly silent, though the recoil was very great. Those who are curious about such things will find it described in the seventh edition of this *Encyclopædia*. The recorded performance of one of these clocks, which is given in some accounts of it, is evidently fabulous.

Dead Escapements.

The escapement which has now for a century and a half been considered the best practical clock escapement (though there have been constant attempts to invent one free from the defects which it must be admitted to possess) is the *dead escapement*, or, as the French call it with equal expressiveness, *l'échappement à repos*,—because instead of the recoil of the tooth upon the pallet, which took place in the previous escapements, it falls dead upon the pallet, and reposes there until the pendulum returns and lets it off again. It is represented in fig. 5. It will be observed that the teeth of the scape-wheel have their points set the opposite way to those of the recoil escapement in fig. 4, the wheels themselves both turning the same way; or (as our engraver has represented it), *vice versa*. The tooth B is here also represented in the act of dropping on to the right hand pallet as the tooth A escapes from the left pallet. But instead of the pallet having a continuous face as in the recoil escapement, it is divided into two, of which BE on the right pallet, and FA on the left, are called the impulse faces, and BD, FG, the dead faces. The dead faces are portions of circles (not necessarily of the same circle), having the axis of the pallets C for their centre; and the consequence evidently is, that as the pendulum goes on, carrying the pallet still nearer to the wheel than the position in which a tooth falls on to the corner A or B of the impulse and the dead faces, the tooth still rests on the dead faces without any recoil, until the pendulum returns and lets the tooth slide down the impulse face, giving the impulse to the pendulum as it goes.

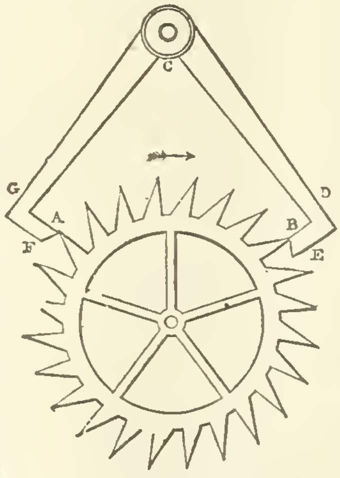

Fig. 5.—Dead Escapement.

The great merit of this escapement is that a moderate variation in the force of the clock train produces a very slight effect in the time of the pendulum. This may be shown in a general way, without resorting to mathematics, thus:—Since the tooth B drops on to the corner of the pallet (or ought to do so) immediately after the tooth A has escaped, and since the impulse will begin at B when the pendulum returns to the same point at which the impulse ceased on A, it follows that the impulse received by the pendulum before and after its vertical position is very nearly the same. Now that part of the impulse which takes place before zero, or while the pendulum is descending, tends to augment the natural force of gravity on the pendulum, or to make it move faster; but in the descending arc the impulse on the pallets acts against the gravity of the pendulum, and prevents it from being stopped so soon; and so the two parts of the impulse tend to neutralize each other's disturbing effects on the times of the pendulum, though they both concur in increasing the arc, or (what is the same thing) maintaining it against the loss from friction and resistance of the air. However, on the whole, the effect of the impulse is to retard the pendulum a little, because the tooth must fall, not exactly on the corner of the pallet, but (for safety) a little above it; and the next impulse does not begin until that same corner of the pallet has come as far as the point of the tooth; in other words, the retarding part of the impulse, or that which takes place after zero, acts rather longer than the accelerating part before zero. Again, the friction on the dead part of the pallets tends to produce the same effect on the time; the arc of course it tends to diminish. For in the descent of the pendulum the friction acts against gravity, but in the ascent with gravity, and so shortens the time; and there is rather less action on the dead part of the pallets in the ascent than in the descent. For these reasons the time of vibration of a pendulum driven by a dead escapement is a little greater than of the same pendulum vibrating the same arc freely; and when you come to the next difference, the variation of time of the same pendulum with the dead escapement, under a moderate variation in the force, is very small indeed, which is not the case in the recoil escapement, for there the impulse begins at each end of the arc, and there is much more of it during the descent of the pendulum than during the ascent from zero to the arc at which the escape takes place and the recoil begins on the opposite tooth; and then the recoil itself acts on the pendulum in its ascent in the same direction as gravity, and so shortens the time. And hence it is that an increase of the arc of the pendulum with a recoil escapement is always accompanied with a decrease of the time. Something more than this general reasoning is requisite in order to compare the real value of the dead escapement with others of equal or higher pretensions, or of the several contrivances that have been suggested for remedying its defects. But we must refer to the *Rudimentary Treatise on Clocks* for details of the mathematical calculations by which the numerical results are obtained, and the relative value of the different kinds of escapements determined.

It cannot be determined *a priori* whether cleaning and oiling a dead escapement clock will accelerate or retard it, for reasons explained in those calculations; but it may be said conclusively that the larger the arc is for any given weight × the fall per day, the better the clock will be; and in order to diminish the friction and the necessity for using oil as far as possible, the best clocks are made with jewels (sapphires are the best for the purpose) let into the pallets.

The pallets are generally made to embrace about one-third of the circumference of the wheel, and it is not at all desirable that they should embrace more; for the longer they are, the longer is the run of the teeth upon them, and the greater the friction. There is a good deal of difference in the practice of clockmakers as to the length of the impulse, or the amount of the angle $\gamma+\beta$ if the impulse begins at β before zero and at γ after zero. Sometimes you see clocks in which the seconds hand moves very slowly and rests a very short time, showing that $\gamma+\beta$ is large in proportion to $2a$; and in others the contrary. The late Mr Dent was decidedly of opinion that a short impulse was the best, probably because there is less of the force of the impulse wasted in friction then. It is not to be forgotten that the scape-wheel tooth does not overtake the face of the pallet immediately, on account of the moment of inertia of the wheel. The wheels of astronomical clocks, and indeed of all English house-clocks, are generally made too heavy, especially the scape-wheel, which, by increasing the moment of inertia, requires a larger force, and consequently has more friction. We shall see presently, from another escapement, how much of the force is really wasted in friction in the dead escapement.

But before proceeding to other escapements, it is proper to notice a very useful form of the dead escapement, which is adopted in many of the best turret clocks, called the *pin-wheel escapement*. Fig. 6 will sufficiently explain its action and construction. Its advantages are—that it does not require so much accuracy as the other; if a pin gets broken it is easily replaced, whereas in the other the wheel is ruined if the point of a tooth is injured; a wheel of given size will work with more pins than teeth, and therefore a train of less velocity will do, and that sometimes amounts to a saving of one wheel in the train, and a good deal of friction; and the blow on both pallets being downwards, instead of one up and the other down, the action is more steady; all which things are of more consequence in the heavy and rough work of a turret clock than in an astronomical one. The details of the construction are given in the *Rudimentary Treatise*. It has been found expedient to make the dead faces not quite dead, but with a very slight recoil, which rather tends to check the variations of arc, and also the general disposition to lose time if the arc is increased; when so made the escapement is generally called "half-dead."

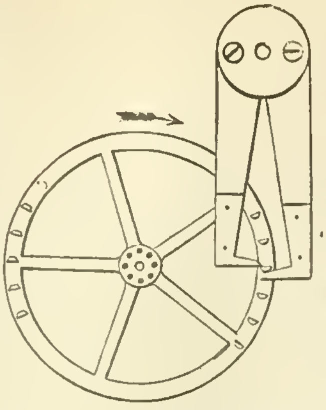

FIG. 6.—Pin-Wheel Escapement.

Passing by the various other modifications of the dead escapement which have been suggested and tried with little or no success, we proceed to describe one of an entirely different form, which was patented in 1851 by Mr C. Macdowall, though it appeared afterwards that one very similar had been tried before, but failed from the proportions being badly arranged. It is represented in fig. 7. The scape-wheel is only a small disc with a single pin in it, made of ruby, parallel and very near to the arbor. The disc turns half round at every beat of the pendulum, and the pin gives the impulse on the vertical faces of the pallets, and the dead friction takes place on the horizontal faces. Its advantages are—that the greatest part of the impulse is given directly across the line of centres, and consequently with very little friction; and therefore also, the friction on the dead faces is less than usual, and scarcely any oil is required; moreover, it is very easy to make. But there must be two more wheels in the train, consuming a good deal of the force of the clock-weight by their friction, which rather more than makes up for the friction saved in the escapement. It was applied successfully to watches, but the expense of the additional wheels prevented their adoption. In order to make the angle of escape not more than 1°, the distance of the pin from the centre of the disc must not be more than $\frac{1}{50}$th of the distance of centres of the disc and pallets.

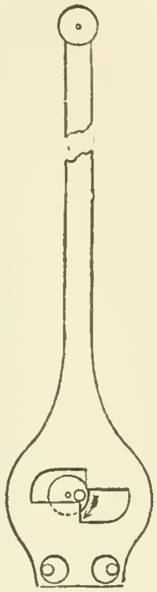

FIG. 7. Macdowall's Escapement.

With the view of getting rid of one of these extra wheels in the train, and that part of the impulse which is least effective and most oblique, Mr Denison shortly afterwards invented the *three-legged dead escapement*; which, though afterwards superseded by his *three-legged gravity escapement*, is still worth notice on account of the exceedingly small force which it requires, thereby giving a practical proof of the large proportion of the force which is wasted in friction in all the other impulse escapements.

In fig. 8, the three long teeth of the scape-wheel are only used for locking on the dead pallets D and E, which are set on the front of the pallet plate; A and B are impulse pallets, being hard bits of steel or jewels set in the pallet-plate, and they are acted upon by the three sharp-edged pins which are set in the scape-wheel and point backwards. As soon as the pendulum moves a little further to the left than is here shown, the long tooth will slip past the dead pallet or stop D, and the pin at B will run after and catch the corner of that impulse pallet and drive it until the wheel has turned through 60°, and then it will escape; and by that time the uppermost tooth will arrive at the stop E, and will slide along it as in the common dead escapement, but with a pressure as much less than that which gives the impulse as the points of the teeth are farther from the centre of the wheel than the impulse pins are. But the impulse is here given with so little friction, that even where the points of the teeth were made identical with the pins, the clock-weight required to keep the same pendulum with the same train (a common turret-clock movement), swinging to 2°, was only one-fifth of what had been required with the pin-wheel escapement; and the scape-wheel which kept the 6 cwt. pendulum of the Westminster clock going for half-a-year, until superseded by the gravity escapement, weighed only a sixth of an ounce. It appears also that it would be possible so to adjust the recoil of the half-dead pallets that the time would not be affected by any small variation of the force and the arc; since it was found that, when a certain amount of recoil was given, the clock gained instead of losing, under an increase of arc due to an increase of clock-weight. And if the force were kept constant by a train remontoire, such as will be described hereafter, there would in fact be nothing capable of altering the arc or the time. But on account of the small depth of intersection of the circles of the pins and the pallets, on which its action depends, this escapement requires very careful adjustment of the pallets, except where they are on a large scale; and considering the superior qualities of the corresponding gravity escapement, it is not likely to be used, except perhaps in clocks required to go a long time, in which economy of force is a matter of consequence. The pallets should be connected with the pendulum by a spring-fork (which indeed is advisable in the common dead escapement with a heavy pendulum, especially the pin-wheel escapement), to prevent the risk of their driving backwards against the scape-wheel when it is not in motion, as it will not clear itself. The distance of the centres should be not less than 25 times the radius of the circle of the edges of the impulse pins.

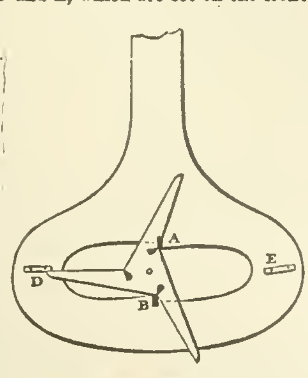

FIG. 8.—Denison's Three-Legged Escapement.

Detached Escapements.

In all the escapements hitherto described the pallets are never out of moving contact with the scape-wheel, and there have been several contrivances for keeping them detached except during the impulse and at the moment of passing a click which is to release the wheel to give the impulse. This is an imitation of the chronometer escapement in watches which is sometimes called the "detached." There are only two of such contrivances which appear worth special notice. One was proposed by Sir G. Airy in vol. ii. of the *Cambridge Transactions*, but not executed (so far as we know) till a few years ago in the standard sidereal clock at Greenwich, which is reported to go extremely well. Suppose a dead escapement consisting of a single pallet only, say the right hand one of the pin-wheel escapement (fig. 6), for the Greenwich clock has a pin escapement, and that the wheel is locked generally by a spring detent hooking into any one of its teeth, and capable of being lifted or pushed aside by the pendulum, *i.e.*, by a pin somewhere on the single pallet as it passes to the right, but also capable of being passed without being lifted as the pendulum goes to the left. We shall see afterwards how this is done, in the article WATCHES. Then as the pendulum goes to the right, it first lifts the detent at about 1° before zero, and then a tooth or a pin drops on to the pallet and gives the impulse, exactly as in the dead pin-wheel escapement, and with exactly the same amount of friction, substituting only for the dead friction the resistance and friction of passing the detent one way and lifting it the other.

A different escapement on the same principle but involving less friction was adopted by Sir E. Beckett in a clock described in the later editions of his book as having gone for above ten years very satisfactorily, except that, like all direct impulse escapements, including Sir G. Airy's, it must vary with the force of the clock train, due to different states of the oil. The scape-wheel (fig. 9) is five-legged, and has five sharp-edged pins which give the impulse to the hard steel pallet P whenever it passes to the right, provided the wheel is then free to move. It is stopped by the detent DEF, which turns on a pivot F, not in the pendulum crutch, as it looks in the drawing, but on the clock-frame. When the pendulum going to the right arrives at the position here drawn, the click CE on the crutch pushes the detent aside and so unlocks the wheel, which then gives the impulse, moving through 72° until another tooth arrives at the detent and is stopped, the click having then got far beyond it. When the pendulum returns the click lightly trips over the top of the detent. Here there is practically no friction in giving the impulse, as it is directly across the line of centres, as in the three-legged dead escapement, and the friction of passing

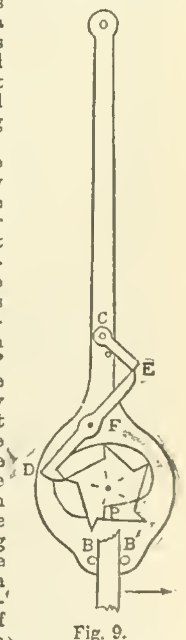

Fig. 9.

and unlocking is as little as possible, for the pressure on the locking teeth is less than half of that of the impulse pins.

In practice the pallet P is a separate bit of steel, screwed on, and therefore adjustable. The locking teeth are about 6 inches long from the centre, and the impulse pin-edges ¼ in. from the centre, which is 7 in. below the top of the pendulum and crutch, so that the impulse begins 1° before zero and ends 1° after, corresponding each to 36° turn of the scape-wheel. If r is the distance of the pins from the centre and p the length of the crutch down to the centre, r sin. 36° must $= p$ sin. 1°, if you want an impulse of 1° on each side of O; which makes $p = 33{\cdot}7r$. BB are eccentric beat pins for adjusting the beat to whatever position of the pendulum you please, *i.e.*, you can make it less than 1° before or after zero as you please. In some respects it would be better to have no crutch, but it would be very difficult to make the adjustments. This escapement should evidently be at the bottom of the clock-frame instead of the top, as in the gravity escapements which will be described presently. The back part of the scape-wheel is carried by a long cock or bridge within which the crutch also moves.

Remontoire or Gravity Escapements.

A remontoire escapement is one in which the pendulum does not receive its impulse from the scape-wheel, but from some small weight or spring which is lifted or wound up by the scape-wheel at every beat, and the pendulum has nothing to do with the scape-wheel except unlocking it. When this impulse is received from a weight the escapement is also called a *gravity escapement;* and inasmuch as all the remontoire clock escapements that are worth notice have been gravity escapements, we may use that term for them at once. The importance of getting the impulse given to the pendulum in this way was recognized long before all the properties of the dead escapement, as above investigated, were known. For it was soon discovered that, however superior to the old recoil escapement, it was far from perfect, and that its success depended on reducing the friction of the train and the pallets as far as possible, which involves the necessity of high-numbered pinions and wheels, small pivots, jewelled pallets, and a generally expensive style of workmanship. Accordingly the invention of an escapement which will give a constant impulse to the pendulum, and be nearly free from friction, has been for a century the great problem of clock-making. We can do no more than shortly notice a very few of the attempts which have been made to solve it. The most simple form of gravity escapement, and the one which will serve the best for investigating their mathematical properties (though it fails in some essential mechanical conditions), is that invented by Mudge. The tooth A of the scape-wheel in fig. 10 is resting against the stop or detent a at the end of the pallet CA, from the axis or arbor of which descends the half fork CP to touch the pendulum. From the other pallet CB descends the other half fork CQ. The two arbors are set as near the point of suspension, or top of the pendulum spring, as possible. The pendulum, as here represented, must be moving to the right, and just leaving contact with the left pallet and going to take up the right one; as soon as it has raised that pallet a little it will evidently unlock the wheel and let it turn, and then the tooth B will raise the left pallet until it is caught by the stop b on that pallet, and then it will stay until the pendulum returns and releases it by raising that pallet still higher. Each pallet therefore descends with the pendulum to a lower point than that where it is taken up, and the difference between them is supplied by the lifting of each pallet by the clock, which does not act on the pendulum at all; so that the pendulum is independent of all variations of force and friction in the train.

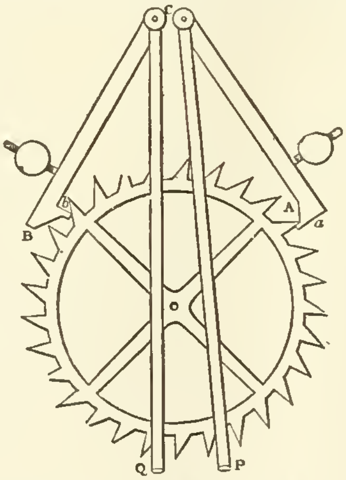

Fig. 10.—Mudge's Gravity Escapement.

Again referring to the *Rudimentary Treatise on Clocks* for the mathematical investigation of the errors of this class of escapements, or to a paper by the late J. M. Bloxam, in the *R. A. S. Memoirs* of 1853, we may say it is proved that though the time of a gravity escapement pendulum differs from that of a free pendulum more than from that of a dead escapement, yet the variations of that difference (which are the real variations of the clock) may be made much less than in any kind of dead escapement.

The difficulty which long prevented the success of gravity escapements was their liability to what is called *tripping.* Referring again to fig. 10, it will be seen at once that if the scape-wheel should happen to move too fast when it is released, the left pallet will not be raised gradually by the tooth B, but be thrown up with a jerk, perhaps so high that the tooth slips past the hook; and then not only will that tooth slip, but several more, and at last when the wheel is stopped it will be running fast, and the points of some of the teeth will probably be bent or broken by catching against the pallets. And even if the pallet is not raised high enough for the tooth to get past or completely trip, it may still be raised so high that the point of the tooth does not rest on the hook exactly where the slope of the pallet ends, but lower, and the friction between them is quite enough to keep the pallet there; and consequently the pendulum does not begin to lift it at the proper angle γ, but at some larger angle; and as the pallet always descends with the pendulum to the same point, the duration of the impulse is increased, and the pendulum made to swing farther. Sir E. Beckett called this *approximate tripping,* and though not so injurious to the clock as actual tripping, it is obviously fatal to its accurate performance, though it appears never to have been noticed before he pointed it out in 1851. Various contrivances have been resorted to for preventing tripping. But on account of the delicacy required in all of them, and other objections, none of them ever came into use until the invention of the three-legged and four-legged escapements to be mentioned presently. The only one which approached near enough to satisfying all the requisite conditions to be worth description is Mr Bloxam's, and we accordingly give a sketch of it in fig. 11, which is copied (with a little alteration for distinctness) from his own description of it, communicated in 1853 to the Astronomical Society, some years after he had had it in action in a clock of his own. This drawing will enable any one conversant with these matters to understand its action. He made the pallet arbors cranked, to embrace the pendulum-spring, so that their centres of motion might coincide with that of the pendulum as nearly as possible,—perhaps an unnecessary refinement; at least the three-legged and four-legge gravity escapements answer very well with the pallet arbors set on each side of the top of the spring. The size of the wheel determines the length of the pallets, as they must be at such an angle to each other that the radii of the wheel when in contact with each stop may be at right angles to the pallet arm; and therefore, for a wheel of this size, the depth of locking can only be very small. The pinion in Mr Bloxam's clock only raises the pallet through 40′ at each beat; *i.e.*, the angle which we called γ is only 20′; and probably, if it were increased to anything like $\frac{a}{\sqrt{2}}$, the escapement would trip immediately. The two broad pins marked E, F, are the fork-pins. The clock which Mr Bloxam had went very well; but it had an extremely fine train, with pinions of 18; and nobody else appears to have been able to make one to answer. In short Bloxam's was not a practical solution of the gravity escapement problem, any more than those of Captain Kater, or Hardy, or various other inventors. A few clocks of Hardy's alone still exist.

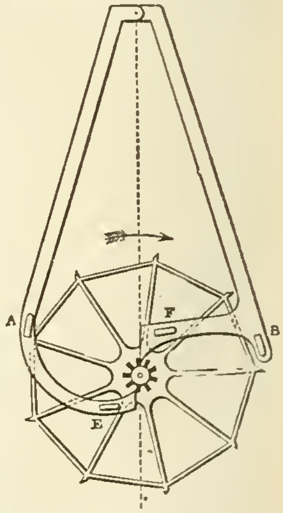

Fig. 11.—Bloxam's Gravity Escapement.

The only gravity escapement or escapements that really have come into common use are the "four-legged" and the "double three-legged" escapements of Sir E. Beckett. They passed through various phases before settling into the present form, of which it is unnecessary to say more now than that the first was the single three-legs described in the last edition of this *Encyclopædia,* which was suggested by his three-legged dead escapement. A five-legged one was also tried; but though it had some slight advantages they are quite overbalanced by disadvantages, and it requires much more delicacy of construction than either the double three-legs or the four-legs which we shall now describe, remarking that the latter is the best for "regulators," and the former in large clocks. Fig. 12 is a back view of the escapement part of an astronomical clock with the four-legged wheel; seen from the front the wheel would turn the other way. The long locking teeth are made about 2 inches long from the centre, and the lifting pins, of which there are four pointing forwards and the other four intermediate pointing backwards, are at not more than one-30th of the distance between the centres EC, of the wheel and pallets; or rather C is the top of the pendulum spring to which the pallets CS, CS′ converge, though their actual action are a little below C. It is not worth while to crank them as Mr Bloxam did, in order to make them coincide exactly with the top of the pendulum, as the friction of the beat pins on the pendulum at P is insignificant, and even then would not be quite destroyed. The pallets are not in the same plane, but one is behind and the other in front of the wheel, with one stop pointing backwards and the other forwards to receive the teeth alternately,—it does not matter which; in this figure the stop S is behind and the stop S′ forward. The pendulum is now going to the right, and just beginning to lift the right pallet and free the stop S′; then the wheel will begin to turn and lift the other pallet by one of the pins which is now lowest, and which moves through 45° across the line of centres, and therefore lifts with very little friction. It goes on till the tooth now below S reaches S and is stopped there. Meanwhile the pallet CS′ goes on with the pendulum as far as it may go, to the end of the arc which we have throughout called α, starting from γ; but it falls with the pendulum again, not only to γ but to $-\gamma$ on the other side of 0, so that the impulse is due to the weight of each pallet alternately falling through 2γ; and the magnitude of the impulse also depends on the obliqueness of the pallet on the whole, *i.e.*, on the distance of its centre of gravity from the vertical through C. The defect of the original three-legged escapement was that the pallets were too nearly vertical.

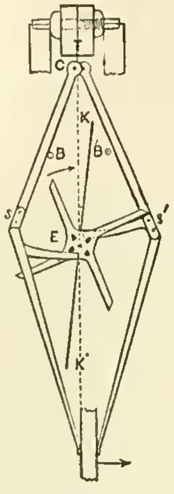

Fig. 12. Four-Legged Gravity Escapement.

Another most material element of these escapements with very few teeth is that they admit of a fly KK on the scape-wheel arbor to moderate its velocity, which both obviates all risk of tripping, wholly or partially, and also prevents the bang which goes all through the clock where there is no fly. The fly is set on with a friction spring like the common striking-part fly, and should be as long as there is room for, length being much more effective than width. For this purpose the second wheel arbor is shortened and set in a cock fixed on the front plate of the clock, which leaves room for a fly with vanes 2 inches long. The back pivot of the scape-wheel is carried by a long cock behind the back plate, so that the escapement is entirely behind it, close to the pendulum. The pallet arbors are short, as they come just behind the centre wheel, which is here also necessarily above the escapement, and the great wheel arbor on a level with it, and at the left hand (from the front) or the string would be in the way of the fly. No beat screws are required, as the pallets end in mere wires which are easily bent. It is found better to make the tails of the pallets long, rather than short as Mr Bloxam did. It is essential, too, that the angle CSE formed by the tooth and the pallet which is struck upwards should not the least fall short of a right angle, nor the other angle CS′E be the least obtuse, or the escapement may very likely trip. Practically, therefore, it is safer to let CSE be just greater than 90° and CS′E a little less, so that there may not be the least tendency in the blow on the stops to drive the pallets outwards. For the purpose of calculation, however, we must make them both 90° and then it follows that, calling the length of the teeth r, and the distance of centres d, and the length of the pallets from C down to the stops p, r must $= d$ sin. $22\frac{1}{2}°$ and $p = d$ cos. $22\frac{1}{2}°$. Therefore if r is made 2 inches CE or d will be 5·22, say $5\frac{1}{4}$ inches, and $p =$ 4·82. The distance of the lifting pins from the centre will be $\frac{1}{3}$ of an inch to make the angle $\gamma = 1°$. It is certainly not desirable to make it more, and even that requires such light pallets for a pendulum of 30 or 40 lb, that $\frac{1}{4}$ inch distance from the centre is more convenient as giving the smaller lift, assuming the scape-wheel to be from 2 to $2\frac{1}{4}$ inches in diameter.

Gravity escapements require more weight than a direct impulse escapement with an equally fine train; and they try the accuracy of the wheelcutting more severely. If there is a weak place in the train of a common clock the scape-wheel only follows the pendulum more weakly; but in a gravity escapement it always has to raise the pallets, and ought to raise them quickly, and especially in clocks for astronomical purposes where you take its exact time from the sound of the beats, and so the lifting must not lag and sound uneven. Therefore although a fine train of high numbers is not requisite it must be perfectly well cut. And as the force of the weight does not reach the pendulum its increase is of no consequence, within reasonable limits. It is worth while to put large friction wheels under the arbor of the great wheel in all astronomical clocks, and it makes a material difference in the friction on account of the necessary thickness of the winding arbor. A variation of arc in dead escapement clocks is sometimes visible between the beginning and the end of the week according as the string is nearest to the thick or the thin end of the great arbor, when there are no friction wheels.

The other form of the gravity escapement, which is now adopted for large clocks by all the best makers, having been first used in the great Westminster clock, is the double three-legged which is shown in fig. 13. The principle of it is the same as of the four-legs; but instead of the pallets being one behind and the other in front of the wheel, with two sets of lifting pins, there are two wheels ABC, *abc*, with the three lifting pins and the two pallets between them like a lantern pinion. One stop B points forward and the other A backward. The two wheels have their teeth set intermediately or 60° apart, though that is not essential, and the angle of 120° may be divided between them in any other proportions, as 70° and 50°, and in that way the pallets may be still more oblique than 30° from the vertical, which however is found enough to prevent tripping even if the fly gets loose, which is more likely to happen from carelessness in large clocks than in astronomical ones. The Westminster one was once found to have been left with the spring loose for several days, and it had not gained a second, and therefore had never tripped. The two wheels must be both squared on the arbor, or on a collar common to them both, and must not depend upon the three pins or they will shake loose. If the wheels are set with the teeth equidistant, their centre is evidently twice the length of the teeth below C, the theoretical centre of the pallets. The pins should not be farther from the centre than one-24th of the radius of the wheel; and they should be so placed that the one which is going to lift next may be vertically over the one which has just lifted, and is then holding up the other pallet. The third will then be level with the centre; *i.e.*, they will stand on the radii which form the acting faces of the teeth of one of the wheels, and half way between those of the other.

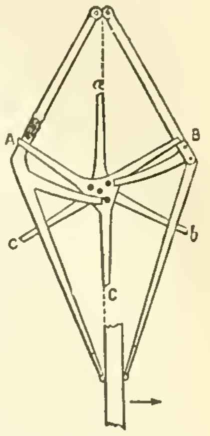

Fig. 13.—Double Three-legged Escapement.

Of course the fly for those escapements in large clocks, with weights heavy enough to drive the hands in all weather, must be much larger than in small ones. For average church clocks with $1\frac{1}{4}$ sec. pendulum the legs of the scape-wheels are generally made 4 inches long and the fly from 6 to 7 inches long in each vane by $1\frac{1}{4}$ or $1\frac{1}{2}$ wide. For $1\frac{1}{2}$ sec. pendulums the scape-wheels are generally made $4\frac{1}{2}$ radius. At Westminster they are 6 inches.

Sir E. Beckett has come to the conclusion that these escapements act better, especially in regulators, if the pallets do not fall quite on the lifting pins, but on a banking, or stops at any convenient place, so as to leave the wheel free at the moment of starting; just as the striking of a common house clock will sometimes fail to start unless the wheel with the pins has a little run before a pin begins to lift the hammer. The best way to manage the banking is to make the beat-pins long enough to reach a little way behind the pendulum, and let the banking be a thin plate of any metal screwed adjustably to the back of the case. This plate cannot well be shown in the drawings together with the pendulum, which, it may be added, should take up one pallet just when it leaves the other.

It is no longer doubtful that these two escapements are far the best of all for large clocks, the three-legs for very large ones, while the four-legs does very well for smaller turret clocks. And they cost no more to make, though rather more is charged for them by some makers under the pretence that they do. It is absolutely impossible for any large clock exposed to the variations of weather and dust to keep as good time as an ordinary good house clock unless it has either a gravity escapement, or a train remontoire, which last is much more expensive, to intercept the variations of force before they reach the pendulum. And though a detached escapement clock while kept clean and the oil in good condition is as good as a gravity one and perhaps better, the gravity one is less affected by variations of the oil, and its rate is altogether more constant. They seem also to have a smaller barometric error.

Going Barrels.

A clock which is capable of going accurately must have some contrivance to keep it going while you are winding it up. In the old-fashioned house clocks, which were wound up by merely pulling one of the strings, and in which one such winding served for both the going and striking parts, this was done by what is called the endless chain of Huyghens, which consists of a string or chain with the ends joined together, and passing over two pulleys on the arbors of the great wheels, with deep grooves and spikes in them, to prevent the chain from slipping. In one of the two loops or festoons which hang from the upper pulleys is a loose pulley without spikes, carrying the clock-weight, and in the other a small weight only heavy enough to keep the chain close to the upper pulleys. Now, suppose one of those pulleys to be on the arbor of the great wheel of the striking part, with a ratchet and click, and the other pulley fixed to the arbor of the great wheel of the going part; then (whenever the clock is not striking) you may pull up the weight by pulling down that part of the string which hangs from the other side of the striking part; and yet the weight will be acting on the going part all the time. And it would be just the same if you wound up the striking part and its pulley with a key, instead of pulling the string, and also the same, if there were no striking part at all, but the second pulley were put on a blank arbor, except that in that case the weight would take twice as long to run down, supposing that the striking part generally requires the same weight × fall as the going part.

This kind of going barrel, however, is evidently not suited to the delicacy of an astronomical clock; and Harrison's going ratchet is now universally adopted in such clocks, and also in chronometers and watches for keeping the action of the train on the escapement during the winding. Fig. 14 (in which the same letters are used as in the corresponding parts of fig. 1) shows its construction. The click of the barrel-ratchet R is set upon another larger ratchet-wheel, with its teeth pointing the opposite way, and its click *r*T is set in the clock-frame. That ratchet is connected with the great wheel by a spring *ss′* pressing against the two pins *s* in the ratchet and *s′* in the wheel. When you wind up the weight (which is equivalent to taking it off), the click T*r* prevents that ratchet from turning back or to the right; and as the spring *ss′* is kept by the weight in a state of tension equivalent to the weight itself it will drive the wheel to the left for a short distance, when its end *s* is held fast, with the same force as if that end was pulled forward by the weight; and as the great wheel has to move very little during the short time the clock is winding, the spring will keep the clock going long enough.

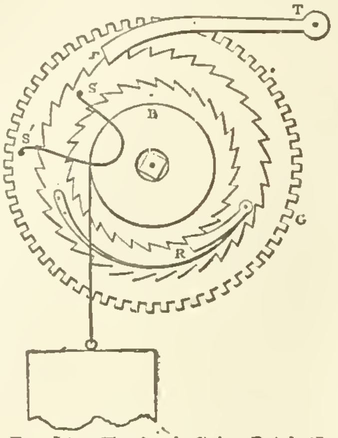

Fig. 14.—Harrison's Going-Ratchet.

In the commoner kind of turret clocks a more simple apparatus is used, which goes by the name of the *bolt and shutter*, because it consists of a weighted lever with a broad end, which shuts up the winding-hole until you lift it, and then a spring-bolt attached to the lever, or its arbor, runs into the teeth of one of the wheels, and the weight of the lever keeps the train going until the bolt has run itself out of gear. In the common construction of this apparatus there is nothing to ensure its being raised high enough to keep in gear the whole time of winding, if the man loiters over it. For this purpose Sir E. Beckett has the arbor of the bolt and shutter made to *pump* in and out of gear; and, instead of the shutter covering the winding-hole, it ends in a circular arc advanced just far enough to prevent the key or winder from being put on, by obstructing a ring set on the end of the pipe. In order to get the winder on, you *must* raise the lever high enough for the arc to clear the ring. During the two or three minutes which the clock may take to wind, the arc will be descending again behind the ring, so that now you cannot get the winder off again without also pulling the maintaining power out of gear; so that even if it is constructed to keep in action ten minutes, if required, still it will never remain in action longer than the actual time of winding. The circular arc must be thick enough, or have a projecting flange added to it deep enough, to prevent the winder being put on by merely pushing back the maintaining power lever without lifting it.

In large clocks with a train remontoire, or even with a gravity escapement, it is hardly safe to use a spring going barrel, because it is very likely to be exhausted too much to wind up the remontoire, or raise the gravity pallets, before the winding is finished, if it takes more than two or three minutes; whereas, with the common escapements, the wheel has only to escape, as the pendulum will keep itself going for some time without any impulse.

Equation Clocks.

It would occupy too much space to describe the various contrivances for making clocks show the variations of solar compared with mean time (called equation clocks), the days of the month, periods of the moon, and other phenomena. The old day of the month clocks required setting at the end of every month which has not 31 days, and have long been obsolete. Clocks are now made even to provide for leap year. But we doubt whether practically anybody ever takes his day of the month from a clock face, especially as the figures are too small to be seen except quite near. Several persons have taken patents for methods of exhibiting the time by figures appearing through a hole in the dial, on the principle of the "numbering machine." But they do not reflect that no such figures, on any practicable scale, are as conspicuous as a pair of hands; and that nobody really reads the figures on a dial, but judges of the time in a moment from the position of the hands; for which reason the minute hand should be straight and plain, while the hour hand has a "heart" near the end; 12 large marks and 48 small ones make a more distinguishable dial than one with figures; and the smaller the figures are the better, as they only tend to obscure the hands.

Striking Clocks.

There are two kinds of striking work used in clocks. The older of them, which is still used in most foreign clocks, and in turret clocks in England also, will not allow the striking of any hour to be either omitted or repeated, without making the next hour strike wrong; whereas, in that which is used in all English house clocks, the number of blows to be struck depends merely on the position of a wheel attached to the going part; and therefore the striking of any hour may be omitted or repeated without deranging the following ones. In turret clocks there is no occasion for the repeating movement; and for the purpose of describing the other, which is called the *locking-plate* movement, we may as well refer to fig. 22, which is the front view of a large clock, striking both hours and quarters on this plan. In the hour part (on the left), you observe a bent lever BAH, called the "lifting-piece," of which the end H has just been left off by the snail on the hour-wheel 40 of the going part; and at the other end there are two stops on the back side of the lever, one behind, and rather below the other; and against the upper one a pin in the end of a short lever 9 B, which is fixed to the arbor of the fly, is now resting, and thereby the train is stopped from running, and the clock from striking any more. The stops are shown on the quarter lifting-piece in the figure (27) of the Westminster clock. We omit the description of the action of the wheels, because it is evident enough. At D may be seen a piece projecting from the lever AB, and dropping into a notch in the wheel 78. That wheel is the locking-wheel or locking-plate; and it has in reality notches such as D all round it, at distances 2, 3, up to 12, from any given point in the circumference, which may be considered as marked off into 78 spaces, that being the number of blows struck in 12 hours. These notches are shown in the locking-plate of the quarter part in fig. 22, but not in the hour part, for want of size to show them distinctly.

When the arm AB of the lifting-piece is raised by the snail depressing the other end H, a few minutes before the hour, the fly-pin slips past the first of the stops at B, but is stopped by the second and lower one, until the lever is dropped again exactly at the hour. Thus the pin can pass, and would go once round, allowing the train to go on a little; but before it has got once round, A B has been lifted again high enough to carry both stops out of the way of the fly-pin, by means of the cylinder with two slices taken off it, which is set on the arbor of the wheel 90, and on which the end of the lifting-piece rests, with a small roller to diminish the friction. If the clock has only to strike one, the lifting-piece will then drop again, and the fly-pin will be caught by the first stop, having made (according to the numbers of the teeth given in fig. 22) 5 turns. But if it has to strike more, the locking-wheel comes into action. That wheel turns with the train, being either driven by pinion 20 on the arbor of the great wheel, or by a gathering pallet on the arbor of the second wheel, like G in fig. 15; and when once the lifting-piece is lifted out of a notch in the locking-plate, it cannot fall again until another notch has come under the bit D; and as the distance of the notches is proportioned to the hours, the locking-plate thus determines the number of blows struck. It may occur to the reader, that the cylinder 10 and roller are not really wanted, and that the locking-plate would do as well without; and sometimes clocks are so made, but it is not safe, for the motion of the locking-plate is so slow, that unless everything is very carefully adjusted and no *shake* left, the corner of the notch may not have got fairly under the bit D before the fly has got once round, and then the lifting-piece will drop before the clock can strike at all; or it may hold on too long and strike 13, as St Paul's clock did once at midnight, when it was heard at Windsor by a sentinel.

Small French clocks, which generally have the striking part made in this way, very commonly strike the half hours also, by having a wide slit, like that for one o'clock, in the locking-plate at every hour. But such clocks are unfit for any place except a room, as they strike one three times between 12 and 2, and accordingly turret clocks, or even large house clocks, are never made so. Sir E. Beckett has lately introduced the plan of making turret clocks strike one at all the half hours except 12½ and 1½, so that any striking of one that is heard between 11½ and 2½ must needs be one o'clock. This is done by having a 12-hour wheel driven by the going part, either continuously or by a gathering pallet moving that wheel only once an hour, and it has two high steps which come under another piece like D in the lifting detent a little before 12½ and 1½ so as to prevent it falling when let off by the snail. In the English or rack striking movement, to be presently described, the same thing may be done by a kind of star wheel with flat ends to the rays, attached to the 12-hour snail, which will let the rack fall enough to strike one at every half hour, but with two longer rays to prevent it falling at all at 12½ and 1½; or it would be better to let those rays, by means of an intervening lever, prevent the lifting piece from falling, as that would involve less friction of the tail of the rack.

In all cases the locking-plate must be considered as divided into as many parts as the number of blows to be struck in 12 hours, *i.e.*, 78, 90, or 88, according as half hours are or are not struck; and it must have the same number of teeth, driven by a pinion on the striking wheel arbor of as many teeth as the striking cams, or in the same ratio.

Fig. 15 is a front view of a common English house clock with the face taken off, showing the repeating or rack striking movement. Here, as in fig. 1, M is the hour-wheel, on the pipe of which the minute-hand is set, N the reversed hour-wheel, and *n* its pinion, driving the 12-hour wheel H, on whose socket is fixed what is called the snail Y, which belongs to the striking work exclusively. The hammer is raised by the eight pins in the rim of the second wheel in the striking train, in the manner which is obvious.

The hammer does not quite touch the bell, as it would jar in striking if it did, and prevent the full sound; and if you observe the form of the hammer-shank at the arbor where the spring S acts upon it, you will see that the spring both drives the hammer against the bell when the tail T is raised, and also checks it just before it reaches the bell, and so the blow on the bell is given by the hammer having acquired momentum enough to go a little farther than its place of rest. Sometimes two springs are used, one for impelling the hammer, and the other for checking it. A piece of vulcanized India-rubber, tied round the pillar just where the hammer-shank nearly touches it, forms as good a check spring as anything. But nothing will check the chattering of a heavy hammer, except making it lean forward so as to act, partially at least, by its weight. The pinion of the striking-wheel generally has eight leaves, the same number as the pins; and as a clock strikes 78 blows in 12 hours, the great wheel will turn in that time if it has 78 teeth instead of 96, which the great wheel of the going part has for a centre pinion of eight. The striking-wheel drives the wheel above it once round for each blow, and that wheel drives a fourth (in which you observe a single pin P), six, or any other integral number of turns, for one turn of its own, and that drives a fan-fly to moderate the velocity of the train by the resistance of the air, an expedient at least as old as De Vick's clock in 1370.

The wheel N is so adjusted that, within a few minutes of the hour, the pin in it raises the *lifting-piece* LONF so far that that piece lifts the click C out of the teeth of the *rack* BKRV, which immediately falls back (helped by a

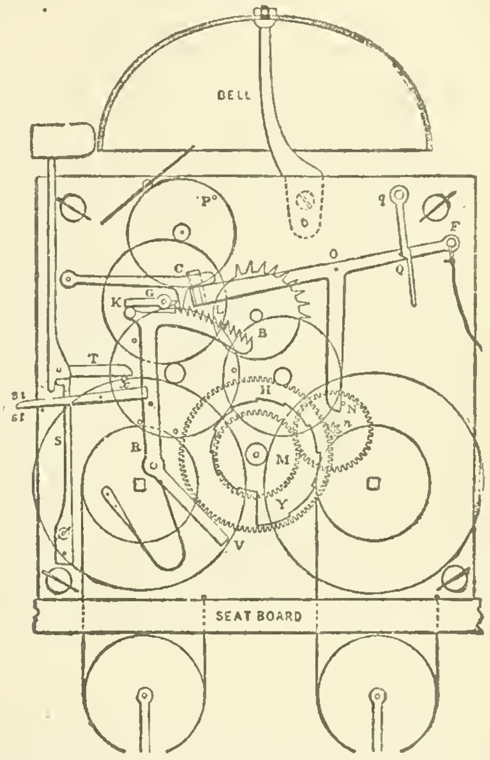

FIG. 15.—Front view of Common English House Clock.

spring near the bottom) as far as its tail V can go by reason of the snail Y, against which it falls; and it is so arranged that the number of teeth which pass the click is proportionate to the depth of the snail; and as there is one step in the snail for each hour, and it goes round with the hour-hand, the rack always drops just as many teeth as the number of the hour to be struck. This drop makes the noise of "giving warning." But the clock is not yet ready to strike till the lifting piece has fallen again; for, as soon as the rack was let off the tail of the thing called the *gathering pallet* G, on the prolonged arbor of the third wheel, was enabled to pass the pin K of the rack on which it was pressing before, and the striking train began to move; but before the fourth wheel had got half round, its pin P was caught by the end of the lifting-piece, which is bent back and goes through a hole in the plate, and when raised stands in the way of the pin P, so that the train cannot go on till the lifting-piece drops, which it does exactly at the hour, by the pin N then slipping past it. Then the train is free; the striking wheel begins to lift the hammer, and the gathering pallet gathers up the rack, a tooth for each blow, until it has returned to the place at which the pallet is stopped by the pin K coming under it. In this figure the lifting-piece is prolonged to F, where there is a string hung to it, as this is the proper place for such a string when it is wanted for the purpose of learning the hour in the dark, and not (as it is generally put) on the click C; for if it is put there and you hold the string a little too long, the clock will strike too many; and if the string accidentally sticks in the case, it will go on striking till it is run down; neither of which things can happen when the string is put on the lifting-piece.

The snail is sometimes set on a separate stud with the apparatus called a *star-wheel* and *jumper;* but as this only increases the cost without any advantage that we can see, we omit any further reference to it. On the left side of the frame we have placed a lever *x*, with the letters *st* below it, and *si* above. If it is pushed up to *si*, the other end will come against a pin in the rack, and prevent it from falling, and will thus make the clock silent; and this is much more simple than the old-fashioned "strike and silent" apparatus, which we shall therefore not describe, especially as it is seldom used now.

If the clock is required to strike quarters, a third "part" or train of wheels is added on the right hand of the going part; and its general construction is the same as the hour-striking part; only there are two more bells, and two hammers so placed that one is raised a little after the other. If there are more quarter-bells than two, the hammers are generally raised by a chime-barrel, which is merely a cylinder set on the arbor of the striking-wheel (in that case generally the third in the train), with short pins stuck into it in the proper places to raise the hammers in the order required for the tune of the chimes. The quarters are usually made to let off the hour, and this connection may be made in two ways. If the chimes are different in tune for each quarter, and not merely the same tune repeated two, three, and four times, the repetition movement must not be used for them, as it would throw the tunes into confusion, but the old locking-plate movement, as in turret clocks; and therefore, if we conceive the hour lifting-piece connected with the quarter locking-plate, as it is with the wheel N, in fig. 15, it is evident that the pin will discharge the hour striking part as the fourth quarter finishes.

But where the repetition movement is required for the quarters, the matter is not quite so simple. The principle of it may shortly be described thus. The quarters themselves have a rack and snail, &c., just like the hours, except that the snail is fixed on one of the hour-wheels M or N, instead of on the twelve-hour wheel, and has only four steps in it. Now suppose the quarter-rack to be so placed that when it falls for the fourth quarter (its greatest drop), it falls against the hour lifting-piece somewhere between O and N, so as to raise it and the click C. Then the pin Q will be caught by the click Q*q*, and so the lifting-piece will remain up until all the teeth of the quarter-rack are gathered up; and as that is done, it may be made to disengage the click Q*q*, and so complete the letting off the hour striking part. This click Q*q* has no existence except where there are quarters.

These quarter clocks are sometimes made so as only to strike the quarters at the time when a string is pulled—as by a person in bed, just like repeating watches, which are rarely made now, on account of the difficulty of keeping in order such a complicated machine in such a small space. In this case, the act of pulling the string to make the clock strike winds up the quarter-barrel, which is that of a spring clock (not yet described), as far as it is allowed to be wound up by the position of a snail on the hour-wheel against which a lever is pulled, just as the tail of the common striking-rack falls against the snail on the twelve-hour wheel; and it is easy to see that the number of blows struck by the two quarter hammers may thus be made to depend upon the extent to which the spring that drives the train is wound up; and it may even be made to indicate half-quarters; for instance, if the snail has eight steps in it, the seventh of them may be just deep enough to let the two hammers strike three times, and the first of them once more, which would indicate 7½ minutes to the hour. It is generally so arranged that the hour is struck first, and the quarters afterwards.

Alarums.

In connection with these bedroom clocks we ought to mention *alarums.* Perhaps the best illustration of the mode of striking an alarum is to refer to either of the recoil escapements (figs. 3 and 4). If you suppose a short hammer instead of a long pendulum attached to the axis of the pallets, and the wheel to be driven with sufficient force, it will evidently swing the hammer rapidly backwards and forwards; and the position and length of the hammer-head may be so adjusted as to strike a bell inside, first on one side and then on the other. Then as to the mode of letting off the alarum at the time required; if it was always to be let off at the same time, you would only have to set a pin in the twelve-hour wheel at the proper place to raise the lifting-piece which lets off the alarum at that time. But as you want it to be capable of alteration, this discharging pin must be set in another wheel (without teeth), which rides with a friction-spring on the socket of the twelve-hour wheel, with a small movable dial attached to it, having figures so arranged with reference to the pin that whatever figure is made to come to a small pointer set as a tail to the hour hand, the alarum shall be let off at that hour. The letting off does not require the same apparatus as a common striking part, because an alarum has not to strike a definite number of blows, but to go on till it is run down; and therefore the lifting-piece is nothing but a lever with a stop or hook upon it, which, when it is dropped, takes hold of one of the alarum wheels, and lets them go while it is raised high enough to disengage it. You must of course not wind up an alarum till within twelve hours of the time when it is wanted to go off.

The *watchman's* or *tell-tale* clock may be seen in one of the lobbies of the House of Commons, and in prisons, and some other places where they want to make sure of a watchman being on the spot and awake all the night; it is a clock with a set of spikes, generally 48 or 96, sticking out all round the dial, and a handle somewhere in the case, by pulling which you can press in that one of the spikes which is opposite to it, or to some lever connected with it, for a few minutes; and it will be observed, that this wheel of spikes is carried round with the hour-hand, which in these clocks is generally a twenty-four hour one. It is evident that every spike which is seen still sticking out in the morning indicates that at the particular time to which that spike belongs the watchman was not there to push it in—or at any rate, that he did not; and hence its name. At some other part of their circuit, the inner ends of the pins are carried over a roller or an inclined plane which pushes them out again ready for business the next night.

Spring Clocks.

Hitherto we have supposed all clocks to be kept going by a weight. But, as is well known, many of them are driven by a spring coiled up in a barrel. In this respect they differ nothing from watches, and therefore for consideration of the construction of parts belonging to the spring reference is made to the article Watches. It may, however, be mentioned here that the earliest form in which a spring seems to have been used was not that of a spiral ribbon of steel rolled up, but a straight stiff spring held fast to the clock frame at one end, and a string from the other end going round the barrel, which was wound up; but such a spring would have a very small range. Spring clocks are generally resorted to for the purpose of saving length; for as clocks are generally made in England, it is impossible to make a weight-clock capable of going a week, without either a case nearly 4 feet high, or else the weights so heavy as to produce a great pressure and friction on the arbor of the great wheel. But this arises from nothing but the heaviness of the wheels and the badness of the pinions used in most English clocks, as is amply proved by the fact that the American and Austrian clocks go a week with smaller weights and much less fall for them than the English ones, and the American ones with no assistance from fine workmanship for the purpose of diminishing friction, as they are remarkable for their want of what is called "finish" in the machinery, on which so much time and money is wasted in English clock-work.

All the ornamental French clocks, and all the short "dials," as those clocks are called which look no larger than the dial, or very little, and many of the American clocks, are made with springs. Indeed we might omit the word "French" after "ornamental;" for the manufacture of ornamental clocks has practically ceased in England, and we are losing more of all branches of the horological trade yearly, as we are unable, *i.e.*, our workmen do not choose, to compete with the cheaper labour of the Continent, or with the much more systematic manufacture of clocks and watches by machinery in America than exists here, though labour there is much dearer. It is true that most of the American clocks are very bad, indeed no better than the old-fashioned Dutch clocks (really German) made most ingeniously of wood and wire, besides the wheels. But some better American ones are also made now, and they will no doubt improve as their machine-made watches have done. Though this has been going on now for 30 years and more, no steps appear to have been taken to establish anything of the kind in this country, except that watch "movements," which means only the wheels set in the frame, are to a certain extent made by machinery in Lancashire and Coventry for the trade, who finish them in London and elsewhere. That is the real meaning of the advertisements of "machine-made watches" here.

The French clocks have also been greatly improved within the same time, and are now, at least some of them, quite different both in construction and execution from the old-fashioned French drawing-room clock which generally goes worse than the cheapest "Dutchman," and is nearly always striking wrong, because they have the locking-plate striking work, which if once let to strike wrong, either by altering the hands or letting it run down, cannot be set right again except by striking the hours all round, which few people know how to do, even if they can get their fingers in behind the clock to do it. The Americans have a slight wire hanging down a little below the dial which you can push up and so make the clock strike. All locking-plate clocks ought to have a similar provision.

There is not much use in having clocks to go more than a little over eight days (to allow the possible forgetting of a day), as a week is the easiest period to remember. The French spring-clocks generally go a fortnight, but most people wind them up weekly. Occasionally English clocks are made to go a month by adding another wheel; and even a year by adding two. But in the latter case it is better to have two barrels and great wheels acting on opposite sides of a very strong pinion between them, as it both reduces the strain on the teeth and the friction of the pivot of that pinion. Such clocks sometimes have a 5 feet or 1¼ sec. pendulum, as the case must be a tall one. The great thing is to make the scape-wheel light, and even then you can never get more than a small arc of vibration, which is undesirable for the reason given above, and such a long train is peculiarly sensitive to friction.

In the American clocks the pinions are all of the kind called *lantern pinions*, which have their leaves made only of bits of wire set round the axis in two collars; and, oddly enough, they are the oldest form of pinion, as well as the best, acting with the least friction, and requiring the least accuracy in the wheels, but now universally disused in all English and French house clocks. The American clocks prove that they are not too expensive to be used with advantage when properly made; although, so long as there are no *manufactories* of clocks here as there are in America, it may be cheaper to make pinions in the slovenly way of cutting off all the ribs of a piece of pinion wire, so as to reduce it to a pinion a quarter of an inch wide, and an arbor 2 or 3 inches long. On the whole, the common English house clocks, so far from having improved with the general progress of machinery, are worse than they were fifty years ago, and at the same time are of such a price that they are being fast driven out of the market by the American plain clocks and by the French and German ornamental ones.

Clocks have been contrived to wind themselves up by the alternate expansion and contraction of mercury and other fluids, under variations of temperature. Wind-mill clocks might be made still more easily, the wind winding up a weight occasionally. Water-clocks have also been made,—not on the clepsydra principle, where the flow of the water determined the time very inaccurately; but the water is merely the weight, flowing from a tap into a hollow horizontal axis, and thence by branches into buckets, which empty themselves as they pass the lowest point of the circle in which they move, or flowing directly into buckets, so emptying themselves. But the slopping of the water, and the rusting of any parts made of iron, and the cost of the water itself always running, destroy all chance of such things coming into use.

Electrical Clocks.

It should be understood that under this term two, or we may say three, very different things are comprehended. The first is a mere clock movement, *i.e.*, the works of a clock without either weight or pendulum, which is kept going by electrical connection with some other clock of any kind (these ought to be called *electrical dials*, not clocks); the second is a clock with a weight, but with the escapement worked by electrical connection with another clock instead of by a pendulum; and the third alone are truly *electrical clocks*, the motive power being electricity instead of gravity; for although they have a pendulum, which of course swings by the action of gravity, yet the requisite impulse for maintaining its vibrations against friction and resistance of the air is supplied by a galvanic battery, instead of by the winding up of a weight.

If you take the weight off a common recoil escapement clock, and work the pallets backward and forwards by hand, you will drive the hands round, only the wrong way; consequently, if the escapement is reversed, and the pallets are driven by magnets alternatively made and unmade, by the well-known method of sending an electrical current through a wire coil set round a bar of soft iron, the contact being made at every beat of the pendulum of a standard clock, the clock without the weight will evidently keep exact time with the standard clock; and the only question is as to the best mode of making the contact, which is not so easy a matter as it appears to be, and though various plans apparently succeeded for a time, and were mechanically perfect, not one has succeeded permanently; *i.e.*, the contact sometimes fails to produce the current of sufficient strength to lift the weight or spring on which the driving of the subordinate clock depends. It is therefore unnecessary to repeat the description of the various contrivances for this purpose by Wheatstone and others.

The first person who succeeded in making one clock regulate or govern others by electricity, Mr R. L. Jones, accordingly abandoned the idea of electrical driving of one clock by another; and instead of making the electrical connection with a standard clock (whether itself an electrical one or not) drive the others, he makes it simply let the pallets or the pendulum of the subordinate clock, driven by a weight or spring, be influenced by attraction at every beat of the standard clock: and, by way of helping it, the pallets are made what we called half-dead in describing the dead escapement, except that they have no impulse faces, but the dead faces have just so much slope that they would overcome their own friction, and escape of themselves under the pressure of the clock train, except while they are held by the magnet, which is formed at every beat of the standard clock, or at every half-minute contact, if it is intended to work the dials by half-minute jumps. This plan has been extensively used for regulating distant clocks from Greenwich Observatory.

The first electrical *clocks*, in the proper sense of the term, were invented by Mr Bain in 1840, who availed himself

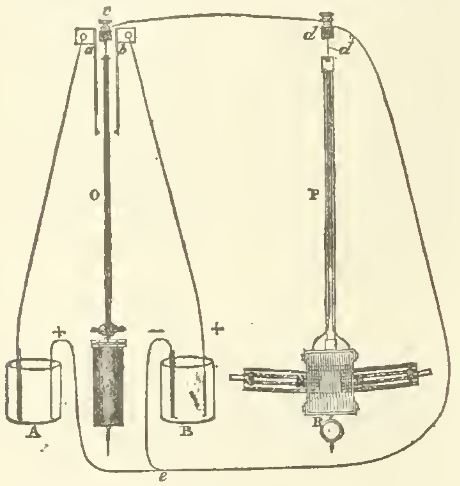

Fig. 16.—Bain's Pendulum.

of the discovery of Oersted that a coil of insulated wire in the form of a hollow cylinder is attracted in one direction or the other by a permanent magnet within the coil, not touching it, when the ends of the coil are connected with the poles of a battery; and if the connection is reversed, or the poles changed, so that the current at one time goes one way through the coil from the − or copper plate to the + or zinc plate, and at other times the other way, the direction of the attraction is reversed. Mr Bain made the bob of his pendulum of such a coil enclosed in a brass case so that it looked like a hollow brass cylinder lying horizontal and moving in the direction of its own axis, and in that axis stood the ends of two permanent magnets with the north poles pointed at each other and nearly touching, as in the right hand part of fig. 16. The pendulum pushed a small sliding bar backwards and forwards so as to reverse the current through the coil as the pendulum passed the middle of the arc, and so caused each magnet in turn to attract the bob. But this also failed practically, and especially in time-keeping, as might have been expected, from the friction and varying resistance of the bar to the motion of the pendulum, and in the attractions.

Mr Ritchie of Edinburgh, however, has combined the principle of Bain's and Jones's clocks in a manner which is testified to be completely successful in enabling one standard clock to control and keep going any number of subordinate ones, which do not require winding up as Jones's do, but are driven entirely by their pendulums. This differs from Wheatstone's plan in this, that his subordinate clocks had no pendulum swinging naturally and only wanting its vibrations helping a little, but the pallets had to be made to vibrate solely by the electrical force. The figures are taken from Mr Ritchie's paper read before the Royal Scottish Society of Arts in 1873. The controlled pendulum P is that just now described as Bain's (seen in fig. 17 the other way, across the plane of vibration); the rod and spring are double, and the wire *cd* is connected with one spring and rod (say the front one) and the wire *d'e* with the other; so that the current has to pass down one spring and one rod and through the coil in the bob and up the other spring. The other pendulum O of the normal or standard clock is a common one, except that it touches two slight contact springs *a*, *b* alternately, and so closes the circuit on one side and leaves it broken on the other. When that pendulum touches *a* the B battery does nothing, and the − current from the battery A passes by *a* to *c* and *d* and down the *d* spring and rod and up through *d'* to *e* and back again to + of A. But when the standard pendulum O touches *b* the A battery does nothing, and the current from − to + of the B battery goes the other way, through the controlled pendulum and its coil. The two fixed magnets SN, NS consequently attract the coil and bob each way alternately. And even if the current is occasionally weak, the natural swing of the pendulum will keep it going for a short time with force enough to drive its clock through a reversed escapement; and further, if that pendulum is naturally a little too fast or too slow the attraction from the standard pendulums will retard or accelerate it. In practice, however, it is found better not to make the contact by springs, which, however light, disturb the pendulum a little, but by a wheel in the train making and breaking contact at every beat; and if the clock has a gravity escapement there is no danger of this friction affecting the pendulum at all.

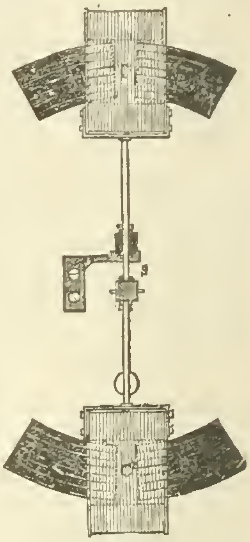

Fig. 17.—Ritchie's Pendulum.

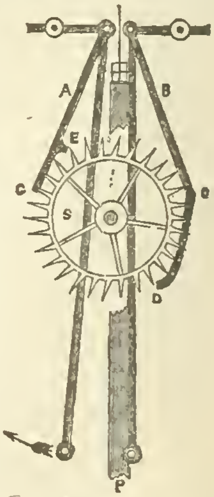

Fig. 18.—Ritchie's Elliptical Escapement.

In order to get the machinery into a smaller compass than a 39 inches pendulum requires, Mr Ritchie uses a short and slow pendulum with two bobs, one above and the other below the suspension, as shewn in fig. 17. Such a pendulum, like a common scale-beam, may be made to vibrate as slow as you like by bringing the suspension nearer to the centre of gravity of the whole mass. But they are quite unfit for independent clock pendulums, having very little regulating power, or what we may call force of vibration. He applies magnets to both the bobs, so as to double the electrical force. Fig. 17 is the section across the plane of vibration.

Fig. 18 shows the kind of reversed escapement, or "propelment," used with these short and slow pendulums. The pendulum here is returning from the extreme right, and has just deposited the right hand pallet BCD with its end D pressing on a tooth of the scape-wheel, but unable to turn it because another tooth is held by the stop G on the left pallet. As soon as the pendulum lifts that pallet the weight of the other pallet turns the wheel, until a tooth falls against the stop C. When the pendulum returns from the left the left pallet presses on a tooth at E but cannot turn the wheel because it is yet held by C, until that is released. In order to prevent the hands being driven back by wind where they are exposed to it, a click is added to the teeth. The wind cannot drive the hands forward by reason of the stops C, G.

Church and Turret Clocks

Seeing that a clock—at least the going part of it—is a machine in which the only work to be done is the overcoming of its own friction and the resistance of the air, it is evident, that when the friction and resistance are much increased, it may become necessary to resort to expedients for neutralizing their effects which are not required in a smaller machine with less friction. In a turret clock the friction is enormously increased by the great weight of all the parts; and the resistance of the wind, and sometimes snow, to the motion of the hands, further aggravates the difficulty of maintaining a constant force on the pendulum; and besides that, there is the exposure of the clock to the dirt and dust which are always found in towers, and of the oil to a temperature which nearly or quite freezes it all through the usual cold of winter. This last circumstance alone will generally make the arc of the pendulum at least half a degree more in summer than in winter; and inasmuch as the time is materially affected by the force which arrives at the pendulum, as well as the friction on the pallets when it does arrive there, it is evidently impossible for any turret clock of the ordinary construction, especially with large dials, to keep any constant rate through the various changes of temperature, weather, and dirt, to which it is exposed.

Within the last twenty years all the best clockmakers have accordingly adopted the four-legged or three-legged gravity escapement for turret clocks above the smallest size; though inferior ones still persist in using the dead escapement, which is incapable of maintaining a constant rate under a variable state of friction, as has been shown before. When the Astronomer Royal in 1844 laid down the condition for the Westminster clock that it was not to vary more than a second a day, the London Company of Clockmakers pronounced it impossible, and the late Mr Vulliamy, who had been for many years the best maker of large clocks, refused to tender for it at those terms. The introduction of the gravity escapement enabled the largest and coarsest looking clocks with cast-iron wheels and pinions to go for long periods with a variation much nearer a second a week than a second a day. And the consequence was that the price for large clocks was reduced to about one-third of what it used to be for an article inferior in performance though more showy in appearance.

Another great alteration, made by the French clockmakers before ours, was in the shape and construction of the frame. The old form of turret clock-frame was that of a large iron cage, of which some of the vertical bars take off, and are fitted with brass bushes for the pivots of the wheels to run in; and the wheels of each train, *i.e.*, the striking, the going, and the quarter trains, have their pivots all in the vertical bar belonging to that part. Occasionally they advanced so far as to make the bushes movable, *i.e.*, fixed with screws instead of rivetted in, so that one wheel may be taken out without the others. This cage generally stood upon a wooden stool on the floor of the clock room. The French clockmakers long ago saw the objections to this kind of arrangement, and adopted the plan of a horizontal frame or bed, cast all in one piece, and with such smaller frames or cocks set upon it as might be required for such of the wheels as could not be conveniently got on the same level. The accompanying sketch (fig. 19) of the

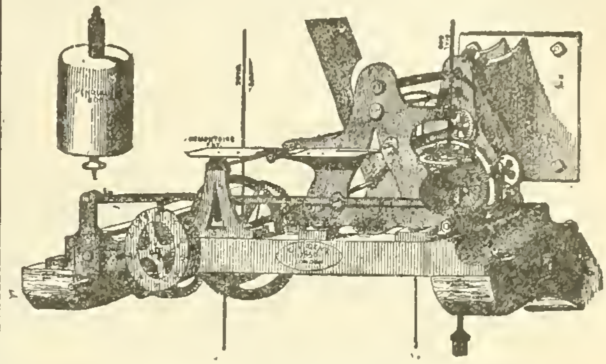

Fig. 19.—Clock at Meanwood Church, Leeds.

clock of Meanwood church, near Leeds, one of the first on that plan, will sufficiently explain it. All the wheels of the going part, except the great wheel, are set in a separate frame called the movement frame, which is complete in itself, and light enough to take off and carry away entire, so that any cleaning or repairs required in the most delicate part of the work can be done in the clock factory, and the great wheel, barrel, and rope need never be disturbed at all. Even this movement-frame is now dispensed with; but we will reserve the description of the still more simple kind of frame in which *all* the wheels lie on or under the great horizontal bed, until we have described train remontoires.

Train Remontoires.

Although the importance of these is lessened by the invention of an effective gravity escapement, they are still occasionally used, and are an essential part of the theory of clockmaking. It was long ago perceived that all the variations of force, except friction of the pallets, might be cut off by making the force of the scape-wheel depend on a small weight or spring wound up at short intervals by the great clock weight and the train of wheels.

This also has the advantage of giving a sudden and visible motion to the minute hand at those intervals, say of half a minute, when the remontoire work is let off, so that time may be taken from the minute hand of a large public clock as exactly as from the seconds hand of an astronomical clock; and besides that, greater accuracy may be obtained in the letting off of the striking part. We believe the first maker of a large clock with a train remontoire was Mr Thomas Reid of Edinburgh, who wrote the article on clocks in the first edition of this *Encyclopædia*, which was afterwards expanded into a well-known book, in which his remontoire was described. The scape-wheel was driven by a small weight hung by a Huyghens's endless chain, of which one of the pulleys was fixed to the arbor, and the other rode upon the arbor, with the pinion attached to it, and the pinion was driven and the weight wound up by the wheel below (which we will call the third wheel), as follows. Assuming the scape-wheel to turn in a minute, its arbor has a notch cut half through it on opposite sides in two places near to each other; on the arbor of the wheel, which turns in ten minutes, suppose, there is another wheel with 20 spikes sticking out of its rim, but alternately in two different planes, so that one set of spikes can only pass through one of the notches in the scape-wheel arbor, and the other set only through the other. Whenever then the scape-wheel completes a half turn, one spike is let go, and the third wheel is able to move, and with it the whole clock-train and the hands, until the next spike of the other set is stopped by the scape-wheel arbor; at the same time the pinion on that arbor is turned half round, winding up the remontoire weight, but without taking its pressure off the scape-wheel. Reid says that, so long as this apparatus was kept in good order, the clock went better than it did after it was removed in consequence of its getting out of order from the constant banging of the spikes against the arbor.

The Royal Exchange clock was at first made in 1844 on the same principle, except that, instead of the endless chain, an internal wheel was used, with the spikes set on it externally, which is one of the modes by which an occasional secondary motion may be given to a wheel without disturbing its primary and regular motion. A drawing of the original Exchange clock remontoire is given in the *Rudimentary Treatise on Clocks;* but for the reasons which will appear presently, it need not be repeated here, especially as the following is a more simple arrangement of a gravity train remontoire, much more frequently used in principle. Let E in fig. 20 be the scape-wheel turning in a

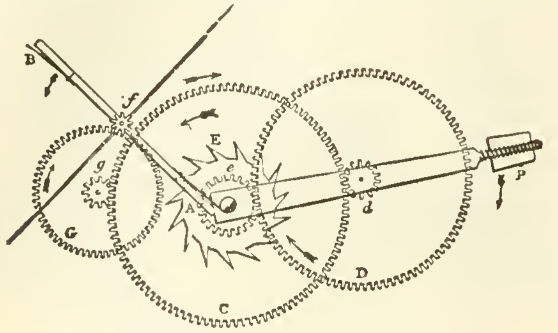

FIG. 20.—Gravity Train Remontoire.

minute, and *e* its pinion, which is driven by the wheel D having a pinion *d* driven by the wheel C, which we may suppose to turn in an hour. The arbors of the scape-wheel and hour-wheel are distinct, their pivots meeting in a bush fixed somewhere between the wheels. The pivots of the wheel D are set in the frame AP, which rides on the arbors of the hour-wheel and scape-wheel, or on another short arbor between them. The hour-wheel also drives another wheel G, which again drives the pinion *f* on the arbor which carries the two arms *f* A, *f* B; and on the same arbor is set a fly with a ratchet, like a common striking fly, and the numbers of the teeth are so arranged that the fly will turn once for each turn of the scape-wheel. The ends of the remontoire arms *f* A, *f* B are capable of alternately passing the notches cut half through the arbor of the scape-wheel, as those notches successively come into the proper position at the end of every half minute; as soon as that happens the hour-wheel raises the movable wheel D and its frame through a small angle; but nevertheless, that wheel keeps pressing on the scape-wheel as if it were not moving, the point of contact of the wheel C and the pinion *d* being the fulcrum or centre of motion of the lever A *d* P. It will be observed that the remontoire arms *f* A, *f* B have springs set on them to diminish the blow on the scape-wheel arbor, as it is desirable not to have the fly so large as to make the motion of the train, and consequently of the hands, too slow to be distinct. For the same reason it is not desirable to drive the fly by an endless screw, as was done in most of the French clocks on this principle in the 1851 Exhibition. There is also an enormous loss of force by friction in driving an endless screw, and consequently considerable risk of the clock stopping either from cold or from wasting of the oil.

Another kind of remontoire is on the principle of one bevelled wheel lying between two others at right angles to it. The first of the bevelled wheels is driven by the train, and the third is fixed to the arbor of the scape-wheel; and the intermediate bevelled wheel, of any size, rides on its arbor at right angles to the other two arbors which are in the same line. The scape-wheel will evidently turn with the same average velocity as the first bevelled wheel, though the intermediate one may move up and down at intervals. The transverse arbor which carries it is let off and lifted a little at half-minute intervals, as in the remontoire just now described; and it gradually works down as the scape-wheel turns under its pressure, until it is freed again and lifted by the clock train.

In all these gravity remontoires, however, it must have been observed that we only get rid of the friction of the heavy parts of the train and the dial-work, and that the scape-wheel is still subject to the friction of the remontoire wheels, which, though much less than the other, is still something considerable. And accordingly, attempts have frequently been made to drive the scape-wheel by a spiral spring, like the mainspring of a watch. One of these was described in the 7th edition of this *Encyclopædia;* and Sir G. Airy, a few years ago, invented another on the same principle, of which two or three specimens were made. But it was found, and indeed it ought to have been foreseen, that these contrivances were all defective in the mode of attaching the spring, by making another wheel or pinion ride on the arbor of the scape-wheel, which produced a very mischievous friction, and so only increased the expense of the clock without any corresponding advantage; and the consequence was that spring remontoires, and remontoires in general, had come to be regarded as a mere delusion. It has however now been fully proved that they are not so; for, by a very simple alteration of the previous plans, a spiral spring remontoire may be made to act with absolutely no friction, except that of the scape-wheel pivots, and the letting-off springs A, B, in the last drawing. The Meanwood clock (fig. 17) was the first of this kind; but it will be necessary to give a separate view of the remontoire work.

In the next figure (21), A, B, D, E, *e*, *f* are the same things as in fig. 20. But *e*, the scape-wheel pinion, is no longer fixed to the arbor, nor does it ride on the arbor, as had been the case in all the previous spring remontoires, thereby producing probably more friction than was saved in other respects; but it rides on a stud *k*, which is set in the clock-frame. On the face of the pinion is a plate, of which the only use is to carry a pin *h* (and consequently its shape is immaterial), and in front of the plate is set a bush *b*, with a hole through it, of which half is occupied by the end of the stud *k* to which the bush is fixed by a small pin, and the other half is the pivot-hole for the scape-wheel arbor. On the arbor is set the remontoire spring *s* (a moderate-sized musical-box spring is generally used) of which the outer end is bent into a loop to take hold of the pin *h*. In fact, there are two pins at *h*, one a little behind the other, to keep the coils of the spring from touching each other. Now, it is evident that the spring may be wound up half or a quarter of a turn at the proper intervals without taking the force off the scape-wheel, and also without affecting it by any friction whatever. When the scape-wheel turns in a minute, the letting-off would be done as before described, by a couple of notches in the scape-wheel arbor, through which the spikes A, B, as in fig. 20, would pass alternately. But in clocks with only three wheels in the train it is best to make the scape-wheel turn in two minutes, and consequently you would want four notches and four remontoire arms, and the fly would only make a quarter of a turn. And

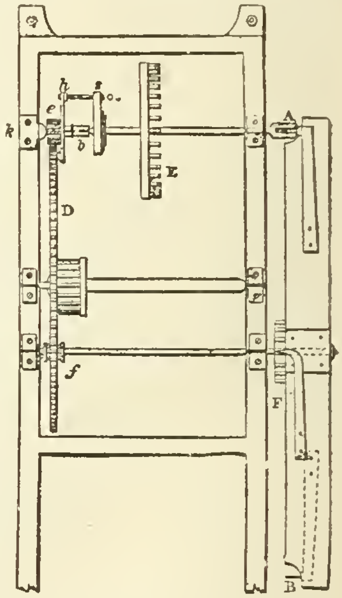

Fig. 21.

therefore Sir E. Beckett, who invented this remontoire, made the following provision for diminishing the friction of the letting-off work. The fly pinion *f* has only half the number of teeth of the scape-wheel pinion, being a lantern pinion of 7 or 8, while the other is a leaved pinion of 14 or 16, and therefore the same wheel D will properly drive both, as will be seen hereafter. The scape-wheel arbor ends in a cylinder about $\frac{3}{4}$ inch in diameter, with two notches at right angles cut in its face, one of them narrow and deep, and the other broad and shallow, so that a long and thin pin B can pass only through one, and a broad and short pin A through the other. Consequently, at each quarter of a turn of the scape-wheel, the remontoire fly, on which the pins A, B are set on springs, as in fig. 20, can turn half round. It is set on its arbor *f* by a square ratchet and click, which enables you to adjust the spring to the requisite tension to obtain the proper vibration of the pendulum. A better construction, afterwards introduced, is to make the fly separate from the letting-off arms, whereby the blow on the cylinder is diminished, the fly being allowed to go on as in the gravity escapement. The performance of this is so much more satisfactory than that of the gravity remontoires, that Mr Dent altered that of the Royal Exchange to a spring one in 1854, which had the effect of reducing the clock-weight by one-third, besides improving the rate of going. It should be observed, however, that even a spring remontoire requires a larger weight than the same clock without one; but as none of that additional force reaches the pendulum, that is of no consequence. The variation of force of the remontoire spring from temperature, as it only affects the pendulum through the medium of the dead escapement, is far too small to produce any appreciable effect; and it is found that clocks of this kind, with a compensated pendulum 8 feet long, and of about 2 cwt., will not vary above a second a month, if the pallets are kept clean and well oiled. No turret clock without either a train remontoire or a gravity escapement will approach that decree of accuracy. The King's Cross clock, which was the first of this kind, went with a variation of about a second in three weeks in the 1851 Exhibition, and has sometimes gone for two months without any discoverable error, though it wants the jewelled pallets which the Exchange clock has. But these clocks require more care than gravity escapement ones, and are certain to be spoilt as soon as they get into ignorant or careless hands; and consequently the gravity ones have superseded them.

The introduction of this remontoire led to another very important alteration in the construction of large clocks. Hitherto it had always been considered necessary, with a view to diminish the friction as far as possible, to make the wheels of brass or gun-metal, with the teeth cut in an engine. The French clockmakers had begun to use cast-iron striking parts, and cast-iron wheels had been occasionally used in the going part of inferior clocks for the sake of cheapness; but they had never been used in any clock making pretensions to accuracy before the one just mentioned. In consequence of the success of that, it was determined by the astronomer royal and Mr Denison, who were jointly consulted by the Board of Works about the great Westminster clock in 1852, to alter the original requisition for gun-metal wheels there to cast-iron. Some persons expressed their apprehension of iron wheels rusting; but nothing can be more unfounded, for the non-acting surfaces are always painted, and the acting surfaces oiled. A remarkable proof of the folly of the clockmakers' denunciations of the cast-iron wheels was afforded at the Royal Exchange the next year. In consequence of the bad ventilation of the clock-room, together with the effects of the London atmosphere, some thin parts of the brass work had become so much corroded that they had to be renewed, and some of it was replaced with iron; for all the polished iron and brass work had become as rough as if it had never been polished at all; the only parts of the clock which had not suffered from the damp and the bad air were the painted iron work. The room was also ventilated, with a draught through it, and all the iron work, except acting surfaces, painted. Even in the most favourable positions brass or gun-metal loses its surface long before cast-iron wants repainting.

There is, however, a curious point to be attended to in using cast-iron wheels. They must drive cast-iron pinions, for they will wear out steel. The smaller wheels of the going part may be of brass driving steel pinions; but the whole of the striking wheels and pinions may be of iron. A great deal of nonsense is talked about gun-metal, as if it was necessarily superior to brass. The best gun-metal may be, and is, for wheels which are too thick to hammer; but there is great variety in the quality of gun-metal; it is often unsound, and has hard and soft places; and, on the whole, it has no advantage over good brass, when not too thick to be hammered. In clocks made under the pressure of competing tenders, if the brass is likely not to be hammered, the gun metal is quite as likely to be the cheapest and the worst possible, like everything else which is always specified to be "best," as the clockmakers know very well that it is a hundred to one if anybody sees their work that can tell the difference between the best and the worst.

Turret Clocks with Gravity Escapement.

Fig. 22 is a front view of a large quarter clock of Sir E. Beckett's design, with all the wheels on the great horizontal bed, a gravity escapement, and a compensated pendulum. They are made in two sizes, one with the great striking wheels 18 inches wide, and the other 14. The striking is done by cams cast on the great wheels, about 1½ inch broad in the large-sized clocks, which are strong enough for an hour bell of thirty cwt., and corresponding quarters. Wire ropes are used, not only because they last longer, if kept greased,

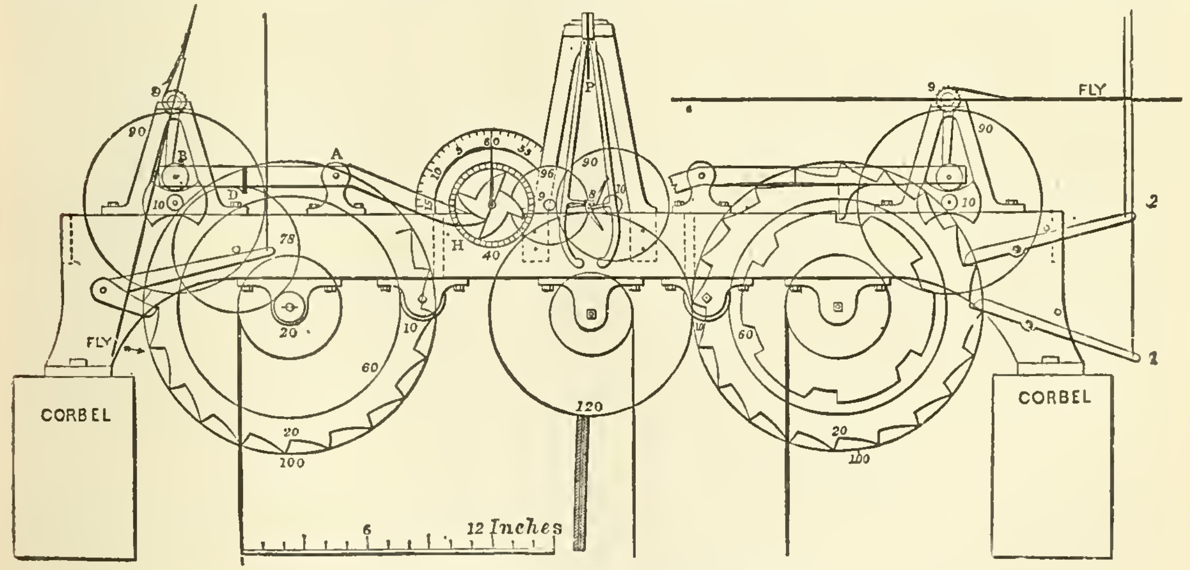

FIG. 22.—Front view of Turret Quarter Clock.

but because a sufficient number of coils will go on a barrel of less than half the length that would be required for hemp ropes of the same strength, without overlapping, which it is as well to avoid, if possible, though it is not so injurious to wire ropes as it is to hemp ones. By this means also the striking cams can be put on the great wheel, instead of the second wheel, which saves more in friction than could be imagined by any one who had not tried both. In clocks of the common construction two-thirds of the power is often wasted in friction and in the bad arrangement of the hammer-work, and the clock is wearing itself out in doing nothing.

The same number of cams are given here to the quarter as to the hour-striking wheel, rather for the purpose of suggesting the expediency of omitting the 4th quarter, as has been done in many clocks made from this design. It is of no use to strike *ding-dong* quarters at the hour, and it nearly doubles the work to be done; and if it is omitted it allows the bells to be larger, and therefore louder, because the 1st quarter bell ought to be an octave above the hour bell. if they are struck at the hour; whereas, if they are not heard together the quarters may be on the 4th and 7th of a peal of eight bells. Moreover, the repetition of the four *ding-dongs* can give no musical pleasure to any one.

The case is different with the Cambridge and Westminster quarter chimes on 4 bells, and the chime at the hour is the most complete and pleasing of all. It is singular that those beautiful chimes (which are partly attributed to Handel) had been heard by thousands of men scattered all over England for 70 years before any one thought of copying them, but since they were introduced by Sir E. Beckett in the great Westminster clock, on a much larger scale and with a slight difference in the intervals, they have been copied very extensively, and are already almost as numerous in new clocks as the old-fashioned ding-dong quarters. Properly, as at Cambridge and Westminster, the hour bell should be an octave below the third or largest but one) quarter bell; but as the interval between the quarters and hour is always considerable, it is practically found that the ear is not offended by a less interval. At Worcester cathedral the great 4½ ton hour bell is only 1½ notes below the 50 cwt. tenor bell of the peal, which is made the fourth quarter bell; and at some other places the quarters are the 2d, 3d, 4th, and 7th of a peal of 8, and the hour bell the 8th. Thereby you get more powerful and altogether better sounding quarters. The quarter bells are the 1st, 2d, 3d, and 6th of a peal of 6—independent of the hour bell; and the following is their arrangement:—

$$\begin{array}{rl}
2d \left\{ \begin{array}{l} 3126 \\ 3213 \end{array} \right. & \\
3d \left\{ \begin{array}{l} 1326 \\ 6213 \\ 1236 \end{array} \right. &
\end{array}
\begin{array}{l}
\left.\begin{array}{l} \\ \\ \\ \\ \end{array}\right\} 4th \\
\quad 1st
\end{array}$$

hour...10

The interval between each successive chime of four should be two or at most two and a half times that between the successive blows. At Cambridge it is three times,—decidedly too slow; at Westminster twice, which is rather too fast; at Worcester cathedral and most of the later large clocks $2\frac{1}{2}$ times, which sounds the best.

At Cambridge the chimes are set on a barrel which turns twice in the hour, as this table indicates, and which is driven by the great wheel with a great waste of power; the clock is wound up every day. An eight-day clock would require a very heavy weight, and a very much greater strain on the wheels, and they are altogether inexpedient for these quarters on any large scale of bells.

Indeed there is some reason for doubting whether the modern introduction of eight-day clocks is an improvement, where they have to strike at all on large bells. Such clocks hardly ever bring the full sound out of the bells; because, in order to do so, the weights would have to be so heavy, and the clock so large, as to increase the price considerably. A good bell, even of the ordinary thickness, which is less than in the Westminster bells, requires a hammer of not less than $\frac{1}{40}$th of its weight, rising 8 or 9 inches from the bell, to bring out the full sound; and therefore, allowing for the loss by friction, a bell of 30 cwt., which is not an uncommon tenor for a large peal, would require a clock weight of 15 cwt., with a clear fall of 40 feet; and either the Cambridge quarters on a peal of ten, or the Doncaster ones on the 2d, 3d, 4th, and 7th bells of a peal of eight, will require above a ton, according to the usual scale of bells in a ringing peal (which is thinner than the Westminster clock bells). Very few clocks are adapted for such weights as these; and without abundance of strength and great size in all the parts, it would be unsafe to use them. But if the striking parts are made to wind up every day, of course $\frac{1}{7}$th of these weights will do; and you may have a more powerful clock in effect, and a safer one to manage, in half the compass, and for much less cost. Churches with such bells as these have always a sexton or some other person belonging to them, and in attendance every day, who can wind up the clock just as well as a clockmaker's man. The going part always requires a much lighter weight, and may as well go a week, and be in the charge of a clockmaker, where it is possible.

There should be some provision for holding the hammers off the bells while ringing, and at the same time a friction-spring or weight should be brought to bear on the fly arbor, to compensate for the removal of the weight of the hammers; otherwise there is a risk of the train running too fast and being broken when it is stopped.

No particular number of cams is required in the striking wheel; any number from 10 to 20 will do; but when four quarters on two bells are used, the quarter-striking wheel should have half as many cams again as the hour-wheel; for, if not, the rope will go a second time over half of the barrel, as there are 120 blows on each quarter bell in the 12 hours to 78 of the hours, while with the three quarters there are only 72. If the two quarter levers are on the same arbor, there must be two sets of cams, one on each side of the wheel; but one set will do, and the same wheel as the hour-wheel, if they are placed as in fig. 23. The hour-striking lever, it will be seen, is differently shaped, so as to diminish the pressure on its arbor by making it only the difference, instead of the sum, of the pressures at the two points of action. This can be done with the two quarter levers, as shown in the *Rudimentary Treatise;* but the arrangement involves a good deal of extra work, and as the quarter hammers are always lighter than the hour one, it is hardly worth while to resort to it. The shape of the cams is a matter requiring some attention, but it will be more properly considered when we come to the *teeth of wheels.* The 4th quarter bell in the Cambridge and Westminster quarters should have two hammers and sets of cams longer than the others, acting alternately, on account of the quick repetition of the blows.

The fly ratchets should not be made of cast-iron, as they sometimes are by clockmakers who will not use cast-iron wheels on any account, because the teeth get broken off by the click. This breaking may perhaps be avoided by making the teeth rectangular, like a number of inverted V's set round a circle, and the click only reaching so far that the face of the tooth which it touches is at right angles to the click; but, as before observed, cast-iron and steel do not work well together.

The hammer of a large clock ought to be left "on the lift," when the clock has done striking, if the first blow is to be struck exactly at the hour, as there are always a good many seconds lost in the train getting into action and raising the hammer. Moreover, when it stops on the lift, the pressure on the stops, and on all the pinions above the great wheel, is only that due to the excess of the power of the clock over the weight of the hammer, and not the full force of the weight, and it is therefore easier for the going part to discharge, and less likely to break the stops.

In fig. 22 the wheel marked 60 in each of the striking parts is a winding wheel on the front end of the barrel, and the winding pinion is numbered 10; a larger pinion will do where the hammer does not exceed 40 lb; and in small clocks no auxiliary winding wheel is needed. But in that case the locking-plate must be driven by a gathering pallet, or pinion with two teeth, on the arbor of the second wheel, with a spring click to keep it steady. In all cases the hammer shanks and tails should not be less than two feet long, if possible; for the shorter they are, the more is lost by the change of inclination for any given rise from the bell. In some clocks with fixed (not swinging) bells, the hammer-head is set on a double shank embracing the bell, with the pivots, not above it in the French way, which makes the hammer strike at a wrong angle, but on each side of the bell, a little below the top. On this plan less of the rise is lost than in the common mode of fixing. The Westminster clock hammers are all fixed in this way.

The first thing to remark in the going part of fig. 22 is that the hour-wheel which carries the snails for letting off the quarters and striking, is not part of the train leading up to the scape-wheel, but independent, so that the train from the great wheel to the scape-wheel, is one of three wheels only. If it were a dead escapement, instead of a gravity escapement clock, the wheel numbered 96 would be the scape-wheel; and as it turns in 90 seconds, it would require 36 teeth or pins for a $1\frac{1}{4}$ sec. pendulum which most of these gravity-escapement clocks have; it is about 6 feet long to the bottom of the bob, which, if sunk just below the floor, brings the clock-frame to a very convenient height. The hour-wheel rides loose on its arbor, or rather the arbor can turn within it, carrying the snails and the regulating hand and the bevelled wheel which drives all the dials, and it is fixed to the hour-wheel by means of clamping screws on the edge of a round plate on the arbor just behind it, which turn by hand. In a gravity escapement clock this adjusting work is not really necessary; because you can set the clock by merely lifting the pallets off the scape-wheel, and letting the train run till the hands point right. The regulating hand, you observe, in fig. 22 turns the wrong way; because, where the dial is opposite to the back of the clock, no bevelled wheels are wanted, and the arbor leads straight off to the dial. It used to be the fashion to put clocks in the middle of the room, so that the leading-off rod might go straight up to the horizontal bevelled wheel in the middle, which drove all the dials. But the clock can be set much more firmly on stone corbels, or on cast-iron brackets built into the wall; and it is not at all necessary for the leading-off rod to be vertical. Provided it is only in a vertical plane parallel to the wall, or the teeth of the bevelled wheels adapted to the inclination, the rod may stand as obliquely as you please; and when it does, it ought on no account to be made, as it generally is, with universal joints, but the pivots should go into oblique pivot-holes at the top and bottom. The joints increase the friction considerably, and are of no use whatever, except where the rod is too long to keep itself straight. Where the rod does happen to be in the middle of the room, and there are three or four dials, the two horizontal bevelled wheels at each end of it must be a little larger than all the others—both the one in the clock and those of the dial-work; for otherwise the three or four wheels in the middle will meet each other and stick fast.

When the pendulum is very long and heavy, it should be suspended from the wall, unless the clock-frame has some strong support near the middle; but a six-feet pendulum, of not more than two cwt., may be suspended from the clock-frame, provided it is as strong as it ought to be for the general construction of the clock, and supported on corbels or iron beams. It has generally been the practice to hang the pendulum behind the clock-frame; but inasmuch as the rope of the going part may always be thinner than that of the striking part, and that part requires less depth in other respects, a different and more compact plan is adopted in the clocks we are describing. The back pivots of the going wheels run in bushes in an intermediate bar, three or four inches from the back of the frame, joining the two cross bars, of which the ends are dotted in the drawing. The pendulum cock is set on the back frame, and the pendulum hangs within it. And in the gravity escapement clocks there is yet another thin bar—about half way between the back frame and the bar on which the bushes of the wheels are set—the only use of which is to carry the bush of the scape-wheel, which is set behind the fly; the wheel, the fly, and the pallets, or gravity-arms, stand between these two intermediate bars; and the pallet-arbors are set in a brass cock screwed to the top of the pendulum-cock. The beat-pins should be of brass, not steel, and no oil put to them, or they are sure to stick. The escapement in fig. 22 is not drawn rightly for the present form of them, which is given in fig. 13.

The same general arrangement will serve for a dead escapement clock with or without a train remontoire; only the pendulum will not stand so high, and the front end of the pallet arbor must be set in a cock like those of the striking flies, on the front bar of the frame. And for a dead escapement, if there are large dials and no remontoire, the pendulum should be longer and heavier than that which is quite sufficient for a gravity escapement. The rod of a wooden pendulum should be as thin as it can conveniently be made, and varnished, to prevent its absorbing moisture.

Dials and Hands.

The old established form of dial for turret clocks is a sheet of copper made convex, to preserve its shape; and this is just the worst form which could have been contrived for it. For, in the first place, the minute-hand, being necessarily outside of the hour-hand, is thrown still farther off the minutes to which it has to point, by the convexity of the dial; and consequently, when it is in any position except nearly vertical, it is impossible to see accurately where it is pointing; and if it is bent enough to avoid this effect of parallax, it looks very ill. Secondly, a convex dial at a considerable height from the ground looks even more convex than it really is, because the lines of sight from the middle and the top of the dial make a smaller angle with the eye than the lines from the middle and the bottom, in proportion to the degree of convexity. The obvious remedy for these defects, is simply to make the dial concave instead of convex. As convex dials look more curved than they are, concave ones look less curved than they are, and in fact might easily be taken for flat ones, though the curvature is exactly the same as usual. Old convex dials are easily altered to concave, and the improvement is very striking where it has been done. There is no reason why the same form should not be adopted in stone, cement, slate, or cast-iron, of which materials dials are sometimes and properly enough made, with the middle part countersunk for the hour hand, so that the minute-hand may go close to the figures and avoid parallax. When dials are large, copper, or even iron or slate, is quite a useless expense, if the stonework is moderately smooth, as most kinds of stone take and retain paint very well, and the gilding will stand upon it better than it often does on copper or iron.

The figures are generally made much too large. People have a pattern dial painted; and if the figures are not as long as one-third of the radius, and therefore occupying, with the minutes, about two-thirds of the whole area of the dial, they fancy they are not large enough to be read at a distance; whereas the fact is, the more the dial is occupied by the figures, the less distinct they are, and the more difficult it is to distinguish the position of the hands, which is what people really want to see, and not to read the figures, which may very well be replaced by twelve large spots. The figures, after all, do not mean what they say, as you read "twenty minutes to" something, when the minute-hand points to VIII. The rule which has been adopted, after various experiments, as the best for the proportions of the dial, is this. Divide the radius into three, and leave the inner two-thirds clear and flat, and of some colour forming a strong contrast to the colour of the hands, black or dark blue if they are gilt, and white if they are black. The figures, if there are any, should occupy the next two-thirds of the remaining third, and the minutes be set in the remainder, near the edge, and with every fifth minute more strongly marked than the rest; and there should *not* be a rim round the dial of the same colour or gilding as the figures. The worst kind of dial of all are the things called skeleton-dials, which either have no middle except the stonework, forming no contrast to the hands, or else taking special trouble to perplex the spectator by filling up the middle with radiating bars. Where a dial cannot be put without interfering with the architecture, it is much better to have none, as is the case in many cathedrals and large churches, leaving the information to be given by the striking of the hours and quarters. This also will save something, perhaps a good deal, in the size and cost of the clock, and if it is one without a train remontoire or gravity escapement, will enable it to go better. The size of public dials is often very inadequate to their height and the distance at which they are intended to be seen. They ought to be at least 1 foot in diameter for every 10 feet of height above the ground, and more whenever the dial will be seen far off; and this rule ought to be enforced on architects, as they are often not aware of it; and indeed they seldom make proper provisions for the clock or the weights in building a tower, or, in short, know anything about the matter.

The art of illuminating dials cannot be said to be in a satisfactory state. Where there happens to be, as there seldom is, a projecting roof at some little distance below the dial, it may be illuminated by reflection, like that at the Horse Guards—about the only merit which that superstitiously venerated and bad clock has; and the same thing may be done in some places by movable lamp reflectors, like those put before shop windows at night, to be turned back against the wall during the day. It has also been proposed to sink the dial within the wall, and illuminate it by jets of gas pointing inwards from a kind of projecting rim, like what is called in church windows a "hood-moulding," carried all round. But it is a great objection to sunk dials, even of less depth than would be required here, that they do not receive light enough by day, and do not get their faces washed by the rain. The common mode of illumination is by making the dials either entirely, or all except the figures and minutes and a ring to carry them, of glass, either ground or lined in the inside with linen (paint loses its colour from the gas). The gas is kept always alight, but the clock is made to turn it nearly off and full on at the proper times by a 24-hour wheel, with pins set in it by hand as the length of the day varies. Self-acting apparatus has been applied, but it is somewhat complicated, and an unnecessary expense. But these dials always look very ill by day; and it seems often to be forgotten that dials are wanted much more by day than by night; and also, that the annual expense of lighting 3 or 4 dials far exceeds the interest of the entire cost of any ordinary clock. Sometimes it exceeds the whole cost of the clock annually. The use of white opaque glass with black figures is very superior to the common method. It is used in the great Westminster clock dials. It is somewhat of an objection to illuminating large dials from the inside, that it makes it impossible to counterpoise the hands outside, except with very short, and therefore very heavy, counterpoises. And if hands are only counterpoised inside, there is no counterpoise at all to the force of the wind, which is then constantly tending to loosen them on the arbor, and that tendency is aggravated by the hand itself pressing on the arbor one way as it ascends, and the other way as it descends; and if a large hand once gets in the smallest degree loose, it becomes rapidly worse by the constant shaking. It is mentioned in Reid's book that the minute-hand of St Paul's cathedral, which is above 8 feet long, used to fall over above a minute as it passed from the left to the right side of XII, before it was counterpoised outside. In the conditions to be followed in the Westminster clock it was expressly required that "the hands be counterpoised externally, for wind as well as weight." The long hand should be straight and plain, to distinguish it as much as possible from the hour hand, which should end in a "heart" or swell. Many clockmakers and architects, on the contrary, seem to aim at making the hands as like each other as they can; and it is not uncommon to see even the counterpoises gilt, probably with the same object of producing apparent symmetry and the same result of producing real confusion.

The old fashion of having chimes or tunes played by machinery on church bells at certain hours of the day has greatly revived in the last few years, and it has extended to town halls, as also that of having very large clock bells, which had almost become extinct until the making of the Westminster clock. The old kind of chime machinery consisted merely of a large wooden barrel about 2 feet in diameter with pins stuck in it like those of a musical box, which pulled down levers that lifted hammers on the bells. Generally there were several tunes "pricked" on the barrel, which had an endway motion acting automatically, so as to make a shift after each tune, and with a special adjustment by hand to make it play a psalm tune on Sundays. But though these tunes were very pleasing and popular in the places where such chimes existed they were generally feeble and irregular, because the pins and levers were not strong enough to lift hammers of sufficient weight for the large bells, and there were no means of regulating the time of dropping off the levers. Probably the last large chime work of this kind was that put up by Dent to play on 16 bells at the Royal Exchange in 1845, with the improvement of a cast-iron barrel and stronger pins than in the old wooden barrels.

A much improved chime machine has been introduced since, at first by an inventor named Imhoff, who sold his patent, or the right to use it, to Messrs Gillett and Bland of Croydon, and also to Messrs Lund and Blockley of Pall Mall, who have both added further improvements of their own. The principle of it is this: instead of the hammers being lifted by the pins which let them off, they are lifted whenever they are down by an independent set of cam wheels of ample strength; and all that the pins on the barrel have to do is to trip them up by a set of comparatively light levers or detents. Consequently the pins are as small as those of a barrel organ, and many more tunes can be set on the same barrel than in the old plan, and besides that, any number of barrels can be kept, and put in from time to time as you please; so that you may have as many tunes as the peal of bells will admit. There are various provisions for regulating and adjusting the time, and the machinery is altogether of a very perfect kind for its purpose, but it must be seen to be understood.

It is always necessary in chimes to have at least two hammers to each bell to enable a note to be repeated quickly. Some ambitious musicians determined to try "chords" or double notes struck at once, in spite of warning that they could not be made to strike quite simultaneously, and so it turned out, and it is useless to attempt them. The largest peals and chimes yet made have been at Worcester cathedral, and the town halls of Bradford and Rochdale, and a still larger one is now making for Manchester, all by Gillett and Bland. The clock at Worcester, which as yet ranks next to Westminster, was made by Mr Joyce of Whitchurch; the others are by Gillett and Bland. At Boston church they have chimes in imitation of some of the foreign ones on above 40 small bells, which were added for that purpose to the eight of the peal; but they are not successful, and it is stated in Sir E. Beckett's book on clocks and bells, that he warned them that the large and small bells would not harmonize, though either might be used separately. Other persons have attempted chimes on hemispherical bells, like those of house clocks; but they also are a failure for external bells to be heard at a distance. This however belongs rather to the subject of bells; and we must refer to that book for all practical information about them.

Teeth of Wheels.

Before explaining the construction of the largest clock in the world it is necessary to consider the shape of wheel teeth suitable for different purposes, and also of the cams requisite to raise heavy hammers, which had been too much neglected by clockmakers previously. At the same time we are not going to write a treatise on all the branches of the important subject of wheel-cutting; but, assuming a knowledge of the general principles of it, to apply them to the points chiefly involved in clock-making. The most comprehensive mathematical view of it is perhaps to be found in a paper by the astronomer-royal in the *Cambridge Transactions* many years ago, which is further expanded in Professor Willis's *Principles of Mechanism.* Respecting the latter book, however, we should advise the reader to be content with the *mathematical* rules there given, which are very simple, without attending much to those of the *odontograph,* which seem to give not less but more trouble than the mathematical, and are only approximate after all, and also do not explain themselves, or convey any knowledge of the principle to those who use them.

For all wheels that are to work together, the first thing to do is to fix the *geometrical,* or *primitive,* or *pitch circles* of the two wheels, *i.e.,* the two circles which, if they rolled perfectly together, would give the velocity-ratio you want. Draw a straight line joining the two centres; then the action which takes place between any two teeth as they are approaching that line is said to be before the line of centres; and the action while they are separating is said to be after the line of centres. Now, with a view to reduce the friction, it is essential to have as little action before the line of centres as you can; for if you make any rude sketch, on a large scale, of a pair of wheels acting together, and *serrate* the edges of the teeth (which is an exaggeration of the roughness which produces friction), you will see that the further the contact begins before the line of centres, the more the serration will interfere with the motion, and that at a certain distance no force whatever could drive the wheels, but would only jam the teeth faster; and you will see also that this cannot happen after the line of centres. But with pinions of the numbers generally used in clocks you cannot always get rid of action before the line of centres; for it may be proved (but the proof is too long to give here), that if a pinion has less than 11 leaves, no wheel of any number of teeth can drive it without some action before the line of centres. And generally it may be stated that the greater the number of teeth the less friction there will be, as indeed is evident enough from considering that if the teeth were infinite in number, and infinitesimal in size, there would be no friction at all, but simple rolling of one pitch circle on the other. And since in clock-work the wheels always drive the pinions, except the hour pinion in the dial work, and the winding pinions in large clocks, it has long been recognized as important to have high numbered pinions, except where there is a train remontoire, or a gravity escapement, to obviate that necessity.

And with regard to this matter, the art of clock-making has in one sense retrograded; for the pinions which are now almost universally used in English and French clocks are of a worse form than those of several centuries ago, to which we have several times alluded under the name of *lantern* pinions, so called from their resembling a lantern with upright ribs. A sketch of one, with a cross section on a large scale, is given at fig. 24. Now it is a property of these pinions, that when they are driven, the action begins just when the centre of the pin is on the line of centres, however few the pins may be; and thus the action of a lantern pinion of 6 is about equal to that of a leaved pinion of 10; and indeed, for some reason or other, it appears in practice to be even better, possibly from the teeth of the wheel not requiring to be cut so accurately, and from the pinion never getting clogged with dirt. Certainly the running of the American clocks, which all have these pinions, is remarkably smooth, and they require a much smaller going weight than English clocks; and the same may be said of the common "Dutch," *i.e.,* German clocks. It should be understood, however, that as the action upon these pinions is all after the line of centres when they are driven, it will be all before the line of centres if they drive, and therefore they are not suitable for that purpose. In some of the French clocks in the 1851 Exhibition they were wrongly used, not only for the train, but for winding pinions; and some of them also had the pins not fixed in the lantern, but rolling,—a very useless refinement, and considerably diminishing the strength of the pinion. For it is one of the advantages of lantern pinions with fixed pins, that they are very strong, and there is no risk of their being broken in hardening, as there is with common pinions.

The fundamental rule for the tracing of teeth, though very simple, is not so well known as it ought to be, and therefore we will give it, premising that so much of a tooth as lies within the pitch circle of the wheel is called its *root* or *flank,* and the part beyond the pitch circle is called the *point,* or the *curve,* or the *addendum;* and moreover, that before the line of centres the action is always between the flanks of the driver and the points of the driven wheel or *runner* (as it may be called, more appropriately than the usual term *follower*); and after the line of centres, the action is always between the points of the driver and the flanks of the runner. Consequently, if there is no action before the line of centres, no points are required for the teeth of the runner.

In fig. 23, let AQX be the pitch circle of the runner, and ARY that of the driver; and let GAP be any curve whatever of smaller curvature than AQX (of course a circle is always the kind of curve used); and QP the curve which is traced out by any point P in the generating circle GAP, as it rolls *in* the pitch circle AQX; and again let RP be the curve traced by the point P, as the generating circle GAP is rolled *on* the pitch circle ARY; then RP will be the form of the point of a tooth on the driver ARY, which will drive with uniform and proper motion the flank QP of the runner; though not without some friction, because that can only be done with *involute* teeth, which are traced in a different way, and are subject to other conditions, rendering them practically useless for machinery, as may be seen in Professor Willis's book. If the motion is reversed, so that the runner becomes the driver, then the flank QP is of the proper form to drive the point RP, if any action has to take place before the line of centres.

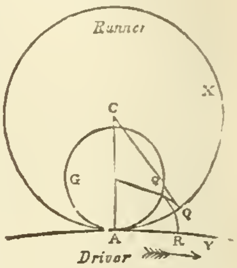

Fig. 23.

And again, any generating curve, not even necessarily the same as before, may be used to trace the flanks of the driver and the points of the runner, by being rolled within the circle ARY, and on the circle AQX.

Now then, to apply this rule to particular cases. Suppose the generating circle is the same as the pitch circle of the driven pinion itself, it evidently cannot roll at all; and the tooth of the pinion is represented by the mere point P on the circumference of the pitch circle; and the tooth to drive it will be simply an *epicycloid* traced by rolling the pitch circle of the pinion on that of the wheel. And we know that in that case there is no action before the line of centres, and no necessity for any flanks on the teeth of the driver. But inasmuch as the pins of a lantern pinion must have some thickness, and cannot be mere lines, a further process is necessary to get the exact form of the teeth; thus if RP, fig. 24, is the tooth that would drive a pinion with pins of no sensible thickness, the tooth to drive a pin of the thickness 2 P*p* must have the width P*p* or R*r* ganged off it all round. This, in fact, brings it very nearly to a smaller tooth traced with the same generating circle; and therefore in practice this mode of construction is not much adhered to, and the teeth are made of the same shape, only thinner, as if the pins of the pinion had no thickness. Of course they should be thin enough to allow a little shake, or "back-lash," but in clock-work the backs of the teeth never come in contact at all.

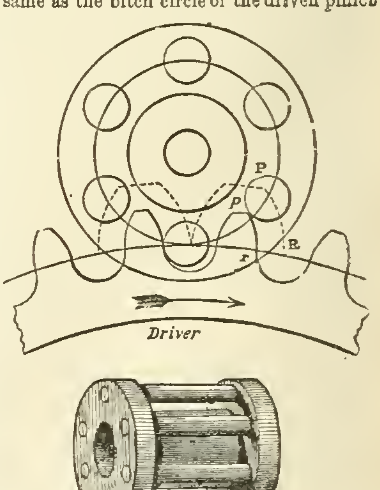

Fig. 24.—Lantern Pinion.

Next suppose the generating circle to be half the size of the pitch circle of the pinion. The curve, or *hypocycloid,* traced by rolling this within the pinion, is no other than the diameter of the pinion and consequently the flanks of the pinion teeth will be merely radii of it, and such teeth or leaves are called radial teeth; and they are far the most common; indeed, no others are ever made (except lanterns) for clock-work. The corresponding epicycloidal points of the teeth of the driver are more curved, or a less pointed arc, than those required for a lantern pinion of the same size and number. The teeth in fig. 25 are made of a different form on the opposite sides of the line of centres CA, in order to show the difference between driving and driven or running teeth, where the number of the pinion happens to be as much as 12, so that no points are required to its teeth when driven, since with that number all the action may be after the line of centres. The great Westminster clock affords a very good illustration of this. In both the striking parts the great wheel of the train and the great winding-wheel on the other end of the barrel are about the same size; but in the train the wheel drives, and in winding the pinion drives. And therefore in the train the pinion-teeth have their points cut off, and wheel-teeth have their points on, as on the right side of fig. 25, and in the winding-wheels the converse; and thus in both cases the action is made to take place in the way in which there is the least friction. Willis gives the following table, "derived organically" (*i.e.*, by actual trial with large models), of the least numbers which will work together without any action before the line of centres, provided there are no points to the teeth of the runner, assuming them to be radial teeth, as usual:—

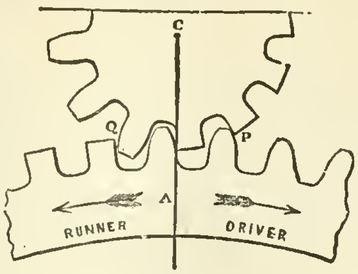

Fig. 25.

Driver.........	54	30	24	20	17	15	14	13	12	11	10	9	8	7	6
Runner.........	11	12	13	14	15	16	17	18	19	21	23	27	35	32	176

In practice it is hardly safe to leave the driven teeth without points, unless the numbers slightly exceed these; because, if there is any irregularity in them, the square edges of those teeth would not work smoothly with the teeth of the driver. Sometimes it happens that the same wheel has to drive two pinions of different numbers. It is evident that, if both are lanterns, or both pinions with radial teeth, they cannot properly be driven by the same wheel, because they would require teeth of a different shape. It is true that on account of the greater indifference of lantern pinions to the accuracy of the teeth which are to drive them, the same wheel will drive two pinions of that kind, differing in the numbers in the ratio of even 2 to 1, with hardly any sensible shake; but that would not be so with radial pinions, and of course it is not correct. Accordingly, in clocks with the spring remontoire, as in fig. 21, where the scape-wheel or remontoire pinion is double the size of the fly pinion, the larger one is made with radial teeth and the smaller a lantern, which makes the same wheel teeth exactly right for both. In clocks of the same construction as fig. 22, and in the Westminster clock, there is a case of a different kind, which cannot be so accommodated; for there the great wheel has to drive both the second wheel's pinion of 10 or 12, and the hour-wheel of 40 or 48; the teeth of the great wheel were therefore made to suit the lantern pinion, and those of the hour-wheel (*i.e.*, their flanks) then depend on those of the great wheel, and they were accordingly traced by rolling a generating circle of the size of the lantern pinion on the inside of the pitch circle of the hour-wheel; the result is a tooth thicker at the bottom than usual. These are by no means unnecessary refinements; for if the teeth of a set of wheels are not properly shaped so as to work smoothly and regularly into each other, it increases their tendency to wear out in proportion to their inaccuracy, besides increasing the inequalities of force in the train. Sometimes turret clocks are worn out in a few years from the defects in their teeth, especially when they are made of brass or soft gun-metal.

In the construction of clocks which have to raise heavy hammers it is important to obtain the best form for the cams, as pins are quite unfit for the purpose. The conditions which are most important are—that the action should begin at the greatest advantage, and therefore at the end of the lever, that when it ceases the face of the lever should be a tangent to the cam at both their points, and that in no part of the motion should the end of the lever scrape on the cam. In the common construction of clocks the first condition is deviated from as far as possible, by the striking pins beginning to act at some distance from the end of the lever; and consequently, at the time when the most force is required to lift the hammer there is the least given, and a great deal is wasted afterwards.

The construction of curve for the cams, which is the most perfect mathematically, is that which is described in mathematical books under the name of the *tractrix*. But there are such practical difficulties in describing it that it is of no use. It should be observed that, in a well known book with an appropriate name (*Camus on the Teeth of Wheels*), a rule for drawing cams has been inserted by some translator, which is quite wrong. It may be proved that epicycloidal cams described as follows are so nearly of the proper mathematical form that they may be used without any sensible error. Let r be the radius of the circle or barrel on which the cams are to be set theoretically, *i.e.*, allowing nothing for the clearance which must be cut out afterwards, for fear the lever should scrape the back of the cams in falling; in other words, r is the radius of the pitch circle of the cams. Call the length of the lever l. Then the epicycloidal cams may be traced by rolling on the pitch circle a smaller one whose *diameter* is $\sqrt{r^2+l^2}-r$. Thus, if l is 4 inches and r 8 inches (which is about the proper size for an 18-inch striking wheel with 20 cams), the radius of the tracing circle from the cams will be 0·9 inch. The advantage of cams of this kind is that they waste as little force as possible in the lift, and keep the lever acting upon them as a tangent at its point the whole way; and the cams themselves may be of any length according to the angle through which you want the lever to move.

Most people however prefer dealing with circles, when they can, instead of epicycloids; and drawing by compasses is safer than calculating in most hands. We therefore give another rule, suggested by Mr E. J. Lawrence, a member of the horological jury in the 1851 Exhibition, which is easier to work, and satisfies the principal conditions stated just now, though it wastes rather more in lift than the epicycloidal curve; and the cams must not have their points cut off, as epicycloidal ones may, to make the lever drop off sooner; because a short cam has to be drawn with a different radius from a long one, to work a lever of any given length. But, on the other hand, the same curve for the cams will suit a lever of any length, whereas with epicycloidal cams you must take care to put the centre or axis of the lever at the exact distance from the centre of the wheel for which the curve was calculated—an easy enough thing to do, of course, but for the usual disposition of workmen to deviate from your plans, apparently for the mere pleasure of doing wrong. It is astonishing how, by continually making one machine after another, with a little deviation each time, the thing gradually assumes a form in which you can hardly recognise your original design at all. The prevention of this kind of blundering is one of the many advantages of making machines by machinery, for which no machine offers more facilities than clocks, and yet there is none to which it is less applied.

In fig. 26 let CA be a radius of the wheel, L in the same straight line the centre of the lever, and AB the space of one cam on the pitch circle of the cams, A being a little below the line of centres; AP is the arc of the lever. Draw a tangent to the two circles at A, and a tangent to the cam circle at B; then T, their point of intersection, will be the centre of the circle which is the face of the cam BP; and TB also = TA, which is a convenient test of the tangents being rightly drawn. The action begins at the point of the lever, and advances a little way up, but recedes again to the point, and ends with the lever as a tangent to the cam at P. The backs of the cams must be cut out rather deeper than the circle AP, but retaining the point P, to allow enough for clearance of the lever, which should fall against some fixed stop or banking on the clock-frame, before the next cam reaches it. The point of the lever must not be left quite sharp, for if it is, it will in time cut off the points of the cast-iron cams.

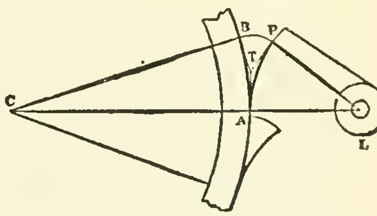

Fig. 26.

Oil for Clocks.

We will add a few words on the subject of oil for clocks. Olive-oil is most commonly used, sometimes purified in various ways, and sometimes not purified at all. We believe, however, that purified animal oil is better than any of the vegetable oils, as some of them are too thin, while others soon get thick and viscid. For turret clocks and common house clocks, good sperm oil is fine enough, and is probably the best. For finer work the oil requires some purification. Even common neat's foot oil may be made fine and clear by the following method. Mix it with about the same quantity of water, and shake it in a large bottle, not full, until it becomes like a white soup; then let it stand till fine oil appears at the top, which may be skimmed off; it will take several months before it has all separated—into water at the bottom, dirt in the middle, and fine oil at the top. And it should be done in cold weather, because heat makes some oil come out as fine, which in cold would remain among the dirty oil in the middle, and in cold weather that fine oil of hot weather will become muddy. There are various vegetable oils sold at tool-shops as oil for watches, including some for which a prize medal was awarded in the Exhibition, but not by any of the mechanical juries; we have no information as to the test which was applied to it, and none but actual use for a considerable time would be of much value.

The Westminster Clock.

It is unnecessary to repeat the account of the long dispute between the Government, the architect of the House of Parliament, the astronomer royal, Sir E. Beckett, and some of the London clockmakers, which ended in the employment of the late E. J. Dent and his successor F. Dent from the designs and under the superintendence of Sir E. Beckett, as the inscription on it records The fullest account of these was given in the 4th and 5th editions of the *Treatise on Clocks*, and we shall now only describe its construction. Fig. 27 is a front elevation or section lengthwise of the clock. The frame is 16 feet long and 5½ wide, and it rests on two iron plates lying on the top of the walls of the shaft near the middle of the tower, down which the weights descend. That wall reaches up to the bell chamber, and those iron plates are built right through it, and so is the great cock which carries the pendulum. The clock-room is 28 feet × 19, the remaining 9 of the square being occupied by the staircase and an air-shaft for ventilating the whole building.

The going part of the clock, however, not requiring such a long barrel as the striking parts, which have steel wire ropes ·55 inch thick, is shorter than they are, and is carried by an intermediate bar or frame bolted to the cross bars of the principal frame. The back of them is about 2½ feet from the wall, to leave room for a man behind, and the pendulum cock is so made as to let his head come within it in order to look square at the escapement. The escapement is the double three legs (fig. 13), and the length of the teeth or legs is 6 inches. The drawing represents the wheels (except the bevelled wheels leading off to the dials) as mere circles to prevent confusion. The numbers of teeth and the time of revolution of the principal ones are inserted and require no further notice. Their size can be taken from the scale; the great wheels of the striking parts are 2½ and of the going part 2 inches thick, and all the wheels are of cast-iron except the smaller ones of the escapement, which are brass, but are painted like the iron ones.

The maintaining power for keeping the clock going while winding is peculiar and probably unique. None of those already described could have kept in gear long enough, maintaining sufficient force all the time, as that part takes 10 minutes to wind, even if the man does not loiter over it. This is managed without a single extra wheel beyond the ordinary winding pinion of large clocks. The winding wheel on the end of the barrel is close to the great wheel, and you see the pinion with the winding arbor in the oblique piece of the front frame of the clock. Consequently that arbor is about 6 feet long, and a little movement of its back end makes no material obliquity in the two bushes; *i.e.*, it may go a little out of parallel with all the other arbors in the clock without any impediment to its action. Its back pivot is carried, not in a fixed bush, but in the lower end of a bar a little longer than the great wheel's radius, hanging from the back of the great arbor; and that bar has a spring click upon it which takes into ratchet teeth cast on the back of the great wheel. When the great wheel is turning, and you are not winding, the ratchets pass the click as usual, but as soon as you begin to wind the back end of the winding arbor would rise but for the click catching those teeth, and so the great wheel itself become the fulcrum for winding for the time. After the winding has gone a few minutes a long tooth projecting from the back of the arbor catches against a stop, because that end of the hanging bar and pinion have all risen a little with the motion of the great wheel.

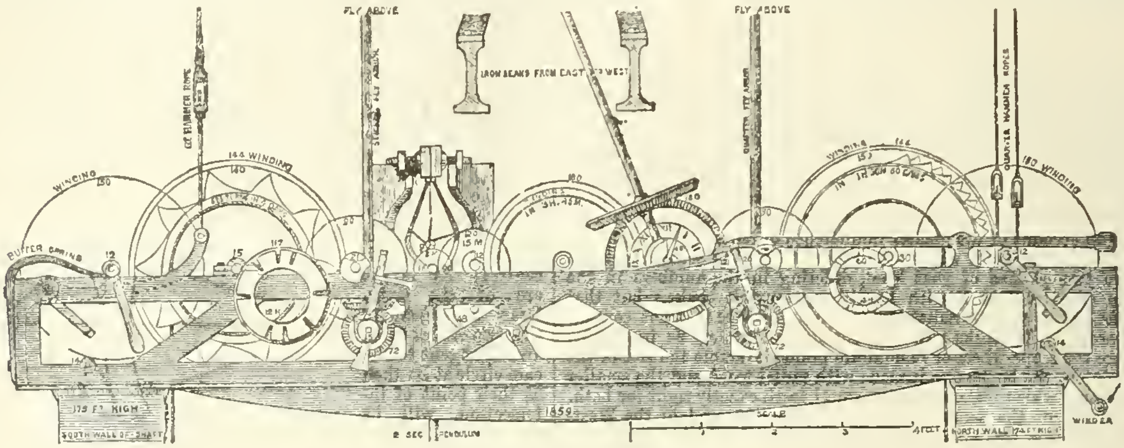

Fig. 27.—Section of Westminster Clock.

Then the man is obliged to turn the handle back a little, which lets down the pinion, &c., and the click takes up some lower teeth; and so if he chooses to loiter an hour over the winding he can do no harm. The winding pinion "pumps" into gear and out again as usual. The going part will go 8½ days, to provide for the possible forgetting of a day in winding. The weight is about 160 ℔; but only one-14th of the whole force of that weight is requisite to drive the pendulum, as was found by trial; the rest goes in overcoming the friction of all the machinery, including a ton and a half of hands and counterpoises, and in providing force enough to drive them through all weathers, except heavy snows, which occasionally accumulate thick enough on several minute hands at once, on the left side of the dials, to stop the clock, those hands being 11 feet long. For the dials are 22½ feet in diameter, or contain 400 square feet each, and there are very few rooms where such a dial could be painted on the floor. They are made of iron framing filled in with opal glass. Each minute is 14 inches wide. The only larger dial in the world is in Mechlin church, which is 40 feet wide; but it has no minute hand, which makes an enormous difference in the force required in the clock. They are completely walled off from the clock-room by a passage all round, and there are a multitude of gas lights behind them, which are lighted by hand, though provision was originally made in the clock for doing it automatically. The hour hands go so slow that their weight is immaterial, and were left as they were made of gun metal under the architect's direction; but it was impossible to have minute hands of that construction and weight without injury to the clock, and so they were removed by Sir E. Beckett, and others made of copper tubes, with a section composed of two circular arcs put together, and are consequently very stiff, while weighing only 28 ℔. The great weight is in the wheels, tubes, and counterpoises. The minute hands are partly counterpoised outside, making their total length 14 feet. to relieve the strain upon their arbors. They all run on friction wheels imbedded in the larger tubes 5½ inches wide, which carry the hour hands, which themselves run on fixed friction wheels.

There is nothing peculiar in the quarter striking part except its size, and perhaps in the barrel turning in an hour and a half, *i.e.*, in three repetitions of the five chimes already described. The cams are of wrought iron with hard steel faces. Each bell has two hammers, which enables the cams to be longer and the pressure on them less. The hour-striking wheel has ten cams 2½ in. wide cast on it; but those cams have solid steel faces screwed on them. All this work was made for a hammer of 7 cwt., lifted 13 inches from the bell, *i.e.*, about 9 inches of vertical lift. The hammer was reduced to 4 cwt. after the partial cracking of the bell. The rod from the lever to the hammer is made of the same wire rope as the weight ropes, and the result is that there is no noise in the room while the clock is striking. The lever is 5 feet 4 inches long, and strikes against the buffer spring shown in the drawing, to prevent concussion on the clock-frame, of which you cannot feel the least. The quarter hammer levers have smaller springs for the same purpose, and the stops of the striking part are also set on springs instead of rigid as usual. The flies, for which there was not room in the drawing, are near the top of the room and are each 2 feet 4 inches square. They make a considerable wind in the room when revolving. The only noise made in striking is their running on over their ratchets when the striking stops. Each striking weight is a ton and a half—or was before the great hammer was reduced. They take 5 hours to wind up, and it has to be done twice a week, which was thought better than making the parts larger and the teeth more numerous and the weights twice as much, to go a week, and of course the winding must have taken twice as long, as it was adapted to what a man can do continuously for some hours. Consequently it was necessary to contrive something to stop the man winding just before each time of striking. And that is done by a lever being tipped over by the snail at that time, which at once stops the winding. When the striking is done the man can put the lever up again and go on. The loose winding wheels are not pumped in and out of gear as usual, being too heavy, but one end of the arbor is pushed into gear by an eccentric bush turned by the oblique handle or lever which you see near the upper corner of each striking part, and they can be turned in a moment. They are held in their place for gear by a spring catch to prevent any risk of slipping out. Moreover the ropes themselves stop the winding when the weights came to the top, pretty much as they do in a spring clock or a watch, though not exactly.

The mode of letting off the hour striking is peculiar, with a view to the first blow of the hour being exactly at the 60th second of the 60th minute. It was found that this could not be depended on to a single beat of the pendulum, and probably it never can in any clock, by a mere snail turning in an hour, unless it was of a very inconvenient size. Therefore the common snail only lets it off partially, and the striking stop still rests against a lever which is not dropped but tipped up with a slight blow by another weighted lever resting on a snail on the 15-minute wheel, which moves more exactly with the escapement than the common snail lower in the train. The hammer is left on the lift, ready to fall, and it always does fall within half a second after the last beat of the pendulum at the hour. This is shown in fig. 28, where BE is the spring stop noticed above, and P the ordinary first stop on the long lifting lever PQ (which goes on far beyond the reach of this figure to the hour snail). The second or warning stop is CD, and BAS is the extra lever with its heavy end at S on the 15-minute snail. When that falls the end B tips up CD with certainty by the blow, and then the striking is free. The first, second, and third quarters begin at the proper times; but the fourth quarter chimes begin about 20 seconds before the hour.

The clock reports its own rate to Greenwich Observatory by galvanic action twice a day, *i.e.*, an electric circuit is made and broken by the pressing together of certain springs at two given hours. And in this way the rate of the clock is ascertained and recorded, and the general results published by the astronomer royal in his annual report. This has been for some years so remarkably uniform, that the error has only reached 3 seconds on 3 per cent. of the days in the year, and is generally under two. He has also reported that "the rate of the clock is certain to much less than a second a week"—subject to abnormal disturbances by thunder storms which sometimes amount to seven or eight seconds, and other casualties, which are easily distinguishable from the spontaneous variations.

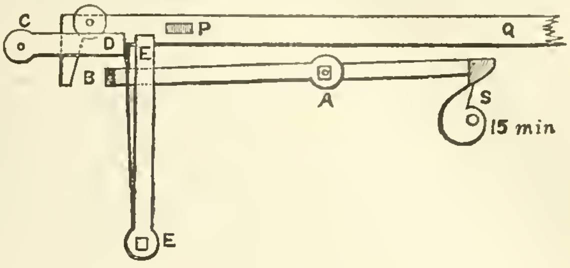

Fig. 28.

The original stipulation in 1845 was that the rate should not vary more than a second a day—not a week; and this was pronounced impossible by Mr Vulliamy and the London Company of Clockmakers, and it is true that up to that time no such rate had ever been attained by any large clock. In 1851 it was by the above-mentioned clock, now at King's Cross Station, by means of the train remontoire, which was then intended to be used at Westminster, but was superseded by the gravity escapement.

The great hour bell, of the note E, weighs 13½ tons and is 9 feet diameter and 9 inches thick. The quarter bells weigh respectively 78, 33½, 26, and 21 cwt.; with diameters 6 feet, 4½, 4, and 3 feet 9 inches, and notes B, E, F sh. and G sh. The hammers are on double levers embracing the bells, and turning on pivots projecting from the iron collars which carry the mushroom shaped tops of the bells. The bells, including £750 for recasting the first great bell, cost nearly £6000, and the clock £4080. The bell frame, which is of wrought iron plates, and the dials and hands, all provided by the architect, cost £11,934—a curious case of the accessories costing more than the principals. (E. B.)

CLOISTER (Latin, *claustrum;* French, *cloître;* Italian, *chiostro;* Spanish, *claustro;* German, *kloster*). The word "cloister," though now restricted to the four-sided enclosure, surrounded with covered ambulatories, usually attached to conventual and cathedral churches, and sometimes to colleges, or by a still further limitation to the ambulatories themselves, originally signified the entire monastery. In this sense it is of frequent occurrence in our earlier literature (*e.g.*, Shakespeare, *Meas. for Meas.*, i. 3, "This day my sister should the *cloister* enter"), and is still employed in poetry. The Latin *claustrum*, as its derivation implies, primarily denoted no more than the enclosing wall of a religious house, and then came to be used for the whole building enclosed within the wall. To this sense the German "kloster" is still limited, the covered walks, or cloister in the modern sense, being called "kloster-gang," or "kreuz-gang." In French, as with us, the word *cloître* retains the double sense.

In the special sense now most common, the word "cloister" denotes the quadrilateral area in a monastery or college of canons, round which the principal buildings are ranged, and which is usually provided with a covered way or ambulatory running all round, and affording a means of communication between the various centres of the ecclesiastical life, without exposure to the weather. According to the Benedictine arrangement, which from its suitability to the requirements of monastic life was generally adopted in the West, one side of the cloister was formed by the church, the refectory occupying the side opposite to it, that the worshippers might have the least annoyance from the noise or smell of the repasts. On the eastern side the chapter-house was placed, with other apartments belonging to the common life of the brethren adjacent to it, and, as a common rule, the dormitory occupied the whole of the upper story. On the opposite or western side were generally the cellarer's lodgings, with the cellars and store-houses, in which the provisions necessary for the sustenance of the confraternity were housed. In Cistercian monasteries the western side was usually occupied by the "domus conversorum," or lodgings of the lay-brethren, with their day-rooms and workshops below, and dormitory above. The cloister, with its surrounding buildings, generally stood on the south side of the church, to secure as much sunshine as possible. A very early example of this disposition is seen in the plan of the monastery of St Gall (ABBEY, vol. i. p. 12). Local requirements, in some instances, caused the cloister to be placed to the north of the church. This is the case in the English cathedrals, formerly Benedictine abbeys, of Canterbury, Gloucester, and Chester, as well as in that of Lincoln. Other examples of the northward situation are at Tintern, Buildwas, and Sherborne. Although the covered ambulatories are absolutely essential to the completeness of a monastic cloister, a chief object of which was to enable the inmates to pass from one part of the monastery to another without inconvenience from rain, wind, or sun, it appears that they were sometimes wanting. The cloister at St Alban's seems to have been deficient in ambulatories till the abbacy of Robert of Gorham, 1151–1166, when the eastern walk was erected. This, as was often the case with the earliest ambulatories, was of wood covered with a pentice roof. We learn from Osbern's account of the conflagration of the monastery of Christ Church, Canterbury, 1067, that a cloister with covered ways existed at that time, affording communication between the church, the dormitory, and the refectory. We learn from an early drawing of the monastery of Canterbury that this cloister was formed by an arcade of Norman arches supported on shafts, and covered by a shed roof.

A fragment of an arcaded cloister of this pattern is still found on the eastern side of the infirmary-cloister of the same foundation. This earlier form of cloister has been generally superseded with us by a range of windows, usually unglazed, but sometimes, as at Gloucester, provided with glass, lighting a vaulted ambulatory, of which the cloisters of Westminster Abbey, Salisbury, and Norwich are typical examples. The older design was preserved in the South, where "the cloister is never a window, or anything in the least approaching to it in design, but a range of small elegant pillars, sometimes single, sometimes coupled, and supporting arches of a light and elegant design, all the features being of a character suited to the place where they are used, and to that only" (Fergusson, *Hist. of Arch.*, i. p. 610). As examples of this description of cloister, we may refer to the exquisite cloisters of St John Lateran, and St Paul's without the walls, at Rome, where the coupled shafts and arches are richly ornamented with ribbons of mosaic, and those of the convent of St Scholastica at Subiaco, all of the 13th century, and to the beautiful cloisters at Arles, in southern France, "than which no building in this style, perhaps, has been so often drawn or so much admired" (Fergusson); and those of Aix, Fontifroide, Elne, &c., are of the same type; as also the Romanesque cloisters at Zurich, where the design suffers from the deep abacus having only a single slender shaft to support it, and at Laach, where the quadrangle occupies the place of the "atrium" of the early basilicas at the west end, as at St Clement's at Rome, and St Ambrose at Milan. Spain also presents some magnificent cloisters of both types, of which that of the royal convent of Huelgas, near Burgos, of the arcaded form, is, according to Mr Fergusson, "unrivalled for beauty both of detail and design, and is perhaps unsurpassed by anything in its age and style in any part of Europe." Few cloisters are more beautiful than those of Monreale and Cefalu in Sicily, where the arrangement is the same, of slender columns in pairs with capitals of elaborate foliage supporting pointed arches of great elegance of form.

All other cloisters are surpassed in dimensions and in sumptuousness of decoration by the "Campo Santo" at Pisa. This magnificent cloister consists of four ambulatories as wide and lofty as the nave of a church, erected in 1278 by Giovanni Pisano round a cemetery composed of soil brought from Palestine by Archbishop Lanfranchi in the middle of the 12th century. The window openings are semicircular, filled with elaborate tracery in the latter half of the 15th century. The inner walls are covered with frescos invaluable in the history of art by Orgagna, Simone Memmi, Buffalmacco, Benozzo Gozzoli, and other early painters of the Florentine school. The ambulatories now serve as a museum of sculpture. The internal dimensions are 415 feet 6 inches in length, 137 feet 10 inches in breadth, while each ambulatory is 34 feet 6 inches wide by 46 feet high.

The cloister of a religious house was the scene of a large part of the life of the inmates of a monastery. When not in church, refectory, or dormitory, or engaged in manual labour, the monks were usually to be found here. The north walk of the cloister of St Gall appears to have served as the chapter-house. The cloister was the place of education for the younger members, and of study for the elders. A canon of the Roman council held under Eugenius II., in 826, enjoins the erection of a cloister as an essential portion of an ecclesiastical establishment for the better discipline and instruction of the clerks. Peter of Blois (*Serm.* 25) describes schools for the novices as being in the west walk, and moral lectures delivered in that next the church. At Canterbury the monks' school was in the western ambulatory, and it was in the same walk that the novices were taught at Durham (Willis, *Monastic Buildings of Canterbury*, p. 44; *Rites of Durham*, p. 71). The other alleys, especially that next the church, were devoted to the studies of the elder monks. The constitutions of Hildemar and Dunstan enact that between the services of the church the brethren should sit in the cloister and read theology. For this purpose small studies, known as *carrols*, from their square shape, were often found in the recesses of the windows. Of this arrangement we have examples at Gloucester, Chester (recently restored), and elsewhere. The use of these studies is thus described in the *Rites of Durham*:—"In every wyndowe" in the north alley "were iii pewes or carrells, where every one of the olde monkes had his carrell severally by himselfe, that when they had dyned they dyd resorte to that place of cloister, and there studyed upon their books, every one in his carrell all the afternonne unto evensong tyme. This was there exercise every daie." On the opposite wall were cupboards full of books for the use of the students in the carrols. The cloister arrangements at Canterbury were similar to those just described. New studies were made by Prior De Estria in 1317, and Prior Selling (1472–94) glazed the south alley for the use of the studious brethren, and constructed "the new framed contrivances, of late styled carrols" (Willis, *Mon. Buildings*, p. 45). The cloisters were used not for study only but also for recreation. The constitutions of Archbishop Lanfranc, sect. 3, permitted the brethren to converse together there at certain hours of the day. To maintain necessary discipline a special officer was appointed under the title of *prior claustri*. The cloister was always furnished with a stone bench running along the side. It was also provided with a lavatory, usually adjacent to the refectory, but sometimes standing in the central area, termed the cloister-garth, as at Durham. The cloister-garth was used as a place of sepulture, as well as the surrounding alleys. The cloister was in some few instances of two stories, as at Old St Paul's, and St Stephen's Chapel, Westminster, and occasionally, as at Wells, Chichester, and Hereford, had only three alleys, there being no ambulatory under the church wall.

The larger monastic establishments had more than one cloister; there was usually a second connected with the infirmary, of which we have examples at Westminster Abbey and at Canterbury; and sometimes one giving access to the kitchen and other domestic offices.

The cloister was not an appendage of monastic houses exclusively. We find it also attached to colleges of secular canons, as at the cathedrals of Lincoln, Salisbury, Wells, Hereford, and Chichester, and formerly at St Paul's and Exeter. It is, however, absent at York, Lichfield, Beverley, Ripon, Southwell, and Wimborne. A cloister forms an essential part of the colleges of Eton and of St Mary's, Winchester, and New and Magdalen at Oxford, and was designed by Wolsey at Christ Church. These were used for religious processions and lectures, for ambulatories for the studious at all times, and for places of exercise for the inmates generally in wet weather, as well as in some instances for sepulture.

For the arrangements of the Carthusian cloisters, as well as for some account of those appended to the monasteries of the East, see the article Abbey. (E. V.)

CLONMEL, a parliamentary and municipal borough of Ireland, in the province of Munster, partly in the south riding of Tipperary and partly in Waterford county, 104 miles south-west from Dublin. It is built on both sides of the Suir, and also occupies Moore and Long Islands, which are connected with the mainland by three bridges. The principal buildings are the parish church, two Roman Catholic churches, a Franciscan friary, two convents, an endowed school dating from 1685, a model school under the national board, a mechanics' institute, a court-house and prison, a fever hospital and dispensary, two lunatic asylums, a market-house, a workhouse, and barracks. Till the Union the woollen manufacture established in 1667 was extensively carried on. The town contains a brewery, flour-mills, and tanneries, publishes two newspapers, and has a considerable export trade in grain, cattle, butter, and provisions. The river is navigable for barges of 50 tons to Waterford. Clonmel is a station on the Waterford and Limerick Railway, and the centre of a system, established by Mr Bianconi, for the conveyance of travellers on light cars, extending over a great part of Leinster, Munster, and Connaught. It is governed by a corporation, consisting of a mayor, free burgesses, and a commonalty, and returns one member to parliament. Population in 1851, 15,203; in 1871, 10,112.

Clonmel, or *Cluain mealla*, the Vale of Honey, is a place of undoubted antiquity. In 1269 it was chosen as the seat of a Franciscan friary by Otho de Grandison, the first English possessor of the district; and it frequently comes into notice in the following centuries. In 1641 it declared for the Roman Catholic party, and in 1650 it was gallantly defended by Hugh O'Neal against the English under Cromwell. Compelled at last to capitulate, it was completely dismantled, and has never again been fortified. Sterne was born in the town in 1713.

CLOOTZ, JEAN BAPTISTE, BARON (1755–1794), better know as Anacharsis Clootz, was born near Cleves. A baron by descent, and heir to a great fortune, he was sent at eleven to Paris to complete his education. There he imbibed the theories of his uncle, Cornelius de Pauw, and of the great anarchists of the epoch. He rejected his title and his baptismal names, adopted the pseudonym of Anacharsis from the famous philosophical romance of Abbé Barthélemy, and traversed Europe, preaching the new ideas as an apostle, and spending his money as a man of pleasure. On the breaking out of the Revolution he returned in 1789 to Paris. In the exercise of the function he assumed of "Orator of the Human Race," he demanded at the bar of the National Assembly a share in the federation for all nations, presenting at the same time a petition against the despots of the world. In 1792 he placed 12,000 livres at the disposal of the Republic—"for the arming of forty or fifty fighters in the sacred cause of man against tyrant." The 10th of August impelled him to a still higher flight; he declared himself the personal enemy of Jesus Christ, abjured all revealed religions, and commenced preaching materialism. In the same month he had the rights of citizenship conferred on him; and having in September been elected a member of the Convention, he voted the king's death in the name of the human race. Excluded at the instance of Robespierre from the Jacobin Club, he was soon afterwards implicated in an accusation levelled against Hébert and others. His innocence was manifest, but he was condemned and put to death.

Clootz left several works in which his extravagances are developed with much solemnity. The principal of these are *La Certitude des Preuves du Mahométisme*, *L'Orateur du Genre Humain*, and *La République Universelle*.

CLOT, ANTOINE (1795–1868), was born in the neighbourhood of Marseilles, and was brought up at the charity school of that town. After studying at Montpellier he commenced to practise as surgeon in his native place; but at the age of twenty-eight he was made chief surgeon to Mehemet Ali, viceroy of Egypt. At Abuzabel, near Cairo, he founded a hospital and schools for all branches of medical instruction, as well as for the study of the French language; and, notwithstanding the most serious religious difficulties, he prevailed on some of the Arabs to study anatomy by means of dissection. In 1832 Mehemet Ali gave him the dignity of bey without requiring him to abjure his religion; and in 1836 he received the rank of general, and was appointed head of the medical administration of the country. In 1849 he returned to Marseilles. Clot published—*Relation des épidémies de cholera qui ont régné à l'Heggiaz, à Suez, et en Egypte* (1832); *De la peste observée en Egypte* (1840); *Aperçu général sur l'Égypte* (1840); *Coup d'œil sur la peste et les quarantaines* (1851); *De l'ophthalmie* (1864).

CLOTILDA, SAINT (475–545), was the daughter of Chilperic, king of Burgundy, and the wife of Clovis, king of the Franks. Her father, mother, and brothers were put to death by Gundebald, her uncle, but Clotilda was spared and educated. Gundebald opposed her marriage with Clovis, but by the aid of the clergy she escaped to the Frankish court (493), was married, and, having adhered all along to the pure Catholic faith of her mother, effected the conversion of Clovis to Christianity (496). He lost no time in avenging the murder of his wife's parents; Gundebald was defeated, and became his tributary. After her husband's death Clotilda persuaded her three sons—Clodomir, Childebert, and Clotaire—to renew the quarrel, and to visit on Sigismund, Gundebald's son, his father's crime. The war which followed resulted in the union of Burgundy to the Frank empire. Clotilda retired to Tours, and practised there the austerities of a devout life till her death. She was buried in the Parisian church of St Geneviève, which Clovis had built, and was canonized a few years afterwards by Pelagius I. Her remains, preserved till the Revolution, were burned at that period by the devout Abbé Rousselet, who dreaded their desecration; the ashes are now in the little church of St Leu. A statue of her adorns the Luxembourg, and a splendid church has recently been erected in her honour in Paris, not far from the spot where her bones rested during so many centuries. See FRANCE.

CLOUGH, ARTHUR HUGH (1819–1861), a minor English poet, was born at Liverpool in 1819, and belonged to a family of old Welsh descent. His father, a cotton merchant, having removed to the United States about 1823, Arthur spent a number of years at home in Charleston; but in 1828 he was brought back to England and sent to school. From Rugby, where he was a favourite pupil of Dr Arnold's, he passed in 1836 to Oxford; and there, in spite of an almost unaccountable failure in some of his examinations, he attained a high reputation for scholarship, ability, and character. In 1842 he was chosen fellow of Oriel, and in 1843 appointed tutor in the same college; but he soon grew dissatisfied with his position, and ultimately decided that it was his duty to resign. Under the influence of the great religious fermentation which had been going on during his university career, he had become deeply sceptical in his habits of thought; and all connection seemed impossible with a system that interfered with the liberty of speculative investigation. After his resignation in 1848 he was for some time principal of University Hall, London. In 1852 he visited America, where he enjoyed the friendship of Longfellow and Emerson; and in the following year he was called home to accept an appointment as examiner in the Education Office of the Privy Council. During the succeeding years he was frequently abroad; and it was on a tour in Italy in 1861 that he was suddenly cut off by fever at Florence. Clough was a man of singular purity and integrity of character, with great sensitiveness of feeling, and fine subtlety of thought, at once reserved and retiring and full of a genial humanity of disposition, with much humour and mirthfulness, and yet capable of a righteous indignation that could hardly have been expected to find fuel in so kindly a breast. A disciple of the great master of Rugby, in the midst of his most relentless scepticism he maintained a spirit of reverence and worship; and his most daring attacks on the popular creed are modified by an undercurrent of toleration and diffidence. His poems are his principal works, and of these the best known is the *Bothie of Tober-na-Vuolich.* It was written and published in 1848, after his removal from Oxford; and while warmly praised by such men as Canon Kingsley it was condemned by others as immoral and communistic. The interest of the poem depends on its graphic description of Scottish scenery and the fine analysis of contrasted characters. Under the influence partly of Longfellow's *Evangeline,* which had been published in 1847, and partly of his own attachment to the old classical forms, he employed the so-called hexameter; but it is seldom that he attains the tuneful cadence of the American poet, and much of the versification is rugged and broken in the extreme. Of greater power than the *Bothie,* at least in individual passages, is the strange irregular tragedy of *Dipsychus,* which shines at times with jagged fragments of satire and irony. *Amours de Voyage,* a rhymed epistolary novelette, and *Mari Magno,* a small collection of tales after the fashion of the *Wayside Inn,* along with various minor poems, have been republished in the second volume of *The Poems and Prose Remains of Arthur H. Clough,* edited by his wife, and accompanied by a sketch of his life by F. T. Palgrave, 1869. These will probably do less to keep green the poet's name than the noble poem of *Thyrsis,* which Matthew Arnold dedicated to his memory. One work of importance remains to be mentioned,—a careful and scholarly rehabilitation of Dryden's Translation of Plutarch, published in 1859.

CLOVES are the unexpanded flower-buds of *Caryophyllus aromaticus,* a tree belonging to the natural order *Myrtaceæ.* They are so named from the French word *clou,* on account of their resemblance to a nail. The clove tree is a beautiful evergreen which grows to a height of from 30 to 40 feet, having large oblong leaves and crimson flowers in numerous groups of terminal cymes. The flower-buds are at first of a pale colour and gradually become green, after which they develop into a bright red, when they are ready for collecting. Cloves are rather more than half an inch in length, and consist of a long cylindrical calyx, terminating in four spreading sepals, and four unopened petals which form a small ball in the centre. The tree is a native of the small group of islands in the Indian Archipelago called the Moluccas, or Spice Islands; but it was long cultivated by the Dutch in Amboyna and two or three small neighbouring islands. Cloves were one of the principal Oriental spices which early excited the cupidity of Western commercial communities, having been the basis of a rich and lucrative trade from an early part of the Christian era. The Portuguese, by doubling the Cape of Good Hope, obtained possession of the principal portion of the clove trade, which they continued to hold for nearly a century, when, in 1605, they were expelled from the Moluccas by the Dutch. That power exerted great and inhuman efforts to obtain a complete monopoly of the trade, attempting to extirpate all the clove trees growing in their native islands, and to concentrate the whole production in the Amboyna Islands. With great difficulty the French succeeded in introducing the clove tree into Mauritius in the year 1770; subsequently the cultivation was introduced into Guiana, and at the end of the century the trees were planted at Zanzibar. The chief commercial sources of supply are now Zanzibar and its neighbouring island Pemba on the East African coast, and Amboyna. Cloves are also grown in Java, Sumatra, Réunion, Guiana, and the West India Islands.

Cloves as they come into the market have a deep brown colour, a powerfully fragrant odour, and a taste too hot and acrid to be pleasant. When pressed with the nail they exude a volatile oil with which they are charged to the unusual proportion of about 18 per cent. The oil is obtained as a commercial product by submitting the cloves with water to repeated distillation. It is, when new and properly prepared, a pale yellow or almost colourless fluid, becoming after some time of a brown colour; and it possesses the odour and taste peculiar to cloves. The essential oil of cloves is a mixture of two oils—one a hydrocarbon isomeric with oil of turpentine, and the other an oxygenated oil, eugenol or eugenic acid, which possesses the taste and odour of cloves. Cloves are employed principally as a condiment in culinary operations, in confectionery, and in the preparation of liqueurs. In medicine they are tonic and carminative, but they are little used except as adjuncts to other substances on account of their flavour, or with purgatives to prevent nausea and griping. The essential oil forms a convenient medium for using cloves for flavouring or medicinal purposes, and it also is frequently employed to relieve toothache.

CLOVIO, GIULIO (1498-1578), by birth a Croat and by profession a priest, is said to have learned the elements of design in his own country, and to have studied afterwards with intense diligence at Rome under Giulio Romano, and at Verona under Girolamo de' Libri. He excelled in historical pieces and portraits, painting as for microscopical examination, and yet contriving to handle his subjects with great force and precision. In the Vatican library is preserved a MS. life of Frederick, duke of Urbino, superbly illustrated by Clovio, who is *facile princeps* among Italian miniaturists.

CLOVIS, king of the Franks. See FRANCE.

CLOYNE (in Irish Cluain-Uamha, or the Meadow of the Cave), a market town and formerly an episcopal see of Ireland, in the county of Cork, and about four miles from the east side of Cork harbour. It is now a small place of 1200 inhabitants, but it still gives its name to a Roman Catholic diocese. The cathedral, which was founded in the 6th century by Colman, a disciple of Fin-Bane of Cork, is still in existence. It contains a few handsome monuments to its former bishops, but, singular to say, nothing to preserve the memory of the illustrious Dr George Berkeley, who filled the see from 1734 to 1753. Opposite the cathedral is a very fine round tower still 96 feet in height, though the conical roof was destroyed by lightning in 1748. The Roman Catholic church is a spacious building with a highly decorated front. The town was several times plundered by the Danes in the 9th century; it was laid waste by Dermot O'Brien in 1071, and was burned in 1137. In 1430 the bishopric was united to that of Cork; in 1638 it again became independent, and in 1660 it was again united to Cork and Ross. In 1678 it was once more declared independent, and so continued till 1835, when it was again joined to Cork and Ross. The Pipe Roll of Cloyne, compiled by Bishop Swaffham in 1364, is a very remarkable record, embracing a full account of the feudal tenures of the see, the nature of the impositions, and the duties the *puri homines Sancti Colmani* were bound to perform at a very early period. The roll is now in the Record Office, Dublin. It was edited by Richard Caulfield in 1859.

CLUB. The records of all nations agree in attributing the institution of clubs and private companies to the earliest, or one of the earliest, rulers or legislators of whom they have retained any memory. Indeed such associations seem, as Addison has said, "to be a natural and necessary offshoot of men's gregarious and social nature." In the infancy of national existences, they are almost essential for purposes of mutual support and protection, and to supply the shortcomings of a weak Government. But over and above those fellowships which spring from the inalienable right of self-preservation, and which are founded either in the ties of kindred or community of material interests, there are commonly found, even in matured and well-organized states, a number of secondary or accidental societies, established for the promotion of some common object; and a wise and strong Government usually protects and encourages them as a most important condition of human progress. They may be roughly divided into four different classes, according to their several objects; they may be either religious, political, commercial, or merely social; and an attempt has been sometimes made to assign these to different periods of national development. Such a distinction, however, cannot be successfully maintained, since the various elements were often most closely united in the same clubs, almost (or quite) from their very foundation. Thus, the corporations in Rome whose foundation was attributed to Numa would seem at first sight to have been merely for convenience of trade. But we are told that they had also a social or political purpose, viz., to break down the barriers which separated Romans from Sabines in the infant state. Moreover, Plutarch introduces a religious element into them also, saying that Numa "fixed certain times of meeting for these companies, and certain honours to the gods, assigning to each what was suitable for them." So again in Greece we have the testimony of Aristotle that members of the same tribe or borough used to club together, men following the same occupations, as soldiers or sailors, and others again for mere social amusement; yet he immediately adds—"these meet together for the sake of one another's company, and to offer sacrifices; when they meet they both pay certain honours to the gods, and at the same time take pleasurable relaxation among themselves." It is clear, then, that whatever may have been the precise object with which each private club or association was originally formed in pagan times, these distinctive marks were very soon blurred, and finally, in the lapse of time, altogether obliterated.

We need not say anything of the religious sodalities which were appointed in a regular way both in Greece and Rome for the worship of the gods recognized by the state. It is the history of secret confraternities for the exercise of foreign religious rites unknown to the state and strictly forbidden that is more curious and attractive. In Athens the penalty of death stood enacted in the statute book against those who should introduce the worship of strange gods; but it is only on very rare and scandalous occasions that we hear of this statute in real life. There was a great invasion of foreign gods into Attica after the Persian war, and they were not so easily driven out as were the hosts of Xerxes who had imported them. Moreover, independently of foreign armies, the mere commercial activity of Athens herself did much to promote the same evil. Her sailors and soldiers, colonists and merchants, had explored the coasts of the Ægean Sea, and had brought home from Thrace, from Phrygia, from Cyprus, and elsewhere, a whole host of deities, not more false indeed, but certainly more dangerous, than those whom they had been wont to worship at home. These gods and goddesses soon found little knots of devotees, who were led to form a kind of confraternity among themselves, for the support of the forbidden worship. Fragments both of tragic and comic poets have preserved to us some notice of the kind of worship that was offered, and it was obviously in every way less respectable than the worship sanctioned by the state. In the state temples the priests and other officers were obliged to be freemen, citizens, and the sons of citizens; any taint of servile or foreign blood was a fatal disqualification. But here slaves, foreigners, and women were admitted indiscriminately. Indeed, if we may judge from monuments that have recently come to light, these secret confraternities found their principal support among these classes. At Rhodes there was one consisting exclusively of the lowest class of slaves,—the public slaves of the town; at Salamis, one exclusively of women; in that of Cnidus eleven members out of twelve were foreigners. All these monuments come from islands; and of course it was there, and in the seaport towns of the peninsula, that such illicit corporations were likely to be first introduced and to take deepest root. By-and-by it became necessary even to give an official recognition to some of them, *e.g.*, in the Piræus, for the convenience of foreigners who were either detained there for a considerable time by business, or perhaps had even taken up their permanent abode there. Excavations made within the last twenty years in the Piræus, and still more recently in the neighbourhood of the silver mines of Laurium, enable us to assist at the birth and early growth of some of these illicit clubs, but there is nothing in the history specially inviting. In Rome the general policy of the state towards foreign religions was more tolerant than in Greece. Nevertheless here also the practice of certain religions was forbidden, and the prohibition naturally produced certain secret societies amongst those who were attached to them. The law indeed forbade the worship of any deity that had not been approved by the senate, but then the senate was by no means illiberal in granting its diploma of approbation, and as often as a new deity was introduced, or even a new temple built to an old deity, a new sodality seems to have sprung up, or to have been officially appointed, to look after its interests. It is disputed whether the prohibition of the worship of unknown, unrecognized gods, applied only to acts of public worship, or extended even to the innermost secrecy of private life. Cicero may be quoted in defence of the latter view, Livy of the former. Probably the letter of the law favoured the stricter side and spoke universally, but traditional practice ruled differently. Certainly the Romans had a scruple about interfering with anything which even pretended to lay claim to a religious character. Even when they repressed with such severity the secret meetings of the Bacchanalians, this was done not so much in the interest of the other gods, as of public order and morality and the security of the state. They even continued to tolerate such foul associations as these, only they imposed the condition that not more than five worshippers should meet together at once; and under cover of this permission the number of *thiasi* was much multiplied in the city, and these exercised a powerful attraction over women by the promise which they made of effecting a real purification of the soul. At a later period, when Augustus destroyed all the temples of Serapis which had been erected in Rome during his absence, he was careful to assign a political motive for this unusual interference with religious liberty.

If we turn from these religious associations to consider the craft-gilds in ancient Rome, the first thing that strikes us is their extraordinary number. In the days of Numa we are told that there were only eight; but as time went on they so multiplied that in the imperial period we count more than fourscore of them, including almost every profession and handicraft one can think of, from bankers and doctors down to donkey-drivers and muleteers. Nor does the mere enumeration of the different trades and professions give us at all an adequate idea of their number; for when a club became very large, it was first subdivided into centuries, and then these again broke off into separate clubs. Again, there was one club or company of the watermen who plied their trade on the Saone, and another of the watermen on the Rhone, though both these companies had their headquarters at Lyons. The other navigable rivers, too, each had its own company. Thus, the most ancient notice we have of Paris is derived from a monument which has come down to us of the watermen on the Seine. We find mention, also, of more craft-gilds than one even in a single street of Rome; nay, further still, within the limits of a single house, *e.g.*, of the imperial palace, and probably of other princely establishments, which counted their hundreds or thousands of dependants. Each class of slaves engaged in different domestic occupations had their own clubs. Thus the *chef de cuisine* (*magister coquorum*) of Augustus bequeathed a sum of money to the collegium, or club, of cooks, in his imperial majesty's household, and there is evidence that there were five or six other clubs in the palace at the same time. We do not know how large each club may have been; an old inscription tells us of forty seats reserved for a particular club in the amphitheatre at Nîmes, but these belonged probably to the officers of the club, not to the ordinary members indiscriminately. Sometimes the number of members was limited, either by the original constitution of the body, or by conditions subsequently imposed by benefactors who did not wish their donations to be frittered away and rendered useless by too minute subdivisions. As to the internal organization of the clubs, the general laws and principles which governed their constitution, both in Athens and in Rome, they were moulded, as was only natural, very much after the pattern of the civil institutions of the country. They were republican therefore in spirit, the administration of affairs being wholly in the hands of the members themselves, all of whom had equal rights; their watchful control was incessant, and their authority absolute; their officers were elected by universal suffrage, sometimes by acclamation; they were called by the same names as were borne by the magistrates of the state, ἄρχοντες, *quæstores*, *magistri quinquennales*, *curatores*, &c.; they were elected annually, and on entering into office they took an oath that they would observe the constitution and laws of the corporation; and on retiring from office they gave an account of their stewardship to the assembled members, who exercised a right of judgment over them. This judgment seems to have been almost uniformly favourable; a commendatory decree was voted almost as much a matter of course as a vote of thanks to the chairman of our own public meetings. In Greece this vote was accompanied by the offering of a crown of leaves, of olive, ivy, or poplar, according to the supposed choice of the god or goddess to whom the club was dedicated. In the East, *e.g.*, Bithynia, we find crowns of ribands and flowers; in Rhodes, Delos, and the adjacent islands, it was not uncommonly of gold,—of very little intrinsic worth, however, and provided by special contributions at each monthly meeting. But the most valued part of the reward to these retiring officers (in Greece) seems to have been the proclamation of the honour obtained, which proclamation took place either after the ceremonies of the chief annual festival, or sometimes on every occasion of meeting. It was also engraved on a column which was set up in some conspicuous spot in or near their place of meeting. When any special services seemed to call for special recognition, the title of benefactor or benefactress was awarded, and this, too, was of course added to the inscription. A still higher and rarer honour was to offer the retiring officer a statue or portrait of himself, either full length or half figure only or sometimes both together, and even more than one of each. But only once among Greek inscriptions belonging to these clubs do we find any mention of a salary awarded to the secretary, in consideration of the zeal and justice with which he had attended to the general interests of the community, the exactness with which he had rendered his own reports and accounts, as well as audited those of others who from time to time had been specially deputed to do anything for the club, and his constant devotion to the interests of all the members both collectively and individually. Even in this instance, however, the zealous and disinterested secretary or treasurer declined the proffered salary, whereupon the club voted him a golden crown, which again he gave up for the decoration of the temple in which they met. And this, indeed, was the usual fate of these complimentary offerings. The officers fulfilled the duties of their post gratuitously, and often at great expense to themselves, just as the civil magistrates were obliged to do; and it seems to have been pretty generally understood, that any extraordinary compliments, such as the offer of a statue or portrait, should, if accepted, be carried out at the expense, not of the donor, but of the receiver. In Rome, also, whenever an inscription states that the members of a *collegium* decree that a statue shall be erected in honour of some patron or benefactor, it is generally added that he undertook to pay for the statue himself (*honore contentus, impensam remisit*). Besides the acting officials of these clubs, there were also certain honorary patrons, whose connection with them was probably much the same as that of most patrons of benevolent societies in our own day. It was a compliment to invite them to become patrons, and they were expected to contribute to the funds in return.

It only remains that we should say a few words about the merely social clubs of pagan times,—those clubs which had no other bond of union, either commercial, political, or religious, but which aimed only at the amusement or private advantage of their members. There was nothing in the functions of these clubs to obtain for them a place in the page of history. The evidence, therefore, of their existence and constitution is but scanty. Monumental inscriptions, however, tell us of clubs of Roman citizens in some of the cities of Spain, of a club of strangers from Asia resident in Malaga, of Phœnician residents at Pozzuoli, and of other strangers elsewhere. These all were probably devised as remedies against that sense of *ennui* and isolation which is apt to come over a number of foreigners residing at a distance from their native country. Something of the same kind of feeling may have led to the toleration of a club consisting of old soldiers who had been in the armies of Augustus; these were allowed to meet and fight their battles over again, spite of the legal prohibition of military clubs. Another military club of a different kind existed among the officers of a regiment engaged in foreign service in Africa. Its existence can have been no secret, for its rules were engraved on pillars which were set up near the headquarters of the general, where they have lately been found in the ruins of the camp. The contribution of each member on admission scarcely fell short of £25, and two-thirds of this sum were to be paid to his heir or representative on the occasion of his death, or he might himself recover this proportion of his original subscription on retirement from military service. The peculiarity, however, of this aristocratic *collegium* was this, that it provided that a portion of the funds might also be spent for other useful purposes, *e.g.*, for foreign travelling. It is to be presumed that a member who had availed himself of this privilege thereby forfeited all claim to be buried at the expense of his club.

Clubs were by no means the exclusive privilege of the male sex in ancient days. Women also were united in similar associations. Their religious sodalities, indeed, were not generally edifying; but they combined together also for social and political purposes. The most remarkable of these was the great assembly of matrons, called at one time, in a mock-heroic way, "the minor senate." This ladies' club received its title from imperial authority, which also legislated as to the needful qualifications of its members, the times of its meeting, and the subjects of its debates. These concerned the gravest questions of etiquette, such as what dress ladies should wear according to their social rank; who was to take precedence one of another on public occasions of state, in processions, or other ceremonies; who might ride in a carriage drawn by horses; who must be content to sit behind mules; whose sedan-chair might have fittings of ivory, whose of silver, &c. Not all ladies could attain to a seat in this little senate, which dealt with such delicate questions of etiquette; but we find them forming other clubs of their own which occasionally meddled with questions of municipal, if not of general, interest. They deliberated on the rewards to be given to this or that magistrate, and voted funds for monuments and statues in honour of those who had earned their approbation. The names of women are not unfrequently set down as patronesses of certain craft-gilds, of which they can hardly have been ordinary members; and in one instance at least in Africa, and in another in Majorca, inscriptions distinctly mention that certain ladies had filled all the official posts in a *collegium*. (J. S. N.)

Modern Clubs.—The word *club*, denoting the promotion of intercommunity and good fellowship, is not very old, and only became common in the time of the *Tatler* and *Spectator;* it claims a descent, however, from the Anglo-Saxon, being derived from *cleofan*, to divide, because the expenses are divided into shares. Thomas Occleve (*temp.* Henry IV.) mentions a club designated *La Court de Bone Compaignie* of which he was a member. Aubrey (1659) speaks thus of the word: "We now use the word *clubbe* for a sodality in a taverne." He also mentions the ballot box, that potential instrument too often used in modern days for the indulgence of secret spleen: "Here we had (very formally) a *ballotting box*, and ballotted how things should be carried." Dr Johnson, according to Boswell, defines a club to be an "assembly of good fellows meeting under certain conditions." And to the same authority may be traced the words "clubable" and "unclubable."

The numerous London clubs which sprang into existence in the last and previous century had their place and origin almost entirely in the coffee-houses and taverns then so much in vogue. Of these the earliest known was the *Bread Street* or *Friday Street Club* originated by Sir Walter Raleigh, and meeting at the Mermaid Tavern. Shakespeare, Beaumont, Fletcher, Selden, Donne, and others were members of this club. Other clubs were subsequently formed, such as that meeting at the Devil Tavern near Temple Bar, of which Ben Jonson was supposed to be the founder; and later on (in 1764) we find the *Literary Club* was established chiefly at the instance of Sir Joshua Reynolds, which soon acquired a renown no more than proportionate to its merits—a renown maintained and brought down to the present day.

Addison, in the *Spectator*, has a paper on the clubs of his day (No. 9, vol. i. 1710). Of the description of club there sketched many exist at the present time, having no object but that of good fellowship and dining. In this category may be included the *Royal Society Club*, the history of which has been written by the late Admiral Wm. Henry Smyth, F.R.S., in the privately printed *Sketch of the Rise and Progress of the Royal Society Club*, published in 1860.

Of the more notable of the clubs of the past and the early part of the present century but few resembled the club of the Victorian era. Of those which survive may be mentioned *White's*, originally established in 1698. This club was formerly of a high Tory character, and though no longer political is still somewhat conservative and undoubtedly aristocratic. *Brooks's* club, similar to *White's* in the character of its members, and nearly coeval in date, has continued to maintain a political aspect, and is considered to be identified with Whig principles. *Boodle's*, of later date, has always been deemed the resort of country gentlemen, and especially of masters of fox-hounds. *Arthur's*, in some respects an offshoot of *White's*, was established fully a century ago, and continues to this day a club of gentlemen associated for no special purpose, but united only by congeniality of tastes and ideas

The number of regularly established clubs in London is upwards of fifty, divided into political, literary and scientific, university, naval and military, and general clubs. Of the political clubs the principal are the *Carlton*, the *Conservative*, the *Junior Carlton*, and the *St Stephen's*, the *Reform*, and the *Devonshire* (a kind of junior *Reform* club), the conditions of admission into which are of a political nature. Of the literary and scientific, the *Athenæum* was "instituted for the association of individuals known for their scientific or literary attainments, artists of eminence in any class of the fine arts, and noblemen and gentlemen distinguished as liberal patrons of science, literature, or the arts," and has long enjoyed a high reputation, rendering admission to its ranks both tedious as regards the length of time a candidate has to wait before being put up for ballot, and difficult when he is subjected to that crucial test. Of university clubs the *United University* is the oldest, the others being the *Oxford and Cambridge*, the *New University*, and others, the qualification for membership of which would be that of connection with the chief universities. The naval and military clubs include the *United Service*, the *Junior United Service*, the *Army and Navy*, with numerous others intended for military and naval officers, and in some instances for officers of militia. The general clubs include the *Travellers'*, to be deemed eligible for which a candidate must have "travelled out of the British Islands to a distance of at least 500 miles from London in a direct line" (not a very onerous condition in the present day, but one of some weight in 1815 when the club was founded), and the *Oriental* and *East India United Service* clubs, intended more especially for members of Her Majesty's Indian services both civil and military. Besides these there are numerous clubs of a special character, such as the *Windham*, whose object is stated to be "to secure a convenient and agreeable place of meeting for a society of gentlemen all connected with each other by a common bond of literary or personal acquaintance;" the *National* club, consisting of "members who hold the doctrines and principles of the Reformed faith, as revealed in Holy Scripture, asserted at the Reformation, and generally embodied in the articles of the Church of England;" or the *Garrick*, which was instituted in 1831 for "the general patronage of the drama, for bringing together the supporters of the drama, and for the formation of a theatrical library with works on costume."

This list might be extended, but the general aims of the modern style of club are sufficiently indicated in this reference to the salient features of the clubs named.

The architectural elevations of the London club-houses are such as have lent dignity and character to the parts of London in which they are situated. Pall Mall notably is thus now a street of palaces. Nor should the contents of these handsome and convenient mansions pass unnoticed. The *Athenæum* has probably the choicest library of its kind, consisting mainly of books of reference, and including 45,000 volumes. The *Garrick* club has an exceedingly valuable collection of oil and water-colour paintings, chiefly as might be expected, relating to dramatic episodes. The *United Service*, the *Reform*, the *Oriental*, and some other clubs have an assemblage of portraits of members who have won fame, or of paintings of celebrated battles and public events. The furniture and arrangements of the different apartments correspond to the exteriors, every convenience and luxury being placed at the disposal of the members.

The mode of election of members varies. In some clubs the committee alone have the power of choosing new members. In others the election is by ballot of the whole club, one black ball in ten ordinarily excluding. In the *Athenæum*, whilst the principle of election by ballot of the whole club obtains, the duty is also cast upon the committee of annually selecting nine members who are to be "of distinguished eminence in science, literature, or the arts, or for public services," and the rule makes stringent provision for the conduct of these elections. On the committee of the same club is likewise conferred power to elect without ballot princes of the blood royal, Cabinet ministers, bishops, speaker of the House of Commons, judges, &c.

The general concerns of clubs are managed by committees constituted of the trustees, who are usually permanent members thereof, and of ordinarily twenty-four other members, chosen by the club at large, one-third of whom go out of office annually. These committees have plenary powers to deal with the affairs of the club committed to their charge, assembling weekly to transact current business and audit the accounts. Once a year a meeting of the whole club is held, before which a report is laid, and any action taken thereupon which may be necessary.

The entrance fee varies from £40 at the *United Service* and *Army and Navy* clubs to 20 guineas at the *Carlton* club. The annual subscription in like manner ranges from 10 guineas in the *Carlton*, *Reform*, and several others, to 7 guineas in the *United Service* club. The largest income derived from these and all other sources may be stated to be that of the *Army and Navy* club, which in the year 1875 amounted to £30,813, of which £19,383 was raised by entrance fees and subscriptions alone. The expenditure is, however, most commonly of nearly equal amount, and of few of the clubs can it be said that they are entirely free from debt. The number of members included in a London club varies from 2200 in the *Army and Navy* to 475 in the *St James's* club.

Numerous provincial clubs are established throughout the country. In both Edinburgh and Dublin are clubs fully coming up to the metropolitan societies. Nor is this great public convenience lacking in the cities and towns of Europe, the United States, and the British colonies.

Of a different nature and with widely different objects are the learned bodies designated publishing clubs, of which the *Abbotsford*, the *Bannatyne*, the *Roxburghe*, and others are examples. These societies devoted themselves solely to the editing of unpublished MSS., or the reprint of rare and valuable works. (J. C. W.)

A.), *Learned Societies and Printing Clubs*, 1847.

CLUB-FOOT (*Talipes*). The pathology and treatment of the various deformities of the foot, which are included under the above general title, come strictly under orthopædic surgery. Several forms of club-foot have been recognized by surgeons There are four primary forms:—(1) *Talipes equinus*, in which the heel does not touch the ground, the child resting on the toes; (2) *Talipes varus*, in which the foot is turned inwards and shortened, the inner edge of the foot raised, the outer edge of the foot only touching the ground; (3) *Talipes calcaneus*, a rare form, in which the heel only touches the ground, the toes being raised; (4) *Talipes valgus*, in which the foot is turned outwards. The third and fourth varieties are so rare that they are of no practical interest, and need not be further alluded to. It is possible to confound true talipes valgus with flat-foot, a deformity which is the result of undue stretching, from weakness, of the fascial and ligamentous structures which maintain the arched form of the foot. In flat-foot the arch is lost, the patient is splay or flat-footed, and as a secondary deformity the foot is turned outwards, resembling and often confounded with true talipes valgus.

The two common primary forms of club-foot are *talipes equinus* and *talipes varus*. These two varieties are frequently combined; the deformity is then termed *talipes equino-varus*. A shortening or contraction of one group, or of allied groups, of muscles is always to be observed; as, for instance, in *talipes equinus*, to which the muscles of the calf are contracted, or in *talipes varus*, in which the group of muscles which turn the foot inwards are contracted, or in *talipes equino-varus*, in which both sets are at fault. This contraction is due either to excessive primary irritation of the muscular group implicated, or is secondary to and the result of paralysis of an opposing group of muscles. In certain cases the paralysis affects more or less all the muscles of the limb; the result of this is a deformity in the direction of the most powerful group. The primary cause of these diseased conditions is some irritation of the cerebro-spinal central nervous system, either occurring before birth, and termed congenital, or appearing after birth, generally during the period of first dentition, and termed non-congenital. As a rule well-marked cases are congenital. Such deformities are frequently hereditary. Both feet may or may not be affected. Recognition of club-foot is of importance, because if not treated early a change takes place in the shape of the bones of the foot, which renders treatment much more difficult, and in some neglected cases it is impossible to restore the foot to its normal shape.

It is to Stromeyer in Germany (1837), and to Little and Adams in England, that we owe a true understanding of the pathology and treatment of these affections.

The following broad principles, which govern the treatment, are now universally understood and adopted by surgeons:—(1) A subcutaneous division, by the operation of tenotomy, of the contracted tendons; and (2) A stretching of the newly-formed embryonic tissue which is deposited between the cut extremities of the tendons in the inter space, the result of their retraction after division. This is managed by means of a mechanical appliance termed a club-foot boot. Various forms of boot have been used by surgeons; in all the essential feature is that the foot is fixed to the boot by sticking-plaster or by straps, and the stretching is gradually accomplished by the elasticity of Indian-rubber bands, or by steel springs, or by screws. In this way the foot gradually assumes a normal appearance.

As a general rule, after it is evident that the deformity is a persistent one, the earlier the operation is performed the better. Only in exceptional cases should interference be delayed beyond the third or fourth month of life. If a change takes place in the bones, or if the child is allowed to walk before treatment of the deformity, the cure is rendered more difficult and more tedious. In many cases when the child is young the cutting operation will not be necessary; the foot can be restored to its normal position by mechanical appliances alone.

Various rules have been laid down for the proper performance of tenotomy. The simple rule to begin with the most tense tendon, and to divide it where it is most tense, is of universal application. In *talipes equinus* the *tendo achillis*, in *talipes varus* the *tibialis posticus* and *tibialis anticus* require division. In the common form *talipes equino-varus*, both groups must be operated on. Very frequently the plantar fascia is shortened and has also to be divided. After the operation, which is greatly facilitated by the administration of chloroform, the foot is kept at rest with a bandage for three or four days until the small punctures are healed. The boot is then carefully applied, and gradually the foot is restored to its normal shape *without causing pain*, which interferes with the object in view, namely, a moulding (by stretching) of the newly-formed tissue between the divided ends of the tendons If there is distinct paralysis the appropriate remedies—friction, passive exercise, and the electric battery —may be indicated. The boot should be worn for some time after the foot has regained its normal appearance, because there is always a tendency for a considerable period to the return of the deformity. (J. C.)

CLUNY, or CLUGNI, a town of France, in the department of Saône-et-Loire, about twelve miles by rail north-west of Macon, on the left bank of the Grône, a tributary of the Saône, crossed there by two bridges. It is a place of upwards of 4000 inhabitants, and carries on a considerable agricultural trade, and the manufacture of pottery, paper, and vinegar. The main interest in the town is due to its specimens of mediæval architecture, which include, besides its celebrated abbey, the church of Notre Dame, dating from the 13th century; the church of Saint Marcel with a beautiful spire; the ruins of Saint Mayeul; portions of the ancient fortifications; and a number of picturesque houses belonging to various periods from the 12th century downwards, classed among the historic monuments of France. A mere village at the time when William the Pious and Bernon, abbot of Gigny and Baume, laid the foundations of what was destined to be one of the principal monasteries of Europe, it gradually increased with the development of the religious fraternity, and was raised to the rank of a town. Before the erection of St Peter's at Rome, the abbey church, which was consecrated by Innocent II., was recognized as the largest building of its kind in Europe, its length being no less than 656 feet and its breadth 130. During the wars of the 16th century the abbatial buildings were greatly damaged; and in the Revolution of 1789 a great part of them were completely demolished. Restorations have since been effected at various times, and different portions of the enormous pile are appropriated to civic purposes. The abbot's palace contains a museum and a library; the cloisters are occupied by a school; and the site of the abbey church affords room for a Government stud. The 12th century was the period at which the monks of Cluny reached the height of their prosperity; and about that time no fewer than 2000 religious establishments throughout Europe acknowledged allegiance. Shortly after they began to decline from the ancient rigidity of their rule; and their influence gave way before the rising power of the Cistercians. Among the great men whom they have produced are Gregory VII., Urban II., and Pascal II. The town residence erected in Paris by the abbots of Cluny about the end of the 15th century is still extant, and, under the name of Hôtel de Cluny, is occupied by the Sommerard archæological collection; but the Collégé de Cluny, which was founded in 1269 by Ives de Vergy, has disappeared.

CLUSIUM. See CHIUSI.

CLUVER, PHILIP (1580–1623), a German geographer still regarded as an authority, was born at Danzig in 1580. After travelling in Poland and Germany, he commenced the study of law at Leyden; but he soon turned his attention to geography, which was then taught there by Joseph Scaliger. Displeased with his desertion of the law, his father refused to support him; and he was forced to enter the army, with which he served for two years in Bohemia and Hungary. After leaving the army he undertook to get printed in Holland an apology for Baron Popel, who had been imprisoned by the emperor; and in consequence he was himself thrown into prison. On his release he visited England, where he married, and became acquainted with Dr Holland and Dr Prideaux. After spending some time in Scotland and France, he returned to Holland; and in 1611 he commenced to publish his works, being, after 1616, supported by a pension from the Academy of Leyden. His principal works are—*Germania Antiqua* (1616), *Siciliæ Antiquæ libri duo, Sardinia et Corsica Antiqua* (1619), *Italia Antiqua* (1624), *Introductio in Universam Geographiam* (1629).

CLYDE, the most important river of Scotland, and the third in point of magnitude, has its origin from numerous small streams rising at a height of about 1400 feet above the level of the sea, in the mountains which separate Lanarkshire from the counties of Peebles and Dumfries. It flows first in a northerly direction, with a slight inclination eastward as far as Biggar, where, in time of floods, a junction is sometimes established with the system of the Tweed by means of the Biggar Water. After uniting with the Douglas near Harperfield, it takes a north-west course, passing Lanark, Hamilton, and Glasgow, and merges in the Firth of Clyde below Dumbarton. From its source to Dumbarton it is about 73 miles in length, the direct district being about 52. Its principal tributaries are the Douglas, the Nethan, the Avon, and the Cart from the left, and the Medwyn, the Mouse, the Calder, the Kelvin, and the Leven from the right. Of the celebrated Falls of Clyde, three are above and one below Lanark; the uppermost is Bonnington Linn, the height of which is about 30 feet; the second is Corra Linn, where the water dashes over the rock in three distinct leaps, and resumes its course at a level 84 feet lower. Dundaff Linn is a small fall of 10 feet; and at Stonebyres there are three successive falls, together measuring 76 feet in height. At high water the Clyde is navigable to Glasgow for the largest class of merchant vessels. See GLASGOW.

CLYDE, LORD (1792–1863), better known as SIR COLIN CAMPBELL, was born at Glasgow on the 16th of October 1792. He received his education at the high school of that city, and when only sixteen years of age obtained an ensigncy in the 9th foot, through the influence of Colonel Campbell, his maternal uncle. The youthful officer had an early opportunity of engaging in active service. He fought under Sir Arthur Wellesley at Vimiera, took part in the retreat of Sir John Moore, and was present at the battle of Coruna. He shared in all the fighting of the next Peninsular campaign, and was severely wounded while leading a storming-party at the attack on San Sebastian. He was again wounded at the passage of the Bidoassa, and compelled to return to England, when his conspicuous gallantry was rewarded with the rank of captain and lieutenant, without purchase. Campbell held a command in the American expedition of 1814; and after the peace of the following year he devoted himself to studying the theoretical branches of his profession. In 1823 he quelled the negro insurrection in Demerara, and two years later obtained his majority by purchase. In 1832 he became lieutenant-colonel of the 98th foot, and with that regiment rendered distinguished service in the Chinese war of 1842. Colonel Campbell was next employed in the Sikh war of 1848–49, under Lord Gough. At Chillianwalla, where he was wounded, and at the decisive victory of Goojerat, his skill and valour largely contributed to the success of the British arms; and his "steady coolness and military precision" were highly praised in official despatches. He was created a K.C.B. in 1849, and specially named in the thanks of Parliament, After rendering important services in India, Sir Colin Campbell returned home in 1853. Next year the Crimean war broke out, and he accepted the command of the Highland brigade, which formed the left wing of the duke of Cambridge's division. The success of the British at the Alma was mainly due to his intrepidity; and with his "thin red line" of Highlanders he repulsed the Russian attack on Balaklava. At the close of the war Sir Colin was promoted to be Knight Grand Cross of the Bath, and elected honorary D.C.L. of Oxford. His military services, however, had as yet met with tardy recognition; but, when the crisis came, his true worth was appreciated. The outbreak of the Indian Mutiny called for a general of tried experience; and on July 11, 1857, the command was offered to him by Lord Palmerston. On being asked when he would be ready to set out, the veteran replied, "Within twenty-four hours." He was as good as his word; he left England the next evening, and reached Calcutta on August 13. The position was one of unusual difficulty, but his energy and resource did not fail for a moment. Having formed an army as hastily as possible, he marched with 6000 men and 36 guns to the relief of Lucknow. The odds against him were great, and nothing save consummate dexterity of manœuvring could have achieved success. When the British guns were silenced by the fire of the rebels, Sir Colin himself headed the final assault, carried the fort, and saved the besieged. He afterwards, by his skilful tactics, thoroughly defeated the enemy, and captured their strongholds,—thus crushing the mutiny and preserving the British rule in India. For these services he was raised to the peerage in 1858, by the title of Lord Clyde; and returning to England in the next year he received the thanks of both Houses of Parliament. He enjoyed a pension of £2000 a year until his death, which occurred on the 14th of August 1863.

Lord Clyde possessed in abundant measure all the qualities which go to make a successful general. He combined the daring of the subaltern with the calm prudence of the veteran commander. The soldiers whom he led were devotedly attached to him; and his courteous demeanour and manly independence of character won him unvarying respect. Though adequate recognition of his merits came slowly, he never allowed any feeling of pique to interfere with duty; and he deserves to be regarded as one of the most distinguished generals that Britain has produced.

CLYTÆMNESTRA, the daughter of Tyndareus and Leda, and wife of Agamemnon. See AGAMEMNON.

CNIDUS, now TEKIR, an ancient city of Caria, in Asia Minor, situated at the extremity of the long peninsula that forms the southern side of the Sinus Ceramicus, or Gulf of Cos. It was built partly on the mainland and partly on the Island of Triopion, or Cape Krio, which anciently communicated with the continent by a causeway and bridge, and is now permanently connected by a narrow sandy isthmus. By means of the causeway the channel between island and mainland was formed into two harbours, of which the larger, or southern, now known as port Freano, was further enclosed by two strongly-built moles that are still in good part entire. The extreme length of the city was little less than a mile, and the whole intramural area is still thickly strewn with architectural remains. The walls, both insular and continental, can be traced throughout their whole circuit; and in many places, especially round the acropolis, at the north-east corner of the city, they are remarkably perfect. Our knowledge of the site is largely due to the mission of the Dilettanti Society in 1812, and the excavations executed by Mr C. T. Newton in 1857–8. The agora, the theatre, an odeum, a temple of Dionysus, a temple of the Muses, a temple of Venus, and a great number of minor buildings have been identified, and the general plan of the city has been very clearly made out. In a temple-enclosure Mr Newton discovered a fine seated statue of Demeter, which now adorns the British Museum; and about three miles south-east of the city he came upon the ruins of a splendid tomb, and a colossal figure of a lion carved out of one block of Pentelic marble, 10 feet in length and 6 in height, which has been supposed to commemorate the great naval victory of Conon over the Lacedæmonians in 394 B.C. (see ARCHITECTURE, vol. ii. p. 412). Among the minor antiquities obtained from the city itself, or the great necropolis to the east, perhaps the most interesting are the leaden καταδεσμοι, or imprecationary tablets, found in the temple of Demeter, and copied in facsimile in the appendix to the second volume of Newton's work.

Cnidus was a city of high antiquity and probably of Lacedæmonian colonization. Along with Halicarnassus and Cos, and the Rhodian cities of Lindus, Camirus, and Ialysus, it formed the Dorian Hexapolis, which held its confederate assemblies on the Triopian headland, and there celebrated games in honour of Apollo, Poseidon, and the nymphs. The city was at first governed by an oligarchic senate, composed of sixty members, known as ἀμνήμονες, and presided over by a magistrate called an ἀρεστήρ; but, though it is proved by inscriptions that the old names continued to a very late period, the constitution underwent a popular transformation. The situation of the city was favourable for commerce, and the Cnidians acquired considerable wealth, and were able to colonize the island of Lipara and founded the city of Corcyra Nigra in the Adriatic. They ultimately submitted to Cyrus, and from the battle of Eurymedon to the latter part of the Peloponnesian war they were subject to Athens. The Romans easily obtained their allegiance, and rewarded them by leaving them the freedom of their city. During the Byzantine period there must still have been a considerable population; for the ruins contain a large number of buildings belonging to the Byzantine style, and Christian sepulchres are common in the neighbourhood. Eudoxus, the astronomer, Ctesias, the writer on Persian history, and Sostratus, the builder of the celebrated Pharos at Alexandria, are the most remarkable of the Cnidians mentioned in history.

See Beaufort's *Ionian Antiquities*, 1811, and *Karamania*, 1818; Hamilton's *Researches*, 1842; Newton's *Travels and Discoveries in the Levant*, 1865; and Waddington in the *Revue Numismatique*, 1851.

CNOSSUS, or GNOSSUS, the most important city of Crete, on the left bank of the Cæratus, a small stream which falls into the sea on the north side of the island. The city was situated at a distance of about 3 miles from the coast, and, according to the old traditions, was founded by Minos, the mythical king of Crete. The locality was associated with a number of the most interesting legends of Grecian mythology, particularly with those which related to Jupiter, who was said to have been born, to have been married, and to have been buried in the vicinity. Cnossus is also assigned as the site of the fabled labyrinth in which the Minotaur was confined, and a physical basis for the legend may perhaps have been found in the caverns and excavations of the district. As the city was originally peopled by Dorians, the manners, customs, and political institutions of its inhabitants were all Dorian. Along with Gortyna and Cydonia, it held for many years the supremacy over the whole of Crete; and it always took a prominent part in the civil wars which from time to time desolated the island. When the rest of Crete fell under the Roman dominion, Cnossus shared the same fate, and became a Roman colony. Ænesidemus, the sceptic philosopher, and Chersiphron, the architect of the temple of Diana at Ephesus, were natives of Cnossus.

COAL

In its most general sense the term coal includes all varieties of carbonaceous minerals used as fuel, but it is now usual in England to restrict it to the particular varieties of such minerals occurring in the older Carboniferous formations. On the continent of Europe it is customary to consider coal as divisible into two great classes, depending upon differences of colour, namely, *brown coal*, corresponding to the term "lignite" used in England and France, and *black* or *stone coal*, which is equivalent to coal as understood in England. Stone coal is also a local English term, but with a signification restricted to the substance known by mineralogists as anthracite. In old English writings the terms pit-coal and sea-coal are commonly used. These have reference to the mode in which the mineral is obtained, and the manner in which it is transported to market.

The root *kol* is common to all the Teutonic nations, while in French and other Romance languages derivatives of the Latin *carbo* are used, *e.g.*, *charbon de terre*. In France and Belgium, however, a peculiar word, *houille*, is generally used to signify mineral coal. This word is supposed to be derived from the Walloon *hoie*, corresponding to the mediæval Latin *hullœ*. Littré suggests that it may be related to the Gothic *haurja*, coal. Anthracite is from the Greek ἄνθραξ, and the term *lithanthrax*. stone coal, still survives, with the same meaning in the Italian *litantrace*.

It must be borne in mind that the signification now attached to the word coal is different from that which formerly obtained when wood was the only fuel in general use. Coal then meant the carbonaceous residue obtained in the destructive distillation of wood, or what is known as charcoal, and the name collier was applied indifferently to both coal-miners and charcoal-burners.

The spelling "cole" was generally used up to the middle of the 17th century, when it was gradually superseded by the modern form, "coal." The plural, coals, seems to have been used from a very early period to signify the broken fragments of the mineral as prepared for use.

Coal is an amorphous substance of variable composition, and therefore cannot be as strictly defined as a crystallized or definite mineral can. It varies in colour from a light brown in the newest lignites to a pure black, often with a bluish or yellowish tint in the more compact anthracite of the older formations. It is opaque, except in exceedingly thin slices, such as made for microscopic investigation, which are imperfectly transparent, and of a dark brown colour by transmitted light. The streak is black in anthracite, but more or less brown in the softer varieties. The maximum hardness is from 2·5 to 3 in anthracite and hard bituminous coals, but considerably less in lignites, which are nearly as soft as rotten wood. A greater hardness is due to the presence of earthy impurities. The densest anthracite is often of a semi-metallic lustre, resembling somewhat that of graphite. Bright, glance, or pitch coal is another brilliant variety, brittle, and breaking into regular fragments of a black colour and pitchy lustre. Lignite and cannel are usually dull and earthy, and of an irregular fracture, the latter being much tougher than the black coal. Some lignites are, however, quite as brilliant as anthracite; cannel and jet may be turned in the lathe, and are susceptible of taking a brilliant polish. The specific gravity is highest in anthracite and lowest in lignite, bituminous coals giving intermediate values (see Table I.) As a rule the density increases with the amount of carbon, but in some instances a very high specific gravity is due to intermixed earthy matters, which may be separated by mechanical treatment.

Coal is perfectly amorphous, the nearest approach to any thing like crystalline structure being a compound fibrous grouping resembling that of gypsum or arragonite, which occurs in some of the steam coals of S. Wales, and is locally known as "cone in cone," but no definite form or arrangement can be made out of the fibres. The impressions of leaves, woody fibre, and other vegetable remains are to be considered as pseudomorphs in coaly matter of the original plant structures, and do not actually represent the structure of the coal itself. There is generally a tendency in coals towards cleaving into cubical or prismatic blocks, but sometimes the cohesion between the particles is so feeble that the mass breaks up into dust when struck. These peculiarities of structure may vary very considerably within small areas; and the position of the divisional planes or cleats with reference to the mass, and the proportion of small coal or slack to the larger fragments when the coal is broken up by cutting-tools, are points of great importance in the working of coal on a large scale.

The divisional planes often contain small films of other minerals, the commonest being calcite, gypsum, and iron pyrites, but in some cases zeolitic minerals and galena have been observed. Salt, in the form of brine, is sometimes present in coal. Some years ago a weak brine occurring in this way was utilized at a bathing establishment at Ashby-de-la-Zouche. Hydrocarbons, such as petroleum, bitumen, paraffin, &c., are also found occasionally in coal, but more generally in the associated sandstones and limestones of the Carboniferous formation. Gases, consisting principally of light carburetted hydrogen or marsh gas, are often present in considerable quantity in coal, in a dissolved or occluded state, and the evolution of these upon exposure to the air, especially when a sudden diminution of atmospheric pressure takes place, constitutes one of the most formidable dangers that the coal miner has to encounter.

Classification. The classification of the different kinds of coal may be considered from various points of view, such as their chemical composition, their behaviour when subjected to heat or when burnt, and their geological position and origin. They all contain carbon, hydrogen, oxygen, and nitrogen, forming the carbonaceous or combustible portion, and some quantity of mineral matter, which remains after combustion as a residue or "ash." As the amount of ash varies very considerably in different coals, and stands in no relation to the proportion of the other constituents, it is necessary in forming a chemical classification to compute the results of analysis after deduction of the ash and hygroscopic water. Examples of analyses treated in this manner are furnished in the last column of Table I., from which it will be seen that the nearest approach to pure carbon is furnished by anthracite, which contains above 90 per cent. This class of coal burns with a very small amount of flame, producing intense local heat and no smoke. It is especially used for drying hops and malt, and in air or blast furnaces where a high temperature is required, but is not suited for reverberatory furnaces. The American anthracite is largely used in iron smelting, as is also that of South Wales, but to a less extent, the latter having the disadvantageous property of decrepitating when first heated.

The most important class of coals is that generally known as bituminous, from their property of softening or undergoing an apparent fusion when heated to a temperature far below that at which actual combustion takes place. This term is founded on a misapprehension of the nature of the occurrence, since, although the softening takes place at a low temperature, still it marks the point at which destructive distillation commences, and hydrocarbons both of a solid and gaseous character are formed. That nothing analagous to bitumen exists in coals is proved by the fact that the ordinary solvents for bituminous substances, such as bisulphide of carbon and benzole, have no effect upon them, as would be the case if they contained bitumen soluble in these re-agents. The term is, however, a convenient one, and one whose use is almost a necessity, from its having an almost universal currency among coal miners. The proportion of carbon in bituminous coals may vary from 80 to 90 per cent.—the amount being highest as they approach the character of anthracite, and least in those which are nearest to lignites. The amount of hydrogen is from $4\frac{1}{2}$ to 6 per cent., while the oxygen may vary within much wider limits, or from about 3 to 14 per cent. These variations in composition are attended with corresponding differences in qualities, which are distinguished by special names. Thus the semi-anthracitic coals of South Wales are known as "dry" or "steam coals," being especially valuable for use in marine steam-boilers, as they burn more readily than anthracite and with a larger amount of flame, while giving out a great amount of heat, and practically without producing smoke. Coals richer in hydrogen, on the other hand, are more useful for burning in open fires—smiths' forges and furnaces—where a long flame is required.

The excess of hydrogen in a coal, above the amount necessary to combine with its oxygen to form water, is known as "disposable" hydrogen, and is a measure of the

fitness of the coal for use in gas-making. This excess is greatest in what we know as cannel coal, the Lancashire kennel or candle coal, so named from the bright light it gives out when burning. This, although of very small value as fuel, commands a specially high price for gas-making. Cannel is more compact and duller than ordinary coal, and can be wrought in the lathe and polished. These properties are most highly developed in the substance known as jet, which is a variety of cannel found in the lower oolitic strata of Yorkshire, and is almost entirely used for ornamental purposes, the whole quantity produced near Whitby, together with a further supply from Spain, being manufactured into articles of jewellery at that town.

When coal is heated to redness out of contact with the air, the more volatile constituents, water, hydrogen, oxygen, and nitrogen are expelled, a portion of the carbon being also volatilized in the form of hydrocarbons and carbonic oxide,—the greater part, however, remaining behind, together with all the mineral matter or ash, in the form of coke, or, as it is also called, "fixed carbon." The proportion of this residue is greatest in the more anthracitic or drier coals, but a more valuable product is yielded by those richer in hydrogen. Very important distinctions—those of caking or non-caking—are founded on the behaviour of coals when subjected to the process of coking. The former class undergo an incipient fusion or softening when heated, so that the fragments coalesce and yield a compact coke, while the latter (also called free-burning) preserve their form, producing a coke which is only serviceable when made from large pieces of coal, the smaller pieces being incoherent and of no value. The reason of this difference is not clearly made out, as non-caking coals are often of very similar ultimate chemical composition as those in which the caking property is very highly developed. As matter of experience, it is found that caking coals lose that property when exposed to the action of the air for a lengthened period, or by heating to about 300 C., and that the dust or slack of non-caking coal may, in some instances, be converted into a coherent cake by exposing it suddenly to a very high temperature.

Lignite or brown coal includes all varieties which are intermediate in properties between wood and coals of the older formations. A coal of this kind is generally to be distinguished by its brown colour, either in mass or in the blacker varieties in the streak. The proportion of carbon is comparatively low, usually not exceeding 70 per cent., while the oxygen and hygroscopic water are much higher than in true coals. The property of caking or yielding a coherent cake is usually absent, and the ash is often very high. The specific gravity is low when not brought up by an excessive amount of earthy matter. Sometimes it is almost pasty, and crumbles to powder when dried, so as to be susceptible of use as a pigment, forming the colour known as Cologne earth, which resembles umber or sepia

In Nassau and Bavaria woody structure is very common, and it is from this circumstance that the term lignite is derived. The best varieties are black and pitchy in lustre, or even bright and scarcely to be distinguished from true coals. These kinds are most common in Eastern Europe. Lignites, as a rule, are generally found in strata of a newer geological age, but there are many instances of perfect coals being found in such strata.

By the term "ash" is understood the mineral matter remaining unconsumed after the complete combustion of the carbonaceous portion of a coal. This represents part of the mineral matter present in the plants from which the coal was originally formed, with such further addition by infiltration and mechanical admixture as may have arisen during consolidation and subsequent changes. The composition of the ashes of different coals is subject to considerable variation. as will be seen by the following list of analyses :—

The composition of the ash of true coal approximates to that of a fire-clay, allowance being made for lime, which may be present either as carbonate or sulphate, and for sulphuric acid. The latter is derived mainly from iron pyrites, which yields sulphate by combustion. An indication of the character of the ash of a coal is afforded by its colour, white ash coals being generally freer from sulphur than those containing iron pyrites, which yield a red ash. There are, however, several striking exceptions, as for instance in the anthracite from Peru, given in Table I., which contains more than 10 per cent. of sulphur, and yields but a very small percentage of a white ash. In this coal, as well as in the lignite of Tasmania, known as white coal or Tasmanite, the sulphur occurs in organic combination, but is so firmly held that it can only be very partially expelled, even by exposure to a very high and continued heating out of contact with the air. An anthracite occurring in connection with the old volcanic rocks of Arthur's Seat, Edinburgh, which contains a large amount of sulphur in proportion to the ash, has been found to behave in a similar manner. Under ordinary conditions, from $\frac{1}{8}$ to $\frac{1}{4}$ of the whole amount of sulphur in a coal is volatilized during combustion. the remaining $\frac{3}{4}$ to $\frac{7}{8}$ being found in the ash.

The amount of water present in freshly raised coals varies very considerably. It is generally largest in lignites, which may sometimes contain 30 per cent. or even more, while in the coals of the coal measures it does not usually exceed from 5 to 10 per cent. The loss of weight by exposure to the atmosphere from drying may be from $\frac{1}{2}$ to $\frac{3}{4}$ of the total amount of water contained.

Coal is undoubtedly the result of the transformation of vegetable matter, mainly woody fibre, by the partial elimination of oxygen and hydrogen giving rise to a substance richer in carbon than the original wood,—the mineral matter being modified simultaneously by the almost entire removal of the alkalies and lime, and the addition of materials analagous in composition to clay, as will be seen by comparing the analyses in Table II. The following table, given by Percy, shows the relative proportions of the different components of mineral fuels.

Mohr has computed that the transformation of wood into coal is attended with a loss of about 75 per cent. in weight; and, having regard to the difference in density of the two substances, the volume of the coal can only be from $\frac{1}{18}$ to $\frac{1}{9}$ of the woody fibre from which it is derived.

The nature of the change is essentially a slow oxidation under water or any covering sufficient to protect the dead wood from the direct action of atmospheric air, as in the latter case the vegetable mould or humus would be produced. The products of such decomposition vary with the length of time and the nature of the plants acted on, and in the case of anthracite the change is so great that no portion of the original plant structure can be recognized, at the same time the density and conductivity for heat and electricity are increased. This, however, is a case of metamorphosis analogous to the transformation of sedimentary into crystalline rocks, the extreme term of such metamorphosis being the production of graphite or plumbago. Daubrée has shown that wood may be converted into anthracite by exposure to the action of superheated water at a temperature of 400° C.

The plants concerned in the production of coal vary very considerably in different geological periods. In the coal measures proper, acrogens, ferns, equisetums, and similar allied forms are most abundant. It is stated by some observers that entire beds of coal are sometimes made up of the spores of ferns. This, however, appears to depend upon the inspection of microscopic sections, and may not be capable of rigorous quantitative demonstration. In the coals of newer date exogenous wood and leaves are more common than in those of the coal measures; the former also contain resins, sometimes in considerable quantity.

The number of species of land plants in the British sedimentary formations, which may be taken as a measure of the comparative prevalence of coal in the different series, is as follows :—

Devonian strata........................	9	species.
Carboniferous do........................	320	,,
Permian do........................	20	,,
Triassic do........................	9	,,
Lias and Oolitic do........................	160	,,
Purbeck and Wealden do........................	38	,,
Cretaceous do........................	19	,,
Tertiary do........................	224	,,

The most generally received opinion is that much if not all coal results from the transformation of plants upon the site of their growth. The principal evidence in favour of such a supposition is afforded by the common occurrence of a bed of clay, the so-called "under-clay," containing the roots of plants, representing the old soil, immediately below every coal seam—a fact that was first pointed out by the late Sir W. E. Logan in South Wales. In Yorkshire the same thing is observed in the siliceous rock called ganister occurring in similar positions, showing that the coal plants grew there upon sandy soils.

The action of water in bringing down drift wood may have also contributed some material, but much less than the local growth. This may probably have been concerned in the production of the very thick masses of coal of small extent found in some coal-fields in Southern Europe.

Another theory, that proposed by Dr Mohr, deserves notice, namely, that coal may be of marine origin, and derived from the carbonization of sea weeds, such as the great kelp plant of the Pacific Ocean. This has been very ingeniously elaborated by the author, and much apparently good evidence adduced in support (see his *Geschichte der Erde*, Bonn, 1875). But the positive evidence afforded by roots found in the under-clays is sufficient to render such an hypothesis unnecessary in the majority of instances.

It must be remembered, however, that, although cellulose or wood fibre is most probably the chief material concerned in the production of coal, this substance is readily convertible into dextrine by the action of protein or analogous fermentescible matters containing nitrogen, a change that is attended with the loss of structure, the fibre being converted into a gummy mass. Some forms of cellulose, such as that in the lichens known as Iceland moss, are soluble in water, and are without fibre. The preservation of recognizable woody tissue therefore in coals can only be regarded as accidental, and any argument founded upon the relative quantity of the recognizable vegetable structures in microscopic sections is likely to be unsound, unless the relative durability of the different portions of the plants be taken into account. Thus the bark of trees is, as a rule, less perishable than the solid wood, while tissues impregnated with resinous matters are almost indestructible by atmospheric agency. Instances of this are afforded by the fossil trees found in the coal measures, which are often entirely converted into siliceous masses, the bulk of the wood having decayed and been replaced by silica, while the bark is represented by an external layer of bright coal. Fossil resins, such as amber, are of common occurrence in coals, especially those of secondary or tertiary age.

In an investigation of the coking properties of the Saarbrücken coals by Schondorff, it was found that they could be separated into three different materials, which he distinguished as glance or bright coal, dull or striped coal, and fibrous coal. The last, which is known in England as "mother of coal," resembles a soft, dull, black charcoal, containing abundant traces of vegetable fibre, and yielding a high proportion of non-coherent coke, behaving, in fact, like charcoal. The bright or glance coal is without any apparent structure, cleaving into cubical masses, contains but little mineral matter, and yields a strong coke. The striped coal consists mainly of a dull substance, with fine alternations of bright matter, and is essentially a gas coal yielding only an inferior coke. These differences are supposed to be due to original differences in the substances from which the coals have been derived. Thus the fibrous coal may result from unaltered cellulose, the glance coal from the insoluble mucilage derived from the maceration of the plants in water, and the dull coal from the soluble parts, such as gum and dextrine, either original or produced by the transformation of cellulose and starch. That something analogous to a pulping process has gone on in the production of coal is evident from the intimate intermixture of the mineral matter constituting the ash, which is quite unrecognizable before burning in the majority of instances.

F. Muck (*Chemische Aphorismen über Steinkohlen*, Bochum, 1873) has recorded some interesting experiments on the behaviour of the three isomeric carbohydrates,—cellulose, starch, and gum arabic,—which are all of the same ultimate composition, namely, $C_6H_{10}O_5$. When subjected to the process of coking, cellulose, in the form of Swedish filter paper, gave a residue of 6·74 per cent. of a perfectly non-coherent coke, starch 11·30 per cent. of a bright vesicular coke like that from strongly coking coal, and gum-arabic 20·42 per cent. of a hard dull coke resembling that produced from imperfectly coking gas coals. The volume of gas given off by cellulose and starch is much larger and of a higher illuminating power than that produced from gum under the same conditions.

The conditions favourable to the production of coal seem therefore to have been—forest growth in swampy ground about the mouths of rivers, and rapid oscillation of level, the coal produced during subsidence being covered up by the sediment brought down by the river forming beds of sand or clay, which, on re-elevation, formed the soil for fresh growths, the alternation being occasionally broken by the deposit of purely marine beds. We might therefore expect to find coal wherever strata of estuarine origin are developed in great mass; and this is actually the case,—the Carboniferous, Cretaceous, and Oolitic series being all coal bearing horizons, though in unequal degrees,—the first being known as the coal measures proper, while the others are of small economic value in Great Britain, though more productive in workable coals on the continent of Europe. The coal measures which form part of the Palæozoic or oldest of the three great geological divisions are mainly confined to the countries north of the Equator, Mesozoic coals being more abundant in the southern hemisphere, while Tertiary coals seem to be tolerably uniformly distributed irrespective of latitude.

The nature of the coal measures will be best understood by considering in detail the areas within which they occur in Britain, together with the rocks with which they are most intimately associated. The general succession of these rocks is given in fig. 1 (cols. 1 to 4), which is taken from the index of strata issued by the Geological Survey. Sequence of carboniferous strata.

commencement of the carboniferous period is marked by a mass of limestones known as the Carboniferous or mountain limestone, which contains a large assemblage of marine fossils, and has a maximum thickness in S.W. England and Wales of about 2000 feet. The upper portion of this group consists of shales and sandstones known as the Yoredale Rocks, which are highly developed in the moorland region between Lancashire and the north side of Yorkshire. These are also called the upper limestone shale, a similar group being found in places below the limestone, and called the lower limestone shale, or, in the North of England, the Tuedian group. Going northward the beds of limestone diminish in thickness, with a proportional increase in the intercalated sandstones and shales, until in Scotland they are entirely subordinate to a mass of coal-bearing strata, which forms the most productive members of the Scotch coal fields. The next member of the series is a mass of coarse sandstones, with some slates and a few thin coals, known as the Millstone Grit, which is about equally developed in England and in Scotland. In the southern coal-fields it is usually known by the miners' name of Farewell Rock, from its marking the lower limit of possible coal working. The Coal Measures, forming the third great member of the carboniferous series, consist of alternations of shales and sandstones, with beds of coal and nodular ironstones, which together make up a thickness of many thousands of feet—from 12,000 to 14,000 feet when at the maximum of development. They are divisible into three parts, the lower coal measures, the middle or Pennant, a mass of sandstone containing some coals, and the upper coal measures, also containing workable coal. The latter member is marked by a thin limestone band near the top, containing *Spirorbis carbonarius*, a small marine univalve.

The uppermost portion of the coal measures consists of red sandstone so closely resembling that of the Permian group, which are next in geological sequence, that it is often difficult to decide upon the true line of demarcation between the two formations. These are not, however, always found together, the coal measures being often covered by strata belonging to the Trias or upper New Red Sandstone series.

The areas containing productive coal measures are usually known as coal fields or basins, within which coal occurs in more or less regular beds, also called seams or veins, which can often be followed over a considerable length of country without change of character, although, like all stratified rocks, their continuity may be interrupted by faults or dislocations, also known as slips, hitches, heaves, or troubles (fig. 2).

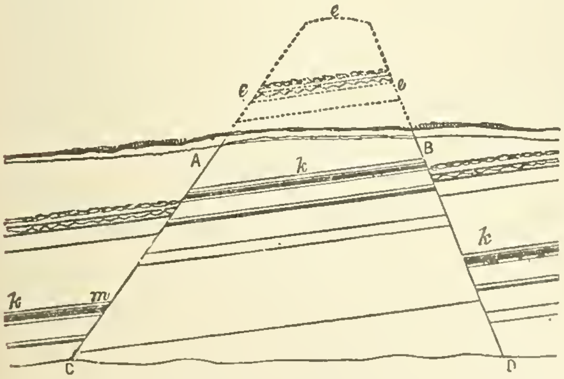

FIG. 2, representing a seam of coal *k*, worked towards *m*, interrupted by faults or hitches. The fault at AC is called an upthrow, that at BD a downthrow.

The thickness of coal seams varies in this country from a mere film to 35 or 40 feet; but in the south of France and in India masses of coal are known up to 200 feet in thickness. These very thick seams are, however, rarely constant in character for any great distance, being found commonly to degenerate into carbonaceous shales, or to split up into thinner beds by the intercalation of shale bands or partings. One of the most striking examples of this is afforded by the thick or ten-yard seam of South Staffordshire, which is from 30 to 45 feet thick in one connected mass in the neighbourhood of Dudley, but splits up into eight seams, which, with the intermediate shales and sandstones, are of a total thickness of 400 feet in the northern part of the coal-field in Cannock Chase. Seams of a medium thickness of 3 to 7 feet are usually the most regular and continuous in character. Cannel coals are generally variable in quality, being liable to change into shales or black-band ironstones within very short horizontal limits. In some instances the coal seams may be changed as a whole, as for instance in South Wales, where the coking coals of the eastern side of the basin pass through the state of dry steam coal in the centre, and become anthracite in the western side.

British Coal-fields.

There are about twenty principal coal-fields of Great Britain, besides several smaller ones, whose position is shown in Plate I., which may be classed under three heads:—1. Those forming complete basins, entirely circumscribed by the lower members of the carboniferous series; 2. Those in which one limb of the basin only is visible, the opposite one being obscured by Permian or other strata of newer date; and 3. Those in which the boundaries are formed by faults, which bring down the upper overlying strata into contact with the coal measures. The South Wales and Dean Forest basins are examples of the first of the above classes, the North of England and Yorkshire and Derbyshire fields of the second, and the South Staffordshire of the third. The last two classes are of the greatest geological interest, as giving rise to the important problem of their probable extension within workable limits beneath the overlying strata. Examples of the three different cases are given in Plate II.,—the first being represented by the section across the Forest of Dean, fig. 1; the second by that of the Lancashire coal-fields, fig. 2; and the third by the North Staffordshire section, fig. 3.

South Wales coal-field.

The largest and most important of the British coal-fields is that of South Wales, which extends from Pontypool in Monmouthshire on the east, to Kidwelly in Pembrokeshire, a length of about 50 miles, and from Tredegar on the north to Llantrissant on the south, a breadth of about 18 miles, in addition to which a further narrow slip of about 20 miles long, E. and W., extends across Pembrokeshire. Excluding the latter portion, it forms a complete basin of an approximately elliptical shape, surrounded by older rocks, the Carboniferous limestone and Devonian shale dipping generally towards the centre. The basin-shaped structure is, however, modified by a central anticlinal axis, which brings the lower bed within reach of the surface. The total thickness of the coal measures is estimated at about 11,000 feet on the south, and 7000 feet on the north side in the western district. In the central portion between Britton Ferry and the River Taff, it diminishes to 4800 feet on the north side, and is still further reduced in Monmouthshire and on the eastern side generally to about 2500 feet. The coal-bearing portions are divisible into three groups, known as—

1. Upper Pennant series.
2. Lower Pennant series.
3. White Ash series.

The Upper Pennant series attains the maximum develop ment of about 3000 feet on the south rise of the measures near Swansea; at Neath the thickness is reduced to about 1200 feet, and in Monmouthshire to between 500 and 700 feet. It contains all the free burning and bituminous coals of the Swansea and Neath districts, and the house-coals of Monmouthshire and the eastern districts, which latter contain 26 seams above 12 inches thick, making a total of about 100 feet of coal, an amount that increases westward to 82 seams and 182 feet. The Lower Pennant series averages from 1100 to 1500 feet between the Taff Vale and Llanelly, but on the north side of the anticlinal thickens to 3000 feet. The average total of workable coal in seams which do not exceed 3 feet is 25 feet, among which are some fair steam coals, associated in places with black-band ironstone and good manufacturing and household coals, yielding slack suitable for coking,—the most valuable among them being those of the Rhondda valley. The lowest or White Ash series contains the bulk of the valuable steam and iron making coals which have given the coal field its great reputation. It is about 500 feet thick on the eastern side, and about 1000 feet in the centre of the basin. The coals and accompanying ironstone are generally thicker and more abundant on the south than on the north coast. The workable coals in this division amount to about 50 feet, in seams varying from 3 to 9 feet in thickness. The western extension into Pembrokeshire belongs to this part of the series; it covers about 70 square miles, extending in a narrow east and west belt, varying from 2 to 6 miles in breadth from Tenby to St Bride's Bay. The measures are very much disturbed, but are probably about 1500 feet, containing in the upper 1000 feet 8 seams of anthracite of about 18 feet total thickness.

The total area of the coal-field is about 1000 square miles, of which amount about 153 square miles lie beneath the sea in Swansea and Carmarthen Bays. Only one square mile is covered by newer formations.

According to the quantity of the coal produced, the area is divided as follows:—

Bituminous coal district	410 square miles
Anthracite, ,,	410 ,,
Intermediate, or Semi-Anthracite	180 ,,

The most valuable class of South Wales coals is the semi-anthracite or smokeless steam coal of the lower measures, which is in constant demand for the use of ocean steamers all over the world. It is principally exported from Cardiff, Neath, and Swansea.

The configuration of the ground, owing to the deep north and south valleys of the Usk, Ebbw, Taff, Rhondda, and Neath Rivers, and the longitudinal anticlinal axis, renders the coals of comparatively easy access. The surface rises to a height of about 2000 feet above the sea-level, and in the valleys a greater vertical range is brought within working limits than is the case in any other coal-field of similar thickness.

The Forest of Dean basin is an outlying portion of that of South Wales, from which, as is shown by Ramsay, it has been separated by denudation. It is of triangular form, occupying an area of 34 square miles, between the Wye and the Severn estuary, with a total thickness of 2765 feet and 31 seams, together 42 feet thick, only 9 of which are above 2 feet in thickness. The depth from the surface to the bottom of the basin, in the centre, is about 2500 feet. The lower beds of sandstone and the Carboniferous limestone contain considerable quantities of brown hematite, in irregular deposits, which is smelted in part on the spot and partly exported to other districts. Owing to the symmetrical basin-shaped form of the measures (Plate II. fig. 1), the coals have been worked from the surface downwards along the outcrops of the seams, leaving large hollows for the accumulation of water, which render the working of the lower ground difficult, on account of the great pumping-power required to keep down the water flowing in from the old shallow mines.

Severn Valley coal-fields.

North of the Malvern Hills a straggling patch of coal measures extends about 35 miles N. and S., from near Worcester to Newport in Shropshire. This is divisible into two nearly equal areas of triangular form. The southern part is known as Forest of Wyre, and the northern as Colebrookdale. The former is unimportant, having a great thickness of measures which rest directly on the Devonian rocks, but scarcely any workable coal seams. The Colebrookdale measures rest upon the Upper Silurian rocks, are about 800 feet thick, with about 50 feet of coal in 18 seams, and many beds of nodular ironstone, which has given the district a celebrity in the production of iron-work, especially high-class castings. The eastern boundary is concealed by overlying Permian strata, and it was formerly supposed that the productive measures had been removed by denudation on this side; but there is little doubt of their continuity towards South Staffordshire.

To the westward of Colebrookdale are the two small fields of Leebotwood and Shrewsbury. These lie on the Silurian rocks. The exposed area of the former extends to 12 square miles; that of the latter (which stretches in a crescent shape to the south and west of Shrewsbury) to 18. Both are partly hidden by Permian strata.

S. Staffordshire coal-field.

The South Staffordshire coal-field extends about 22 miles N. and S., from Rugeley to Halesowen, with a greatest breadth of about 10 miles from Wolverhampton to Oldbury. It is entirely surrounded by New Red Sandstone rocks, which in some places are faulted against the coal measures, rendering it difficult to decide upon the chances of a profitable extension beneath the visible boundaries. The coal measures rest upon the Upper Silurian rocks, which are exposed at several points within the area, especially at Dudley and the Wren's Nest. This district is remarkable as containing the thickest known coal seam in England, the Thick or Ten Yard Seam, which varies from 30 to 45 feet in thickness in the neighbourhood of Dudley, but splits up northwards into several thinner seams in the northern or Cannock Chase district. There are 6 principal seams, with a total of from 57 to 70 feet in 1300 feet of measures. The field was formerly very productive of clay ironstone, but the supply has now considerably diminished. The coals are also subject to curious alterations in places, from the intrusion of igneous rock, especially in the Rowley Hills, near Dudley.

Tamworth coal-field.

The Warwickshire or Tamworth coal-field is a narrow strip of measures, with a maximum thickness of 3000 feet, extending about 12 miles in a N.W. and S.E. line from Coventry to Tamworth. It contains 5 seams, which are mainly worked for house coal and steam purposes. It is entirely surrounded by New Red Sandstone strata, except for a short distance near Atherstone, where it is seen to rest upon the millstone grit, which is altered into quartzite by intrusive igneous rocks.

The Leicestershire or Ashby coal-field is an irregular patch of 30 square miles, on the east side of Charnwood Forest, about midway between Leicester and Burton-on-Trent. It has 7 principal seams, and probably rests upon the mountain limestone, except at the eastern end, where it may lie upon the old slatey rocks of Charnwood Forest. Southward it extends under the New Red marl towards Leicester. In the centre is a patch of barren measures upon which the town of Ashby-de-la-Zouche stands, after which the coal-field is often named. The eastern side, which contains the mines of Whitwick, Snibston, and Cole-Orton, contains some igneous rocks apparently connected with those of Charnwood Forest. which are not seen on the western or Moira side, which contains the more important workings None of the seams occurring in either division can be identified with certainty in the other, although only a few miles distant. The total thickness of the coal measures is about 2500 feet, the principal seams occurring about the middle, as is also the case in Warwickshire.

North of the Trent the carboniferous strata present a more complete and regular development than is seen in the central coal-fields The Carboniferous limestone and millstone grit formations form a central ridge of high moorlands and hills, the so-called Pennine chain, in a gently sloping anticlinal, running nearly north and south from the north of Derbyshire to the borders of Scotland. The coal measures occur on both flanks of this ridge, the largest connected mass being that of the Derbyshire and Yorkshire coal-field, which extends north and south for about 60 miles from Bradford to within a few miles from Derby, where it is covered by the New Red Sandstone formation. The exposed breadth varies from 9 miles at the south end to 22 miles at the north. The measures dip regularly at a low angle to the eastward, and pass under the Permian or magnesian limestone formation, which forms the eastern boundary continuously from Nottingham through Worksop and Doncaster to Wakefield. The total thickness of measures is about 4000 feet (with about 20 seams), belonging to the middle and lower ganister series, the upper series being absent. A generalized section of the strata in this coal-field is given in the fifth column of fig. 1. The principal seams are the Black shale, or Silkstone, from 5 to 7 feet thick, which is extensively worked as a house coal, and the Top hard, or Barnsley coal, which is much used for steam purposes. At the north end of the field, in the neighbourhood of Leeds and Bradford, two thin seams, known as the Low Moor black bed and better bed, remarkable for their exceptional purity, are used for iron-making purposes at Bowling and Low Moor. Iron ores are also found in considerable quantity on the Derbyshire side of the field, which are smelted at Butterly and other works near Chesterfield. The area covered by the magnesian limestone formation has been proved by several borings and sinkings, the first winning having been opened at Shireoak near Worksop, where the Top hard coal was reached at 1548 feet below the surface. It is estimated that about two-thirds of the total area of this field is to be looked for within the concealed part.

On the west side of the Pennine axis, and between the same parallels as the Derbyshire and Yorkshire coal-fields, are those of North Staffordshire and Lancashire, which extend from Longton on the south to Colne on the north, the continuity being, however, broken by a small fold of the Carboniferous limestone shales, which is brought to the surface between Macclesfield and Congleton. Parallel to this group, however, and to the eastward of it, is situated the small but important coal-field of North Staffordshire, also known as the Pottery coal-field. It has an exposed area of about 94 square miles, which is very irregular in form, being 17 miles in greatest breadth E. to W., and about 13 miles from N. to S. The south-eastern portion, which is nearly detached, is known as the basin of Cheadle, or Froghall, which is chiefly remarkable for a band of calcareous iron ore formerly exported to Staffordshire, but now nearly exhausted. The main or western portion consists of a mass of strata about 5000 feet thick, with 37 seams of coal, out of which 22, measuring together 97 feet, are over 2 feet in thickness; in addition to which there are many valuable beds of ironstone, both argillaceous and black-band The strata, which are less regularly arranged than those of S. Lancashire, as will be seen by the transverse sections, figs. 2 and 3 in Plate II., being bent in contrasted curves, and much broken by faults, form the eastern limb of a basin having a general westerly dip, which carries them in a short distance below the New Red marl plain of Cheshire.

ı ›rd coal

The Lancashire coal-field is of an irregular four-sided form. The greatest breadth, from Oldham on the east to Saint Helen's on the west, is about 52 miles, and the length, from Burnley on the north to Ashton-under-Lyne, about 19 miles. Within the area are, however, two large islands of the millstone grit, which divide the northern or Burnley district from the main coal-field of Wigan and Manchester. This barren area is about compensated by a tongue of coal measure, which extends southward from Stockport to Macclesfield. The thickness of the measure is very great, and as the ground is much broken by faults, and the beds dip at a high angle, the workings have extended a greater depth than in any other district, the deepest workings being at Rose Bridge pits near Wigan, which have been sunk to 815 yards, and at Dukinfield, east of Manchester, where the Astley pit is 672 yards deep, and the coals have been wrought to a total depth of 772 yards by inclines. The greatest thickness is observed in the Manchester district, where the total section is as follows, according to Hull.

Upper Coal-Measures 2013 feet.	Limestone series,	600	feet.
	To Oppenshaw Coal,	600	,,
	To Yard Coal,	485	,,
Middle Coal Measures 4247 feet.	Barren Measures,	1678	,,
	Unknown Strata,		
	Sod Mine to Black Mine, ...	2000	,,
Lower Coal Measures Ganister, 1370 feet.	Black Mine to Royley Mine,	897	,,
	Royley Mine to Rough Rock,	1370	,,
Millstone Grit,		2000	,,
Limestone Shale, about		2000	,,

There is a total of 100 feet of coal in workable seams (exceeding 2 feet), which are chiefly situated in the 3000 feet forming the bottom of the middle and top of the lower coal measures. In the Wigan district there are 18 workable seams, about 65 feet in all, the total section being:—

Upper Measures, barren,	1500	feet.
Middle Measures, mass seams,	2550	,,
Ganister Measures,	1800	,,

The Wigan district is remarkable for the production of a large quantity of cannel coal.

In the Burnley district the lower and middle coal measures together are from 2500 to 3000 feet in thickness, the upper measures being unrepresented.

Northumberland and Durham coal-field.

The coal-field of Northumberland and Durham lies north of that of Yorkshire, on the east side of the Pennine axis. In the intermediate ground between Leeds and Darlington, about 55 miles, the lower Carboniferous rocks are directly overlain by the magnesian limestone, which preserves the north and south course observed further south until it reaches the sea at the mouth of the Tyne. The coal-field extends north and south from Darlington through Durham to the mouth of the Coquet, about 65 miles, with a greatest breadth of about 22 miles in Durham. From the Tyne to the Coquet the eastern boundary is formed by the sea, while in the remaining area, from the Tyne to the Tees, which is included in Durham, the coal measures dip beneath the magnesian limestone. The measures are, as a rule, very regular, their dip being lower than that observed in other districts. The total thickness is about 2000 feet, with 16 seams of coal, together about 47 feet thick. The millstone grit is continuously exposed below the coal measures along the eastern edge as far as the Tees, where it is overlapped by the magnesian limestone and Triassic rocks, so that there is a portion of the coal-field hidden beyond the exposed southern boundary, but the extent is probably not large. The seaward extension has been proved in several deep mines in the neighbourhood of Sunderland, more especially at Ryhope and Monkwearmouth which are worked at a depth of about 1850 feet to a short distance from the shore. At these points the coals are nearly flat, but at Harton, near Shields, they rise to the eastward, proving that the centre of the basin has there been passed. The best estimate gives 11 feet of coal, and about 16 square miles of area, as the probable extent of this submarine portion of the coal measures. The character of the coal produced varies in the different parts of the basin. The southern and western districts adjoining Bishop Auckland and Ferryhill produce a strongly caking coal, which is chiefly employed in the manufacture of a pure and dense coke for use in the Cleveland and Cumberland iron works, a considerable amount being also exported for foundry use. The central district, adjoining Newcastle and Sunderland, produces the best class of house coal, known in London under the name of Wallsend, from the pits on the Tyne where it was originally mined, which were close to the eastern termination of the wall built by the Romans to protect the country between the Tyne and the Solway from the incursions of the Picts. These collieries have been long since abandoned, but the name is still given in the London market to the best Durham house coals, and even to much that has been produced in other places, as indicating a coal of superlative excellence. The great merit of Wallsend coal is in its small proportion of ash, which also, being dark-coloured, is not so obtrusive on the hearth as the white ash generally characteristic of the Midland coals. The strongly caking property, and the large amount of gas given out in burning, tend to produce a bright and enduring fire. In the district north of the Tyne the produce is principally steam coal, which is known as Hartley coal, being named after one of the principal collieries. It is largely used for sea-going steamers, and was lately in use in the Royal Navy mixed with South Wales coal, a combination which was supposed to give a higher evaporating value in raising steam than when either class was burnt alone. Although of a lower calorific power, and making more smoke than South Wales coal, the north country coal deteriorates less rapidly than the former when stored in hot climates. There are two small coal-fields in the mountain limestone district of the Tyne near Hexham, and another on the Solway at Cannobie; these are, however, of small importance.

The Cumberland field extends along the coast of the South Irish Channel from Saint Bees northward for 15 miles to Maryport, where it turns eastward for about 17 miles, and is exposed with constantly diminishing breadth until it disappears under the Permian rocks of the Vale of Eden. The greatest breadth is about 5 miles at Whitehaven and Workington, but, as in Northumberland and Durham, the beds dip and the coals have been worked below the sea to a distance of $1\frac{1}{2}$ miles from the shore or $2\frac{1}{2}$ miles from the pit. The total thickness of the measures is 1500 feet, with three workable seams. The produce is largely consumed within the district, a considerable portion of the export being to Belfast and other Irish ports.

The coal measures of North Staffordshire and Lancashire reappear on the western side of the plain of Cheshire in the coal-fields of Denbighshire and Flintshire, which form a nearly continuous tract from the neighbourhood of Oswestry through Ruabon and Wrexham to the mouth of the Dee, and along the Welsh coast near Mostyn. The separation between them is formed by a slight roll in the mountain limestone near Gresford, corresponding to that dividing the two coal-fields on the eastern out-crop. The Denbighshire field is about 18 miles long, having 7 seams, together from 26 to 30 feet in thickness. The principal workings are near Ruabon, where there are several large collieries producing a much esteemed house coal. The Flintshire field is about 15 miles long. The greatest breadth is in the neighbourhood of Mold, whence it narrows in a N.W. direction, being covered by the estuary of the Dee. At Mostyn coal has been extensively worked under the river, but great difficulty was experienced in keeping the mines clear of water. The details of the measures in this district have not been fully worked out, but the southern portion is the most valuable. The higher measures contain six seams, including some valuable beds of cannel, the total being about 28 feet. In the northern district bordering the Dee the beds are much disturbed by faults, but the deeper coals are said to be of good quality.

The basin formed by the North Wales, Lancashire, and North Staffordshire coal-field is probably the most extensive tract of coal measures in the country, as it may be assumed to extend under the overlying Triassic strata under the Dee and the Mersey to South Lancashire and across the plain of Cheshire, an area of 800 to 1000 square miles. Much of this, however, is far beyond workable limits, the depth to the top of the coal measures being estimated at 10,000 feet below the surface at the point of greatest depression. The area within the limits of 4000 feet below the surface, which has been assumed as a possible maximum working depth, may be seen by reference to Plate I.

Anglesea.

There is a small coal-field in the Island of Anglesea, which is interesting for its geological peculiarities, but it is of very small economic value.

Somersetshire coal-field.

The Somersetshire coal-field appears at the surface in the form of several disconnected patches, the largest of which extends northward of Bristol for about 12 miles, while the remainder stretches southward for about the same distance to the Mendip hills. The Carboniferous limestone is seen at many places along the western flank, but the connection is generally hidden by a peculiar modification of the New Red Sandstone known as the Dolomitic Conglomerate, which overlaps both formations indifferently. Towards the east the measures are further obscured by the overlap of the lias and oolitic rocks, this being the only field in which such an overlap takes place in England. The exposed area of the coal measures is only about 14 square miles, but it is estimated that they extend over 238 square miles, the remainder being concealed by overlying strata. The character of the measures is similar to those of South Wales and Dean Forest, namely an upper and lower productive series separated by a nearly barren mass of Pennant sandstones. The sections, which vary very considerably, are summarized by Prestwich as follows:—

Upper series, ...	2600 feet thick,	with 16 seams,	together 26 ft.	10 in.	thick.
Pennant sandstone,	2500 to 3000 "	" 4 "	" 5	0	"
Lower series, ...	2800 " "	" 26 "	" 66	6	"
Together, ...	7900 to 8400	46	98	4	

The disturbance of the strata by faults is much greater than in any other British coal-field. The whole series is squeezed into a comparatively narrow trough, which throws the bottom of the basin to about 8000 feet below the surface. The coals are in some instances tilted up vertically, or even turned over, a kind of disturbance which is usually attended with considerable shattering of the strata. In one instance the upper series of measures have been shifted horizontally by an inclined or slide fault for a distance of about 200 feet above the lower series. In spite of the difficulties caused by these disturbances, coal seams of only a foot in thickness are regularly worked in Somersetshire, which is far below the limits considered to be profitable in other districts.

The coal-bearing strata of Scotland[1] are confined to the

[1] For the following account of the coal-fields of Scotland the writer is indebted to Mr J. Geikie, F.R.S.

Carboniferous formation, the only exceptions being the little patch of Oolitic coal at Brora in Sutherland and certain thin seams which occur intercalated among the Miocene volcanic rocks of the Western Islands. The Scottish Carboniferous Formation is divisible into four series, viz.,—1. Coal Measures; 2. Millstone Grit; 3. Carboniferous Limestone series; 4. Calciferous Sandstone series. Coal is confined chiefly to the first and third of these groups, but in West Lothian and Mid-Lothian the lowest (calciferous sandstones) yields some coals, one of which has been worked (Houston coal, 6 feet thick). These coals are associated with the well-known "oil-shales," forming a peculiar development of the upper portion of the calciferous sandstone series which is not repeated elsewhere in Scotland. The millstone grit contains no workable coals. The coal bearing strata of the coal measures and limestone series are irregularly distributed over the central or lowland district of the country between a line drawn from St Andrews to Ardrossan, and a second line traced parallel to the first from Dunbar to Girvan. Throughout this region the strata are disposed in a series of basins, of which there are properly speaking only three, namely,—(1) The basin of Mid-Lothian and Fifeshire, which is bounded on the west by the calciferous sandstone series and some older strata, forming the Pentland hills, Arthur's Seat, the rolling ground that extends west of Edinburgh into Linlithgowshire, and the heights behind Burntisland in Fifeshire, and in the east by the barren sandstones and igneous rocks of the calciferous sandstone series in the east of Haddingtonshire and Fifeshire; (2) The basin of Lanarkshire and Stirlingshire, the eastern boundary of which begins in the south at Wilsontown, and runs north by Bathgate and Borrowstounness to the borders of Clackmannan, extends west to the foot of the Campsie and Kilbarchan Hills, and is separated by the Paisley and Dunlop Hills from (3) the basin of Ayrshire, the main mass of which is bounded in the south and east by the valley of the Doon, the Silurian uplands behind Dalmellington and New Cumnock, and the calciferous sandstone and Old Red Sandstone heights which overlook the heads of the Ayr and Irvine valleys. Two small outlying coal-fields lie beyond these boundary lines, viz., the Girvan and Sanquhar (Dumfriesshire) coal-fields, but both belong geologically to the Ayrshire basin. Although there are thus only three great basins, it is usual, nevertheless, to speak of five principal coal-fields, each of which is named after the county in which it is most abundantly developed. Thus we have the coal-fields of Ayrshire, Lanarkshire, Stirlingshire, Fifeshire, and Mid-Lothian.

Ayrshire Coal-fields.—The Ayrshire basin, owing to undulations and faultings of the strata, comprises a number of subsidiary coal-fields, such as those of Girvan, Sanquhar (Dumfriesshire), Dalmellington, New Cumnock, Lugar and Muirkirk, Kilmarnock, Kilwinning, Dalry, &c. The coal measures of this basin are of variable thickness; they contain from 5 to 8 and 11 principal coal-seams, yielding a united thickness of from 13 ft. to 40 ft. The Carboniferous limestone series of Ayrshire sometimes contains no workable seams of coal, while occasionally its seams equal or surpass in number and thickness those of the coal measures. Thus in the Girvan field there are 7 coals with an aggregate thickness of 50 feet, while at Muirkirk the same number yield a thickness of 40 feet of workable coal. The Ayrshire coals consist chiefly of common coals, including "hard" or "splint" and "soft" varieties. In some districts the intrusion of igneous rocks has converted certain seams into "blind coal," a kind of anthracite, much used for steam purposes. Gas or parrot coal (so called from its decrepitating or chattering when heated) is met with here and there, chiefly near New Cumnock. Parrot coal often occurs in thin lines or bands, which, when intercalated and alternating with dark carbonaceous ironstone and coaly matter, form seams of what is called black-band ironstone. The Ayrshire black-bands occur chiefly at Dalry, Lugar, and Dalmellington.

Lanarkshire Coal-fields.—These are the most extensive in Scotland, covering an area of not less than 150 square miles. The coal measures, which attain a thickness of upward of 2000 feet, contain about 18 workable coals; but all these are not continuous throughout the whole coal-field, while some are too thin in places to pay the cost of working. At their best they yield an aggregate thickness of 70 feet or thereabout, but in many places they do not average more than 40 or 30 feet, or even less. The limestone series is well-developed in the Lanarkshire coal-fields, but it is a very variable group, as indeed is the case throughout Scotland It consists of upper, middle, and lower groups, the coals being confined chiefly to the middle group, only one or two seams occurring in the lower, while in the upper only one seam occasionally attains a workable thickness. The principal coals of the limestone series vary in number from 1 to 9, their aggregate thickness seldom reaching more than 15 feet. The Lanarkshire coals consist chiefly of varieties of common coal, namely, hard or splint, soft, dross, &c. But here and there excellent gas coal is worked, as at Auchenheath, Wilsontown, &c., the former being considered the finest of all the Scotch gas coals. Another well-known parrot coal is that of Boghead near Bathgate, the subject of much litigation. Parrot or gas coal frequently occurs forming a part of mussel-band and black-band ironstones, which seams, when traced along their crop, are often seen to pass into gas coal. The best known blackbands are those wrought at Palacecraig, Airdrie, and Quarter, Bellside, Calderbraes, Bowhousebay and Braco, Goodockhill and Crofthead. Earnockmuir, Possil, Garscadden, and Johnstone.

At Quarrelton, Renfrewshire, an abnormal development of coal seams occurs below the horizon of the main or Hurlet limestone, which is usually the lowest important bed in the limestone series. The strata underlying that limestone contain here and there irregular lenticular patches of coal, never of any value. At Quarrelton, however, a number of these seams come together, and form a mass of coal more than 30 feet thick.

Stirlingshire Coal-fields.—These embrace the coal-fields of Falkirk, Carron, and Grangemouth, Slamannan, Clackmannan, and Borrowstounness. In the Falkirk, Carron, and Grangemouth fields, the coal measures are about 600 feet thick, and contain 9 workable seams of coal, yielding an aggregate thickness of 30 or 31 feet; the thickest seam is only 4 feet. In the Slamannan field, the coal measures are some 720 feet thick, and show 6 workable coals, yielding an aggregate thickness of 15 or 16 feet, the thickest seam being $4\frac{1}{2}$ feet. A small outlier of coal measures at Coneypark, however, gives a depth of 1140 feet of strata, containing 12 workable coals (two of which are 7 feet thick respectively), which yield an aggregate thickness of 44 feet. The coal measures of the Clackmannan district attain a thickness of 900 feet, and yield 10 workable seams of coal (thickest seam 9 feet) with an united thickness of 41 feet. The limestone measures of the Stirlingshire basins contain, as a rule, few coal seams. Where these are best developed, they vary in number from 5 (Bannockburn) to 11 seams (Oakley); and their aggregate thickness ranges from $11\frac{1}{2}$ feet to 37 feet. The coals embrace the variety usually met with in Scotland, viz., hard (or splint) and soft coals, some of the seams being good caking coals. Good gas coal was formerly obtained at Oakley; and other coarse parrot coals occur in various parts of the fields. Oil shale and black-band ironstone are also met with. The coal-field of Bor-

Stirlingshire

rowstounness is remarkable for containing thick sheets of basalt rocks, which are of contemporaneous origin, and do not alter the beds that rest upon them

Mid-Lothian and Fifeshire Coal Fields.—The Mid-Lothian coal field is disposed in what are for Scotland unusually symmetrical and unbroken lines. The basins lie with their principal synclinal axes from north to south. In the deepest basin the coal measures lie in a trough 2¼ miles broad and 9 miles in length, stretching from the sea at Musselburgh through Dalkeith to Carrington. The trough is underlaid by the millstone grit (Roslin Sandstone or Moor Rock), whose outcrop surrounds that of the coal measures in a band rarely more than half a mile broad. The Carboniferous limestone series rises from beneath the basin of millstone grit and coal measures on its west side, and crosses at a high angle, in a band about a mile in breadth, through Portobello, Gilmerton, and Penicuik. South of Penicuik the millstone grit forms another basin at Auchencorse Moss, but the trough is not deep enough to bring in the coal measures. West of Dalkeith the limestone series forms a shallow undulating basin with an outcrop of about 7 miles broad, extending from the sea at Cockenzie by Tranent and Pathhead. The Dalkeith basin of the coal measures has a total thickness of 1180 feet. There are 14 coal seams of a workable thickness, with an aggregate of 43 ft. 4 in. The limestone series of Mid-Lothian contains numerous coal seams. The total thickness of the series is 1582 feet, with 23 workable coal seams, aggregating 68 ft. 3 in. The "great seam" averages between 8 and 11 feet, and in one place is 12 ft. 6 in. thick. The coals of the Mid-Lothian basins are of the usual varieties met with in Scotland. The basins of the Mid-Lothian coal-fields reappear on the southern coast of Fife, and are undoubtedly continuous (though somewhat denuded) beneath the Firth of Forth. A segment of the western half of the coal measures trough (the prolongation of that of Dalkeith) extends from Dysart by Markinch, Kennoway, and Largo Bay. On the north this trough is bounded by faults, and on the east and south it is covered by the sea. Measured from Coaltown to Methil (at right angles to the line of strike) the thickness of the coal measure strata exposed to view may be roughly estimated at 4600 feet; but as the centre of the basin is not reached at the coast, the total thickness of strata is not seen. There are about 11 workable seams, with an aggregate of 61 feet. The Dysart Main coal is 16 feet thick. Another little basin, comprising the lower seams of the coal measures, occurs at Kinglassie. The Dysart or Leven coal measure basin occupies about 18 square miles, and that of Kinglassie from 3 to 4. The limestone series of Fife lies in several much broken basins on the south side of the Ochils and Lomond Hills from Alloa to Earlsferry. The principal coal fields in this series are those of Dunfermline, Halbeath, Lochgelly, and Kelty; but coals have been worked in many other places. as at Ceres, Radernie, Largo Ward, Markinch, &c. The coal-bearing strata vary in thickness, but do not exceed 600 feet. In the Dunfermline coal-field there are 10 seams, with an aggregate thickness of 41 feet. Halbeath coal-field yields 8 seams, with an aggregate thickness of 29½ feet; Lochgelly coal-field contains some 14 seams, with an aggregate thickness of about 65 feet; in the Kelty and Beath coal-field there are 12 seams, yielding an aggregate of 43½ feet. The workable seams in these separate fields range in thickness from about 2 feet up to 10 and 14 feet. The 14 feet coal of Lochgelly is divided by thin ribs of stone, which thicken out eventually so as to divide the coal into 5 separate workable seams, which, with the intervening strata, yield a thickness of 10 fathoms of strata. It is worth noting that, in the lower Carboniferous rocks of Fifeshire, two coals are worked at Balcarmo and elsewhere. As a rule, this series in Scotland is barren.

The carboniferous strata of Ireland consist chiefly of the Carboniferous limestone, which covers the greater portion of the island in one connected mass. The coal measures have probably been at one time nearly as extensive, but they have been almost entirely removed by denudation, the largest remaining basins being that of Castlecomer, near Kilkenny, and another in the west, between Tralee, Mallow, and Kilarney. In the north the small basin of Coal Island, on the west side of Lough Neagh, is partly covered by New Red Sandstone strata, and trials have been made to discover a possible extension of the coal measures in the valley of the Lagan, between Belfast and Lisburn.

The two coal fields of South Wales and Somersetshire differ from those of the central and northern counties in their strike or direction, their longer axes being placed east and west, instead of north and south, which is the prevailing direction of the latter,—the strata in the Somersetshire area being sharply bent and broken on a north and south line in a manner which is not seen elsewhere in this country, but is reproduced on a much larger scale in the north of France and Belgium. The most easterly point in England at which the coal measures have been worked is near Bath, where the overlying Liassic and New Red Sandstone strata are about 360 feet thick, beneath which the coal has been followed for some 5 or 6 miles from the outcrop. From this point nothing certain is known of their extension until we reach the neighbourhood of Valenciennes, where a coal field, known as that of Hainault and Valenciennes, extends with a general east and west strike as far as Namur, a distance of 65 miles. At Namur the width is about 2 miles, near Charleroi from 7 to 8, and through the north of France from 6 to 7. Only the eastern half, between Charleroi and Namur, comes to the surface, the western portion being covered by Tertiary and Cretaceous strata. Within 30 miles of Calais the coal measures end, the shales of the Carboniferous limestone having been pierced in a boring of 1113 feet deep at the latter place. East of Namur the coal measures come in again at Liége, continuing for about 45 miles, with a width of from 3 to 8 miles to beyond Aix la Chapelle, where they are divided by a ridge of Carboniferous limestone into two parallel basins, covered by Cretaceous and newer deposits, till they appear again on the right bank of the Rhine in the valley of the Ruhr, in the great Westphalian basin, which is probably the largest in Europe.

The same general structure is apparent along the whole of this line, which, from the western end of the South Wales basin to Frome, and from the N. of France to the Ruhr, is about 470 miles long. The measures generally dip regularly from N. to S. along the northern line of outcrop where it is known, but on the southern side they are bent into sharp folds by the elevation force which has uplifted the underlying Carboniferous limestone and Devonian strata along an east and west line, extending from the old slaty rock of the Ardennes to the Mendip Hills and the western part of Pembrokeshire. The known coal fields extend for about 350 miles out of the above amount of 470, and from the similarity of their position and structure many geologists are of opinion that other basins similarly placed may be reasonably supposed to exist in the intermediate ground between Somersetshire and Belgium. This subject has been treated in great detail by Mr Godwin Austen and Prof. Prestwich in the Reports of the Royal Commission upon Coal. The probable direction of this axis is shown on the map, Plate I. The only actual determinations of the rocks made within this area have been in two borings at Kentish Town and Harwich. In the former, sandstones, supposed to be of Devonian age, were reached below the Cretaceous strata at 1113 feet, and in the latter the Carboniferous limestone shale at 1025 feet. The most likely positions for the coal measure trough are considered by Prestwich to be in Essex and Hertfordshire, while Mr Godwin Austen places them in the valley of the Thames or under the North Downs. The latter seems to be the more probable than the line further north. The point, however, is purely speculative in the absence of any trial borings as guides; and a great number of these would certainly be required before any generalization as to the position of workable coal measures even within a wide range could be accepted. The deep boring on the southern part of the Wealden area, near Hastings, which it was supposed would have thrown a considerable amount of light on this matter, has hitherto been without other result than the proof of the existence of a totally unexpected and exceedingly great thickness of the upper Oolitic clays, similar to what is known on the French coast, near Boulogne.

On the south side of the Mendip axis a very large area in Devonshire is occupied by the lowest coal measures or culm series, which consist almost entirely of clay slates, with a few beds of anthracite in the northern portion of the district, near Barnstaple and Bideford. These are only worked to a small extent, their principal use being, not for fuel, but as a pigment for covering iron-work, which is known as Bideford black.

[Br]itish [Se]condary [an]d Terti[ar]y coals.

The coal-bearing areas of Secondary and Tertiary age in the United Kingdom are of very small importance. In Devonshire a lignite-bearing series of strata of Miocene age occurs in the flank of the granite of Dartmoor at Bovey Tracey, near Newton Abbot. This is principally remarkable for its associated clays, which are derived from the waste of the granite, and contain numerous impressions of dicotyledonous leaves and other plant remains. The coal is a lignite resembling a mere heap of tree stems drifted together and partially decomposed. It is not now worked, the original excavations being filled with water; and as the demand is restricted to supplying the wants of the local potteries, there is no opening for profitable mining.

In the Great Oolite of Yorkshire, some thin seams of coal or lignite were formerly worked at numerous points upon the moors between the Cleveland Hills and the Vale of Pickering. The most important product of this district, however, is the jet which is obtained from the waste of coal-bearing strata of the same age along the cliffs near Whitby, where it is manufactured into ornaments. The largest Oolitic coal deposit in this country is that of Brora in Sutherland, where a seam of about 3½ feet in thickness has been worked at intervals for a considerable period, but never to any considerable extent except during the prevalence of high prices in the coal trade.

[C]ontinent[a]l Second[a]ry coals.

Another area in which coal is found in strata of Secondary age is that of Scania, near Helsingborg, in south-western Sweden, in the three coal-fields of Hoganas, Stabbarp, and Röddinge. These are situated in the uppermost Triassic or Rhætic series. At the first, which is the most important locality, the strata vary from 100 to 800 feet in thickness, with two seams of coal respectively 1 and 4½ feet in thickness. There is a good fire-clay associated with the lower seam, which is extensively worked for fire bricks and pottery, a large proportion of the coal being used on the spot. In the Danish Island of Bornholm similar coal-bearing strata, probably of Liassic age, form a narrow belt along the south and south-west coast, which it is supposed may continue under the alluvial plain of the Baltic into Pomerania.

The Coal-fields of the Continent of Europe.

The coal-fields of the continent of Europe, though more scattered and disturbed than those of England, may be similarly divided into two groups according to their geological structure, the first being those in which the series is complete, the coal measures being symmetrically arranged upon the Carboniferous limestone and Devonian strata. Examples of this structure are afforded by the long line of coal-fields extending through the north of France and Belgium to the Rhine valley on the north side of the Ardennes, and those of the more easterly district of Silesia and of the north of Spain. The remaining and far more numerous European coal-fields are either contained in hollows in crystalline schists, or rest on the older Palæozoic rocks, *e.g.*, the central and southern French basins, and those of Saxony and Bohemia. Further east, in central and southern Russia, the order observed in Scotland is reproduced, there being a large development of coal in Carboniferous limestone strata, and something of the same kind seems to be probably the case in China.

Franco-Belgian coal-field

The best developed portions of the Franco-Belgian coal-field are seen within the territory of Belgium, the westerly extension into France being entirely covered by a great thickness of newer strata. Commencing at the eastern side, the first field or basin is that of Liége, which extends from the Prussian frontier near Verviers in a S.W. direction for about 45 miles, the greatest breadth being about 9 miles near Liége. The principal working points are concentrated on the western edge, where the lower beds rest on the Carboniferous limestone, the eastern portion being partly covered by Cretaceous and Tertiary strata. The number of coal seams is 83, the upper series of 31 being so-called fat coals, suitable for coking and smiths' fires; the middle series of 21 seams are semi-dry or flaming coals; and the remainder or lower series of 31 are dry, lean, or semi-anthracitic coals. The upper series, which are the most valued, are found only in a small area near the centre of the basin at Ougrée, near Liége. The seams vary from 6 inches to 5½ feet in thickness, the average being barely 3 feet. This order of succession is observed in the whole of the districts along this axis. The same general structure also prevails throughout the strata which have a comparatively small slope on the northern crop, and are very sharply contorted, faulted, or broken along on the south side of the basins. The local terms *platteurs* and *dressants* are used to distinguish the flat and steep portions of the coals respectively.

The next basin, that of the Sambre, extends for about 30 miles from Namur to Charleroi, the greatest exposed breadth being about 9½ miles. The western and a greater part of the northern side are covered by Tertiary strata, which are very heavily watered. At Montceau, near Charleroi, there are 73 seams, which pass through the various conditions of fat, flaming, and dry coals, from above downwards, according to the order already described.

The most important development of the coal measures in Belgium is in the basin of Mons, which extends from Mons to Thulin, a length of about 14 miles, with a breadth of about 7 or 8 miles, a large portion of the area being covered by newer strata. The number of known coal seams is 157, out of which number from 117 to 122 are considered to be workable, their thickness varying generally between 10 and 28 inches, only a very few exceeding 3 feet. These are classified, according to position, into the following groups, which are taken as a standard for the whole of the north of France and Belgium:—

1. Upper series (*charbon flenu*), 47 seams. These, which occur chiefly in the neighbourhood of Mons, are very rich bituminous coals, especially adapted for gasmaking.

2. Hard coal series (*charbon dur*), 21 seams. These are, in spite of their name, soft caking coals, less rich in volatile matter than the flenu, but excellent for coking purposes.

3. Forge coal series, 29 seams. These are chiefly used for smithy purposes and iron works, but the lower members approximate to dry steam coals.

4. Dry or lean coals, 20 to 25 seams, forming the bottom series. They are of small value, being chiefly used for brick or lime burning.

The amount of compression to which the strata have been subjected in these coal-fields, has caused them to be sharply contorted into zig-zag folds. In the neighbourhood of Mons a single seam may be passed through six times in a pit of 350 yards vertical depth, and the strata, which if flat would be 9 miles broad, are squeezed into a space 7 miles across and about 8200 feet deep to the bottom of the basin. At Charleroi the compression is still greater, a breadth of 8½ miles of flat strata being narrowed to rather less than half that quantity by contortion into 22 zig-zag folds.

The thickness of the overlying Tertiary and Cretaceous strata in the neighbourhood of Mons is from 500 to 900 feet; towards the French frontier the thickness is between 200 and 400 feet, and at Valenciennes about 250 feet. At Aniche these overlying measures, or *terrains morts*, are 400 feet thick, below which the coal measures are found to contain 23 feet of coal in 12 seams. At Anzin, near Denain, there are 18 seams, together 39 feet, which is about the maximum development in the north of France. This coal-field, which was unknown before 1734, has reached a very high state of production in spite of great difficulties interposed by the water-bearing strata covering the coal measures. It extends for about 45 miles, diminishing in extent and value to the westward. The structure is very similar to that of the Belgian, one of the most remarkable features being the inclined fault called the *cran de retour*, which brings the lower or dry coal series of the north side against the higher coking coals of the south side, as shown in the section, Plate II. fig. 4.

At Hardinghen, near Boulogne, a small patch of disturbed coal strata was formerly worked. These are now supposed to be of the age of the Carboniferous limestone.

The coal-fields of central and southern France are mostly small in area and irregular in structure, with at times remarkable single accumulations of coal of enormous thickness, which do not, however, extend for any distance. The most important basin is that of Saint Etienue and Rive de Gier, south of Lyons, on the right bank of the Rhone. It is of triangular form, about 28 miles long, with a base of 8 miles. The thickness of the three principal seams at the latter place is about 33 feet, but at Saint Etienne there are from 15 to 18 seams, making together about 112 feet in a total depth of measures of about 2500 feet.

The basin of the Saône et Loire, near Chalons and Autun, is about 25 miles long in a S.W. and N.E. line. At Creusot, on the north crop, the coals, which are in places extremely thick (the main seam averaging 40 feet, but occasionally swelling out to 130 feet), dip at a high angle below a covering of New Red Sandstone strata, and appear in a modified form, both as regards thickness and position, on the south side at Blanzy. An attempt has been made to prove the continuity of the series in the bottom of the basin by a deep boring, which was, however, abandoned at a depth of over 3000 feet without passing through the overlying strata. At Montchanin a remarkable seam or mass of coal was found extending for about 650 yards, with a thickness varying from 60 to 200 feet at the surface, which, however, diminished to one half 60 yards down, and wedged out at 140 yards deep. Another coal field of considerable importance is that of Alais and Grand Combe near Nîmes, which is partly covered by Liassic strata, and has a total maximum thickness of 80 feet of coal.

In addition to these must be mentioned the anthracitic series of the Alps, which extend along the flanks of that chain from Savoy and the Tarentaise into Styria and Carinthia. They are of small economic importance.

The Secondary and Tertiary coals of France are of comparatively small importance. Lignite is worked, among other places, near Dax in the Pyrenees, and at Trets and Fuveau near Marseilles.

The coal-fields of Prussia, situated on the extension of the Franco-Belgian axis, are the two small basins of the Inde and Worm, east of Adelnau, near Stolberg and Eschweiler, which are included in single sharply sloped folds of the mountain limestone, and the great Westphalian basin east of the Rhine, in the valley of the Ruhr. The latter, which is one of the most important in Europe, extends for about 30 miles east and west from Essen to Dortmund. The breadth is unknown; the beds are exposed for about 15 miles at the broadest part, but the actual boundaries to the north and north-east are hidden by Cretaceous rocks. The greatest depth from the surface to the bottom of the basin is probably about 5000 feet. It is divided lengthways by transverse axes of elevation into four principal basins, besides several smaller ones. The total thickness of measures already proved is from 6000 to 8000 feet, with about 130 seams of coal, together about 300 feet thick. These are divided into three series by two bands of barren measures. The thickness of the individual coal seams varies from 8 inches to 7 feet. Seventy-six are considered to be workable, having a combined thickness of 205 feet, and 54 are unworkable, containing 42 feet of coal. The proportion of workable coal to the whole thickness of strata is as 1 to 33. The order of succession as regards quality is similar to that observed in Belgium, the most highly valued gas and coking coals being at the top of the series, and the dry semi-anthracitic seams at the bottom. On the south side of the axis of the Rhenish Devonian strata, which is the high ground known as the Eifel and Hunsruck, carboniferous strata reappear in what is known as the Pfalz-Saarbrücken basin, occupying a rectangular area between Bingen, Donnersberg, Saarbrücken, and Mettlach, about 60 miles long and 20 miles broad, the productive coal measures being restricted to a triangular space of about 175 square miles in the S.W. corner. The Carboniferous limestone is absent, but the thickness of the coal measures is very great, the upper or Ottweiler series measuring from 6500 to 11,700 feet, with about 20 feet of coal in different parts of the district, and the lower or Saarbrücken series from 9000 to 5200 feet, with 82 workable and 142 unworkable coal seams, making a total of about 350 to 400 feet of coal. The greatest thickness of the upper strata is found in those localities where the lower are thinnest, but the total thickness is computed to be about 20,000 feet in the thickest known section. The coals of the lower division are divided into groups by certain well-marked horizons, usually prominent seams, which have this peculiarity that the best coking and gas coals are found in the bottom of the series, and the drier ones at the top, thus reversing the order observed in the basins on the northern slope. The amount of hygroscopic water in the coal is also found to diminish downwards.

In the district between the Ems and the Weser, are situated the small coalfields of Ibbenbüren, on the easterly extension of the Westphalian basin, and the Piesberg, near Osnabrück, which are of true Carboniferous age. Besides these, there is a curious development of coal in the Wealden strata which extend in a narrow discontinuous band E. and W. for about 150 miles. The coals are or have been worked at Tecklenburg and Borgloh in the Teutoburger Wald, at Bückeburg in Schaumburg, and in the Osterwald south of Hanover. The coal seams are small and of inferior quality, but are interesting as showing how nearly the conditions prevailing at the time of the older coal measures were repeated over a part of the same area in Cretaceous times. There are traces of thin discontinuous coal-beds in the Wealden strata of Sussex, but nowhere approaching to the extent of those in the Wealden strata of N. Germany.

In the low ground north of Halle, small and irregular patches of coal measures are found at Wettin, Löbejun, and Plötz. These are probably the remains of a single coal-field which has been disturbed and broken up at the time of the eruption of a great mass of igneous rocks which is found in a nearly central position between them. The coal measures are also found in the Thüringer Wald, the Schwarzwald, on the south side of the Harz, and in the Bavarian Oberpfalz, but none of these localities are important as centres of production. In Saxony there are two principal coal-fields, the first being that of the Plauens'che Grund, near Dresden, which is chiefly interesting for the very disturbed condition of the measures, and the consequent difficulty in working; and the other that of Zwickau, which is one of the most important in Europe. It forms an elliptical basin, about 20 miles long, between Zwickau and Chemnitz, and from 6 to 7 miles in maximum breadth, the greater portion being covered by New Red Sandstone strata. The coal measures, which rest upon old argillaceous schists, are about 1700 feet thick at a maximum, containing 12 principal seams of coal, besides several smaller ones. The most important is the so-called soot coal (Russkohle), which at times attains to a thickness of 25 feet. The series is divided by Geinitz into groups, according to the prevailing character of the associated fossil plants, as follows :—

1. Zone of Ferns, corresponding to the upper group.
2. Zone of Annularia and Calamites, or middle group.
3. Zone of Sigillaria, or lower group.

A fourth, or Sagenaria zone, found in Silesia, corresponding to the culm measures of Devonshire, completes this classification.

The most important coal-fields of Eastern Europe are those of Silesia. The Carboniferous limestone series and the lowest coal measures or culm strata reappear in these basins, and are associated with numerous valuable mineral deposits, mainly of zinc and lead ore. The coal-field of Lower Silesia and Bohemia forms a basin between Glatz, Waldenburg, Landshüt, and Schatzlar, about 38 miles long and 22 miles broad. The number of seams from $3\frac{1}{2}$ to 5 feet thick is very considerable (from 35 to 50); but it is difficult to trace any one continuously for any great distance, as they are liable to change suddenly in character. The lower seams usually lie at a higher angle than those above them. There does not appear to be any relation between the coking power of the coals and their geological position, and the same seam often varies in quality in neighbouring mines.

The upper Silesian coal district extends in several disconnected masses from Mährisch-Ostrau in Moravia, in a N.W. direction, by Rybnik and Gleiwitz in Prussia, and Myslowitz in Poland, being held partly by Austria, Prussia, and Russia, the Prussian portion between Zrabze and Myslowitz being the most important, extending over 20 miles in length, by nearly 15 in breadth. The greatest thickness of coal in workable seams (from $2\frac{1}{2}$ to 60 feet thick) is estimated at a total of 333 feet, the thickness of the measures being about 10,000 feet. A very large proportion of this coal-field is hidden by New Red and Cretaceous strata.

The Tertiary coals or lignites of Germany are of considerable importance, being distributed over large areas, the seams often attaining a great thickness, although rarely continuous for any great distance. The principal deposits are situated in the lower parts of the valleys of the Rhine and the Elbe, in Nassau, and in the high ground of the Rhon in Bavaria. The lignite district of the Rhine extends from near Bonn down to Deutz and Bensberg belc Cologne. The pigment known as Cologne earth is a sepia-coloured lignite, which can be ground to a fine powder when dried. In Nassau the so-called bituminous wood, a variety of lignite containing flattened masses of wood of a light brown colour, is very common. The produce of these districts is mainly consumed for house fuel and steam boilers, some small quantity having been used for the production of paraffin and photogen oil.

The coal-fields of the empire of Austria-Hungary are of very considerable interest, from the great diversity in their geological position. Coals of Carboniferous age are mainly confined to the northern provinces of Bohemia, Moravia, and Silesia; but in Hungary and the Alpine lands, especially in Styria, coals of Tertiary age are found, which approach very closely in composition and quality to those of the coal measures.

First in importance among the former class, is the basin of Pilsen in Bohemia, which covers an area of about 300 square miles. It rests upon Silurian shale, and is covered unconformably by Permian conglomerate and sandstone. The coals vary considerably in different localities; the total thickness of the workable seams, from 3 to 5 in number, does not exceed 20 feet. There is a remarkable bed of slaty cannel in the upper part of the series, which contains animal remains of Permian types associated with the ordinary coal flora. Another important basin, that of Schlan-Kladno, E. of Prague, appears along the north edge of the Silurian strata, extending for about 35 miles E. and W. At Kladno, where it is best developed, it contains two principal seams, of which the upper is from 10 to 20 feet, and the lower or main seam from 19 to 40 feet thick.

At Rossitz, near Brünn, in Moravia, a belt of coal measure, resting upon crystalline rocks, has been considerably worked. There are three seams, together from 27 to 30 feet thick. These beds are said to be the equivalent of the upper seams of Pilsen and Kladno.

In Moravia, Silesia, and Poland the coal measures are associated with the mountain limestone, which in Central Germany, east of Westphalia, is generally absent. The upper Silesian coal-field is situated in Prussia, Austria, Silesia, and Russian Poland, the largest portion being in the first country. The area of this basin is about 1700 square miles, a considerable portion of it being hidden by Secondary and Tertiary strata. In the Austrian portion at Ostrau in Moravia there are 370 seams, of which 117 are workable, with a thickness of about 350 feet of coal. The largest seams are situated in the upper series, the principal one being about 13 feet thick. The coals of the neighbourhood of Ostrau are very full of gas, which occasionally finds its way into the cellars of the houses in the town, besides giving off large quantities of fire damp in the workings. A bore hole put down 150 feet to a seam of coal in 1852, gave off a stream of gas which was ignited at the surface, and has continued to burn, with a flame many feet in length, to the present time. The same coal-field extends into the district of Cracow, where it contains numerous seams of great thickness, which, however, have been but partially explored. In the Austrian Alps anthracitic coals occur at various points along the northern slopes, in strata of the age of the culm measures, but nowhere in any great quantity. In the Carpathian countries true coal measures are not largely developed, the principal locality being near Reschitza in the Banat, where 4 seams, from 3 to 10 feet in thickness, are worked to a certain extent.

At Steyerdorf, near Oravicza on the Danube, a remarkable coal-field is found in the Lias. There are 5 seams, from 3 to 7 feet in thickness, which are bent into an anticlinal, besides being disturbed by numerous faults. The coal is of a very good quality, yielding a coke suitable fc iron-smelting. The annual production is about 260,000 tons. Similar coals occur in the Lias at Drenkowa, and near Fünfkirchen, where there are 25 workable seams, together about 80 feet thick, also of a good coking quality, but very tender in working, making a great deal of slack.

Secondary coals occur in the Trias and Oolitic strata at various points in the Alps, but are only of local interest.

In the Gosau strata belonging to the chalk, coal is worked at various points in the Alpine lands, the average annual production being about 25,000 tons. Eocene coals occur in Dalmatia, and Miocene lignite in the Vienna basin in Southern Moravia, one seam, about 10 feet thick, covering an area of about 120 square miles. In the Styria-Hungarian Tertiary basin, Tertiary coals are developed on a very great scale, especially in Styria, at Salgo Tarjan in N. Hungary, and in the depression between the Matra and the crystalline rocks of Upper Hungary. These localities represent only those best known by workings, many more being undeveloped. The lignite beds are often of great thickness, *e.g.*, 70 feet at Hrastnigg, and 130 feet at Trifail. The production of Tertiary coal in Styria is about 500,000 tons annually. At Leoben and Fohnsdorf, lignites are worked of a quality closely approaching to that of Carboniferous coal, and are largely consumed in the production of iron and steel, having almost entirely replaced charcoal in the local forges. In Bohemia, Miocene brown coal strata cover a very large area, the principal basins being those of Eger, Carlsbad, and Teplitz, together about 600 square miles, the main seam occasionally attaining a thickness of over 100 feet. The trade in this coal is very considerable along the entire valley of the Elbe.

The coal-fields of Russia have been but imperfectly known until a comparatively recent period, when the demand for fuel caused by the extension of railways and the increase in manufacturing industries has stimulated explorations, which have resulted in the discovery of coal-bearing strata of considerable magnitude and extent. These belong to the period of the Carboniferous limestone, like the lower coals of Scotland.

In Central Russia the coal-bearing area belonging to the Carboniferous limestone is said to cover about 13,000 square miles, the centre of the basin being at Tula, S. of Moscow. There are two principal seams, 3 ft. 6 in. and 7 feet thick, in the bottom of the series near the top of the Old Red Sandstone. The coal is of inferior quality, containing about 12 to 16 per cent. of ash, and from 2 to 5 per cent. of sulphur.

In Southern Russia, between the river Donetz and the head of the sea of Azoff, a more important coal-field occurs, also in the Carboniferous limestone, covering an area of 11,000 square miles. There are sixty seams of coal, forty-four being workable, with a total thickness of 114 feet. The best is a dry or semi-anthracitic coal, resembling that of South Wales. At Lugan and Lissitchia Balka, a thickness of 30 feet of coal is found in 900 feet of strata.

In the Ural, coal is found in sandstones, interstratified in the Carboniferous limestone in the district north of Perm, between the parallels of 57° and 60° N. latitude. The strata dip at a high angle to the west, under the Permian strata. The thickest coals are at Lithwinsk at the northern end, where there are three seams worked, measuring from 30 to 40 feet each; further south they become thinner. The coals appear to be similar in quality to those of the central coal-field.

In Poland, about Bendzin and Lagorze, N. of Myslowitz, an extension of the Upper Silesian coal-field covers an area of about 80 square miles, being partly covered by Permian strata. Nine seams of coal are known, varying from 3 to 20 feet in thickness; but they do not occur together, except in a small part of the centre of the basin. The aggregate thickness of coal is about 60 feet. This is the only district in which true coal measure strata are found in European Russia.

Among the southern countries of Europe, the first place must be given to the coal-fields of Spain, but even these are of comparatively small importance, when measured by a northern standard, consisting of a few small and scattered basins, in which both Carboniferous and Secondary coals are represented. The Carboniferous limestone acquires a considerable development in the Cantabrian chain along the north coast, and is associated with overlying coal measures near Oviedo and Leon. In the former area the coals are often considerably disturbed, becoming anthracitic at the same time. The best seams are from 5 to 8 feet thick. In the Satero valley near Sotillo, N.E. of Leon, a seam called El Carmen, averaging 60 feet, is sometimes 100 feet thick, and is said to be in places associated with another which is occasionally 180 feet thick. Another basin of importance is that of Belmez and Espiel, occupying a narrow valley in older Palæozoic strata, about 20 miles north of Cordova, which has recently been traversed by a railway connecting it with the main lines from Lisbon and Cadiz. This produces coking and gas coals of good quality, which are in considerable demand for smelting in the lead and other mineral districts in the neighbourhood. The other principal localities are at Villaneuva del Rio near Seville, and San Juan de la Abaderas in Catalonia. Coals of Neocomian age are found at Montalban, in the province of Teruel, and lignites of Miocene age, among other places, at Alcov in Valencia, and Calas in Catalonia.

In Portugal a small tract of lower Carboniferous strata, containing anthracite, occurs at San Pedro de Cova, near Coimbra, but the produce is very small. Portugal.

In Italy there is very little Carboniferous coal, what does occur being mainly of an anthracitic character in very disturbed strata in the Piedmontese Alps. Tertiary lignites are worked at several places in Tuscany and in Naples, but the total output is inconsiderable when measured by the standards of more northern countries. Italy.

Extra-European Coal-fields.

In Turkey, Carboniferous coal is found at Heraclea in Asia Minor, and has been worked from time to time, but hitherto without much influence upon the coal produce of Europe. Lignites are known to occur near Smyrna, and in the Lebanon and various other points in Syria. Turkey.

It is doubtful whether any Carboniferous coal exists in Africa. Coal-bearing strata, probably of the age of the New Red Sandstone, the so-called Karoo beds, cover a considerable area, both in the Cape Colony and Natal, but little is known of the details of the coal-beds beyond statements of the excellence of the quality of the coals. Lignite occurs in the high lands of Abyssinia, and probably at numerous other points in the interior. Africa.

The coal-bearing strata of India occur in numerous detached basins, which are widely distributed over the whole peninsula, their aggregate area, however, being but small. The principal development is in the valley of the Damodar river, one of the southern tributaries of the Hugli, the largest coal field being that of Raniganj, on the line of the East Indian Railway, about 140 miles W. of Calcutta, which covers an area of about 500 square miles. It is a basin resting upon crystalline schists, and partly covered by Triassic sandstones in the centre, and by jungle and alluvium to the eastward, so that the real area is not yet known. The strata are divisible into three series as follows:— India.

Upper or Raniganj series—coal-bearing.
Middle or Ironstone series—no coals.
Lower or Barrakur series—coal-bearing.

The total thickness may be from 3000 to 4000 feet; the ironstone series is a group of shales containing nodular ironstone about 1500 feet thick, but diminishing westward. Numerous coal seams are worked at different points, but they cannot be traced continuously for more than a short distance without change. In the upper series an average of 11 seams, together about 120 feet thick, are known in the eastern or Raniganj district, and 13 seams, together 100 feet, on the western side. Occasionally single seams acquire a great thickness (from 20 to 80 feet), but the average of those worked locally is from 12 to 18 feet. In the lower series, 4 seams, together 69 feet, are known. The coals are generally of inferior quality, containing a considerable amount of ash, and are non-coking in character. The coals of the lower series are better, yielding fairly good coking and gas coal at Sanktoria, near the Barrakur River.

A small coal-field at Kurhurbali, near Luckeeserai, on the East Indian Railway, has recently been developed to a considerable extent for locomotive purposes. It covers about 11 square miles, with an aggregate of 3 seams, varying from 9 to 33 feet in thickness. They are of better quality than those of any other Indian coal-field at present known, and are of great value to the railway, which is now supplied with fuel at a lower rate than probably any other railway company in the world.

There are several other coal-fields in Bengal, especially that at Jherria, near the sacred mountain of Parisnath, those south of Hazaribagh, and those on the Sone River, but none are as yet developed to any extent, being away from the great lines of communication. On the western side of India the principal workings are at Mopani, on the Nerbudda, on the line of the Great Indian Peninsular Railway, the coal being used by the railway. It is of inferior quality, and the strata are inclined at a considerable angle, rendering the working difficult.

In the Central Provinces a new coal-field of considerable extent has been recently discovered, almost entirely by boring, on the Wardha and Chanda districts, on the upper tributaries of the Godaveri, a considerable portion being within the Nizam's province of Berar. It is probable that this may become one of the most important sources of coal supply for Central and Western India, but no great amount of work has as yet been done upon it.

Besides the above, there are several other known coal-fields, for details of which the reader is referred to the Reports of the Geological Society of India.

The age of the Indian coals is generally supposed to be Permian, the only fossils that have been found in them being plants which are referred to Permian types in Europe. If, however, the overlying sandstones, containing reptilian fossils, generally reputed to be of Triassic age, should, as seems likely, prove to be Permian, it is not improbable that the coal-bearing strata may actually belong to the period of the upper coal measures, and the Indian coal-fields would then be strictly analogous to the deep irregular basins of Southern France and Central Europe, with which they have many structural points in common. No marine strata, or anything approximating to the character of the Carboniferous limestone, are known anywhere on the plains of India, although they are found in the salt range of the Punjab and in the Himalayas.

The coal-fields of China are known, from the researches of Baron von Richthofen, Prof. Pumpelly, and other travellers, to cover a very large area, comparable only with those of North America; but, as may be imagined, no very detailed information has as yet been obtained concerning them. According to the first-named authority, there are no newer formations than the Trias in China other than alluvial deposits of enormous thickness, but Palæozoic strata, from the Silurian upwards, are developed on a very large scale. Coal of Carboniferous age exists in Manchuria, mostly in inaccessible mountain valleys, and further west all along the Great Wall. Near Peking there are beds 95 feet thick, which supply the city with fuel. The most extensive development is to the west and north-west, on the south of the great mountain range which stretches across Western China, where there is an area of Carboniferous strata of 100,000 square miles. The great plain of China is bounded by a limestone escarpment from 2000 to 3000 feet high, which is capped by a plateau covered by 30,000 square miles of coal measures, in which the coal seams, 30 feet thick, lie perfectly horizontal for 200 miles, and are reported to extend beyond the frontier into Mongolia. Most of the localities are, however, far in the interior. The coal of Shantung, though not near good harbours, is the most accessible of all Chinese coal from the sea. It also occurs in the other maritime provinces, but in districts offering fewer facilities for export. It is obvious, from the enormous dimensions given to these coal-fields, that it will be a long time before anything like a moderately accurate estimate of their value can be obtained.

Japan. In Japan coal is worked at several points, but no detailed account of the mode of its occurrence has been published. At the island of Takasima, near Nagasaki, a colliery is worked by the Japanese Government for the supply of their steamers on a tolerably large scale.

In the great islands of the Indian and South Pacific Oceans, coal-bearing strata are known at many different points; but in the absence of systematic investigation, no general estimate can be formed of their position, extent, or value. In the Dutch settlements, coal has been found in Sumatra and Borneo, the best known deposit being that of Pengaron, on the south-east of the latter island, where a mine has been worked by the Dutch authorities for several years. The section of the strata, as proved by a level, shows a series of 15 seams above 1 foot in thickness, together about 36 feet, in about 520 feet of measures, 6 of these having been worked. The best appear to be somewhat similar to the steam coal of the North of England. In the British settlement of Labuan, off the north coast of Borneo, 5 workable seams, together about 27 feet thick, are estimated to cover the whole island. This is probably of Tertiary age, but approximates in composition to many of the non-coking coals of the coal measures. The Labuan coal is also remarkable for containing large masses of fossil resin.

Borneo.

Labuan.

Australia. The most important southern coal deposits, however, are those of Australia, which extend, with short intervals, from the Gulf of Carpentaria to Bass's Straits. In the northern districts, the distribution appears to be somewhat similar to that seen in South America, Secondary and Tertiary basins occupying the ground near the sea, while true Carboniferous coal is found further inland; but in New South Wales, where their development is greatest, older coal-bearing strata extend along the eastern slope of the continent, between the parallels of 29 and 35 degrees S. latitude, covering a very large area in several detached portions, the largest probably exceeding 12,000 miles, and come down to the sea. The principal workings are situated near Newcastle, at the mouth of the Hunter River, at Wollongong, 60 miles south of Sydney, and at Hartley, about 90 miles inland. The coal seams vary from 3 to 30 feet in thickness in the Newcastle district, 16 seams above three feet thick being known. The coals are mainly of a free-burning class, but some are bituminous, giving a good coke. In the uppermost part of the series oil shales and cannel are found. The age of the Australian coal measures has been the subject of considerable controversy. Formerly it was supposed that they were Oolitic, from the supposed affinities of the fossil plants; but it has since been shown that the coal-bearing portions of the series are interstratified with marine strata, containing fossils of Carboniferous and Devonian types. The same association is observed in the coal series of Bowen River in Queensland, and on those of the Mersey River in Tasmania, showing the extension of the Carboniferous strata in a chain of detached basins from the 20th to the 40th parallel of S. lat., or about 1400 miles. In Queensland the strata are estimated to cover an area of 24,000 square miles, without taking into account possible extension under the Cretaceous strata of the interior. Up to the present time, however, very little has been done towards their development, the districts in which they occur being too far from the settled portions of the country. The principal mines now open are on newer strata of Cretaceous age nearer the sea, at Ipswich, in the neighbourhood of Brisbane. Some of these coals are remarkably like those of South Durham, and yield a good hard coke, suitable for blast-furnace purposes.

True coal measures are not known to exist in New Zealand, but coal-bearing strata of two different periods have been described by Dr Hector, Dr Haast, Captain Hutton, and other geologists. The newer series yield a lignite, which is described in the reports as hydrous coal; while the older, which is probably of Cretaceous or Jurassic age, yields a superior class of combustible known as anhydrous coal. These minerals occur at many different points in the two larger islands, and although no systematic detailed account of them is as yet available, a considerable amount of information on this subject is contained in the various geological reports published by the New Zealand surveyors.

In North America, the Carboniferous strata are divided by geologists into two principal groups,—the lower or sub-Carboniferous, which correspond to the Carboniferous limestone of Europe, and the Carboniferous. which includes the millstone grit and coal measures.

The first of these is about 5000 feet thick in Pennsylvania, consisting mainly of shales and sandstones; but in the Mississippi valley, in Illinois, Iowa, and Missouri, a considerable thickness of limestone is developed in this part of the series. In the former region some thin coal seams are found, the relation between the two areas being in this respect similar to that of the Carboniferous limestone in England to the coal-bearing formations of similar age in Scotland.

The millstone grit forms a mass of sandstones and conglomerates from 1200 to 1400 feet thick in Eastern Pennsylvania, but thins rapidly to the westward, being only from 100 to 250 feet thick in Ohio and Tennessee. In Arkansas, the compact siliceous rock known as novaculite, or Arkansas hone stone, occurs in this member of the Carboniferous series.

The coal measures proper cover a very large area, both in the United States and in Canada. First in importance is the Appalachian coal-field, covering about 60,000 square miles, extending through parts of Pennsylvania, Ohio, Virginia, eastern Kentucky, Tennessee, and Alabama. The maximum thickness of strata is from 2500 to 3000 feet; that of included coal is 120 feet near Pottsville, 62 feet at Wilkesbarre, and about 25 feet at Pittsburg, showing a gradual diminution to the westward. The most persistent coal is the Pittsburg seam, which is known over an area measuring 225 miles by 100 miles, but with a thickness varying from 2 to 14 feet.

The anthracite district of central Pennsylvania occupies an area of about 650 miles on the left bank of the Susquehanna River. The strata between Pottsville and Wyoming, which belong to the lowest portion of the coal measures, are probably about 3000 feet thick, but it is difficult to arrive at an exact estimate, owing to the numerous folds and contortions. There are from ten to twelve seams above 3 feet in thickness; the principal one, known as the Mammoth or Baltimore vein, is 29½ feet thick at Wilkesbarre, and in places even exceeds 60 feet.

The Illinois and Missouri basin covers a considerable part of these States, as well as of Indiana and Kentucky, Iowa, Kansas, and Arkansas. Its area is estimated at 60,000 square miles, the thickness varying from 600 feet in Missouri to 3000 feet in western Kentucky. The aggregate thickness of coal is about 70 feet. A good furnace coal is obtained in Indiana, the so-called block coal of Brazil near Indianopolis, which, like the splint coals of Scotland and those of Staffordshire, can be used in the blast furnace without coking.

In Michigan a nearly circular area of coal measures, of about 5000 square miles, occurs in the lower peninsula between lakes Huron and Erie. The thickness is only 120 feet, and the coals unimportant.

Other coal-bearing areas of less value are known in Texas and Rhode Island.

The Carboniferous strata are largely developed in the eastern provinces of the Dominion of Canada, notably in New Brunswick and Nova Scotia. The lower Carboniferous group here consists of about 6000 feet of red sandstones and green marls, with thick beds of fossiliferous limestones, accompanied by gypsum. The limestones increase in thickness southward. In this series occurs the peculiar pitch-like or asphaltic coal of the Albert mine in New Brunswick, of which an analysis is given in Table I., *supra*. The overlying coal measures, including the millstone grit, occupy an area estimated at 18,000 square miles. The whole thickness of this group at South Joggins is about 14,750 feet, with 76 included coal seams, together 45 feet in thickness, which are contained in the middle division of the series. At Pictou there are six seams, together measuring 80 feet in thickness. The coal measures in this area approach more near to the great coal-fields of Europe in thickness than those of the other American Carboniferous districts. Rocks of Carboniferous age occur in various places on both flanks of the Rocky Mountains, and in the Arctic Archipelago, but have not yet been explored.

Lignite-bearing strata of Cretaceous and Tertiary age occupy a very considerable area in the central and western portions of North America, especially in the upper Missouri and Saskatchewan valleys, in Utah and Texas, and in California, Oregon, and Vancouver Island. In the last locality coal has been extensively mined near Nanaimo, on the east coast, for several years past, in strata of Cretaceous age. Tertiary lignites are worked in Bellingham Bay, at Coose Bay in Oregon, and at Monte Diabolo, near San Francisco. The lignitic formations of the eastern flank of the Rocky Mountains, which are considered by Hayden to occupy a position between the Cretaceous and Eocene Tertiary strata, occupy an area estimated at about 50,000 square miles within the United States, and extend both northward into Canada and southward into Mexico.

In South America coal, probably of Carboniferous age, is found in the Brazilian provinces of São Pedro, Rio Grande do Sul, and Santa Catharina, and in the neighbouring state of Uraguay. The largest area is that known as the Candiota coal-field, which is exposed for about 50 miles in the valley of the river of the same name. The sections exposed show 5 seams from 9 to 25 feet each, or together about 65 feet of coal. Other basins are known at S. Sepé and S. Jeronimo, on the Jacabahay River. The latter is the only point at which mines are worked, as the coals, though thinner than those of the other localities mentioned, are situated within the reach of navigable waters, having only to bear a land carriage of 8 miles to the river.

On the west coast of South America, Cretaceous coals are worked at Lota, in Chili, and at Sandy Point, in the Straits of Magellan. In Peru both Secondary and Carboniferous coals are known at various points in the interior, the former occupying a position on the first rise of the table land of the Andes, while the latter occur in higher ground, at a greater distance from the coast. Good coal is also found at many points in the Santa valley.

Much of the Peruvian coal has undergone considerable disturbance and metamorphism subsequent to its deposition. At Porton, 45 miles east of Truxillo, a ridge of coal-bearing sandstones has been changed into a hard quartzite, with an interstratified seam of anthracite in a nearly vertical position. The coal is remarkable as containing a large amount of sulphur (see analysis Table I.). The hitherto inaccessible position of these places, which are usually more than 10,000 feet above the sea-level, has prevented the development of coal-mining in Peru; but the extension of railways into the mountains will probably bring them into importance by stimulating a local demand for fuel.

Extent of existing Workable Coal.

The following summary of the amount of coal estimated as workable remaining in the different districts, which is taken from the report of the Royal Commission on coal, and founded upon investigations made in the years 1866–71, furnishes an approximate measure of the comparative value, present and prospective, of the different coal-fields of the United Kingdom. The quantities represent the probable aggregate yield of all seams above 1 foot thick.

Coal remaining in exposed Coal-fields.

Coal-Fields.	Within 4000 feet. Tons.	Below 4000 feet. Tons.
South Wales,	32,456,208,913	4,109,987,004
Forest of Dean,	265,000,000	
Somersetshire,	4,218,970,762	1,885,340,220
South Staffordshire, Shropshire, Forest of Wyre, Clee Hills,	1,906,119,768	
Leicestershire	836,798,734	
Warwickshire,	458,652,714	
North Wales,	2,005,000,000	
Anglesea,	5,000,000	
North Staffordshire,	3,825,488,105	1,000,785,488
Yorkshire and Derbyshire,	18,172,071,433	234,728,010
Yorkshire (Oolitic, &c.)	70,000,000	
Lancashire and Cheshire,	5,546,000,000	90,000,000
Northumberland and Durham,	10,036,660,236	
Cumberland,	405,203,792	
Scotland,	9,839,965,930	
do (Oolitic),	3,500,000	
Ireland,	155,600,000	
	90,206,240,387	7,320,840,722

The quantity estimated as lying above the workable limit of 4000 feet under the Permian and other formations, in the central and northern counties of England, is 56,248,000,000 tons, covering an area of 2044 square miles, in addition to which in the flat ground between the Mersey, Denbighshire, the North Staffordshire hills, Cannock Chase, and Colebrookdale, a further area of 843 square miles at inaccessible depths is computed to contain—

Between 4000 and 6000 feet,	29,341,649,067	tons.
,, 6000 ,, 10000 ,,	15,302,741,333	,,
	41,144,300,400	,,
Adding to this the amount below 4000 feet from the previous table,	7,320,840,722	,,
Total unavailable coal,	48,465,141,122	,,
As compared with	146,454,240,387	,,

the quantity of workable coal, as made up of the two amounts, 90,206,240,387 and 56,248,000,000 tons, given above. From this it follows that, out of the probable total quantity of coal in the British coal measures, rather more than three-fourths may become available for consumption, or about 1170 times the amount of the present annual output of 125 million tons.

Similar estimates have been formed for the coal-fields of other countries, especially in France and Germany, but it is doubtful whether the necessary structural details are sufficiently well known to admit of more than a tolerably rough guess being made.

COAL-MINING.

The opening and laying out, or, as it is generally called, "winning," of new collieries is rarely undertaken without a preliminary examination of the character of the strata by means of borings, either for the purpose of determining the number and nature of the coal-seams in new ground, or the position of the particular seam or seams which it is proposed to work in extensions of known coal-fields.

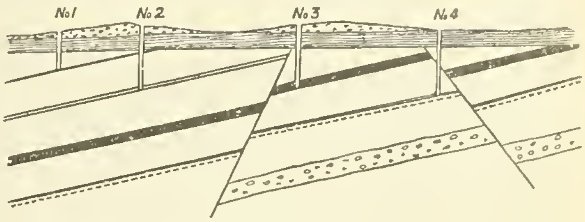

Fig. 3.

The principle of proving a mineral field by boring is illustrated by figure 3, which represents a line direct from the dip to the rise of the field, the inclination of the strata being one in eight. No. 1 bore is commenced at the dip, and reaches a seam of coal A, at 40 fathoms; at this depth it is considered proper to remove nearer to the outcrop, so that lower strata may be bored into at a less depth, and a second bore is commenced. To find the position of No. 2, so as to form a continuous section, it is necessary to reckon the inclination of the strata, which is 1 in 8; and as bore No. 1 was 40 fathoms in depth, we multiply the depth by the rate of inclination, $40 \times 8 = 320$ fathoms, which gives the point at which the coal seam A should reach the surface. But there is generally a certain depth of alluvial cover which requires to be deducted, and which we call 3 fathoms, then $(40 - 3 = 37) \times 8 = 296$ fathoms; or say 286 fathoms is the distance that the second bore should be placed to the rise of the first, so as to have for certain the seam of coal A in clear connection with the seam of coal B. In bore No. 3, where the seam B, according to the same system of arrangement, should have been found at or near the surface, another seam C is proved at a considerable depth, differing in character and thickness from either of the preceding. This derangment being carefully noted, another bore to the outcrop on the same principle is put down for the purpose of proving the seam C; the nature of the strata at first is found to agree with the latter part of that bored through in No. 3, but immediately on crossing the dislocation seen in the figure it is changed, and the deeper seam D is found.

The evidence therefore of these bores (3 and 4) indicates some material derangement, which is then proved by other bores, either towards the dip or the outcrop, according to the judgment of the borer, so as to ascertain the best position for sinking pits.

The methods of boring are similar to those adopted for deep wells, or in other departments of mining. For shal- Methods of boring.

low bores, the boring is generally with wrought iron rods screwed together in lengths, armed with a cutting chisel, and working by percussion, the tool being lifted by hand and allowed to fall with its full weight upon the rock. The pounded material is removed at intervals, by substituting a shell pump or tube with valves at the bottom, whose action is similar to that of the foot valves of an ordinary lifting pump. The sludge brought to the surface indicates the nature of the ground passed through. In very deep borings, however, the use of rigid rods and fixed tools is found to present two serious evils, namely, the excessive weight on the tool caused by the increased length of the rods, and the great length of time required to withdraw the tool and remove the detritus. The first of these difficulties has been overcome by the use of the free falling cutters, where the tool, instead of being attached rigidly to the rod, moves in a guide-block in such a manner as to be lifted with the rods, falling freely when the top of the stroke is reached. The rods, when lowered, pick up the tool at the bottom of the hole in readiness for the next lift. By this means the momentum of the tool is kept constant whatever may be the weight of rods employed.

The use of a wire rope winding on a drum, instead of rods for suspending the boring tool, allows the latter to be withdrawn and replaced with much greater rapidity than can be done with rods. This method has been very successfully adopted by Messrs Mather & Platt of Salford. But perhaps the best methods of expeditious boring are those (Fauvelle's) whereby the detritus is removed as it forms by continuously flushing out the hole with water, hollow rods being used down which the water flows while it rises through the annular space between the rod and the lining tube of the bore hole. This has the advantage of giving a clear surface for the tool to cut on, instead of its having to work through its own sludge, as is the case when the shell pump is only used at intervals. Of late years the value of boring for exploratory purposes has been much increased by the adoption of tubular or crown borers, which cut out an annular groove, leaving a core of unbroken rock in the centre, which is then brought out by a grapnel in a solid piece. One of the most successful of these methods is that due to Leschot of Geneva, where a rotating cutter, armed with amorphous black diamond, the hardest known substance, is used, the detritus being continuously removed by water on Fauvelle's plan. The machinery adopted for this purpose, as modified by Messrs Beaumont & Appleby, has been employed with great success to bore holes exceeding 2000 feet in depth.

Methods of working.

The working of coal may be conducted either by means of levels or galleries driven from the outcrop in a valley, or by shafts or pits sunk from the surface. In the early days of coal mining, open working, or quarrying from the outcrop of the seams, was practised to a considerable extent; but there are now few if any places in England where this can be done. In 1873 there could be seen, in the thick coal seams of Bengal, near Raniganj, a seam about 50 feet thick laid bare, over an area of several acres, by stripping off a superficial covering varying from 10 to 30 feet, in order to remove the whole of the coal without loss by pillars. Such a case, however, is quite exceptional. The operations by which the coal is reached and laid out for removal are known as "winning," the actual working or extraction of the coal being termed "getting." In the accompanying figure, No. 4, A B is a cross cut-level, by which the seams of coal 1 and 2 are won, and C D a vertical shaft by which the seams 1, 2, and 3 are won. When the field is won by the former method, the coal lying above the level is said to be "level-free." The mode of winning by level is of less general application than that by shafts, as the capacity for production is less, owing to the smaller size of roadways by which the coal must be brought to the

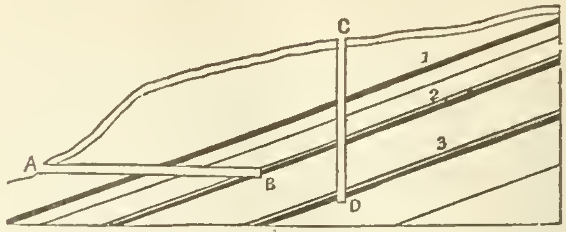

Fig. 4.

surface, levels of large section being expensive and difficult to keep open when the mine has been for some time at work. Shafts, on the other hand, may be made of almost any capacity, owing to the high speed in drawing which is attainable with proper mechanism, and allow of the use of more perfect arrangements at the surface than can usually be adopted at the mouth of a level on a hill side. A more cogent reason, however, is to be found in the fact that the principal coal-fields are in flat countries, and where the coal can only be reached by vertical sinking.

The methods adopted in driving levels for collieries are generally similar to those adopted in other mines. The ground is secured by timbering, or more usually by arching in masonry or brick-work. Levels like that in fig. 4, which are driven across the stratification, or generally anywhere not in coal, are known as "stone drifts." The sinking of colliery shafts, however, differs considerably from that of other mines, owing to their generally large size, and the difficulties that are often encountered from water during the sinking. The actual coal measure strata, consisting mainly of shales and clays, are generally impervious to water, but when strata of a permeable character are sunk through, such as the magnesian limestone of the north of England, the Permian sandstones of the central countries, or the chalk and greensand in the north of France and Westphalia, special methods are required in order to pass the water-bearing beds, and to protect the shaft and workings from the influx of water subsequently. Of these methods one of the chief is the plan of tubbing, or lining the excavation with an impermeable casing of wood or iron, generally the latter, which is built up in segments forming rings, that are piled upon each other throughout the whole depth of the water-bearing strata. This method necessitates the use of very considerable pumping power during the sinking, as the water has to be kept down in order to allow the sinkers to reach a water-tight stratum upon which the foundation of the tubbing can be placed. This consists in a heavy cast-iron ring, known as a wedging crib, or curb, also fitted together in segments, which is lodged in a square-edged groove cut for its reception, tightly caulked with moss, and wedged into position. Upon this the tubbing is built up in segments, usually from 10 to 12 being required for the entire circumference, the edges being made perfectly true. The thickness varies according to the pressure expected, but may be taken at from $\frac{3}{4}$ to $1\frac{1}{2}$ inches. The inner face is smooth, but the back is strengthened with angle brackets at the corners. A small hole is left in the centre of each segment, which is kept open during the fitting to prevent undue pressure upon any one, but is stopped as soon as the circle is completed. In the north of France and Belgium wooden tubbings, built of polygonal rings, were at one time in general use. The polygons adopted were of 20 or more sides approximating to a circular form.

Sinking of shafts.

Tubbing.

Pneumatic sinking.

The second principal method of sinking through water-bearing ground is that which was first adopted by M

Triger, in France, and has also been used by civil engineers in putting down deep foundations for bridge piers, namely, by compressed air. The shaft is lined with a cylinder of wrought iron, within which a tubular chamber, provided with doors above and below, known as an air-lock, is fitted by a telescopic joint, which is tightly packed so as to close the top of the shaft air-tight. Air is then forced into the inclosed space by means of a compressing engine, until the pressure is sufficient to oppose the flow of water into the excavation, and to drive out any that may collect in the bottom of the shaft through a pipe which is carried through the air-sluice to the surface. The miners work in the bottom in the same manner as divers in an ordinary diving-bell. Access to the surface is obtained through the double doors of the air sluice, the pressure being reduced to that of the external atmosphere when it is desired to open the upper door, and increased to that of the working space below when it is intended to communicate with the sinkers, or to raise the stuff broken in the bottom. This method has been adopted in various sinkings on the Continent. At Bracquenie, near Mons, the miners worked in an atmosphere up to 45 lb pressure on the square inch, without experiencing any great difficulty, but they were found to be more susceptible to pulmonary disorder upon changes of weather than those who worked under the ordinary conditions of pressure.

Shaft boring. The third method of sinking through water-bearing strata is that of boring, adopted by Messrs Kind & Chaudron in Belgium and Germany. For this purpose a horizontal bar armed with vertical cutting chisels is used, which cuts out the whole section of the shaft simultaneously. In the first instance, a smaller cutting frame is used, boring a hole from 3 to 5 feet in diameter, which is kept some 50 or 60 feet in advance, so as to receive the detritus, which is removed by a shell pump of large size. The large trepan or cutter weighs about 16 tons, and cuts a hole of from 9 to 15 feet in diameter. The water-tight lining may be either a wrought iron tube, which is pressed down by jack screws as the bore hole advances, or cast-iron tubbing put together in short complete rings, in contradistinction to the old plan of building them up of segments. The tubbing, which is considerably less in diameter than the bore hole, is suspended by rods from the surface until a bed suitable for a foundation is reached, upon which a sliding length of tube, known as the moss box, bearing a shoulder, which is filled with dried moss, is placed. The whole weight of the tubbing is made to bear on the moss, which squeezes outwards, forming a completely water-tight joint. The interval between the back of the tubbing and the sides of the bore hole is then filled up with concrete, which on setting fixes the tubbing firmly in position.

The introduction of these special methods has considerably simplified the problem of sinking through water-bearing strata. Some of the earlier sinkings of this kind, when pumps had to be depended on for keeping down the water, were conducted at great cost, as, for instance, at South Hetton, and more recently Ryhope, near Sunderland, through the magnesian limestone of Durham.

The size and form of colliery shafts varies in different districts, but the tendency is now generally to make them round, and from 12 to 15 feet in diameter. In the Midland counties, from 7 to 9 feet is a very common size, but larger dimensions are adopted where a large production is required. At Bagillt, on the Dee, a shaft of 22 feet in diameter was commenced a few years ago, but was reduced in diameter a short distance down. Since the accident at Hartley colliery, caused by the breaking of the pumping engine beam, which fell into the shaft and blocked it up, whereby the whole company of men in the mine were starved to death—it has been made compulsory upon mine owners to have two pits for each working, in place of the single one divided by walls or brattices which was formerly thought sufficient. The use of two independent connections—whether separate pits or sections of the same pit, between the surface and the workings—is necessary for the service of the ventilation,—fresh air from the surface being carried down one, known as the "downcast," while the foul or return air of the mine rises through the other or "upcast" pit back to the surface. Where the mine is heavily watered, it is often necessary to establish a special engine pit, with pumps permanently fixed, or a division of one of the pits may be devoted to this purpose. The use of direct-acting high-pressure pumping engines placed at the bottom of the shaft has become common during the last ten years. They have the advantage of doing away with the heavy reciprocating rod from the engine at the surface, and may be worked either by steam pipes carried down the pit, or, what is now more common, by boilers underground, which supply also steam for the underground hauling engines. Where the water does not accumulate very rapidly it is a very common practice to allow it to collect in a pit or sump below the working bottom of the shaft, and to draw it off in a water tub or bucket by the main engine, when the latter is not employed in raising coal.

Laying out workings. The laying out of a colliery, after the coal has been won, by sinkings or levels, may be accomplished in various ways, according to the nature of the coal, its thickness and dip, and the extent of ground to be worked. In the South Staffordshire and other Midland coal-fields, where only shallow pits are required, and the coals are thick, a pair of pits may be sunk for a very few acres, while in the North of England, on the other hand, where sinking is expensive, an area of some thousands of acres may be commanded from the same number of pits. In the latter case, which represents the most approved practice, the sinking is usually placed about the centre of the ground, so that the workings may radiate in every direction from the pit bottom, with the view of employing the greatest number of hands to advantage. Where a large area cannot be commanded, it is best to sink to the lowest point of the field for the convenience of drawing the coal and water which become level-free in regard to the pit. Where properties are much divided, it is always necessary to maintain a thick barrier of unwrought coal between the boundary of the mine and the neighbouring workings, especially if the latter are to the dip. If a prominent line of fault crosses the area, it may usually be a convenient division of the field into sections or districts. The first process in laying out the workings consists in driving a gallery on the level along the course of the coal seam, which is known as a "dip head level," and a lower parallel one, in which the water collects, known as a "lodgment level." Galleries driven at right angles to these are known as "dip" or "rise headings," according to their position above or below the pit bottom. In Staffordshire the main levels are also known as "gate roads." To secure the perpendicularity of the shaft, it is necessary to leave a large mass or pillar of the seam untouched around the pit bottom. This pillar is known in Scotland as the "pit bottom stoop." The junction of the levels with the pit is known as the "pit eye;" it is usually of an enlarged section, and lined with masonry or brickwork, so as to afford room for handling the waggons or trams of coal brought from the working faces. In this portion of the pit are generally placed the furnaces for ventilation, and the boilers required for working steam-engines underground, as well as the stables and lamp cabin.

Figs. 5 and 6 represent the pit bottom arrangements at Cambois colliery in Northumberland, which are of an extremely commodious character. There are four large Cornish boilers, supplying steam to the engines drawing coals from the workings, as well as to a direct-acting pumping engine, the flame and smoke being discharged by drifts into the upcast pit. For the purpose of handling large pieces of machinery and boilers, the level at the bottom is increased to a chamber 18 feet high, and roofed with rolled iron girders of a double T section. To protect the fillers working at the bottom, strong diagonal guard timbers are placed at S in order to deflect any materials falling down the shaft, and prevent them falling into the workings. This is an unusually large example, but is taken from a pit in the highest state of development, and making a very large daily outturn.

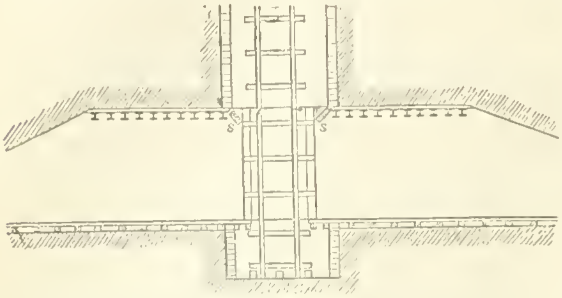

Fig. 5.—Pit eye, Cambois Colliery—Vertical Section.

The removal of the coal after the roads have been driven may be effected in many different ways, according to the

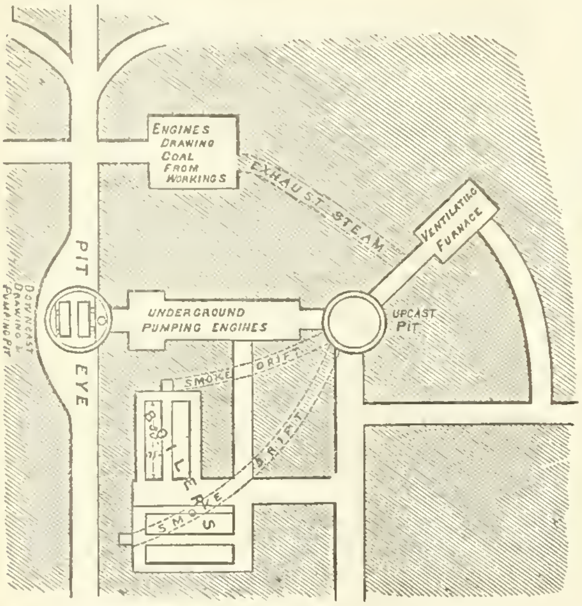

Fig. 6.—Pit bottom arrangements, Cambois Colliery.

custom of the district. These may, however, all be considered as modifications of two systems viz., pillar work and long-wall work. In the former, which is also known as "port and stall" or "bord and pillar" in the north of England, "pillar and stall" in South Wales, and "stoop and room" in Scotland, the field is divided into strips by numerous openings driven parallel to the main rise headings, called "bords" or "bord gates," which are again divided by cutting through them at intervals, so as to leave a series of pillars arranged chequer-wise over the entire area. These pillars are left for the support of the roof as the workings advance, so as to keep the mine open and free from waste. Fig. 1, Plate III. represents the oldest form of this class of working as practised in Scotland, from which it will be seen that if the size of the pillar is equal to the width of the stall or excavation, about ¾ of the whole seam will be removed, the remainder being left in the pillars. A portion of this may be got by the process known as robbing the pillars, but the coal so obtained is liable to be very much crushed from the pressure of the superincumbent strata. This crushing may take place either from above or below, producing what are known as "creeps" or "sits."

A coal seam with a soft pavement and a hard roof is the most subject to a "creep." The first indication is a dull hollow sound heard when treading on the pavement or floor, probably occasioned by some of the individual layers parting from each other as shown at *a* fig. 7;

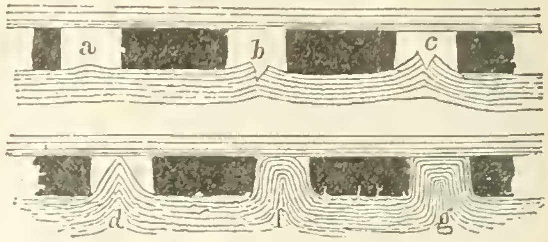

Fig. 7.—"Creeps" in Coal-Mines.

the succeeding stages of creep are shown at *b*, *c*, *d*, *f*, and *g*, in the same figure; the last being the final stage, when the coal begins to sustain the pressure from the overlying strata, in common with the disturbed pavement.

"Sits" are the reverse of creeps; in the one case the pavement is forced up, and in the other the roof is forced or falls down, for want of proper support or tenacity in itself. This accident generally arises from an improper size of pillars; some roofs, however, are so difficult to support that sits take place where the half of the coal is left in pillars.

Fig. 8 will convey a general idea of the appearance of sits,—*k*, *m*, *n* showing different stages.

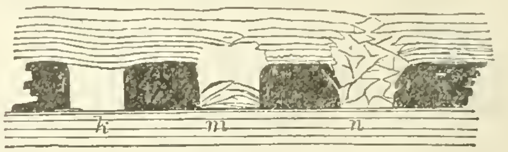

Fig. 8.—"Sits" in Mines.

The modern method of pillar working is shown in Plate IV. In the Northumberland steam-coal district, where it is carried out in the most perfect manner, the boards are 5 to 6 yards in width, while the pillars are 22 yards broad and 30 yards long, which are subsequently got out on coming back. In the same figure is also shown the method of working whole coal and pillars at the same time, a barrier of two or three ranges of pillars or a rib of solid coal being left between the working in the solid and those in the pillars. The space from which the entire quantity of coal has been removed is known in different districts as the "goaf," "gob," or "waste."

Fig. 9 represents the Lancashire system of pillar-working. The area is laid out by two pairs of level drifts, parallel to each other, about 150 yards apart, which are carried to the boundary. About 100 yards back from the boundary a communication is made between these levels, from which other levels are driven forward, dividing the coal into ribs of about 25 or 30 yards wide, which are then cut back by taking off the coal in slices from the level towards the rise in breadths of about six yards. By this method the whole of the coal is got backwards, the main roads being kept in solid coal; the intermediate levels not being driven till they are wanted, a greater amount of sur-port is given, and the pillars are less crushed than is usual in pillar working.

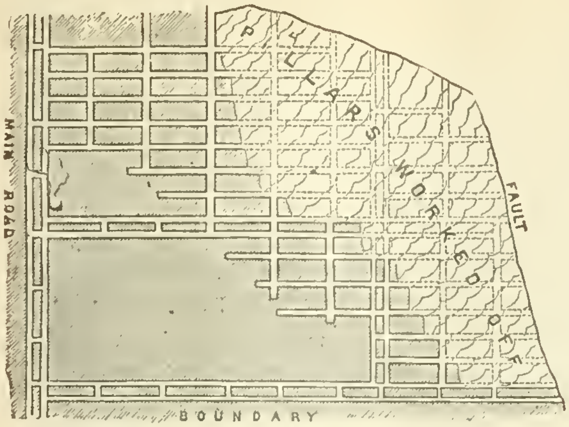

FIG. 9.—Lancashire method of working Coal.

In the South Wales system of working, cross headings are driven from the main roads obliquely across the rise to get a sufficiently easy gradient for horse roads, and from these the stalls are opened out with a narrow entrance, in order to leave support on either side of the road, but afterwards widening to as great a breadth as the seam will allow, leaving pillars of a minimum thickness. The character of such workings is very irregular in plan, and as the ventilation is attended with considerable difficulty, it is now becoming generally superseded by more improved methods.

The second great principle of working is that known as long-wall or long-work, in which the coal is taken away either in broad faces from roads about 40 or 50 yards apart and parallel to each other, or along curved faces between roads radiating from the pit bottom—the essential feature in both cases being the removal of the whole of the coal at once, without first sub-dividing it into pillars, to be taken away at a second working. The roof is temporarily supported by wooden props or pack walling of stone, for a sufficient breadth along the face to protect the workmen, and allow them to work together behind. The general character of a long-wall working is shown in fig. 10, which

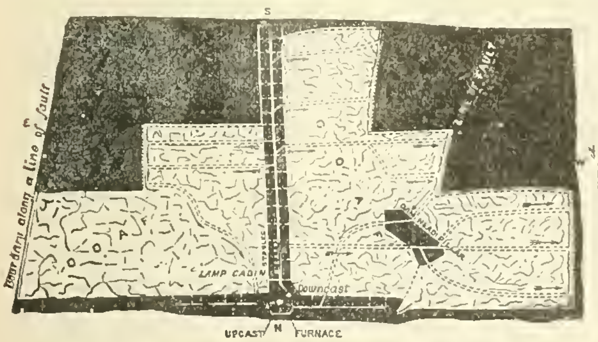

FIG. 10.—Long-wall method of working Coal in Derbyshire.

represents an area of about 500 acres of the bottom hard steam coal at Shipley in Derbyshire. The principal road extends from the shafts southward; and on both sides of it the coal has been removed from the light-shaded area by cutting it back perpendicularly towards the boundaries, along faces about 50 yards in length, those nearest to the shaft being kept in advance of those farther away, producing a step-shaped outline to the face of the whole coal. It will be seen that by this method the whole of the seam, with the exception of the pillars left to protect the main roadways, is removed. The roads for drawing the coal from the working faces to the shaft are kept open by walling through the waste or goaf produced by the fall of the unsupported roof. The straight roads are the air-ways for carrying pure air from the down-cast shaft to the working faces, while the return air passes along the faces and back to the up-cast by the curved road. The above is the method of working long-wall forward, *i.e.*, taking the coal in advance from the pit towards the boundary, with roads kept open through the gob. Another method consists in driving towards the boundary, and taking the coal backward towards the shafts, or working homeward, allowing the waste to close up without roads having to be kept open through it. This is of course preferable, but is only applicable where the owner of the mine can afford to expend the capital required to reach the limit of the field in excess of that necessary when the raising of coal proceeds *pari passu* with the extension of the main roads. Fig. 9 is substantially a modification of this kind of long-wall work. Plate III. fig 2, represents a method of working practised in the South Yorkshire district, known as bords and banks. The field is divided by levels and headings into rectangular banks, while from the main levels bords or wickets about 30 yards wide, separated from each other by banks of about the same width, are carried forward in long-wall work, as shown on the left side of the figure, the waste being carefully packed behind so as to secure the ventilation. When these have been worked up to the extremity, as shown on the right side, the intermediate bank is removed by working backward towards the level. This system, therefore, combines both methods of long-wall working, but is not generally applicable, owing to the difficulty of ventilation, due to the great length of air-way that has to be kept open around the waste on each bank.

South Yorkshire method.

The relative advantages of the different methods may be generally stated as follows. Long-wall work is best suited for thin coals, and those having a good roof, *i.e.*, one that gives way gradually and fills up the excavation made by removing the coal without scaling off suddenly and falling into the working faces, when practically the whole of the coal may be removed. Against these advantages must be placed the difficulties attending the maintenance of roads through the goaves, and in some cases the large proportion of slack to round or large coal obtained. Pillar working, in the whole coal, is generally reputed to give a more advantageous proportion of round coal to slack, the latter being more abundantly produced on the removal of the pillars, but as these form only a small portion of the whole seam, the general yield is more advantageous than in the former method. The ventilation of pillar working is often attended with difficulty, and the coal is longer exposed to the influence of the air, a point of importance in some coals, which deteriorate in quality when exposed to a hot damp atmosphere. The great increase in the size of the pillars in the best modern collieries worked upon this principle has, however, done much to approximate the two systems to an equality in other respects.

The working of very thick seams presents certain special peculiarities, owing to the difficulties of supporting the roof in the excavated portions, and supplying fresh air to the workings. The most typical example of this kind of working in England is afforded by the thick coal of South Staffordshire, which consists of a series of closely associated coal seams, varying from 8 to 12 or 13, divided from each other by their partings, but making together one great bed of from 25 to 40 feet or more in thickness. The partings together do not amount to more than 2 or 3 feet. The method of working which has been long in use is represented in fig. 11. The main level or gate road is driven in the benches coal, or lower part of the seam, while a smaller drift for ventilation, called an air heading, is carried above it in one of the upper beds called the slipper coal. From the gate road a heading called a bolt-hole is opened, and extended into a large rectangular chamber, known as a "side of work," large pillars being left at regular

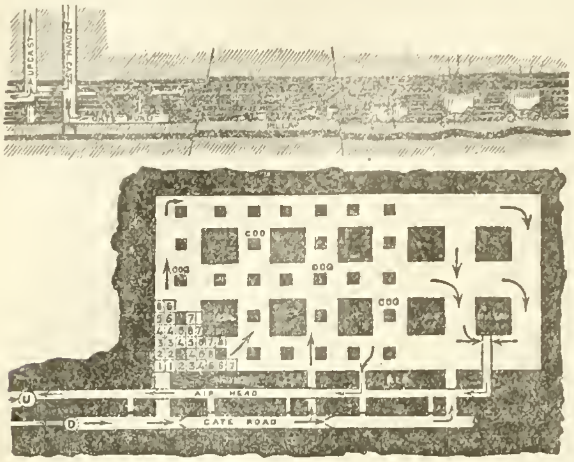

FIG. 11.—South Staffordshire method of working Thick Coal.

intervals, besides smaller ones or cogs. The order in which the coal is cut is shown in the dotted and numbered squares in the figure. The coal is first cut to the top of the slipper coal from below, after which the upper portion is either broken down by wedging or falls of itself. The working of these upper portions is exceedingly dangerous, owing to the great height of the excavations, and fatal accidents from falls of roof are in consequence more common in South Staffordshire than in any other coal-field in this country. The air from the down-cast shaft enters from the gate road, and passes to the up-cast through the air heading above. About one-half of the total coal (or less) is obtained in the first working; the roof is then allowed to fall, and when the gob is sufficiently consolidated, fresh roads are driven through it to obtain the ribs and pillars left behind by a second or even, in some cases, a third working. The loss of coal by this method is very considerable, besides great risk to life and danger from fire. It has, therefore, been to some extent superseded by the long-wall method, the upper half being taken at the first working, and removed as completely as possible, working backwards from the boundaries to the shaft. The lower half is then taken in the same manner, after the fallen roof has become sufficiently consolidated to allow the mine to be re-opened.

In the working of thick seams inclined at a high angle, such as those in the south of France, and in the lignite mines of Styria and Bohemia, the method of working in horizontal slices, about 12 or 15 feet thick, and filling up the excavation with broken rock and earth from the surface, is now generally adopted in preference to the systems formerly used. At Monceaux les Mines, in France, a seam 40 feet thick, and dipping at an angle of 20 degrees, is worked in the following manner. A level is driven in a sandstone forming the floor, along the course of the coal, into which communications are made by cross cuts at intervals of 16 yards, which are driven across to the roof, dividing up the area to be worked into panels. These are worked backwards, the coal being taken to a height of 20 feet, the opening being packed up with stone sent down from the surface. As each stage is worked out, the floor level is connected with that next below it by means of an incline, which facilitates the introduction of the packing material. Stuff containing a considerable amount of clay is found to be the best suited for the purpose of filling, as it consolidates readily under pressure.

Metho of cuttin coal.

The actual cutting of the coal is chiefly performed by manual labour, the tool employed being a sharp-pointed double-armed pick, which is nearly straight, except when required for use in hard rock, when the arms are made with an inclination or "anchored." The terms pike, pick, mandril, and slitter are applied to the collier's pick in different districts, the men being known as pikemen or hewers. In driving levels it is necessary to cut grooves vertically parallel to the walls, a process known as shearing; but the most important operation is that known as holing or kirving, which consists in cutting a notch or groove in the floor of the seam to a depth of about 3 feet, measured back from the face, so as to leave the overhanging part unsupported, which then either falls of its own accord within a few hours, or is brought down either by driving wedges along the top, or by blasting with gunpowder. The process of holing in coal is one of the severest kinds of human labour. It has to be performed in a constrained position, and the miner lying on his side has to cut to a much greater height, in order to get room to carry the groove in to a sufficient depth, than is required to bring the coal down, giving rise to a great waste in slack as compared with machine work. This is sometimes obviated by holing in the beds below the coal, or in any portion of a seam of inferior quality that may not be worth working. This loss is proportionately greater in thin than in thick seams, the same quantity being cut to waste in either case. The method of cutting coal on the long-wall system is seen in fig. 12, repre-

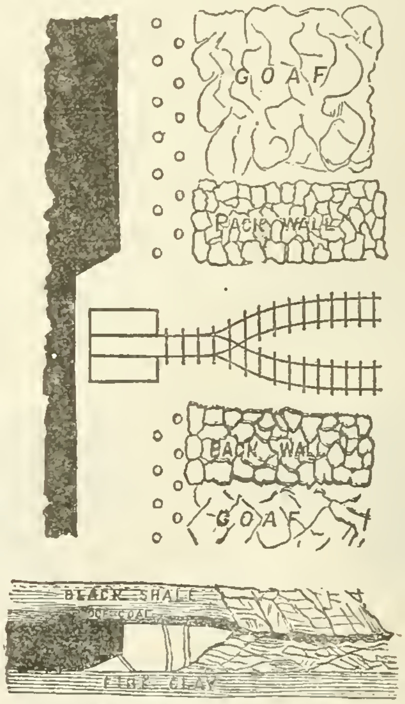

FIG. 12.—Long-wall working-face—Plan and Section.

senting the working at the Shipley colliery. The coal is 40 inches thick, with a seam of fire-clay and a roof of black shale; about 6 inches of the upper part, known as the roof coal, not being worth working, is left behind. A groove of triangular section of 30 inches base and 9 inches high is cut along the face, inclined timber props being placed at intervals to support the overhanging portion until the required length is cut. These are then removed, and the coal is allowed to fall, wedges or blasting being employed when necessary. The roof of the excavation is supported as the coal is removed, by packing up the waste material, and by a double row of props, two feet from each other, placed temporarily along the face. These are placed 5 feet apart, the props of the back row alternating with those in front. The props used are preferably of small oak or English larch, but large quantities of fir props, cut to the right length, are also imported from the north of Europe. As the work proceeds onwards, the props are withdrawn and replaced in advance, except those that may be crushed by the pressure or buried by sudden falls of the roof.

In Yorkshire hollow square pillars, formed by piling up short blocks of wood or chocks, are often used instead of props formed of a single stem. Iron pit props have been proposed at different times, but their use has not become general. When the coal has been under-cut for a sufficient length, the struts are withdrawn, and the overhanging mass is allowed to fall during the time that the workmen are out of the pit, or it may be brought down by driving wedges, or if it be of a compact character a blast of gunpowder in a bore hole near the roof may be required. Sometimes, but rarely, it happens that it is necessary to cut vertical grooves in the face to determine the limit of the fall, such limits being usually dependent upon the cleet or divisional planes in the coal, especially when the work is carried perpendicular to them or on the end.

The substitution of machinery for hand labour in cutting coal has long been a favourite problem with inventors, the earliest plan being that of Menzies, in 1761, who proposed to work a heavy pick underground by power transmitted from an engine at the surface, through the agencies of spear-rods and chains passing over pulleys; but none of the methods suggested proved to be practically successful until the general introduction of compressed air into mines furnished a convenient motive power, susceptible of being carried to considerable distances without any great loss of pressure. This agent has of late years been applied in various ways, in machines which either imitate the action of the collier by cutting with a pick or make a groove by rotating cutters attached to an endless chain or a revolving disc or wheel. The most successful of the first class, or pick machines, is that of Mr William Firth of Sheffield, represented in fig. 13. It consists essen- Coal-cutting machines.

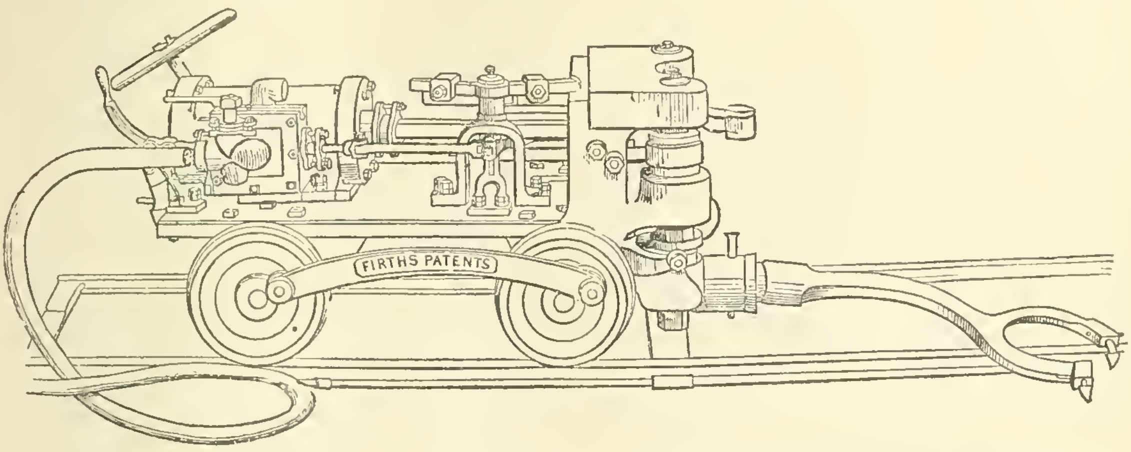

FIG. 13.—Firth's Coal-cutting Machine.

tially of a horizontal piston and cylinder engine fixed upon a platform carried upon four wheels, which are coupled together by side rods, so that on motion being communicated by means of a mitre wheel in the hind axle, it can be moved forward by hand. On the forward end of the frame are two bosses forming the centres for a pair of bell cranks or bent levers placed close to the ground, and facing in opposite directions, either one of which can be connected with the piston rod. The outer arm of each lever carries a square socket, into which is fixed the pick, which has two cutting heads, one placed a little in front of the other so as to cut to the whole depth at one operation. In the older forms picks of different length were used, and it was necessary to go over the work a second or third time, in order to hole to the full depth. The cutting points are loose, being secured by cotters to the pick head, so that broken or blunted ones can be readily replaced without removing the pick arm. The power used is air, at about 40 to 60 lb above atmospheric pressure. It is conducted from the reservoir connected with a compressing engine at the surface, through iron pipes fixed in the pit, and along the main roads to the working face, where thick vulcanized india-rubber pipes are used, sufficient length of pipe lying loose on the ground to allow the engine to move freely, the connection being made by a screwed joint at the back of the slide-valve chest. The valve is worked by tappets on the piston-rod, so as to be perfectly self-acting when properly adjusted; it can also be moved by hand. The pick holders face in opposite directions, in order that the machine may be worked from either side. The size of the machine as ordinarily made is about 4 feet in length, 2 feet 2 inches high, and from 18 to 24 inches gauge of rails. The weight is about 15 cwt. The working speed is from 60 to 90 strokes per minute, corresponding to a length of from 10 to 20 yards, cut to a depth of 3 feet per hour. At the former rate, or 60 yards per shift of 6 hours, the work done corresponds to that of twelve average men. The width of the groove is from 2 to 3 inches at the face, diminishing to $1\frac{1}{2}$ inches at the back, the proportion of waste being very considerably diminished as compared with the system of holing by hand. The use of this machine has allowed a thin seam of cannel, from 10 to 14 inches in thickness, to be worked to profit, which had formerly been abandoned as too hard to be worked by hand-labour.

An earlier form of the second class of machine, in which the cutters have a continuous motion like those of a slotting machine, is that invented by Mr William Peace in the Wigan district, which is reproduced from the last edition as illustrating the principle which has since been carried out by other inventors in a more convenient and simplified form. It is represented in Plate V., figs. 1, 2, and 3. AAA is the frame, upon which are fixed one or more cylinders B, arranged so as to turn a crank shaft C, fixed to the frame, as is also another shaft D. This latter is capable of being turned by the former, by means of mitre or bevel wheels EEE; upon the lower end of the latter shaft D is placed a wheel termed the driving wheel, having upon its periphery a groove with suitable projections for working into and propelling a chain or band. Beneath or to the side of the frame (or both) is fixed temporarily or otherwise a lever, the extremity of which is constructed to carry a wheel called the terminal wheel, marked HH; a chain or band is made to pass round the driving and terminal wheels, and by means of the driving wheel FF it is made to revolve. Into the chain are fixed cutters of different forms (see the parts marked, figs. 4, 5, 6, and 7), which, when the machine is in action, revolve with it, and upon being pressed or drawn against the coal, erode and excavate the same. The distance of the excavation from the face of the coal is governed by the dimensions of the machine, and by the length of the lever and the distance between the driving and terminal wheels. The arrangements of the lever allow it to revolve, and to excavate any given range; see dotted lines fig. 1.

If found necessary, two or even three levers may be in operation at the same time, and arranged to cut in any direction. Other parts of the machine not particularly described are capable of elevating and depressing the front part of the machine, marked V, T, U, W; and those marked X, Y, Z, and K are capable of propelling the machine whilst at work, by acting against the prop.

The Gartsherrie machine of Messrs Baird is of the same character, but the chain of cutters works round a fixed frame or jib projecting at right angles from the engine carriage, instead of traversing upon a centre, an arrangement which makes it necessary to cut from the end of the block of coal to the full depth, instead of holing into it from the face. The forward feed is given by a chain winding upon a drum, which hauls upon a pulley fixed to a prop about 30 yards in advance. This is one of the most compact form of machines, the smaller size being only 20 inches high. With an air pressure of from 35 to 40 ℔ per square inch, a length of from 300 to 350 feet of coal is holed, 2 ft. 9 in. deep, in the shift of from 8 to 10 hours.

One of the simplest forms of coal-cutting machines is that of Messrs Winstanly & Barker (fig. 14), which is driven

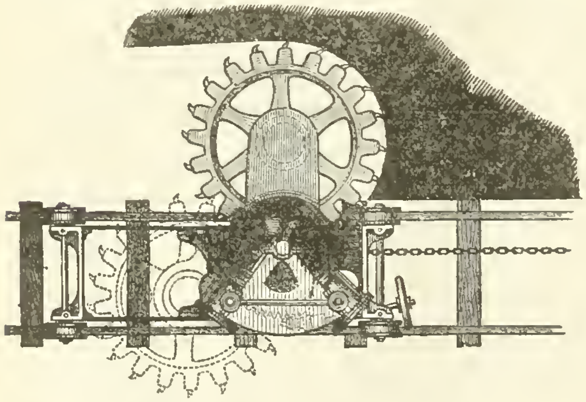

FIG. 14.—Winstanly & Barker's Coal-cutting Machine—Plan.

by a pair of oscillating engines placed on a frame running on rails in the usual way. The crank shaft carries a pinion which gears into a toothed wheel of a coarse pitch, carrying cutters at the ends of the teeth. This wheel is mounted on a carrier which, being movable about its centre by a screw gearing worked by hand, gives a radial sweep to the cutting edges, as in the machine figured in Plate V. When at work it is slowly turned until the carrier is at right angles to the frame, when the cut has attained the full depth. The forward motion is given by a chain-winding upon a crab placed in front, which is worked by a boy who hauls it slowly forward. With 25 ℔ pressure it will hole 3 feet deep, at the rate of 30 yards per hour, the cut being only 2¾ in. high, but it will only work on one side of the carriage.

Another kind of application of machinery to coal mining is that of Messrs Bidder & Jones, which is intended to replace the use of blasting with gunpowder for bringing down the coal, a practice which in fiery collieries is often attended with considerable danger from the flash of the explosion firing the gas given off the coal. It consists of a small hydraulic press, which forces a set of expanding bits or wedges into a bore-hole previously bored by a long screw augur or drill, worked by hand, the action of the press being continued until a sufficient strain is obtained to bring down the coal. The arrangement is, in fact, a modification of the plug and feather system used in stone quarrying for obtaining large blocks, but with the substitution of the powerful rending force of the hydraulic press for hand-power in driving up the wedges. This apparatus has been used at Harecastle in North Staffordshire, and found to work well, but with the disadvantage of bringing down the coal in unmanageably large masses. The use of gunpowder in very fiery mines is always attended with danger, and a method of wedging down coal sufficiently perfected to be of general application would add greatly to the security of the colliers in working such mines.

The removal of the coal when broken from the working faces to the pit bottom or to the main levels is effected mainly by hand labour when the mine is small, and the distances to be traversed inconsiderable, and in mines of greater extent by horse or steam traction. The simplest method is that of loading the broken coal on to a sledge, which is dragged along the floor to the level, but now the practice of carrying railways to the face is almost universal. The old form of flat rail or tram is still largely used, the waggons having sharp-edged disc wheels, but probably edge rails and flanged wheels are now more general. The class of rail used is generally a flat-bottomed or bridge section, weighing from 15 to 25 ℔ per yard, laid upon cross sleepers, which, in roads that are intended to be kept open for some time, are fixed down firmly, but are laid in a temporary manner along the working faces, and in similar positions where it is necessary to be continually shifting them, as, for instance, where coal-cutting machines are used. The arrangement of the drawing roads at the face of a long-wall colliery is seen in the plan fig. 12, where the rails are brought to the face upon a smooth iron plate, upon which the trams can be easily handled by turning on the flanges of the wheels. The names applied to the vehicles in which the coal is carried vary considerably, as do also their size and capacity. The word "corf" or "corve," representing the old basket sledge, is one of the most generally used, as are "tram," signifying a tram waggon, and "tub," of the same signification as the last, but a representative of the old method of drawing in wooden buckets. In South Staffordshire and other Midland districts, a contrivance called a "skip" is the representative method of conveyance; this consists of a platform with tram wheels, upon which the coal is built up to a considerable height, the large pieces round the sides being kept together by loose rings of sheet iron, and the intermediate spaces packed full with small coal,—the whole arrangement representing a kind of cask. This, however, like most of the similar primitive methods, is giving way to the more improved system of tubs or trams. These are small railway trucks, generally with flanged wheels and square-sided bodies, either of wood or wrought iron, varying in capacity from 4 cwt. in thin seams to 10 or 12 cwt. in thicker seams.

In the removal of the coal from the workings the first portion of the journey is generally performed by hand-power, boys bieng employed to push the trams before them to the main roads. In the thin seams of South Yorkshire and other places, considerable journeys are often performed in this way, the boys known as "hurriers" or "putters" being obliged to crawl at full length, owing to the lowness of the excavation. As a general rule boys are not allowed to work in collieries when below 12 years of age, but in these thin mines special exemptions are granted, permitting the use of younger boys as putters when required. Where the levels are large, horse traction is in common use; the trams are formed up into trains, and from 6 to 15 vehicles are drawn by one horse. A considerable number of ponies are imported into the northern ports of this country from Norway and Iceland for this purpose every year. The supply of horses is, however, becoming scarcer, and the price higher, so that the use of underground engines is generally adopted where the output is sufficiently large to justify the expenditure. This is done by hauling or, as it is called in the North of England, leading the trains of tubs by rope traction. In a large colliery where the shafts are situated near the centre of the field, and the workings extend on all sides, both to the dip and rise, the drawing roads for the coal may be of three different kinds,—(1) levels driven at right angles to the dip, suitable for horse roads, (2) rise ways, known as jinny roads, jig-brows, or up-brows, which, when of sufficient slope, may be used as self-acting planes, *i.e.*, the loaded waggons may be made to pull back the empty ones to the working faces, and (3) dip or down-brows, requiring engine power. A road may be used as a self-acting or gravitating incline when the gradient is 1 in 30 or steeper, in which case the train is lowered by a rope passing over a pulley or brake drum at the upper end, the return empty train being attached to the opposite end of the rope and hauled up by the descending load. The arrangements for this purpose vary, of course, with the amount of work to be done with one fixing of the machinery; where it is likely to be used for a considerable time, the drum and brake are solidly constructed, and the ropes of steel or iron wire carefully guided over friction rollers, placed at intervals between the rails to prevent them from chafing and wearing out on the ground. Where the load has to be hauled up a rising gradient, underground engines, driven by steam or compressed air, are now generally used. In some cases steam generated in boilers at the surface is carried in pipes to the engines below, but this can be done with less loss of power by sending down compressed air in the same way. The use of underground boilers placed near the upcast pit, as in fig. 6, so that the smoke and gases help the ventilating furnace, is most convenient in the majority of cases. Water-pressure engines, driven by a column of water equal to the depth of the pit, have also been employed for hauling. These can, however, only be used advantageously where there are fixed pumps, the fall of water generating the power resulting in a load to be removed by the expenditure of an equivalent amount of power in the pumping engine above that necessary for keeping down the mine water.

There are four principal methods in which steam power can be applied to underground traction. These, which have been discussed in the fullest manner in the Report of the North of England Institute of Mining Engineers for 1867-68, are as follows:—

1. Tail rope system.
2. Endless chain system.
3. Endless rope system on the ground.
4. Endless rope system overhead.

The three last may be considered as modifications of the same principle. In the first, which is that generally used in Northumberland and Durham, a single line of rails is used, the loaded tubs being drawn "out bye," *i.e*, towards the shaft, and the empty ones returned "in bye," or towards the working faces, by reversing the engine; while in the other systems, double lines, with the rope travelling continuously in the same direction, are the rule. On the tail rope plan the engine has two drums worked by spur gearing, which can be connected with, or cast loose from, the driving shaft at pleasure. The main rope, which draws out the loaded tubs, coils upon one drum, and passes near the floor over guide sheaves placed about 20 feet apart. The tail rope, which is of lighter section than the main one, is coiled on the second drum, passes over similar guide sheaves placed near the roof or side of the gallery round a pulley at the bottom of the plane, and is fixed to the end of the train or set of tubs. When the load is being drawn out, the engine pulls directly on the main rope, coiling it on to its own drum, while the tail drum runs loose paying out its rope, a slight brake pressure being used to prevent its running out too fast. When the set arrives out bye, the main rope will be wound up, and the tail rope pass out from the drum to the end and back, *i.e.*, twice the length of the way; the set is returned in bye, by reversing the engine, casting loose the main, and coupling up the tail drum, so that the tail rope is wound up, and the main rope paid out. This method, which is the oldest, having been in use for twenty-five years or more in the North of England, is best adapted for ways that are nearly level, or when many branches are intended to be worked from one engine, and can be carried round curves of small radius without deranging the trains; but as it is intermittent in action, considerable engine-power is required in order to get up the required speed, which is from 8 to 10 miles per hour. From 8 to 10 tubs are usually drawn in a set, the ways being often from 2000 to 3000 yards long. In dip workings the tail rope is often made to work a pump connected with the bottom pulley, which forces the water back to the cistern of the main pumping engine in the pit.

For the endless chain system, which is much used in the Wigan district a double line of way is necessary, one line for full and the other for empty tubs. The chain passes over a pulley driven by the engine, placed at such a height as to allow it to rest upon the tops of the tubs, and round a similar pulley at the far end of the plane. The forward edge of the tub carries a projecting pin or horn, with a notch into which the chain falls which drags the tub forward. The road at the outer end is made of a less slope than the chain, so that on arrival the tub is lowered, clears the pin, and so becomes detached from the chain. The tubs are placed on at intervals of about 20 yards, the chain moving continuously at a speed of from 2½ to 4 miles per hour. This system presents the greatest advantages in point of economy of driving power, especially where the gradients are variable, but is expensive in first cost, and is not well suited for curves, and branch roads cannot be worked continuously, as a fresh set of pulleys worked by bevel gearing is required for each branch.

The endless rope system may be used with either a single or double line of way, but the latter is more generally advantageous. The rope, which is guided upon sheaves between the rails, is taken twice round the head pulley; or a Fowler's clip pulley may be used. It is also customary to use a stretching pulley to keep the rope strained when the pull of the load diminishes. This is done by passing a loop at the upper end round a pulley mounted in a travelling frame, to which is attached a weight of about 15 cwt. hanging by a chain. This weight pulls directly against the rope; so if the latter slacks, the weight pulls out the pulley frame and tightens it up again. The tubs are usually formed into sets of from 2 to 12 the front one being coupled up by a short length of chain to a clamping hook formed of two jaws moulded to the curve of the rope which are attached by the "run rider," as the driver accompanying the train is called. This system in many respects resembles the tail rope, but has the advantage of working with one-third less length of rope for the same length of way.

The endless rope system overhead is substantially similar to the endless chain. The waggons are attached at intervals by short lengths of chain lapped twice round the rope and hooked into one of the links, or in some cases the chains are hooked into hempen loops on the main rope.

One of the most important branches of colliery work is the management of the ventilation, involving as it does the supply of fresh air to the men working in the pit, as well as the removal of inflammable gases that may be given off by the coal. This is effected by carrying through the workings a large volume of air which is kept continually moving in the same direction, descending from the surface by one or more pits known as intake or downcast pits, and leaving the mine by a return or upcast pit. Such a circulation of air can only be effected by mechanical means when the workings are of any extent, as will be apparent from the following considerations:—

If the shafts A and B, fig. 15, were of equal depth from the horizontal plane, and connected by the mine C, the air would fill the openings and remain quiescent. If the one were to the dip of the other, but communicating with the surface at a higher level, as by fig. 16, it would sometimes happen, in summer, that D would be the downcast, and E the upcast, and in winter, E the downcast, and D the upcast. These conditions are induced by the temperature of the earth at a certain depth being nearly constant, while the atmosphere is changeable,—the column of air in D d being at a lower temperature in summer than the column of air E e, and the reverse in winter.

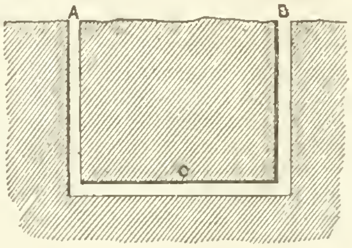

Fig. 15.

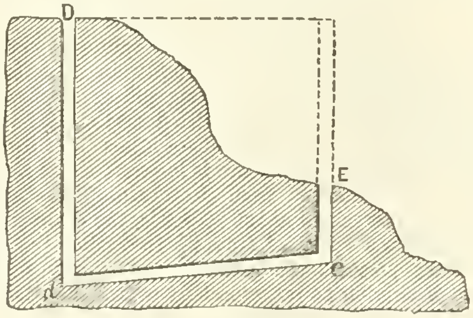

Fig. 16.

The methods actually adopted are—(1) The rarefaction of the air in the upcast pit by a furnace placed at the bottom; and (2) Exhaustion by machinery at the surface. The former plan, although hitherto most generally used, is in many places becoming replaced by some form of machine.

The usual form of ventilating furnace is a plain fire-grate placed under an arch, and communicating with the upcast shaft by an inclined drift. It is separated from the coal by a narrow passage walled and arched in brickwork on both sides. The size of the grate varies with the requirements of the ventilation, but from 6 to 10 feet broad and from 6 to 8 feet long are usual dimensions. At Shireoaks Colliery, in Nottinghamshire, a furnace consuming 6 tons of slack per 24 hours upon a grate surface of 72 square feet maintains a circulation of about 120,000 cubic feet per minute. At Hetton Colliery, Durham, the grate is a long, narrow rectangle, 25 feet by 5 feet, with numerous furnace-doors on the long side, so arranged that the surface fired may be varied according to the amount of draught required. There are two bunker-holes for coals, and a stoking passage, 7 feet wide, in front of the furnace. The fire should be kept as thin and bright as possible, to reduce the amount of smoke in the upcast. When the mine is free from gas, the furnace may be worked by the return air, but it is better to take fresh air directly from the downcast by a scale, or split, from the main current. The return air from fiery workings is never allowed to approach the furnace, but is carried into the upcast by a special channel, called a dumb drift, some distance above the furnace drift, so as not to come in contact with the products of combustion until they have been cooled below the igniting point of fire-damp. Where the upcast pit is used for drawing coal, it is usual to discharge the smoke and gases through a short lateral drift near the surface into a tall chimney, so as to keep the pit-top as clear as possible for working. Otherwise the chimney is built directly over the mouth of the pit.

Mechanical ventilation.

Various kinds of machines for ventilation, both by direct exhaustion and centrifugal displacement, have been tried both in England and in Belgium. Of the former class are the great bell machines, resembling gasometers, 12 feet to 22 feet in diameter, and 9 feet high, moving in a water tank with balanced flap valves for alternately admitting and exhausting the air. These were used at Marihaye, near Liége, and at Cwm Avon in South Wales, by Mr Struvé. Perhaps the largest of the class of piston machines is that at Nixon's Navigation Pit, near Aberdare, which has rectangular pistons, 30 feet by 22 feet, moving horizontally through a stroke of 7 feet, the lower edge being supported by rollers running on rails. The great weight of the moving parts in this class of machine makes them incapable of acting at any very high speed, and consequently expensive for the amount of work done. This is in some degree obviated in the rotary piston machines of Fabry and Lemielle, the former resembling in principle Root's blower, now so much used in blowing foundry and smiths' fires, but on a larger scale. Lemielle's ventilator is a vertical drum revolving eccentrically within a cylindrical casing. The drum carries three jointed blades, which are drawn in or out by radius bars as it revolves, so as to enclose and sweep out at each revolution the body of air included between the two cylinders. This is one of the best machines of its class, producing a comparatively high effect for the power expended. An American machine of this kind is described and figured in the article BELLOWS, vol. iii. p. 552, fig. 5.

Of late years various kinds of centrifugal machines, or fans, have come into use instead of ventilating furnaces. One of the most successful of these is that invented by Mr Guibal of Liége, represented in fig. 17. The fan has eight arms, framed together of wrought-iron bars, with diagonal struts, so as to obtain rigidity with comparative lightness, carrying flat close-boarded blades at their extremities. It revolves with the smallest possible clearance in a chamber of masonry, one of the side walls being perforated by a large round hole, through which the air from the mine is admitted to the centre of the fan. The lower quadrant of the casing is enlarged spirally, so as to leave a narrow rectangular opening at the bottom, through which the air is discharged into a chimney of gradually increasing section carried to a height of about 25 feet. The size of the discharge aperture can be varied by means of a flexible wooden shutter sliding in a groove in a cast-iron plate, curved to the slope of the casing. By the use of the spiral guide casing and the

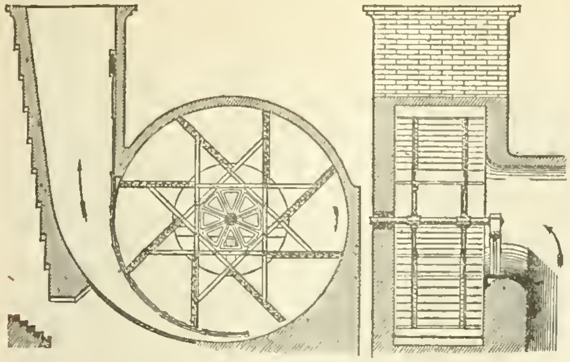

Fig. 17.—Guibal's Fan.

chimney, the velocity of the effluent air is gradually reduced up to the point of final discharge into the atmosphere, whereby a greater useful effect is realized than is the case when the air streams freely from the circumference with a velocity equal to that of the rotating fan. The power is applied by steam acting directly on a crank at one end of the axle. In most of the newer examples, which are generally of large size, the power is divided, an engine being placed on each side. At Washington Colliery, Durham, a machine of 36 feet diameter, 12 feet breadth of face, and 13 feet diameter of intake passage, draws 120,000 cubic feet of air per minute, when making 38 revolutions. Another at Usworth, 48 feet diameter and 12 feet breadth of face, driven by two high-pressure engines, with cylinders 3 feet in diameter and 3 feet stroke, equal to about 280 horse-power, exhausts 200,000 cubic feet per minute. The useful effect realized under the most favourable conditions is as much as 50 per cent. of that of the steam power employed.

Waddle's fan, represented in fig. 18, is an example of

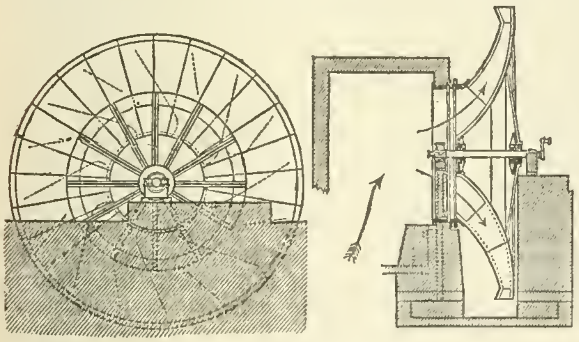

Fig. 18.—Waddle's Fan.

another class of centrifugal ventilator, in which a close casing is not used, the air exhausted being discharged from the circumference directly into the atmosphere. It consists of a hollow sheet-iron drum formed by two conoidal tubes, united together by numerous guide blades, dividing it up into a series of rectangular tubes of diminishing section, attached to a horizontal axle by cast-iron bosses and wrought-iron arms. The tubes at their smallest part are connected to a cast-iron ring, 10 feet in diameter, but at their outer circumference they are only 2 feet apart. The extreme diameter is 25 feet. A fan of these dimensions at Brownhills in Staffordshire, in making 50 revolutions per minute, circulates 47,000 cubic feet of air through the workings. It has also been in use for some years in South Wales, and is found to work well; it is less expensive in first cost than Guibal's, although proportionally less economical from the smaller effect realized for the power expended.

Another method of colliery ventilation is that by jets of steam blowing off at a high velocity into the upcast shaft, and producing a draught similar to that of the exhaust blast in the chimney of a locomotive. This plan found several advocates some years since, and was the subject of numerous comparative trials against the ventilating furnace in the North of England, but the results were unfavourable, the amount of air circulation produced being exceedingly small for the fuel expended. It seems probable, however, that this want of success was in great part due to the defective character of the apparatus applied, and that, with properly-constructed aspirators and discharge passages, the steam jet may prove to be a very efficient means of ventilation.

The comparative merits of furnace and machine ventilation have long been discussed without any definite result. The former was at one time regarded in England as practically superior in every respect, but this opinion has been modified since the introduction of the improved forms of fans which have been worked to a considerable extent. In France and Belgium, on the contrary, machine ventilation has been more generally in favour. For a deep and extensive mine where the coal is not fiery, the furnace is undoubtedly the simplest and most efficacious method of producing a large circulation of air; but for moderate depths, especially with fiery return air, a ventilating machine at the surface is in many cases to be preferred. There is also an important advantage procured by the latter, namely, that of reserve power, so that a larger circulation may be obtained immediately in case of need, *e.g.*, when the barometer falls suddenly, by merely increasing the speed of rotation, which cannot so readily be done with the furnace, which has a tendency to slacken at the time when the increased work is wanted.

Distribution of air underground.

The quantity of air required for a large colliery depends upon the number of men employed, as for actual respiration from 100 to 200 cubic feet per minute should be allowed. In fiery mines, however, a very much larger amount must be provided in order to dilute the gas to the point of safety. Even with the best arrangements a dangerous increase in the amount of gas is not unfrequent from the sudden release of stored up masses in the coal, which, overpowering the ventilation, produce magazines of explosive material ready for ignition when brought in contact with the flame of a lamp or the blast of a shot. The management of such places, therefore, requires the most constant vigilance on the part of the workmen, especially in the examination of the working places that have been standing empty during the night, in which gas may have accumulated, to see that they are properly cleared before the new shift commences.

The actual conveyance or coursing of the air from the intake to the working faces is effected by splitting or dividing the current at different points in its course, so as to carry it as directly as possible to the places where it is required. In laying out the mine, it is customary to drive the levels or roads in pairs, communication being made between them at intervals by cutting through the intermediate pillar, the air then passes along one, and returns by the other. As the roads advance other pillars are driven through in the same manner, the passages first made being closed by stoppings of broken rock, or built up with brick and mortar walls, or both. When it is desired to preserve a way from one road or similar class of working to another, double doors placed at sufficient intervals apart to take in one or more trams between them when closed are used, forming a kind of lock or sluice. These are made to shut air-tight against their frames, so as to prevent the air from taking a short cut back to the upcast, while preserving free access between the different districts without following the whole round of the airways. The ventilation of ends is effected by means of brattices or temporary partitions of thin boards placed midway in the drift, and extending to within a few feet of the face. The air passes along one side of the brattice, courses round the free end, and returns on the other side. In many cases a light but air-proof cloth, specially made for the purpose, is used instead of wood for brattices, as being more handy and more easily removed. In large mines where the air-ways are numerous and complicated, it often happens that currents travelling in opposite directions are brought together at one point. In these cases it is necessary to cross them in the manner shown in fig. 2, Plate III. The return air is usually made to pass over the intake by a curved drift carried some distance above in the solid measures, both ways being arched in brickwork, or even in some cases lined with sheet-iron so as to ensure a separation not likely to be destroyed in case of an explosion. The relation of the ventilation to the workings under the different systems is indicated on the several plates by arrows and other signs, from which the general character of the arrangements adopted can be made out without further description.

Lighting. The lighting of underground workings in collieries is closely connected with the subject of ventilation. In many of the smaller pits in the Midland districts, and generally in South Staffordshire, the coals are sufficiently free from gas, or rather the gases are not liable to become explosive when mixed with air, to allow the use of naked lights, candles being generally used. Oil lamps are employed in many of the Scotch collieries, and are almost universally used in Belgium and other Continental countries. The buildings near the pit bottom, such as the stables and lamp cabin, and even the main roads for some distance, are often in large collieries lighted with gas brought from the surface, or in some cases the gas given off by the coal is used for the same purpose. Where the gases are fiery, the use of protected lights or safety lamps becomes a necessity.

The nature of the gases evolved by coal when freshly exposed to the atmosphere has been investigated by several chemists, more particularly by Playfair and Meyer. The latter observer found the gases given off by coal from the district of Newcastle and Durham to contain carbonic acid (anhydride), marsh gas or light carburetted hydrogen (the fire-damp of the miner), oxygen, and nitrogen. A newer investigation, by Mr J. W. Thomas, of the gases dissolved or occluded in coals from South Wales basin shows them to vary considerably with the class of coal. The results given below, which are selected from a much larger series published in the *Journal of the Chemical Society*, were obtained by heating samples of the different coals in vacuo for several hours at the temperature of boiling water.

Quality.	Colliery.	Volume per ton in cubic feet.	Composition in Volumes per cent.

In one instance, about 1 per cent. of hydride of ethyl was found in the gas from a blower in a pit in the Rhondda district, which was collected in a tube and brought to the surface to be used in lighting the engine-room and pit-bank. The gases from the bituminous house coals of South Wales are comparatively free from marsh gas, as compared with those from the steam coal and anthracite pits. The latter class of coal contains the largest proportion of this dangerous gas, but holds it more tenaciously than do the steam coals, thus rendering the workings comparatively safer. It was found that, of the entire volume of occluded gas in an anthracite, only one-third could be expelled at the temperature of boiling water, and that the whole quantity, amounting to 650 cubic feet per ton, was only to be driven out by a heat of 300° C. Steam coals being softer and more porous give off enormous volumes of gas from the working face in most of the deep pits, many of which have been the scene of disastrous explosions.

The gases evolved from the sudden outbursts or blowers in coal, which are often given off at a considerable tension, are the most dangerous enemy that the collier has to contend with. They consist almost entirely of marsh gas, with only a small quantity of carbonic acid, usually under 1 per cent., and from 1 to 4 per cent. of nitrogen.

Fire-damp when mixed with from four to twelve times its volume of atmospheric air is explosive; but when the proportion is above or below these limits, it is inflammable, burning quietly with a pale blue flame. When a lighted candle is exposed in a non-explosive mixture of this gas, the flame gradually elongates, forming a conical cap, floating above the wick, which may be extinguished by cautious withdrawal without communicating the fire to the surrounding atmosphere. This method of testing for gas in the working places and wastes, which is obviously only to be trusted in skilled hands, used to be commonly practised, but since the introduction of safety lamps it has fallen into disuse.

The principle involved in the construction of safety-lamps consists in surrounding the flame of a lamp by a protecting metal case, perforated with numerous small holes, through which the air for feeding the flame may freely enter, and the products of combustion pass out, while the passage of flame, or gases sufficiently heated to cause the ignition of the external air when laden with explosive gases, is prevented. In 1816 Sir Humphrey Davy made the great discovery that these conditions are fulfilled by the use of tubes reduced to a mere section, such as the apertures in wire gauze, when the substance of the wire is rightly proportioned to the size of the aperture. The standard adopted as the limit for safety at that time was a gauze of 28 iron wires to the linear inch, having 784 apertures per square inch, which has been used ever since. The common safety or Davy lamp consists of a small cylindrical oil lamp, covered with a cylinder of wire gauze about 6 inches long and $1\frac{1}{2}$ inches in diameter, with a flat gauze top. The upper part of the gauze is doubled to prevent its being worn into holes by the products of combustion, and the air for feeding the flame enters round the wick. The gauze is mounted in a cage, consisting of three upright wires, screwed into a flat brass ring at each end. A handle is attached to the upper ring, while the lower one screws on to a collar on the oil-vessel of the lamp. When the two parts are screwed together the lamp is locked by a bolt passing through both parts, which is screwed down flush with or below the surface of the outer ring, so that the gauze cannot be removed without the use of a key. Safety lamps.

In Stephenson's safety-lamp, generally known as the "Geordie," from the inventor George Stephenson, the light is covered by a glass chimney, surrounded by an outer casing and top of wire gauze. The feed air is admitted through numerous small holes in a copper ring a little below the level of the wick. This is one of the safest forms of lamp, but requires considerable care in use, especially in keeping the small feed holes clear from dust and oil; the glass protects the gauze from becoming overheated.

and when the air is dangerously charged with gas the light is extinguished.

Various forms of safety-lamps have been introduced at different times, for the purpose of increasing the amount of light by substituting a glass cylinder for the lower portion of the wire gauze. The oldest of these is that of Dr Clanny, contemporary with those of Davy and Stephenson. The air for supplying the flame, entering at the bottom of the gauze, and passing down the inner side of the glass, protects the latter to some extent from becoming overheated, but a large amount of light is lost by absorption in the glass, so that there is no great advantage over the ordinary Davy lamp to compensate for the extra weight and cost, especially as the safety property of the lamp depends upon the glass cylinder, which may be readily broken when subjected to the ordinary accidents of working. A more perfect form of lamp of the same character is that of Museler, which is extensively used in Belgium. It differs from Clanny's lamp by the addition of a conical chimney above the flame, which produces a rapid draught, and consequently a more perfect cooling of the glass cylinder by the down-draught of feed air for the flame.

Boty's lamp, which was recommended by a commission of the Belgian Government as being safe in use, is essentially that of Dr Clanny with Stephenson's perforated ring for admitting air at the level of the wick. Another Belgian variety is that of Eloin, in which the glass is shaped to the surface produced by the revolution of a parabolic arc, so as to disperse the light in parallel lines. The air is admitted by a Stephenson ring, combined with an Argand cap, the glass being surrounded by a brass chimney with a gauze top. In another form of the same lamp Museler's chimney is added.

The locking of safety-lamps, so as to render them incapable of being opened by the miners when at work, is a point that has given play to a large amount of ingenuity. One of the most favourite devices is a combination of the wick-holder with the locking bolt, so that the latter cannot be withdrawn without lowering the wick and extinguishing the flame. Another method consists in the use of a lead rivet, uniting the two parts of the lamp, impressed with a seal, which cannot be removed without defacing the device. All this class of contrivances have the defect of only being efficacious when the miners are not provided with matches, or other means of obtaining a light. A more physically perfect method is that adopted by Bidder, where the locking bolt is magnetized and held in place by a force which can only be overcome by the application of a battery of heavy and powerful steel magnets. These are kept in the lamp cabin at the pit bottom, where the lamps are cleaned and served out lighted to the miners at the commencement of the shift, and are collected before they return to the surface.

When a Davy lamp is exposed to an atmosphere containing less than 8 per cent. of marsh gas, the flame lengthens and becomes smoky; when that amount is reached the flame returns to its usual size, but a column of blue flame rises to the top of the gauze. With 10 per cent. the flame of the wick is extinguished, the whole of the space within the gauze being filled with a blue flame of burning gas. If the lamp is allowed to remain too long in a fiery atmosphere it becomes dangerous, as the gauze being heated to redness may fire the gas. The safety of the lamp is also endangered by an exposure to a current of gas moving at the rate of more than 6 or 8 feet per second, as the flame can then be readily driven through the gauze. It is therefore usual to protect the flame by a sliding shield of tin plate, horn, or mica from the direct action of any sudden outburst of gas in the workings. Lamps with glass cylinders are generally very safe, except from the risk of accidental breakage, which, however, is less frequent than might be imagined, and those taking air through a feed ring, such as Stephenson's, are readily extinguished in a foul atmosphere.

The danger arising from gas in the workings may be considerably increased by the presence of coal dust in the air. This point has been the subject of investigation by Galloway, who found that an explosion may be produced by ignited particles of coal dust through the agency of a safety-lamp which under ordinary circumstances would be perfectly trustworthy. At Blanzy, in France, several fatal explosions have been traced to the firing of coal dust from the flame of a shot, even in cases where no fire-damp was present in the workings.

An electric lamp, where the light is obtained from the discharge in a Geissler vacuum tube, has been proposed by Benoit-Dumas, instead of the ordinary safety lamps, or for use in exploring after explosions or in bad air ways. This consists of a box containing a galvanic battery, consisting of two Bunsen cells, and a small induction coil, with connecting wires which convey the current to the lamp. The Bunsen cells may be conveniently replaced by a single bottle-shaped bichromate battery. The cost and complication of this apparatus must necessarily limit its use.

Apparatus, originating in France, known as aerophores, which enable the miner to carry sufficient fresh air for his own respiration, and to keep a lamp alight for a short time in a totally irrespirable atmosphere, have of late years come into use for the purposes of saving life after explosions, and repairing shafts and pit-work under water. There are two principal patterns, those of Galibert and Denayrouze. The former, which is the simplest, consists of an air-tight bag of about 12 cubic feet capacity, containing air at a little above atmospheric pressure, which is carried on the miner's back like a knapsack. The air, after being used, is returned with the products of respiration into the bag, and can be used over again until it becomes too impure for further use. It is obvious, therefore, that such an apparatus must be of very limited application, but its simplicity and cheapness are points in its favour for use in sudden emergencies. The Denayrouze apparatus consists of a series of sheet metal cylinders, containing air compressed to 300 or 350 ℔ to the square inch, which can be carried on the back, and served out at a pressure very slightly above that of the atmosphere by means of a reducing valve, whose construction is essentially the same in principle as that of the ordinary pressure regulator used in gas-works, *i.e.*, a conical plug closed against its seat by the pressure of the air in the reservoir, which is constantly opposed by an external force tending to open it. This force is supplied by a disc of vulcanized india-rubber, which opens the valve at each inspiration, and allows a fresh supply of air to escape into the chamber of the regulator through the small aperture of the valve. Of course, all communication with the external air must be cut off, so that respiration can only take place through the mouth, the air-tube being attached by an india-rubber mask called a mouth-closer, and the nostrils closed by a spring clip. A similar regulator valve, so constructed as to keep the india-rubber spring under a slight excess pressure in order to maintain a flow of air, is in connection with the lamp. This is of the ordinary Museler construction, with the addition of a chamber outside the gauze to receive the products of combustion, which are discharged through a conical valve at the top, a reflux of the exterior gases being prevented by the pressure of a counter spring. The air is carried to the lamp by an india-rubber tube, which is sufficiently flexible to allow a certain freedom of motion. The distance that an explorer can penetrate with this apparatus is obviously limited by the capacity of the air-cylinders

Aerophores.

These have been made large enough to supply air to a man with a lamp for an hour, but this is an inconvenient size, being too large to be carried on the back.

Fires in mines. Underground fires are not uncommon accidents in coal-mines. In the thick coal workings in South Staffordshire the slack left behind in the sides of work is especially liable to fire from so-called spontaneous combustion, due to the rapid oxidization that is set up, when finely-divided coal is brought in contact with air. The best remedy in such cases is to prevent the air from gaining access to the coal by building a wall round the burning portion, which can in this way be isolated from the remainder of the working, and the fire prevented from spreading, even if it cannot be extinguished. When the coal is fired by the blast of an explosion it is often necessary to completely isolate the mine by stopping up the mouths of the pits with earth, or in extreme cases it must be flooded with water or carbonic acid before the fire can be brought under. There have been several instances of this being done in the fiery pits in the Barnsley district, notably at the great explosion at the Oaks colliery in 1866, when 360 lives were lost.

Methods of winding. The drawing or winding of the coal from the pit bottom to the surface is one of the most important operations in coal mining, and probably the department in which mechanical appliances have been brought to the highest state of development. In the simplest case, where the mine is worked by levels, the trains of coal may be drawn from the working faces directly to the level mouth by horse power, or in some exceptional cases locomotives worked by compressed air are used. In South Wales the power for lifting the load in the shaft is still in some small workings furnished by a water balance, that is, a box which is filled with water at a high level, and in descending raises the loaded trucks by a rope passing over a pulley at the surface. This method is only available when there is a free drainage level for the water to run off when the box reaches the lowest point. Other hydraulic motors, such as wheels, pressure engines, &c., are used in different localities as well as animal power, where the amount of coal to be drawn is small, but as a general rule it is necessary to have recourse to steam power to maintain an adequate output. The old custom of drawing the coals in tubs or hutches (*cuffat* of the French miner), swinging freely from the end of the drawing rope, is now almost entirely superseded by the adoption of cages sliding between fixed guides, which allow the load to move freely up and down while checking lateral oscillation. This improvement, which is due to Mr John Curr of Sheffield, was originally introduced in 1798, but made surprisingly little progress for nearly half a century. It was first brought into general use in the North of England, but in many of the smaller pits of the Midland counties the older custom prevailed until recently.

The different elements making up the drawing arrangements of a colliery are—(1) the cage, (2) the shaft or pit fittings, (3) the drawing-rope, (4) the engine, and (5) the surface arrangements. The cage, as its name implies, consists of one or more platforms connected by an open framework of vertical bars of wrought iron or steel, with a top bar to which the drawing-rope is attached. It is customary to have a curved sheet-iron roof or bonnet when the cage is used for raising or lowering the miners, to prevent them from injury by falling materials. The number of platforms or decks varies considerably; in small mines only a single one may be used, but in the larger modern pits two, three, or even four-decked cages are used. The use of several decks is necessary in old pits of small section, where only a single tram can be carried on each. In the large shafts of the Northern and Wigan districts the cages are made about 8 feet long and 3½ feet broad, being sufficient to carry two large trams on one deck. These are received upon a railway made of two strips of angle iron of the proper gauge for the wheels, and are locked fast by a latch falling over their ends.

The guides or conductors in the pit may be constructed of wood, in which case rectangular fir beams, about 3 by 4 inches, are used, attached at intervals of a few feet to buntons or cross-beams, built into the lining of the pit. Two guides are required for each cage; they may be placed opposite to each other, either on the long or short sides—the latter being preferable. The cage is guided by shoes of wrought iron, a few inches long and bell-mouthed at the ends, attached to the horizontal bars of the framing, which pass loosely over the guides on three sides. In some of the large collieries in Northumberland wrought iron guides have been adopted with advantage. They are applied on one side of the cage only, forming a complete vertical railway,—light flange rails such as are used for the roadways underground being used instead of wooden rods and iron cross sleepers, with proper seats for the rails instead of wooden buntons; the cage is guided by curved shoes of a proper section to cover the heads of the rails. Rigid guides connected with the walling of the pit are probably the best and safest, but they have the disadvantage of being liable to distortion, in case of the pit altering its form, owing to irregular movements of the ground, or other causes. Wooden guides being of considerable size, block up a certain portion of the area of the pit, and thus offer an impediment to the ventilation, especially in upcast shafts, where the high temperature, when furnace ventilation is used, is also against their use. In the Wigan district, wire-rope guides have been introduced to a very considerable extent, with a view of meeting the above objections. These are simply wire-ropes, from ¾ to 1½ inches in diameter, hanging from a cross-bar connected with the pit-head framing at the surface, and attached to a similar bar at the bottom, which are kept straight by a stretching weight of from 30 cwt. to 4 tons attached to the lower bar. In some cases four guides are used—two to each of the long sides of the cage; but a more general arrangement is to have three—two on one side, and the third in an intermediate position on the opposite side. Many colliery managers, however, prefer to have only two opposite guides, as being safer. The cage is connected by tubular clips, made in two pieces and bolted together, which slide over the ropes. In addition to this, it is necessary to have an extra system of fixed guides at the surface and at the bottom, where it is necessary to keep the cage steady during the operations of loading and landing, there being a much greater amount of oscillation during the passage of the cage than with fixed guides. For the same reason it is necessary to give a considerable clearance between the two lines of guides, which are kept from 15 to 18 inches apart, to prevent the possibility of the two cages striking each other in passing. With proper precautions, however, wire guides are perfectly safe for use at the highest travelling speed.

The cage is connected with the drawing-rope by short lengths of chain from the corners known as tackling chains, gathered into a central ring, to which the rope is attached. Round steel wire-ropes, about 2 inches in diameter, are now commonly used; but in very deep pits they are sometimes tapered in section to reduce the dead weight lifted. Flat ropes of steel or iron wire were and are still used to a great extent, but round ones are now generally preferred. In Belgium flat ropes of aloe fibre are in high repute, being considered preferable by many colliery managers to wire, in spite of their great weight. In South Staffordshire, flat link chains made with three or more parallel links, with a stud of wood filling up the hollow, are or were in general use in the numerous shallow pits working the thick coal in the neighbourhood of Dudley, &c.

The best modern engines for drawing in collieries are usually direct-acting, with either horizontal or vertical cylinders. In the north of England a single engine with a heavy fly-wheel is often used, but the more general arrangement is to have two engines coupled to the opposite ends of the winding drum-shaft. In almost all cases steam is used at high pressure without condensation.

The drum, when round ropes are used, is a plain broad cylinder, with flanged rims, and cased with soft wood packing, upon which the rope is coiled; the breadth is made sufficient to take the whole length of the rope at two laps. One drum is usually fixed to the shaft, while the other is loose, with a screw link or other means of coupling, in order to be able to adjust the two ropes to exactly the same length, so that one cage may be at the surface when the other is at the bottom, without having to pay out or take up any slack rope by the engine.

For flat ropes, the drum or bobbin consists of a solid disc, of the width of the rope fixed upon the shaft, with numerous parallel pairs of arms or horns, arranged radially on both sides, the space between being just sufficient to allow the rope to enter and coil regularly upon the preceding lap. This method has the advantage of equalizing the work of the engine throughout the journey, for when the load is greatest, with the full cage at the bottom and the whole length of rope out, the duty required in the first revolution of the engine is measured by the length of the smallest circumference; while the assistance derived from gravitating action of the descending cage in the same period is equal to the weight of the falling mass through a height corresponding to the length of the largest lap, and so on, the speed being increased as the weight diminishes, and *vice versa*.

The same thing can be effected in a more perfect manner by the use of spiral or scroll drums, in which the rope is made to coil in a spiral groove upon the surface of the drum, which is formed by the frusta of two obtuse cones placed with their smaller diameters outwards. This plan, though mechanically a very good one, has certain defects, especially in the possibility of danger resulting from the rope slipping sideways, if the grooves in the bed are not perfectly true. The great size and weight of such drums are also disadvantages, as giving rather unmanageable dimensions in a very deep pit.

The use of a counterbalance chain for the winding engines is common in the collieries of the Midland districts of England. In this method a third drum is used to receive a heavy flat link chain, shorter than the main drawing-ropes, the end of which hangs down a special or balance pit. At starting, when the full load is to be lifted, the balance chain uncoils, and continues to do so until the desired equilibrium between the working loads is attained, when it is coiled up again in the reverse direction, to be again given out on the return trip.

The surface arrangements of a modern colliery are often of considerable extent and complexity, the most important feature being the pit-frame carrying the guide-pulleys or rope-rolls which lead the drawing-ropes from the vertical line of the pit to the engine-drum. This consists essentially of an upright framework, carefully braced together, and strutted by diagonal beams against the wall of the engine-house, or other solid abutment. It is generally necessary to have a clear head-room, 10 or 20 feet or more, for the working arrangements at the surface above the level of the ground, especially in flat countries; the pit-frames are made of considerable height, from 50 to 70 feet being not uncommon; and when, as is generally the case, they are made of wood, they afford opportunities for the exercise of skilful carpentry. Of late years, however, wrought iron pit-frames have been adopted to some extent, which allows of a comparatively simpler construction being used, the main elements of the frame consisting of hollow latticed pillars and beams, similar to the construction now generally adopted for the pillars of railway signals, but of course of a more solid construction. They have one great advantage over wooden frames, in not being liable to destruction by fire, an accident which has occasionally happened with the latter. The guide-pulleys for iron or steel wire-ropes are made of very large dimensions, to avoid strain upon the wires by sudden change of

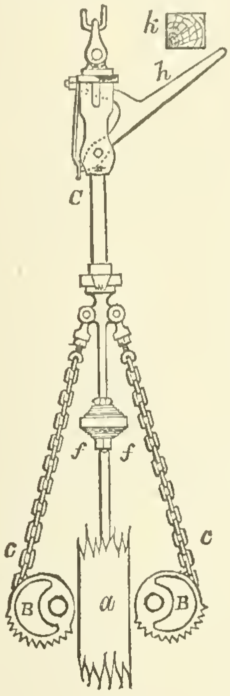

Fig. 19.

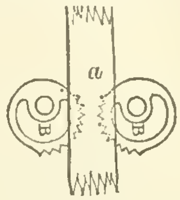

Fig. 20.

direction when moving at a high speed. The usual construction is a deep channeled rim or tire of cast-iron, from 7 to 20 feet in diameter, supported by numerous thin wrought iron arms, inclining inwards from a central cast-iron boss,—a form combining rigidity with comparative lightness. They are in fact very similar to the driving wheels of the large modern bicycles, supposing a channeled rim to be substituted for the india-rubber tire.

Safety catches.

To prevent accidents from the breakage of the rope on the shaft, or from overwinding when the engine is not stopped at the right moment, whereby the cage may be

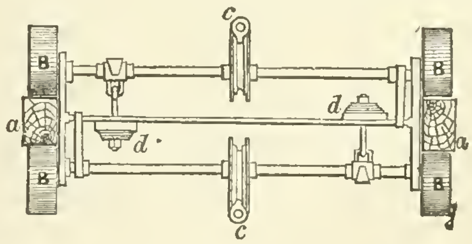

Fig. 21.

Figs. 19–21.—White and Grant's Safety Catch.

dragged up to the head pulleys (both which kinds of accident are unhappily not uncommon), various forms of safety catch and disengaging hooks have been proposed. These consist of variously-constructed toothed levers, cams, or eccentrics, mounted upon transverse axes, attached to the top of the cage, whose function is to take hold of the guides, and support the cage in the event of its becoming detached from the rope. They are generally applied by means of springs acting against the pull of the rope. Figs. 19–21 represent a form of safety catch, introduced some years since by Messrs White and Grant of Glasgow. The catches BB consist of partially toothed eccentrics, which when released are forced inwards against the wooden guide *a* by the coiled springs *d d*, as shown in fig. 21.

When the rope is drawing, the catches are lifted by the pull of the chains attached to the pulleys c c, which turn the broad toothed portions outwards, and away from the guides. The connection with the rope is made by the slide bar C and spring catch h having a projecting trigger, which, if the cage is lifted too high, strikes against the cross-bar of the framing k, and detaches the cage, which is then left hanging by the catches to the guides in the pit. The use of safety catches is more common in the collieries of France, Belgium, and Germany than in England, where they are not generally popular, owing to their uncertainty in action, as they are often found to fail when most wanted. The constant drag of the catches on the guides when the rope slacks is also objectionable, but this has been overcome to a great extent in a very ingenious contrivance invented by Mr Calow, where the catches are not brought into action unless the cage is actually falling clear of the rope, with a certain acquired momentum of its own. The only real safeguards against accidents in winding are to be found in constant vigilance, in maintaining the ropes in working efficiency, and in the use of proper signals and brake power in the engine-house.

The speed attained by the load in the shaft in the best-appointed English collieries is very considerable, and may be paralleled with that of a fast railway train. At Shireoaks Colliery, Nottinghamshire, the cage with a load of 34 cwts. of coal in five tubs, and weighing in all 60 cwts., or with the rope at the bottom 92½ cwts. is raised from a depth of 516 yards in 45 seconds, corresponding to an average of 35 feet per second, or 24 miles per hour, the maximum speed when the load is mid-way being 50 feet per second, or nearly 35 miles an hour. The ropes used are round, of steel wire, weighing 13 lbs. to the yard, winding on to a spiral drum, increasing from 17 to 20 feet in diameter. There are two engines with vertical cylinders, 32 inches diameter and 6 feet stroke, developing a useful effect of about 320 horse-power. The guide pulleys are 12 feet in diameter.

The above may be taken as a good example of the modern class of winding engines, such as are required to draw from 600 to 1200 tons in the shift of 10 hours. When the pits are of small depth it is better to increase the weight of the load than to draw at a very high speed, as the loss of time in filling and unloading or striking the cages is the same for a short as for a long journey, so that it becomes advantageous to diminish the number of journeys for a given quantity of coal drawn.

The great amount of dead weight required to be raised in the ordinary system of winding (*e.g.*, in the instance given above, the total weight moved is nearly four times that of the nett load drawn, that of the ropes being nearly 1½ times as much as the latter), has led to the proposal of various plans to obtain a more mechanically economical method, but none of these have at present been brought into successful use. One of the latest is that of M. Blanchet, who proposes to draw a number of tubs linked together into a long vertical train in a closed tube about 5½ feet in diameter, by exhausting the air above them in the manner adopted in the pneumatic tubes used for the transmission of parcels. An experimental apparatus of this class has been recently constructed at Creusot, in France, designed to lift a cage with 9 tubs, attached to a piston, weighing in all about 12½ tons.

When the cage arrives at the surface, or rather the platform forming the working top above the mouth of the pit, it is received upon the keeps, a pair of hinged gratings which are kept in an inclined position over the pit-top by counterbalance weights, so that they are pushed aside to allow the cage to pass upwards, but fall back and receive it when the engine is reversed. The tubs are then removed or struck by the landers, who pull them forward on to the platform, which is covered with cast-iron plates; at the same time empty ones are pushed in from the opposite side. The cage is then lifted by the engine clear of the keeps, which are opened by a lever worked by hand, and the empty tubs start on the return trip. When the cage has several decks, it is necessary to repeat this operation for each, unless there is a special provision made for loading and discharging the tubs at different levels. An arrangement of this kind for shifting the load from a large cage at one operation has recently been introduced by Mr Fowler at Hucknall, in Leicestershire, where the trains are received into a framework with a number of platforms corresponding to those of the cage, carried on the head of a plunger movable by hydraulic pressure in a vertical cylinder. The empty tubs are carried by a corresponding arrangement on the opposite side. By this means the time of stoppage is reduced to a minimum, 8 seconds for a three-decked cage as against 28 seconds, as the operations of lowering the tubs to the level of the pit-top, discharging, and replacing them are performed during the time that the following load is being drawn up the pit.

The tub when brought to the surface, after passing over a weigh-bridge, where it is weighed and tallied by a weigher specially appointed for the purpose by the men and the owner jointly, is run into a tipping cage, and the contents are discharged into an inclined screen with bars about 1 inch to 1½ inches apart. The large coal remaining passes through a spout into a railway waggon placed below, the discharge being regulated by a valve at the lower end. The small coal passing through is either sold as such, or may be lifted by an elevator to a second series of screens, either fixed or rotating, with half-inch apertures. These make a further separation of larger pieces, which are sold as "nuts," while the small, or slack, passing through is sent to the coke ovens, if the quality of the coal is suitable. As a rule, non-caking coals are not very closely screened, as the small is of comparatively little value, and therefore must have a proportion of larger sizes mixed with it to form saleable slack.

Illustrations of surface arrangements. Figs. 22–24, representing the surface arrangements adopted at a pair of pits in the Wigan district, may be taken as fairly representative of the fittings of a large modern colliery, where a considerable output of coal has to be screened and loaded in an ordinary working day of less than twelve hours. The details, of course, will vary, according to the nature of the outlet or vend, which may be by retailing into carts sent by purchasers, or by canals or railways, or by a combination of all three. In the example selected, the coal is loaded directly from the screens into full-sized trucks, each carrying from 6 to 8 tons, on a main line of railway. Of the two pits, one is an upcast, and is surmounted by a chimney at the surface,—the drawing being confined to the downcast, which is 310 yards deep and 10½ feet in diameter. 600 tons of coal are drawn from this depth in 10 hours by a pair of direct-acting engines, with vertical cylinders working a spiral drum, increasing from 13½ feet to 17½ feet in diameter. The pit-head frame is of wood, with guide pulleys 7 feet in diameter,—a much smaller size than is now usually adopted; the iron wire drawing-ropes are round, weighing 5 lb to the yard. Double-decked cages of a light construction in wrought iron are used, carrying four tubs at a time. The landing platform is raised upon pillars 20 feet above the surface of the ground, and covered with iron plates. As soon as the cage arrives at the surface, the tubs are run into tumbling cages, which discharge their contents on to fixed screens, with bars of 1 to 1¼ inch aperture. The large coal passes by a shoot directly into the railway waggon, while the first screenings fall into a channel below, which is traversed by a series of scrapers attached to an endless chain, and are carried to an elevator or Jacob's ladder, and discharged into rotatory drum sieves of about ½-inch aperture, producing a second size of saleable coal known as nuts, and

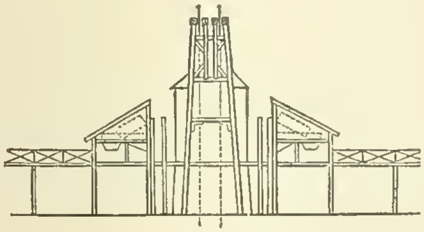

FIG. 24.—Transverse Elevation.
FIGS. 22-24.—Surface arrangements of Colliery.

slack, which is sent away to the coke ovens attached to the colliery. The whole of the labour required in the screening the output of 600 tons in the day of ten hours is performed by one engineman, who has charge of all the mechanical arrangements, and nine boys, who pick out any large lumps of stone from the coal as it passes the first screens. The engine driving the screens and elevators is in charge of a special engineman.

Fig. 25 represents one of a pair of pits at Pemberton Colliery, near Wigan, having the pit frames constructed in wrought iron lattice truss-work instead of wood. The screens for large coal (S) are arranged symmetrically on the landing platform, three on each side of the pit top, and discharge directly into waggons on the railway below. The small coal from these screens is passed by a screw creeper C, like those used in flour mills, to a bucket elevator E, which delivers it at the top of the second set of screens R, where the nuts and slack are separated. The platform, as in most of the new collieries in this district, is roofed over to protect the workmen from the weather. The second pit, which occupies a corresponding position on the opposite side of the engine-house, is in every respect similar.

The large collieries in the steam-coal district of Northumberland are among the most productive; thus, at Bedlington, near Morpeth, 1200 tons are raised daily, and at North Seaton from 1500 to 1800 tons.

When the coal is very much mixed with shale, the slack often contains so much mineral matter as to be quite worthless, until at least a partial separation has been effected. This is now done by means of coal-washing machines, which were first adopted in France, but have now become general in other countries. There are many different forms, but the most usual is a fixed sieve plate, upon which the slack is received and subjected to the action of a current of water forced through the holes by the action of a fast-moving short-stroke plunger pump, which puts the

Plan.

FIG. 25.—Surface arrangements, Pemberton Pit, Wigan.

whole of the materials into suspension, and allows them to fall through the water at each stroke. By this means the coal, being the lighter material, travels to the surface, and the heavier shale and stone going to the bottom are discharged through a valve there. The apparatus is in fact a form of the hydraulic jigging hutch used for the dressing of lead and other ores, except that in this case the lighter and not the heavier part is the valuable mineral. In another form of coal-dressing machine introduced by Mr Evrard, the jigging action is produced by a jet of steam acting directly upon the water instead of a plunger piston. Washed slack when suitable is used for conversion into coke, but in France and Belgium it is now generally employed in the production of agglomerated fuel, or briquettes, or what is usually known in England as patent fuel. These consist of coal dust mixed with a sufficient amount of gas-pitch to be moulded into coherent bricks or cylinders, which are afterwards dried at a high temperature, but below the point of carbonization. The consolidation of the slack may also be effected by the use of starch or dextrine, or even by cement or clay. This class of fuel is much used upon the French railways, being convenient for stowage and economical in use; but as a rule it is disagreeable to the passengers from the large amount of coal-dust carried off by the exhaust steam, and the unpleasant vapours produced by the burning pitch. The principal production of patent fuel in Britain is in South Wales.

The anthracite coal of Pennsylvania is subjected to the exceptional treatment of breaking between toothed rollers, and an elaborate system of screening before it is fit for sale. The largest or lump coal is that which remains upon a riddle having the bars four inches apart; the second, or steamboat coal, is above 3 inches; broken coal includes sizes above $2\frac{1}{2}$ or $2\frac{3}{4}$ inches; egg coal, pieces above $2\frac{1}{4}$ inches square; large stove coal, $1\frac{3}{4}$ inches; small stove, 1 to $1\frac{1}{2}$ or $1\frac{1}{3}$ inches; chestnut coal, $\frac{2}{3}$ to $\frac{3}{4}$ inch; pea coal, $\frac{1}{2}$ inch; and buckwheat coal, $\frac{1}{3}$ inch. The most valuable of these are the egg and stove sizes, which are broken to the proper dimensions for household use, the larger lumps being unfit for burning in open fire-places.

The proportion of coal utilized in the working, as compared with the total contents of the seam, varies very considerably in different districts, being greatest in seams of moderate thickness, from 3 to 5 feet, which on the long-wall system can be entirely removed. In thick coals, such as the ten-yard seam of South Staffordshire, the waste is very considerable. In Cheshire and Lancashire about 1330 tons of saleable coal are obtained from an acre for each foot of thickness in the seam, only 8 per cent. of the total being left behind in the workings.

At Dowlais, on the north of the South Wales coal-field, the yield is 1190 tons to the foot by long-wall, but only 866 tons when the same seam was worked by the pillar and stall system; but on the south side of the basin, where the seams lie at a steep slope, the loss is often much greater, being from 20 to 50 per cent. on pillar and stall workings. In the Barnsley district, the yield is from 1150 to 1280 tons in thick seams, and a maximum of 1417 tons has been obtained in a thin seam, the solid contents of the whole coal being estimated at 1556 tons per foot per acre. In Northumberland about 1200 tons are got out of a total of 1300. In the thick coal of South Staffordshire, from 12,000 to 16,000 tons per acre are got at the first working on an average thickness of $25\frac{1}{2}$ feet, or about 640 tons to the foot, or from 50 to 60 per cent. of the whole, which is increased by the second and third working to 70 or 75 per cent., making a loss of from 25 to 30 per cent. This amount is reduced, however, by the long-wall method of working.

Ownership of coal.

Probably from 10 to 15 per cent. may be taken as the unavoidable loss in working under the most favourable conditions, but in many cases the proportion is considerably higher.

In the United Kingdom the ownership of coal, like that of other minerals, is in the proprietor of the soil, and passes with it, except when specially reserved in the sale. The greater number of collieries are worked upon leases, the rents or royalties being variously charged in different localities. A minimum reserved rent to cover a certain output, with a rate per ton on any quantity in excess, is the most general practice; but in Lancashire and Yorkshire the royalties are charged at a fixed rate per acre per annum upon each seam worked, and in South Staffordshire at a proportion (from $\frac{1}{6}$ to $\frac{1}{16}$) of the coal at the pit's month.

Coal lying under the sea below low-water mark belongs to the Crown, and can only be worked upon payment of royalties, even when it is approached from shafts sunk upon land in private ownership.

In the Forest of Dean, which is the property of the Crown as a royal forest, there are certain curious rights held by a portion of the inhabitants known as the Free Miners of the Forest, who are entitled to mine for coal and iron ore, under leases, known as gales, granted by the principal agent or gaveller representing the Crown, in tracts not otherwise occupied. This is the only instance in Great Britain of the custom of free mining under a Government grant or concession, which is the rule in almost every country on the Continent.

Coal Mines Regulation Act.

The working of collieries in the United Kingdom is subject to the provisions of the Coal Mines Regulation Act of 1872, 35 and 36 Vict. cap. 76, which is administered by inspectors appointed by the Home Office, and forms a complete disciplinary code in all matters connected with coal-mining. Among the chief provisions of the Act are the following:—

1. Females and boys under 10 are not allowed to work underground.
2. Boys between 10 and 12 are not allowed to work except in thin mines.
3. No boy under 12 to drive a gin horse. or under 18 a steam-engine.
4. Wages not to be paid at public-houses.
5. Working of mines by a single shaft prohibited.
6. Managers to be certificated as competent by a board of examiners.
7. Annual return of coal wrought to be made to Inspectors.
8. Notice of accidents to be sent to Inspector.
9. Openings of abandoned workings to be fenced.
10. Plans to be kept up to within six months of date.
11. Plans of abandoned mines to be deposited with Home Office.
12. General rules for the safety of miners in fiery mines, management of ventilation, safety lamps, and gunpowder, protection against accidents in shafts and levels, &c.
13. Power to frame special rules subject to approval of the Secretary of State.

Breaches of the provisions of the Act are punishable by fine and imprisonment by a conrt of summary jurisdiction, subject to appeal to the Quarter Sessions, or to the Circuit Court in Scotland.

Proportion of hands to output.

The relation between the number of hands employed and the output of collieries varies considerably in different districts, being highest in those where the coal is moderately thick, soft, easily cut, regularly shaped, and with a good roof, and least in faulted and disturbed seams, and those with a bad roof, where the accessory operations of timbering and driving stone drifts requires the employment of a large proportion of the working staff on non-productive work, *i.e.*, other than cutting coal. The following figures give the relative force employed above and below ground in two large steam-coal collieries in South Wales, each producing about 500 tons per day:—

Colliers cutting coal	225	200
Other underground hands	229	174
Surface hands	43	36
	497	410

showing in the one case an average of about 1 ton, in the other about $1\frac{1}{4}$ ton per hand per day, but if the hands cutting coal be alone considered, the amount is about the same in both cases, or a little over two tons per day.

The annual output per man on the total force employed in several of the principal European coal-fields has been computed as follows:—

Newcastle	315 tons per man per annum.
Westphalia	215 ,, ,,
Saarbrücken	170 ,, ,,
France—Loire	200 ,, ,,
,, Nord	149 ,, ,,
Belgium—Charleroi	147 ,, ,,
,, Mons	124 ,, ,,

These figures refer to some years back, and are probably not quite accurate at the present date, as the amount of work done by the individual collier has sensibly decreased in most countries. It will be seen that the output is smallest in the thin disturbed measures of the Franco-Belgian coal-field.

In Prussia in 1874, with an output of 33,000,000 tons of coal and 8,000,000 tons of lignite, the average per underground hand was about 243 tons for the former and about 600 tons for the latter. The larger comparative yield in lignite mines is due to the fact that a very large proportion are worked as quarries.

The annual production of coal throughout the world may be roughly estimated at about 260 millions of tons for 1874, which quantity includes about 17 million tons of lignite and coal from formations newer than the coal measures in Europe. Nearly one-half of the total is raised in the United Kingdom, the approximate quantities of the different countries being as follows :—

	Tons.		
United Kingdom	125,000,000		
United States of America	48,000,000		
Germany......	35,000,000	Lignite,	9,000,000
Belgium	17,000,000		
France...	17,500,000	,,	320,000
Austria......................	4,700,000	,,	5,700,000
New South Wales	1,300,000		
Russia	1,000,000	,,	30,000
Spain	750,000	,,	50,000
India	700,000		
Smaller European States.	125,000	,,	105,000
British North America...	750,000		
Chili.....................	200,000		
Other Australian Colonies	50,000		

There is no trustworthy information as to the produce of China and Japan, but these probably do not exceed 100,000 tons. In the larger coal-producing European countries the output was very high in 1873, the following year having shown a slight falling off, but in America the annual increase was maintained.

According to the official mineral statistics, the produce of coal in the United Kingdom for the years 1873, 1874, 1875, classified according to districts, was as shown in the following table, from which it will be seen that the check in 1874 was followed by great increase of production in 1875 :—

	1873.	1874.	1875.
	Tons.	Tons.	Tons.

Amount exported, including coke and patent fuel...	12,748,390	14,045,325	14,544,916
Leaving for home consumption	115,268,357	111,022,591	117,363,189
Valne at pit s mouth..	£47,029,787	£45,848,194	£43,969,370

The quantities of coal consumed by the different branches of manufacturing industry as well as for lighting, heating, and other purposes, was investigated by the Royal Commission on Coal, from vol. iii. of whose Report, published in 1870, the following summary is taken. The figures refer to the year 1869.

			Tons.
Total ouantity of coal raised		....	107,427,537
Do.		exported..................	9,775,470
Leaving for home consumption		....	97,652,087
1.	Coal used for	iron mauufacture	32,446,606
2.	Do.	producing power and general manufacturing purposes...	25,327,213
3.	Do.	domestic purposes	18,481,527
4.	Do.	gas and water supply.........	7,811,980
5.	Do.	mines and collieries	7,225,423
6.	Do.	steam navigation	3,277,562
7.	Do.	railways	2,027,500
8.	Do.	smelting metals other than iron	859,231
9.	Do.	miscellaneous purposes	195,045
			97,652,087

The above quantities may be proportionally classified as follows :—

Mineral and metallurgical industries (1, 5, 8)	44	per cent.
Domestic consumption, including gas and water (3, 4)	26	,,
General manufacturing purposes (2)	25	,,
Locomotion by sea and land (6, 7)	5	,,
	100	

Coal-mining is unfortunately a dangerous occupation, more than a thousand deaths from accident being reported annually by the inspectors of mines as occurring in the collieries of the United Kingdom. The following table shows the number of lives lost during the last five years, classified according to the inspectors' returns :—

Year.	Explosions of fire-damp.	Falls of ground.	Other underground accidents.	Accidents in shafts.	Accidents at surface.	Total.
1871	269	435	176	123	72	1075
1872	154	456	217	155	78	1060
1873	100	491	221	171	86	1069
1874	166	413	214	154	109	1056
1875	288	458	227	172	99	1244

The principal sources of danger to the collier, as distinguished from other miners, are explosion of fire-damp and falls of roof in getting coal,—these together make up about 70 per cent. of the whole number of deaths. It will be seen that the former class of accidents, though attended with great loss of life at one time, are less fatal than the latter. The great increase in the deaths from explosion in 1875, over the preceding year, is to be attributed to the Swaithe Main explosion at Barnsley on December 6th, when 143 lives were lost.

The following return expresses the relation between the fatal accidents and the total number of miners employed, and the amount of coal raised for each death. The latter quantities are in some degree conjectural, being dependent upon estimated returns of produce, and are probably somewhat too large.

Year.	1 death for	
1871......	345 miners employed	109,246 tons coal raised
1872......	394 ,, ,,	116,409 ,, ,,
1873......	479 ,, ,,	133,667 ,, ,,
1874.....	510 ,, ,,	133,251 ,, ,,
1875......	430 ,, ,,	118,730 ,, ,,

In Prussia, in the year 1874, there were 484 deaths from accidents, which corresponds to about three deaths per thousand hands employed, or, according to the above classification, 1 in 334, with a produce of about 65,000 tons of coal for each death. It would appear, therefore, that the proportional loss of life, in the collieries of the United Kingdom, is less than that in foreign countries.

Assay and Analysis.—The chemical examination of a coal may be either complete or partial. When it is desired to obtain information as to the exact composition, the analysis is conducted in the same manner as the analysis of organic compounds by combustion with oxide of copper or chromate of lead in a hard glass tube, the carbonic acid and water formed being absorbed by solution of hydrate of potassium and dry chloride of calcium respectively, and the proportion of carbon and hydrogen being calculated from the increase of weight in the tubes containing the absorbing media. It is usual to operate upon a small sample (about 5 grains), which is very finely powdered and placed in a small trough or boat of platinum in the tube, the combustion being aided by a stream of oxygen from a gasholder. By this means the incombustible residue or ash is left in a condition for weighing, being free from admixture of foreign substances. Sulphur is determined by the fusion of a weighed quantity with a mixture of salt and nitrate of potassium in a platinum vessel, producing sulphate of potassium, which, on the addition of a salt of barium, is precipitated as sulphate of barium. Care must be taken to perform the operation over a flame free from the vapour of sulphur compounds, which may vitiate the result by apparently increasing the amount of sulphur present. For this reason, the flame of a spirit lamp is to be preferred in making the fusion to that of coal gas, which is rarely free from sulphur compounds. Sulphur existing in the form of gypsum or sulphate of calcium may be removed by washing a sample with boiling water, and determining the sulphuric acid in the solution. The washed sample is then fused with nitre in the usual way to determine the proportion of sulphur existing as iron pyrites. This distinction is of importance in the examination of coals intended for iron smelting, as the sulphates of the earthy metals are reduced by the gases of the furnace to sulphides, which pass into the slag without affecting the quality of the iron produced, while the sulphur of the metallic sulphides in the ash acts prejudicially upon the metal.

The difference between the original weight of the sample and that of the carbon, hydrogen, sulphur, and ash, after making allowance for hygroscopic water, is attributed to oxygen and nitrogen, which are not directly determined.

The character of the ash affords some guide to the quality of the coal from which it is derived. Thus, a red tint is generally indicative of the presence of iron pyrites, and a light or white colour of its absence. Phosphorus if present will be found in the ash, and may be determined by the ordinary processes of analysis. A useful approximate method of determining the character of a coal is by exposing a coarsely powdered sample of known weight, in a covered crucible, to a strong red heat as long as inflammable vapours are given off, when it is cooled and weighed. The loss of weight represents the volatile constituents—hydrogen, oxygen, and hydrocarbon gases, produced by destructive distillation, while the residual coke includes the ash, and is called fixed carbon. The character of the button of coke obtained is a good indication as to the caking or non-caking quality of the coal from which it is derived, and the amount of ash may be determined by burning it in a muffle or over the flame of a Bunsen burner. The fitness of a coal for gas-making is usually determined by operating upon a sample of a few pounds' weight in a special apparatus which reproduces the processes of manufacture upon a small scale.

One of the most important factors in the economic valuation of a coal, is the so-called calorific power or value, by which is usually understood the number of pounds of water at boiling point that can be evaporated by the complete combustion of one pound of coal. This may be obtained theoretically, when the composition of the coal is known, by computing the heating effect of the carbon and the disposable hydrogen; but in the absence of an analysis, it may also be determined directly by several approximate methods. One of the most convenient instruments for this purpose is Thompson's calorimeter. This consists of a copper cylinder in which a weighed quantity of coal intimately mixed with chlorate or nitrate of potassium is deflagrated under a copper case like a diving-bell, placed at the bottom of a deep glass jar filled with a known weight of water. The gases produced by the combustion rising through the water are cooled, with a corresponding increase of temperature in the latter, so that the difference between the temperature observed before and after the experiment furnishes a measure of the evaporative power desired. The instrument is so constructed that 30 grains of coal are burnt in 29,010 grains of water, or in the proportion of 1 to 937, these numbers being selected that the observed rise of temperature in Fahrenheit degrees corresponds to the required evaporative value in pounds, subject only to a correction for the amount of heat absorbed by the mass of the instruments, for which a special co-efficient is required, and must be experimentally determined. Another approximate method, due to Berthier, is based upon the reduction of oxide of lead by the carbon and hydrogen of the coal, the amount of lead reduced affording a measure of the oxygen expended, whence the heating power may be calculated, 1 part of pure carbon being capable of producing $34\frac{1}{2}$ times its weight of lead. The operation is performed by mixing the weighed sample with a large excess of litharge in a crucible, and exposing it to a bright red heat for a short time. After cooling, the crucible is broken and the reduced button of lead is cleaned and weighed. The results obtained by this method are less accurate with coals containing much disposable hydrogen and iron pyrites than with those approximating to anthracite, as the heat equivalent of the hydrogen in excess of that required to form water with the oxygen of the coal is calculated as carbon, while it is really about four times as great. Sulphur in iron pyrites also acts as a reducing agent upon litharge, and increases the apparent effect in a similar manner.

The theoretical evaporative power of a coal found by either of the above methods is always considerably above that obtained by actual combustion under a steam boiler, as in the latter case numerous sources of loss, such as imperfect combustion of gases, loss of unburnt coal in cinders, &c., come into play, which cannot be allowed for in theoretical experiments. It is usual, therefore, to determine the value of a coal by the combustion of a weighed quantity in the furnace of a standard boiler, and measuring the amount of water evaporated by the heat developed. Various investigations of this kind have been made at different times, both in Europe and America, the most extensive being the following:—

Johnson, *Report on American Coals*, Washington, 1844; De la Beche and Playfair, *Three Reports on Coal suited to the Steam Navy*, London, 1848-49-51; P. W. Brix, *On the Heating Power of Fuel used in Prussia*, Berlin, 1853; Hartig, *Heating Power of Saxon Coal*, Dresden, 1860.

The following table of the average results obtained from these investigations shows the number of pounds of water evaporated for every pound of the different kinds of coal burnt.

The literature relating to coal and coal mining, is very extensive, but tho following list includes the titles of the moro important works upon these subjects.

ENGLAND AND AMERICA.—*The Report of the Royal Coal Commission* (3 vols., fol., with Atlas, London, 1870) This is the most comprehensive work upon the subject Hull, *Coal Fields of Great Britain* (3d ed. London, 1873). *Reports and Maps of the Geological Surveys of the United Kingdom.* Descriptive memoirs of each coal field published as completed. Percy, *Metallurgy*, vol. i., on Fuel (2d ed. London, 1875), containing full details of the chemistry of coal. Greenwell, *Practical Treatise on Mine Engineering* (2d ed. London, 1869). André, *Practical Treatise on Coal Mining* (London, 1876). Smyth, *Coal and Coal Mining* (2d ed. London 1872). Jevons, *The Coal Question* (2d ed. London, 1866). Rogers, *Geology of Pennsylvania* (2 vols., Edinburgh, 1850). *Proceedings of the South Wales Institute of Engineering* (8 vols., Merthyr, 1858-73). *Transactions of the North of England Institute of Mining Engineers* (23 vols., Newcastle, 1852-74). Various Geological Reports of the State and General Governments of the United States; including Newberry's *Ohio Reports*, Cox's *Indiana Reports*, and Hayden's *Reports of Geological Survey of the Territories.*

FRANCE AND BELGIUM.—Burat, *Géologie de la France* (8vo. Paris, 1864). *Cours d'Exploitation de Mines* (1871). *Matériel des Houillières en France, &c.* (1861-68). *Bulletin de la Société de l'Industrie Minérale, S. Etienne* (20 vols. since 1855). Ponson, *Traité de l'Exploitation des Mines de Houille* (2d ed. Liege, 1868-71). Supplement to the above (1867-72). De Kuyper, *Revue Universelle des Mines, &c.* (Liége, since 1854).

GERMANY.—Geinitz, *Die Steinkohlen Deutschlands, &c.* (3 vols. 4to, Munich, 1865). This is the most complete book on the subject. Zincken, *Die Braunkohle* (2 vols., Hanover, 1865-71) *Zeitschrift fur Berg Hütten und Salinenwesen, &c.* (4to. Berlin, 22 vols. since 1851) (H. B.)

COANZA, or QUANZA, an important river of Western Africa, in the country of Angola. It takes its rise in the Mossamba Mountains, not far from the source of the Cunene, probably in 14° S. lat., and its total length is about 600 miles It receives a large number of tributaries, the most important of which are the Loando and the Cutato in the upper part of its course, the Gango and the Quige in the middle portion, and the Lucalla in the lower. Its progress is broken by several falls, and in the last 200 miles of its journey it descends no less than 4800 feet This diminishes its value as a means of transit; but it is navigable for large boats about 140 miles from its mouth, which is situated 50 miles south of Loando, in 9° 15′ S. lat. It there forms a number of islands, and pours into the sea a turbid current, which is visible for some distance outwards by its contrast of colour.

COATBRIDGE, a town of Scotland, in the county of Lanark, and parish of Old Monkland, ten miles east of Glasgow by rail, and about two miles west of Airdrie. It owes it rise to the importance of the surrounding district as a mining field. The town itself is of a straggling description, and is intersected by a branch of the North Calder Water, the Monkland Canal, and the Caledonian Railway. It contains eight places of worship, a literary association, and five branch banks. In the immediate neighbourhood are the Gartsherrie iron works, and there are engineering establishments in the town itself. The population of town in 1871, including Gartsherrie, High Sunnyside, and Langloan, numbered 15,802, of whom 8599 were males and 7203 females.

COBALT, a metal of the iron group. The name is derived from the German *Kobold*, a miner's term for gnome, or evil spirit, akin to the English *goblin*, which was applied to a mineral found associated with silver ores, and often replacing them in the mines of Schneeberg in Saxony. The use of the oxide of cobalt in colouring glass was only discovered in 1540 by Scheurer, and till then the metal had been supposed to be worthless It was first produced, but in an imperfectly purified condition, in 1733, by Brandt.

Cobalt is found alloyed in small quantity together with nickel in many meteoric irons. The principal mode of occurrence, however, is in various complex minerals containing arsenic and sulphur and the allied metal nickel. The following are the most important:—

1. Smaltine or speiss cobalt, an arsenide of the isomorphous bases, cobalt, nickel, and iron, of the formula $(CoNiFe)As_2$, is a mineral of the cubical system, forming steel or lead-grey crystals of a metallic lustre, tarnishing in damp air to a pink or green tint according to the preponderance of cobalt or nickel that is present. In the purest condition it may contain 28·2 per cent. of cobalt to 71·8 per cent. of arsenic, but nickel and iron are almost invariably present to some extent. The principal locality is at Schneeberg in Saxony, where it is associated with silver, bismuth, and nickel ores.

2. Cobalt glance, or cobaltine, is a compound of sulphide and arsenide of cobalt, $CoS_2 + CoAs_2$, the typical composition being cobalt 35·5, arsenic 45·2, and sulphur 19·3 per cent. It occurs in very brilliant complex crystals belonging to the cubical system, the principal locality being at Tunaberg in Sweden. A part of tho metal is sometimes replaced by iron, but as a rule it is free from nickel.

3. Linnæite, or cobalt pyrites, is analogous in composition to copper pyrites, being represented by the formula $Co_2S + Co_2S_3$, with 58 per cent. of cobalt and 42 of sulphur. As a general rule a portion of the base is replaced by copper, nickel, or iron. It is a rare mineral, being found only in the Siegen district in Prussia and in Sweden. Cobalt bloom is a hydrated arseniate produced by the action of air and water upon the above minerals; the composition is $Co_3As_2O_8 + 8H_2O$, *i.e.*, 37½ per cent. of oxide of cobalt. Earthy cobalt ore is a variety of bog manganese, or wad, a mineral of indefinite composition, but containing at times as much as 8 or 10 per cent. of oxide of cobalt with oxides of manganese, iron, and copper. Cobaltic bismuth ore is a mixture of finely crystalline speiss cobalt with native bismuth, found occasionally in the Schneeberg mines.

The materials from which cobalt is produced by the smelter consist generally of iron or arsenical pyrites, containing a minute quantity of the two metals cobalt and nickel, or various products derived from the smelting of the ores of silver and copper in which these metals are concentrated as sulphur or arsenic compounds.

When in a compact form cobalt is a steel-grey metal with a slightly reddish tint, taking a very high lustre when polished, and breaking with a finely granular fracture. The specific gravity is variously stated at from 8·52 to 8·70. It is slightly malleable, and when quite pure of a higher degree of tenacity than iron, according to Deville. The brittle character attributed to it by former observers is due to impurities, such as arsenic and manganese. It melts at about the same temperature as iron, or a little lower, requiring the strongest heat of a wind furnace. The specific heat is 0·10696 (Regnault). It is susceptible of being magnetized by touch, and retains its magnetism at temperatures below a strong red heat when free from arsenic. Chemically it belongs to the same group as iron, zinc, nickel, manganese, and chromium, which cannot be separated as sulphides by H_2S from an acid solution. It is diatomic; its atomic weight is 58·6, and its symbol Co. Like iron it may be reduced from its oxides by heating with charcoal or in hydrogen gas; in the former case a small quantity of carbon is retained, forming a substance analogous to cast-iron. When reduced by hydrogen at a low temperature it forms a black powder which is pyrophoric, or ignites spontaneously in the air, especially if mixed with finely-divided alumina. At a red heat it decomposes water vapour, producing hydrogen and oxide of cobalt.

There are two principal oxides. The protoxide, CoO, is obtained as a black powder by calcining the hydrate CoH_2O_2. The latter is a red substance obtained by precipitation with alkalies from the solution of a cobalt salt. The higher, or sesquioxide, Co_2O_3, is produced in a hydrated form from the hydrated protoxide by the action of chlorine, bromine, chloride of lime, or similar oxidizing agents. It may be rendered anhydrous by careful heating, but at a red heat it decomposes, giving off part of its oxygen, and produces a compound analogous in composition to magnetic oxide of iron, Fe_3O_4.

The protoxide forms numerous salts, which are usually of a fine rose-red colour. A weak solution of the nitrate or chloride forms the so-called *sympathetic ink*, which gives a colourless writing when cold, but appears of a bluish-green colour when heated, and fades again on cooling. This effect may be reproduced a great number of times if the writing is not too strongly heated, in which case the colour becomes permanent from the formation of a basic salt. With ammonia the oxides of cobalt form a series of compound bases, which give rise to salts of great interest and complexity; these may be regarded as ammonium salts, in which part of the hydrogen is replaced by ammonium and another part by cobalt in various conditions of atomicity corresponding to the oxides.

The alloys of cobalt are not of much importance. It combines most readily with arsenic or antimony, forming the highly crystalline compounds known by the general name of *speiss*, which can scarcely be considered as alloys. With gold and silver it forms brittle compounds, with mercury a silver-white magnetic amalgam. With copper and zinc the alloy is white, resembling the corresponding compounds of the same metals with nickel and manganese. With tin it forms a somewhat ductile alloy of a violet colour. The presence of cobalt in the alloy of copper, zinc, and nickel, known as German silver, is objectionable, as it renders it hard and difficult to roll.

The chief use of cobalt in the arts is for the preparation of colours. The protoxide has an intense colouring power when vitrified, and forms the basis of all the blue colours used in glass and porcelain manufacture. The purity of the tint is much affected by traces even of other metallic oxides, especially those of iron, nickel, or copper. Another preparation, known as *smalts*, is a glass formed by melting cobalt oxide with pure quartz sand and carbonate of potassium. Sometimes the first two substances are subjected to a preliminary heating to produce fritted silicate of a reddish or purple colour, known as *zaffre*, which when fused with the alkaline carbonate in an ordinary glass furnace produces a deep blue glass. This is rendered friable by running it into water, and is then ground between granite millstones, and finally levigated in water. The various products of the levigation are classified into different qualities according to the fineness of the grain and the strength of the colour,—the best being those occupying a medium position, the colour diminishing as the fineness of the grain increases. The coarsest variety, known as strewing blue, consisting of rough angular fragments up to about $\frac{1}{8}$ inch diameter, is used for the ground-work of the old-fashioned blue and gold signboards, a very effective and durable kind of surface ornamentation. The highest coloured varieties contain from 6 to 7 per cent. of oxide of cobalt. Glass containing only $\frac{1}{250}$th part of the oxide is of a distinct blue: with more than 18 per cent. it is black.

The principal use of smalts is for bluing paper; it was formerly employed almost exclusively for this purpose, but has now been to a very considerable extent superseded by the use of artificial ultramarine, which is cheaper and more easily applied, but is less permanent, as the colour is easily discharged by acids, which is not the case when smalts is used. The pigment known as cobalt blue, used both in oil and water-colour painting, is obtained by mixing the solutions of a cobalt salt and alum, precipitating with an alkaline carbonate, and strongly heating the gelatinous precipitate of the hydrated oxides of the two metals. Thenard's blue, a phosphate of cobalt and alumina, is produced in a similar manner, by precipitation with an alkaline phosphate. Cobalt green, or Rinman's green, is a mixture of the oxides of zinc and cobalt produced from the solutions of their sulphates by precipitation with carbonate of sodium and ignition.

In analysis cobalt is always determined as protoxide, but the separation from the metals with which it is usually associated, especially nickel, is a difficult and tedious operation. Many different processes have been devised, but the most accurate are those of H. Rose and Liebig. The former depends upon the power possessed by chlorine (or bromine) of converting protoxide of cobalt when in solution into sesquioxide, while the corresponding oxide of nickel is not changed. The solution when completely saturated with chlorine is precipitated by carbonate of barium, which carries down the whole of the cobalt as sesquioxide; the precipitate is redissolved in hydrochloric acid, the whole of the barium salt separated by sulphuric acid, and the cobalt finally precipitated by means of hydrate of potassium. In Liebig's method the oxides of the two metals are heated with cyanide of potassium and boiled, which produces cobalticyanide of potassium, $K_2Co_2Cy_6$, and cyanide of nickel and potassium, $KNiCy_2$. By the addition of finely-divided red oxide of mercury the whole of the nickel is precipitated, partly as cyanide and partly as hydrate, while the cobalt compound remains in solution, and is afterwards separated by means of sulphate of copper as cobalticyanide of copper, which is redissolved; the copper is separated by sulphuretted hydrogen, and the cobalt then obtained as oxide by boiling with caustic potash. The complexity of the composition of the ores, and the high value of the two metals, has led to the application of more refined methods of chemical analysis in their investigation than are required in the assay of the ores of the commoner metals. Plattner's method of dry assay of cobalt and nickel ores is much more rapidly performed than an analysis, and in practised hands is susceptible of considerable accuracy. It depends upon the fact that when a speiss or arsenical compound, containing the four metals—iron, cobalt, nickel, and copper—is melted with a vitreous flux such as borax in an oxidizing atmosphere, the metals will be oxidized and pass into a slag with the borax in the order indicated above, no cobalt being taken up until the iron has been entirely removed, and similarly the nickel remaining until the cobalt has been completely oxidized. The steps in the process may be easily recognized owing to the difference in the characteristic colour of the oxides, the dark green or black of the iron slag being rendered distinctly blue by the faintest trace of cobalt, and the blue of the latter being similarly affected by nickel, which has a strong brown colouring power. The arsenides of cobalt and nickel, being of a constant composition, are weighed at each step of the process in the proportion of the metal removed calculated from the difference. Cobalt may be readily detected by the blow-pipe even when in very small quantity, or by the characteristic blue imparted to a bead of borax or salt of phosphorus.

On the large scale cobalt is produced chiefly as an accessory in the treatment of nickel ores. These consist chiefly of mixtures of small quantities of the purer minerals with pyrites, sulphuretted copper ores, or lead and silver ores, which require to be subjected to concentrating processes in order to get rid of the bulk of the iron, sulphur, and arsenic, and produce a small amount of enriched regulus or metal, in which the more valuable metals are in combination with sulphur and arsenic. This is done by calcination, which drives off the sulphur and arsenic combined with the iron, the latter being oxidized and subsequently converted into slag by fusion with fluxes containing silica. Small quantities of cobalt, nickel, and copper ores, when associated with lead and silver ores, are in like manner gradually accumulated in a regulus by passing the regulus of the first fusion several times through the smelting furnace, whereby the lead and silver are in great part removed. The treatment of these purified and enriched products is conducted on the large scale in a somewhat similar manner to a chemical analysis, in order to obtain both cobalt and nickel. The speiss, or regulus, is calcined and treated with strong hydrochloric acid to dissolve the oxides formed. By the addition of caustic lime, iron and arsenic are precipitated, and the clear liquid is treated with sulphuretted hydrogen so long as metallic sulphides are produced, the precipitate being allowed to settle. The solution then containing only cobalt and nickel compounds, the former is separated by the addition of bleaching powder and caustic lime as sesquioxide, Co_2O_3, and the latter as hydrated oxide by a subsequent precipitation with lime.

In making smalts the purer arsenical ores are used. They are first calcined in a reverberatory or muffle furnace provided with chambers for condensing the arsenical fumes as completely as possible. The roasted ore, if it does not contain quartz, is mixed with a proportion of fine glass-house sand and carbonate of potassium, but when it is sufficiently siliceous, as in the mixtures of cobalt ore and silica known as zaffre, only the alkaline carbonate is required. The fusion takes place in pots like those used in plate-glass making, and requires about eight hours. The blue glass is led out into water till the pot is nearly empty, when a speiss containing the whole of the nickel of the ore is found at the bottom. The blue glass is then ground and levigated as already described.

The chief localities producing cobalt ores are Modum in Norway, Tunaberg in Sweden, Schneeberg in Saxony, Musen in Rhenish Prussia, and Mine Lamotte in Missouri; a considerable amount has also been obtained from Bolivia. In the Transvaal in South Africa a very pure variety of speiss cobalt free from nickel has been recently discovered. Smaller quantities of speiss or regulus are obtained from the smelting of silver and lead ores, at Freiberg, in the Harz, in Bohemia, and elsewhere. (H. B.)

COBÁN, or SANTO DOMINGO COBAN, a city of Central America, in the republic of Guatemala, and the department of Vera Paz, situated about 90 miles north of the city of Guatemala, on the direct route to Flores, not far from the source of the Rio de Cajabon, which flows into the Golfo Dolce. It occupies the slopes of a rounded hill, on the top of which is the central square or plaza, with the cathedral and the ruins of the once magnificent Dominican monastery on the one side, and on the others the shops and houses of the merchants and artizans. The houses of Cobán are low and covered with tiles; and, as each with its garden and croft attached is curtained by a dense and lofty hedge, the streets have rather the appearance of woodland avenues. The cathedral is a large and imposing edifice, decorated in the interior with a barbaric profusion of ornament; but like the rest of the public buildings of the town it shows signs of decay. Since the removal of the seat of the Provincial Government to Salama, the prosperity of Cobán has greatly declined, but it still contains about 12,000 inhabitants, who carry on the weaving of cotton cloth, the cultivation of coffee, sugar, and pimento, and a considerable trade with the neighbouring provinces. The Spanish and Ladino part of the population does not exceed 2000; and the rest are Indians originally from the mountains of Chichen and Jucamel, who still speak the Kacchi or Quecchi language. Cobán owes its origin to the missionary labours of the Dominicans of the 16th century, and more especially to Fray Pedro de Angulo, whose portrait is preserved in the cathedral. It was made the political capital of the province of Vera Paz, and obtained the arms of a city of the first rank.

COBBETT, WILLIAM (1766–1835), one of the most vigorous of English political writers, was born near Farnham in Surrey, according to his own statement, on the 9th March 1766. He was the grandson of a farm-labourer, and the son of a small farmer; and during his early life he worked on his father's farm. At the age of sixteen, inspired with patriotic feeling by the sight of the men-of-war in Portsmouth harbour, he offered himself as a sailor; and at seventeen (May 1783) having, while on his way to Guildford fair, met the London coach, he suddenly resolved to accompany it to its destination. He arrived at Ludgate Hill with exactly half-a-crown in his pocket, but an old gentleman who had travelled with him invited him to his house, and obtained for him the situation of copying clerk in an attorney's office. He greatly disliked his new occupation; and rejecting all his father's entreaties that he would return home, he went down to Chatham early in 1784 with the intention of joining the marines. By some mistake, however, he was enlisted in a regiment of the line, which rather more than a year after proceeded to St John's, New Brunswick. All his leisure time during the months he remained at Chatham was devoted to reading the contents of the circulating library of the town, and getting up by heart Lowth's *English Grammar*. His uniform good conduct, and the power of writing correctly which he had acquired, quickly raised him to the rank of corporal, from which, without passing through the intermediate grade of sergeant, he was promoted to that of sergeant-major. In November 1791 he was discharged at his own request, and received the official thanks of the major and the general who signed his discharge. But Cobbett's connection with the regiment did not end in this agreeable manner. He brought a serious charge against some of its officers, and instead of appearing at the trial fled to France (March 1792). The inquiry which was held in his absence resulted in a complete acquittal of the accused.

In the previous February Cobbett had married the daughter of a sergeant-major of artillery; he had met her some years before in New Brunswick, and had proved her to be endowed with energy and self-control equal to his own. In September of the same year (1792) he crossed to the United States, and for a time supported himself at Wilmington by teaching English to French emigrants. Among these was Talleyrand, who employed him, according to Cobbett's story, not because he was ignorant of English, but because he wished to purchase his pen. Cobbett made his first literary sensation by his *Observations on the Emigration of a Martyr to the Cause of Liberty*, a clever retort on Dr Priestley, who had just landed in America complaining of the treatment he had received in England. This pamphlet was followed by a number of papers, signed "Peter Porcupine," and entitled *Prospect from the Congress Gallery*, the *Political Censor*, and the *Porcupine's Gazette*. In the spring of 1796, having quarrelled with his publisher, he set up in Philadelphia as bookseller and publisher of his own works. On the day of opening, his windows were filled with prints of the most extravagant of the French Revolutionists and of the founders of the American Republic placed side by side, along with portraits of George III., the British ministers, and any one else he could find likely to be obnoxious to the people; and he continued to pour forth praises of Great Britain and scorn of the institutions of the United States, with special abuse of the French party. Abuse and threats were of course in turn showered upon him, and in August, for one of his attacks on Spain, he was prosecuted, though unsuccessfully, by the Spanish ambassador. Immediately on this he was taken up for libels upon American statesmen, and bound in recognizances to the amount of $4000, and shortly after he was prosecuted a third time for saying that a certain Dr Rush, who was much addicted to bleeding, killed nearly all the patients he attended. The trial was repeatedly deferred, and was not settled till the end of 1799, when he was fined $5000. After this last misfortune, for a few months Cobbett carried on a newspaper called the *Rushlight;* but in June 1800 he set sail for England.

At home he found himself regarded as the champion of order and monarchy. Windham invited him to dinner, introduced him to Pitt, and begged him to accept a share in the *True Briton.* He refused the offer and joined an old friend, John Morgan, in opening a book shop in Pall Mall. For some time he published the *Porcupine's Gazette*, which was followed in January 1802 by the *Weekly Political Register.* In 1801 appeared his Letters to Lord Hawkesbury (afterwards earl of Liverpool) and Mr Addington, in opposition to the peace of Amiens, the terms of which had been agreed to by the former on behalf of Great Britain in the October of that year, but which was not finally concluded till 1802. On the conclusion of the peace Cobbett made a still bolder protest; he determined to take no part in the general illumination, and—assisted by the sympathy of his wife, who, being in delicate health, removed to the house of a friend—he carried out his resolve, allowing his windows to be smashed and his door broken open by the angry mob. The *Letters to the Rt. Hon. Henry Addington* are among the most polished and dignified of Cobbett's writings; but by 1803 he was once more revelling in personalities. The government of Ireland was singled out for wholesale attack; and a letter published in the *Register* remarked of Hardwicke, the lord-lieutenant, that the appointment was like setting the surgeon's apprentice to bleed the pauper patients. For this, though not a word had been uttered against Hardwicke's character, Cobbett was fined £500; and two days after the conclusion of this trial a second commenced, at the suit of Plunkett, the solicitor-general for Ireland, which resulted in a similar fine. About this time he began to write in support of Radical views; and to cultivate the friendship of Sir Francis Burdett, from whom he received considerable sums of money, and other favours, for which he gave no very grateful return. In 1809 he was once more in the most serious trouble. He had bitterly commented on the flogging of some militia, because their mutiny had been repressed and their sentence carried out by the aid of a body of German troops, and in consequence he was fined £1000 and imprisoned for two years. His indomitable vigour was never better displayed. He still continued to publish the *Register*, and to superintend the affairs of his farm; a hamper containing specimens of its produce and other provisions came to him every week; and he amused himself with the company of some of his children and with weekly letters from the rest. On his release a public dinner, presided over by Sir F. Burdett, was held in honour of the event. He returned to his farm at Botley in Hampshire, and continued in his old course, extending his influence by the publication of the *Twopenny Trash*, which, not being periodical, escaped the newspaper stamp tax. Meanwhile, however, he had contracted debts to the amount of £34,000 (for it is said that, notwithstanding the aversion he publicly expressed to paper currency, he had carried on his business by the aid of accommodation bills to a very large amount); and in March 1817 he fled to the United States. But his pen was as active as ever; from Long Island the *Register* was regularly despatched to England; and it was here that he wrote his clear and interesting *English Grammar*, of which 10,000 copies were sold in a month.

His return to England was accompanied by his weakest exhibition—the exhuming and bringing over of the bones of Tom Paine, whom he had once heartily abused, but on whom he now wrote a panegyrical ode. Nobody paid any attention to the affair; the relics he offered were not purchased; and the bones were reinterred.

Cobbett's great aim was now to obtain a seat in the House of Commons. He calmly suggested that his friends should assist him by raising the sum of £5000; it would be much better, he said, than a meeting of 50,000 persons. He first offered himself for Coventry, but failed; in 1826 he was by a large number of votes last of the candidates for Preston; and in 1828 he could find no one to propose him for the office of common councillor. In 1830, that year of revolutions, he was prosecuted for inciting to rebellion, but the jury disagreed, and soon after, through the influence of one of his admirers, Mr Fielden, who was himself a candidate for Oldham, he was returned for that town. In the House his speeches were listened to with amused attention. His position is sufficiently marked by the sneer of Peel that he would attend to Mr Cobbett's observations exactly as if they had been those of a "respectable member;" and the only striking part of his career was his absurd motion that the king should be prayed to remove Sir Robert Peel's name from the list of the privy council, because of the change he had proposed in the currency in 1819. In 1834 Cobbett was again member for Oldham, but his health now began to give way, and in June 1835 he left London for his farm, where he died on the 16th of that month.

Cobbett's account of his home-life makes him appear singularly happy; his love and admiration of his wife never failed; and his education of his children seems to have been distinguished by great kindliness, and by a good deal of healthy wisdom, mingled with the prejudices due to the peculiarities of his temper and circumstances. Cobbett's ruling characteristic was a sturdy egotism, which had in it something of the nobler element of self-respect. A firm will, a strong brain, feelings not over-sensitive, an intense love of fighting, a resolve to get on, in the sense of making himself a power in the world—these are the principal qualities which account for the success of his career. His opinions were the fruits of his emotions. It was enough for him to get a thorough grasp of one side of a question, about the other side he did not trouble himself; but he always firmly seizes the facts which make for his view, and expresses them with unfailing clearness. His argument, which is never subtle, has always the appearance of weight, however flimsy it may be in fact. His sarcasm is seldom polished or delicate, but usually rough, and often abusive, while coarse nicknames were his special delight. His style is always extremely forcible, and marked by unusual grammatical correctness.

Cobbett's contributions to periodical literature occupy 100 volumes, twelve of which consist of the papers published at Philadelphia between 1794 and 1800, and the rest of the *Weekly Political Register*, which ended only with Cobbett's life (June 1835). An abridgment of these works, with notes, has been published by his sons, John M. Cobbett and James P. Cobbett. Besides this he published—*An Account of the Horrors of the French Revolution*, and a work tracing all these horrors to "the licentious politics and infidel philosophy of the present age" (both 1798); *A Year's Residence in the United States; Parliamentary History of England from the Norman Conquest to* 1800 (1806); *Cottage Economy; Roman History; French Grammar*, and *English Grammar*, both in the form of letters; *Geographical Dictionary of England and Wales; History of the Regency and Reign of George IV.*, containing a defence of Queen Caroline, whose cause he warmly advocated (1830–4); *Life of Andrew Jackson, President of the United States* (1834); *Legacy to Labourers; Legacy to Peel; Legacy to Parsons*, an attack on the secular claims of the Established Church; *Doom of Tithes; Rural Rides; Advice to Young Men and Women; Cobbett's Corn;* and *History of the Protestant Reformation in England and Ireland*, in which he defends the monasteries, Queen Mary, and Bonner, and attacks the Reformation, Henry VIII., Elizabeth, and all who helped to bring it about, with such vehemence that the work was translated into French and Italian, and extensively circulated among Roman Catholics.

In 1798 Cobbett published in America an account of his early life, under the title of *The Life and Adventures of Peter Porcupine*; and he left papers relating to his subsequent career. These materials were embodied in an anonymous *Life of Cobbett* which appeared soon after his death. See also Sir Henry Bulwer's *Historical Characters; Biographies of John Wilkes and William Cobbett* by Rev. John Watson; and the abridged and annotated edition of the *Register*.

COBDEN, Richard (1804–1865), was born at a farm-house called Dunford, near Midhurst, in Sussex, on the 3d of June 1804. The family had been resident in that neighbourhood for many generations, occupied partly in trade and partly in agriculture. Formerly there had been in the town of Midhurst a small manufacture of hosiery with which the Cobdens were connected, though all trace of it had disappeared before the birth of Richard. His grandfather was a maltster in that town, an energetic and prosperous man, almost always the bailiff or chief magistrate, and taking rather a notable part in county matters. But his father, forsaking that trade, took to farming at an unpropitious time. He was amiable and kind-hearted, and greatly liked by his neighbours, but not a man of business habits, and he did not succeed in his farming enterprise. He died when his son Richard was a child, and the care of the family devolved upon the mother, who was a woman of strong sense and of great energy of character, and who, after her husband's death, left Dunford and returned to Midhurst.

The educational advantages of Richard Cobden were not very ample. There was a grammar school at Midhurst, which at one time had enjoyed considerable reputation, but which had fallen into decay. It was there that he had to pick up such rudiments of knowledge as formed his first equipment in life, but from his earliest years he was indefatigable in the work of self-cultivation. When fifteen or sixteen years of age he went to London to the warehouse of Messrs Partridge and Price, in East Cheap, one of the partners being his uncle. His relative noting the lad's passionate addiction to study, solemnly warned him against indulging such a taste, as likely to prove a fatal obstacle to his success in commercial life. Happily the admonition was unheeded, for while unweariedly diligent in business, as his rapid after success abundantly proved, he was in his intervals of leisure a most assiduous student. During his residence in London he found access to the London Institution, and made ample use of its large and well-selected library.

When he was about twenty years of age he became a commercial traveller, and throwing into that, as he ever did into whatever his hand found to do, all the thoroughness and vigour of his nature, he soon became eminently successful in his calling. But never content to sink into the mere trader, he sought to introduce among those he met on the "road" a higher tone of conversation than usually marks the commercial room, and there were many of his associates who, when he had attained eminence, recalled the discussions on political economy and kindred topics with which he was wont to enliven and elevate the travellers' table. In 1830 Cobden learnt that Messrs Fort, calico printers at Sabden, near Clitheroe, were about to retire from business, and he, with two other young men, Messrs Sheriff and Gillet, who were engaged in the same commercial house as himself, determined to make an effort to acquire the succession. They had, however, very little capital among them. But it may be taken as an illustration of the instinctive confidence which Cobden through life inspired in those with whom he came into contact, that Messrs Fort consented to leave to these untried young men a large portion of their capital in the business. Nor was their confidence misplaced. The new firm had soon three establishments,—one at Sabden, where the printing works were, one in London, and one in Manchester for the sale of their goods. This last was under the direct management of Cobden, who, in 1830 or 1831, settled in the city with which his name became afterwards so closely associated. The success of this enterprize was decisive and rapid, and the "Cobden prints" soon became known through the country as of rare value both for excellence of material and beauty of design. There can be no doubt that if Cobden had been satisfied to devote all his energies to commercial life he might soon have attained to great opulence, for it is understood that his share in the profits of the business he had established amounted to from £8000 to £10,000 a year. But he had other tastes, which impelled him irresistibly to pursue those studies which, as Lord Bacon says, "serve for delight, for ornament, and for ability." Mr Prentice, the historian of the Anti-Corn-Law League, who was then editor of the *Manchester Times*, describes how, in the year 1835, he received for publication in his paper a series of admirably written letters, under the signature of "Libra," discussing commercial and economical questions with rare ability. After some time he discovered that the author of these letters was Cobden, whose name was until then quite unknown to him.

In 1835 he published his first pamphlet, entitled *England, Ireland, and America, by a Manchester Manufacturer*. It attracted great attention, and ran rapidly through several editions. It was marked by a breadth and boldness of views on political and social questions which betokened an original mind. In this production Cobden advocated the same principles of peace, non-intervention, retrenchment, and free trade to which he continued faithful to the last day of his life. Immediately after the publication of this pamphlet, he paid a visit to the United States, landing in New York on the 7th June 1835. He devoted about three months to this tour, passing rapidly through the seaboard States and the adjacent portion of Canada, and collecting as he went large stores of information respecting the condition, resources, and prospects of the great Western Republic. Soon after his return to England he began to prepare another work for the press, which appeared towards the end of 1836, under the title of *Russia*. It was mainly designed to combat a wild outbreak of Russophobia which, under the inspiration of Mr Daniel Urquhart, was at that time taking possession of the public mind. But it contained also a bold indictment of the whole system of foreign policy then in vogue, founded on ideas as to the balance of power and the necessity of large armaments for the protection of commerce. While this pamphlet was in the press, delicate health obliged him to leave England, and for several months, at the end of 1836 and the beginning of 1837, he travelled in Spain, Turkey, and Egypt. During his visit to Egypt he had an interview with the redoubtable ruler of that country, Mehemet Ali, of whose character as a reforming monarch he did not bring away a very favourable impression. He returned to England in April 1837. From that time Cobden became a conspicuous figure in Manchester, taking a leading part in the local politics of the town and district. Largely owing to his exertions, the Manchester Athenæum was established, at the opening of which he was chosen to deliver the inaugural address. He became a member of the Chamber of Commerce, and soon infused new life into that body. He threw himself with great energy into the agitation which led to the incorporation of the city, and was elected one of its first aldermen. He began also to take a warm interest in the cause of popular education. Some of his first attempts in public speaking were at meetings which he convened at Manchester, Salford, Bolton, Rochdale, and other adjacent towns, to advocate the establishment of British schools. It was while on a mission for this purpose to Rochdale that he first formed the acquaintance of Mr John Bright, who afterwards became his distinguished coadjutor in the free trade agitation. Nor was it long before his fitness for parliamentary life was recognized by his friends. In 1837, the death of William IV. and the accession of Queen Victoria led to a general election. Cobden was candidate for Stockport, but was defeated, though not by a large majority.

In 1838 an Anti-Corn-Law Association was formed at Manchester, which, on his suggestion, was afterwards changed into a national association, under the title of the Anti-Corn-Law League. This is not the place to recount the history of that famous association, of which from first to last Cobden was the presiding genius and the animating soul. During the seven years between the formation of the league and its final triumph, he devoted himself wholly to the work of teaching his countrymen sound economical doctrines, for the agitation which he and his associates conducted with such signal ability and success was preeminently an educational agitation. His labours were as various as they were incessant,—now guiding the councils of the League, now addressing crowded and enthusiastic meetings of his supporters in London or the large towns of England and Scotland, now invading the agricultural districts, and challenging the landlords to meet him in the presence of their own farmers, to discuss the question in dispute, and now encountering the Chartists led on by Feargus O'Connor, who had deluded a portion of the working classes into fanatical opposition to free frade. But whatever was the character of his audience he never failed, by the clearness of his statements, the force of his reasoning, and the felicity of his illustrations, to carry conviction to the minds of his hearers.

In 1841, Sir Robert Peel having defeated the Melbourne ministry in Parliament, there was a general election, when Cobden was returned for Stockport. His opponents had confidently predicted that he would fail utterly in the House of Commons. He did not wait long, after his admission into that assembly, in bringing their predictions to the test. Parliament met on the 19th August. On the 24th, in course of the debate on the Address, Cobden delivered his first speech. "It was remarked," says Miss Martineau, in her *History of the Peace*, "that he was not treated in the House with the courtesy usually accorded to a new member, and it was perceived that he did not need such observance." With perfect self-possession, which was not disturbed by the jeers that greeted some of his statements, and with the utmost simplicity, directness, and force, he presented the argument against the corn-laws in such a form as startled his audience, and also irritated some of them, for it was a style of eloquence very unlike the conventional style which prevailed in Parliament.

From that day he became an acknowledged power in the House, and though addressing a most unfriendly audience, he compelled attention by his thorough mastery of his subject, and by the courageous boldness with which he charged the ranks of his adversaries. He soon came to be recognized as one of the foremost debaters on those economical and commercial questions which at that time so much occupied the attention of Parliament; and the most prejudiced and bitter of his opponents were fain to acknowledge that they had to deal with a man whom the most practised and powerful orators of their party found it hard to cope with, and to whose eloquence, indeed, the great statesman in whom they put their trust was obliged ultimately to surrender. On the 17th of February 1843 an extraordinary scene took place in the House of Commons. Cobden had spoken with great fervour of the deplorable suffering and distress which at that time prevailed in the country, for which, he added, he held Sir Robert Peel, as the head of the Government, responsible. This remark, when it was spoken, passed unnoticed, being indeed nothing more than one of the commonplaces of party warfare. But a few weeks before, Mr Drummond, who was Sir Robert Peel's private secretary, had been shot dead in the street by a lunatic. In consequence of this, and the manifold anxieties of the time with which he was harassed, the mind of the great statesman was no doubt in a moody and morbid condition, and when he arose to speak later in the evening, he referred in excited and agitated tones to the remark, as an incitement to violence against his person. Sir Robert Peel's party, catching at this hint, threw themselves into a frantic state of excitement, and when Cobden attempted to explain that he meant official, not personal responsibility, they drowned his voice with clamorous and insulting shouts. But Peel lived to make ample and honourable amend for this unfortunate ebullition, for not only did he "fully and unequivocally withdraw the imputation which was thrown out in the heat of debate under an erroneous impression," but when the great free trade battle had been won, he took the wreath of victory from his own brow, and placed it on that of his old opponent, in the following graceful words:—"The name which ought to be, and will be associated with the success of these measures, is not mine, or that of the noble Lord (Russell), but the name of one who, acting I believe from pure and disinterested motives, has, with untiring energy, made appeals to our reason, and has enforced those appeals with an eloquence the more to be admired because it was unaffected and unadorned; the name which ought to be chiefly associated with the success of these measures is the name of Richard Cobden." Cobden had, indeed, with unexampled devotion, sacrificed his business, his domestic comforts, and for a time his health to the public interests. His friends therefore felt, at the close of that long campaign, that the nation owed him some substantial token of gratitude and admiration for those sacrifices. No sooner was the idea of such a tribute started than liberal contributions came from all quarters, which enabled his friends to present him with a sum of £80,000. Had he been inspired with personal ambition, he might have entered upon the race of political advancement with the prospect of attaining the highest official prizes. Lord John Russell, who, soon after the repeal of the corn laws, succeeded Sir Robert Peel as first minister, invited Cobden to join his Government. But he preferred keeping himself at liberty to serve his countrymen unshackled by official ties, and declined the invitation. He withdrew for a time from England. His first intention was to seek complete seclusion in Egypt or Italy, to recover health and strength after his long and exhausting labours. But his fame had gone forth throughout Europe, and intimations reached him from many quarters that his voice would be listened to everywhere with favour.

in advocacy of the doctrines to the triumph of which he had so much contributed at home. Writing to a friend in July 1846, he says,—"I am going to tell you of a fresh project that has been brewing in my brain. I have given up all idea of burying myself in Egypt or Italy. I am going on an agitating tour through the continent of Europe." Then, referring to messages he had received from influential persons in France, Prussia, Austria, Russia, and Spain to the effect mentioned above, he adds:—"Well, I will, with God's assistance, during the next twelve months, visit all the large states of Europe, see their potentates or statesmen, and endeavour to enforce those truths which have been irresistible at home. Why should I rust in inactivity? If the public spirit of my countrymen affords me the means of travelling as their missionary, I will be the first ambassador from the people of this country to the nations of the Continent. I am impelled to this by an instinctive emotion such as has never deceived me. I feel that I could succeed in making out a stronger case for the prohibitive nations of Europe to compel them to adopt a freer system than I had here to overturn our protection policy." This programme he fulfilled. He visited in succession France, Spain, Italy, Germany, and Russia. He was received everywhere with marks of distinction and honour In many of the principal capitals he was invited to public banquets, which afforded him an opportunity of propagating those principles of which he was regarded as the apostle. But beside these public demonstrations he sought and found access in private to many of the leading statesmen, in the various countries he visited, with a view to indoctrinate them with the same principles. During his absence there was a general election, and he was returned for Stockport and for the West Riding of Yorkshire. He chose to sit for the latter.

When Cobden returned from the Continent he addressed himself to what seemed to him the logical complement of free trade, namely, the promotion of peace and the reduction of naval and military armaments. His abhorrence of war amounted to a passion. Throughout his long labours in behalf of unrestricted commerce he never lost sight of this, as being the most precious result of the work in which he was engaged,—its tendency to diminish the hazards of war and to bring the nations of the world into closer and more lasting relations of peace and friendship with each other. He was not deterred by the fear of ridicule or the reproach of Utopianism from associating himself openly, and with all the ardour of his nature, with the peace party in England. In 1849 he brought forward a proposal in Parliament in favour of international arbitration, and in 1851 a motion for mutual reduction of armaments. He was not successful in either case, nor did he expect to be. In pursuance of the same object, he identified himself with a series of remarkable peace congresses—international assemblies designed to unite the intelligence and philanthropy of the nations of Christendom in a league against war—which from 1848 to 1851 were held successively in Brussels. Paris, Frankfort, London, Manchester, and Edinburgh.

On the establishment of the French empire in 1851–2 a violent panic took possession of the public mind. Without the shadow of producible evidence the leaders of opinion in the press promulgated the wildest alarms as to the intentions of Louis Napoleon, who was represented as contemplating a sudden and piratical descent upon the English coast without pretext or provocation. Shocked by this pitiful display of national folly, Cobden did not hesitate to throw himself into the breach and withstand the madness of the hour. By a series of powerful speeches in and out of Parliament, and by the publication of his masterly pamphlet, *1793 and 1853*, he sought to calm the passions of his countrymen. By this course he sacrificed the great popularity he had won as the champion of free trade, and became for a time the best abused man in England. Immediately afterwards, owing to the quarrel about the Holy Places which arose in the east of Europe, public opinion suddenly veered round, and all the suspicion and hatred which had been directed against the emperor of the French were diverted from him to the emperor of Russia. Louis Napoleon was taken into favour as our faithful ally, and in a whirlwind of popular excitement the nation was swept into the Crimean war. Cobden, who had travelled in Turkey, and had studied the condition of that country with great care for many years, utterly discredited the outcry about maintaining the independence and integrity of the Ottoman empire which was the battle-cry of the day. He denied that it was possible to maintain them, and no less strenuously denied that it was desirable even if it were possible. He believed that the jealousy of Russian aggrandizement and the dread of Russian power to which our countrymen delivered themselves at that time were absurd exaggerations. He maintained that the future of European Turkey was in the hands of the Christian population, and that it would have been our wisdom to ally ourselves with them rather than with the doomed and decaying Mahometan power. "You must address yourselves," he said in the House of Commons, "as men of sense and men of energy, to the question—what are you to do with the Christian population? for Mahometanism cannot be maintained, and I should be sorry to see this country fighting for the maintenance of Mahometanism . . . . . You may keep Turkey on the map of Europe, you may call the country by the name of Turkey if you like, but do not think you can keep up the Mahometan rule in the country." The reader may be left to judge how far his sagacity and statesmanship have been vindicated by the event. But for the time the torrent of popular sentiment in favour of war was irresistible; and Messrs Cobden and Bright, who with admirable courage and eloquence withstood what they deemed the delusion of the hour, were overwhelmed with obloquy.

At the beginning of 1857 tidings from China reached England of a rupture between the British plenipotentiary in that country and the governor of the Canton provinces in reference to a small vessel or lorcha called the "Arrow," which had resulted in the English admiral destroying the river forts, burning 23 ships belonging to the Chinese navy, and bombarding the city of Canton. After a careful investigation of the official documents, Cobden became convinced that those were utterly unrighteous proceedings. He brought forward a motion in Parliament to this effect, which led to a long and memorable debate, lasting over four nights, in which he was supported by Mr Sydney Herbert, Sir James Graham, Mr Gladstone, Lord John Russell, and Mr Disraeli, and which ended in the defeat of Lord Palmerston by a majority of sixteen. But this triumph cost him his seat in Parliament. On the dissolution which followed Lord Palmerston's defeat, Cobden became candidate for Huddersfield, but the voters of that town gave the preference to his opponent, who had supported the Russian war and approved of the proceedings at Canton. Cobden was thus relegated to private life, and retiring to his country house at Dunford, he spent his time in perfect contentment in cultivating his land and feeding his pigs.

He took advantage of this season of leisure to pay another visit to the United States. During his absence the general election of 1859 occurred, when he was returned unopposed for Rochdale. Lord Palmerston was again prime minister, and having discovered that the advanced liberal party was not so easily "crushed" as he had apprehended, he made overtures of reconciliation, and invited

Cobden and Milner Gibson to become members of his government. In a frank, cordial letter which was delivered to Cobden on his landing in Liverpool, Lord Palmerston offered him the Presidency of the Board of Trade, with a seat in the Cabinet Many of his friends urgently pressed him to accept; but without a moment's hesitation he determined to decline the proposed honour. On his arrival in London he called on Lord Palmerston, and with the utmost frankness told him that he had opposed and denounced him so frequently in public, and that he still differed so widely from his views, especially on questions of foreign policy, that he could not, without doing violence to his own sense of duty and consistency, serve under him as minister. Lord Palmerston tried good-humouredly to combat his objections, but without success.

But though he declined to share the responsibility of Lord Palmerston's administration, he was willing to act as its representative in promoting freer commercial intercourse between England and France. But the negotiations for this purpose originated with himself in conjunction with Mr Bright and M. Michel Chevalier. Towards the close of 1859 he called upon Lord Palmerston, Lord John Russell, and Mr Gladstone, and signified his intention to visit France and get into communication with the emperor and his ministers, with a view to promote this object. These statesmen expressed in general terms their approval of his purpose, but he went entirely on his own account, clothed at first with no official authority. His name, however, carried an authority of its own. On his arrival in Paris he had a long audience with Napoleon, in which he urged many arguments in favour of removing those obstacles which prevented the two countries from being brought into closer dependence on one another, and he succeeded in making a considerable impression on his mind in favour of free trade. He then addressed himself to the French ministers, and had much earnest conversation, especially with M. Fould, Ministre d'État, and M. Rouher, minister of commerce, both of whom, and especially the latter, he found well inclined to the economical and commercial principles which he advocated. After a good deal of time spent in these preliminary and unofficial negotiations, the question of a treaty of commerce between the two countries having entered into the arena of diplomacy, Cobden was requested by the British Government to act as their plenipotentiary in the matter in conjunction with Lord Cowley, their ambassador in France. But it proved a very long and laborious undertaking. He had to contend with the bitter hostility of the French protectionists, which occasioned a good deal of vacillation on the part of the emperor and his ministers. There were also delays, hesitations, and cavils at home, which were more inexplicable. He was, moreover, assailed with great violence by a powerful section of the English press, while the large number of minute details with which he had to deal in connection with proposed changes in the French tariff, involved a tax on his patience and industry which would have daunted a less resolute man. But there was one source of embarrassment greater than all the rest. One strong motive which had impelled him to engage in this enterprise was his anxious desire to establish more friendly relations between England and France, and to dispel those feelings of mutual jealousy and alarm which were so frequently breaking forth and jeopardizing peace between the two countries. This was the most powerful argument with which he had plied the emperor and the members of the French Government, and which he had found most efficacious with them. But unhappily, while he was in the very thick of the negotiations, Lord Palmerston brought forward in the House of Commons a measure for fortifying the naval arsenals of England, which he introduced in a warlike speech pointedly directed against France, as the source of danger of invasion and attack, against which it was necessary to guard. This produced irritation and resentment in Paris, and but for the influence which Cobden had acquired, and the perfect trust reposed in his sincerity, the negotiations would probably have been altogether wrecked. At last, however, after nearly twelve months' incessant labour, the work was completed in November 1860 "Rare," said Mr Gladstone, "is the privilege of any man who, having fourteen years ago rendered to his country one signal service, now again, within the same brief span of life, decorated neither by land nor title, bearing no mark to distinguish him from the people he loves, has been permitted to perform another great and memorable service to his sovereign and his country."

On the conclusion of this work honours were offered to Cobden by the Governments of both the countries which he had so greatly benefited. Lord Palmerston offered him a baronetcy and a seat in the Privy Council, and the emperor of the French would gladly have conferred upon him some distinguished mark of his favour. But with characteristic disinterestedness and modesty he declined all such honours.

It has already been remarked that Cobden's efforts in furtherance of free trade were always subordinated to the highest moral purposes—the promotion of peace on earth and good-will among men. This was his desire and hope as respects the Commercial Treaty with France. He was therefore deeply disappointed and distressed to find the old feeling of distrust towards our neighbours still actively fomented by the press and some of the leading politicians of the country. He therefore, in 1862, published his pamphlet entitled *The Three Panics*, the object of which was to trace the history and expose the folly of those periodical visitations of alarm, as respects the designs of our neighbours with which this country had been afflicted for the preceding fifteen or sixteen years.

There was one other conspicuous service which Cobden rendered, or tried to render, to his country before his death. When the great civil war threatened to break out in the United States, it was matter to him of profound affliction. But after the conflict became inevitable his sympathies were wholly with the North, because the South was fighting for slavery. His great anxiety, however, was that the British nation should not be committed to any unworthy course during the progress of that struggle. And when our relations with America were becoming critical and menacing in consequence of the depredations committed on American commerce by vessels issuing from British ports, he brought the question before the House of Commons in a series of speeches of rare clearness and force, in which he pointed out the perilous responsibilities we were incurring by connivance or neglect in regard to those vessels. He was first attacked with great animosity both in and out of Parliament for taking this line, but after results amply vindicated his political sagacity and patriotism.

For several years Cobden had been suffering severely at intervals from bronchial irritation and a difficulty of breathing. Owing to this he had spent the winter of 1860 in Algeria, and every subsequent winter he had to be very careful and confine himself to the house, especially in damp and foggy weather. In November 1864 he went down to Rochdale and delivered a speech to his constituents—the last he ever delivered. That effort was followed by great physical prostration, and he determined not to quit his retirement at Midhurst until spring had fairly set in. But in the month of March there were discussions in the House of Commons on the alleged necessity of constructing large defensive works in Canada. He was deeply impressed with the folly of such a project, and he was seized with a strong desire to go up to London and deliver his sentiments on the subject. But on the 21st of March, the day on which he left home, a bitter easterly wind blew, and struck him in the throat and chest. He recovered a little for a few days after his arrival in London; but on the 29th there was a relapse, and on the 2d of April 1865, he expired peacefully at his apartments in Suffolk Street.

On the following day there was a remarkable scene in the House of Commons. When the clerk read the orders of the day Lord Palmerston rose, and in impressive and solemn tones declared "it was not possible for the House to proceed to business without every member recalling to his mind the great loss which the House and country had sustained by the event which took place yesterday morning." He then paid a generous tribute to the virtues, the abilities, and services of Cobden, and he was followed by Mr Disraeli, who with great force and felicity of language delineated the character of the deceased statesman, who, he said, "was an ornament to the House of Commons and an honour to England." Mr Bright also attempted to address the House, but after a sentence or two delivered in a tremulous voice, he was overpowered with emotion, and declared he must leave to a calmer moment what he had to say on the life and character of the manliest and gentlest spirit that ever quitted or tenanted a human form.

In the French Corps Législatif, also, the vice-president, M. Forçade la Roquette, referred to his death, and warm expressions of esteem were repeated and applauded on every side. "The death of Richard Cobden," said M. la Roquette, "is not alone a misfortune for England, but a cause of mourning for France and humanity." M. Drouyn de Lhuys, the French minister of foreign affairs, made his death the subject of a special despatch, desiring the French ambassador to express to the Government "the mournful sympathy and truly national regret which the death, as lamented as premature, of Richard Cobden had excited on that side of the Channel. "He is above all," he added, "in our eyes the representative of those sentiments and those cosmopolitan principles before which national frontiers and rivalries disappear; whilst essentially of his country, he was still more of his time; he knew what mutual relations could accomplish in our day for the prosperity of peoples. Cobden, if I may be permitted to say so, was an international man."

He was buried at West Lavington Church, on the 7th of April, by the side of his only son, whose death, eight or nine years before, had nearly broken his father's heart. His grave was surrounded by a large crowd of mourners, among whom were Mr Gladstone, Mr Bright, Mr Milner Gibson, Mr Villiers, and a host besides from all parts of the country. (H. RI.)

COBIJA, or, as it is officially called in honour of the first president of the republic, PUERTO LA MAR, is the principal port of Bolivia, and the chief town of the province of Atacama or Cobija. It is situated on the coast of the Pacific, about 800 miles north of Valparaiso in Chili, in 22° 32′ 50″ S. lat. and 70° 21′ 2″ W. long.; and it occupies a low-lying position on the beach, at the foot of a lofty range of hills. The surrounding district is desolate in the extreme, and Cobija is totally dependent on importation even for the common necessaries of life. Water is very scarce; the wells only satisfy the wants of about 400 or 500 persons, and the rest of the population has to be supplied by the distillation of the salt water from the sea. At one time fish formed a valuable article of consumption; but since the rise of the mining industries the fishers have for the most part forsaken their nets. The town itself is poorly built, and consists of little more than one broad, long street. The harbour is comparatively safe; but the landing-place is bad, and the danger from the surf considerable. As a free port and the principal means of communication with the interior, Cobija attracts a considerable amount of foreign trade. It owes its foundation in the course of last century to Charles III. of Spain; it was declared a free port in 1827; and it attained the rank of capital of the department in 1837. In 1827 it consisted of little more than a few huts inhabited by Changas, or seafaring Indians; and in 1855 it only numbered 500 or 600 of a population. In 1858, however, the permanent inhabitants were no fewer than 2000, and the floating population amounted to 4000 souls. (See Tschudi, *Reise von San Pedro de Atacama nach Cobija*, 1860.)

COBLENTZ (German, *Coblenz*), the capital of Rhenish Prussia, is pleasantly situated at the confluence of the Rhine and Moselle. From this circumstance it derived its ancient name of *Confluentes*, of which Coblentz is a corruption. This city is still of consequence from a military point of view, since it commands the junction of two great rivers. Its fortifications, which are very extensive, not only protect the town, but connect the works on the left bank of the Rhine with the fortress of Ehrenbreitstein on

the other side of the river. The city is almost triangular in shape; two sides are bounded by the Rhine and Moselle, the third by strong fortifications. These are pierced by two massive gates, the Löhr and Mayence gates, with drawbridges over the fosse. The military works, which were constructed on the combined systems of Carnot and Montalembert, include no fewer than 26 forts, and form a fortified camp capable of containing 100,000 men. The Rhine is crossed here by a bridge of boats 485 yards long, and by the Iron Bridge, built for railway purposes in 1866 The Moselle is spanned by a Gothic freestone bridge of 14 arches, 1100 feet in length, erected in 1344, and also by a railway bridge. In the more ancient part of Coblentz are several buildings which possess an historical interest. Prominent among these, at the point of confluence of the rivers, is the church of St Castor, built in the early Lombard style of architecture, and surmounted by four towers. The church was originally founded in 836 by Lewis the Pious, but the present edifice is considerably less ancient. It was here that the sons of Charlemagne met in 843, when they divided the empire into France, Germany, and Italy. In front of the church of St Castor stands a fountain, erected by the French in 1812, with an inscription to commemorate Napoleon's invasion of Russia. Not long after, the Russian troops occupied Coblentz; and St Priest, their commander, added in irony these words—"*Vu et approuvé par nous, Commandant Russe de la Ville de Coblence: Janvier 1er*, 1814." In this quarter of the town there is also the Liebfrauenkirche, a fine specimen of the old cathedral style, built in 1259; the ancient town-hall; the Castle of the Electors of Treves, erected in 1280, now converted into a manufactory of japan-ware; and the family-house of the Metternichs, where Prince Metternich, the Austrian statesman, was born in 1772. The more modern part of the town has open, regular streets, and many of its public buildings are handsome. The principal of these is the Palace or Royal Castle, with one front looking towards the Rhine, the other into the Neustadt, or Great Square. It was built in 1778–86, and contains among other curiosities some fine Gobelin tapestry work. Another large edifice is the Palace of Justice, where the law courts sit, and assizes are held every three months. Coblentz has also a gymnasium (formerly a convent of Jesuits), a hospital, managed by the sisters of charity, an orphan asylum, a valuable town library, a theatre, a casino, a picture gallery, a musical institute, and a medical school. Above the Iron Bridge are *Anlagen*, or pleasure-grounds, much resorted to by the town's-people. The manufactures consist chiefly of linens, cottons, japan-ware, furniture, and tobacco. Coblentz is a free port, and carries on an extensive commerce by means of the Rhine, Moselle, and Lahn. Being in the centre of the hock wine district, a large trade in this class of produce is carried on with Great Britain, Holland, and other countries. Large exports of mineral waters are also made, about one million jars of seltzer being shipped annually. Among the products of the neighbouring provinces which are exported from Coblentz are corn, iron, volcanic stones, potter's clay, stoneware, and bark. The population is 28,000.

Coblentz was one of the military posts established by Drusus about 9 B.C. It is not unfrequently mentioned during the early centuries of the Christian era as the residence of the Frankish kings, and in 860 and 932 it was the seat of ecclesiastical councils. In 1018 it obtained the rights of a city from Henry II., but at the same time was made subject to the Bishop of Treves, who entrusted the administration to the count palatine of the Rhine. In the following century the fief was held by the counts of Arnstein and the counts of Nassau; but it returned to the bishops in 1253. Archbishop Arnold surrounded the city with new walls in 1249–54, and, in spite of an insurrection on the part of the inhabitants, founded the citadel which still overlooks the town. As a member of the League of the Rhenish cities which took its rise in the 13th century, Coblentz attained to great prosperity; and it continued to advance till the disasters of the Thirty Years' War occasioned a rapid decline. When in 1632 the Elector Philip Christopher of Sötern surrendered Ehrenbreitstein to the French the town received an imperial garrison, which was soon, however, expelled by the Swedes. They in their turn handed the city over to the French, but the imperial forces succeeded in retaking it by storm. In 1688 it was besieged by the French Marshal Boufflers, but was successfully defended by Count Lippe. In 1786 the elector of Treves, Clemens Wenceslas, took up his residence in the town, and gave great assistance in its extension and improvement; and a few years later it became, through the invitation of his minister, Duminique, one of the principal rendezvous of the French émigrés. In 1794 it was taken by the Revolution army, and, after the peace of Lunéville, it was made the chief town of the Rhine and Moselle department. In 1814 it was occupied by the Russians, and by the Congress at Vienna it was assigned to Prussia.

COBRA (*Naja tripudians*), a poisonous Colubrine Snake, belonging to the family *Elapidæ*, known also as the Hooded Snake, or Cobra di Capello. In this species the anterior ribs are elongated, and by raising and bringing forward these, the neck, which otherwise is not distinct from the head, can be expanded at will into a broad disc or hood, the markings on which bear a striking resemblance to a pair of barnacles, hence the name "Spectacle Snake" also applied to the cobra. It possesses two rows of palatine teeth in the upper jaw, while the maxillary bones bear the fangs, of which the anterior one only is in connection with the poison gland, the others in various stages of growth remaining loose in the surrounding flesh until the destruction of the poison fang brings the one immediately behind to the front, which then gets anchylosed to the maxillary bone, and into connection with the gland secreting the poison, which in the cobra is about the size of an almond. Behind the poison fangs there are usually one or two ordinary teeth. The cobra attains a length of nearly 6 feet and a girth of about 6 inches, and with the exception of the markings on the hood is of a uniform brown colour above and bluish-white beneath. There are, however, many distinct varieties, in some of which the spectacle markings on the hood are awanting. The cobra may be regarded as nocturnal in its habits, being most active by night, although not unfrequently found in motion during the day. It usually conceals itself under logs of wood, in the roofs of huts, and in holes in old walls and ruins, where it is often come upon inadvertently, inflicting a death wound before it has been observed. It feeds on small quadrupeds, frogs, lizards, insects, and the eggs of birds, in search of which it sometimes ascends trees. When seeking its prey it glides slowly along the ground, holding the anterior third of its body aloft, with its hood distended, on the alert for anything that may come in its way. "This attitude," says Sir J. Fayrer, "is very striking, and few objects are more calculated to inspire awe than a large cobra when, with his hood erect, hissing loudly, and his eyes glaring, he prepares to strike." It is said to drink large quantities of water, although, like reptiles in general it will live for many months without food or drink. The cobra is oviparous; and its eggs, which are from 18 to 25 in number, are of a pure white colour, somewhat resembling in size and appearance the eggs of the pigeon, but sometimes larger. These it leaves to be hatched by the heat of the sun. It is found in all parts of India from Ceylon to the Himalayas, where it occurs at a height of 8000 feet, and it is justly regarded as the most deadly of the Indian Thanatophidia. A large proportion of the deaths from snake bite, where the species inflicting the wound has been ascertained, is shown to be due to the cobra; and it is estimated that fully one-half of the 20,000 deaths that annually occur in India from this cause may be attributed to this unluckily common species. The bite of a vigorous cobra will often prove fatal in a few minutes, and as there is no known antidote to the poison, it is only in rare instances that such mechanical expedients as cauterizing, constriction, or amputation can be applied with sufficient promptitude to prevent the virus from entering the circulation. Of late years, owing to a small reward offered by the Indian Government for the head of each poisonous snake, great numbers of cobras have been destroyed; but only low caste Hindus will engage in such work, the cobra being regarded by the natives generally with superstitious reverence, as a divinity powerful to injure, and therefore to be propitiated; and thus oftentimes when found in their dwellings this snake is allowed to remain, and is fed and protected. "Should fear," says Sir J. Fayrer, "and perhaps the death of some inmate bitten by accident prove stronger than superstition, it may be caught, tenderly handled, and deported to some field, where it is released and allowed to depart in peace, not killed" (*Thanatophidia of India*). Great numbers, especially of young cobras, are killed by the adjutant birds and by the mungoos—a small mammal which attacks it with impunity, apparently not from want of susceptibility to the poison, but by its dexterity in eluding the bite of the cobra. Mere scratching or tearing does not appear to be sufficient to bring the poison from the glands; it is only when the fangs are firmly implanted by the jaws being pressed together that the virus enters the wound, and in those circumstances it has been shown by actual experiment that the mungoos, like all other warm-blooded animals, succumbs to the poison. In the case of reptiles, the cobra poison takes effect much more slowly, while it has been proved to have no effect whatever on other venomous serpents. The cobra is the snake usually exhibited by the Indian jugglers, who show great dexterity in handling it, even when not deprived of its fangs. Usually, however, the front fang at least is extracted, the creature being thus rendered harmless until the succeeding tooth takes its place, and in many cases all the fangs, with the germs behind, are removed—the cobra being thus rendered innocuous for life. The snake charmer usually plays a few simple notes on the flute, and the cobra, apparently delighted, rears half its length in the air and sways its head and body about, keeping time to the music. The cobra, like almost all poisonous snakes, is by no means aggressive, and when it gets timely warning of the approach of man endeavours to get out of his way. It is only when trampled upon inadvertently, or otherwise irritated, that it attempts to use its fangs. It is a good swimmer, often crossing broad rivers, and probably even narrow arms of the sea, for it has been met with at sea at least a quarter of a mile from land.

COBURG, or, in German *Koburg*, the capital of the duchy of Saxe-Coburg-Gotha and, alternately with Gotha, the residence of the duke and the seat of the administration, is situated on the left bank of the Itz, an affluent of the Regen, and on the southern slope of the Frankenwald, 40 miles S.S.E. of Gotha. The town is for the most part old, and contains a large number of remarkable buildings. The ducal palace, or Ehrenburg, is a fine Gothic edifice, with an extensive library, and collections of coins, paintings, and specimens in natural history; it was originally a convent of the Barefooted Friars, received its present appropriation from John Ernest in 1549, and was restored by Ernest in 1844. In front of the palace is a bronze statue of the latter duke by Schwanthaler, and in the court-garden is the ducal mausoleum. Among the churches the most remarkable is the Moritzkirche, with a tower 335 feet high, the beautiful Hofkirche, and the modern Roman Catholic church. The educational institutions include a gymnasium, founded in 1604 by Casimir, and thus known as the Casimirianum; a Realschule, established in 1848, a normal college, a deaf and dumb asylum, and a school of architecture. The arsenal contains a public library; and the so-called *Augustenstift*, where the ministry of the duchy is located, has an extensive collection of objects in natural history. Coburg further possesses a town-house, Government buildings, an observatory, and a theatre. On a commanding eminence in the vicinity is the ancient castle of Coburg, which dates at least from the 11th century. Till 1348 it was the residence of the counts of Henneberg, and till 1547 belonged to the dukes of Saxony; in 1781 it was turned into a penitentiary and lunatic asylum; but in 1835–8 it received a complete restoration. The most interesting room in this building is that which was occupied by Luther for three months in 1530, and thus became the birthplace of his famous hymn, *Eine feste Burg ist unser Gott*; the bed on which he slept and the pulpit from which he preached in the old chapel are still shown. Coburg is a place of considerable industry, and possesses a large brewery, factories for the weaving of linen and cotton goods, tanneries, and dye-works; and there is an important trade in the cattle reared in the neighbourhood. Among various places of interest in the vicinity are the ducal residences of Callenberg and Rosenau, in the latter of which Albert, the Prince Consort, was born in 1819; the castle of Lauterberg; and the village of Neuses, with the house of the poet Rückert, who died there in 1866, and on the other side of the river the tomb of the poet Thümmel. Population in 1871, 12,819.

COCA. See Cuca.

COCCEIUS, or COCH, JOHANN (1603–1669), a Dutch theologian, was born at Bremen. After studying at Hamburg and Franecker he became in 1629 professor of Hebrew in his native town. In 1636 he was transferred to Franecker, where he held the chair of Hebrew, and from 1643 the chair of theology also, until 1650, when he became professor of theology at Leyden. He died on the 4th November 1669. Cocceius was a profound Oriental scholar, and his chief services were rendered in the department of Hebrew philology and exegesis. The common statement that he held that every passage has as many meanings as it can be made to bear is founded on an entire misconception of his fundamental law of interpretation. What he really maintained was the sound principle that individual words and phrases are to be interpreted according to their contextual connection, and not according to any predetermined dogmatic system, whether patristic or scholastic. As one of the leading exponents of the "federal" theology, he spiritualized the Hebrew scriptures to such an extent that it was said that Cocceius found Christ everywhere in the Old Testament and Grotius found him nowhere. He held millenarian views, and was the founder of a school of theologians who were called after him Cocceians. His most distinguished pupil was the celebrated Vitringa. He wrote commentaries on most of the books of the Old Testament, but his most valuable work was his *Lexicon et Commentarius Sermonis Heb. et Chald.* (Leyden, 1669), which has been frequently republished. The federal or covenant theology which he taught is fully expounded in his *Summa Doctrinæ de Fœdere et Testamento Dei* (1648). His collected works were published in twelve folio volumes at Amsterdam in 1701.

COCHABAMBA, a city and bishop's see of Bolivia, capital of a province and department, is situated about 8370 feet above the level of the sea, on both banks of the Rio de la Rocha, a sub-tributary of the Rio Grande, to the south of a considerable Cordillera. It is about 122 miles N.N.W. of Sucre, its latitude is 17° 27′ S., and its longitude 65° 46′ W. The streets are broad, and the houses for the most part of one story and surrounded by gardens, so that the area of the city is great in comparison with its population. There are fifteen churches, a gymnasium, and a cabildo; and an extensive industry is maintained in the production of woollen and cotton stuffs, leather, soap, glass-ware, and pottery. The population is largely composed of Indians; and the prevailing language is Quichua. Cochabamba was founded in the 16th century, and for a time was called Oropesa. In the revolution of 1815 the women of the city distinguished themselves by their bravery, and successfully attacked the Spanish camp; and in 1818 a number of the heroines were put to death by the Spanish forces. In 1874 the city was seized by Miguel Aguirre, and a large part of it laid in ruins, but peace was soon afterwards restored, and the regular authorities reinstated. The population in 1858 was 40,678.

COCHIN, a feudatory state of Southern India, situated within the presidency of Fort St George or Madras, between 9° 48′ and 10° 50′ N. lat., and between 76° 5′ and 76° 58′

E. long. The state, which is of irregular shape, is bounded on the W., N., and E. by the districts of South Malabar and Coimbatore, and for some distance on the W. by the Indian Ocean; on the S. it is bounded by the state of Travancore. Cochin contains a total area of 1361 square miles, and a population, according to a census taken in 1875, of 598,353 souls, dwelling in 118,196 houses. The state is divided into seven *táluks*, or sub-districts, viz., Cochin, Cannanore, Mugundapuram, Trichur, Tallapalli, Chitur, and Cranganore.

Cochin consists for the most part of a maritime lowland hemmed in between the sea and the *Gháts*. It includes, however, the mountains which thus wall it out from inner India, and the lower portion is copiously watered by the torrents which pour down them. These torrents dwindle in the hot weather to rivulets, but during the rains they swell into great cataracts, rising in one instance at least 16 feet in twenty-four hours. On the lowlands, they unite as elsewhere on the western coast into shallow lakes or "backwaters," lying behind the beach line and below its level. In the monsoon the Cochin backwaters are broad navigable channels and lakes; in the hot weather they contract into shallows in many places not 2 feet deep. The vegetation is luxuriant; rich crops of rice are grown on the lowlands; the hills send down vast quantities of timber by means of the torrents. The remains of once fine forests of teak are preserved in the north-eastern corner of the state, and still form a considerable source of wealth. Coffee has of late years received much attention and promises well. The other products are the usual ones of an Indian state,—cotton, pepper, betel-nut, chillies, ginger, various spices, cardamoms, arrowroot, &c. An excellent account of Cochin will be found in Dr Day's *Land of the Permauls*. The rájás of Cochin claim to hold the territory by descent from Chermán Perumál, who governed the whole of the surrounding country, including Travancore and Malabar, as viceroy of the Cholá kings, about the beginning of the 9th century, and who afterwards established himself as an independent rájá. In 1776 Cochin was subjugated by and became tributary to Hyder Alí. In 1792 Tippu ceded the sovereignty to the British, who made over the country to the hereditary rájá, subject to a tribute of Rs.100,000. The state is now in subsidiary alliance with the British Government, under a treaty dated 17th October 1809. By this engagement, which was entered into on the suppression of an insurrection on the part of the rájás of Cochin and Travancore against the British power, the Cochin chief agreed to pay, in addition to the tribute of Rs.100 000, an annual sum, equal to the expense of maintaining a battalion of native infantry, or Arcot Rs.176,037, making an aggregate annual payment of Rs. 276,037. In return for this payment, and certain engagements entered into by the rájá, the East India Company undertook to defend the integrity of the state territory against all enemies. Subsequently the annual tribute to the British Government was reduced to Rs. 240,000, and again afterwards to Rs. 200,000 (£20,000) at which it now stands. A British resident represents the government of India in Cochin conjointly with Travancore. The present rájá succeeded to the throne in March 1864.

The total revenue of Cochin for the Malabar year 1049 (1873–74 A.D.), amounted to £130,851, being the highest income recorded for any year; the principal items were the land revenue, £61,764; customs, £11,035; and salt, £15,713. The disbursements for the same year amounted to £111,858, leaving a surplus for the year of £18,993. The state has now the sum of £200,000 invested in British Government securities. A high school, with an average of 170 pupils, and 5 district schools are maintained by the state. Hospitals and dispensaries and a post-office are also kept up, and a considerable sum, amounting to £13,669 in 1874, is annually spent in public works. The military force is a nominal one of 1 commissioned officer and 340 non-commissioned officers and men. The two trading ports (exclusive of the British port of Cochin) are Malipuram and Narakel, at which 31 vessels, a burden of 22,626 tons, arrived in 1873–74. The capabilities of Narakel as a port of shelter during the S.W. monsoon have been satisfactorily proved, and the mail-steamers of the British India Company touch there for four or five months of the year, when the neighbouring English port of Cochin is unapproachable.

COCHIN, a town and port of British India, belonging to the Malabar district of Madras, situated in 9° 58′ 5″ N. lat. and 76° 13′ 55″ E. long. The town lies at the northern extremity of a strip of land about twelve miles in length, but at few places more than a mile in breadth, which is nearly insulated by inlets of the sea and estuaries of streams flowing from the Western Gháts. These form the Cochin backwater described in the article on the Cochin state. The town of Cochin is about a mile in length by half a mile in breadth. Its first European possessors were the Portuguese, from whom it was captured by the Dutch in 1663. Under the Dutch the town prospered, and about 1778 an English traveller describes it as a place of great trade; "a harbour filled with ships, streets crowded with merchants, and warehouses stored with goods from every part of Asia and Europe, marked the industry, the commerce, and the wealth of the inhabitants." In 1796 Cochin was captured from the Dutch by the British, and in 1806 the fortifications and public buildings were blown up by order of the authorities. The explosion destroyed much private property, and for a long time seriously affected the prosperity of the town. Under Dutch rule Cochin was very populous, containing Europeans, Moplas or Musalmáns, Hindus, Arabs, Persians, and Christians of various sects, comprising natives, Armenians, Indo-Portuguese, and those denominated Syrian Christians. The Jews have also a settlement here. They are of two classes, the Fair or White Jews, of more recent arrival and settlement in the country, and the Black Jews, who reside apart in a village outside the town. According to the census of 1871, Cochin town contains 2731 houses and a population of 13,840 souls, classified as follows:—Hindus, 3883, Muhammadans, 2174; Christians, 7783; and "Others," 46. The town is constituted a municipality, and in 1873–74 the municipal income (excluding balances) amounted to £1573 10s., and the expenditure to £1560 10s. The entrance to the port of Cochin is obstructed by a bar across the mouth of the river, and during the S.W. monsoon, which lasts for four or five months, vessels can neither enter nor depart from it in safety. Notwithstanding the difficulties of navigation, however, the port has a considerable maritime trade. In 1873–74, 171 British vessels of a burden of 108,579 tons, 27 foreign vessels of 7010 tons, and 1644 native craft of a total of 49,215 tons burden entered the port, and paid a total of £1974 as port dues,—by far the greater part, £1520, being paid by the British ships. The value of the exports in 1873–74 amounted to £755,796, and of the imports to £547,252, paying a total customs duty of £5161. A lighthouse at the south entrance of the harbour marks the entrance to the port, and is visible at a distance of 15 miles.

COCHIN CHINA, a name applied to the eastern division of the Indo-Chinese peninsula, composed of the territories of Anam proper, Tong-king, and the French colony of Cochin China. It forms a long strip of country which stretches in an arc of a circle along a coast-line of 1240 miles from 8° 30′ to 23° N. lat. With a breadth of 372 miles in the north of Tong-king, it is afterwards narrowed by a chain of mountains parallel to the China Sea, and has no more than 50 miles of breadth in the greater part of the kingdom of Hué; but in Lower Cochin China it widens out again to about 190 miles. The most western point, in Tong-king, reaches 102° 20′ E. long., and the most eastern, Cape Varela, in Cochin China, is in 109° 40′. The boundaries are—on the N. the Chinese provinces of Yun-nan and Kwang-se, on the E. and S. the China Sea, on the W. the Gulf of Siam, the kingdom of Cambodia, and the Laos country tributary to the Siamese empire. According to the most probable estimates the empire of Anam has an area of from 190,000 to 230,000 square miles, or about the same extent as France; while the French colony occupies about 21,630. The western limits of this empire are, however, very imperfectly determined, and the regions to the west of Tong-king are still unexplored. The N. of Cochin China is washed by the Gulf of Tong-king, a great

Sketch-Map of Cochin China.

inlet formed by the coast of Tong-king on the W. and the island of Hai-nan and the peninsula of Lien-chow on the E. At its mouth, towards Tiger Island and the S.W. part of Hai-nan, the gulf has a breadth of about 138 English miles, which almost represents its medium breadth. Near the west coast are several islands, and towards the head of the gulf a great number of islets and banks. From soundings which have been taken throughout its whole extent, it has been found that in the middle of the entrance there is a depth of from 210 to 330 feet, which diminishes towards the coasts; and the depth is less half-way up the gulf, where the bottom is generally soft.

Passing along the coast from Cape Pak-loung, where the frontier commences between China and Tong-king, we find that all the part north of the Gulf of Tong-king is little known; it is said to be fringed with banks and rocks, and some large islands have been visited by English vessels in pursuit of pirates. The most important are the Pirate Island, a group of multitudinous islets in a bay of which the Chinese name is Fie-tzi-long, and the Pearl Islands. Next we find the mouth of the River Lach-Huyen, which is deep, but obstructed about a mile inland by a bar preventing the entrance of any vessel drawing more than 11½ feet. Next come the mouths of the River of Tong-king, Song-Coi, or Hong-kiang (Red River). The delta of this river is formed by four main branches—Cua[1] trà lay, Cua lac, Cua dhai, Cua ba lat—which communicate with each other both by natural channels, called arroyos, and by artificial canals. These are charged with alluvial matter, and produce considerable increase of soil. Mr E. Ploix, a hydrographic engineer who visited the gulf between 1857 and 1859, estimates the annual advance of the coast at about 330 feet. It is by these rivers that Ke-cho, or Ha-noi, the capital of Tong-king, can be reached. This town and the port of Ninh-hai, in the province of Hai-dzuong, were opened to foreign commerce by a treaty concluded between France and the Government of Hué, March 15, 1874. To allow a ship to pass up the river at any season its draught must not exceed 5½ feet, and from the end of May to the end of November, vessels drawing 12 feet can cross the bars.

About 18° 10′ N. lat. lies the island Hon-tseu, or Goats' Island, near a prominent cape about 1410 feet high. A little to the south of Hon-tseu is the point to the north of which there is only one tide in 24 hours, except during a period of two weeks, when on three or four days there are two tides of little force. At Cape Boung-Qui-hoa there is a good anchorage well sheltered by islands, of which the chief is South Watcher Island, or South Vigie. In front of Cape Lay is the little Tiger Island, where the west coast of the Gulf of Tong-king terminates. On the China Sea the coast presents successively, as we pass southward, the mouth of the River Hué, defended by a fort; the Bay of Tourane, wide, deep, and well sheltered, but unfortunately situated in an unhealthy district, and in the poorest part of the country; the Bay of Quit-Quit, a very good anchorage, and the safest on this coast during the N.E. monsoon; the Island Cu-lao-re, or Pulo Canton; the port of Qui-nhon, or Binh dhinh, in the province of this name, opened to European commerce by the treaty of March 1874; the bay and the commodious port of Phu-yen; Cape Varela, or Mui-nai, a very lofty peak visible 30 nautical miles out at sea, and to the south of the cape the port of Hon-re, safe at all seasons of the year; the Bay of Phan-rang and Cape Padaran, or Mui-Din, districts bordered by coral banks; Cape Ke-ga; and Cape Ba-kee, which forms the limit between lower Cochin China and the kingdom of Anam. Between Cape Padaran and Cape Ba-kee the coast is low, and bordered by dangerous banks. In front are the little islands of Pulo Cecir, Catwick, and Pulo Sapate, of difficult access.

The whole of lower Cochin China being formed of alluvial deposits, its coast is very low, has little irregularity of surface, and is covered with mangroves. The different mouths of the River Cambodia or Me-kong form a delta of more than 70 miles in extent. The soil is subject to frequent changes on account of the alluvial deposits of the river, which is bordered by sand banks stretching seawards out of sight of land. At the entrance of the River Don-nai, which leads to Saigon, rises Cape St Jacques, a peak 920 feet above the level of the sea. At 45 sea-miles from the coast and from the mouths of the Me-kong, is the island of Pulo Condore, with a good port, and a penitentiary established by the French Government. On the west coast of Lower Cochin China, in the Gulf of Siam, is the port of Ha-Tien, communicating by a canal with one of the arms of the Me-kong.

To the north of Tong-king terminate the last underfalls of the high plateau of Thibet; a long chain stretches parallel to the Sea of China as far as the south of the kingdom of Anam of which it forms the western boundary. The highest point of this chain does not exceed 5250 feet. Between the last ramifications of the mountains of Thibet there descend from the plateau of Yun-nan and in a south-east direction the affluents of the great River Song-Coi or Hong-kiang, which undergoes periodic variations in the supply of its waters. In the month of March it is very

[1] Cua signifies embouchure.

low; but every year about the month of July it leaves its channel, floods a part of the country, and rolls along with a very powerful current. Before passing Ha-noi it receives the tribute of two great rivers, known to the natives by the names of the Black River and the Clear River

The kingdom of Anam, closely shut in between the mountains and the sea, is drained by numerous but unimportant streams. Lower Cochin China, or French Cochin China, is abundantly watered by the numerous mouths and the canals which form the delta of the Me-kong or Cambodia. This river takes its rise in the mountains of Thibet, waters the southern provinces of China and the district of Laos tributary to Siam, and crosses through the kingdom of Cambodia, where it divides into three branches. The first, which does not penetrate into Cochin China, turns towards the north-west and loses itself in the Lake of Touli Sap. The second, which takes the name of Hinder River (Hau-giang or Song-sau) flows south-east, enters Cochin China, communicates with the Sea of Siam by the Canal Vinh-te of Ha-tien and by that of Rach-gia, and enters the China Sea by two mouths. The third branch, named Front River (Tien-giang or Song-truoc), flows parallel to the preceding, divides at Vinh-long into four arms, and debouches by six mouths. These streams form numerous islands and communicate with each other by means of canals or arroyos. In spite of the length of its course and the great mass of its waters, the Me-kong cannot be utilized as a means of communication with Central China, because of the numerous *ressauts* and rapids which encumber its course. It is besides subject to an annual flood; the waters begin to rise in May, attain their maximum in October, and decrease until March. From the month of March to the month of May the level is almost constant. Two other streams water the east of Lower Cochin China,—the Vaico, divided into two branches, and the Donnai. These rivers communicate with each other and with the mouths of the Me-kong by numerous arroyos. The Donnai receives the Saigon River; and it is by this means that the largest vessels reach the town of that name.

The climate of the north of Anam differs much from that of the south. In Tong-king, though it is usual to divide the year into a dry and a wet season, there is properly speaking no dry season. In December and January the thermometer falls to 41° or 43° Fahr. Summer corresponds to the period of the rains from the end of April to the month of August; and at that time it is excessively hot. Storms are frequent, and the coasts are often visited by typhoons. At the same time Tong-king is a healthy country; the weather during four months is excellent; and the French colony of Saigon might find there—what has never been discovered in Cochin China proper—a suitable site for a sanatorium. The climate of the French colony is unhealthy for Europeans; they cannot be acclimatized. The mortality of the troops is rather high; and before their residence was shortened to two years it might be calculated at 9 or 10 per cent. for a three years' residence. The chief cause of the maladies which affect Europeans is the character of the soil. On the banks of the rivers, in the salt marshes, and along the shores of the sea, intermittent fevers of great severity are frequent. In the forest land rages the terrible wood-fever, from which the native himself cannot escape, though he lives unharmed in the midst of the rice swamps. But the great plague of Lower Cochin China is dysentery,—a disease which, endemic in all warm countries, proves in Cochin China particularly fatal. It is to it that the greater part of the deaths among Europeans are to be ascribed; and they often succumb to its effects after their return to their native country. Most of the children born of European parents in Cochin China die a short time after birth. White women are there exposed to many dangers, especially during their delivery; and there is consequently little hope of forming there a race of creoles. The native women, on the contrary, are very prolific, and suffer surprisingly little in childbirth. It is also interesting to observe that the Anamites, like the races of the extreme East, recover from wounds of the greatest severity, which would infallibly kill Europeans even in their own country.

The mean temperature of Lower Cochin China is 83° Fahr. The greatest heat in April and May within doors is 97° Fahr. In the mornings of December the temperature falls to 65° Fahr. The year is divided into the dry season, which corresponds to the N.E. monsoon, and the rainy season, which corresponds to the S.W. monsoon. What renders the climate peculiarly injurious and enervating is that, besides the very slight difference between the temperatures of day and night, the hygrometric readings are always very high. The surface of Cochin China, composed of recent alluvial deposits, is absolutely flat, and in some places is below the level of the sea. The slightness of the slope of this vast plain allows the tide to advance far inland, and the borders of the rivers to be alternately covered with water and exposed to the perpendicular rays of the sun. All the coasts are covered by mangroves (the marsh-tree of the tropics), which with their dull monotonous foliage everywhere betoken the unhealthiness of the soil.

The finest species of tiger, the royal tiger, is to be met with from the mountains which bound Tong-king on the north as far as the south of Lower Cochin China; and a short time ago it was still to be found in the wooded hills close to Saigon. The other wild animals are the panther, the rhinoceros, the elephant—which the people of Anam have not learned to domesticate—the cocoa-nut bear, the stag, the wild boar, the wild ox, and monkeys of various kinds. The domestic animals are goats, horses, buffaloes (with which the Indo-Chinese carry on the difficult and unhealthy cultivation of the rice-fields), and pigs, which are kept in great numbers. There are numerous birds of many species, which—as in all tropical regions—are remarkable for the beauty of their plumage. Among the rest may be mentioned pea-fowl, pheasants, turtle-doves, the green pigeons of Pulo Condore, paroquets, hornbills, sultana fowls, and various species of wading birds and palmipeds. The rivers abound with life; and the fish, though of poor quality, form an important part of the food of the people. They are caught, along with frogs and snakes, even in the mud of the rice-fields. The crocodile is frequently met with, and adds another item to the native cuisine. This hot damp country swarms with reptiles, of which some species are very dangerous. Among these are the huge cobra di capello (*Naja*), many species of adders, and the immense python, which is of much use in destroying during the night all kinds of rats, including the intolerable musk-rat.

The forests furnish several kinds of timber for building. In the plains and valleys are numerous fruit-trees,—the banana, the guava, the papaw, the medlar-tree, the orange, the citron, and, most abundant of all, the cabbage-palm and the cocoa-tree, and the cinnamon of which Tong-king furnishes a superior quality. The people of Anam are essentially agricultural. Besides rice, which is the chief production of the country, the cultivated lands furnish cotton, mulberry, sugar-cane, maize, betel-nut, and vegetables, especially potatoes, earth-nuts, and pepper. Tea is cultivated also, especially in Tong-king, but the people of Anam do not know how to prepare it.

To the traveller who pays only a brief visit the kingdom of Anam appears ill provided with metals. If a mine be discovered the natives forbid access to it, and still more frequently, for fear of the authorities, are unwilling to give any information. Two excellent authors, Messrs T. Crawfurd and M'Culloch have supported this false opinion in their works. More precise information has, however, been obtained, recent explorers of the country stating that Tong-king is very rich in metals, and furnishes especially gold, silver, brass, zinc, and iron. It is from Tong-king that the famous tam-tams, the manufacture of which is still a secret to Europeans, are obtained. Cochin China, properly so-called, furnishes also gold, silver, brass, and marble; and coal is found there in several places. Lower Cochin China, like all alluvial plains, is poor in minerals; quarries, however, of granite and of jet are worked.

There is little industrial activity in Anam, but in Tong-king the manufacture of articles inlaid with mother-of-pearl is carried on. From China Cochin China receives a large quantity of manufactured goods, cotton and silk stuffs, porcelain, and tea. The importation from France is also very considerable. The principal exports are rice (which forms of itself half the sum total), salt fish, provided principally by the fisheries at the mouth of the two chief rivers, salt, undyed cotton, pepper, and the skins of animals. The great commercial importance of Cochin China arises from the excellence of its situation, as a way of communication with the rich and populous provinces of middle China. England has long been seeking to open a route for trade between the north-east of India, or Pegu, and the south-west of China, but up to the present time, notwithstanding the courage and devotion of explorers, these attempts have failed.

auni-
1.

From 1866 to 1868 a French expedition, commanded by Captain Doudart de Lagrée, followed up the course of the Me-kong, and penetrated into middle China. This expedition cost its chief his life, for he died in consequence of the fatigue which he underwent in Yun-nan. This examination of the Me-kong proved that this fine river is, as already noticed, unfit for regular navigation. Another route, however, by the Tong-king, may be opened up; and it is comparatively easy and habitually used by the natives. In 1872 Mr Dupuis, a French merchant, passed up the course of the Hong-kiang as far as Mang-Hao, a town of Yun-nan, where the river ceases to be navigable. He came down the river again in 1873. He declares it to be navigable in every season, and has thus solved the problem which Captain Doudart de Lagrée sought to solve by means of the Me-kong. M. Dupuis's expedition led the French authorities, at the solicitation of the Government of Hué, to despatch M. Francis Garnier to the Tong-king; but the gallant explorer was assassinated by pirates in the neighbourhood of Ha-noi.

The native of Anam is the worst built and the ugliest of all the Indo-Chinese who belong to the Mongolian race. He is scarcely of middle height, and is shorter and less vigorous than his neighbours. His complexion is tawny, darker than that of the Chinese, but clearer than that of the Cambodian; his skin is thick; his forehead low; his skull slightly depressed at the top, but well developed at the sides. His face is flat, with highly protruding cheek-bones, and is lozenge-shaped or eurygnathous to a degree that is nowhere exceeded. His nose is not only the flattest, but also the smallest among the Indo-Chinese; his mouth is large, and his lips thick; his teeth are blackened and his gums destroyed by the constant use of the betel-nut, the areca-nut, and lime, a custom which perhaps originated in hygienic reasons. His neck is short, his shoulders slope greatly, his body is thick-set, large, all of one piece, as it were, and wanting in suppleness. His pelvis is large, with a considerable separation of the upper part of the femora, giving to his gait a curious swagger, which has, not without reason, been described as theatrical. This odd swagger by itself suffices to distinguish the Anamese from every other Indo-Chinese people without exception. Another peculiarity, which especially distinguishes this race from the other Indo-Chinese branches, is a greater separation of the big toe from the rest than is found in any of the other peoples that walk bare-footed. It is sufficiently general and well marked to serve as an ethnographic test; and it indicates that the people of Anam are not descended—as some authors have asserted—from a mingling of indigenous savages with the Chinese, but have existed as a distinct race for a long time. According to Father Legrand de la Liraye (*Notes historiques sur la nation Annamite*, Saigon, 1865), this curious feature has served to distinguish the people of Anam since the year 2285 B.C., that is to say, 63 years after the Biblical deluge. This statement, taken as it is from the Chinese annals, shows that the Anamese could not have received this characteristic from their neighbours; and it is a very curious fact that it has been transmitted to the present inhabitants despite the frequent intermarriages with other races which must have taken place during this period of forty centuries. The inhabitants of Lower Cochin China are evidently weaker and smaller than those of Tong-king, and this probably results from their dwelling in marshy rice-fields.

In the midst of the Anamese live Cambodians and immigrant Chinese, the latter, associated together according to the districts they come from, carrying on nearly all the commerce of the country. In the forests on the frontiers of Cochin China dwell certain wretched savages called Mois, or Stiengs, of whom little is known; and alongside of these are the Chams, a Mahometan people which appear to be of Arab origin, and, in spite of a strong infusion of Chinese blood, preserve the warlike qualities of their ancestors, their love of fighting, their gay and open character, and their abstinence from theft. Their stature is tall, and they are characterized by the enormous projection of the soft parts of the abdomen. Their women, while mixing freely in society without veiling, have a high-spirited virtue which forms a contrast to the corruption that prevails around them. Their language shows that they once knew the lion and the chamois; and while they are now inferior in civilization, they preserve traces in their vocabulary of a higher condition. Among the different races which inhabit Indo-China numerous mixtures take place. There are crosses of the Anamite with the Hindu, with the Malay, with the Cambodian, and with the Chinese. The last of these half breeds, who are called Min-huongs, are the most numerous and interesting.

Language.

Evidently derived from the Chinese, of which it appears to be a very ancient dialect, the Anamese language is composed of monosyllables, of slightly varied articulation, expressing absolutely different ideas according to the tone in which they are pronounced. It is quite impossible to connect with our musical system the utterance of the sounds of which the Chinese and Anamese languages are composed. What is understood by a "tone" in this language is distinguished in reality, not by the number of sonorous vibrations which belong to it, but rather by a use of the vocal apparatus special to each. Thus, the sense will to a native be completely changed according as the sound is the result of an aspiration or of a simple utterance of the voice. Thence the difficulty of substituting our phonetic alphabet for the ideographic characters of the Chinese, as well as for the ideophonetic writing partly borrowed by the Anamese from the letters of the celestial empire. We owe to the Jesuit missionaries the introduction of an ingenious though very complicated system, which has caused remarkable progress to be made in the employment of phonetic characters. By means of six accents, one bar, and a crotchet, it is possible to note with sufficient precision the indications of tone without which the Anamese words have no sense for the natives. This system is universally adopted in French Cochin China, and the new generation, almost without exception, are able to read and write in Latin characters.

The Anamese are idle, incapable of deep emotion, and fond of ease. They show much outward respect for superiors and parents, but they take great delight in mocking and banter. They cherish great love of their native soil and native village, and cannot long remain far from home. On the whole they are mild, or rather apathetic, but the facility with which they learn is remarkable. Buddhism, mingled with coarse popular beliefs, is the dominant creed, but the learned hold the doctrine of Confucius, and in truth the people of Anam are but slightly religious. Nevertheless, like their neighbours, the Chinese and the Cambodians, they have a great respect for the dead, and their worship almost entirely consists of ceremonies in honour of their ancestors. Like the Chinese they dispose of the body by inhumation. Among the savage tribes of the interior there is scarcely any idea of a God, and the superstitious practices to which they are addicted can scarcely be considered as the expression of a definite religious idea. Christianity counts 400,000 adherents in Tong-king and 5000 in Lower China.

Government. The system of government in the empire of Anam is pure and absolute monarchy without any other constitution than powerful custom. The succession to the throne follows the order of primogeniture. Between the citizens there exists the most complete equality, since public offices are open to all, and there are no other social distinctions than those due to office or fortune. The sovereign, at once high priest and supreme judge, governs despotically with the assistance of six ministers. The army, or rather the military list, for a large part of the force exists only on paper, is composed of 80 regiments, with 500 men in each. It is recruited from Cochin China; Tong-king furnishes no soldiers. It is under the command of a commander-in-chief, a kind of constable of the kingdom, or grand marshal, who is personally responsible for the defence of the citadel of Hué. The marine, which has no ships, is composed of 30 regiments, under an admiral-in-chief, who is assisted by a vice-admiral and two rear-admirals, each of whom commands 10 regiments. The mandarins, as in China, form two distinct classes—the civil and the military. The first class are scholars who have passed literary examinations. The latter are chosen chiefly on account of physical fitness; and it is only in the highest ranks that well-educated respectable men are to be found. The people have a great regard for the learned, who have all received a higher moral education,—that of Confucius. The mandarins are divided into nine degrees, and each degree comprises two classes. Besides the French colony, the empire of Anam is divided into 24 provinces placed each under the authority of a governor. The province is subdivided into departments, arrondissements, cantons, and communes. The French colony, administered by a governor assisted by a privy council, comprehends the six ancient provinces of the south. It is now divided into four provinces, bearing the names of their chief cities,—Saigon, Mî-thô, Vinh-long, and Bassac. The provinces form together 19 inspectorships with an administrator of native affairs at the head of each.

The chief town and the ancient capital of Tong-king, Ha-noi, or Ke-cho (*i.e.*, the market), situated on one of the branches of the Song-Coi, though at present greatly fallen, still contains at least 50,000 inhabitants. It possesses a very large citadel, which serves as the residence of the viceroy and of the special envoy or royal commissioner, who is the first authority in Tong-king. This citadel, at present badly kept in repair and poorly equipped, was built in the course of last century according to plans furnished by European engineers. The provincial capitals of Hai-dzuong (30,000 inhabitants), Bac-Ninh, Nam-Dinh, likewise possess important citadels; and that of Minh-binh, also the chief town of a province, is the strongest of all Tong-king. Hué, or Phu-tua-tien, capital of the kingdom of Anam, is composed of two portions—the inner town, a vast fortress built on the Vauban system according to the plans of French engineers, and occupied by the Government; and the outer town, which is inhabited by the mass of the population, who are estimated at 100,000 souls. Mention may also be made of Tourane and Quin-nhon, or Binh-dhinh, important ports open to European commerce. Saigon, the capital of the French colony, is composed of three towns:—1st, an Asiatic town, inhabited by Anamese husbandmen, fishers, or servants, by mercantile Chinamen, by Malays, Tagals, and Hindus engaged in various occupations; 2d, the town of the colonists; and 3d, the Government town, inhabited by the Government employés, administrators, officers, and physicians. The houses are mainly built of brick. Two gardens, one belonging to the governor and the other the botanical, overlook the town. The latter is very interesting, containing as it does a fine collection of trees and plants, both indigenous and exotic, as well as a very curious menagerie. At the port of Saigon 387 vessels entered and 398 left in 1874, which forms about half of the whole maritime trade in the colony. Eight miles from Saigon is the town of Cho-len (*i.e.*, the great market), a Chinese town with an extensive commerce, and according to some writers 80,000, according to others 30,000 or 40,000 inhabitants. The other towns of the colony are Go-cong to the south-west of Saigon, where, in the midst of the rice fields, there lives an agricultural population, which presents in all its purity the true Anamese type; Mî-thô, a port on one of the arms of the Me-kong, and the second town of the colony; the fort and the town of Vinh-long; the fort and town of Chaudoc; Ha-tien, on the Gulf of Siam, one of the most unhealthy places on the coast, inhabited by Chinese and Anamese; and at the Cape St Jacques, the military port and fort of Ba-ria.

Population. It is difficult to state the exact number of the population of the empire of Anam, and authors vary greatly in their estimates. The data which appear most worthy of credit give a total sum of 10 or 12 millions. As to the French colony, the last official census of which the results have been published was made in 1873; it gives 1,487,200 inhabitants, of whom 49,500 were Chinese and 82,700 Cambodians. The Europeans numbered 1114, exclusive of the Government officials and the garrison.

The Anamese, according to their own annals, are natives of the south of China. "In the 2d or 3d century before Abraham," says Père Legrand de la Liraije, "four barbarous tribes occupied the limits of the Chinese empire; to the south was the tribe of the Giao-chi." It is from this tribe that the Anamese claim to have descended; and at the time when history begins to acquire some degree of certitude, about 2357 before our era, the Chinese annals mention the Anamese under the name of Giao-chi, which signifies "with the big toe." According to native scholars the history of this epoch is of a legendary character. It results from their labours that for twenty centuries the race of Giao-chi was governed in vassalage to the empire by a dynasty of Chinese origin, which lasted till 257 B.C. From that date till 110 before the Christian era the throne was held by two other vassal dynasties; and from 110 B.C. till 907 A.D. these dynasties were replaced by Chinese governors. In the beginning of the 10th century some of the native chiefs, weary of the Chinese rule, revolted; and their efforts were crowned with success. From 960 downwards, under the government of native princes, the Anamese lived independent, and preserved rather the name than the reality of vassalage to the Chinese empire. Since that time the nation, with a most remarkable aptitude for expansion, has aggrandized itself at the expense of its neighbours, and has conquered from the Cambodians Tsiampa and the six provinces of the south which now form the French colony. It is to be noted that the Cambodians, though endowed with physical force far superior to that of the Cochin Chinese, have been beaten by them in every encounter.

It is nearly a century since the first treaty of alliance was signed between France and the kingdom of Anam. By this treaty, dated the 28th November 1787, the king of Cochin-China ceded to France in full property the Peninsula of Tourane and the Isle of Pulo-Condore. The agreement was only partially executed, but it was sufficient to render the influence of France predominant in Cochin China; and Christianity made rapid progress in Tong-king. At the death of the king Gia-long, in 1820, the party hostile to strangers prevailed; and several attempts to protect the French missionaries and establish the French influence had failed, when in 1858, in consequence of the murder of M. Diaz,—who was put to death by order of the king, merely on account of the news that a French ship was cruising in sight of the coast,—a squadron was sent under the command of Admiral Rigault de Genouilly, who seized Tourane. Shortly after the admiral made explorations in the south, seeking a better situation for a settlement than Tourane, and passing up the River Don-naï, he took possession of Saigon, the true capital of Lower Cochin China. On the 5th June 1862 the court of Hué accepted a treaty, by which it abandoned three provinces to France, and bound itself to pay an indemnity of war. After various expeditions occasioned by revolts, France occupied in 1867 the three other provinces of Lower Cochin China, and after long negotiations a treaty was signed at Saigon, on the 15th March 1874, definitively abandoning the six provinces to France. This treaty opens besides to the commerce of all nations one port in eastern Cochin China and one port in Tong-king, and guarantees liberty of transit from the sea as far as Yun-nan.

Bibliography.—M. Barbié du Bocage, secretary of the Central Commission of the Geographical Society at Paris, published in 1867 a very complete bibliography of the books, periodicals, manuscripts, and plans relating to the history and geography of Anam, in a pamphlet of 105 pages, 8vo. In M. Vivien de Saint Martin's well-known work—*L'Année Géographique*, Hachette and Cie—there is to be found a list well up to date of new works on Indo-China, among which we may mention—Fr. von Richthofen, *Sur les Provinces Sud-ouest de la Chine;* MacMahon (Colonel A. P.) *Routes du Sud-ouest de la Chine; Edinburgh Review*, April 1873; F. Vial, *Les premières années de la Cochinchine*, 1874; Romanet du Caillaux, *La France au Tong King;* Aymonnier, *Dictionnaire français-cambodgien et Géographie du Cambodge*, 1876; G. Coryton, "On the Rontes between British Burmah and the West of China," in vol. xix. of *Journ. R. G. S.*, 1849; Papers read by Docteur Mondières and Docteur A. Morice before the Societé d'Anthropologie, in Jan. 1875; Dr Harmand, *Aperçu pathologique sur la Cochinchine;* Bigrel, *Carte générale de la Cochinchine française*, with an interesting note on the proper names. The following recent works have not been mentioned in the *Année Géographique*.—*Instructions nautiques publiées par le Ministère de la Marine; Tableaux de Population, de Culture, de Commerce, et de Navigation, publiés par le Ministère de la Marine; Petit cours de Géographie de la Basse Cochinchine*, by P. J. B. Truong-vinh-ky, Saigon, 1875; *Cours d'histoire annamite à l'usage des écoles de la Basse Cochinchine*, by Truong-vinh-ky; *Voyage d'Exploration en Indo-Chine pendant les années* 1866, 1867, 1868, *sous le Commandement de M. Doudart de Lagrée, publié sous la direction de M. Francis Garnier*, 2 vols., Hachette, 1873—a magnificent work. The following are of earlier date:—*Viaggi di Tre Vescovi in* 1669; Barrow, *A Voyage to Cochin China in the years* 1792 *and* 1793; Bissachère, *Etat actuel de Cochinchine*, 1812; Crawfurd's *Embassy to the Courts of Siam and Cochin China*, 1828; Gutzlaff "Geography of the Cochin Chinese Empire," in *Journ. Roy. Soc.*, 1849); Bouillevaux, *Voyage dans l'Indo-Chine*, 1848-56. Paris, 1858; Veuillot, *La Cochinchine et la Tonquin*, 1859; Cortambert and De Rosny, *Tableau de la Cochinchine;* Mouhot, *Siam, Cambodia, and Lao*, 1864. A *Dictionnarium anamiticum, lusitanum, et latinum* was published at Rome in 1671 by Père Alex. de Rhode; and another, the combined work of Pigneaux and Tabard, appeared in 1838. An essay on the language and writing was published by Schott in 1855. (C. MA.)

COCHINEAL, a dye-stuff used for the production of scarlet, crimson, orange, and other tints, and for the preparation of lake and carmine. It consists of the females of *Coccus cacti*, an insect of the order *Hemiptera*, which feeds upon various species of the *Cactaceæ*, more especially the nopal plant, *Opuntia coccinellifera*, a native of Mexico and Peru. The dye was introduced into Europe from Mexico, where it had been in use long before the entrance of the Spaniards in the year 1518, and where it formed one of the staple tributes to the Crown for certain districts. In 1523 Cortes received instructions from the Spanish court to procure it in as large quantities as possible. It appears not to have been known in Italy so late as the year 1548, though the art of dyeing then flourished there. Cornelius van Drebbel, at Alkmaar, first employed cochineal for the production of scarlet in 1650. Until about 1725 the belief was very prevalent that cochineal was the seed of a plant, but Dr Lister in 1672 conjectured it to be a kind of kermes, and in 1703 Leeuwenhoeck ascertained its true nature by aid of the microscope. Since its introduction cochineal has supplanted kermes (*Coccus ilicis*) over the greater part of Europe. The male of the cochineal insect is half the size of the female, and, unlike it, is devoid of nutritive apparatus; it has long white wings, and a body of a deep red colour, terminated by two diverging setæ. The female is apterous, and has a dark-brown plano-convex body; it is found in the proportion of 150 to 200 to one of the male insect. The dead body of the mother insect serves as a protection for the eggs until they are hatched. Cochineal is now furnished not only by Mexico and Peru, but also by Algiers and the S. of Spain. In Teneriffe it was successfully cultivated in 1858, on the failure of the vines there through disease, but the diminished value of cochineal of late years has much affected its production in the Canaries. Cochineal is collected thrice in the seven months of the season. The insects are carefully brushed from the branches of the cactus into bags, and are then killed by immersion in hot water, or by exposure to the sun, steam, or the heat of an oven—much of the variety of appearance in the commercial article being caused by the mode of treatment. The dried insect has the form of irregular, fluted, and concave grains, which weigh about $\frac{1}{10}$ of a grain, as many as 70,000 insects being estimated to weigh 1 lb. Cochineal has a musty and bitterish taste. There are two principal varieties—silver cochineal, which has a greyish-red colour, and the furrows of the body covered with a white bloom or fine down, and black cochineal, which is of a dark reddish-brown, and destitute of bloom. Granilla is an inferior kind, gathered from uncultivated plants. The best crop is the first of the season, which consists of the unimpregnated females; the later crops contain an admixture of young insects and skins, which contain proportionally little colouring matter.

Cochineal owes its tinctorial power to the presence of a substance termed *cochinealin*, or *carminic acid*, a compound of hydrogen, carbon, and oxygen, which may be prepared from the aqueous decoction of cochineal. The comparative value of different specimens of cochineal may be ascertained by a method based upon the bleaching action of ferricyanide of potassium upon a weak potash solution of the dye. The black variety of cochineal is sometimes sold for silver cochineal by shaking it with powdered talc, or heavy-spar; but these adulterations can be readily detected by means of a lens. The duty on cochineal was repealed in 1845. In 1869 the exports of cochineal from the Canaries reached 6,310,000 lb, value £842,921. Of this amount 4,232,600 lb, consisting of *grana, granilla,* and *polro*, were shipped to Great Britain, value £554,092. More than half of this quantity was supplied by the Island of Grand Canary. In three months ending 31st March 1876 the imports were 10,094 cwts, value £112,534.

For a monograph of the *Coccidæ*, including the cochineal insect, see Signoret, *Ann. Soc. Ent. France*, 1868–74. For accounts of the cochineal insect consult also—Theis, *ibid.*, v. p. 1; Burmeister, *Handbuch der Entomologie;* Vincent, *Ann. Sci. Nat.*, vol. viii., 1st *ser.;* Westwood, *Modern Classification of Insects*, pp. 448, 449. For a description of the cultivation of cochineal in Java, see *Veth's Woordenbock van Nederlandsch Indië—Cochenille.* See also "Observations on the Making of Cochineal in Jamaica," in *Phil. Tran.*, 1691, pp. 502–3; and Royle's *Essay on the Productive Resources of India*, pp. 47–65, 1840.

COCKATOO (*Cacatuidæ*), a family of Scansorial Birds, distinguished from other Old World parrots by their greater size, by a crest of feathers on the head, which can be raised or depressed at will, and by their enormously developed bills. They inhabit the Indian Archipelago, New Guinea, and Australia, and are gregarious, frequenting woods and feeding on seeds, fruits, and the larvæ of insects. Their note is generally harsh and unmusical, and although they are readily tamed when taken young, becoming familiar, and in some species showing remarkable intelligence, their powers of vocal imitation are exceedingly limited. Of the true cockatoos (*Cacatua*) the best known is the Crested Cockatoo (*Cacatua galerita*), of a pure white plumage with the exception of the crest, which is deep sulphur yellow, and of the ear and tail coverts, which are slightly tinged with yellow. The crest when erect stands 5 inches high. Those birds are found in Australia in flocks varying from 100 to 1000 in number, and do great damage to newly sown grain, for which reason they are mercilessly destroyed by farmers. They deposit their eggs—two in number, and of a pure white colour—in the hollows of decayed trees, or in the fissures of rocks, according to the nature of the locality in which they reside. This is the species usually kept in Europe as a cage bird. Leadbetter's Cockatoo (*Cacatua Leadbeateri*), an inhabitant of South Australia, excels all others in the beauty of its plumage, which consists in great part of white, tinged with rose colour, becoming a deep salmon colour under the wings, while the crest is bright crimson at the base, with a yellow spot in the centre and white at the tip. It is exceedingly shy and difficult of approach, and its note is more plaintive while less harsh than that of the preceding species. In the cockatoos belonging to the genus *Calyptorhynchus* the general plumage is black or dark brown, usually with a large spot or band of red or yellow on the tail, and in some species behind the ear also. The largest of these is known as the Funereal Cockatoo (*Calyptorhynchus funereus*), from the lugubrious note or call which it utters, resembling the two syllables Wy—la—, the native name of the species. It deposits its eggs in the hollows of the large gum trees of Australia, and feeds largely on the larvæ of insects, in search of which it peels off the bark of trees, and when thus employed it may be approached closely. "When one is shot, the remainder of the company," says Gould, "fly round for a short distance, and perch on the neighbouring trees until the whole are brought down."

COCKATRICE, a fabulous monster, the existence of which was firmly believed in throughout ancient and mediæval times,—descriptions and figures of it appearing in the natural history works of such writers as Pliny and Aldrovandus, those of the latter published so late as the beginning of the 17th century. Produced from a cock's egg hatched by a serpent, it was believed to possess the most deadly powers, plants withering at its touch, and men and animals dying poisoned by its look. It stood in awe, however, of the cock, the sound of whose crowing killed it, and consequently travellers were wont to take this bird with them in travelling over regions supposed to abound in cockatrices. The weasel alone among mammals was unaffected by the glance of its evil eye, and attacked it at all times successfully; for when wounded by the monster's teeth it found a ready remedy in rue—the only plant which the cockatrice could not wither. This myth reminds one of the real contests between the weasel-like mungoos of India and the deadly cobra, in which the latter is generally killed. The term "cockatrice" is employed on four occasions in the English translation of the Bible, in all of which it denotes nothing more than an exceedingly venomous reptile; it seems also to be synonymous with "Basilisk," the mythical king of serpents.

COCKBURN, MRS ALISON (1712–1794), justly celebrated for having written one of the most exquisite of Scottish ballads, the "Flowers of the Forest,"[1] was the daughter of a border laird, Robert Rutherfurd of Fairnalee, and was born in the heart of the Southern Highlands in the autumn of 1712. Her education was slight. She spent her youth in rambling and riding about the country-side, and in paying visits to an aged minister in the neighbourhood, of whose "heavenly affection" for her she wrote enthusiastically in after years. She was a graceful dancer, spent two winter seasons in Edinburgh, and was one of the Edinburgh belles of her time. Different causes have been assigned for the composition of the "Flowers of the Forest." Mr Chambers states that it was written on the occasion of a great commercial disaster which ruined the fortunes of some Selkirkshire lairds. Her later biographers, however, think it more probable that it was written on the departure to London of a certain John Aikman, between whom and Alison there appears to have been an early attachment. In 1731 Alison Rutherfurd was married to Patrick Cockburn of Ormiston, one of a family of stanch Whigs and Presbyterians, and an advocate at the Scottish bar. After her marriage she knew all the intellectual and aristocratic celebrities of her day. In the memorable year 1745 she vented her Whiggism in a squib upon Prince Charlie, and narrowly escaped being taken by the Highland guard as she was driving through Edinburgh in the family coach of the Keiths of Ravelston, with the parody in her pocket. Mrs Cockburn was an indefatigable letter-writer and a composer of parodies, squibs, toasts, and "character-sketches"—then a favourite form of composition—like other wits of her day; but the "Flowers of the Forest" is the only thing she wrote that possesses great literary merit. She survived her husband forty-one years, living to the age of eighty-two, and to the last she maintained her social popularity. At her house on Castle-hill, and afterwards in Crighton Street, she received many illustrious friends, among whom were Mackenzie, Robertson, Hume, Home, Monboddo, the Keiths of Ravelston, the Balcarres family, and Lady Anne Barnard, the authoress of "Auld Robin Gray." She was in Edinburgh when Dr Johnson visited that city, towed thither by the triumphant Boswell. She saw and commented upon Burns's short, bright Edinburgh career. As a Rutherfurd she was a connection of Sir Walter Scott's mother, and was her intimate

[1] There are two versions of this song,—the one by Mrs Cockburn, the other by Miss Jean Elliot of Minto. Both were founded on the remains of an ancient Border ballad. It is believed by the descendants of her family that Mrs Cockburn composed her version—that beginning "I've seen the smiling of fortune beguiling"—before her marriage in 1731. Anyhow, it was composed many years before Jean Elliot's sister verses, beginning, "I've heard them lilting at our ewe-milking." These were written in 1756, and printed soon afterwards. Mrs Cockburn's song, however, was not published until 1765, when Jean Elliot's was already popular.

friend. Lockhart quotes an interesting letter written by Mrs Cockburn in 1777, describing the precocious conduct of little Walter Scott, then scarcely six years old, during a visit which she paid to his mother. It was Mrs Cockburn also who wrote the character-sketch of Scott's father, which, when it was given as a toast, was so true as to be immediately recognized. Scott himself spent pleasant evenings at Mrs Cockburn's house when she was a very old lady and he a young advocate. Mrs Cockburn died in 1794, having survived her only child, Captain Adam Cockburn, fourteen years.

COCKBURN, SIR GEORGE (1772–1853), admiral, was of Scottish extraction, and was born in London. He entered the navy in his ninth year. After serving on the home station, and in the East Indies and the Mediterranean, he assisted, as captain of the "Minerve," at the blockade of Leghorn in 1796, and a year afterwards he fought in the battle of Cape St Vincent. In 1809, in command of the naval force on shore, he contributed greatly to the reduction of Martinique, and signed the capitulation by which that island was handed over to the English; for his services on this occasion he received the thanks of the House of Commons. After service in the Scheldt and at the defence of Cadiz he was sent in 1811 on an unsuccessful mission for the reconciliation of Spain and her American colonies. He was made rear-admiral in 1812, and in 1813–14 he took a prominent part in the American war, especially at the battle of Bladensburg and the capture of Washington. Early in 1815 he received the Order of the Bath, and in the autumn of the same year he carried out, in the "Northumberland," the sentence of deportation to St Helena which had been passed upon Bonaparte. In 1818 he received the Grand Cross of his Order, and was made a Lord of the Admiralty; and the same year he was returned to parliament for Portsmouth. He was promoted to the rank of vice-admiral in 1819, and to that of admiral in 1837; he became senior naval lord in 1841, and held office in that capacity till 1846. From 1827 he was a privy councillor. In 1851 he was made Admiral of the Fleet, and in 1852, a year before his death, his brother's baronetcy fell to him by inheritance. See O'Byrne, *Naval Biography*; James, *Naval History*; *Gentleman's Magazine* for 1853.

COCKBURN, HENRY DUNDAS (1779–1854), known as Lord Cockburn, was born in Edinburgh, October 26, 1779. He was educated at the High School and at the university of Edinburgh; and he was a member of the famous Speculative Society, to which Scott, Brougham, and Jeffrey belonged. He entered the faculty of advocates in the year 1800, and attached himself, not to the party of his relatives, who could have afforded him most valuable patronage, but to the Whig or Liberal party, and that at a time when it held out few inducements to men ambitious of success in life. On the accession of Earl Grey's ministry in 1830, he became Solicitor-General for Scotland. In 1834 he was raised to the bench, and on taking his seat as a judge in the Court of Session he adopted the title of Lord Cockburn. Cockburn's forensic style was remarkable for its clearness, pathos, and simplicity; and his conversational powers were unrivalled among his contemporaries. The extent of his literary ability only became known after he had passed his seventieth year, on the publication of his biography of Lord Jeffrey in 1852, and from the *Memorials of his Time*, which appeared posthumously in 1856. He died on the 26th of April 1854, at his mansion of Bonaly, near Edinburgh.

COCKER, EDWARD, the reputed author of the famous *Arithmetick*, the popularity of which has added a phrase to the list of English proverbialisms, was born about 1632, and died between 1671 and 1675. He was an engraver, and also taught writing and arithmetic. He is credited with the authorship and execution of some fourteen sets of copy slips, one of which, *Daniel's Copy-Book, ingraven by Edward Cocker, Philomath*, is preserved in the British Museum. Pepys, in his *Diary*, makes very favourable mention of Cocker, who appears to have displayed great skill in his art. *Cocker's Arithmetick*, the fifty-second edition of which appeared in 1748, and which has passed through some sixty editions in all, was not published during the lifetime of its reputed author, the first impression bearing date of 1678. The late Professor De Morgan in his *Arithmetical Books* (1847) adduces proofs, which may be held to be conclusive, that the work was a forgery of the editor and publisher, John Hawkins; and there appears to be no doubt that the *Decimal Arithmetic* (1684), and the *English Dictionary* (second edition, 1715), issued by Hawkins under Cocker's name, are forgeries also. De Morgan condemns the *Arithmetick* as a diffuse compilation from older and better works, and dates "a very great deterioration in elementary works on arithmetic" from the appearance of the book, which owed its celebrity far more to persistent puffing than to its merits. He pertinently adds,—"This same Edward Cocker must have had great reputation, since a bad book under his name pushed out the good ones."

COCKERELL, CHARLES ROBERT (1788–1863), architect, was born in London. After a severe preliminary training in his profession, he visited and studied the great architectural remains of Greece, Italy, and Asia Minor. At Ægina, Phigalia, and other places of interest, he conducted excavations on a large scale, enriching the British Museum with many fine fragments, and adding several valuable monographs to the literature of archæology, the best of which is said to be that on the mausoleum of Halicarnassus. Elected in 1829 an associate of the Royal Academy, he became a member in 1836, and in 1839 he was appointed professor of architecture, his lectures in which capacity were so greatly esteemed as to be attended by all the students of the several arts professed within the school. On the death in 1837 of Soane, the distinguished architect of the Bank of England, Cockerell was appointed his successor, and successfully carried out the alterations that have been needed in that building. In addition to branch banks at Liverpool and Manchester he erected in 1840 the New Library at Cambridge, and in 1845 the university galleries at Oxford, the last one of the architect's least happy efforts, as well as the Sun and the Westminster Fire Offices in Bartholomew Lane and in the Strand; and Tite and he were joint architects of the London and Westminster Bank. On the death of Henry Lonsdale Elmes in 1847, Cockerell was selected to finish the St George's Hall, Liverpool, a task which he executed with great success. Cockerell's best conceptions were those inspired by classic models; his essays in the Gothic—the college at Lampeter, for instance, and the chapel at Harrow—are by no means so successful. Among his numerous publications, however, may be mentioned those *On the Iconography of Wells Cathedral*, and *On the Sculptures of Lincoln and Exeter Cathedrals*, which prove his thorough knowledge of Gothic art as well as of Greek. His *Tribute to the Memory of Sir Christopher Wren* (1838) is a collection of the whole of Wren's works drawn to the same scale.

COCKERMOUTH, a parliamentary borough and market-town of England, in the county of Cumberland, 25 miles by rail from Carlisle, at the confluence of the Derwent and the Cocker, both of which are crossed by bridges in the immediate vicinity. The town is irregularly built, but is clean and well paved. It has remains of an old castle, built soon after the Conquest, a town-hall, a free grammar school, and a house of correction; and its manufactures include linen and woollen goods, thread, hosiery, hats, and paper. In the neighbourhood are extensive coal mines, which give employment to nearly 2000 workmen. In 1871 the township had a population of 5115; the borough (which returns one member to parliament), with an area of 8467 acres, had 6936. Of the early occupation of the site of Cockermouth conclusive evidence is afforded by the relics discovered from time to time; directly north of the town is a tumulus called Toot's Hill; and at Pap Castle, about half a mile to the north-west, are the remains of a Roman camp. The barony or honour of Cockermouth was held shortly after the Conquest by Waltheof, lord of Allerdale, and has since passed through a long series of possessors, including the Umfravilles, Multens, Lucies, Percies, and Nevilles, down to the present Lord Leconfield. The town was captured in 1387 by the Scotch under Douglas; and in 1648 the castle, garrisoned for king Charles, was taken and dismantled by the Parliamentarians. Wordsworth the poet was born at Cockermouth in 1770; and Tickell, the friend of Addison, at the village of Bridekirk, about two miles to the north.

COCKLE (*Cardium*), a genus of Acephalous Mollusks belonging to the family *Cardiadæ*, and comprising about 200 species, nearly a third of which are said to occur in the Indian Ocean, while only a few, but these exceedingly abundant in individuals, and widely distributed, are found in northern and temperate latitudes. The shells of cockles are highly convex, and almost invariably show a ridge-and-furrow sculpture, the ridges or ribs being often spiny, and the valves locking closely together. The animal inhabiting the shell is provided with a large, fleshy, and highly elastic foot, by means of which it can rapidly bury itself in the soft muddy sand which it frequents, reappearing above the surface with equal facility. In performing those leaps, for which it is remarkable, "the long taper foot," says Gosse, "is thrust to its utmost, and feels about for some resisting surface, a stone for instance, which it no sooner feels than the hooked point is pressed stiffly against it, the whole foot, by muscular contraction, is made suddenly rigid, and the entire creature—mantle, siphons, foot, shell, and all—is jerked away in an uncouth manner." Many of the species are of considerable value as articles of food, especially the Common Cockle (*Cardium edule*), gregarious everywhere in the sandy bays and estuaries around the British coast, from low-water mark to a few fathoms deep, and extending from Iceland to the Canaries, and as far east as the Caspian and Aral Seas, where it occurs in one of its varieties. The shell of the cockle is liable to considerable variation, getting thinner and more elongated posteriorly in sheltered situations and in muddy ground, more convex and thicker when exposed to rougher conditions. They vary also in size from ·1 inch to 2½ inches in breadth. They occur in great abundance on several parts of the British coast, and in many places cockle-gathering gives employment to large numbers of people; thus at Penclawdd in Glamorganshire, the women and children are regularly employed in gathering and preparing cockles, which they afterwards dispose of in the Swansea market. At Starcross they have "cockle-gardens," where those mollusks are reared, and these are said to possess a better flavour than the ordinary cockle. Some species or other of *Cardium* is used for food by the maritime populations of almost every country in the world, and the dietetic value of these mollusks appears to have been equally appreciated in prehistoric times, as the shell-mounds or kjökkenmöddings of many countries abundantly testify. As cockle shells contain about 90 per cent. of carbonate of lime, they are calcined and used instead of common lime where the latter cannot readily be obtained.

COCKROACH (*Blattidæ*), a family of Orthopterous Insects, distinguished by their flattened bodies, long thread-like antennæ, and shining leathery integuments. Cockroaches are nocturnal creatures, secreting themselves in chinks and crevices about houses, issuing from their retreats when the lights are extinguished, and moving about with extraordinary rapidity in search of food. They are voracious and omnivorous, devouring, or at least damaging, whatever comes in their way, for all the species emit a disagreeable odour, which they communicate to whatever article of food or clothing they may touch. The Common Cockroach (*Blatta orientalis*) is not indigenous to Europe, but is believed to have been introduced from the Levant in the cargoes of trading vessels. The wings in the male are shorter than the body; in the female they are rudimentary. The eggs, which are 16 in number, are deposited in a leathery capsule fixed by a gum-like substance to the abdomen of the female, and thus carried about till the young are ready to escape, when the capsule becomes softened by the emission of a fluid substance. The larvæ are perfectly white at first, although in other respects not unlike their parents, but they are not mature insects until after the sixth casting of the skin. The American Cockroach (*Blatta americana*) is larger than the former, and is not uncommon in European seaports trading with America, being conveyed in cargoes of grain and other food produce. The largest known species is the Drummer of the West Indies (*Blatta gigantea*), so called from the tapping noise it makes on wood, sufficient, when joined in by several individuals, as usually happens, to break the slumbers of a household. It is about 2 inches long, with wings 3 inches in expanse, and forms one of the most noisome and injurious of insect pests. The best mode of destroying cockroaches is, when the fire and lights are extinguished at night, to lay some treacle on a piece of wood afloat on a broad basin of water. This proves a temptation to the vermin too great to be resisted. The chinks and holes from which they issue should also be filled up with unslaked lime, and some may be scattered on the ground.

COCLES, HORATIUS, a Roman hero, who, with Spurius Lartius and Titus Herminius as sole companions, defended the Sublician bridge against Lars Porsena and the whole army of the Etruscans. While the three heroes kept back the enemy the Romans cut down the bridge behind. When it was almost ready to fall his comrades retreated, but Horatius waited till the work was complete, and Rome was saved. Then, despite the arrows of the enemy, he swam in safety to the opposite shore. A statue was erected in his honour, and he received as much land as he could plough round in a single day. According to another story, Horatius was alone in his heroism, and gave his life for his country. The former version is adopted by Lord Macaulay in his *Lays of Ancient Rome*.

COCOA, or more properly CACAO, is a valuable dietary substance yielded by the seeds of several small trees belonging to the genus *Theobroma*, of the natural order *Sterculiaceæ*. The whole genus, which comprises nine or ten species, belongs to the tropical parts of the American continent; and although the cocoa of commerce is probably the produce of more than one species, by far the greatest and most valuable portion is obtained from the *Theobroma Cacao* of Linnæus. The generic name is derived from θεός (god) and βρῶμα (food), and was bestowed by Linnæus as an indication of the high appreciation in which he held the beverage prepared from the seeds, which he considered to be a food fit for the gods.

The common cocoa tree is of low stature, seldom exceeding 16 or 18 feet in height, but it is taller in its native forests than it is in cultivated plantations. The leaves are large, smooth, and glossy, elliptic-oblong and acuminate in form, growing principally at the ends of branches, but sometimes springing directly from the main trunk. The flowers are small, and occur in numerous clusters on the main branches and the trunk, a very marked peculiarity which gives the matured fruit the appearance of being artificially attached to the tree. Generally only a single fruit is matured from each cluster of flowers. When ripe the fruit or "pod" is elliptical-ovoid in form, from 7 to 10 inches in length, and from 3 to 4½ inches in diameter. It has a hard, thick, leathery rind of a rich purplish yellow colour, externally rough and marked with ten very distinct longitudinal ribs or elevations. The interior of the fruit has five cells, in each of which is a row of from 5 to 10 seeds embedded in a soft delicately pink acid pulp. Each fruit thus contains from 20 to 40 or more seeds, which constitute the raw cocoa or "cocoa beans" of commerce.

Branch of Cocoa Tree, with Fruit in section.

The tree appears to have been originally a native of Mexico; but it can be cultivated in suitable situations within the 25th parallels of latitude. It, however, flourishes best within the 15th parallels, at elevations ranging from near the sea-level up to about 2000 feet in height. It is now cultivated in Mexico, Honduras, Guatemala, Nicaragua, Brazil, Peru, Ecuador, New Granada, Venezuela, Guiana, and most of the West Indian Islands. Its cultivation has also been attempted in other tropical regions of the globe; but the industry has hitherto not been developed on any considerable scale away from the American continent and the West Indian Islands.

For the successful cultivation of the cocoa tree a rich well-watered soil and a humid atmosphere, with freedom from cold winds and protection from violent storms, are necessary. As the young plants are extremely delicate and tender, they are reared in nursery grounds till they attain a height of from 15 to 18 inches, and after planting out they still require protection from the wind and sun, which is provided by growing "provisions" (food-yielding plants), and the coral-bean tree, *Erythrina Corallodendron*, among the young trees. The trees begin to bear in the fourth or fifth year, but they do not attain their full productive vigour till about their eighth year, and they ought to continue prolific for from thirty to forty years thereafter. As the trees carry buds, flowers, and fruit in all stages at the same time, ripe pods may be collected at any period of the year, but there are periodical harvests dependent on the suitability of the weather for collecting the fruit and curing the seeds. In Venezuela, where the famous Caracas cocoa is grown, the gathering takes place in June and December, these being the crop of St John and the Christmas crop respectively. In gathering the workman is careful to cut down only fully ripened pods, which he adroitly accomplishes with a long pole armed with two prongs or a knife at its extremity. The pods are left in heaps on the ground for about twenty-four hours; they are then cut open, and the seeds are taken out, and carried in baskets to the place where they undergo the operation of sweating or curing. There the acid juice which accompanies the seeds is first drained off, after which they are placed in a sweating box, in which they are enclosed and allowed to ferment for some time, great care being taken to keep the temperature from rising too high. The fermenting process is, in some cases, effected by throwing the seeds into holes or trenches in the ground, and covering them with earth or clay. The seeds in this process, which is called claying, are occasionally stirred to keep the fermentation from proceeding too violently. The sweating is a process which requires the very greatest attention and experience, as on it to a great extent depend the flavour of the seeds and their fitness for preservation. The operation varies in duration according to the state of the weather, but a period of about two days yields the best results. Thereafter the seeds are exposed to the sun for drying, and those of a fine quality should then assume a warm reddish tint, which characterizes beans of a superior quality.

The cocoa tree was cultivated, and its produce held in the highest esteem, in Mexico and Peru previous to the discovery of the American continent by Columbus. Prescott, in his *Conquest of Peru*, says of the followers of Pizarro, that as they sailed along the Pacific coast they saw "hill-sides covered with the yellow maize and the potato, or checkered in the lower levels with blooming plantations of cacao." The same writer, referring to the use of cocoa in Mexico, says of the Emperor Montezuma that "he was exceedingly fond of it, to judge from the quantity, no less than 50 jars or pitchers being prepared for his own daily consumption; 2000 more were allowed for that of his household." "Traffic," he adds again, "was carried on partly by barter and partly by means of a regulated currency of different values. This consisted of transparent quills of gold dust, of bits of tin cut in the form of a T, and bags of cacao containing a specified number of grains."

A knowledge of this valuable article of food was first brought to Europe by Columbus, but some time elapsed ere its virtues were appreciated in the Old World. Spain was the first nation in which its use became common; and to this day cocoa is much more extensively consumed among the Spaniards than by any other European community. The earliest intimation of the introduction of cocoa into England is found in an announcement in the *Public Advertiser* of Tuesday, 16th June 1657, notifying that "In Bishopgate Street, in Queen's Head Alley, at a Frenchman's house, is an excellent West India drink, called chocolate, to be sold, where you may have it ready at any time, and also unmade, at reasonable rates." About the beginning of the 18th century chocolate had become an exceedingly fashionable beverage, and the cocoa tree was a favourite sign and name for places of public refreshment. Cocoa and chocolate are frequently mentioned in contemporary literature, and among others Pope, in his *Rape of the Lock*, alludes to it; the negligent spirit, fixed like Ixion—

> "In fumes of burning chocolate shall glow,
> And tremble at the sea that froths below."

The high price at which it was retailed kept chocolate among the luxuries of the wealthy; and coffee, which had been introduced two or three years before chocolate, and tea, which came a year later, both soon far out-stripped their rival beverage in public estimation.

Raw cocoas are distinguished in commerce by the name of the localities of their growth; and it is found that the produce of particular regions maintains, pretty constantly, a distinctive character and appearance. The most esteemed of all varieties is that obtained from Venezuela, known in commerce as Carácas cocoa, next to which in value stand the red "nuts" of Trinidad. The finest qualities are in form and size not unlike thick round almonds; they have a husk of a clear brick-red colour, and the cotyledons, which are of a deep chocolate brown, have a fine membrane permeating their entire substance, and dividing them into numerous irregular segments, into which the seeds are easily broken down. The kernels are astringent in taste, with a mild, not disagreeable flavour. In chemical composition, as well as in physical characteristics, they vary within certain limits; but the analysis by Payen may be taken as representing their average constitution. It is as follows:—

Fat (Cocoa Butter)	52·00
Nitrogenous compounds	20·00
Starch	10·00
Cellulose	2·00
Theobromine	2·00
Saline substances	4·00
Water	10·00
Cocoa red } Essential oil }	traces
	100·00

The constituent upon which the peculiar value of cocoa depends is the theobromine, an alkaloid substance which till recently was supposed to be distinct from, though closely allied to, the theine of tea and coffee. It is now, however, known that the alkaloid in these and in two or three other substances similarly used is identical, and their physiological value is consequently the same. The fat or cocoa butter is a firm, solid, white substance at ordinary temperatures, having an agreeable taste and odour, and very remarkable for its freedom from any tendency to become rancid. It consists essentially of stearin with a little olein, and is used in surgical practice, and in France as a material for soap and pomade manufacture. The starch grains present in raw cocoa are small in size, and of a character so peculiar that there is no difficulty in distinguishing them under the microscope from any other starch granules. As an article of food cocoa differs essentially from both tea and coffee. While only an infusion of these substances is used, leaving a large proportion of their total weight unconsumed, the entire substance of the cocoa seeds is prepared as an emulsion for drinking, and the whole is thus utilized within the system. While the contents of a cup of tea or coffee can thus only be regarded as stimulant in its effect, and almost entirely destitute of essential nutritive properties, a cup of prepared cocoa is really a most nourishing article of diet, as, in addition to the value of the theobromine it contains, it introduces into the system no inconsiderable proportion of valuable nitrogenous and oleaginous elements.

The manufacturing processes through which raw cocoa passes have for their object the development of the aroma peculiar to the substance, and its preparation in a soluble palatable and digestible form. The first operation consists in roasting the seeds, whereby the empyreumatic aromatic substance is formed, and the starch particles are changed into dextrin. The roasting is accomplished in large revolving cylinders, after the completion of which the roasted seeds are taken to the crushing and winnowing machine. Here the seeds are reduced to the form of nibs, which are separated from the shells or husks by the action of a powerful fan blast. The nibs are next subjected to a process of winnowing in small quantities in hand sieves, by which the hard cocoa "germs" are sifted out, and mouldy or discoloured fragments are at the same time removed by hand. Nibs so prepared constitute the simplest and purest preparation in which manufactured cocoa is sold; but they require prolonged boiling to effect their complete disintegration. The nibs when ground to a fine meal can be cooked with much greater facility. Another form in which the pure seeds are prepared is in flaked cocoa, which consists of the nibs ground up into a rather coarse uniform paste. The grinding is effected in cylinder machines, having an outer fixed casing within which a drum revolves. The nibs are fed in by a hopper on the upper part of the apparatus, and are carried round its circumference by the revolution of the drum, and delivered as a thin uniform pasty mass, the heat developed by the friction within the cylinder being sufficient to liquefy the oil, which again sets on cooling of the paste. Of late years a preparation called extract of cocoa has come into extensive use. It is made by removing a certain proportion of the fat from the seeds, whereby the remaining substance can be ground to an impalpable powder, which yields a beverage much more palatable and agreeable to many stomachs then either entire nibs or the so-called soluble cocoas. The removal of the fat is effected by placing nibs, after they have been reduced by grinding to a fine smooth paste, in bags, and subjecting them to powerful pressure in heated presses. The fat exudes slowly and quickly solidifies, and a solid compact cake is left in the press, which only requires to be broken up and finely powdered for use.

Most other preparations, whether sold as cocoa or chocolate, are mixtures of various substances with ground nibs, the object of the mixture being to mask the presence of the cocoa fat, and to render the whole readily miscible with boiling water. The ordinary distinction between these soluble cocoas and chocolate is that the cocoa is usually sold in the form of a powder, the chocolate being made up in cakes, which require to be scraped down, boiled, and "milled" or frothed before being ready for drinking. In making the soluble cocoa, which is sold under such names as homœopathic, Iceland moss, pearl cocoa, &c., the nibs are first ground up in a heated stone mill, and, while in a soft pasty condition, thoroughly mixed with certain proportions of sugar and arrowroot, or other and inferior starches. The compound is afterwards ground to fine powder and sold under various names and at different prices, according to the quality of the cocoa and the nature and proportion of the ingredients which are combined with it. The finer chocolates are combinations of cocoa with sugar alone, flavoured with some aromatic substance, generally vanilla; but into the composition of cheap qualities starchy substances enter. The nibs for chocolate are brought to a fine pasty state in a heated mill, and the sugar or sugar and starch with vanilla are then added and thoroughly incorporated in the mill. The paste is next passed several times between heavy horizontal rollers to produce a thoroughly homogeneous mixture. It is lastly cast into moulds while still in a thin pasty state, and after cooling it forms hard solid cakes, and is ready to wrap up for the market. Chocolates for eating are prepared with large proportions of sugar and various flavouring substances, and the elegant preparations of these and of chocolate creams by Ménier of Paris and Fry and Sons of Bristol undoubtedly form most wholesome, palatable, and nutritious confections. To the last-named firm we have to express our obligation for information courteously placed at our disposal.

Preparations of cocoa are still much more largely consumed in Spain than in any other European country. In Great Britain the consumption, partly stimulated by the improvements effected in its manufacture, is steadily increasing, although as compared with the consumption of tea and coffee its employment is yet on a very restricted scale. The following figures exhibit the ratio of increase of cocoa entered for home consumption since 1820:—

1820	267,321 lb	1860	4,583,124 lb
1830	425,382	1870	6,943,102
1840	2,645,470	1874	8,863,646
1850	3,080,641	1875	9,973,926

In addition to these quantities of raw cocoa, a considerable quantity of prepared cocoa and chocolate is now imported from France. In 1820 the imports of manufactured cocoa only amounted to 14 lb, but in 1874 91,466 lb were imported. An import duty of 1d. per lb on raw and 2d. per lb on manufactured cocoa is levied in Great Britain.

COCOA-NUT PALM (*Cocos nucifera*), sometimes, and perhaps more correctly, called the coco-nut palm, is a very beautiful and lofty palm-tree, growing to a height of from 60 to 100 feet, with a cylindrical stem which attains a thickness of 2 feet. The tree terminates in a crown of graceful waving pinnate leaves. The leaf, which may attain to 20 feet in length, consists of a strong mid-rib, whence numerous long acute leaflets spring, giving the whole the appearance of a gigantic feather. The flowers are arranged in branching spikes 5 or 6 feet long, enclosed in a tough spathe, and the fruits mature in bunches of from 10 to 20. The fruits when mature are oblong, and triangular in cross section, measuring from 12 to 18 inches in length and 6 to 8 inches in diameter. The fruit consists of a thick external husk or rind of a fibrous structure, within which is the ordinary cocoa-nut of commerce. The nut has a very hard, woody shell, enclosing the nucleus or kernel, within which again is a milky liquid called cocoa-nut milk. The palm is so widely disseminated throughout tropical countries that it is impossible to distinguish its original habitat. It flourishes with equal vigour on the coast of the East Indies, throughout the tropical islands of the Pacific, and in the West Indies and tropical America. It, however, attains its greatest luxuriance and vigour on the sea shore, and it is most at home in the innumerable small islands of the Pacific seas, of the vegetation of which it is eminently characteristic. Its wide distribution, and its existence in even the smallest coral islets of the Pacific, have been favoured by the peculiar triangular shape of the fruit, which dropping into the sea from trees growing on any shores would be carried by tides and currents to be cast up and to vegetate on distant coasts.

The cocoa-nut palm, being the most useful of its entire tribe to the natives of the regions in which it grows, and furnishing many valuable and important commercial products, is the subject of careful cultivation in many countries. On the Malabar and Coromandel coasts of India the trees grow in vast numbers; and in Ceylon, which is peculiarly well suited for their cultivation, it is estimated that twenty millions of the trees flourish. The wealth of a native in Ceylon is estimated by his property in cocoa-nut trees, and Sir J. Emerson Tennent notes a law case in a district court in which the subject in dispute was a claim to the 2520th part of ten of the precious palms. The cultivation of cocoa-nut plantations in Ceylon is thus described by Sir J. E. Tennent. "The first operation in cocoa-nut planting is the formation of a nursery, for which purpose the ripe nuts are placed in squares containing about 400 each; these are covered an inch deep with sand and sea-weed or soft mud from the beach, and watered daily till they germinate. The nuts put down in April are sufficiently grown to be planted out before the rains of September, and they are then set out in holes 3 feet deep and 20 to 30 feet apart. . . . . . Before putting in the young plant it is customary to bed the roots with soft mud and sea-weed, and for the first two years they must be watered and protected from the glare of the sun under shades made of the plaited fronds of the cocoa-nut palm, or the fan-like leaves of the palmyra." The palm begins to bear fruit from the fifth to the seventh year of its age, each stock carrying from 5 to 30 nuts, the tree maturing on an average 60 nuts yearly.

The uses to which the various parts of the cocoa-nut palm are applied in the regions of their growth are almost endless. The nuts supply no inconsiderable proportion of the food of the natives, and the milky juice enclosed within them forms a pleasant and refreshing drink. The juice drawn from the unexpanded flower spathes forms "toddy," which may be boiled down to sugar, or it is allowed to ferment and is distilled, when it yields a spirit which, in common with a like product from other sources, is known as "arrack." The trunk yields a timber (known in European commerce as porcupine wood) which is used for building, furniture, firewood, &c.; the leaves are plaited into cajan fans and baskets, and used for thatching the roofs of houses; the shell of the nut is employed as a water vessel; and the external husk or rind yields the coir fibre, with which are fabricated ropes, cordage, brushes, &c. The cocoa-nut palm also furnishes very important articles of external commerce, of which the principal is cocoa-nut oil. It is obtained by pressure or boiling from the kernels, which are first broken up into small pieces and dried in the sun, when they are known as copperah or copra. It is estimated that 1000 full-sized nuts will yield upwards of 500 lb of copra, from which 25 gallons of oil should be obtained. The oil is a white solid substance at ordinary temperatures, with a peculiar, rather disagreeable odour, from the volatile fatty acids it contains, and a mild taste. Under pressure it separates into a liquid and a solid portion, the latter, cocoa-stearin, being extensively used in the manufacture of candles. Cocoa-nut oil is also used in the manufacture of marine soap, which forms a lather with sea water. Coir is also an important article of commerce, being in large demand for the manufacture of coarse brushes, door mats, and woven coir matting for lobbies and passages. A considerable quantity of fresh nuts is imported, chiefly from the West Indies, and sold as a dainty among the poorer classes, or used in the preparation of a kind of confection.

COCYTUS, a tributary of the Acheron, a river of Thesprotia, which flows into the Ionian Sea. Its modern name is the Vuvo. The name is also applied, in classical mythology, to a tributary of the Acheron, a river in Hades. The etymology suggested is from *κωκύειν*, to wail.

COD (*Morrhua vulgaris*), a well-known species of *Gadidæ*, a family of Anacanthine Fishes, possessing, in common with the other members of the genus, three dorsal and two anal fins, and a single barbel at the chin. It is a widely distributed species, being found throughout the northern and temperate seas of Europe, Asia, and America, extending as far south as Gibraltar, but not entering the Mediterranean, and inhabits water from 25 to 50 fathoms deep, where it always feeds close to the bottom. It is exceedingly voracious, feeding on the smaller denizens of the ocean—fish, crustaceans, worms, and mollusks, and greedily taking almost any bait the fisherman chooses to employ. The cod spawns in February, and is exceedingly prolific, the roe of a single female having been known to contain upwards of eight millions of ova, and to form more than half the weight of the entire fish. Only a small proportion of these get fertilized, and still fewer ever emerge from the egg. The number of cod is still further reduced by the trade carried on in roe, large quantities of which are used in France as ground-bait in the sardine fishery, while it also forms an article of human food. The young are about an inch in length by the end of spring, but are not fit for the market till the second year, and it has been stated that they do not reach maturity, as shown by the power of reproduction, till the end of their third year. They usually measure about 3 feet in length, and weigh from 12 to 20 lb, but specimens have been taken from 50 to 70 lb in weight. As an article of food the cod-fish is in greatest perfection during the three months preceding Christmas. It is caught on all parts of the British and Irish coasts, but the Dogger Bank, and Rockall, off the Outer Hebrides, have been specially noted for their cod-fisheries. Until recently, the London market was in great part supplied from the former of these; but now the fishery is chiefly carried on along the coast of Norfolk and Suffolk, where great quantities of the fish are caught with hook and line, and conveyed to market alive in "well-boats" specially built for this traffic. Such boats have been in use since the beginning of the 18th century. The most important cod-fishery in the world is that which has been prosecuted for centuries on the Newfoundland banks, where it is not uncommon for a single fisherman to take over 500 of these fish in 10 or 11 hours. The fish have lately been decreasing in that well-worn locality, but that the yield is still enormous is seen from recently published returns, from which it appears that the quantity of cod obtained by the Canadian fishery alone in 1875 weighed over 31,000 tons, while in 1874 it reached 34,500 tons. These, salted and dried, are exported to all parts of the world, and form, when taken in connection with the enormous quantity of fresh cod consumed, a valuable addition to the food resources of the human race. The swimming bladder of this fish furnishes isinglass, little, if at all, inferior to that obtained from the sturgeon, while from the liver is obtained cod-liver oil, now largely used in medicine as a remedy in scrofulous complaints and pulmonary consumption. "The Norwegians," says Cuvier, "give cod heads with marine plants to their cows for the purpose of producing a greater proportion of milk. The vertebræ, the ribs, and the bones in general, are given to their cattle by the Icelanders, and by the Kamtchatdales to their dogs. These same parts, properly dried, are also employed as fuel in the desolate steppes of the Icy Sea." At Port Logan in Wigtonshire cod-fish are kept in a large reservoir, scooped out of the solid rock by the action of the sea, egress from which is prevented by a barrier of stones, which does not prevent the free access of the water. These cod are fed chiefly on mussels, and when the keeper approaches to feed them they may be seen rising to the surface in hundreds and eagerly seeking the edge. They have become comparatively tame and familiar. Frank Buckland, who some years ago visited the place, states that after a little while they allowed him to take hold of them, scratch them on the back, and play with them in various ways. Their flavour is considered superior to that of the cod taken in the open sea.

COD-LIVER OIL is an oil of great medicinal value, obtained from the liver of the common cod (*Morrhua vulgaris*), and also to some extent from the ling (*Lota molva*), the whiting (*Merlangus vulgaris*), the pollack (*Merlangus pollachius*), as well as other members of the *Gadidæ*. The oil obtained from the livers differs in quality from a very pure pale-coloured liquid to a dark evil-smelling product, according to the care exercised and the processes adopted for its extraction. The very dark coloured rank oils are used only for burning and lubricating, and in commerce are known as cod oil. The purer qualities, up to an oil having a brown sherry colour, are alone used medicinally as cod-liver oil. Various methods of extracting the oil are adopted in the different countries where its preparation is prosecuted. Generally it may be stated that the medicinal oil is obtained from selected livers, which are carefully examined, cleaned, spilt up, and thrown together into a large vessel. From these a very small proportion of a pure and almost colourless oil exudes spontaneously, and exposure to the heat of the sun causes a further exudation. By the application of heat in a steam or water bath to a temperature not exceeding 180° Fahr., a proportion of still pale, or straw-coloured oil is obtained. The oil which results from the application of a higher heat and pressure, and that obtained from unhealthy and from putrid livers, are only used industrially as cod oil. The extraction of the oil is most extensively prosecuted in Newfoundland and in Norway; but a considerable quantity is also prepared in the Shetland Islands and along the east coast of Scotland.

Three varieties of medicinal oil are recognized in commerce—pale, light brown, and brown; but these insensibly merge into each other, and are only the result of different processes or periods of preparation, as mentioned above. The pale oil possesses a fishy odour and a slightly acrid taste, while with the darker oil there is a distinctly disagreeable empyreumatic odour and taste. In composition the oil contains olein and margarin, with small proportions of free butyric and acetic acids, a peculiar principle termed gaduin, certain bile acids, free phosphorus, phosphatic salts, and traces of iodine and bromine. Cod-liver oil is valuable in medicine on account of its great nutrient properties; it adds rapidly to the store of fat within the human frame, and it enriches the blood in red corpuscles. It is much more digestible than other animal oils, a fact which may account for its superior therapeutic value. At one time it was supposed that its virtues resided in the iodine and bromine which the oil generally contains; but these are present only in exceedingly minute proportions, and sometimes they cannot be traced at all. The oil has long been favourably known in medicine as a remedy for rheumatic complaints, but its great value in pulmonary consumption has been demonstrated only in comparatively recent times. It is administered internally in chronic rheumatism, scrofula, phthisis, chronic skin diseases, and general debility; and it is sometimes externally applied in affections of the skin. The oil is taken with facility by young children; but the repugnance of adults to its taste and eructations is not easily overcome, and many methods have been suggested for masking its taste. With that view the oil is enclosed in gelatinous capsules, or prepared in the form of aromatized emulsions, of equal parts of mucilage, of gum tragacanth, and the oil. There are numerous other forms of emulsions recommended, as well as combinations with medicinal syrups, and cod-liver oil creams, jellies, and bread; and various devices are familiarly employed as in the administration of unpleasant medicines. Failing all these, cod-liver oil has been introduced into the system by injection.

CODE. A code is a complete and systematic body of law, or a complete and exclusive statement of some portion of the law. Such, at least, is the sense in which the word is used when it is proposed to recast the laws of a country like England in the form of a code. Many collections of laws, however, which are commonly known as codes, would not correspond to this definition. The Code of Justinian, the most celebrated of all, is not in itself a complete and exclusive system of law. It is a collection of imperial constitutions, just as the Pandects are a collection of the opinions of jurisconsults. The Code and the Pandects together being, as Austin says, "digests of Roman law in force at the time of their conception," would, if properly arranged, constitute a code. Codification in this sense is merely a question of the *form* of the laws, and has nothing to do with their goodness or badness from an ethical or political point of view. Sometimes codification only means the changing of unwritten into written law; in the stricter sense it means the changing of unwritten or badly written law into law well written.

Roman Codes.—Under the empire the *constitutiones* or *edicta* of the chief of the state had the force of law. The practice of collecting the constitutions of the emperors seems to have been begun by private lawyers—such at all events is the character of the oldest collection, known as the *Codex Gregorianus et Hermogenianus*, which formed the model for the imperial codes of Theodosius and Justinian. The Theodosian code was the work of a commission of sixteen, to whom, in 435 A.D., the emperor intrusted the task of collecting the edicts and constitutions from the time of Constantine. It was finished in 438, and promulgated as the law of the empire.

In 528 the Emperor Justinian ordered a new collection to be made, and appointed a commission of ten for that purpose, including the celebrated Tribonian. The commissioners were to compile one code out of the "three codes— Gregorian, Hermogenian, and Theodosian," and the constitutions which had been ordained since the last of these was confirmed. The commissioners had full power to make such changes as might be necessary in the language of the constitutions, and to omit all that was unnecessary, obsolete, or inconsistent. The collection was to include rescripts as well as constitutions, and was to supersede (as the Theodosian code also did) the sources from which it had been compiled. The code was finished within fourteen months, but a revised edition was rendered necessary by some new decisions and constitutions of the emperor. In 534 the new code was published and the first edition superseded. The second is the Code we now possess; the first has been lost. The Code is divided into twelve books, and each book into titles, under which the constitutions are arranged in chronological order, and with the names of the emperors by whom they were enacted. There is a general correspondence between the order of the Digest and the Code of Justinian, but neither the Digest nor any of the codes pretended to scientific classification. The arrangement was dictated by the order of writers on the Prætorian Edict.

The same causes which made these collections necessary in the time of Justinian have led to similar undertakings among modern peoples. The actual condition of laws until the period when they are consciously remodelled is one of confusion, contradiction, repetition, and disorder; and to these evils the progress of society adds the burden of perpetually increasing legislation. Some attempt must be made to simplify the task of learning the laws by improving their expression and arrangement. This is by no means an easy task in any country, but in our own it is surrounded with peculiar difficulties. The independent character of English law has prevented us from attempting what has already been done for other systems which have the basis of the Roman law to fall back upon.

The most celebrated modern code is the *Code Napoléon*. The necessity of a code in France was mainly caused by the immense number of separate systems of jurisprudence existing in that country before 1789, justifying Voltaire's sarcasm that a traveller in France had to change laws about as often as he changed horses. The conception of a general code for the whole country had occurred to jurists and statesmen before Napoleon, and the Convention, in fact, discussed two projects presented by Cambacérès, one of which had been found too complicated and the other too condensed. Napoleon, on becoming consul, appointed a commission headed by M. Tronchet to review previous efforts and present a new project. In four months the project was presented to the Government, submitted to the judges, and discussed by the Council of State—Napoleon himself taking part in the deliberations. At first published under the title of *Code Civil des Français;* it was afterwards entitled the *Code Napoléon*,—the emperor wishing to attach his name to a work which he regarded as the greatest glory of his reign. The Code Napoleon consists of 2281 articles, arranged under titles and divided into three books, preceded by a preliminary title. The subjects of the different books are—1st, "Des personnes"; 2d, "Des biens et des différents modifications de la propriété;" 3d, "Des différents manières d'acquérir la propriété." The code, it has been said, is the product of Roman and customary law, together with the ordinances of the kings and the laws of the Revolution. In form it has passed through several changes caused by the political vicissitudes of the country, and it has of course suffered from time to time important alterations in substance, but it still remains virtually the same in principle as it left the hands of its framers. The code has produced a vast number of commentaries, among which may be named those of Duranton, Troplong, and Demolombe. The remaining French codes are the *Code de procédure civile*, the *Code de commerce*, the *Code d'instruction criminelle*, and the *Code pénal*. The merits of the French code have entered into the discussion on the general question of codification. Austin agrees with Savigny in condemning the ignorance and haste with which it was compiled. "It contains," says Austin, "no definitions of technical terms (even the most leading), no exposition of the *rationale* of distinctions (even the most leading), no exposition of the broad principles and rules to which the narrower provisions expressed in the code are subordinate; hence its fallacious brevity." The French codes have, however, taken firm root in most of the countries of continental Europe. Introduced by French conquest they nevertheless were eagerly adopted by the people after the French arms had withdrawn. The Penal Code, for example, was thus established in Italy, Sicily, Holland, Belgium, the Rhine Provinces, Poland, and Switzerland. The principles of the French code prevail in most of the Latin races.

The Prussian code (*Code Fréderic*) was published by Frederick the Great in 1751. It was intended to take the place of "Roman, common Saxon, and other foreign subsidiary laws and statutes," the provincial laws remaining in force as before. One of the objects of the king was to destroy the power of the advocates, whom he hoped to render useless. The Italian civil code, published in 1866, on the establishment of Italian unity, is founded mainly on the French code. The object of all these codes was to frame a common system to take the place of several systems of law, rather than to restate in an exact and exhaustive form the whole laws of a nation, which is the problem of English codification. The French and Prussian codes, although they have been of great service in simplifying the law, have failed to prevent outside themselves that accumulation of judiciary and statute law which in England has been the chief motive for codification. A more exact parallel to the English problem may be found in the *Code of the State of New York*. The revised constitution of the State, as adopted in 1846, "ordered the appointment of two commissions, one to reduce into a written and a systematic code the whole body of the law of the State, and the other to revise, reform, simplify, and abridge the rules and practice, pleadings, &c., of the courts of record." By an Act of 1837, the State Legislature declared that the body of substantive law should be contained in three codes—the Political, the Civil, and the Penal. The works of both commissions, completed in 1865, now fills six volumes, containing the Code of Civil Procedure (including the law of evidence), the Book of Forms, the Code of Criminal Procedure, the Political Code, the Penal Code, and the Civil Code. In the introduction to the Civil Code it is claimed that in many departments of the law the codes have "provided for every possible case, so that when a new case arises it is better that it should be provided for by new legislation." The New York code is defective in the important points of definition and arrangement. Much interest has attached to the Penal Code drawn up by Edward Livingston for the State of Louisiana, about 50 years ago. The system consists of a Code of Crime and Punishments, a Code of Procedure, a Code of Evidence, a Code of Reform and Prison Discipline, and a Book of Definitions. "Though the State for which the codes were prepared," says Chief-Justice Chase, "neglected to avail itself of the labours assigned and solicited by itself, they have proved, together with their introductions, a treasure of suggestions to which many States are indebted for useful legislation." A complete edition of Livingston's works has recently been published by the National Prison Association of the United States.

Since the time of Bentham, the codification of the law of England has been the dream of our most enlightened jurists and statesmen. In the interval between Bentham and our own time there has been an immense advance in the scientific study of law, but it may be doubted whether the problem of codification is at all nearer solution. Interest has mainly been directed of late to the historical side of legal science, to the phenomena of the evolution of laws as part of the development of society, and from this point of view the question of remodelling the law is one of minor interest. To Bentham the problem presented itself in the simplest and most direct form possible. What he proposed to do was to set forth a body of laws, clearly expressed, arranged in the order of their logical connection, exhibiting their own *rationale*, and excluding all other law. On the other hand the problem has in some respects become easier since the time of Bentham. With the Benthamite codification the conception of reform in the substantive law is more or less mixed up. If codification had been possible in his day, it would, unless it had been accompanied by the searching reforms which have been effected since, and mainly through his influence, perhaps have been more of an evil than a good. The mere dread that, under the guise of codification or improvement in form, some change in substance may secretly be effected has long been a practical obstacle in the way of legal reform. But the law has now been brought into a state of which it may be said that, if it is not the best in all respects that might be desired, it is at least in most respects as good as the conditions of legislation will permit it to be. Codification, in fact, may now be treated purely as a question of form. What is proposed is that the law, being, as we assume, in substance what the nation wishes it to be, should be made as accessible as possible, and as intelligible as possible. These two essential conditions of a sound system of law are, we need hardly say, far from being fulfilled in England. The law of the land is embodied in thousands of statutes and tens of thousands of reports. It is expressed in language which has never been fixed by a controlling authority, and which has swayed about with every change of time, place, and circumstance. It has no definitions, no rational distinctions, no connection of parts. Until the passing of the Judicature Act it was pervaded throughout its entire sphere by the flagrant antinomy of law and equity, and that Act has only ordered, not executed, its consolidation. No lawyer pretends to know more than a fragment of it. Few practical questions can be answered by a lawyer without a search into numberless Acts of Parliament and reported cases. To laymen, of course, the whole law is a sealed book. As there are no authoritative general principles, it happens that the few legal maxims known to the public, being apprehended out of relation to their authorities, are as often likely to be wrong as to be right. It is hopeless to think of making it possible for every man to be his own lawyer, but we can at least try to make it possible for a lawyer to know the whole law. The earlier advocates of codification founded their case mainly on the evils of judiciary law, *i.e.*, the law contained in the reported decisions of the judges. Bentham's bitter antipathy to judicial legislation is well known. Austin's thirty-ninth lecture (*Lectures*, ed. 1869) contains an exhaustive criticism of the tenable objections to judiciary law. All such law is embedded in decisions on particular cases, from which it must be extracted by a tedious and difficult process of induction. Being created for particular cases it is necessarily uncomprehensive, imperfect, uncertain, and bulky. These are evils which are incident to the nature of judiciary laws. Of late years the defective form of our existing statute law has also given rise to loud complaints. Year by year the mass of legislation grows larger, and as long as the basis of a system is judiciary law, it is impossible that the new statutes can be completely integrated therewith. The prevailing mode of framing Acts of Parliament, and especially the practice of legislating by reference to previous Acts, likewise produce much uncertainty and disorder.

Whether any attempt will ever be made to supersede this vast and unarranged mass by a complete code seems very doubtful. Writers on codification have for the most part insisted that the work should be undertaken as a whole, and that the parts should have relation to some general scheme of the law which should be settled first. The practical difficulties in the way of an undertaking so stupendous as the codification *uno cœtu* of the whole mass of the law hardly require to be stated. The probability is that attempts will be made from time to time to cast the leading portions of the law into the form of a code. Some years ago it was believed that the proper preliminary to a code would be a digest of the law, and a commission was appointed in 1866, under which draughtsmen were set to work to prepare specimen digests of three selected portions of law. The attempt was abandoned in 1872, the commissioners being of opinion that it could not be properly proceeded with in detail, and they recommended that a general digest should be undertaken.

In discussions on codification two difficulties are insisted on by its opponents, which have some practical interest—(1) What is to be done in those cases for which the code has not provided? and (2) How is new law to be incorporated with the code? The objection that a code will hamper the opinions of the court, destroy the flexibility and elasticity of the common law, &c., disappears when it is stated in the form of a proposition, that law codified will cover a smaller number of cases, or will be less easily adapted to new cases, than law uncodified. The *Code Napoléon* orders the judges, under a penalty, to give a decision on all cases, whether contemplated or not by the code, and refer them generally to the following sources:—(1) Equité naturelle, loi naturelle; (2) Roman law; (3) ancient customs; (4) usages, examples, decisions, jurisprudence; (5) droit commun; (6) principes généraux, maximes, doctrine, science. The Prussian code, on the other hand, requires the judges to report new cases to the head of the judicial department, and they are decided by the legislative commission. No provision was made in either case for incorporating the new law with the code, an omission which Austin justly considers fatal to the usefulness of codification. It is absurd to suppose that any code can remain long without requiring substantial arbitration. Cases will arise when its meaning must be extended and modified by judges, and every year will produce its quota of new legislation by the state. The courts should be left to interpret a code as they now interpret statutes, and provision should be made for the continual revision of the code, so that the new law created by judges or directly by the state may from time to time be worked into the code. The process of gradual codification adopted in India has been recommended for imitation in England by those who have had some experience of its working. The first of the Indian codes was the Penal Code drawn up by Macaulay, and presented to the Governor-general in 1837. It did not become law, however, till 1860. It has been highly praised, and its merit is the more remarkable as Macaulay had only a slight professional acquaintance with the law before he went to India. A code of Civil Procedure became law in 1759, and was followed by a code of Penal Procedure in 1861. The substantial law was then undertaken which published its first instalment in 1865. The use of illustrations is a peculiar feature of the Indian code. (E. R.)

CODOGNO, a town of Italy, in the province of Milan, and district of Lodi, with a station at the junction of the railway from Milan to Piacenza with that between Cremona and Pavia, about 20 miles from the last-named city. In the parish church is an Ascension of the Virgin, the best painting of Callista Piazza, an artist of the 16th century. The town is chiefly important as the centre of a large trade in Parmesan cheese; and it also carries on the manufacture of silk. Population upwards of 11,000.

CODRINGTON, SIR EDWARD (1770–1851), admiral, belonged to an old Gloucestershire family. He entered the navy in 1783. In 1794 he served as lieutenant on board Howe's flagship in the actions off Brest, and was sent home with despatches announcing the result. In 1805 he received the command of the "Orion," a seventy-four, in which he fought at Trafalgar, receiving a gold medal for his conduct in the action. In 1808 he was gazetted to the "Blake," another seventy-four, in command of which he shared in the Walcheren expedition, assisting in the forcing of the Scheldt in 1809. During the next three years he was on active service off the Spanish coast. In 1813 he sailed for North America, where he was made rear-admiral and captain of the fleet. Returning to England at the close of the war, he received a Knight Commandership of the Bath in 1815; and six years afterwards (1821) he was gazetted vice-admiral. In 1826 he was appointed to the command-in-chief of the Mediterranean squadron of eleven sail sent to restrain Ibrahim Pasha from operating against the Greeks, and sailed in the "Asia" for the Morea. Here he was joined by the French and Russian contingents, of five and eight sail respectively, under Admirals de Rigny and Heiden, who were put under his orders. A literal interpretation of instructions led to the battle of Navarino, in which the Turkish and Egyptian fleets, of 36 sail, with a cloud of gunboats, schooners, and craft of all sorts, were almost entirely destroyed. For his share in this action Codrington received a Grand Cross of the Bath; but the steps which led to it occasioned considerable dissatisfaction in England, and he was recalled in 1828. He was returned to Parliament for Devonport in 1832 in the Liberal interest, and was re-elected in 1835 and 1837. In the latter year he was gazetted admiral. He accepted the Chiltern Hundreds in 1839, on his appointment as commander-in-chief at Portsmouth, and his three years' tenure of that office concluded his public life. He died in London, April 28, 1851. A memoir of Codrington, by his daughter, Lady Bourchier, appeared in 1873, and an abridgment of the larger work in 1875.

CODRUS, the hero of an early Athenian legend, was the last king of Athens, and belongs to the 11th century B.C. According to the story, it was prophesied that the Dorians would conquer Attica if they spared the life of the Attic king. Devoting himself to his country, Codrus, in disguise, provoked a quarrel with some Dorian soldiers. He fell, and the Dorians retreated homeward. To so noble a patriot no one was thought worthy to succeed; and the title of king was thenceforth abolished, that of archon taking its place.

COEHORN, MENNO, BARON VAN (1641–1704), "the Dutch Vauban," was of Swedish extraction, and was born at Leeuwarden, in Friesland. He served in the campaign of 1667 against Turenne, and later distinguished himself at the sieges of Maestricht (1673) and Graave (1674), and at the battles of Senef (1674), Cassel (1677), and St Denis (1678). The genius of Vauban had made a fine art of the attack and defence of fortified places, and Coehorn, who had already invented the mortar, had imposed on himself the task of meeting and beating that fine engineer on his own ground. But William of Orange did not recognize the abilities of his young captain, and in despair of success Coehorn had determined to transfer his services to France. William, hearing of this, seized the person of the engineer, and by a mixture of force and persuasion obliged him to renounce his design, and to accept a coloneley in the Dutch service, with the command of two of the Nassau-Friesland battalions. The peace secured by the Treaty of Nimeguen (1678) gave Coehorn his first great opportunity. He repaired and perfected the defences of many strong places, and he rushed into polemics with a rival engineer, a certain Paen. His criticism and rejoinder appeared at Leeuwarden in 1682 and 1683, and in 1685 he gave to the world, in Dutch, his first great work, *The New System of Fortification* (Leeuwarden, folio), two French editions of which appeared in 1706, while three others were issued from the Hague in 1711, 1714, and 1741 respectively. From 1688 to 1691 Coehorn's genius and activity answered the innumerable demands that were made upon them. In 1692 Vauban himself laid siege to Namur, and Coehorn waited within the city. The town was reduced in a week; but the castle in its quintuple enceinte, manned by Coehorn and his own regiment, seemed impregnable. The Dutch chief, however, was severely wounded, and the castle capitulated, with the honours of war, eight days after the city. The campaign of 1695 brought his revenge. He reduced the city, on which Vauban in the meanwhile had expended all the resources of his art, and the castle fell a month afterwards. The Peace of Ryswick (1697) sent Coehorn back to his task of repairing and improving. He laid out the entrenchments round Zwoll and Groningen, and built the fortifications round Nimeguen, Breda, Namur, and Bergen-op-Zoom. In 1701, however, the war of the Spanish succession broke out, and Coehorn went at once to the front. By the siege and capture in succession of Venloo, Stevensworth, Ruremond, and Liége, he rendered the allies masters in a single campaign of the line of the Meuse from Holland to Huy. He followed up these exploits by the investment and reduction of Bonn (1703), and passing thence into Flanders, with Sparr, he forced the French lines in the Waes, between the sea and the left bank of the Scheldt. Returning to the centre of operations on the Meuse, he besieged and took Huy in the same year, under the very eyes of Villeroi. Thence he went to the Hague to confer with Marlborough concerning the next campaign, and was there cut off by apoplexy, March 17, 1704. A monument to him was raised by his children at Wykel, and an historical eulogy of him was published at Frankfort in 1771. For a description and critical estimate of the engineering theories of Coehorn, see Marini, *Biblioteca di Fortificazione* (1810), and Bonomer, *Essai général de Fortification* (1814).

CŒLENTERA, or, less correctly, CŒLENTERATA, the name of a group of animals, including the classes Hydrozoa, Anthozoa, and Ctenophora. (The two last-mentioned classes are by Huxley and a few others placed in a single class, Actinozoa.) The reader will consult the articles on ACTINOZOA, CORALS, and HYDROZOA, with that on the ANIMAL KINGDOM, for the more important details touching the structure, classification, and affinities of cœlenterate animals.

According to Van Beneden, R. Leuckart, and some others, the Sponges also have their place among Cœlentera,—a view which has of late years received much support in consequence of the profounder study of the calcarious[1] sponges begun by Miklucho-Maclay and diligently followed up by Haeckel. There is much to be said in favour of regarding the sponges as an aberrant (and, at the same time, degraded) cœlenterate class, but, for the present, it will be well to treat them as a group apart.

It is usual to consider the Cœlentera (with or without the sponges) as a primary group, or sub-kingdom, of animals; and a high authority has stated that the institution of this group has been the greatest improvement in the arrangement of the animal kingdom effected since the time of Cuvier. But, should we so interpret the results of certain recent embryological inquiries as to throw the Cœlentera into one great division along with all the higher invertebrates, such a mode of treatment would reduce Cœlentera to the rank of a province.

Name.—The word Cœlentera (or rather its German equivalent) first occurs on page 38 of *Beiträge zur Kenntniss wirbelloser Thiere*, von Frey und Leuckart, Braunschweig (Vieweg), 1847.[2]

Here it should be mentioned that Burmeister (*Zoonomische Briefe*, Zweiter Theil, p. 279) has given the same name to a very different group of animals. He denotes by it the majority of the nematoid worms, placing in a separate section (Amorphocœla) Gordius and its allies, whose alimentary canal is more or less atrophied. In this sense Cœlentera is nearly equivalent to Cœlelminthes of Cuvier.

Cœlentera is derived from κοῖλος (hollow) and ἔντερον (intestine or viscus).

Definition.—Allowing for the difficulty of expressing modern scientific concepts by compounds formed from words in common use, the meaning of which needs to be somewhat stretched, this etymology guides us to the definition of the Cœlentera as animals having a conspicuous alimentary canal, which, with its prolongations, occupies the whole interior of the body,[3] and does the work of a vascular as well as of a digestive system. It is not true to add, however, that the Cœlentera are invariably destitute of cavities comparable (morphologically) to the blood vessels, perivisceral spaces, and other serous passages of the higher animals. Such cavities, hitherto usually overlooked, undoubtedly exist in some cases, as appears from the investigations of Metschnikoff,[4] Eilhard Schulze,[5] and others.

The wall of the body in the Cœlentera has the same fundamental composition as among the higher animals, and exhibits various degrees of differentiation.[6] Inner and outer layers of epithelial tissue, splinted by connective tissue (in close relation with which we usually find muscular fibres), are always developed.

Neither the absence of nervous tissues nor the presence of those curious microscopic organs known as thread-cells can henceforth be enumerated among the characters common to and distinctive of Cœlentera Though a nervous system remains to be discovered in many, it certainly exists in some; and in yet other cases, where anatomical evidence is wanting, its presence may reasonably be conjectured from purely physiological data.

Most, if not all, Cœlentera have thread-cells; but these exist likewise in other organisms, notably in certain mollusks which were formerly supposed to derive them from the cœlenterate animals on which they preyed.

The plant-like aspect of many Cœlentera arises in two ways. In the simple (not compound) cœlenterates, such as most sea-anemones, the tentacles or prehensile appendages are so arranged as to simulate, when not too closely inspected, the petals of ordinary flowers (particularly flowers with numerous narrow petals, *e.g.*, Mesembryanthemum) or the strap-shaped corollas of composite plants, like dahlias. In the compound species buds and branches are formed, marking changes in direction of growth; and hence those wonderful phytoid aggregates which for so many centuries puzzled naturalists.

Affinities.—The nearest relations of Cœlentera are undoubtedly the Echinoderms, whose remarkable vascular system is developed from one or more rudiments primarily formed as diverticula of the alimentary canal. The Cœlentera exhibit, even more perfectly than the echinoderms, a rediated arrangement of their parts, and, to a lesser degree, have this primitive disposition controlled by a superinduced bilateral symmetry. On the other hand the affinities of cœlenterates to worms, save through the echinoderms, are very obscure.[7]

Of animals inferior to the Cœlentera in complexity of structure their nearest reputed allies are the Infusoria. We are not yet able, however, to demonstrate the existence of any relationship of this kind, in spite of all that has been urged in its favour by Claparède, Greef, and other eminent anatomists. (J. R. G.)

COELLO, ALONSO SANCHEZ (1515–1590), painter, according to some authorities a native of Portugal, was born, according to others, at Benifacio, near the city of Valencia. He studied many years in Italy; and returning to Spain in 1541 he settled at Madrid, and worked on religious themes for most of the palaces and larger churches. He was a follower of Titian, and, like him, excelled in portraits and single figures, elaborating the textures of his armours, draperies, and such accessories in a manner so masterly as strongly to influence Velasquez in his treatment of like objects. Many of his pictures were destroyed in the fires that consumed the Madrid and Prado palaces, but many good examples are yet extant, among which may be noted the portraits of the Infantes Carlos and Isabella, now in the Madrid gallery, and the St Sebastian painted in the church of San Gerónimo, also in Madrid. Coello left a daughter, Isabella Sanchez, who studied under him, and painted excellent portraits.

COEN, JAN PIETERSZOON (1587–1630), the founder of Batavia, was born at Hoorn, and was sent when a youth to Rome to be instructed in the principles of commerce. In 1607 he went to India, but returned some four years afterwards, and in 1612 was sent out a second time, with the command of two ships. He acquitted himself so well of

[2] See further another work by Leuckart, *Ueber die Morphologie und die Verwandtschaftsverhältnisse der wirbellosen Thiere*, ibid., 1848; and the valuable "Bericht" contributed by the same writer to the *Archiv für Naturgeschichte* from that date to the present; also his university programme, entitled—*De Zoophytorum et historia et dignitate systematica*, Lipsiæ, 1873.

[3] The doubts suggested on this point by R. Leuckart (*Bericht* f. 1868–9, p. 188), in opposition to the views of Noschin, Semper, and Kowalewsky, may now at length be regarded as set at rest by the appearance of the last-named writer's recent *Memoir on the Development of the Cœlentera*. This indispensable work has unfortunately been printed in the Russian language, but the reader may consult its figures, in conjunction with the excellent German abstract, by Hoyer, in the second vol. of the *Jahresberichte* of Hofmann and Schwalbe.

his commission, and made himself so remarkable by the brilliance and success of his practice of commerce, that in 1613 he was named director-general of the Indian trade. In 1617 he was made president at Bantam; and in 1619, having taken and destroyed Jacatra, he founded on its ruins the city of Batavia, which he forthwith proclaimed the capital of the Dutch East Indies. In 1622 Coen revisited Europe, but five years afterwards he returned to Java. In 1629 the Javanese emperor attempted to dislodge the interlopers, and laid siege to Batavia; but Coen beat off all his attacks. He died the following year.

CŒNOBITES (from κοινός, common, and βίος, life), a religious order living in a convent, or in community,—in opposition to the anchorets or hermits who live in solitude. See MONASTICISM.

CŒUR, JACQUES, founder of the trade between France and the Levant, was born at Bourges, near the close of the 14th century. His father, Pierre Cœur, was one of the richest peltry merchants of the flourishing city of Bourges; and we hear first of Jacques in 1418, when he married Macée de Léodepart, daughter of an influential citizen, afterwards provost, a quondam valet of John of Berry. About 1429 he formed a commercial partnership with two brothers named Godard; and in 1432 he is heard of at Damascus, buying and bartering, and transporting Levantine ware (gall-nuts, wools and silks, goats' hair, brocades and carpets) to the interior of France by way of Narbonne. In the same year he established himself at Montpellier, and there commenced those gigantic operations which have made him illustrious among financiers of all time. Details are absolutely wanting; but it is certain that in a few years he placed his country in a position to contend not unsuccessfully with the great trading republics of Italy and Catalonia, and acquired such reputation as to be able, mere trader as he was, to render material assistance to the Order of Rhodes and to Venice herself.

In 1436 Cœur was summoned to Paris by Charles VII., and made master of the mint that had been established in that city. The post was of vast importance, and the duties were onerous in proportion. The country was deluged with the base monies of three reigns, charged with superscriptions both French and English; and Charles had determined on a sweeping reform. In this design he was ably seconded by the great merchant, who, in fact, inspired or prepared all the ordinances concerning the coinage of France issued between 1435 and 1451. In 1438 he was made steward of the royal expenditure; and in 1440 he and his family were ennobled by letters patent. In 1444 he was sent as one of the royal commissioners to preside over the new parliament of Languedoc—a dignity he bore through successive years till the day of his disgrace. In 1445 his agents in the East negotiated a treaty between the Sultan of Egypt and the Knights of Rhodes; and in 1447, at his instance, Jean de Village, his nephew by marriage, was charged with a mission to Egypt. The results of this communication were most important; concessions were obtained which greatly improved the position of the French consuls in the Levant, and that influence in the East was thereby founded which, though often interrupted, was for several centuries a chief commercial glory of France. In the same year Cœur assisted in an embassy to the counts of Savoy; and in 1448 he represented the French king at the court of Nicholas V., who treated him with utmost distinction, lodged him in the Papal palace, and gave him a special licence to traffic with the Infidels. From about this time he made large advances to Charles for carrying on his wars; and in 1449, after fighting at the king's side through the campaign, he entered Rouen in his train

At this moment the great trader's glory was at its height. He had represented France in three embassies, and had supplied the sinews of that war which had ousted the English from Normandy. He was invested with various offices of dignity, and possessed the most colossal fortune that had ever been amassed by a private Frenchman. The sea was covered with his ships; he had 300 factors in his employ, and houses of business in all chief cities of France. He had built hotels and chapels and had founded colleges in Paris, at Montpellier, at Bourges. Dealing in all things—money and arms, peltry and jewels, brocades and woollens—broking, banking, farming, he had absorbed the trade of the country, and merchants complained they could make no gains on account of "that Jacquet." Soon, however, he was a broken man and a fugitive. Charles was surrounded with the enemies of the merchant; he was "unstable as water," and he was always needy. Jacques Cœur had to go the way of others who had been the friends and favourites of the king.

In February 1449 Agnes Sorel, the mistress of Charles, died of puerperal fever. It was maintained, however, that the Dauphin Louis had procured her death; and some considerable time after her death, Jacques Cœur, who had been named one of her executors, was accused formally of having poisoned her. There was not even a pretext for such a charge, but for these and other alleged crimes, the king, on the 31st July 1451, gave orders for the arrest of Jacques Cœur and for the seizure of his goods, reserving to himself a large sum for the war in Guienne. Commissioners extraordinary, the merchant's declared enemies, were chosen to conduct the trial, and an inquiry commenced, the judges in which were either the prisoner's debtors or the holders of his forfeited estates. He was accused of having paid French gold and ingots to the Infidels, of coining light money, of kidnapping oarsmen for his galleys, of sending back a Christian slave who had taken sanctuary on board one of his ships, and of committing frauds and exactions in Languedoc to the king's prejudice. He defended himself with all the energy of his nature. His innocence was manifest; but a conviction was necessary, and in spite of strenuous efforts on the part of his friends, after twenty-two months of confinement in five prisons, he was condemned to do public penance for his fault, to pay the king a sum equal to about £1,000,000 of modern money, and to remain a prisoner till full satisfaction had been obtained; his sentence also embraced confiscation of all his property, and exile during royal pleasure. On June 5, 1453, the sentence took effect; at Poitou the shameful form of making honourable amends was gone through; and for nearly three years nothing is known of him. It is probable that he remained in prison; it is certain that his vast possessions were distributed among the intimates of Charles.

In 1455 Jacques Cœur, wherever confined, contrived to escape into Provence. He was pursued; but a party headed by Jean de Village and two of his old factors, carried him off to Tarascon, whence, by way of Marseilles, Nice, and Pisa, he managed to reach Rome. He was honourably and joyfully received by Nicholas V., who was fitting out an expedition against the Turks. On the death of Nicholas, Calixtus III. continued his work, and named his guest captain of a fleet of sixteen galleys sent to the relief of Rhodes and the Archipelago. He set out on this expedition, but was taken ill at Chios, and died there, November 25, 1456. He was buried on the island, but his place of sepulchre is not known. The stain was not removed from his honour till the reign of Louis XI., when, at the instance of Geoffroy Cœur, the great merchant's name was finally rehabilitated.

COFFEE (French, *Café*; German, *Kaffee*). This important and valuable article of food is the produce chiefly of *Coffea arabica*, a Rubiaceous plant indigenous to Abyssinia, which, however, as cultivated originally, spread outwards from the southern parts of Arabia. The name is probably derived from the Arabic K'hăwah, although by some it has been traced to Caffa, a province in Abyssinia, in which the tree grows wild. In the genus *Coffea*, to which the common coffee tree belongs, from 50 to 60 species were formerly enumerated, scattered throughout the tropical parts of both hemispheres; but by referring the American plants to a different genus, the list is now restricted to about 22 species. Of these 7 belong geographically to Asia; and of the 15 African species 11 are found on the west coast, 2 in Central and East Africa, and 2 are natives of Mauritius. Besides being found wild in Abyssinia, the common coffee plant appears to be widely disseminated in Africa, having been seen on the shores of the Victoria Nyanza and in Angola on the west coast. Within the last year or two considerable attention has been devoted to a West African species, *C. liberica*, belonging to the Liberian coast, with a view to its extensive introduction and cultivation. Its produce, obtained from native plants, have been several years in the English market.

The common coffee shrub or tree is an evergreen plant, which under natural conditions grows to a height of from 18 to 20 feet, with oblong-ovate, acuminate, smooth, and shining leaves, measuring about 6 inches in length by $2\frac{1}{2}$ wide. Its flowers, which are produced in dense clusters in the axils of the leaves, have a five-toothed calyx, a tubular five-parted corolla, five stamens, and a single bifid style. The flowers are pure white in colour, with a rich fragrant odour, and the plants in blossom have a lovely and attractive appearance, but the bloom is very evanescent. The fruit is a fleshy berry, having the appearance and size of a small cherry, and as it ripens it assumes a dark red colour. Each fruit contains two seeds embedded in a yellowish pulp, and the seeds are enclosed in a thin membranous endocarp (the parchment). The seeds which constitute the raw coffee of commerce are plano-convex in form, the flat surfaces which are laid against each other within the berry having a longitudinal furrow or groove. They are of a soft, semi-translucent, bluish or greenish colour, hard and tough in texture. The regions found to be best adapted for the cultivation of coffee are well-watered mountain slopes at an elevation ranging from 1000 to 4000 feet above sea-level, in latitudes lying between 15° N. and 15° S., although it is successfully cultivated from 25° N. to 30° S. of the equator in situations where the temperature does not fall beneath 55° Fahr. The Liberian coffee plant, *C. liberica*, which has been brought forward as a rival to the ordinarily cultivated species, is described as a large leaved and large-fruited plant of a robust and hardy constitution. The seeds yield a highly aromatic and fine-flavoured coffee; and so prolific is the plant, that a single tree is said to have yielded the enormous quantity of 16 lb weight at one gathering. It is a tree, moreover, which grows at low altitudes, and it probably would flourish in many situations which have been proved to be unsuitable for the Arabian coffee. Should it come up to the sanguine expectations of Ceylon planters and others to whom it has been submitted, there is no doubt that it will prove a formidable rival to the species which has hitherto received the exclusive attention of planters. It grows wild in great abundance along the whole of the Guinea coast.

Fig. 1.—Branch of *Coffea arabica*.

The early history of coffee as an economic product is involved in considerable obscurity, the absence of historical fact being compensated for by an unusual profusion of conjectural statements and by purely mythical stories. According to a statement contained in a manuscript belonging to the Bibliothèque Nationale in Paris, the use of coffee was known at a period so remote as 875 A.D., or exactly 1000 years ago. In a treatise published in 1566 by an Arab sheikh it is stated that a knowledge of coffee was first brought from Abyssinia into Arabia about the beginning of the 15th century by a learned and pious Sheikh Djemal-eddin-Ebn-Abou-Alfagger. According to the treatise alluded to the use of coffee as a beverage was prevalent among the Abyssinians from the most remote period, and in Arabia the beverage when first introduced only supplanted a preparation from the leaves of the cat, *Celastrus edulis.* Its peculiar property of dissipating drowsiness and preventing sleep was taken advantage of in connection with the prolonged religious services of the Mahometans, and its use as a devotional antisoporific stirred up a fierce opposition on the part of the strictly orthodox and conservative section of the priests. Coffee was by them held to be an intoxicant beverage, and therefore prohibited by the Koran; and the dreadful penalties of an outraged sacred law were held over the heads of all who became addicted to its use. Notwithstanding the threats of divine retribution, and though all manner of devices were adopted to check its growth, the coffee-drinking habit spread rapidly among the Arabian Mahometans, and the growth of coffee as well as its use as a national beverage became as inseparably associated with Arabia as tea is with China. For about two centuries the entire supply of the world, which, however, was then limited, was obtained from the province of Yemen in South Arabia, where the celebrated Mocha or Mokha is still cultivated.

The knowledge of and taste for coffee spread but slowly outwards from Arabia Felix, and it was not till the middle of the 16th century that coffee-houses were established in Constantinople. Here also the new habit excited considerable commotion among the ecclesiastical public. The popularity of the coffee-houses had a depressing influence on the attendance at the mosques, and on that account a fierce hostility was excited among the religious orders against the new beverage. They laid their grievances before the sultan, who imposed a heavy tax upon the coffee-houses, notwithstanding which they flourished and extended. After the lapse of another hundred years coffee reached Great Britain, a coffee-house having been opened in 1652 in London by a Greek, Pasqua Rossie. Rossie came from Smyrna with Mr D. Edwards, a Turkey merchant, and in the capacity of servant he prepared coffee daily for Mr Edwards and his visitors. So popular did the new drink become with Mr Edwards's friends that their visits occasioned him great inconvenience to obviate which he directed Rossie to establish a public coffee-house, which he accordingly did. The original establishment was in St Michael's Alley, Cornhill, over the door of which Rossie erected a sign with his portrait, subsequently announcing himself to be "the first who made and publicly sold coffee drink in England." It is remarkable that the introduction of coffee into England encountered the same hostility that it was fated to meet in other countries. Charles II., in 1675, attempted to suppress coffee-houses by a royal proclamation, in which it was stated that they were the resort of disaffected persons "who devised and spread abroad divers false, malicious, and scandalous reports, to the defamation of His Majesty's Government, and to the disturbance of the peace and quiet of the nation." On the opinion of legal officials being taken as to the legality of this step, an oracular deliverance was given to the effect "that the retailing of coffee might be an innocent trade, but as it was used to nourish sedition, spread lies, and scandalize great men, it might also be a common nuisance." In England as well as in other countries the most effective check on the consumption of coffee was found to be a heavy tax, which, while restricting honest trade, opened a channel for extensive smuggling operations. Coffee is spoken of as being in use in France between 1640 and 1660, and thereafter it may be said that the use of coffee was an established custom in Europe. It is noteworthy that the three principal dietetic beverages of the world were introduced into Great Britain within a few years of each other. Cocoa was the first of the three which actually appeared in Europe, having been brought to Spain from South America; coffee followed, coming from Arabia by way of Constantinople; and tea, the latest of the series, came from China by the hands of the Dutch.

Down to 1690 the only source of coffee supply was Arabia, but in that year Governor-General Van Hoorne of the Dutch East Indies received a few coffee seeds by traders who plied between the Arabian Gulf and Java. These seeds he planted in a garden at Batavia, where they grew and flourished so abundantly that the culture, on an extended scale, was immediately commenced in Java. One of the first plants grown in that island was sent to Holland as a present to the governor of the Dutch East India Company. It was planted in the Botanic Garden at Amsterdam, and young plants grown from its seeds were sent to Surinam, where the cultivation was established in 1718. Ten years later the plant was introduced in the West Indian Islands, and gradually the culture extended throughout the New World, till now the progeny of the single plant sent from Java to Holland produces more coffee than is grown by all the other plants in the world. The cultivation is now general throughout all civilized regions of the tropical world. In point of quantity Brazil heads the list of coffee-growing countries, its annual produce probably exceeding that of all other localities combined. It is calculated that no less than 530,000,000 coffee trees are at present flourishing throughout that empire. During the Brazilian financial year ending 1872, more than 2,000,000 bags, each containing 160 ℔, were exported from Brazil; and the United States alone absorb upwards of 200,000,000 ℔ of Brazilian coffee annually. The other principal American localities for coffee-growing are Costa Rica, Guatemala, Venezuela, Guiana, Peru, and Bolivia, with Jamaica, Cuba, Porto Rico, and the West Indian Islands generally. In the East the principal coffee regions, following Brazil in amount, but much superior in the quality of their produce, are Java and Ceylon. The annual produce of Java reaches to about 130,000,000 ℔; and from Ceylon about 100,000,000 ℔ is annually exported. The culture of coffee is an important and rapidly growing feature in Southern India, and it is also prosecuted in Sumatra, Réunion, Mauritius, and Southern Arabia, and on the west coast of Africa. The present total annual production of the world has been estimated to amount to not less than 1,000,000,000 ℔. At the beginning of the 18th century, while Arabia was still the only source of supply, probably not more than 7,500,000 ℔ was yearly exported from that country; the consumption of Europe in 1820 was stated by A. Von Humboldt at about 140,000,000 ℔, while 300,000,000 ℔ probably represented the quantity used throughout the world. The yearly consumption in Great Britain has for about 30 years been drooping in the face of a rapidly increasing population and consuming capacity, while the quantity absorbed by other countries has increased with extraordinary rapidity. The whole amount entered for home consumption in 1790 was 973,110 ℔; and an increase in the duty charged caused the consumption to drop in 1796 to 396,953 ℔. A reduction in the duty caused the consumption in 1808 to shoot up suddenly from 1,069,691 ℔ in that year to 9,251,837 ℔ in 1809. The quantity consumed never again mounted so high till in 1825 it was affected by another reduction of duty, and 10,760,112 ℔ was retained for the home market. Thereafter the consumption rapidly and steadily increased, reaching 22,669,253 ℔ in 1830, 28,664,341 ℔ in 1840, and in 1847 coming to its maximum of 37,441,373 ℔, from which point it again declined. In 1857 the consumption had fallen to 34,352,123 ℔; in 1867 it was 31,567,760; and in 1869 it fell so low as 29,109,113 ℔. The total imports for the year 1874 amounted to 157,351,376 ℔, but of this only 31,859,408 ℔ were retained for home consumption. The chief cause of the declining popularity of coffee in Great Britain is doubtless to be found in the extraordinary hold which its rival beverage—tea—has taken on the community; but something of the falling off is also attributable to the extent to which coffee was for a long period made the subject of adulteration and sophistication. Indeed for some years, between 1840 and 1852, much of what was sold under the name of coffee was actually chicory, a root which at that period was cultivated and manufactured duty free, while coffee was subject to a heavy import duty.

The different estimation in which coffee is held in various countries is well brought out in the following estimate of the consumption per head calculated from the official returns for 1873:—

	Total imports of Coffee for consumption.	Average per head.
France	98,635,000 ℔	2·73 ℔
Belgium	9,771,000	13·48
Switzerland	8,779,500	7·03
Russia, European	14,740,920	0·19
Sweden	26,555,213	6·11
Norway	17,636,080	9·80
Denmark	26,035,652	13·89
Holland	72,395,800	21·00
Hamburg (Germany)	178,715,936	
Austria (1871)	76,876,576	2·13
Greece	2,131,367	1·42
Italy (1871)	28,511,560	1·00
United Kingdom	32,330,928	1·00
United States	293,293,833	7·61

The commercial distinctions as established in the British market relate—first, to qualities, as "fine," "middling," "ordinary," "low," and "triage," the last being broken and damaged seeds; and secondly, to localities of production.

Shape, size, and colour of seeds are the principal elements which determine the commercial value of coffee. Shape, according to Mr W. P. Hiern (in a communication to the Linnean Society, April 20, 1876), is related to the particular part of the plant upon which the seed grows; size and succulence correspond with the nature of the locality of growth; and colour has reference to the degree of maturity attained by the fruit at the time of gathering. The highly prized variety known as peaberry is the result of the coalescence of the two seeds within the fruit, thus producing the appearance of a single rounded seed, usually of small size, whence the name. Regarding the famous Mocha or "Mokha" coffee of Arabia, Mr W. G. Palgrave has the following remarks:—

"The best coffee, let cavillers say what they will, is that of Yemen, commonly entitled 'Mokha,' from the main port of exportation. Now, I should be sorry to incur a lawsuit for libel or defamation from our wholesale or retail tradesmen; but were the particle *not* prefixed to the countless labels in London shop windows, that bear the name of the Red Sea haven, they would have a more truthy import than what at present they convey. Very little, so little indeed as to be quite unappreciable, of the Mokha or Yemen berry ever finds its way westward of Constantinople. Arabia itself, Syria, and Egypt consume fully two-thirds, and the remainder is almost exclusively absorbed by Turkish and Armenian œsophagi. Nor do these last get for their share the best or the purest. Before reaching the harbours of Alexandria, Jaffa, Beyrout, &c., for further exportation, the northern bales have been, while yet on their way, sifted and re-sifted, grain by grain, and whatever they may have contained of the hard, rounded, half-transparent, greenish-brown berry, the only one really worth roasting and pounding, has been carefully picked out by experienced fingers; and it is the less generous residue of flattened, opaque, and whitish grains which alone, or almost alone, goes on board the shipping. So constant is this selecting process that a gradation, regular as the degrees in a map, may be observed in the quality of Mokha, that is, Yemen coffee, even within the limits of Arabia itself, in proportion as one approaches to or recedes from Wadi Nejrān and the neighbourhood of Mecca, the first stages of the radiating mart."

The "Mocha" of the English market is principally the produce of India, but a good deal of American coffee is also passed into consumption under that abused name.

The conditions most favourable for coffee planting are found in hilly situations, where the ground is at once friable, well drained, and enriched by the washing down of new soil from above by the frequent rains. The seeds are first sown in a nursery, and the young plants when they are a few inches high are planted out in the permanent plantation at distances from each other of from 6 to 8 feet. The operation of planting is one which requires great care, and much labour must be expended on drainage, weeding, and cleaning the plantation, and in pruning or "handling" the plants. Chiefly for convenience of securing the crop, the trees are rarely allowed to exceed from 4 to 6 feet in height, and being so pruned down they extend their branches laterally in a vigorous manner. The plants begin bearing in their second year, and by the third year they should yield a fairly remunerative crop. The berries are ready for picking when they have assumed a dark-red colour and the skin shrivels up. Immediately after the berries are gathered they are conveyed to the storehouse, where they undergo the operation of pulping; and on some hill estates in Ceylon, having suitable situation and water supply, the gathered berries are carried by a water run through galvanized pipes to the store. The pulping is performed in an apparatus having two roughened cylinders which move in opposite directions. Between these the berries are carried forward with a flow of water, and the seeds are deprived of their surrounding pulp, being left invested in the skin or parchment. In this condition they are spread out to dry, and as soon as practicable they are freed from the husk or parchment by passing them between heavy wooden rollers and winnowing away the broken husks. The shelled coffee is then sized by passing it down a tube perforated throughout its length with holes of regularly increasing diameter, and the various sizes are next hand-picked to free them from defective or malformed seeds; the coffee is then ready to pack for export. A tree in good bearing will yield from 1½ to 2 ℔ of berries in a year; but its fertility depends largely upon conditions of climate, situation, and soil. Generally trees planted in lofty dry situations and in light soils yield small berries, which give a rich aromatic coffee, while in low, flat, moist climates a more abundant yield of a large-sized berry is obtained. The greater weight of the coarser qualities of coffee more than makes up for the smaller price obtained for them as against the higher cost of the finer growths; and therefore quality is too often sacrificed to quantity.

The cultivation of coffee is attended with many risks and much anxiety. In Ceylon, where British capital and enterprize have hitherto found their principal scope, the estates are exposed to the attacks of a most mischievous and destructive rodent, the coffee or Golunda rat. A species of insect called the coffee bug, *Lecanium coffeæ*, is a still more formidable and alarming pest with which planters have to contend. Of recent years prominent attention has been drawn to two diseased conditions arising in Singalese and Indian plantations by fungus growths. The first, called the coffee-leaf disease, appeared in Ceylon in 1869, and in Mysore a year later. The fungus in this case, *Hemileia vastatrix*, is endophytous, growing within the substance of the leaf, and while no effective cure has been discovered for it, it is not yet clear that it seriously affects the quality or amount of coffee yielded by the plants. The second, known as the coffee-rot, on the other hand, works great havoc in the Mysore plantations, in which it has been observed, being especially hurtful in wet seasons. This fungus has been examined by Mr M. C. Cooke, who names it *Pellicularia koleroga*, and describes the affected leaves as being covered with a slimy gelatinous film, under which the leaves become black and quickly drop off, as do also the clusters of coffee berries.

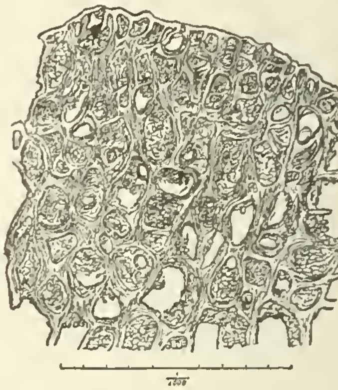

Fig. 2.—Microscopic structure of Coffee.

Raw coffee seeds are tough and horny in structure, and are devoid of the peculiar aroma and taste which are so characteristic of the roasted seeds. In minute structure coffee is so distinct from all other vegetable substances that it is readily recognized by means of the microscope, and as roasting does not destroy its distinguishing peculiarities, microscopic examination forms the readiest means of determining the genuineness of any sample. The substance of the seed, according to Dr Hassall, consists "of an assemblage of vesicles or cells of an angular form, which adhere so firmly together that they break up into pieces rather than separate into distinct and perfect cells. The cavities of the cells include, in the form of little drops, a considerable quantity of aromatic volatile oil, on the presence of which the fragrance and many of the active principles of the berry depend" (see fig. 2). The testa or investing membrane of the seeds has a layer of long cells with a peculiar pitted structure. In chemical composition the seeds are complex, and they contain variable proportions of proximate principles. The following represents the average constitution of raw coffee according to the analysis of M. Payen:—

Cellulose	34
Water	12
Fat	10 to 13
Glucose, dextrin, and organic acid	15·5
Legumin and casein	10
Other nitrogenous substances	3
Caffeine	0·8

Caffetannate of caffeine and potassium	3·5 to 5·0
Viscid essential oil (insoluble in water)	0·001
Aromatic oils (some lighter some heavier than water)	0·002
Ash	6·7

The physiological and dietetic value of coffee depends principally upon the alkaloid caffeine which it contains, in common with tea, cocoa, maté or Paraguay tea, guarana, and the African kola nut. Its commercial value is, however, determined by the amount of the aromatic oil, caffeone, which develops in it by the process of roasting. By prolonged keeping it is found that the richness of any seeds in this peculiar oil is increased, and with increased aroma the coffee also yields a blander and more mellow beverage. Stored coffee loses weight at first with great rapidity, as much as 8 per cent. having been found to dissipate in the first year of keeping, 5 per cent. in the second, and 2 per cent. in the third; but such loss of weight is more than compensated by improvement in quality and consequent enhancement of value.

In the process of roasting, coffee seeds swell up by the liberation of gases within their substance,—their weight decreasing in proportion to the extent to which the operation is carried. Roasting also develops with the aromatic caffeone above alluded to a bitter soluble principle, and it liberates a portion of the caffeine from its combination with caffetannic acid. Roasting is an operation of the greatest nicety, and one, moreover, of a crucial nature, for equally by insufficient and by excessive roasting much of the aroma of the coffee is lost; and its infusion is neither agreeable to the palate nor exhilarating in its influence. The roaster must judge of the amount of heat required for the adequate roasting of different qualities, and while that is variable, the range of roasting temperature proper for individual kinds is only narrow. In Continental countries it is the practice to roast in small quantities, and thus the whole charge is well under the control of the roaster; but in Britain large roasts are the rule, in dealing with which much difficulty is experienced in producing uniform torrefaction, and in stopping the process at the proper moment. The coffee-roasting apparatus is usually a malleable iron cylinder mounted to revolve over the fire on a hollow axle which allows the escape of gases generated during torrefaction. Messrs W. and G. Law of Edinburgh have introduced a very ingenious adaptation of the cylinder whereby a compound simultaneous horizontal and vertical motion is secured, causing the seeds to be tossed about in all directions and communicating a uniform heat to every portion of the cylinder. The roasting of coffee should be done as short a time as practicable before the grinding for use, and as ground coffee especially parts rapidly with its aroma, the grinding should only be done when coffee is about to be prepared. Any ground coffee which may be kept should be rigidly excluded from the air.

While Arabia produces the choicest variety of coffee, the roasting of the seeds and the preparation of the beverage are also here conducted with unequalled skill. Mr W. G. Palgrave gives the following account of these operations in his *Central and Eastern Arabia*:—

"Without delay Sowelylim begins his preparations for coffee. These open by about five minutes' blowing with the bellows, and arranging the charcoal till a sufficient heat has been produced. Next he places the largest of the coffee-pots, a huge machine, and about two-thirds full of clear water, close by the edge of the glowing coal pit, that its contents may become gradually warm while other operations are in progress. He then takes a dirty knotted rag out of a niche in the wall close by, and having untied it, empties out of it three or four handfuls of unroasted coffee, the which he places on a little trencher of platted grass, and picks carefully out any blackened grains, or other non-homologous substances commonly to be found intermixed with the berries when purchased in gross; then, after much cleansing and shaking, he pours the grains so cleansed into a large open iron ladle, and places it over the mouth of the funnel, at the same time blowing the bellows and stirring the grains gently round and round till they crackle, redden, and smoke a little, but carefully withdrawing them from the heat long before they turn black or charred, after the erroneous fashion of Turkey and Europe; after which he puts them a moment to cool on the grass platter. He then sets the warm water in the large coffee-pot over the fire aperture, that it may be ready boiling at the right moment, and draws in close between his own trouserless legs a large stone mortar with a narrow pit in the middle, just enough to admit the black stone pestle of a foot long and an inch and a half thick, which he now takes in hand. Next pouring the half-roasted berries into the mortar he proceeds to pound them, striking right into the narrow hollow with wonderful dexterity, not ever missing his blow till the beans are smashed, but not reduced into powder. He then scoops them out, now reduced to a sort of coarse reddish grit, very unlike the fine charcoal powder which passes in some countries for coffee, and out of which every particle of real aroma has long since been burned or ground. After all these operations . . . . . he takes a smaller coffee-pot in hand, fills it more than half with hot water from the larger vessel, and then, shaking the pounded coffee into it, sets it on the fire to boil, occasionally stirring it with a small stick as the water rises, to check the ebullition and prevent overflowing. Nor is the boiling stage to be long or vehement; on the contrary, it is and should be as slight as possible. In the interim he takes out of another rag-knot a few aromatic seeds called heyl, an Indian product, but of whose scientific name I regret to be wholly ignorant, or a little saffron, and after slightly pounding these ingredients, throws them into the simmering coffee to improve its flavour,—for such an additional spicing is held indispensable in Arabia, though often omitted elsewhere in the East. Sugar, I may say, would be a totally unheard-of profanation. Last of all, he strains off the liquor through some fibres of the inner palm-bark, placed for that purpose in the jug-spout, and gets ready the tray of delicate party-coloured grass and the small coffee-cups ready for pouring out."

There is no doubt that were proper attention bestowed upon the preparation of coffee it would become a much more popular beverage in Great Britain than it now is; but to obtain it in perfection much greater care is requisite than is necessary in the case of tea. To obtain coffee with a full aroma it must be prepared as an infusion with boiling water, or the water may simply be allowed to reach the boiling point after infusion and nothing more. Dr Parkes has, however, pointed out that by infusion alone much of the valuable soluble matter in ground coffee remains unextracted; and he recommends that the coffee which has already been used for infusion should be preserved and boiled, and that the liquor therefrom should be used for infusing a fresh supply. By this means the substance of the previously infused coffee and the aroma of the new are obtained together. Among the numerous devices which have been proposed for preparing coffee, none is more elegant and efficient than an apparatus constructed by Mr James R. Napier, F.R.S., for which a patent was obtained by Mr David Thomson of Glasgow. It consists of a glass globe *a* (fig. 3), an infusing jar *b*, of glass or porcelain and a bent tube *c*, of block tin or German silver fitted by a cork stopper into the neck of the globe and passing to the bottom of the jar, where it ends in a finely perforated disc. The apparatus also requires a spirit lamp *d* or other means of communicating a certain amount of heat to the globe. The coffee is infused with

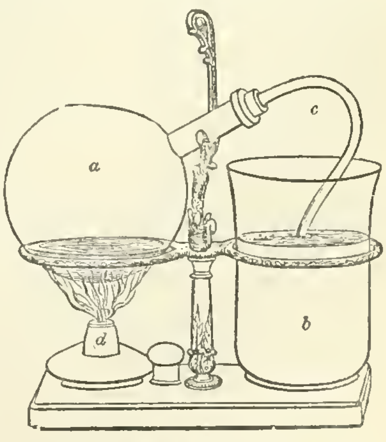

Fig. 3.—Napier's Coffee Apparatus.

boiling water in the jar, and a small quantity of boiling water is also placed in the globe. The tube is then fitted in, and the spirit lamp is lighted under the globe. The steam generated expels the air from the globe, and it bubbles up through the jar. When the bubbles of air cease to appear almost the whole of the air will have been ejected, and on withdrawing the lamp the steam in the globe condenses, creating a vacuum, to fill up which the infused coffee rushes up through the metal tube, being at the same time filtered by the accumulated coffee grounds around the perforated disc. An error of very frequent occurrence in the preparation of coffee, which results probably from the habit of tea-making, consists in using too little coffee. For a pint of the infusion from an ounce to an ounce and a half of coffee ought to be used. According to the experiments of Aubert a cup of coffee made from a Prussian loth (·587 oz.) contains from 1·5 to 1·9 grains of caffeine.

Coffee belongs to the medicinal or auxiliary class of food substances, being solely valuable for its stimulant effect upon the nervous and vascular system. It produces a feeling of buoyancy and exhilaration comparable to a certain stage of alcoholic intoxication, but which does not end in depression or collapse. It increases the frequency of the pulse, lightens the sensation of fatigue, and it sustains the strength under prolonged and severe muscular exertion. The value of its hot infusion under the rigours of Arctic cold has been demonstrated in the experience of all Arctic explorers, and it is scarcely less useful in tropical regions, where it beneficially stimulates the action of the skin. It has been affirmed that coffee and other substances containing the alkaloid caffeine have an influence in retarding the waste of tissue in the human frame, but careful and extended observation has demonstrated that they have no such effect.

Although by microscopic, physical, and chemical tests the purity of coffee can be determined with perfect certainty, yet ground coffee is subjected to many and extensive adulterations. Chief among the adulterant substances, if it can be so called, is chicory root; but it occupies a peculiar position, since very many people on the Continent as well as in Great Britain deliberately prefer a mixture of chicory with coffee to pure coffee. Chicory is indeed destitute of the stimulant alkaloid and essential oil for which coffee is valued; but the facts that it has stood the test of prolonged and extended use, and that its infusion is, in some localities, used alone, indicate that it performs some useful function in connection with coffee, as used at least by Western communities. For one thing, it yields a copious amount of soluble matter in infusion with hot water, and thus gives a specious appearance of strength and substance to what may be really only a very weak preparation of coffee. The mixture of chicory with coffee is easily detected by the microscope, the structure of both, which they retain after torrefaction, being very characteristic and distinct. The granules of coffee, moreover, remain hard and angular when mixed with water, to which they communicate but little colour; chicory, on the other hand, swelling up and softening, yields a deep brown colour to water in which it is thrown. The specific gravity of an infusion of chicory is also much higher than that of coffee. Among the numerous other substances used to adulterate coffee are roasted and ground roots of the dandelion, carrot, parsnip, and beet; beans, lupins, and other leguminous seeds; wheat, rice, and various cereal grains; the seeds of the broom, fenugreek, and iris; acorns; and "negro coffee," the seeds of *Cassia occidentalis*. These with many more similar substances have not only been used as adulterants, but under various high-sounding names several of them have been introduced as substitutes for coffee; but they have neither merited nor obtained any success, and their sole effect has been to bring coffee into undeserved disrepute with the public.

The leaves of the coffee tree contain caffeine in larger proportion than the seeds themselves, and their use as a substitute for tea has frequently been suggested. The leaves are actually so used in Sumatra, but being destitute of any attractive aroma such as is possessed by both tea and coffee, the infusion is not palatable. It is, moreover, not practicable to obtain both seeds and leaves from the same plant, and as the commercial demand is for the seed alone, no consideration either of profit or of any dietetic or economic advantage is likely to lead to the growth of coffee trees on account of their leaves. (J. PA.)

COFFER-DAMS have from very early times been employed as useful, and in some cases indispensable, structures in executing works of marine and river engineering. By excluding the water from the area they enclose, the work can be carried on within them with nearly the same ease as on dry land. Whether used on a small or a large scale—whether as low-tide dams of clay or concrete of only a few feet in height, or as high-water dams of timber and puddle formed to resist the waves of the sea, they are in every sense structures of great importance in the practice of hydraulic engineering.

Tide-dams are chiefly used in laying the foundations of piers or other works that must be founded under low-water level. They are generally made of clay and planking, and are only carried to the height of about 3 feet above low-water. The water being pumped out during the last of the ebb tide affords one or two hours work at low-water, the dam being submerged on the rise of the tide. In such dams a sluice should be introduced, which when open may allow the water to escape with the falling tide and so save pumping. Such tide-dams when exposed to a considerable wash of sea may advantageously be made of cement rubble masonry, of the application of which to coffer-dams the earliest account we know is that stated in Stevenson's *Account of the Bell-Rock Lighthouse* (p. 230), where he successfully employed that method of construction in 1808 in excavating the foundation of that work. When it is required to sink the foundation some feet into sand and gravel, a convenient expedient is the portable dam proposed by Mr Thomas Stevenson described in the *Trans. of the Roy. Scot. Society of Arts*, 1848, to which reference is made. The feature in this tide-dam is the use of double framed walings to support and direct the driving of the sheet piles, and its advantages are its cheapness, its portability, and its ready adaptation to a sloping or even very irregular bottom.

But when it is necessary entirely to exclude the water from large areas, as, for example, in dock-works, it is necessary to adopt coffer-dams of varied construction suited to the circumstances of each case, and as these protecting coffer-dam works, notwithstanding their temporary nature, demand much of the engineer's skill in their design and construction, we propose to notice some of the different modes of construction that have been adopted in such cases to suit the varying sub-soil and other features of different works.

It may here be mentioned that, particularly in bridge building, caissons were employed in early times instead of coffer-dams, but they are now entirely out of use. The caisson was a flat-bottomed barge constructed of strongly framed timber-work, in which the under courses forming the foundation of the piers of a bridge, for example, were built at any convenient spot near the banks of the river. The caisson was then floated to the site of the pier, the bed of the river having previously been dredged so as to present a comparatively level and smooth surface. On the bed so prepared the caisson was sunk by admitting the water gradually by means of a valve provided for that purpose. The sides were so constructed as to admit of their easy removal from the bottom of the caisson when it had been sunk to its bed. Rankine mentions a caisson described by Becker which measured 63 feet long, 21 feet broad, and 15 feet deep over all. The bottom beams used in constructing this large caisson were 10 inches square and 2 feet 10 inches apart from centre to centre, and the uprights forming the sides were 10 inches square and 5 feet 8 inches apart from centre to centre.

But to return to the subject of this article. The dams used in soft bottoms, where piles can be driven, are constructed of timber, and vary in strength according to the head of water they have to sustain. But the general style of construction is in all cases the same. The dams are formed of parallel rows of piles driven into the bottom, the space between the rows being filled by a mass of clay puddle of sufficient thickness to exclude the water which percolates between the joints of the piles. In cases where the head of water is not great, the coffer-dam is generally constructed as shown in fig 1., where the gauge piles *a*

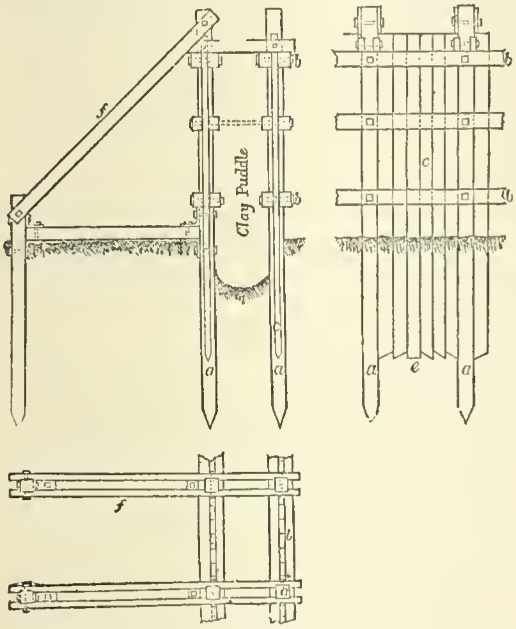

Fig. 1.—Coffer-dam for Soft Bottom.

are driven at distances varying from 4 to 8 feet apart, to which walings *b* are fixed, and between the walings sheet piles *c* are driven. The sheet piles are shod with iron, having a sloping edge to cause the piles to cling while being driven, and in the centre of each bay there is a key pile *e*, having a slight taper which on being driven down compresses the sheet piles on either side of it closely together. In cases where the water pressure is great the sheeting piles are dispensed with, and the dam is formed of two or sometimes three rows of whole timbers having the clay puddle between them. Fig. 2 is a dam on this principle, used in the construction of the Thames embankment, and described in the *Transactions of the Institution of Civil Engineers* by Mr Thomas Ridley, and after the explanations that have been given, its construction will be easily understood as an outer and inner dam formed of two rows of close-driven whole logs with intervening spaces of 6 feet filled with clay puddle. In all cases the dams must be supported by sufficient stays or struts, abutting on firm ground, or, when this cannot be got, on dwarf piles driven deep enough to afford sufficient resistance. It is also important to remove the soft matter between the rows of piles to as great a depth as possible, and to fill in the excavated space with clay puddle, for although the timber-work of the dam must be constructed so as to resist pressures, it will generally be found that the greatest risk of failure arises from the filtration of water under the bottom of the sheeting piles and puddle.

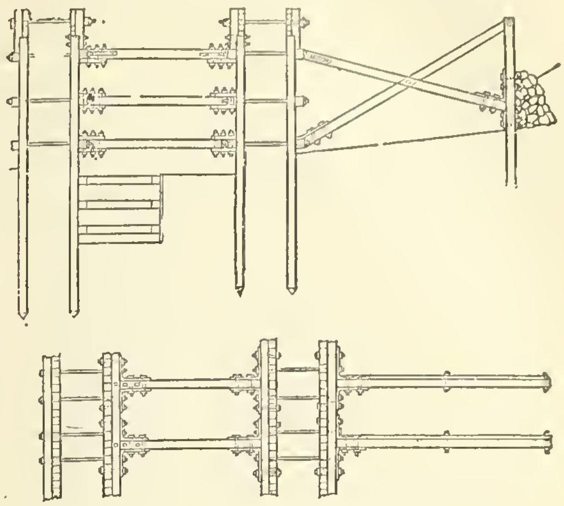

Fig. 2.—Coffer-dam used at Thames Embankment.

The coffer-dams described illustrate the general construction of such works, but various arrangements of the timber work have been adopted to suit particular situations, such as Mr James Walker's coffer-dam for constructing the foundations of the river terrace of the Houses of Parliament at Westminster (vide *Min. of Proc. of Inst. of C. E.*, vol. i.), and Sir John Hawkshaw's dam for the middle level drainage of Lincoln (*Min. of Proc. of Inst. of Civil Engineers*, vol. xxii.)

All the examples that have been given are applicable to situations where the bottom is sufficiently soft to admit of piles being driven. But cases occur where this is impossible. Such, for example, as the removal of obstructions from the beds of rivers where it may be necessary to lay dry a large area of solid rock, and in that case it is necessary to adopt a totally different construction of dam. The accompanying cut (fig. 3) shows a coffer-dam designed by Mr D. Stevenson, which is specially adapted to a hard bottom where piles cannot be driven.[1] It is formed of two rows of iron piles placed 3 feet apart and jumped into the rock, which supports two linings of planking, the intermediate space being filled with puddle and the whole structure properly stayed. This dam has been successfully employed on many works, and on the Ribble navigation, where it was first introduced, it was used to excavate a bed of rock 300 yards in length and of a maximum depth of 13 feet 6 inches. The maximum depth at high water against the dam was 16 feet, but in high river floods the whole dam was completely submerged, and on the water subsiding it was found that the iron rods, although jumped only 15 inches into the rock, were not drawn from their fixtures.

Dams must be designed with a special regard to their sufficiency to resist the water pressures they have to bear, and Professor Rankine gives the following formulæ, in his *Manual of Civil Engineering*, p. 612, for calculating the pressure which the struts may have to bear.

Let b = breadth in feet of the division of the dam sustained by one strut,
x = the depth of water in feet,
w = the weight of a cubic foot of water in lbs.
P = the pressure of water against that division of dam;

[1] *Transactions of Institution of Civil Engineers*, vol. iii. p. 337.

Then—

$$P = wbx^2 \div 2$$

and the moment of that pressure relative to a horizontal axis at the level of the ground is

$$M = wbx^3 \div 6.$$

Let h be the height above the ground at which the strut abuts against the dam, and i its inclination to the horizon; the thrust along the strut is

$$T = M \text{ sec. } i \div h,$$

from which the scantling required, depending on the sort of timber employed, can be calculated.

In conclusion it may be noticed that the introduction of iron cylinders and compressed air for founding the piers of bridges has not only superseded the use of timber coffer-

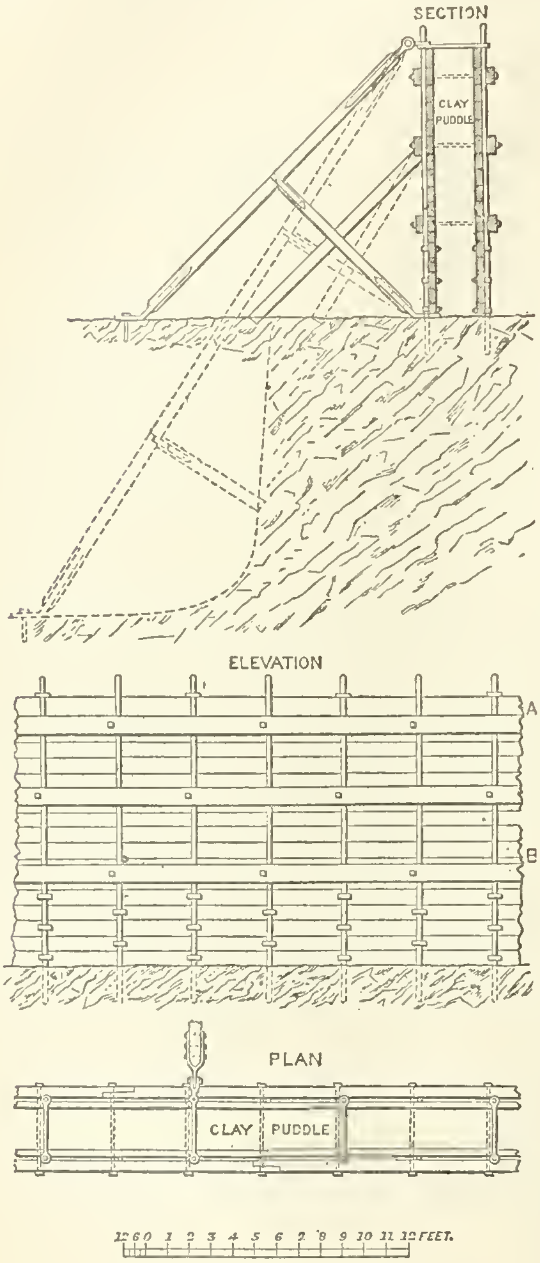

Fig. 3.—Cofferdam for Hard Bottom
A, High Water; B, Low Water.

dams for piers in soft bottoms, but has enabled bridges to be securely placed in situations where no timber dams could have answered the purpose. On the other hand, there are many engineering works connected with river, harbour, and dock improvements, to which the cylinder system is quite inapplicable, and for which extensive and costly coffer-dams of the kind we have described must continue to be employed. The method of founding by iron cylinders has been described in the article Bridge, to which the reader is referred. (D. S.)

COGNAC, a town of France, at the head of an arrondissement in the department of Charente, on the left bank of the River Charente, about 32 miles by rail west of Angoulême. It has a tribunal of commerce, a communal college, a prison, a hospital, a church of the 12th century dedicated to St Leger, and an old castle, now used as a wine-store, in the park of which is a bronze statue of Francis I., marking the spot where, according to tradition, he was born in 1494. The most important industry of Cognac is the distillation and exportation of the celebrated brandy to which the town gives its name (see Brandy). Iron is also manufactured, and a considerable trade is maintained in grain and cattle. Cognac is probably to be identified with one of the many places that bore the name of Condate; it was known as Coniacum in the Middle Ages. At an early period it was governed by lords of its own, but in the 12th century it became subject to the counts of Angoumois. In 1238 it was the seat of an ecclesiastical council summoned by Gerard of Bordeaux; and in 1526 it gave its name to a treaty concluded against Charles V. by Francis I., Henry VIII. of England, the Pope, Venice, and Milan. In 1562 the town was captured by the Huguenots, and in 1651 it defied the prince of Condé. Before the Revolution it possessed a fine Benedictine monastery and two other convents. The population, which was only 4000 about the middle of the 18th century, had increased by 1872 to 12,950.

COHESION. See Attraction, Capillary Action, and Constitution of Bodies.

COHOES, one of the most important manufacturing centres in the United States, is situated in Albany County, in the State of New York, at the confluence of the Mohawk with the Hudson, just below the famous Cohoes fall on the former river, to which it is indebted for its prosperity. It contains seven churches and twenty-two public schools, the most remarkable of the churches being the Roman Catholic St Bernard's and the Episcopal St John's. The manufacturing establishments comprise six cotton mills with 4000 looms, eighteen knitting mills, a rolling mill, a pin factory, a knitting-needle factory, two foundries, three machine shops, a paper-mill, and a bedstead factory. In 1870 there were produced 54,342,000 yards of cloth, 33,600,000 knitting-needles, and 350,000 packages of pins; while the turn-out of hosiery formed a third of the whole amount manufactured in the United States. The whole water-power of the river for some distance both above and below the falls is the property of the Cohoes Company instituted in 1826; and the various manufactories obtain their share at a fixed annual charge for each horse-power. The supply is regulated by a dam erected above the falls in 1865, and by a system of five canals. Cohoes owes its rise to the incorporation of the Cohoes Manufacturing Company in 1811. It obtained the rank of a village in 1848 and that of a city in 1869. Its population in 1850 was 4229; in 1860, 8800; and in 1870, 15,357. A large number of French Canadians are to be found among the operatives.

COIMBATORE, a district of British India, in the Presidency of Fort St George or Madras, situated between 10° 45′ and 11° 48′ N. lat. and between 76° 50′ and 78° 10′ E. long. It is bounded on the N. by Mysore, on the E. by the district of Salem, the Cauveri River marking the entire boundary line, on the S. by Madura and Travancore State, and on the W. by Cochin State, Malabar District, and the

Nilgirí Hills. Coimbatore may be described as a flat, open country, hemmed in by mountains on the north, west, and south, but opening eastwards on to the great plain of the Carnatic; the average height of the plain above sea-level is about 900 feet. The principal mountains are the Anamálí Hills, in the south of the district, rising at places to a height of between 8000 and 9000 feet. In the west, the Palghát and Vallagirí Hills form a connecting link between the Anamálí range and the Nilgirís, with the exception of a remarkable gap known as the Palghát Pass. This gap, which completely intersects the Gháts, is about twenty miles wide. In the north is a range of primitive trap-hills known as the Cauveri (Kaverí) chain, extending eastwards from the Nilgirís, and rising in places to a height of 4000 feet. The principal rivers are the Cauveri, Bháwaní, Noyel, and Amráwatí. Numerous canals are cut from the rivers for the purpose of affording artificial irrigation, which has proved of immense benefit to the country. Well and tank water is also largely used for irrigation purposes. The total area of Coimbatore is 7432 square miles, of which 3877½ square miles or 2,488,000 acres were returned as under cultivation in 1874–75, viz., 2,089,000 acres under food grains or corn crops, 80,000 acres oilseeds, 61,000 acres green and garden crops, 5000 acres orchards, and 253,000 acres under special crops. Excellent cotton and tobacco of a superior quality are produced. Extensive teak forests exist in the neighbourhood. Coimbatore is subdivided into 10 *táluks* or sub-districts, and contains 1515 villages. The census report of 1872 returns the population of the district as follows:—Hindus, 1,715,081; Muhammadans, 36,026; Native Christians, 11,443; Europeans and Eurasians, 595; Buddhists, or Jains, 56; others, 73; total, 1,763,274. The principal town is Coimbatore, situated in 10° 59′ 41″ lat. and 76° 59′ 46″ long.; it forms a station on the line of railway between Beypur and Madras. Population in 1872—Hindus, 30,801; Muhammadans, 2599; Christians, 1892; Buddhists, 18; total, 35,310. The municipal revenue of the town amounted in 1874–75 to £3720, and the expenditure to £3367. Two other small towns—Karur and Erode—are also constituted municipalities. The total district revenue in 1874–75 amounted to £304,818, of which £253,536 was derived from land. Coimbatore district was acquired by the British in 1799 at the close of the war which ended with the death of Tippu.

COIMBRA, a city of Portugal, capital of the province of Beira, on the north bank of the Mondego, 115 miles N.N.E. of Lisbon, in 40° 14′ N. lat. and 8° 24′ W. long. It is built for the most part on rising ground, and presents from the other side of the river a picturesque and imposing appearance; though in reality its houses have individually but little pretension, and its streets are, almost without exception, narrow and mean. It derives its present importance from being the seat of the only university in the kingdom,—an institution which was originally established at Lisbon in 1291, was transferred to Coimbra in 1306, was again removed to Lisbon, and was finally fixed at Coimbra in 1527. There are five faculties,—theology, law, medicine, mathematics, and philosophy, with fifty-two professors and twenty-one substitutes; and in 1874–5 the number of students was 667, of whom 15 came from the Azores and 11 from Brazil. The library contains 80,000 volumes, and the museums and laboratories are on an extensive scale. In connection with the medical faculty there are regular hospitals; the mathematical faculty maintains an observatory from which an excellent view can be obtained of the whole valley of the Mondego; and outside of the town there is a botanic garden (especially rich in the flora of Brazil), which also serves as a public promenade. Among the other educational establishments are military college, a royal college of arts, and an episcopal seminary. The city is the seat of a bishop, suffragan to the archbishop of Braga; and it possesses two cathedrals, eight parish churches, and several conventual buildings. The new cathedral is of little interest; but the old is a fine specimen of the Romanesque style, and retains portions of the mosque which it replaced. The principal churches are Santa Cruz, of the 16th century, and San Salvador, founded by Esterão Martinez in 1169. On the bank of the Mondego stand the ruins of the once splendid monastery of Santa Clara, established by Don Mor Dias in 1286; and on the other side of the river, crossed by a fine bridge of several arches, is the celebrated *Quinta das lagrimas*, or Villa of Tears, where Inez de Castro is believed to have been murdered. The town is supplied with water by means of an aqueduct of 20 arches. The trade is purely local, as the river is navigable only in flood, and the port of Figueira is 20 miles distant; but there are manufactures of pottery, linen, cloth, and articles of horn; and a three days' market is held yearly in front of the Clara monastery. The country to the south is the most fertile and salubrious in Portugal, and the neighbourhood is accordingly thickly studded with farm-houses and villas. The population of the city in 1864 was 18,147.

Coimbra is identified with the ancient *Conembrica*, the site of which, however, seems to have been a little to the south. The city was for a long time a Moorish stronghold, but in 1064 it was captured by Ferdinand the Great and the Cid. Previous to the 16th century it was the capital of the country, and no fewer than seven kings—Sancho I. and II., Alphonso I., II., and III., Pedro, and Ferdinand—were born within its walls. In 1755 it suffered considerably from the earthquake. In 1810 a division of the French army, under Massena, were made prisoners by the English in the neighbourhood. In 1834 Don Miguel made the city his headquarters; and in 1846 it was the scene of a Miguelist insurrection.

COIN, a town of Spain, in the province of Malaga, and 20 miles west of the city of that name. It is well built, and has two large churches, an episcopal palace, and a town hall. Population, 8000.

COINAGE AND COINS. See Bullion, Mint, Money, and Numismatics.

COIR, a rough, strong, fibrous substance obtained from the outer husk of the cocoa-nut. See Cocoa-Nut Palm.

COIRE (the German *Chur*, Italian *Coira*, and *Quera* of the Romance language spoken in the district), the capital of the Swiss canton of the Grisons or Graubünden, at the foot of the valley of the Plessur, a short distance above the confluence of that river with the Rhone, in 46° 50′ 54″ N. lat. and 9° 31′ 26″ E. long. It lies 1830 feet above the level of the sea, and is overshadowed by the Mittenberg and Pizokelberg. The streets are narrow, and the general appearance of the place bespeaks its antiquity. The upper part of the town, or Bishop's Quarter, was once surrounded with walls, and it is still distinguished from the lower portion as the almost exclusive residence of the Roman Catholic population. The cathedral church of St Lucius is its most remarkable building, ascribed in part to Bishop Tello of the 8th century, and deriving its name from a legendary British king, who is reputed to have suffered martyrdom in the town. Of antiquarian interest are the statues of the Four Evangelists, the ancient wood carvings, and several monuments by Holbein and Dürer. The episcopal palace on the other side of the court is believed to occupy the site of a Roman castle; and two ancient towers, probably dating from the 10th century, are popularly regarded as of Roman construction, the opinion being supported by deriving their names, Marsoel and Spinoel, from the Latin *Mars in Oculis* and *Spina in Oculis.* The episcopal school is now administered by the canton, and contains a rich collection of native literature. In the lower town are situated the great town-house, with a public library and three stained-glass windows of the 16th century;

the churches of St Martin and St Regula; the administrative buildings; and the hospital founded by Theodosius, a superior of the Capuchins. The prosperity of Coire is chiefly maintained by its transit trade between Germany and Italy; but it also engages in the manufacture of cotton, wool, leather, and pewter wares, has dye-works, and breweries, and deals in cattle and grain. The population, which is mainly Protestant, numbered 7552 in 1870.

Coire is identified with *Curia Rhætorum*, a late Roman city, first mentioned about the 4th century. Its bishopric, which held sway over an extensive district, seems to have been founded in 470 by Asimo. In the 15th century the town made itself free from episcopal control, and in 1460 obtained from the emperor, Frederick IV., the rank of an imperial city; but before the beginning of the next century it split with the empire and joined the confederacy of the Grisons. In 1526 the Reformation was introduced; and a conspiracy for the restoration of the former ecclesiastical regime was vigorously suppressed. In the 17th century the city was frequently the centre of the great struggle between the Cantons and the Austrian empire which raged with such fury and so many alternations of success. In 1802 the French general Massena occupied the town, and from that date the bishops have had no territorial possessions.

COJUTEPEC, a town of Central America, in the republic of San Salvador and the department of Cuscatlan, about 15 miles east of the capital. It has a population of about 15,000, and from 1854 to 1858 it served as the seat of government instead of San Salvador, which had been ruined by an earthquake. In 1872 it took part in a revolutionary outbreak against the existing Government, and the Indian population unsuccessfully attacked the garrison. The town gives its name to a neighbouring volcano, which rises to a height of 5700 feet, and also to the extensive lake, otherwise known as the Lake of Ilopango, which lies a few miles to the south and gives rise to the Rio Jiboa.

COKE, the carbonaceous residue produced when coal is subjected to a strong red heat, out of contact with the air, until the volatile constituents are driven off It consists essentially of carbon, the so-called fixed carbon, together with the incombustible matters or ash contained in the coal from which it is derived. In addition to these it almost invariably contains small quantities of hydrogen, oxygen, and nitrogen, the whole, however, not exceeding 2 or 3 per cent. It also contains water, the amount of which may vary considerably according to the method of manufacture. When produced rapidly and at a low heat, as in gas-making, it is of a dull black colour, and a loose spongy or pumice-like texture, and ignites with comparative ease, though less readily than bituminous coal, so that it may be burnt in open fire-places; but when a long-continued heat is used, as in the preparation of coke for iron and steel melting, the product is hard and dense, is often prismatic in structure, has a brilliant semi-metallic lustre and silvery-grey colour, is a good conductor of heat and electricity, and can only be burnt in furnaces provided with a strong chimney draught or an artificial blast. The strength and cohesive properties are also intimately related to the nature and composition of the coals employed, which are said to be caking or non-caking according to the compact or fragmentary character of the coke produced.

The simplest method of coking, that in open heaps or piles, is conducted in a very similar manner to charcoal burning. The coal is piled in a domed heap about 30 feet in diameter and 5 feet high, with a chimney of bricks arranged in open chequer work in the centre, around which the largest lumps of coal are placed so as to allow a free draught through the mass. The outside of the heap is covered with a coating of wet coke dust, except a ring about a foot high at the bottom. Fire is communicated by putting a few live coals near the top of the chimney, or from the interior by throwing them down the chimney, and the combustion proceeds downwards and outwards by the draught through the uncovered portion at the bottom. Whenever the fire takes too strong a hold and burns out to the surface it is damped by plastering over the spot with wet coke dust and earth, this being a point requiring considerable skill on the part of the coke burner. When flame and smoke are no longer given off, which usually happens in from five to six days, the whole surface is smothered with coke dust, and the chimney is stopped for three or four days longer, when the heap is sufficiently cooled to allow of the coke being broken up and removed, or, as it is called, drawn. The cooling is usually expedited by throwing water upon the heap before drawing. The principle of coking in rectangular piles is generally similar to the foregoing, but chimneys are not used. The dimensions generally adopted are a height of from $3\frac{1}{2}$ to 5 feet, and a breadth of 12 feet at the base.

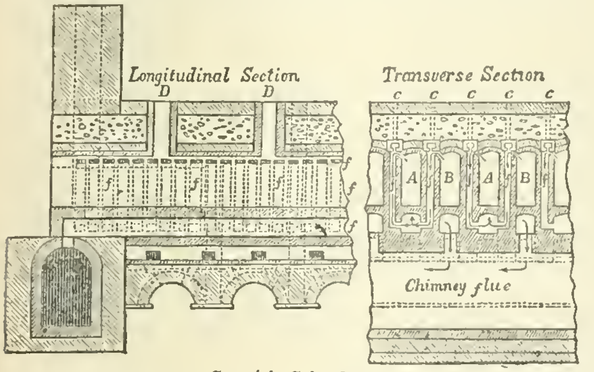
In coking by clamps or kilns a rectangular pile of coal is enclosed between upright walls, having a system of vertical and horizontal passages traversing them at intervals, which serve as chimneys to conduct the combustion through the pile. This system has been used at different times in South Wales, Germany, and other places, but is now generally abandoned, as the draught holes have a tendency to consume the coal unnecessarily unless very carefully watched.

The largest proportion of the coke used for industrial purposes is made in close kilns or ovens. These vary very considerably in form and details of construction, but the same general principles are observed in all, the object being to effect the coking as much as possible by the consumption of the volatile inflammable gases given off above the surface of the coal, and to protect the latter from the direct access of currents of air. A further object is the utilization of the heat given off by the waste gases, which may be employed to heat the oven by circulating them in flues round the outside, and further by employing them for the accessory objects of raising steam, heating air, &c., in collieries and iron-works.

In its oldest and simplest form, the coke oven consists of a round chamber from 7 to 10 feet in diameter, with a low cylindrical wall, and a domed roof rising about 20 inches in height above the floor. A hole about 1 foot in diameter in the crown of the roof serves for charging, and the finished coke is drawn through a door in the wall, about $2\frac{1}{2}$ feet square. When cleared for a fresh charge, the oven being red-hot, small coal is introduced through the hole in the roof, and spread uniformly over the floor, until it is filled up to the level of the springing of the roof, when the doorway is filled up with loose bricks which give a sufficient passage between them for the admission of air to ignite the gases given off by the distillation of the heated coal. After a few hours these air-ways must be closed by plastering up the brickwork, except the top layer, which is left open for twenty-four hours. The heat developed by the burning gases causes the coking to proceed downwards until the entire charge is converted, this taking from three to four days, according to the quantity of coal. When the escape of flame from the hole in the roof ceases, all apertures are stopped whereby air can enter to the incandescent mass, which being no longer protected by an atmosphere of combustible gases, would burn to waste if brought in contact with the atmosphere. At this point, therefore, all holes in the oven and chimney are completely closed for about twelve hours, when the door is opened, and the coke, which forms a coherent mass, somewhat less in size than the original charge, and divided by a system of columnar joints, is removed by an iron drag, or cross-bar, inserted at the far end of the floor, and moved by a chain and windlass, a stream of water from a hose being used to quench the glowing coke as it is brought out. This class of oven, which is now not much used, was adopted by most of the railway companies, when coke was burnt exclusively in locomotives, and is also common in the Durham coal-field. They are generally known as beehive ovens, also as bakers' ovens. Usually from six to ten, or twelve, or more ovens are placed side by side in one block of brickwork, which is supplied with a tall chimney, the individual ovens being connected by pillars, with well-regulated dampers. A railway is generally laid along the top of the range of ovens, so that the charging can be effected directly from the colliery trucks. The yield of coke by this method may be from 55 to 65 per cent., according to the nature of the coal. With charges varying from 3 to 10 tons, the operation, including the period of cooling, lasts from four to seven days. The coke obtained is of the highest quality, being dense and well burned. In some cases the cooling of the coke is effected by watering it before drawing. There is a certain amount of sulphur removed by this method, as the steam generated being brought into contact with the sulphide of iron in the heated mass, formed from pyrites in the coal, produces sulphuretted hydrogen and magnetic oxide of iron. The amount of desulphurization by this method is, however, practically insignificant, as the operation does not last a sufficient time to allow the mass of the fuel to be affected. The proportion of sulphur in finished coke, as compared with that of the original coal, may be roughly stated at about one-half. It has been sought to reduce the amount by decomposing the residual ferrous sulphide in various ways, as by the addition of salt, carbonate of soda, lime, &c., to the coal before coking but none of these methods is found to be practically useful.

In the South Wales coal-field the ordinary form of coke oven is nearly rectangular, being about 14 feet long, 5 feet wide at the back, and 6 feet at the front or drawing ends; the height to the crown of the cylindrical roof is 5 feet 6 inches, with usually two charging holes. Two charges are worked weekly, the first, of $4\frac{1}{2}$ tons, is finished in three days, while the second, of 5 tons, is allowed four days, so as to remain in the oven over Sunday. The yield in both cases is about the same.

The addition of heating flues exterior to the wall of the oven allows the time of coking to be very much shortened. Of the numerous contrivances proposed for this purpose, that of a Belgian engineer, Mr Coppee, has latterly come into favour in many places, as very well adapted for use with comparatively dry coal. The coking chamber is a long narrow retort of fire brick, measuring about 30 feet in length, 17 inches in width at the front, and about 2 inches more at the back, where the charge is pushed out, with vertical walls about $3\frac{1}{2}$ feet high, covered by a low arched roof. One of these walls is solid, but the other contains twenty-eight vertical descending flues (f) which communicate with the interior at the springing of the roof, and below with the large flue of the same width as the oven, and running along its entire length. As usually built, a series or battery includes about thirty ovens, which are arranged in pairs as in the figure, from which it will be seen that



Coppée's Coke Oven.

the left hand oven (A) is heated by the joint current of gases on both sides, while B is heated on one side by its own gas, and on the other by that of the next oven to the right. The current then passes along the bottom flue of A, and back through that of B, whence it escapes by a flue to the chimney, or may be led to a steam boiler if the waste heat is used, as is generally the case, for raising steam. The working of the adjacent pair of ovens is so arranged that they are drawn alternately at exactly intermediate periods; thus supposing the time of coking to be forty-eight hours, A is drawn twenty-four hours after the charging of B, while the latter is in full activity, and keeps up the heat of the empty oven during charging, while necessarily the burning hydrocarbon gases given off during the first heating of the coal tend to keep up the heat in the adjoining oven. At Ebbw Vale, in Monmouthshire, where the coking requires only twenty-four hours, the ovens are numbered consecutively, the odd numbers being drawn and re-charged in the morning, and the even ones twelve hours later. The combustion of the gases is effected by air which is brought in through special channels (c) in the brickwork communicating with the gas flues at the top, and becomes heated in the passage. The object sought to be obtained is the combustion of the gases as much as possible in the flues, and not in the oven itself. The oven is closed at both ends by cast-iron doors in two parts, which can be opened together or separately during the drawing and recharging. The charging is effected through three holes (D D) in the roof, the coal, in the form of slack, being contained in hopper-shaped trams, running upon rails, which are run over the holes and emptied by drawing a slide. The charge is about 3 tons, and the yield from 36 to 44 cwt., according to the nature of the coal operated upon. The finished coke forms a prismatic mass, 30 feet long, 3 feet high, and 16 inches broad; it is pushed out by a ram, shaped like the cross section of the oven, which is moved by steam power acting upon a long racked rod. This apparatus, together with the engine and boiler for moving it, is mounted on a carriage moving on a railway in front of the range of ovens, so that it can be brought up to any one of them as required. The mass of coke is pushed out on to a floor running along the back, where it is immediately broken, and quenched by heavily watering the fragments. The whole operation, including the drawing and recharging of the empty oven, is effected in about eight minutes. The yield of coke very closely approximates to that obtained by experiments in crucibles. A similar kind of oven with outside heating flues, that of the Brothers Appolt, has been in use for several years on the Continent, more particularly in France. It differs from Coppée's in the position of the coking chambers, which are vertical instead of horizontal, the coal being charged from the top, and the finished coke dropped into a truck placed below. Various schemes have been proposed at different times for the purpose of utilizing the condensible products, such as tar, ammoniacal water, &c., given off during the earlier stages of the process of coking, but they are not generally found to be applicable to the manufacture of metallurgical coke, being only suited for gas-works, where the quality of the coke is only a secondary consideration.

The slack of dry or non-caking coal, or anthracite, which cannot be coked alone, may be converted into a useful coke by mixing it with a proportion of bituminous coal, or gas-pitch, or a mixture of both. At Swansea, a mixture of 60 to 70 per cent. of anthracite with from 30 to 35 per cent. of bituminous coal, and 5 or 6 of gas pitch, made by grinding the ingredients in one of Carr's disintegrator mills, is coked in the ordinary South Wales ovens, a thin layer of bituminous coal being placed above the charge before it is lighted, to prevent the pitch from burning to waste. The yield of coke is about 80 per cent. of the weight of the charge. It is exceedingly hard, and about 23 per cent. heavier than that made from bituminous coal, with a correspondingly higher calorific value.

Coke is used for all purposes where a smokeless fire is required, as, for instance, in drying malt or hops, or in raising steam in locomotives within the limits of towns, also for producing strong local heat, as in melting metals (gold, silver, brass, or steel) in crucibles in air furnaces. In blast furnaces its value depends upon the difficulty of combustion, so that the particles keep their form until they reach the proper place of combustion at the point of entry of the blast in the lower part of the furnace. The great economy of fuel that has been effected in the process of iron smelting in the Cleveland district by increasing the height of the furnaces, is in great part due to the strength of the coke used, which is made in the south part of the Durham coal-field, and has sufficient cohesive power to bear the pressure of a column of iron-making materials from 80 to 100 feet in height without crushing, a result which cannot be obtained with the coke of other districts. Finely ground coke is used mixed with clay for making crucibles for steel melting, and also for filling the hearths of blast-furnaces in many German smelting works.

Apart from its convenience for special purposes, coke is not an economical fuel, the useful heating effect being about the same as that of an equal weight of coal. This circumstance has led to the nearly general abandonment of coke and the substitution of raw coal as fuel in locomotive engines on railways.

For full accounts of the different systems of coke ovens and details of their construction, see Percy's *Metallurgy*, introductory volume on fuel, &c., 2d edition, London, 1875, and Jordan's *Album du Cours de Metallurgie*, Paris, 1874. (H. B.)

COKE, Sir Edward (1552–1633), one of the most erudite of English lawyers, was born at Mileham, in Norfolk, on February 1, 1552. When only ten years old he lost his father, who was a bencher of Lincoln's Inn. From the grammar-school of Norwich he passed to Trinity College, Cambridge; and after a course of three years, in 1572 he entered the Inn to which his father had belonged. To the study of law he devoted himself from the first with the intensest application; he slept only six hours, and from three in the morning till nine at night he read or took notes of the cases tried in Westminster Hall with as little interruption as possible. In 1578 he was called to the bar, and in the next year he was chosen reader at Lyon's Inn. His extensive and exact legal erudition, and the skill with which he argued the intricate cases of Lord Cromwell and Edward Shelley, soon brought him a practice never before equalled, and caused him to be universally recognized as the greatest lawyer of his day. In 1586 he was made recorder of Norwich, and in 1592 recorder of London, solicitor-general, and reader in the Inner Temple. In 1593 he was returned as member of parliament for his native county, and also chosen speaker of the House of Commons. In 1594 he was promoted to the office of attorney-general, despite the claims of Bacon, who was warmly supported by the earl of Essex. As crown lawyer his treatment of the accused was marked by more than the harshness and violence common in his time; and the fame of the victim has caused his behaviour in the trial of Raleigh to be lastingly remembered against him. While the prisoner defended himself with the calmest dignity and self-possession, Coke burst into the bitterest invective, brutally addressing the great courtier as if he had been a servant, in the phrase, long remembered for its insolence and its utter injustice,—"Thou hast an English face, but a Spanish heart!"

In 1582 Coke married the daughter of John Paston, a Suffolkshire gentleman, receiving with her a fortune of £30,000; but in six months he was left a widower. Shortly after he sought the hand of Lady Elizabeth Hatton, daughter of Thomas, second Lord Burghley, and granddaughter of the great Cecil. Bacon was again his rival, and again unsuccessfully; the wealthy young widow became—not, it is said, to his future comfort—Coke's second wife.

In 1606 Coke was made chief-justice of the Common Pleas, but in 1613 he was removed to the office of chief-justice of the King's Bench, which gave him less opportunity of interfering with the court. The change, though it brought promotion in dignity, caused a diminution of income as well as of power; but Coke received some compensation in being appointed a member of the Privy Council. The independence of his conduct as a judge, though not unmixed with the baser elements of prejudice and vulgar love of authority, has partly earned forgiveness for the harshness which was so prominent in his sturdy character. Full of an extreme reverence for the common law which he knew so well, he defended it alike against the Court of Chancery, the ecclesiastical courts, and the royal prerogative. In a narrow spirit, and strongly influenced, no doubt, by his enmity to the chancellor, Egerton, he sought to prevent the interference of the Court of Chancery with even the unjust decisions of the other courts. In the case of an appeal from a sentence given in the King's Bench, he advised the victorious, but guilty, party to bring an action of præmunire against all those who had been concerned in the appeal, and his authority was stretched to the utmost to obtain the verdict he desired. On the other hand, Coke has the credit of having repeatedly braved the anger of the king. He freely gave his opinion that the royal proclamation cannot make that an offence which was not an offence before. An equally famous but less satisfactory instance occurred during the trial of Peacham, a divine in whose study a sermon had been found containing libellous accusations against the king and the Government. There was nothing to give colour to the charge of high treason with which he was charged, and the sermon had never been preached or published; yet Peacham was put to the torture, and Bacon was ordered to confer with the judges individually concerning the matter. Coke declared such conference to be illegal, and refused to give an opinion, except in writing, and even then he seems to have said nothing decided. But the most remarkable case of all occurred in the next year (1616). A trial was held before Coke in which one of the counsel denied the validity of a grant made by the king to the bishop of Lichfield of a benefice to be held *in commendam*. James, through Bacon, who was then attorney-general, commanded the chief-justice to delay judgment till he himself should discuss the question with the judges. At Coke's request Bacon sent a letter containing the same command to each of the judges, and Coke then obtained their signatures to a paper declaring that the attorney-general's instructions were illegal, and that they were bound to proceed with the case. His Majesty expressed his displeasure, and summoned them before him in the council-chamber, where he insisted on his supreme prerogative, which, he said, ought not to be discussed in ordinary argument. Upon this all the judges fell on their knees, seeking pardon for the form of their letter; but Coke ventured to declare his continued belief in the loyalty of its substance, and when asked if he would in the future delay a case at the king's order, the only reply he would vouchsafe was that he would do what became him as a judge. Soon after he was dismissed from all his offices on the following charges,—the concealment, as attorney-general, of a bond belonging to the king, a charge which could not be proved, illegal interference with the Court of Chancery, and disrespect to the king in the case of commendams. He was also ordered by the council to revise his book of reports, which was said to contain many extravagant opinions (June 1616).

Coke did not suffer these losses with patience. He offered his daughter Frances, then little more than a child, in marriage to Sir John Villiers, brother of the favourite Buckingham. Her mother, supported at first by her husband's great rival and her own former suitor, Bacon, objected to the match, and placed her in concealment. But Coke discovered her hiding-place; and she was forced to wed the man whom she declared that of all others she abhorred. The result was the desertion of the husband and the fall of the wife. It is said, however, that after his daughter's public penance in the Savoy Church, Coke had heart enough to receive her back to the home which he had forced her to leave. Almost all that he gained by his heartless diplomacy was a seat in the council and in the Star-Chamber.

In 1620 a new and more honourable career opened for him. He was elected member of parliament for Liskeard; and henceforth he was one of the most prominent of the constitutional party. It was he who proposed a remonstrance against the growth of Popery and the marriage of Prince Charles to the infanta of Spain, and who led the Commons in the decisive step of entering on the journal of the House the famous petition of the 18th December 1621, insisting on the freedom of parliamentary discussion, and the liberty of speech of every individual member. In consequence, together with Pym and Sir Robert Philips, he was thrown into confinement; and, when in the August of the next year he was released, he was commanded to remain in his house at Stoke-Poges during his Majesty's pleasure. Of the first and second parliaments of Charles I. Coke was again a member. From the second he was excluded by being appointed sheriff of Buckinghamshire. In 1628 he was at once returned for both Buckinghamshire and Suffolk, and he took his seat for the former county. After rendering other valuable support to the popular cause, he took a most important part in drawing up the great Petition of Right. The last act of his public career was to bewail with tears the ruin which he declared the duke of Buckingham was bringing upon the country. At the close of the session he retired into private life; and the six years that remained to him were spent in revising and improving the works upon which, at least as much as upon his public career, his fame now rests. He died on the 3d September 1633.

Coke published *Institutes*, of which the first is also known as "Coke upon Littleton," *Reports*, *A Treatise of Bail and Mainprize*, *The Complete Copyholder*, *A Reading on Fines and Recoveries*.

COLBERG, or KOLBERG, a fortified seaport town of Prussia, in the former province of Pomerania, and the government of Köslin, on the right bank of the Persante, which falls into the Baltic about a mile below the town. It has a handsome market-place, adorned since 1864 with a statue of Frederick William IV.; and there are several pretty extensive suburbs, of which the most important is the Munde, in great measure the growth of the present century. The principal buildings are the cathedral of St Mary's, one of the most remarkable churches in Pomerania, dating from 1316, the council-house erected after the plans of Zwirner, the citadel, and the aqueduct by which the town is supplied with water. Colberg also possesses several hospitals, a workhouse, a house of correction, an orphan asylum, a gymnasium, a preparatory school of navigation, and an exchange. Its bathing establishments are largely frequented and attract a considerable number of summer visitors. Woollen cloth and spirits are manufactured; there is an extensive salt-mine in the neighbouring Zillenberg; the salmon and lamprey fisheries are important; and a fair amount of commercial activity is maintained. Population in 1872, 13,106.

Colberg was the seat of a bishop as early as the 10th century, though it not long after lost this distinction. Till 1277 it was the chief town of the Cassubian Wends, and after that date it ranked as the most important place in the episcopal principality of Kamin, with which it passed in 1648 to Brandenburg. In the Thirty Years' War it was captured by the Swedes, after a protracted siege in 1631; and in the Seven Years' War it was one of the centres of the conflict. In 1758 it withstood the attacks of General Palmbach and his army of 10,000 men, and in 1760 it held out against the Russian and Swedish forces, both by sea and land, till it was relieved by the advance of Werner; but in 1761 it was compelled by famine to yield to Romanzoff after a four months' investment and violent bombardment. In 1807 it was surrounded by 18,000 men under the command of Feulié, Loison, and Mortier; but the burgher Nettelbeck within and the free-fighter Schill without succeeded in defending it till the peace of Tilsit brought the war to a close.

COLBERT, JEAN BAPTISTE (1619–1683), one of the greatest among the great statesmen of France, was born on the 29th of August 1619, at Rheims, where his father and grandfather were merchants. He claimed to be the descendant of a noble Scottish family, but those who have investigated the matter have almost without exception decided against the pretension. His youth is said to have been spent in a Jesuit college, in the office of a Parisian banker, and in that of a Parisian notary, Chapelain, the father of the poet. But the first fact on which we can rely with confidence is that, when not yet twenty, he obtained a post in the war-office, by means of the influence that he possessed through the marriage of one of his uncles to the sister of Michel Le Tellier, the secretary of state for war. During some years he was employed in the inspection of troops and other work of the kind, but at length his ability, his extraordinary energy, and his untiring laboriousness induced Le Tellier to make him his private secretary. These qualities, combined, it must be confessed, with a not over-delicate readiness to seize every opportunity of advancement, soon brought Colbert both wealth and influence. In 1647 we find him receiving the confiscated goods of his uncle Pussort, in 1648 obtaining 40,000 crowns with his wife Marie Charron, in 1649 appointed councillor of state.

It was the period of the wars of the Fronde; and in 1651 the triumph of the Condé family drove Cardinal Mazarin from Paris. Colbert, now aged thirty-two, was engaged to keep him acquainted with what should happen in the capital during his absence. At first Colbert's position was far from satisfactory; for the close wary Italian treated him merely as an ordinary agent. On one occasion, for example, he offered him 1000 crowns. The gift was refused somewhat indignantly; and by giving proof of the immense value of his services, Colbert gained all that he desired. His demands were not small; for, with an ambition mingled, as his letters show, with strong family affection, he aimed at placing all his relatives in positions of affluence and dignity; and many a rich benefice and important public office was appropriated by him to that purpose. For these favours, conferred upon him by his patron with no stinted hand, his thanks were expressed in a most remarkable manner; he published a letter defending the cardinal from the charge of ingratitude which was often brought against him, by enumerating the benefits that he and his family had received from him (April 1655). Colbert obtained, besides, the higher object of his ambition; the confidence of Mazarin, so far as it was granted to any one, became his, and he was intrusted with matters of the gravest importance. In 1659 he was giving directions as to the suppression of the revolt of the gentry which threatened in Normandy, Anjou, and Poitou, with characteristic decision arresting those whom he suspected and arranging every detail of their trial, the immediate and arbitrary destruction of their castles and woods, and the execution of their chief, Bonnesson. In the same year we have evidence that he was already planning his great attempt at financial reform. His earliest tentative was the drawing up of a *mémoire* to Mazarin, showing that of the taxes paid by the people not one-half reached the king. The paper also contained an attack upon the superintendent, Fouquet, who, first recommended to Le Tellier by Colbert himself, had since developed into the most shameless of extortioners; and being opened by the postmaster of Paris, who happened to be a spy of Fouquet's, it gave rise to a bitter quarrel, which, however, Mazarin repressed during his lifetime.

In 1661 the death of Mazarin allowed Colbert to take the first place in the administration. It was some time before he assumed official dignities; but in January 1664 he obtained the post of superintendent of buildings; in 1665 he was made controller-general; in 1669 he became minister of the marine; and he was also appointed minister of commerce, the colonies, and the king's palace. In short, he soon acquired power in every department except that of war.

A great financial and fiscal reform at once claimed all his energies. This he saw was the first step toward raising France to the lofty position he intended her to occupy. The country was in economic chaos. Those who had the fiscal administration in their hands, from the superintendent to the meanest of the tax-farmers, robbed and misappropriated almost as they pleased. The Government loans were arranged, not so as to be most advantageous to the state, but so as most to aggrandize the individuals who were interested in them. Not only the nobility, but many others who had no legal claim to exemption, paid no taxes; the weight of the burden fell on the wretched country-folk. Colbert sternly and fearlessly set about his task. Supported by the young king, Louis XIV., he aimed the first blow at the greatest of the extortioners—the bold and powerful superintendent, Fouquet. He was accused of high treason, not without sufficient grounds, for it was known that he had prepared to meet an arrest formerly contemplated by an appeal to force. The most minutely careful precautions were taken by Colbert for his seizure, and he was tried before a specially prepared chamber of justice. Nevertheless the trial was protracted during three years, and the sentence passed was not death but banishment. The Government, however, carried out its plans. The superintendent was safely disposed of in the state prison of Pignerol; just disgrace fell upon Councillor d'Ormesson and the other judges who had averted the punishment Fouquet richly deserved; and many minor officials, convicted of peculation, were treated with great severity, some being banished, some sent to the galleys, some even hanged.

The office of superintendent and many others dependent upon it being abolished the supreme control of the finances was vested in a royal council The sovereign was its president; but Colbert, though for four years he only possessed the title of intendant, was its ruling spirit, great personal authority being conferred upon him by the king. The career on which Colbert now entered must not be judged without constant remembrance of the utter rottenness of the previous financial administration. His ruthlessness in this case, dangerous precedent as it was, was perhaps necessary; individual interests could not be respected. Guilty officials having been severely punished, the fraudulent creditors of the Government remained to be dealt with. Colbert's method was simple. Some of the public loans were totally repudiated, and from others a percentage was cut off, which varied, at first according to his own decision, and afterwards according to that of the council which he established to examine all claims against the state.

Much more serious difficulties met his attempts to introduce equality in the pressure of the taxes on the various classes. To diminish the number of the privileged was impossible, but false claims to exemption were firmly resisted, and the unjust direct taxation was lightened by an increase of the indirect taxes, from which the privileged could not escape. The mode of collection was at the same time immensely improved.

Order and economy being thus introduced into the working of the government, the country, according to Colbert's vast yet detailed plan, was to be enriched by commerce. Manufactures were fostered in every way he could devise. New industries were established, inventors protected, workmen invited from foreign countries, French workmen absolutely prohibited to emigrate. To maintain the character of French goods in foreign markets, as well as to afford a guarantee to the home consumer, the quality and measure of each article were fixed by law, breach of the regulations being punished by public exposure of the delinquent and destruction of the goods, and, on the third offence, by the pillory. But whatever advantage resulted from this rule was more than compensated by the disadvantages it entailed. The production of qualities which would have suited many purposes of consumption was prohibited, and the odious supervision which became necessary involved great waste of time and a stereotyped regularity which resisted all improvements. And other parts of Colbert's scheme deserve still less equivocal condemnation. By his firm maintenance of the corporation system, each industry remained in the hands of certain privileged bourgeois; in this way, too, improvement was greatly discouraged; while to the lower classes opportunities of advancement were closed. With regard to international commerce Colbert was equally unfortunate in not being in advance of his age; the tariffs he published were protective to an extreme. The interests of internal commerce were, however, wisely consulted. Unable to abolish the duties on the passage of goods from province to province, he did what he could to induce the provinces to equalize them. The roads and canals were improved. The great canal of Languedoc was planned and constructed by Riquet under his patronage. To encourage trade with the Levant, Senegal, Guinea, and other places, privileges were granted to companies; but, like the more important East India Company, all were unsuccessful. The chief cause of this failure, as well as of the failure of the colonies, on which he bestowed so much watchful care, was the narrowness and rigidity of the Government regulations.

The greatest and most lasting of Colbert's achievements was the establishment of the French marine. The royal navy owed all to him, for the king thought only of military exploits. For its use, Colbert reconstructed the works and arsenal of Toulon, founded the port and arsenal of Rochefort, and the naval schools of Rochefort, Dieppe, and Saint-Malo, and fortified, with some assistance from Vauban (who, however, belonged to the party of his rival Luvois), among other ports those of Calais, Dunkirk, Brest, and Havre. To supply it with recruits he invented his famous system of classes, by which each seaman, according to the class in which he was placed, gave six months' service every three or four or five years. For three months after his term of service he was to receive half-pay; pensions were promised; and, in short, everything was done to make the navy popular. There was one department, however, that was supplied with men on a very different principle. Letters exist written by Colbert to the judges requiring them to sentence to the oar as many criminals as possible, including all those who had been condemned to death; and the convict once chained to the bench, the expiration of his sentence was seldom allowed to bring him release. Mendicants also, against whom no crime had been proved, contraband dealers, those who had been engaged in insurrections, and others immeasurably superior to the criminal class, nay, innocent men—Turkish, Russian, and negro slaves, and poor Iroquois Indians, whom the Canadians were ordered to entrap—were pressed into that terrible service. By these means the benches of the galleys were filled, and Colbert took no thought of the long unrelieved agony borne by those who filled them.

Nor was the mercantile marine forgotten. Encouragement was given to the building of ships in France by allowing a premium on those built at home, and imposing a duty on those brought from abroad; and as French workmen were forbidden to emigrate, so French seamen were forbidden to serve foreigners on pain of death.

Even ecclesiastical affairs, though with these he had no official concern, did not altogether escape Colbert's attention. He took a subordinate part in the struggle between the king and Rome as to the royal rights over vacant bishoprics; and he seems to have sympathized with the proposal that was made to seize part of the wealth of the clergy. In his hatred of idleness, he ventured to suppress no less than seventeen fêtes, and he had a project for lessening the number of those devoted to clerical and monastic life, by fixing the age for taking the vows some years later than was then customary. With heresy he was at first unwilling to interfere, for he was aware of the commercial value of the Huguenots; but when the king, under the influence of Mme. de Maintenon, resolved to make all France Catholic, he followed his Majesty, and urged his subordinates to do all that they could to promote conversions.

In art and literature Colbert took much interest. He possessed a remarkably fine private library, which he delighted to fill with valuable manuscripts from every part of Europe where France had placed a consul. He has the honour of having founded the Academy of Sciences (now called the Institut de France), the Observatory, which he employed Perrault to build and brought Cassini from Italy to superintend, the Academies of Inscriptions and Medals, of Architecture, and of Music, the French Academy at

Rome, and Academies at Arles, Soissons, Nîmes, and many other towns, and he reorganized the Academy of Painting and Sculpture which Richelieu had established. He was a member of the French Academy; and one very characteristic rule, recorded to have been proposed by him with the intention of expediting the great Dictionary, in which he was much interested, was that no one should be accounted present at any meeting unless he arrived before the hour of commencement and remained till the hour for leaving. In 1673 he presided over the first exhibition of the works of living painters; and he enriched the Louvre with hundreds of pictures and statues. He gave many pensions to men of letters, among whom we find Molière, Corneille, Racine, Boileau, Huet, and Varillas, and even foreigners, as Huyghens, Vossius the geographer, Carlo Dati the Dellacruscan, and Heinsius the great Dutch scholar. There is evidence to show that by this munificence he hoped to draw out praises of his sovereign and himself; but this motive certainly is far from accounting for all the splendid, if in some cases specious, services that he rendered to literature, science, and art.

Indeed to everything that concerned the interests of France Colbert devoted unsparing thought and toil. Besides all that has been mentioned, he found time to do something for the better administration of justice (the codification of ordinances, the diminishing of the number of judges, the reduction of the expense and length of trials), for the establishment of a superior system of police, and even for the improvement of the breed of horses and the increase of cattle. As superintendent of public buildings he enriched Paris with boulevards, quays, and triumphal arches; he relaid the foundation-stone of the Louvre, and brought Bernin from Rome to be its architect; and he erected its splendid colonnade upon the plan of Claude Perrault, by whom Bernin had been replaced. He was not permitted, however, to complete the work, being compelled to yield to the king's preference for residences outside Paris, and to devote himself to Marly and Versailles.

Amid all these public labours his private fortune was never neglected. While he was reforming the finances of the nation, and organizing its navy, he always found time to direct the management of his smallest farm. He died a millionaire, and left fine estates all over France. For his eldest son, who was created Marquis de Seignelay, he obtained the reversion of the office of minister of marine; his second son became archbishop of Rouen; and a third son, the Marquis d'Ormoy, became superintendent of buildings.

In estimating the value of Colbert's ministry, two distinct questions must be considered—What its results would have been in the absence of counteracting influences, over which he had no control, and what they actually were. To the first it may be answered that France, peaceful, enriched by a wide-spread commerce, and freed from the weight of taxes, alike heavy and intrinsically mischievous, would probably have developed powers that would have enabled her to throw aside what was harmful in his policy, and possibly to attain liberty without the frenzied struggle of the Revolution. To the second question a very different reply must be given. What the great "ministre de la paix" built up was torn down, even as he built it, to erect the unholy fabric of his master's military glory. The war department was in the hands of Colbert's great rival, Luvois; and to every appeal for peace Louis was deaf. He was deaf also to all the appeals against the other forms of his boundless extravagance which Colbert, with all his deference towards his sovereign, bravely ventured to make.[1] Thus it came about that, only a few years after he had commenced to free the country from the weight of the loans and taxes which crushed her to the dust, Colbert was forced to heap upon her a new load of loans and taxes more heavy than the last. Henceforth his life was a hopeless struggle, and the financial and fiscal reform which, with the great exception of the establishment of the navy, was the most valuable service to France contemplated by him, came to nought.

Depressed by his failure, deeply wounded by the king's favour for Luvois, and worn out by overwork, Colbert's strength gave way at a comparatively early age. In 1680 he was the constant victim of severe fevers, from which he recovered for a time through the use of quinine prescribed by an English physician. But in 1683, at the age of sixty-four, he was seized with a fatal illness, and on the 6th of September he expired. It was said that he died of a broken heart, and a conversation with the king is reported in which Louis disparagingly compared the buildings of Versailles, which Colbert was superintending, with the works constructed by Luvois in Flanders. He took to bed, it is true, immediately afterwards, refusing to receive all messages from the king; but his constitution was utterly broken before, and a post-mortem examination proved that he had been suffering from stone. His body was interred in the secrecy of night, for fear of outrage from the Parisians, by whom his name was cordially detested.

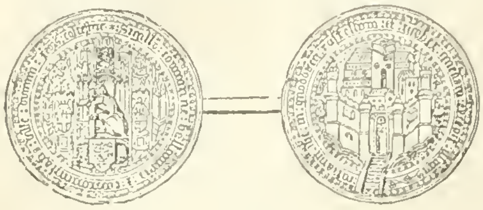
Colbert was a great statesman, who did much for France, and would have done vastly more had it been possible. Yet his insight into political science was not deeper than that of his age; nor did he possess that superiority in moral qualities which would have inspired him to bring in a reign of purity and righteousness. His rule was a very bad example of over-government. In popular liberty he did not believe; the parliaments and the States-General received no support from him. The technicalities of justice he never allowed to interfere with his plans; justice herself he sometimes commanded to stay her course, and beware of crushing any friend of his who happened to lie in her way. He trafficked in public offices for the profit of Mazarin and in his own behalf. He caused the suffering of thousands in the galleys; he had no ear, it is said, for the cry of the suppliant. There was indeed a more human side to his character, as is shown in his letters, full of wise advice and affectionate care, to his children, his brothers, his cousins even. Yet to all outside he was "the man of marble." To diplomacy he never pretended; persuasion and deceit were not the weapons he employed; all his work was carried out by the iron hand of authority. He was a great statesmen in that he conceived a magnificent yet practicable scheme for making France first among nations, and in that he possessed a matchless faculty for work, neither shrinking from the vastest undertakings nor scorning the most trivial details.

Numerous *vies* and *éloges* of Colbert have been published; but the most thorough student of his life and administration was Pierre Clément, member of the Institute, who in 1846 published his *Vie de Colbert*, and in 1861 the first of the 9 vols. of the *Lettres, instructions, et mémoires de Colbert*. The historical introductions prefixed to each of these volumes have been published by Mme. Clément under the title of the *Histoire de Colbert et de son administration* (1874). Among Colbert's papers are *Mémoires sur les affaires de finance de France* (written about 1663), a fragment entitled *Particularites secrètes de la vie du Roy*, and other accounts of the earlier part of the reign of Louis XIV. (T. M. W.)

COLCHESTER, a market-town, municipal and parliamentary borough, and river-port of England, in the county of Essex, 51 miles from London by the Great Eastern Railway, on the Colne, which is there crossed by three bridges. The town within the walls forms an oblong of

[1] See especially a *mémoire* presented to the king in 1666, published in the *Lettres, etc., de Colbert*, vol. ii.

about 108 acres; but new streets stretch far beyond these limits. Large alterations have taken place since the accession of Queen Victoria: the Middle Row and various other districts have been abolished or rebuilt; the streets have been repaved, and a new supply of water obtained for the town. Of the buildings in Colchester of interest for their antiquity the first is the castle or keep, which occupies an area of 21,168 square feet (or nearly twice that of the White Tower of London), and thus forms the largest specimen extant of this department of Norman architecture. It was founded in 12th century by Eudo, the steward of



Arms of Colchester.

Henry I., to whom the city was also indebted for the Benedictine abbey of St John's now almost totally demolished. Of the churches the oldest is St Peter's, which like several others has been restored within recent years; the remains of the church of St Botolph's priory, founded in the early part of the 12th century, present fine examples of Norman workmanship; and St James's, St Giles's, and St Leonard's at the Hythe are all of antiquarian interest. The last preserves some early frescoes. The present century has added largely to the number of the churches and chapels, and many of the newer buildings are not unworthy of the city in which they stand. Of secular structures the most important are the town hall, the county police station (formerly the county jail), the borough jail, the theatre, two corn exchanges, the Eastern Counties asylum for idiots and imbeciles, the Essex and Colchester hospital, the assembly rooms, and the public baths. The town also possesses a free grammar-school, with a scholarship at St John's College, Cambridge; a literary institute with a library attached, botanic gardens, a literary, a medical, and other societies. Colchester is the centre of a large agricultural district, and has very extensive corn and cattle markets. Baize was formerly the principal manufacture; but this has been superseded by silk, more especially the kind employed for umbrellas. The minor industrial establishments include flour-mills, vinegar-works, foundries, engineering works, rope-yards, printing offices, and lime-works. The import and export trade is conducted at the suburb of Hythe, to which vessels of 150 tons can come up the river. In 1874 the value of the imports was £48,377, and of the exports £9173. The oyster fishery, for which the town has been famous for centuries, is not so extensive as it once was; but it is still carried on under the control of the Colchester town council, and measures are taken for its maintenance and development. The borough, which returns two members to parliament, has an area of 11,314 acres; the population was in 1871 26,343, an increase since 1861 of 2534, and since 1801 of 14,823. Colchester is the head-quarters of the Eastern Military District.

That Colchester occupied the site of some important Roman city was all along abundantly evident; but it is only within the present century that it has been definitively identified with Camulodunum. This Roman settlement was established by Claudius, to assist in the reduction of the fierce Silurians; but its existence was jeopardized by the sudden rise of the Iceni to avenge the wrongs of Boadicea. The colonists were massacred, their houses burned, and the site left a mass of ruins. The Roman general, Suetonius Paullinus, however, soon after recovered possession of the place; strong fortifications were erected, and the colony soon attained a high degree of prosperity. To the present day the walls then erected remain almost intact, and form one of the noblest specimens of Roman architecture in the island. Minor antiquities—such as Samian pottery, coins, articles of ornament—occur in the greatest profusion; and, both within the city and in the neighbourhood, numerous villas have been discovered, with tesselated pavements, hypocausts, and baths. The coins belong to all periods, down to the secession of the Romans from the island. On the arrival of the Saxons the old name of Camulodunum gave place to that of Colneceastor, or the Castrum on the Colne, which is still preserved in the present modification. In 921 the town was recovered from the Danes by Edward the Elder, and its fortifications were strengthened. At the time of the *Domesday Book* it was a place of decided importance, and in the reign of Edward III. it sent five ships and 140 seamen to the siege of Calais. In 1348 and 1360 it was ravaged by the plague, which again visited it in the dreadful year of 1665. Meanwhile it was the scene of a memorable siege; having in 1648 declared for the Royalists, it was captured by Fairfax, after an investment of eleven weeks, its gallant defenders, Sir C. Lucas and Sir C. Lisle, were put to death, and the castle was dismantled. See Morant's *Essex;* Rev. Henry Jenkins's "Observations on the Site of Camulodunum" in vol. xxix. of the *Archæologia*, 1842, and the same author's *Colchester Castle built as a Temple of Claudius Cæsar*, 1852; Rev. Edward A. Cutts's *Colchester Castle not a Roman Temple*, 1853.

COLCHESTER, Charles Abbot, Lord (1757–1829), born at Abingdon, was the son of Dr John Abbot, rector of All Saints, Colchester, and, by his mother's second marriage, half-brother of the famous Jeremy Bentham. From Westminster School, Charles Abbot passed to Christ Church College, Oxford, where he gained the chancellor's medal for Latin verse and the Vinerian Scholarship. In 1795, after having practised twelve years as a barrister, and published a treatise proposing the incorporation of the judicial system of Wales with that of England, he was appointed to the office previously held by his brother of clerk of the rules in the King's Bench; and in June of the same year he was elected member of parliament for Helston, through the influence of the duke of Leeds. In 1796 Abbot commenced his career as a reformer in parliament, by obtaining the appointment of two committees,—the one to report on the arrangements which then existed as to temporary laws or laws about to expire, the other to devise methods for the better publication of new statutes. To the latter committee, and a second committee which he proposed some years later, it is owing that copies of new statutes were thenceforth sent to all magistrates and municipal bodies. To Abbot's efforts were also due the establishment of the Royal Record Commission, the reform of the system which allowed the public money to lie for some time at long interest in the hands of the public accountants, and, most important of all, the Act for taking the first census, that of 1801. On the formation of the Addington ministry in March 1801, Abbot became chief secretary and privy seal for Ireland; and in the February of the following year he was chosen speaker of the House of Commons—a position which he held with universal satisfaction till 1817, when an attack of erysipelas compelled him to retire. In response to an address to the Commons, he was raised to the peerage as Baron Colchester, with a pension of £4000, of which £3000 was to be continued to his heir. On the 8th May 1829, he died of erysipelas. His speeches against the Roman Catholic claims were published in 1828.

COLCHICUM, the Meadow Saffron, or Autumn Crocus (*Colchicum autumnale*), is a perennial plant of the natural order *Melanthaceæ* or *Colchicaceæ*, found wild in rich moist meadow-land in England and Ireland, in Middle and Southern Europe, and in the Swiss Alps. It has pale-purple flowers, rarely more than three in number; the perianth is funnel-shaped, and produced inferiorly into a long slender tube, in the upper part of which the six stamens are inserted. The ovary is three-celled, and lies at the bottom of this tube. The leaves are three or four in number, flat, lanceolate, erect, and sheathing; and there is no stem. Propagation is by the formation of corms from the parent bulb, and by seeds. The latter are numerous, round, reddish-brown, and of the size of black mustard-seeds. The bulb of the meadow-saffron attains its full size in June or early in July. A smaller bulb is then formed from the old one, close to its root; and this in September and October produces the crocus-like flowers. In the succeeding January or February it sends up its leaves, together with the ovary, which perfects its seeds during the summer. The young corm, at first about the diameter of the flower-stalk, grows continuously, till in the following July it attains the size of a small apricot. The parent bulb remains attached to the new one, and keeps its form and size till April in the third year of its existence, after which it decays. In some cases a single corm produces several new plants during its second spring by giving rise to immature corms.

Colchicum owes its medicinal properties to an alkaloid, named *colchicine*, which is present in all parts of the plant. It was discovered by Pelletier and Caventon, and was identified as distinct from veratrine by Geiger and Hesse in 1833. According to Oberlin, colchicine is a complex body, containing a crystallizable neutral substance, colchiceine. Hübler assigns to colchicine the formula $C_{17}H_{19}NO_5$, and considers it to be isomeric with colchiceine (*Arch. der Pharm.*, tom. cxi. 194; *Journ. de Pharm. et de Chim.*, tom. ii. 490, 4th ser). It is an intensely bitter body, soluble in alcohol and water, but insoluble in ether, and is a powerful poison, small quantities causing violent vomiting and purging; tannin, which precipitates it from solution, has been recommended as an antidote for it. Colchicine is present in smaller quantity in the seeds than in the bulbs; and in the latter, according to Stolze, it is more abundant in spring than in autumn; Shroff, however, states that the corms for medicinal use should be collected after or during the time of flowering. The preparations of colchicum employed as medicine are the extract, made by macerating dried shreds of the bulbs in sherry or acetic acid, the expressed juice of the bulbs, purified and concentrated by heating, straining, and evaporation at a temperature below 160° Fahr., and an alcoholic tincture of the seeds. Whether swallowed or injected into the veins colchicum acts as an irritant of the stomach and intestines and a nervine sedative; small doses stimulate the secreting and excreting functions, but when continued they impair the appetite, and much disturb the stomach. Large quantities produce vomiting, profuse perspiration, heat in the abdomen, considerable reduction of the rate of the pulse, and dysenteric symptoms, and may cause death from exhaustion.

Colchicum was known to the Greeks under the name of Κολχικόν, from Κολχίς, or Colchis, a country in which the plant grew; and it is described by Dioscorides as a poison. In the 17th century the corms were worn by some of the German peasantry as a charm against the plague. The drug was little used till 1763, when Baron Störck of Vienna introduced it for the treatment of dropsy. In febrile diseases it was first extensively employed by Mr Haden. As a specific for gout colchicum was early employed by the Arabs; and the preparation known as *eau médicinale*, much resorted to in the last century for the cure of gout, owes its therapeutic virtues to colchicum; but general attention was first directed by Sir Everard Home to the use of the drug in gout. Full doses are apt to provoke sickness and diarrhœa, but give immediate relief from the sufferings caused by arthritic disease; whereas small quantities are not effectual for several days. According to Dr A. B. Garrod, the beneficial effects of colchicum are not explicable either by its purgative properties, or by its sedative influence on the vascular system; nor is there evidence that it produces any of its effects by causing an increase in the elimination of urea and uric acid by the kidneys. Dr Graves considers that colchicum operates in gout by lessening the formation of uric acid in the system.

Colchicum may often be employed in acute rheumatism, in the treatment of bronchitis, asthma, eruptions of the skin, and of dyspepsia in gouty patients; also as a cholagogue instead of mercurials. The "hermodactyl" of ancient writers is supposed to be the same as the modern drug of that name, which consists of the corms of a species of colchicum.

(1876); *English Botany*, ed. J. T. Boswell Syme, 3d ed., vol. ix. p. 225 (1869); Balfour, *Class Book of Botany*, 3d ed., p. 931 (1871). On Colchicine, see Watts's *Chemical Dictionary*, vol. i.; Wurtz, *Dictionnaire de Chimie*, t. ii.

COLCHIS, in ancient geography, a nearly triangular district of Asia Minor, at the eastern extremity of the Black Sea, was bounded on the N. by the Caucasus, which separated it from Asiatic Sarmatia, E. by Iberia and the Montes Moschici, S. by Armenia and part of Pontus, and W. by the Euxine. The ancient district is represented by the modern province of Mingrelia, and part of Abasia. The name of Colchis is first found applied to this country by the Greek poets Æschylus and Pindar. It was celebrated in Greek mythology as the destination of the Argonauts, the residence of Medea, and the special domain of sorcery. At a remote period it seems to have been incorporated with the Persian empire, though the inhabitants ultimately erected their territory into an independent state; and in this condition it was found by Alexander the Great, when he invaded Persia. From this time till the era of the Mithridatic wars nothing is known of the history of Colchis. At the time of the Roman invasion it seems to have paid a nominal homage to Mithridates, and to have been ruled over by Machares, the second son of that monarch. On the defeat of Mithridates by Pompey, it became a Roman province. After the death of Pompey, Pharnaces, the son of Mithridates, rose in rebellion against the Roman yoke, subdued Colchis and Armenia, and made head, though but for a short time, against the Roman arms. After this Colchis was incorporated with Pontus, and the Colchians are not again alluded to in ancient history till the 6th century, when, along with the Abasci, they joined Chosroes I., king of Persia, in his war against Justinian. Colchis was inhabited by a number of tribes whose settlements lay chiefly along the shore of the Black Sea. The chief of these were the Lazi, Moschi, Apsidæ, Abasci, Sagadæ, Suani, and Coraxi. These tribes differed so completely in language and appearance from the surrounding nations, that the ancients themselves originated various theories to account for the phenomenon. Herodotus, for example, believed them to have sprung from the relics of the army of Sesostris, and thus identified them with the Egyptians. Though this theory was not generally adopted by the ancients, it has been defended, but not with complete success, by some modern writers. From the first-named of these tribes, the Lazi, the country was latterly known as Terra Lazica.

COLDSTREAM, a town of Scotland, in Berwickshire, 15 miles west of Berwick, on the north bank of the Tweed, there crossed by a bridge of five arches. It is situated on the principal thoroughfare between England and Scotland, and in the neighbourhood of the ford by which the Scotch and English armies were wont to cross the river in olden times. In the period before the Reformation it was the seat of a priory famous in history as the place where the Papal legate, in the reign of Henry VIII., published a bull against the printing of the Scriptures; and in the present century, by a curious irony of fate, the very site of the building was occupied by an establishment under Dr Adam Thomson for the production of Bibles at a low rate. Coldstream, like Gretna Green, was formerly celebrated for its irregular marriages. The regiment of Foot Guards known as the "Coldstream Guards" was so named from General Monk having set out with it from the town on his march into England in 1659. Population in 1871, 2619.

COLEBROOKE, Henry Thomas (1765–1837), an eminent Oriental scholar, the third son of Sir George, the second baronet of that name, was born in London. He was educated at home; and when only fifteen he had made considerable attainments in classical and mathematical studies. From the age of twelve to sixteen he resided in France, and in 1782 was appointed to a writership in India. About a year after his arrival there he was placed in the Board of Accounts in Calcutta; and three years later he was removed to a situation in the revenue department at Tirhoot, where he pursued his studies in Eastern science and literature. In 1789 he was removed to Purneah, where he investigated the resources of that part of the country, and published his *Remarks on the Husbandry and Commerce of Bengal*, in which he advocated free trade between Great Britain and India. After eleven years' residence in India, Colebrooke began the study of Sanskrit; and to him was confided the translation of the great digest of Hindu law, which had been left unfinished by Sir William Jones. After filling a number of important offices, and publishing some works on Oriental literature, including a Sanskrit grammar and dictionary, he returned to London, where he died, March 18, 1837. He was a director of the Asiatic Society, and many of the most valuable papers in the Society's *Transactions* were communicated by him.

COLEOPTERA, or Beetles, a vast and remarkably homogeneous order of Insects, characterized, as the name implies (κολεός, a sheath, and πτερά, wings), by the structure of the upper wings, or *elytra*, as they are called, which are so modified as to form shields for the protection of the under wings—the true organs of flight in those insects. The name was given, and the principal characters of the order defined, by Aristotle; and owing doubtless to their singular and varied forms and habits, the brilliant colouring and great size of numerous species, and that solid consistence which renders their collection and preservation comparatively easy, Coleopterous insects have since the days of the Stagirite received the special attention of entomologists.

The body in Coleoptera is enclosed in a chitinous integument of a more or less rigid consistence, and is somewhat oval in form, although in most cases greatly longer than broad. In this respect, however, the utmost diversity prevails even among the members of the same family, the form being modified to suit the habits of the insect. Thus, according to Bates, among the South American forms of *Dermestidæ*, the species of one group are cubical in shape, and live in dung; those of another, inhabiting the stems of palm trees, are much flatter; those of a third, only found under the bark of trees, are excessively depressed, some species being literally "as thin as a wafer;" while the members of a fourth group of the same family are cylindrical in shape, and are woodborers, "looking," says Bates, "like animated gimlets, their pointed heads being fixed in the wood, while their glossy bodies work rapidly round so as to create little streams of saw-dust from the holes" (*Naturalist on the Amazons*). The body, in common with that of all other insects, is divided into three parts,—head, thorax, and abdomen. The head, which is usually rounded or somewhat triangular in shape (except in the Weevil tribe, where it is produced into an elongated rostrum or snout), bears the organs of the senses. The eyes of beetles are two in number and compound, and in predaceous species are somewhat protuberant, thus affording greater range of vision. The simple eyes, or *ocelli*, common among butterflies and moths, are almost unknown among beetles, although present in the larvæ. In many species, especially of Lamellicorn Beetles, these organs are more or less completely divided by a process known as the *canthus;* and in the *Gyrinidæ*, or Whirligigs, the intersection is so complete as to give the appearance of a pair of eyes on each side. In burrowing and cave-dwelling species, whose lives are spent in almost total darkness, the eyes, although distinctly visible in the young, become more or less atrophied in the adult forms. The two antennæ, supposed by some to be organs of hearing, and by others of smell, are placed between or in front of the eyes, and usually consist of 11 joints. These differ greatly in form and size, not only in different species, but in the two sexes of the same species, the most prevalent forms being the setaceous, moniliform, serrate, pectinate, clavate, and lamellate. In many groups the antennæ are exceedingly short, while in such forms as the Longicorn Beetles they, in a few cases, measure four times the length of the body.

The parts which go to form the mouth are typically developed in beetles, and for this among other reasons the order Coleoptera has generally been placed at the head of the class of insects. It is known as the masticatory mouth, and consists of the four parts (Plate VI. fig. 1). (1) The *labrum*, or upper lip, is usually a continuation of the upper surface of the head. (2) The *mandibles*, or true masticatory organs, consist of two powerful arched jaws generally dentated, moving horizontally and opposed to each other, the teeth in some cases interlocking, in others, as in the Tiger Beetles, crossing like the blades in a pair of scissors. In many species they are so small as to be almost concealed within the cavity of the mouth, while in such forms as the Stag Beetles they measure half the length of the entire body. The form and texture of the mandibles are largely dependent on the nature of the insect's food, being acute and sharply dentated in predaceous species, and thick and blunt in vegetable feeders. Their margins are soft and flexible in those which feed on decaying animal and vegetable matters, while the entire mandibles are soft and flattened in those which live on fluids. (3) The *maxillæ*, or lesser jaws, placed beneath the mandibles, and like them moving horizontally, serve to hold the food and guide it to the mouth. Their extremities are in many cases furnished with a movable claw, and their inner surfaces with a series of bristles, which are probably of use in straining the juices from their food. The maxillæ are provided with a pair of appendages called maxillary palps—delicate organs that vibrate intensely, and are supposed to be principal organs of touch. (4) The *labium*, or lower lip, also provided with palps.

The thorax bears the organs of locomotion, consisting of three pairs of legs and two pairs of wings (Plate VI. fig. 2). The legs vary in their structure and development according to the habits of the species; thus in running and walking beetles these organs are usually of equal length, and generally similar in other respects, the anterior pair, however, being often stronger in the male than in the female; and in a few species, as the Harlequin Beetle, the anterior legs are enormously elongated and proportionately thickened. In burrowing beetles the anterior legs are developed into fossorial organs with broad and strongly dentated tarsi, and in arboreal forms the under side of the tarsi is usually covered with hair, forming a cushion-like sole terminating in toothed claws, by which they are enabled to keep their footing on the leaves and branches of trees. Water beetles generally have the posterior pair of legs elongated, flattened, and ciliated, so as to form swimming organs; those known as Whirligigs using the middle and posterior pairs for this purpose, while the anterior limbs are employed as rudders; and jumping beetles, as *Halticidæ*, have the thighs of the posterior pair of legs greatly thickened for saltatory purposes (Plate VIII. fig. 10). The two anterior wings become solidified in beetles, and are thus rendered useless as organs of flight. They are termed *elytra* (ἔλυτρον, a shield), and serve to protect the delicate wings beneath, as well as the *stigmata*, or breathing pores, placed along the sides of the abdomen. The elytra are always present except in the females of a few species, as the Glow-worm, and are generally large enough to cover the upper surface of the abdomen and to conceal the under wings when at rest. In Brachelytrous Beetles, however, they are exceedingly short, and the wings in these are only shielded by being folded more than once beneath them. The elytra when at rest meet on the middle of the back, their internal margins forming a straight longitudinal line or suture highly characteristic of the Coleoptera; but even this character is not universal, as in the Oil Beetles (*Meloë*) and a few others the one elytron partly folds over the other. The posterior wings are large, veined, and membranaceous and form the true organs of flight, but they are much more frequently absent than the elytra, and where this occurs, as in many Carabideous Beetles, the latter are more or less soldered together. During flight the elytra are either extended horizontally or merely raised without being separated, as in the Rose-Chafers (*Cetonia*); and as might be expected from their general stoutness of body and comparative deficiency of wings, the flight of beetles is heavy and seldom long sustained. Their weakness in this respect is further shown in the apparent inability of many species suddenly to alter their course so as to avoid collision with any object that may unexpectedly come in their way, a defect popularly but erroneously attributed, in the phrase "as blind as a beetle," to weakness of sight rather than of wing. In certain water beetles (*Dytiscidæ*) a pair of *alulæ*, or winglets, are developed at the inner angle of the elytra.

The colouring of the chitinous integument of beetles is often exceedingly brilliant, and the elytra and other parts of many species are largely used in the manufacture of personal ornaments. This colouring can in many instances be shown to bear a close resemblance to that of surrounding nature; thus burrowing beetles, and those which dwell in subterranean caves, are generally black or brown; Weevils, found on the ground, are earth-coloured; while arboreal species of this and other groups are of various shades of green. Bates found a species of beetle, on a particular tree in South America, which so resembled the bark on which it spent its existence as to be, when motionless, no longer visible. This assimilation in colour to surrounding nature is probably useful in assisting them to elude their enemies; and when the markings are such as to render the beetle conspicuous it is often provided with, and no doubt protected by, an offensive odour or nauseous juices; thus the naturalist already mentioned found on a sandy beach two species of Tiger Beetles, the one of a pallid hue like the sand it ran upon, the other of a brilliant and conspicuous copper colour, but having "a strong, offensive, putrid, and musky odour," from which the other was entirely free. Fireflies, a group of Coleopterous insects, are also exceedingly conspicuous, but are similarly protected. The phenomena of mimicry, or the imitation of one animal by another for protective purposes, have been observed in several instances among beetles. Mr Belt, in his interesting work, *The Naturalist in Nicaragua*, states that he captured what he supposed was a hairy caterpillar, but on closer inspection he found it to be a Longicorn Beetle, the antennæ being concealed among the hair. Hairy caterpillars are almost universally rejected by insect-eating animals, and thus probably this beetle shared in the immunity from attack accorded to its model. A species of beetle found in South America closely resembles a bee found in the same locality, its body being covered with hair and its legs similarly tufted; another, with yellow banded abdomen, sufficiently resembled a wasp as to make its captor both cautious and timid in handling it at first. One of the *Chrysomelidæ* (*Crioceris merdigera*) is said to disguise itself by covering its upper surface with its own dung; while many species to be afterwards noticed, when in danger, simulate death. Brilliant colouring in beetles is not as in some orders of animals a characteristic mainly of the male sex, both sexes being usually similar in this respect, while in those cases in which they differ, the female is generally the more gaudy insect. The chief external difference, however, between the sexes in many beetles is to be found in the presence of horns on the head and thorax of the males. These vary exceedingly in their development even in individuals of the same species, while in their form they resemble the horns of the rhinoceros, and the antlers of the stag; and as among mammals the reindeer is exceptional in the possession of antlers by both sexes, so among beetles there is at least one species, *Phanæus lancifer*, in which both male and female are similarly equipped. The male beetle has not been observed to use its horns either for purposes of offence or defence, some of the most pugnacious species being entirely destitute of them; and in Darwin's opinion these appendages have been acquired merely as ornaments.

The abdomen of Coleopterous insects is sessile, that is, attached to the thorax by its largest transverse diameter. On the under side it is always of a firm horny consistence, while the upper surface is generally soft, being protected by the elytra and wings; when these, however, are absent or abbreviated, it is as hard above as below. It bears the organs of generation as well as the respiratory openings, or *stigmata*, which form the apertures of the tracheæ by means of which air is disseminated through all parts of the insect system. Beetles belonging to several distinct families possess stridulating organs, and these are generally found in both sexes. The apparatus by which the sound, loud enough to be heard in many cases at some yards distance, is produced, consists of a couple of delicate rasps placed on the upper surface of the abdomen, on the elytra, or on the prothorax, and a scraper formed by the margins of the elytra, the edges of the abdominal segments, or the mesothorax, the rapid motion of the latter over the rasps producing the sound. In many cases, according to Darwin, the males only stridulate, the females being destitute of those organs, and in such cases the sound is employed as a call to the female; with most beetles, however, the stridulation proceeds from both sexes and serves as a mutual call. Beetles are entirely destitute of stinging organs, but a few are furnished with a retractile tube, or *ovipositor*, at the extremity of the abdomen, by means of which they deposit their eggs in the cracks of wood and other suitable localities.

The eggs of beetles are deposited in a great variety of situations, and in the case of a certain group of *Staphylinidæ* found in the nests of white ants in South America, it was recently discovered by Schödte that the eggs are not deposited at all, but remain in the abdomen until they are hatched. These ovo-viviparous beetles are only one-tenth of an inch in length, and have the abdominal region enormously distended and turned over so as to rest on the back. Dung beetles deposit their eggs in the midst of the manure on which the future larvæ feed; the Sacred Beetle of Egypt rolling each of hers about until a globular pellet is formed, when the whole is buried in the ground; while the Sexton Beetle finds an appropriate *nidus* for her eggs in the dead bodies of animals. One species of *Cleridæ* selects the nest of the solitary bee, another (Plate VII. fig. 31) that of the hive bee, while several species of Rose Beetles choose the nest of the ant for this purpose. The water beetles belonging to the genus *Hydrophilus* deposit their eggs in a single mass, which they surround with a cocoon, formed of a silky substance secreted by certain glands in the abdomen, and then either fix this to the leaf of an aquatic plant or leave it to float on the surface of the water. Certain species of the Weevil tribe deposit their eggs on the leaves of trees, splitting the median nervures in several places, and afterwards rolling them up. In its progress from the egg to the perfect insect the beetle undergoes complete metamorphosis, passing from the larval to the pupa stage, and remaining totally quiescent during the latter. Coleopterous larvæ generally consist of 13 segments, of which those forming the head and thorax are usually of a hard horny texture,—the mouth, as in the perfect insect, being masticatory, and the eyes, when present, simple, or *ocelli*. They have usually six legs, and prolegs, as in caterpillars, are occasionally present; but the larvæ of many species are legless grubs, while in others the limbs are but feebly developed. In those groups in which the elytra are abbreviated, the larvæ are exceedingly active and closely resemble the perfect insect. Like their parents the larvæ of beetles feed on living animals, on plants, or on decaying animal and vegetable substances, but greatly exceed the perfect insect in the quantity of food which they consume, and it is in this condition that beetles do most injury to field crops and forest trees. The larvæ of burrowing beetles, known as "White Worms," spend their existence in the earth, and are destitute of eyes; those of the Stag Beetles and other wood-boring groups live in the trunks of decaying trees; mealworms—the larvæ of *Tenebrio molitor*—live enveloped in flour, and those of the Corn Weevil in the heart of the wheat grain; while those of another species of Weevil make their homes in the fleshy parts of the receptacles of composite flowers. The larvæ of Oil Beetles (*Meloë*), or at least certain species of them whose life-history has been observed, after leaving the egg, which the perfect insect has deposited just beneath the surface of the ground, climb upon the stems of plants, and take the first opportunity of attaching themselves to any insect that may happen to alight near them, and in this way they are occasionally conveyed into the hives of bees, in which alone they meet with their appropriate food. Only a few of them are thus fortunate, the majority of the larvæ getting attached to the wrong insect, and so perishing of hunger. The species probably owes its preservation to the great number of eggs, amounting to upwards of 4000, deposited by a single female. The larvæ of one group of water beetles, *Hydrophilus*, swim readily by means of their ciliated legs, those of another group, *Dytiscus*, make use also of their flexible abdomen provided at its extremity with a pair of leaf-like appendages (Plate VII. fig. 6); while the Whirligig larvæ (*Gyrinus*), in addition to ciliated swimming organs, are provided with four movable hooks on the posterior segment, by which they are enabled to take extensive leaps (Plate VII. fig. 17). The duration of the larval state varies in different groups of beetles, being comparatively short in leaf-eating species, but lasting for three or four years in those which burrow in the earth or in wood. The larvæ in the latter case pass the winter in a torpid state, abstaining almost entirely from food, until awakened from their temporary trance by the return of genial weather, when they greedily attack their favourite food, and grow rapidly. In passing from the condition of a larva, the beetle does not, like the butterfly, assume a form altogether different from that of the perfect insect, but in the pupa or nymph state shows all the parts of the future insect, only in a condition of almost complete immobility. In preparing for this quiescent period, the larvæ of many species surround themselves with a cocoon, consisting, in the case of the *Scarabæidæ*, of earth and small pieces of wood glued together with saliva, and in that of the Goliath Beetles, of mud. Others resemble the larvæ of moths in constructing tubes in which to undergo their transformations, while the larvæ of Lady-Birds—*Coccinella*—suspend themselves by the tail and make use of their larval covering as a protection to the nymph within. When the condition of nymph is assumed in autumn, no further change takes place till the ensuing spring, but under suitable conditions of heat this stage does not last usually for more than three or four weeks, after which it emerges a full-blown beetle.

The number of known species of beetles is estimated at 70,000, and these are probably not more than one-half of the total number in existence—Great Britain alone possessing 3614 indigenous species. They occur in greatest abundance in the wooded parts of tropical regions. "A large proportion of the beetles of the tropics," says Wallace, "are more or less dependent on vegetation and particularly on timber, bark, and leaves in various stages of decay. In the untouched virgin forest the beetles are found at spots where trees have fallen through decay and old age." The number gradually decreases towards the poles, only a few species occurring as far north as Greenland. The six zoological provinces proposed by Mr Sclater in 1859 as applicable to the existing distribution of birds, have lately been shown by Mr A. R. Wallace, in his admirable work on the *Geographical Distribution of Animals* (1876), to mark off equally characteristic groups of Coleopterous insects, a conclusion arrived at from a study of the distribution of the following six important families :—

Cicindelidæ or Tiger Beetles,	containing	35	genera and	803	species.
Carabidæ or Ground Beetles,	,,	620	,,	8500	,,
Cetoniidæ or Rose-Chafers,	,,	120	,,	970	,,
Lucanidæ or Stag Beetles,	,,	45	,,	529	,,
Buprestidæ or Metallic Beetles,	,,	109	,,	2686	,,
Longicornia or Long-horned Beetles	,,	1488	,,	7576	,,

The Palæarctic Region, which comprises Europe, Africa north of the Sahara, and Northern Asia, possesses about 20,000 species of beetles, and is specially characterized by abundance of *Carabidæ*, nearly two-fifths of the entire number belonging to this region; Longicorns are also well represented by 196 genera, of which 51 are peculiar to it. The Coleoptera of the Canary Islands, Madeira, and the Azores are Palæarctic, but are peculiar in the total absence of such forms as the Tiger Beetles, the Chafers, and the Rose-Chafers, also in the great number of wingless species. The latter are specially numerous in groups of beetles peculiar to those islands, but they also occur in other cases, 22 genera which either usually or at least sometimes are winged in Southern Europe having only wingless species in Madeira, while at least three species winged in Europe occur in those islands in an apterous condition. On the other hand, those species in Madeira which possess wings have them more largely developed than they are among allied continental forms; the strong-winged and the wingless thus appearing best suited to live in islands exposed, as these Atlantic groups are, to frequent storms. The Ethiopian Region, which includes Africa south of the Sahara and Madagascar, is specially rich in *Cetoniidæ*, possessing 76, or more than half of the known genera, with 64 of these peculiar to it, of which no less than 21 are found exclusively in Madagascar. It has also 262 genera of Longicorns, 216 of which are peculiar. The Oriental Region, comprising Southern Asia and the islands adjacent, contains some of the most remarkable forms of *Carabidæ*, as *Mormolyce phyllodes*, and is rich in gorgeous metallic beetles (*Buprestidæ*) and in Longicorns, having 360 genera of the latter, with 70 per cent. peculiar to it. The Australian Region shows affinity with the Oriental in its Coleoptera, it is equally rich in peculiar forms of Longicorns, and is the richest of all the regions in *Buprestidæ*, having 47, or more than one-half of the known genera, and 20 of these confined to it. Several genera belonging to this and other families have their species divided between the Australian and Neotropical or South-American Regions,

and this resemblance has given rise to the supposition that at some distant period a land connection existed between the two continents; it is more probable, however, as Wallace holds, "that it may have arisen from intercommunication during the warm southern period when floating timber would occasionally transmit a few larvæ from island to island across the Antarctic seas." The Neotropical Region comprehends southern and Central America and the West Indies, and is enormously rich in Longicorn Beetles, having no fewer than 516 genera, of which 487 are found nowhere else. The most remarkable fact in the distribution of the Stag Beetles (*Lucanidæ*) is their almost total absence from the tropical parts of this region, and their presence in North America, while in the old world they are specially characteristic of the hottest parts of the Oriental and Australian Regions. The Nearctic Region comprises the northern and temperate parts of America, and is comparatively poor in Coleoptera, showing greater affinity, however, with the Palæarctic than with the contiguous Neotropical Region.

The insects belonging to this extensive Order comprise numerous well-defined and generally recognized families, but great diversity of opinion exists as to the best mode of grouping these together so as to exhibit their natural affinities. Geoffroy, a French naturalist, was the first to make use of the number of joints in the tarsi for this purpose, a method adopted and extended by Olivier, and brought into general use by Latreille. According to the tarsal system the Coleoptera are divided into the following four sections:—(1) PENTAMERA, in which all the tarsi are five-jointed; (2) HETEROMERA, with five articulations to the first four tarsi and four to the posterior pair; (3) TETRAMERA, with four articulations to all the tarsi; and (4) TRIMERA, with all the tarsi three-jointed. Macleay, an English naturalist, altogether rejected the tarsal system of Geoffroy, and founded his five primary divisions on characters derived from the larvæ of those insects—a system adopted by Stephens in his *Classification of British Insects*, and by several other English writers on this subject. The tarsal system is to a large extent artificial, and when slavishly followed brings together forms which in other respects differ very widely, while separating many that are as obviously related. Its simplicity and consequent easiness of application have, in the absence of a more natural system, led to its very general adoption by both British and foreign naturalists, who do not, however, apply it where obviously unnatural.

PENTAMERA.—The majority of the beetles in this section have the tarsi of the feet five-jointed, and they comprise fully one-half of all the known species of Coleoptera. It is subdivided into the following 8 groups:—

I. *Geodephaga*, or Predaceous Land Beetles, resemble the succeeding group and differ from other Coleoptera in having the outer lobe of the maxillæ distinct and articulated, thus appearing to possess six palpi. They are extremely active, their legs being admirably adapted for running; the majority are nocturnal in their habits, secreting themselves under stones and clods of earth; and all are carnivorous, feeding on other insects and occasionally devouring individuals of their own species, while their larvæ are equally predaceous. They are exceedingly numerous in temperate regions, and are eminently serviceable in checking the increase of insects which feed on fruit and grain. The mandibles, by which they seize and tear their living prey, are long horny organs, hooked and sharp at the points, and toothed on the inner edges. This group includes the Tiger Beetles, *Cicindelidæ* (Plate VI. figs. 4, 9–12), so called from the fierceness of their disposition, and probably also from the spots and stripes with which the elytra are generally adorned. Most of the species are diurnal, frequenting hot sandy districts, enjoying the bright sunshine, and flying for short distances with great velocity. They are elegant in form and adorned with brilliant metallic colours, the prevalent hue being a golden green. The habits of the larvæ of these insects are very remarkable. Unfit, from the softness of their bodies and the slowness of their motions, effectually to protect themselves from the attacks of their enemies, or to capture their prey on the surface of the ground, the larvæ of the Tiger Beetles have recourse to stratagem in order to effect these purposes. By means of their short thick legs, assisted by their powerful sickle-shaped jaws, they dig burrows in the sandy banks which they frequent, vertical for some distance, and afterwards curving so as to become horizontal. These are about a foot in depth, and within them the Tiger Beetle remains during its larval and pupa stages. In seeking its food the creature makes its way from the bottom of its den until the head segment, which is broad and flat, reaches the level of the ground, and thus blocks up the aperture of its tunnel. It remains fixed in this position by means of two bent hooks placed on the upper surface of the eighth segment, which is considerably thicker than the others, until an unsuspecting ant or other insect passing over or close to it is seized by its formidable jaws and speedily conveyed to the bottom of the pit-fall, where it is greedily devoured. Should the tunnels of different individuals happen to come in contact, the more powerful larva is said to devour its weaker neighbour. When full grown it closes the mouth of its burrow and there undergoes metamorphosis. The best known and most beautiful of British species is the Tiger Beetle, *Cicindela campestris*, of a sea-green colour with six whitish spots on the elytra. When handled it exhales, according to Westwood, a pleasant odour like that of roses. Ground beetles (*Carabidæ*) are generally less brilliant in colour than the Tiger forms, being more nocturnal in their habits, and with the jaws less formidably toothed. Many of the species are entirely apterous, with the elytra more or less soldered together, and the majority of them secrete an acrid juice which they expel when menaced or attacked. Of the latter the most remarkable are the Bombardier Beetles, *Brachinus* (Plate VI. fig. 8). These congregate together under stones, and when disturbed discharge a caustic fluid of an extremely penetrating odour, and so volatile that no sooner does it come in contact with the atmosphere than it passes into a vapour, accompanied by a considerable explosion, during which they seek to escape. When placed on the tongue this fluid causes a sharp pain and leaves a yellow spot somewhat similar to that produced by a drop of nitric acid. The Bombardiers are said to be capable of giving off as many as 18 of such discharges at a time. One of the most beautiful of European beetles is the *Calosoma sycophanta* (Plate VII. fig. 2), belonging to this group. Its body is of a deep violet colour, and the elytra, which are striated and punctured, are of a rich green and gold tint. Both in the larva and perfect states these beetles frequent the trunks and branches of the oak, where they find their favourite food—the large caterpillars of the Processionary Moth (*Bombyx processionea*), of which they devour enormous numbers, apparently undeterred by the hairs which clothe the body of the caterpillar, and which when seized by the human hand cause considerable pain. One of the most curious of Carabideous Beetles, *Mormolyce phyllodes* (Plate VI. fig. 5), is a native of Java. Its body is about 3 inches long and $1\frac{1}{2}$ inches across the elytra. The latter are flat, thin, and greatly dilated, while the other parts of the body are remarkably depressed, the beetle thus somewhat resembling the Orthopterous leaf-insects, and hence the specific name *phyllodes*, or leaf-like. Many of the ground beetles, such as the typical *Carabi* (Plate VI. figs. 6, 7) and the *Calosoma*, live in the sunshine and are generally brilliant in colouring; others spend their existence in subterranean caves, and are both colourless and blind; while such forms as *Blennis areolatus*, found on the coast of Normandy, live for the most part under water, being only found when the tide is low.

II. *Hydradephaga*, or Carnivorous Water Beetles, are oval and somewhat depressed in form, with the two posterior pairs of legs flattened and otherwise fitted for swimming. They include the Diving Beetles (*Dytiscus*) and the Whirligigs (*Gyrinus*). The former (Plate VII. figs. 3–7) occur in all quarters of the globe, and are truly amphibious, for although water is their favourite element, they survive for a long time on moist land, and most of them fly about in the evening and morning twilight with great power and speed. When needing to breathe they allow themselves to float on the surface of the water, raise their elytra, and expose their stigmata to the atmosphere, thus getting quit of exhausted air and obtaining a fresh supply, which is stored up by closing the elytra. They are exceedingly voracious, devouring aquatic insects, as *Hydrophilus piceus*, much larger than themselves, and doing considerable damage in fish ponds by devouring the young fish. They are readily kept in confinement, having been known to live thus for 3½ years, feeding on raw beef and insects. The larvæ are even more voracious than the perfect insects, sucking the juices of their prey through perforated mandibles, and protected from attack by their horny integuments. Whirligigs (*Gyrinus*) (Plate VII. figs. 10, 11) differ from the Diving Beetles in the antennæ, which are short and stout, and are so placed as somewhat to resemble ears. They are sociable creatures, and may be seen in ponds and ditches, congregated in groups varying from 2 to 100, swimming upon the surface with their backs above the water, and chasing each other in circles or darting about in more irregular gyrations. Unlike other water beetles their backs show a brilliant metallic lustre, and when darting about in the sunshine they look like pearls dancing on the surface. Their eyes are so divided as to appear to consist of two turned upwards and another pair looking downwards. The larvæ (Plate VII. fig. 17) are long, slender creatures somewhat resembling small centipedes, having each of the abdominal segments provided with a pair of slender ciliated appendages employed as organs of respiration as well as of locomotion, while the last segment is provided with four hooked organs by means of which they leap about.

III. *Philhydrida*, or Water-loving Beetles, are aquatic or subaquatic in their habits, being found in the water or on the moist margins of ponds and marshes. Along with the two following groups they feed on decaying animal and vegetable substances, and for this reason those insects have been classed together as *Rhypophaga*, or Cleansers. The antennæ are short and clavate, and they are specially distinguished from other aquatic forms by the great length of the maxillary palps, a feature which has procured for them the name *Palpicornes*, often applied to them. The best known forms belong to the family *Hydrophilidæ*, of which one species, and that the largest, *Hydrophilus piceus* (Plate VII. fig. 32), is an inhabitant of Europe. This beetle is oval in form, and of a dark olive colour, and measures 1½ inches in length. It uses its hind legs for swimming or rather paddling, moving them not together, as the true water beetles do, but alternately. Its movements in the water are thus slower than those of the former, but speed in this case is less necessary, their principal food consisting of aquatic leaves. In the larval stage, however, *H. piceus* makes an approach to the true water beetles in its food, and is so ferocious as to have earned the name *ver assassin* on the Continent. The mode of respiration in the perfect insect is curious; unable to raise its upper surface above the water, it merely protrudes its head, and folding its club-shaped antennæ, the ends of which are slightly hollow, it thus conveys little bubbles of air beneath the surface of the water, where it brings them into contact with the tracheal openings. The larvæ swim with facility, and are provided at the posterior extremity with two appendages which serve to maintain them at the surface when they ascend to breathe.

IV. *Necrophaga* are the beetles of most service in removing decaying animal matter, although a few species live on putrescent fungi, and others resemble the carnivorous groups in attacking and devouring the larvæ of other insects. They are chiefly marked by the form of the antennæ, which are not much longer than the head, and get thickened or club-shaped at the extremity. This group comprises the Sexton Beetles (*Necrophorus*), of which *Necrophorus vespillo* (Plate VII. fig. 27) may be taken as the type. These insects have thick bodies and powerful limbs, and owe their popular name to the peculiar manner in which they provide a *nidus* for their eggs. Their sense of smell is exceedingly acute, and no sooner does one of the smaller quadrupeds, as mice or moles, die, than several of those burying beetles, gathering about, begin to remove the earth from beneath the dead animal, and in a few hours succeed in sinking the carcase beneath the level of the ground, which they then cover over with earth. Having thus prevented the body from being devoured by other carrion-eating animals, or from having its juices dried up by exposure to the sun, they make their way into the carcase and there deposit their eggs. Several individuals generally work together in this grave-digging operation, although *Necrophorus germanicus* is said to labour alone, and they have been known to show considerable intelligence in performing this operation; thus Gleditsch states that in order to get possession of the body of a mole, fixed on the end of a stick, they undermined the latter and thus brought the dead body to the ground. The larvæ on leaving the egg thus find themselves surrounded by an abundance of food; and when full grown they bury themselves fully a foot beneath the surface of the ground, where they form an oval chamber, the walls of which are strengthened by a coating of a gluey liquid, and in which they undergo metamorphosis. Shield Beetles (*Silpha*) (Plate VII. fig. 22)—so called from the flattened form of their bodies, feed chiefly on carrion; some, however, climb upon plants, particularly the stems of wheat and other grain, where they find small *helices* on which they prey; while others, as *Silpha punctata*, dwell on trees and devour caterpillars. They exhale a disagreeable odour, probably arising from the nature of their food, and when they are seized a thick dark-coloured liquid exudes from their bodies. The *Dermestidæ* are a family of small but widely-distributed beetles, which work great havoc among skins, furs, leather, and the dried or stuffed animals in museums. The perfect insects are timid creatures, which when disturbed fold their short contractile feet under their bodies, and, remaining perfectly motionless, admirably counterfeit death. The mischief is mainly wrought by the larvæ. These shed their skins several times, and take nearly a year in attaining their full growth. One of the most common and injurious species of this family is the Bacon Beetle (*Dermestes lardarius*) (Plate VII. fig. 14)—so called from its fondness for lard, but equally ready to attack the furrier's wares. Their tastes are exceedingly general, as they have been known to destroy a whole cargo of cork and even to perforate asbestos. The larvæ of *Anthrenus museorum*, a species not exceeding one-tenth of an inch in length, is exceedingly injurious to collections of insects, among which it eludes observation by its minuteness and by working in the interior of the specimens, which are thus ruined before the damage is observed.

V. *Brachelytra* (Plate VII. figs. 12, 15 20) are readily distinguished from the other groups of beetles by having the elytra much shorter than the abdomen, although they still suffice to cover the long membranous wings, which when not in use are completely folded beneath. The abdomen is long and exceedingly mobile, and is employed in folding and unfolding the wings. It is furnished at its extremity with two vesicles which can be protruded or withdrawn at pleasure, and from which, when irritated, many species emit a most disagreeable odour, although in a few the scent is more pleasing; "one species," says Kirby, "which I once took, smelt precisely like a fine high scented pear, another like the water-lily, a third like water-cresses, and a fourth like saffron." They are very voracious both in the larval and perfect states, feeding chiefly upon decaying animal and vegetable matters, although a few species devour living prey. Many of the smaller forms reside in and feed on mushrooms, some are found abundantly under putrescent plants, others in manure heaps, where they feed upon the maggots of flies, while there are a few forms which make their homes in the nests of the hornet and the ant. The larvæ bear a considerable resemblance to their parents in form and habits, and have the terminal segment of the abdomen prolonged into a tube with two conical and hairy appendages attached. The Brachelytrous beetles form an extensive group, almost entirely confined to the temperate regions of the northern hemisphere, Great Britain alone possessing nearly 800 species. They are familiarly known in this country as Cock-tails, one of the largest and most familiar species being that known as the Devil's Coach-horse (*Goërius olens*) It is about an inch in length, of a black colour, and its eggs are larger than those of any other British insect. It may often be seen crossing garden walks; and when approached or otherwise threatened, it immediately assumes a most ferocious aspect and attitude, elevating its head and opening wide its formidable jaws, raising and throwing back its tail after the manner of the scorpion, protruding its anal vesicles, and emitting a disagreeable odour. It is carnivorous.

VI. *Clavicornes* have the antennæ terminating in a solid or perfoliated club, and include the Pill Beetles (*Byrrhidæ*) and the Mimic Beetles (*Histeridæ*). The former are small insects, generally short, oval, and highly convex, although a few species found under the bark of trees are flattened. They most frequently occur in sand-pits and on pathways, and when in danger withdraw their highly contractile legs into cavities prepared for them on the under side of the body, at the same time folding up their antennæ and remaining motionless. In this condition they may readily be mistaken for oval seeds or pills, hence the common name. The Mimic Beetles (Plate VII. fig. 13) seldom exceed one-third of an inch in length, and are of very solid consistence, their elytra being so hard that the pin of the entomologist is with difficulty made to enter. They are somewhat square in form, with the upper surface highly polished, feeding chiefly on putrid substances and found in great abundance in spring on the dung of oxen and horses. Like Pill Beetles they roll themselves up on the approach of danger and feign death with great perseverance, and to this they owe their generic name *Hister*, from *histrio*, a stage mimic.

VII. *Lamellicornes* comprise a vast assemblage of beetles, many of which, especially such as feed on flowers and living plants, are remarkable alike for beauty of form and splendour of colour. They are distinguished by the form of their antennæ, which always terminate in a club composed of several leaf-like joints, disposed like the spokes of a fan, the leaves of a book, or the teeth of a comb, or in a series of funnels placed above and within each other. The males often differ from the females in having horn-like projections on the head and thorax, and in the greater size of their mandibles. They are all winged insects, although somewhat dull and heavy in their flight; and alike in the larval and perfect states they are herbivorous, feeding either on living vegetation and flowers or on putrescent plants and excrementitious substances. The following species may be regarded as illustrative of the most important subdivisons of the Lamellicorn Beetles:—Stag Beetles (*Lucanidæ*) (Plate VIII. fig. 14), with the club of the antennæ composed of leaflets disposed perpendicularly to its axis like the teeth of a comb, owe their most striking feature to the immense development of the mandibles in the males, the purpose served by these formidable looking organs being by no means fully understood. The males appear to be more numerous than the females, and fierce contests take place among the former for possession of the latter. The Stag Beetle (*Lucanus cervus*), of a uniform brown colour, measures 2 inches in length including the mandibles, and is the largest of British beetles. It inhabits woods, passing its immature stages in the interior of the oak and beech, and may be seen flying in the evening in search of the female. It has a patch of golden-coloured hair towards the base of the foreleg with which it cleans its antennæ after these have been in contact with any sticky substance. After coupling and depositing their eggs both sexes soon die. The Dor Beetle (*Geotrupes stercorarius*, is the type of a large tribe of dung-eating beetles (Plate VII. figs. 21, 25, 26). It is a black insect, with brilliant metallic blue or purple reflections on the under side, and well known as "wheeling its drowsy flight" during fine evenings. This it does in search of a patch of cow-dung, through which it makes its way until reaching the ground, where it bores a perpendicular tunnel about 8 inches deep, and as wide as a man's finger; then ascending to the surface it conveys a quantity of dung to the bottom, and on this it proceeds to deposit an egg; another layer of the same material and another egg follow until the entire shaft is filled. The larvæ on leaving the egg thus find themselves surrounded with their appropriate food. The Sacred Beetle of Egypt, *Ateuchus sacer* (Plate VII. fig. 29), somewhat resembles the Dor in form and habits. After depositing her egg on a piece of dung the female rolls the mass about in the sunshine with her forelegs until it forms a rounded ball. The process of hatching is thus accelerated, and a thin hardened crust is formed around the softer material inclosing the egg. A hole is then dug in the earth by means of its powerful forelegs, into which the ball is rolled and then covered over with earth, where it remains until fully developed. Those beetles show great perseverance in conveying the egg-laden pellets to their destination, frequently carrying them over rough ground on the broad flat surface of their heads, and seeking, when unable singly to complete the work, the assistance of their fellows. Two species of Sacred Beetles were worshipped by the ancient Egyptians, who regarded them as emblems of fertility, and as representing the resurrection of the soul, owing to their sudden appearance in great numbers on the banks of the Nile after the annual subsidence of that river. They form a conspicuous feature in the hieroglyphics of that nation, and are found sculptured on their monuments, sometimes of gigantic size. They were also formed into separate figures, as seals and amulets, made of gold and other precious materials, and hung around the necks of the living, or buried along with their mummies. The insect itself is sometimes found in their coffins. The male Hercules Beetle (*Scarabæus hercules*) of Guiana has the head produced into an enormous horn, bent downwards at the extremity, and clothed on the under surface with a reddish brown pile, and measures 6 inches in length. The Cockchafers, *Melolonthidæ* (Plate VII. fig. 28), have a short labrum and strong mandibles suited for feeding on leaves. The club of the antennæ consists of a variable number of plates, those in the male being considerably elongated and resembling a folded fan (Plate VII. fig. 23). The common Cockchafer (*Melolontha vulgaris*) is of a pitchy black colour clothed with a white pubescence or layer of minute scales. It is one of the commonest and most destructive of beetles, feeding in the perfect state on the leaves of the oak, beech, poplar, and elm, and sometimes appearing in such numbers as to utterly destroy the foliage over large districts; thus in the year 1688 they are said to have covered the hedges and trees in a district of Galway in such infinite numbers as to have hung in clusters like bees when they swarm. When on the wing they almost darkened the light of day, and when feeding the noise of their jaws might have been mistaken for the sawing of timber. In a short time the foliage of the trees for miles round was so totally consumed that at midsummer the country wore the aspect of leafless winter. Destructive as they are in the perfect state they are still more injurious as larvæ. The female buries herself beneath the surface of the ground and there deposits about 40 eggs. The larvæ produced from these feed on the roots of grass and grain, thus "undermining," according to Kirby and Spence, "the richest meadows, and so loosening the turf that it will roll up as if cut with a turfing spade." These grubs continue their ravages for three years before undergoing metamorphosis, and thus do incalculable damage to the agriculturist. They are believed to have spread with the progress of agriculture, for it is only on soil rendered light and porous by tillage that they thrive. Enormous numbers of the grub are consumed by birds of the crow tribe, and it is principally in search of these that rooks so industriously follow the plough in England and France. The species is rare in Scotland. "Spinning" the cockchafer is a favourite but barbarous sport, practised by the boys of most countries in which this beetle commonly occurs, and seems to be at least as ancient as the time of Aristophanes, who refers to it in his *Clouds* as practised by the youth of Greece. Rose Beetles, *Cetoniidæ* (Plate VIII. fig. 7), a beautiful tribe of insects, are distinguished from other Lamellicorn Beetles by the membranaceous character of their mandibles and maxillæ. The Rose-Chafer (*Cetonia aurata*) is common in the south of England, where it feeds on the juices and petals of the rose, honeysuckle, and privet. It is about an inch long, of a brilliant-golden green above with coppery reflections beneath, and with whitish markings on the elytra. Its eggs are deposited among decayed wood, but certain species make use for this purpose of the nests of ants. The Goliath Beetles (Plate VIII. fig. 11) of tropical Africa are the largest of known Coleoptera, and their larvæ form enormous cocoons of mud in which they undergo metamorphosis. One of these, *Goliathus cacicus*, is said to be roasted and eaten by the natives.

VIII. *Serricornes* form a group of beetles chiefly distinguished from the others by their elongate filiform antennæ of equal thickness throughout, or tapering towards the extremity, but generally serrated or pectinated. They are subdivided into the *Sternoxi*, characterized by the solid consistence of their bodies, and by having the middle portion of the thorax elongated and advanced as far as beneath the mouth, and usually marked by a groove on each side, in which the short antennæ are lodged, while the opposite extremity is prolonged into a point which is received into a cavity on the hinder part of the breast; and the *Malacodermata*, characterized by their bodies being generally, in whole or in part, of a soft or flexible texture, and by the absence of the prolongation just referred to. The *Sternoxi* include the Metallic Beetles, *Buprestidæ* (Plate VII. figs. 18 19) the most gorgeous of the Coleopterous families. "Nothing can exceed," says Westwood, "the splendour of colour in many of the species, being decorated with the most brilliant metallic tints; some have a general coppery hue, whilst some present the beautiful contrast of fine yellow spots and marks upon a highly polished blue or green ground, and others exhibit the appearance of burnished gold or of rubies, inlaid on emerald or ebony." The elytra of the Metallic Beetles are those usually employed in the embroidery of ladies' dresses and for other purposes of personal ornament. They are most plentiful in the thick forests of tropical countries, and seem partial to the various species of fir-trees. They pass their larval stage in the heart of timber, and there is an instance recorded of the escape of *Buprestis splendens* from the wood of a desk which had stood in one of the Guildhall offices for over twenty years. Springing Beetles, *Elateridæ* (Plate VII. fig. 30), are narrower and more elongate than the former, and their legs are so short that when they fall on their backs they are as unable to right themselves as a capsized turtle, but by bending the head and thorax backwards, and making use of the prolongation already described, they are enabled to spring to a height fully ten times their own length, and this operation they repeat until they fall on their feet. The noise which accompanies the springing process has earned for them the name of Click Beetles. Some species of *Elateridæ* are luminous in the dark, and are known as Fireflies. A South American form diffuses during the night from its thoracic spots a strong and beautiful light sufficient to enable a person to read ordinary type, particularly if several are placed together in a glass vessel. By means of this natural illumination the women of the country can pursue their ordinary work, and ladies use this fire-fly as an ornament, placing it among their tresses during their evening promenades. The larva of *Elater lineatus* is known as the Wire-worm, a grub which often does great damage to the turnip crop. The *Malacodermata* include the Glow-worms, *Lampyridæ* (Plate VII. fig. 1), of which the best known is the common Glow-worm (*Lampyris noctiluca*) (Plate VII. figs. 8, 9, 16), found in meadows and under hedges in England, but rare in Scotland. The male of this beetle has large wings and elytra, and flies swiftly, but the female is wingless and is a sluggish nocturnal creature; the latter, however, emits a beautiful phosphorescent light by means of which the male, who is generally concealed by day in the trunks of trees, is directed to his mate. In the perfect insect the luminous matter chiefly occupies the under part of the three last segments of the abdomen, which differ from the rest in colour, being usually of a yellow hue, and the luminous property is apparently under the control of the Glow-worm, for when approached it may frequently be observed to diminish or extinguish its light. In form the larvæ somewhat resemble the female, and possess in common with the pupæ and eggs a slight degree of luminosity. The larvæ are predaceous, attacking and devouring the smaller snails and slugs, but in the perfect state they become entirely herbivorous, only eating the tender leaves of plants. Many of the *Malacodermata* are wood-borers; these include the Death-watch Beetles (*Anobium*), which as larvæ perforate chairs, tables, and other wood-work in such numbers as usually to render the wood completely rotten. During the pairing season they make a noise like the ticking of a watch, by striking with their jaws against the object on which they rest. This is intended as a mutual call of the sexes, but it has long been regarded by the ignorant as of evil omen, hence the name, and the import of Gay's words—

> "The solemn death-watch clicked the hour she died.

Another species, *Lymexylon navale*, abundant in the forests of Northern Europe, does great damage by boring into the timber of the oak tree.

HETEROMERA.—The beetles comprising this section have five joints to the first four tarsi, and four to the posterior pair, and form two groups, *Trachelia* and *Atrachelia*.

I. *Trachelia* have the head triangular or heart-shaped, and connected with the thorax by a kind of neck or abrupt pedicle. Most of the species in the perfect state live on various plants, of which they devour the foliage or suck the juices, and many when seized bend their heads, contract their limbs, and simulate death. This group includes the Oil Beetles (*Melöe*) (Plate VIII. fig. 2), large black insects, destitute of wings, and with short elytra. They secrete an oily fluid possessing slightly blistering properties, which when alarmed they emit from the joints of their legs, and when eaten by cattle, as they sometimes are when feeding on the wild buttercups of pasture-lands, they produce sores in the mouth. In some parts of Spain they are used instead of the Blistering Fly, or are mixed with it. The young larvæ of several species of Oil Beetles, it has been ascertained, get conveyed to the nests of bees, where alone they can find their appropriate food, and where also they undergo metamorphosis. The most important insect of this group is the Spanish Fly, or Blistering Beetle (*Lytta vesicàtoria*) (Plate VIII. fig. 19), found abundantly in South-Western Europe, but of rare occurrence in England. It is a handsome insect of a golden green colour, and measures about three-fourths of an inch in length. In Spain, where this species is most abundant, they are collected for commercial purposes in the month of June. A sheet is placed beneath the trees frequented by the blister-flies, and the branches are shaken, so as to cause the insects to fall off. They are then killed by exposure to the vapour of vinegar, and completely dried after they are dead. The blistering principle, known to chemists as cantharadin, is contained in their integuments. See CANTHARIDES.

II. The *Atrachelia* have no distinct neck, the part of the head behind the eyes being immersed in the thorax. They are in most cases nocturnal insects, obscure in colour, and slow in motion. The Church-yard Beetle (*Blaps mortisaga*) (Plate VIII. fig. 1) is one of the commonest species. It is of a shining black colour, avoids the light, and emits an offensive odour. It is found in cellars, store-rooms, and the neglected parts of houses, feeding on rubbish of all kinds, and regarded as of evil omen by the superstitious. It is very tenacious of life, having been known to survive several hours immersion in spirits of wine, and cases are on record in which the larvæ have been discharged from the human stomach. The Meal-worm is the larva of *Tenebrio molitor* (Plate VIII. figs. 4, 5), a well-known insect belonging to this group, which appears in the evening in the least frequented parts of houses. It is found abundantly in flour-mills and bake-houses, greatly relishing the heat of the latter. The larvæ, which are long, cylindrical, and of an ochry yellow colour, pass their lives enveloped in the flour which forms their favourite food, and in the midst of which they become pupæ. While injurious to flour and bran, and destroying great quantities of ship biscuits, the Meal-worm is used as bait by fishermen, and as food for the nightingale and other pet insectivorous birds.

TETRAMERA.—The beetles composing this section have four apparent joints to all the tarsi, but in most cases the tarsi are in reality five-jointed, the fourth being so minute as to have been overlooked by the founders of the tarsal system. For this reason Westwood proposed the term Pseudo-tetramera in place of Tetramera, a change which has been adopted by several systematic writers. This section includes a vast number of small or moderate sized beetles, all vegetable feeders, found in the perfect state on flowers and plants. It is subdivided into the three following groups:—

I. *Rhynchophora*, the species of which are readily recognized by having the front of the head produced into a rostrum or snout, which bears the organs of the mouth at its extremity. The larvæ are either entirely destitute of legs, or have them in the form of small fleshy tubercles, and are in most cases equally destitute of eyes. The most numerous and best-known tribe of Rhynchophorous beetles are the Weevils (Plate VIII. figs. 8, 9, 15, 16, 20, 22), of which several thousand species have been described, and whose larvæ, dwelling in the interior of fruits and seeds, do immense damage to the produce of the farmer, the grain dealer, and the horticulturist. They are generally minute in size and exceedingly varied in colour, the South American forms, known as Diamond Beetles, being among the most gorgeous of insects. These owe their colour, which in the finest of them is a light-green tinged with golden yellow, to the presence of minute scales on the elytra. The Weevil *par excellence* (*Calandra granaria*) measures about one-eighth of an inch in length, is of a pitchy red colour, and does great damage in granaries. The female buries herself among the grains of wheat, in each of which she bores a small hole, where she deposits a single egg, thereafter closing the aperture with a glutinous secretion. The egg is soon hatched, and the larva, furnished with two strong mandibles, eats out the interior of the grain, becomes a nymph, and in the course of eight or ten days is transformed into the perfect insect, ready to raise another brood. The whole time occupied with their reproduction, from the union of the sexes to the appearance of the perfect Weevil, is not more than 50 days, and it has been calculated that from a single pair 23,600 individuals may thus take origin in a single season. Grain injured by these insects is readily detected, from the fact that it floats when immersed in water. Kiln-drying the grain is the mode most generally adopted for arresting the evil. Filberts, acorns, rice, the sugar-cane, and the palm tree have each its own species of Weevil. The Palm Tree Weevil (*Calandra palmarum*) is the largest of the tribe, measuring 2 inches in length, and its larvæ, as well as those of the sugar-cane species, are, when cooked, considered delicacies by the natives of Guiana and the West Indies. *Bruchus pisi* (Plate VIII. fig. 12), belonging to another family of this group, deposits its eggs in peas, the interior of which is devoured by the larva. It has probably been introduced into Britain from America, where its ravages are occasionally such as totally to destroy the pea crop over large districts. The larvæ of many species burrow beneath the bark of trees and thus destroy immense quantities of timber. Of these the most familiar are *Scolytus destructor*, whose curiously designed burrows in the bark of the elm are well known, and the Typographic Beetle (*Tomicus typographicus*), so called from the resemblance which its burrows, made in the soft wood immediately beneath the bark, bear to printed characters.

II. *Longicornes* (Plate VIII. fig. 13) form an extensive group of beetles characteristic of tropical forests, and readily distinguished by the great length of their antennæ, which in some cases are several times longer than the body. These are usually setaceous or filiform, and are occasionally adorned with tufts of hair at the joints (Plate VIII. fig. 3). The larvæ of almost all the Longicorns live in the interior, or beneath the bark, of trees, perforating the timber of the largest forest trees, and thus hastening in these the natural process of decay. They are either apodal, or furnished with inconspicuous feet, but progress chiefly by the aid of small tubercles on the upper and under surfaces of the segments. The female is provided with an ovipositor of horny consistence, issuing from the posterior segment, by means of which the eggs are deposited in cracks and fissures of wood. The larvæ remain for several years buried in the heart of timber, and in this way many exotic species are conveyed to this country, and are occasionally taken alive in the London and Liverpool docks. Several of the Longicorn Beetles are among the largest of Coleopterous insects, *Prionus giganteus* measuring 5 inches in length, while its eggs are nearly as large as those of the smaller birds. The Harlequin Beetle (*Acrocinus longimanus*), so called from the variety of its colouring, the grotesqueness of its markings, and the enormous elongation of its front pair of legs, is a South American species of this group, as is also the Musk Beetle (*Callichroma moschata*), one of the handsomest of our native species, and remarkable for the musky odour of its body.

III. *Phytophaga* comprise the tetramerous beetles which have neither the rostrum of the first group nor the lengthened antennæ of the second. They are small insects of an oval or quadrate shape, and include the Golden Beetles, *Chrysomelidæ* (Plate VIII. fig. 21), ornamented with metallic colours, among which blue, green, gold, and copper are conspicuous. The Turnip-fly (*Haltica nemorum*), a small species belonging to a family in which the posterior thighs are enlarged for leaping, devours the young leaves of the turnip as soon as they appear above ground, and occasionally does immense injury to the turnip crop. Helmet or Tortoise Beetles, *Cassidæ* (Plate VIII. figs. 20, 24), so called from the thorax and elytra overlapping so as to shield the limbs and abdomen on all sides, are oval, and in some cases almost square, flat insects, and often beautifully marked with combinations of green and golden hues. They are herbivorous, and are specially fond of artichoke and thistles. The larvæ are provided at the posterior extremity with a two-branched fork, curved over the back, and usually bearing a pile of excrementitious matter, under which they lie partly concealed. It can elevate or depress this stercoraceous parasol at pleasure, according as it needs shade or shelter. The Colorado Potato Beetle (*Doryphora decemlineata*) belongs to the phytophagous family *Chrysomelidæ*. It measures nearly half an inch in length; its body is of a tawny or yellow cream colour, darkly spotted; and the elytra are marked with ten black longitudinal stripes. It is a native of the eastern slopes of the Rocky Mountains, where it fed on a wild solanaceous plant, *Solanum rostratum*, until the introduction of the potato plant, consequent on the settlement and cultivation of the "Far West," provided it with what appears to have been a more appropriate food. Since 1859 it has travelled eastward, towards the more highly cultivated lands, at the rate of nearly 100 miles per annum, until it has reached the Atlantic Coast. It is now found over all the central and northern parts of the United States east of the Rocky Mountains, and throughout Canada, and has already done incalculable mischief to the potato crops of those regions. The damage is chiefly wrought by the larvæ, which are hatched on, and greedily devour, the leaves and stalk of the potato plant. They are said to produce three broods annually.

Trimera.—The majority of the beetles composing this section have only three apparent joints to the tarsi of all the feet, but a small articulation has been found to lie between the second and third joints, so that they are in reality four-jointed, and for this reason Westwood has changed the name of the section to Pseudotrimera.

Trimerous beetles form a single group, the species of which are partly herbivorous, feeding on fungi (Plate VIII. figs. 17, 18), and partly carnivorous, devouring *aphides* or plant lice. The most familiar examples of this group are Lady-birds, *Coccinellidæ* (Plate VIII. fig. 23), small convex insects of a black colour, spotted with red or yellow, or of a reddish colour, spotted with black. The larvæ do great service by devouring the plant lice, which usually infest garden bushes. When alarmed the Lady-birds retract their limbs and emit a yellow juice from their joints, which has a very disagreeable odour. They occasionally occur in great numbers, extending for miles, in the south-eastern districts of England, where they are invaluable for freeing the hops of *aphides*. They walk slowly but fly well. The Seven-Spotted Lady-bird (*Coccinella 7-punctata*), the common species of Britain, is found in all quarters of the globe.

On Collecting and Preserving Coleopterous Insects.—The collector of beetles, in order to obtain perfect specimens, need not have recourse to the plan adopted by the lepidopterist of rearing the insect from the egg. The successful rearing of these is much more difficult than in the case of butterflies and moths, and the specimens so procured are generally inferior to those collected in the ordinary way. The complete life history, however, of comparatively few even of our native species has yet been fully traced; and although the collector thus might not greatly enrich his cabinet with specimens of his own rearing, yet by adopting this method he would almost certainly add to the general stock of knowledge regarding the transformations of these insects. Beetles may often be obtained in what may be termed accidental situations,—sand-pits into which they have fallen, or artificial traps set for them, as a white sheet spread on the grass; but "sweeping" and "beating" are the means mainly relied on by the coleopterist for filling his cabinet, and for these all the apparatus necessary consists of an umbrella-net and a stick for beating. The net is swept over the grass, and among the foliage of trees, and when the branches are shaken with the hand, or beaten with the stick, the net is held beneath to catch the falling insects. An umbrella inverted, or a sheet placed beneath the tree, serves the same purpose. A knowledge of the habits of the various tribes of beetles will give the collector a clue to the localities in which, and the time when, he may expect to find the species he is in search of. In this way the bark and timber of trees, decaying branches and leaves, putrescent fungi, the droppings and the dead bodies of mammals, fresh water ponds, and even the nests of wasps, bees, and ants will all be found to yield their own harvest of Coleoptera. Beetles when caught may either be dropped into a phial containing spirits of any kind, or into what is known as the "killing bottle," the bottom of which contains cyanide of potassium covered over with a layer of gypsum. In either case, with few exceptions, the beetles die almost instantaneously. If kept too long in spirits, however, the limbs get loosened through maceration and fall off. The "setting" of a beetle, or of any other insect, consists in placing its limbs and antennæ in a natural position and fixing them there by means of pins until they stiffen on a board on which there is a layer of cork. If not set when either moist or recent, they may be softened by being placed for a night in any small vessel containing a layer of wet sand, and covered with a damp cloth to prevent evaporation. The smaller beetles are usually mounted on card, each insect being stuck on a small dab of gum with its legs and antennæ properly set; all others are pinned through the centre of the upper part of the right elytron. In the case of large beetles as much of the contents of the body as possible should be removed by making an opening in the abdomen; and with the Oil Beetles it is necessary to stuff the abdomen. This can be best effected by separating the latter from the body, emptying it, and refilling with wadding; it can then be readily gummed to the body. Mould may be got rid of by exposing the specimens to a strong heat for some hours, and mites and grease by washing the beetles with a small brush dipped in benzine. (J. GI.)

COLERAINE, a municipal and parliamentary borough and market-town of Ireland, in the county of Londonderry on the Bann, four miles from its mouth, and 145 miles north of Dublin. The town stands upon both sides of the river, which is there crossed by a handsome stone bridge of three arches, 288 feet in length by 32 in breadth. The principal part is on the east bank, and consists of a central square called the "Diamond," and several diverging streets; the portion on the west side is called the Waterside, or Killowen. Coleraine has two parish churches, two Roman Catholic churches, a town-hall, a market-house, a work-house, an endowed school, a national model school, and free schools founded by the Irish Society of London. The linen trade has long been extensively carried on in the town, from which, indeed, a fine description of cloth is known as "Coleraines." Pork-curing and the salmon and eel fisheries are prosecuted. The mouth of the river, which was formerly obstructed by a bar, now admits vessels of 200 tons. The principal trade is carried on through Port Rush, where a harbour is formed by two moles, with an entrance of 200 feet wide, an area of 8 acres, and a depth of from 15 to 20 feet at the wharves. In 1873, 422 vessels entered with a tonnage of 46,589. The parliamentary borough has a population of 6552, and returns one member. Coleraine is reputed to have been the seat of a Christian bishop previous to the arrival of the great apostle of Ireland. It owes its modern importance mainly to the Company for the New Plantation of Ulster, on which it was bestowed in 1613. Though fortified only by an earthen wall, it managed to hold out against the rebels in 1641.

COLERIDGE, Hartley (1796–1849), the elder son of Samuel Taylor Coleridge, was born on the 19th of September 1796, at Clevedon, a small village near Bristol. His early years were passed at Keswick, where his education was conducted in a somewhat desultory manner. He gave promise of great mental power, but derived less advantage from systematic studies than from intercourse with S. T. Coleridge, Wordsworth, Southey, De Quincey, and Professor Wilson. In 1815 he went to Oxford, as scholar of Merton College, the means for his support being principally provided by Southey. His university career, however, was very unfortunate. He had inherited the weakness of purpose, as well as the splendid conversational powers, of his father, and, having never enjoyed the benefit of a regular discipline, lost all self-restraint amidst the gaieties of Oxford, and finally lapsed into habits of intemperance. He was successful in gaining an Oriel fellowship, but at the close of the probationary year was judged to have forfeited it. The authorities could not be prevailed on to reverse their decision; but they awarded to him a free gift of £300. With this, Hartley Coleridge came to London in 1821, and remained there for two years, during which he wrote short poems for the *London Magazine*. His next step was to set up school at Ambleside, but this scheme failed, after five years of struggle in a position for which he was wholly unfit. Coleridge then removed to Grasmere, where he lived in great seclusion,—writing between 1826 and 1831 *Essays* for *Blackwood*, and in 1832 his *Biographia Borealis*, or *Lives of Northern Worthies*. In 1839 appeared his last work, the *Life of Massinger*, an elaborate and artistic production. The closing decade of Coleridge's life was wasted in what he himself calls "the woeful impotence of weak resolve." In 1848 his health became sensibly affected, and he expired on the 6th of January 1849. The prose style of Hartley Coleridge is marked by much finish and vivacity; but his literary reputation must chiefly rest on his poetical remains. Of these the *Sonnets*, and *Prometheus*, an unfinished lyric drama, are the finest. The influence of Wordsworth is discernible in his poetry, but it does not on that account want originality. (See *Memoir of Hartley Coleridge* by Derwent Coleridge).

COLERIDGE, Sir John Taylor (1790–1876), nephew of S. T. Coleridge, was born at Tiverton, and was educated, with Arnold and Keble, at Corpus Christi College, Oxford. In 1810 he won the Latin verse prize; in 1812 he obtained a first class in classics; and in 1813 both the English and Latin essay prizes were awarded him. He was soon after made a fellow of Exeter; in 1819 he was called to the bar, and practised for some years on the Western Circuit In 1824, on Gifford's retirement, he assumed the editorship of the *Quarterly Review*, resigning it a year afterwards in favour of Lockhart. In 1825 he published his excellent edition of *Blackstone's Commentaries*, and in 1832 he was made a serjeant-at-law. In 1835 he was appointed one of the judges of the King's Bench. In 1852 his university created him a D.C.L., and in 1858 he resigned his judgeship, and was made a member of the Privy Council. In 1869, although in extreme old age, he produced his pleasant *Memoir of the Rev. John Keble, M.A.*, a third edition of which was issued within a year.

COLERIDGE, Samuel Taylor (1772–1834), one of the most remarkable of English poets and thinkers, was born, on the 21st of October 1772, at his father's vicarage of Ottery St Mary's, Devonshire. His father was a man of some mark. He was known for his great scholarship, simplicity of character, and affectionate interest in the pupils of the grammar school, where he reigned until his promotion to the vicarage of the parish. He had married twice. The poet was the youngest child of his second wife, Anne Bowden, a woman of great good sense, and anxiously ambitious for the success of her sons. On the death of his father, a presentation to Christ's Hospital—acceptable in a family of ten—was procured for Coleridge by Judge Buller, an old pupil of his father's. He had already begun to give evidence of a powerful imagination, and he has described in a letter to his valued friend, Mr Poole, the pernicious effect which the admiration of an uncle and his circle of friends had upon him at this period. For eight years he continued at Christ's Hospital. Of these school-days Charles Lamb has given delightful glimpses in the *Essays of Elia*. The head master, Bowyer, though a severe disciplinarian, was on the whole respected by his pupils. Middleton, afterwards known as a Greek scholar, and bishop of Calcutta, reported Coleridge to Bowyer as a boy who read Virgil for amusement, and from that time Bowyer began to notice him, and encouraged his reading. Some compositions in English poetry, written at sixteen, and not without a touch of genius, give evidence of the influence which Bowles, whose poems, now forgotten, were then in vogue, had over his mind at this time. Before he left school his constitutional delicacy of frame, increased by imprudent bathing in the New River, began to give him serious discomfort.

In February 1791, he was entered at Jesus College, Cambridge. A school-fellow who followed him to the university has described in glowing terms evenings in his rooms, "when Æschylus, and Plato, and Thucydides were pushed aside, with a pile of lexicons and the like, to discuss the pamphlets of the day. Ever and anon a pamphlet issued from the pen of Burke. There was no need of having the book before us;—Coleridge had read it in the morning, and in the evening he would repeat whole pages verbatim."

Frend, a fellow of Jesus, accused of sedition and Unitarianism, was at this time tried and expelled from Cambridge. Coleridge had imbibed his sentiments, and joined the ranks of his partisans. He grew discontented with university life, and, pressed by debt, in a moment of spleen enlisted as a soldier. One of the officers of the dragoon regiment, finding a Latin sentence inscribed on a wall, discovered the condition of the very awkward recruit

Shortly afterwards a Cambridge friend recognized him, and informed some members of his family, who with difficulty procured his discharge. He returned for a short time to Cambridge, but quitted the university without a degree in 1794. In the same year he visited Oxford, and made the acquaintance of Southey, who continued through life, in spite of Coleridge's many misunderstandings, his firm friend and most devoted admirer. The French Revolution had stirred the mind of Southey to its depths. He received with rapture his new friend's scheme of Pantisocracy. On the banks of Susquehanna was to be founded a brotherly community, where selfishness was to be extinguished, and the virtues were to reign supreme. No funds were forthcoming, and in 1795, to the chagrin of Coleridge, the scheme was dropped. In October of the same year, Coleridge was married to Sarah Fricker, and took up his residence at Clevedon on the Bristol Channel. A few weeks afterwards Southey married a sister of Mrs Coleridge, and on the same day quitted England for Portugal.

The cares of matrimony induced Coleridge to commence lectures. The Bristol public did not encourage his efforts on politics and religion. Coleridge embodied these in his first prose publication, *Conciones ad Populum.* The book contained much invective against Pitt, and in after life he declared that with this exception, and a few pages involving philosophical tenets which he afterwards rejected, there was little or nothing he desired to retract In the course of a summer excursion at this period, he met for the first time the brother poet with whose name his own will be for ever associated. Wordsworth and his sister had established themselves at Racedown in Dorsetshire,—a retired spot,—and it was here the friends first met. There are few things in literary history more remarkable than this meeting. The gifted Dorothy Wordsworth described Coleridge as " thin and pale, the lower part of the face not good, wide mouth, thick lips, not very good teeth, longish, loose, half-curling, rough, black hair,"—but all was forgotten in the magic charm of his utterance. Wordsworth, who declared, " The only wonderful man I ever knew was Coleridge," seems at once to have desired to see more of his new friend. He and his sister soon removed to Coleridge's neighbourhood, and in the most delightful and unrestrained intercourse the friends spent many happy days. It was the delight of each one to communicate to the other the productions of their minds, and the creative faculty of both poets was now at its best One evening, on the Quantock Hills, '*The Ancient Mariner* first took shape. Coleridge was anxious to embody a dream of a friend, and the suggestion of the shooting of the albatross came from Wordsworth. A joint volume was planned. The poetry of common life was to be the work of Wordsworth, while Coleridge was to indulge in romance. From this sprang the *Lyrical Ballads*, and after much cogitation the book was published by the amiable but gossiping bookseller at Bristol, Cottle, to whose reminiscences, often indulging too much in detail, we owe the account of this remarkable time. Coleridge projected a periodical called *The Watchman*, and undertook a journey, well described in the *Biographia Literaria*, to enlist subscribers. *The Watchman* had a brief life of two months, and at this time, in the year 1796, the *Juvenile Poems*, for which Cottle, always ready to help his literary friends, gave thirty guineas, appeared. The volume met with success, but at this time Coleridge began to think of becoming a Unitarian preacher, and abandoning literature for ever. Hazlitt has recorded his very favourable impression of a remarkable sermon delivered at Birmingham; but there are other accounts of Coleridge's preaching not so enthusiastic. In 1798 an annuity, granted him by the brothers Wedgwood, led him to abandon his scheme of life For many years he had desired to see the Continent, and in September of the same year—the year in which the *Lyrical Ballads* appeared—in company with Wordsworth and his sister, he left England for Hamburg.

A new period in Coleridge's life now began. He soon left the Wordsworths to attend lectures at Göttingen. A great intellectual movement had begun in Germany. Coleridge was soon in the full whirl of excitement. He learnt much from Blumenbach and Eichhorn, and took interest in all that was going on around him. During his stay of fourteen months in Germany, he made himself master of the language to such purpose that the translation of Wallenstein—his first piece of literary work after his return to England—was actually accomplished in six weeks. It was published in 1800, and, although it failed to make any impression on the general public, it became at once prized by Scott and others as it deserved. In several passages Coleridge has expanded and paraphrased the thought and expression of the original, but few, even amongst the greatest sticklers for accuracy, will be inclined to quarrel with the departure of the translator. It is matter for regret that a request to Coleridge that he should undertake to translate *Faust* never received serious attention from him. During the first two years of this century Coleridge wrote many papers for the *Morning Post.* He had vehemently opposed Pitt's policy, but a change came over the spirit of his mind, and he found himself separated from Fox on the question of a struggle with Napoleon. Much has been written of this political attitude, but there is no real reason to doubt his own account of the matter. Like the first Lord Minto, Mr Windham, and many other Whigs, he felt that all questions of domestic policy must at a time of European peril be postponed. From this time, however, his value for the ordered liberty of constitutional government increased; and though never exactly to be found among the ranks of old-fashioned Constitutionalists, during the remainder of his life he kept steadily in view the principles which received their full exposition in his well-known work on *Church and State.* In the year 1801 Coleridge left London for the Lakes. His home was for a time with Southey. A temporary estrangement had entirely been forgotten, and Southey, it should be said, for many years extended to Coleridge's wife and family the shelter and care of true friendship.

For fifteen years the record of Coleridge's life is a miserable history. He sank under the dominion of opium. The *Ode to Dejection* and the poem of *Youth and Age* are sad evidences of the utter prostration of spirit, which was his terrible penalty for many a year. Few things are so sad to read as the letters in which he details the consequences of his transgression. He was occasionally seen in London during the first years of this century, and wherever he appeared he was the delight of admiring circles. A visit to Malta in 1804, when for a short time he acted as secretary to the governor, and a brief stay at Rome in the following year, were the chief events of what may be called the opium period. In 1809 he published *The Friend*, and during that and the two following years he lectured on Shakespeare and education. The tragedy of *Remorse* was produced in 1813, and met with considerable success. Three years after this, the evil habit against which he had struggled bravely but ineffectually, determined him to enter the family of Mr Gillman, who lived at Highgate. The letter in which he discloses his misery to this kind and thoughtful man gives a real insight into his character. Under kind and judicious treatment the hour of mastery at last arrived. The shore was reached, but the vessel had been miserably shattered in its passage through the rocks. He hardly, for the rest of his life. ever left his home at Highgate. During his residence there, *Christabel*, written many years before, and known to a favoured few, was first published. He read widely and wisely, in poetry, philosophy, and divinity. In 1816 and the following year, he gave his *Lay Sermons* to the world. The *Biographia Literaria* and a revised edition of *The Friend* soon followed. Seven years afterwards his maturest and best prose work—*The Aids to Reflection*—first appeared. His last publication, in 1830, was the work on *Church and State*. In 1833 he appeared at the meeting of the British Association at Cambridge, and in the following year he passed away, and was buried in the churchyard close to the house of Mr Gillman, where he had enjoyed every consolation which friendship and love could render. Coleridge died in the communion of the Church of England, of whose polity and teaching he had been for many years a loving admirer. An interesting letter to his god-child, written twelve days before his death, sums up his spiritual experience in a most touching form.

Of the extraordinary influence which he exercised in conversation it is impossible to speak fully here. Many of the most remarkable among the younger men of that period resorted to Highgate as to the shrine of an oracle, and although one or two disparaging judgments, such as that of Mr Carlyle, have been recorded, there can be no doubt that since Samuel Johnson there had been no such power in England. His nephew, Henry Nelson Coleridge, gathered together some specimens of the *Table Talk* of the few last years. But remarkable as these are for the breadth of sympathy and extent of reading disclosed, they will hardly convey the impressions furnished in a dramatic form, as in Boswell's great work. Four volumes of *Literary Remains*—lately reprinted and rearranged—were published after his death, and these, along with the chapters on the poetry of Wordsworth in the *Biographia Literaria*, may be said to exhibit the full range of Coleridge's power as a critic of poetry. In this region he stands supreme. With regard to the preface, which contains Wordsworth's theory, Coleridge has honestly expressed his dissent:—"With many parts of this preface, in the sense attributed to them, and which the words undoubtedly seem to authorize, I never concurred; but, on the contrary, objected to them as erroneous in principle, and contradictory (in appearance at least) both to other parts of the same preface, and to the author's own practice in the greater number of the poems themselves." This disclaimer of perfect agreement renders the remaining portion of what he says more valuable. Whoever desires to trace the real essential characteristics of poetry must turn to these pages, where the provinces of imagination and fancy are rightly discriminated. "Here," as Principal Shairp has well said, "are canons of judgment, not mechanical but living." Coleridge was in England the creator of that higher criticism which had already in Germany accomplished so much in the hands of Lessing and Goethe. It is enough to refer here to the fragmentary series of his Shakespearian criticisms, containing evidence of the truest insight, and a marvellous appreciation of the judicial "sanity" which raises the greatest name in literature far above even the highest of the poets who approached him.

As a poet Coleridge's own place is safe. His niche in the great gallery of English poets is secure. Of no one can it be more emphatically said that he was "of imagination all compact." His peculiar touch of melancholy tenderness may prevent his attaining a high place in popular estimation. He does not possess the fiery pulse and humaneness of Burns, but the exquisite perfection of his metre and the subtle alliance of his thought and expression must always secure for him the warmest admiration of true lovers of poetic art. In his early poems may be found traces of the fierce struggle of his youth. The most remarkable is the *Monody on the Death of Chatterton* and the *Religious Musings*. In what may be called his second period, the ode entitled *France*, considered by Shelley the finest in the language, is most memorable. The whole soul of the poet is reflected in the *Ode to Dejection*. The well-known lines—

> "O Lady! we receive but what we give,
> And in our life alone does nature live;
> Ours is her wedding garment, ours her shroud,"

with the passage which follows, contain more vividly, perhaps, than anything which Coleridge has written, the expression of the shaping and colouring function which he assigns, in the *Biographia Literaria*, to imagination. *Christabel* and the *Ancient Mariner* have so completely taken possession of the highest place, that it is needless to do more than allude to them. The supernatural has never received such treatment as in these two wonderful productions of his genius, and though the first of them remains a torso, it is the noblest torso in the gallery of English literature. Although Coleridge had, for many years before his death, almost entirely forsaken poetry, the few fragments of work which remain, written in later years, show little trace of weakness, although they are wanting in the unearthly melody which imparts such a charm to *Kubla Khan*, *Love*, and *Youth and Age*.

In one of the most remarkable of his republished essays, Mr Mill has contrasted Coleridge with Bentham, and called especial attention to his position as a political theorist. Few will be tempted to dispute the justice of Mr Mill's exposition of Coleridge's views. He regards him as having in his *Lay Sermons* done his best to establish principles involved in English opinions and institutions. He admits, moreover, that in bringing into prominence the trust inherent in landed property Coleridge has done service to those who desire to conserve much of the existing system.

The fifth chapter of the work on *Church and State* contains the exposition of Coleridge's idea of a church establishment. The clerisy of the nation is with him the body of true leaders in all that concerns national life. Theology is only a part of the great province within national control—"it is no essential part of the being of the national church, however conducive, or even indispensable, it may be to its well-being." This doctrine, however novel it may have been on its first appearance, has long been adopted by those who desire to preserve the endowments of establishments. In all his political writings Coleridge is at war with what has been called the *laissez-faire* doctrine, and no one has more emphatically declared what the real objects of a state are.

In everything which Coleridge wrote, there are traces of the philosophy which had become to him a second nature. After having abandoned the teaching of Hartley, he directed his attention for a time to Leibnitz and Spinoza. But the systems of these two great men never really captivated him. It was to Kant that he owed his initiation into the higher sphere of philosophy, and it is to Kant that he repeatedly refers as to a master who had moulded his thought. It is impossible to enter here upon the question as to whether Coleridge has represented Kant's system completely. De Quincey, in one of his *Letters to a Young Man*, has referred to the modification and alteration which all things received in passing through Coleridge's thoughts, and has declared that this "indocility of mind" has led Coleridge to make various misrepresentations of Kant. A similar accusation has been preferred by Dean Mansel; but to these charges it may be answered that Coleridge nowhere professes to interpret or describe Kant's teaching. He was content to adopt the distinction between the understanding and the reason, but it was to the doctrine of the practical reason dominating and controlling speculation that he was irresistibly attracted. The immediate contemplation of truth enjoyed by the reason was the sum and substance of his speculations in this province. This doctrine constituted in Coleridge's mind the bridge of passage from metaphysics to theology. "There," to use the words of Mr Hort, in an able essay on Coleridge, "he found an assurance that man's reasoning powers are not man himself, and that he may rise above their impotence, and have direct faith in unseen realities." At a time when low and grovelling ideas had obtained great predominance, Coleridge recalled men's thoughts to the reality of spiritual truth, and attempted again to enlist interest for a reconciliation between metaphysics and ordinary modes of thought. *The Friend* contains an interesting application of the Platonic idea to induction. Coleridge declares that there is no real opposition between the method of Plato and that pursued by Bacon. It must, however, be acknowledged that the ground of his defence of Bacon hardly satisfies; and the observation of Dr Whewell, "that Bacon does not give due weight to the ideal element of our knowledge" will occur to the reader of the *Essays on Method*, however he may admire the skill and finish of Coleridge's treatment. Scattered throughout the fragmentary writings of Coleridge may be found remarkable protests against the school of moral philosophy of which Paley was the chief. The governing nature of the moral principle with him determined the quality of moral action. Morality and religion are in his system twin stars, never to be divided. The real code, imperatively demanding the subjugation of man, issues from the divine will, resident, in a measure, in each man. He eagerly disclaims, however, all theories which would claim an inherent power in reason to determine questions of civil government. His contention against Rousseau is most effective, and even at the present time must possess an interest for all engaged in political deliberation. Since the able defence of Sara Coleridge, contained in her edition of her father's *Biographia Literaria*, discussions regarding the plagiarisms of Coleridge may be said to have been forgotten. The infirmity of his character, and the mental confusion caused by the unhappy habit which so long had dominion over him, indisposed him for the exactitude rightly demanded from all who undertake philosophical discussion. An interesting communication from Schelling to Dean Stanley declares that that great thinker vindicated Coleridge from the charge of plagiarism. In the latter part of his life, more than one of those admitted to his confidence have given curious instances of his confusion between the words of an author and the *marginalia* which he had written in that author's pages. A letter to Mr Cottle, written in the year 1807, describes in an interesting way Coleridge's abandonment of Unitarianism and his final acquiescence in the creed of the church. As a theologian he contended earnestly for the self-evidencing nature of revealed religion. To historical and miraculous proof he may be said to have assigned a secondary place. Grasping the idea of the Incarnation, he held that miracles were the needful outcome of the great fact, and he taught that the adaptation of truth to the moral nature constituted its strongest evidence. For the teaching of Luther he had a profound admiration, and with the works of the great English divines he was thoroughly familiar In the *Aids to Reflection*—a work which has been the especial favourite of some of the most remarkable of recent divines—after discussing the difficulties of thought and speculation, he grapples with the moral impediments which surround the doctrines of original sin and atonement. His earnest, passionate yearning after truth is manifested in every page of this remarkable book. Whatever may be thought of the conclusions at which he arrives, the convictions of the writer, and his intense sympathy with all inquiring spirits, lift the book into a place in the affections of its readers. It is impossible almost to convey any adequate idea of the richness and variety of Coleridge's speculations on theology and religion, scattered throughout his too fragmentary works. *The Confessions of an Inquiring Spirit*, published since his death, intended not to lessen but to increase the reverence with which Christians regard the Bible, has been more misunderstood than any portion of his writings. That the real object of Coleridge was to conserve and not to destroy, now that the mists of controversy are dispelled, must be apparent to every one who peruses this little volume. Much, indeed, that seemed startling in it on its first appearance has now been accepted as matter of familiar truth.

The fame of Coleridge as a philosophic thinker is undoubtedly, at present, not so great as it was during the twenty years immediately after his death. The generation of those who "owed" to his teaching "even their own selves" has nearly passed away. But the influence which he exerted as a stimulating force, and the intellectual activity of many of his disciples, remain to testify to the greatness of the services which he rendered to philosophy and religion. He was a true lover of light, and desired that all philosophical investigation should be conducted in the independent spirit which is reflected in the noble aphorism of his *Aids to Reflection*—"he who begins by loving Christianity better than truth will proceed by loving his own sect and church better than Christianity, and end in loving himself better than all."

After Coleridge's death several of his works were edited by his nephew, Henry Nelson Coleridge, the husband of Sara, the poet's only daughter. In 1847 Sara Coleridge published the *Biographia Literaria*, enriched with annotations and biographical supplement from her own pen. Three volumes of political writings, entitled *Essays on his own Times*, were also published by Sara Coleridge in 1850. Besides the essay on Coleridge contained in the first volume of J. S. Mill's *Dissertations*, there is a very complete study of Coleridge in Principal Shairp's *Studies in Poetry and Philosophy*. Mr Hort's Essay, in the *Cambridge Essays* of 1856, is full of interest. In Archdeacon Hare's *Mission of the Comforter* will be found valuable reflections on the theological position of Coleridge. (G. D. B.)

COLERIDGE, SARA (1802–1852), was the fourth child and only daughter of Samuel Taylor Coleridge and his wife Sarah Fricker of Bristol. She was born December 22, 1802, at Greta Hall, Keswick, the residence of her parents, where they were shortly afterwards joined by Southey and his wife, who was Mrs Coleridge's sister, and by Mrs Lovell, a third sister, and widow of the young quaker poet, Robert Lovell. Here, after 1803, they all lived together; but Coleridge was often away from home; and "Uncle Southey" was a *pater familias*. The Wordsworths at Grasmere were their neighbours; and the children of the three families grew up together. Wordsworth, in his poem, the *Triad*, has left us a description, or "poetical glorification," as Sara Coleridge calls it, of the three girls—his own daughter Dora, Edith Southey, and Sara Coleridge, the "last of the three, though eldest born." Greta Hall was Sara Coleridge's home until her marriage; and the little Lake colony of poetical and speculative genius seems to have been her only school. Guided by Southey, and with his ample library at her command, she read by herself the chief Greek and Latin classics, and before she was five-and-twenty had learnt French, German, Italian, and Spanish.

In 1822 Sara Coleridge published a translation in three large volumes of Dobrizhoffer's *Account of the Abipones*, undertaken in connection with Southey's *Tale of Paraguay*, which had been suggested to him by Dobrizhoffer's volumes; and Southey alludes to his niece, the translator (canto iii, stanza 16), where he speaks of the pleasure the old missionary would have felt if

> ". . . . he could in Merlin's glass have seen
> By whom his tomes to speak our tongue were taught."

In less grandiloqent terms, Charles Lamb, writing about the *Tale of Paraguay* to Southey in 1825, says, "How she Dobrizhoffered it all out, puzzles my slender Latinity to conjecture." In 1825 her second work appeared, a translation from the mediæval French, in 2 volumes, called *The Right Joyous and Pleasant History of the Feats, Jests, and Prowesses of the Chevalier Bayard, the Good Knight without Fear and without Reproach: By the Loyal Servant.*

In September 1829, at Crosthwaite Church, Keswick, after an engagement of seven years' duration, Sara Coleridge was married to her cousin, Henry Nelson Coleridge, then a Chancery barrister in London. The first eight years of her married life were spent in a little cottage on Downshire Hill, in the town of Hampstead. There four of her children were born, of whom two survived. In 1834 Mrs Coleridge published her *Pretty Lessons in Verse for Good Children; with some Lessons in Latin in Easy Rhyme.* These were originally written for the instruction of her own children. On their publication they became very popular; and a new edition has been lately published by Henry S. King & Co. In 1837 the Coleridges removed to Chester Place, Regent's Park; and in the same year appeared *Phantasmion, a Fairy Tale,* Sara Coleridge's longest original work. An edition of this also was published in 1874 by Henry S. King & Co., with a preface by Lord-Chief-Justice Coleridge. The *Songs of Phantasmion* were much admired at the time by Leigh Hunt and other critics; and Mr Justice Coleridge is not afraid to say of them in his preface that they are "surely worthy of any great lyrical writer." Without meriting such praise as this, however, some of these songs, such as "Sylvan Stay" and "One Face Alone," are extremely graceful and musical, and the whole fairy tale is noticeable for the beauty of the story and the richness of its language.

In 1843 Mr Henry Coleridge died, leaving to his widow the unfinished task of editing her father's works. To these she added some compositions of her own, among which are the *Essay on Rationalism, with a special application to the Doctrine of Baptismal Regeneration,* appended to Coleridge's *Aids to Reflection,* a Preface to the *Essays on his Own Times, by S. T. Coleridge,* and the Introduction to the *Biographia Literaria.* During the last few years of her life Sara Coleridge was a confirmed invalid. Shortly before she died she amused herself by writing a little autobiography for her daughter. This, which reaches only to her ninth year, was completed by her daughter, and published in 1873, together with some of her letters, under the title *Memoirs and Letters of Sara Coleridge.* These letters show a cultured and highly speculative mind. They contain many apt criticisms of known people and books, and are specially interesting for their allusions to Wordsworth and the Lake Poets. Sara Coleridge died at Chester Place, May 3, 1852, and was buried by the side of her father, mother, and husband, in Highgate churchyard.

COLET, John (1466–1519) dean of St Paul's, the eldest son of Sir Henry Colet, was born at London in 1466. His education commenced in St Anthony's school in that city, from which, in 1483, he was sent to Magdalen College, Oxford. After seven years' study of logic and philosophy, he took his degree in arts. About the year 1493 he went to Paris, and thence to Italy, in order to improve himself in the Greek and Latin languages, which at that time were imperfectly taught in our universities. During his residence abroad he became acquainted with Budæus and Erasmus. On his return to England in 1497 he took orders, and settled at Oxford, where he read lectures, without fee, on the Epistles of St Paul. At this period he held the rectory of St Dennington in Suffolk, to which he had been instituted at the early age of nineteen; and he was also prebendary of York, and canon of St Martin's le Grand, London. In 1502 he became prebendary of Sarum, in 1505 prebendary of St Paul's, and immediately afterwards dean of that cathedral, having previously taken the degree of doctor of divinity. He was no sooner raised to this dignity than he introduced the practice of preaching and expounding the Scriptures; and he soon afterwards established a perpetual divinity lecture, on three days in each week, in St Paul's Church,—an institution which helped to pave the way for the Reformation. About the year 1508 Dean Colet formed his plan for the foundation of St Paul's school, which he completed in 1512, and endowed with estates of an annual value of £122 and upwards. The celebrated grammarian William Lilly was the first master, and the company of mercers were appointed trustees. The dean's religious opinions were so much more liberal than those of the contemporary clergy, that they deemed him little better than a heretic; and on this account he was so frequently molested that he at last determined to spend the rest of his days in peaceful retirement. To carry this resolution into effect he built a house near the palace of Richmond; but being seized with the sweating sickness, he died in 1519, in the fifty-third year of his age. He was buried on the south side of the choir of St Paul's, where a stone was laid over his grave, with no other inscription than his name. Besides the preferments above mentioned, he was rector of the guild of Jesus at St Paul's, and chaplain to Henry VIII. Dean Colet, though in communion with the Church of Rome, disapproved of auricular confession, of the celibacy of priests, and other tenets and ceremonies which have since been rejected by all Protestants. He wrote—*Absolutissimus de octo orationis partium constructione Libellus* (Antwerp, 1530), *Rudimenta Grammatices* (London, 1539), *Daily Devotions, Monition to a Godly Life, Epistolæ ad Erasmum,* and commentaries on different parts of the sacred books, together with a number of smaller theological works.

COLET, Louise Revoil (1808–1876), French poetess and novelist, belonged to a Provençal family, and was born at Aix. In 1834 she came to Paris; and in 1836 appeared her *Fleurs du Midi,* a volume of verse, of liberal tendency, which made some noise, and gained her the friendship of Teste and Cousin. It was followed in 1839 by *Penserosa,* a second volume of verse; by *Le Musée de Versailles,* a poem crowned by the Institute; by *La Jeunesse de Goethe,* a one-act comedy; and by *Les Cœurs Brisés,* a novel. In 1840 she published *Les Funérailles de Napoléon,* a poem, and *La Jeunesse de Mirabeau,* a reckless novel. The criticisms on her books, however, on her academical successes, and on her connection with several celebrated men about this time, exasperated her to an incredible degree; and in 1841 Paris was diverted by her attempted reprisals on Alphonse Karr for certain notices in *Les Guêpes.* In 1849 she had to defend an action brought against her by the heirs of Madame Récamier, whose correspondence with Benjamin Constant she had taken it upon herself to publish in the columns of the *Presse.* She was crowned five or six times by the Institute, a distinction which she owed, however, to the influence of Cousin rather than to the quality of her work. She produced a host of writings in prose and verse—novels, plays, anacreontics, didactic poems, travels, copy for a milliner's journal, translations from Shakespeare—singularly unequal in matter and style. Only one of her books has survived—*Lui: Roman Contemporain,* the novel in which she told the story of her life; and that, whatever value it may possess as an historical document, is worthless as a work of art. Madame Colet seems to have been a woman of some literary talent, wanting altogether in the quality of self-respect and the power of self-control.

COLIC (from κῶλον, the large intestine). By this term is generally understood an attack of pain in the abdomen, usually seated in the neighbourhood of the navel, of spasmodic character, and attended for the most part with constipation of the bowels. Various forms of this complaint are described by medical writers. The most important are simple or flatulent colic and lead colic. The former of these commonly arises from the presence in the alimentary canal of some indigestible matter, which not only excites spasmodic contraction of the muscular coats of the intestines, but also, by beginning to undergo decomposition, gives rise to the presence of gases, which painfully distend the bowels and increase the patient's suffering. The pain of colic is relieved by pressure over the abdomen, and there is no attendant fever—points which are of importance in distinguishing it from inflammation.

Attacks of this form of colic may occur in connection with a variety of causes other than that above mentioned, *e.g.*, from accumulations of feculent matter in the intestines in the case of those who suffer from habitual constipation; also as an accompaniment of nervous and hysterical ailments, and not unfrequently as the result of exposure to cold and damp, particularly where the feet become chilled as in walking through snow. Similar attacks of colic are apt to occur in young infants, especially those who are fed artificially; and in such cases it will generally be found that the food is passing through them almost wholly undigested, and that a temporary change of diet will be necessary. The duration of an attack of simple colic is seldom long, and in general no ill consequences follow from it. It is, however, not free from risk, especially that of sudden obstruction of the bowel from twisting, or invagination of one part within another (intussusception) during the spasmodic seizure, giving rise to the terrible disease known as ileus.

Of greater importance and interest in a medical point of view is the disease known as lead colic (*Syn.* painters' colic, *colica Pictonum*, Devonshire colic, dry belly-ache), from its having been clearly ascertained to be due to the absorption of lead into the system. This disease had been observed and described long before its cause was discovered. Its occurrence in an epidemic form among the inhabitants of Peitou was recorded by Francis Citois, in 1617, under the title of *Novus et popularis apud Pictones dolor colicus biliosus.* The disease was thereafter termed *colica Pictonum.* It was supposed to be due to the acidity of the native wines, but it was afterwards found to depend on lead contained in them. A similar epidemic broke out in certain parts of Germany in the end of the 17th century, and was at the time believed by various physicians to be caused by the admixture of acid wines with litharge to sweeten them.

About the middle of last century this disease, which had long been known to prevail in Devonshire, was carefully investigated by Sir George Baker, who succeeded in tracing it unmistakably to the contamination of the native beverage, cider, with lead, either accidentally from the lead-work of the vats and other apparatus for preparing the liquor, or from its being sweetened with litharge

It has subsequently been made out that this complaint is apt to affect all persons who work among lead or its preparations, especially lead-miners, manufacturers of white lead, colour-grinders, and painters, also to a less extent plumbers, potters, type-founders, &c. It is said to have occurred in persons who have slept for only a few nights in a newly-painted room. It has frequently arisen from the use of drinking water containing salts of lead in solution, as also from food and condiments adulterated with preparations of this metal, and it has even been known to follow the habitual use of cosmetics composed in part of white lead.

The colic due to lead poisoning, which in its general characteristics is essentially the same as ordinary colic, is only one of a train of symptoms produced by the absorption of lead into the body. From prolonged exposure to the action of this poison, the general nutrition of the body becomes deteriorated, and serious nervous phenomena present themselves, sometimes in the form of epilepsy and coma, but more usually as a variety of palsy. This palsy is of local character, affecting in the first instance the muscles composing the ball of the thumb, and also those muscles of the fore-arm which extend the wrist, and giving rise to the condition known as "wrist-drop," from the circumstance that when the arm is extended the hand hangs down and cannot be raised by voluntary effort. The affected muscles undergo atrophy while the paralysis continues. If the patient is removed from further exposure to the influence of the lead poison, and suitable treatment employed, complete recovery from all the ill effects may take place; but otherwise all the symptoms become aggravated, the health becomes completely ruined, and death may result.

One of the phenomena which accompany lead poisoning is the existence of a blue line along the margins of the gums where they meet the teeth. This is almost never absent, and is an important aid to the diagnosis of the disease.

The absorption of copper into the system produces a series of symptoms similar to those of lead poisoning, including a form of colic. It is of comparatively rare occurrence, being chiefly observed among workers in copper.

The treatment of colic consists in means to relieve the spasmodic pain, and in the removal, where possible, of the cause upon which it depends. The former of these indications is fulfilled by the administration of opiates (except in the case of children) and the application of warm fomentations to the abdomen. Where the attack appears to depend on accumulations of irritating matter in the alimentary canal, a brisk purgative will, in addition, be called for.

In the case of lead colic it is imperatively necessary that the patient be removed from the source of the lead poisoning. Here, too, the free evacuation of the bowels by castor oil or saline purgatives is an important part of the treatment. As an antidote to the lead absorbed into the system, the administration of iodide of potassium is recommended, while for the paralysis nerve tonics, such as quinine and strychnia, and the use of galvanism, will in general yield good results. Where the patient's occupation necessitates his exposure to the constant influence of the lead poison, as in the case of colour-grinders or manufacturers of white lead, the evil consequences can in great measure be averted by scrupulous attention to cleansing the body, particularly before eating, by abstention from eating in the work places, and by the habitual use of a drink slightly acidulated with sulphuric acid.

The terms *hepatic colic* and *renal colic* are applied to that violent pain which is produced, in the one case, where a biliary calculus or gall stone passes down from the gall bladder into the intestine, and in the other where a renal calculus descends from the kidney along the ureter into the bladder. These affections are, however, entirely different from true colic. (J. O. A.)

COLIGNI, GASPARD DE (1517–1572), admiral of France, was son of the Marshal Gaspard de Coligni and Louise de Montmorency, and was born at Chatillon-sur-Loing, the hereditary domain of his house. At twenty-two he came to court, and there contracted a friendship with Francis of Guise. In the campaign of 1543 Coligni distinguished himself greatly, and was wounded at the sieges of Montmédy and Bains. In 1544 he served in the Italian campaign under the Duc d'Enghien, and was knighted on the field of Cerisolles. Returning to France, he took part in different military operations; and having been made colonel-general of the infantry, exhibited great capacity and intelligence as a military reformer. He was soon afterwards made admiral in room of D'Annebaut. At the battle of Renty (1554) began the quarrel between him and Francis of Guise, which was to bring such evil on both their houses, and on their native land; and the enmity was increased tenfold in 1556 by the rupture, at the instance of Guise, of the Treaty of Vauxcelles. In 1557 he was intrusted with the defence of Saint Quentin. In the siege he displayed great courage, resolution, and strength of character; but the place was taken, and he was imprisoned in the stronghold of L'Ecluse. On payment of a ransom of 50,000 crowns he recovered his liberty. But he had by this time become a Huguenot, through the influence of his brother Dandelot; and he busied himself secretly with protecting his co-religionists, a colony of whom he sent to Brazil, whence they were afterwards expelled by the Portuguese. On the death of Henry II. he placed himself, with Louis, prince of Condé, in the front of his sect, and demanded religious toleration and certain other reforms. In 1560, at the Assembly of Notables at Fontainebleau, the hostility between Coligni and Francis of Guise broke violently forth; the death of Francis II. and the policy of Catharine precipitated matters to an issue; the civil war began; and the battle of Dreux (1562), clearing the ground of the Constable Montmorency and the prince of Condé, set the two great rivals at the head of their respective parties. In 1563, however, the Pacification of Amboise was effected; Francis of Guise was assassinated; and peace was maintained for some years. The Huguenot attempt to seize on the person of Charles IX. at Monceaux brought about a resumption of hostilities. At St Denis (1567) Coligni defeated Montmorency; in 1569 he was defeated at Jarnac by the duke of Anjou, and repaired with the remains of his army to Cognac. There he was joined by the prince of Navarre, who was forthwith placed at the head of the Protestant party; the two laid siege to Poitiers, which was defended by Henry of Guise; but the siege was raised, and the Huguenots were routed at Moncontour (1569) with terrible slaughter. A price of 50,000 crowns was set upon the admiral's head; but the peace of St Germain was concluded in 1570, and he returned to court. He grew rapidly in favour with Charles IX. As a means of emancipating the king from the tutelage of his mother and the faction of the Guises, the admiral proposed to him a descent on Spanish Flanders, with an army drawn from both sects, and commanded by Charles in person. The king's regard for the admiral, and the bold front of the Huguenots, alarmed the queen mother; and the massacre of St Bartholomew was the consequence. On 22d August 1572 Coligni was shot in the street by Maurevert, a bravo in the pay of Henry of Guise; the bullets, however, only tore a finger from his right hand and shattered his left elbow. The king visited him, but the queen mother prevented all private intercourse between them. On the 24th August, the night of the massacre, he was attacked in his house by the minions of Guise, led by a German named Behme, who slew him and cast him from a window into the courtyard at their master's feet. His body was gibbeted at Montfaucon; it was, however, carried off by his retainers, and buried at Chatillon, where it remained till 1786, when Montesquieu had it reinterred at his own estate of Maupertuis. His papers were seized and burned by the queen mother; among them, according to Brantôme, was a history of the civil war "très-beau et très-bien faict, et digne d'estre imprimé."

COLIMA, the capital of the state of Colima, Mexico, in 19° N. lat. and 103° 7′ W. long. The town is situated in a fertile and well-watered plain. It has regular streets, mostly paved, a Government house, a college, several schools and churches, and two squares, and is a place of considerable trade in linens, woollens, cotton goods, and hardware. The population exceeds 31,000. Colima was founded by Gonzalo de Sandoval in 1522, received incorporation from Philip II., and attained the rank of a city in 1824. Thirty miles to the N.E. is the volcano of Colima, the most westerly in Mexico, and 12,000 feet in height. For some days previous to the earthquake which visited the Pacific coast of Mexico on the 20th December 1868, the volcano emitted smoke and steam; and in 1869, after 40 years' inactivity, there was another eruption. Manzanilla, the port of Colima, about 60 miles west of that town, has a good anchorage, and is sheltered from the south winds prevalent during the rainy season; but, on account of the proximity of a stagnant marsh, it is an unhealthy place; and it abounds, moreover, with mosquitoes and sandflies.

COLIN, Alexander (1526–1612), a Flemish sculptor, was born at Mechlin. In 1563 he went, at the invitation of the emperor Ferdinand I., to Innsbruck, to work on the magnificent monument which was being erected to Maximilian I. in the nave of the Franciscan church. Of the twenty-four marble alti-rilievi, representing the emperor's principal acts and victories, which adorn the sides of this tomb, twenty were executed by Colin, apparently in three years. The work displays a remarkable combination of liveliness and spirit with extreme care and finish, its delicacy rivalling that of a fine cameo. Thorwaldsen is said to have pronounced it the finest work of its kind. Colin, who was sculptor in ordinary both to the emperor and to his son, the archduke Ferdinand, did a great deal of work for his patrons at Innsbruck, and in its neighbourhood; particular mention may be made of the sepulchres of the archduke and his first wife Philippa, both in the same church as the Maximilian monument. His tomb in the cemetery at Innsbruck bears a fine bas-relief executed by himself.

COLLAERT, Hans, a Flemish engraver, was the son of Adrian Collaert, a draughtsman and engraver of repute, and was born at Antwerp about 1545. After working some years in his father's studio, he went to Rome to perfect himself in his art. His engravings after Rubens are very highly esteemed. He left many works; among the best may be mentioned a Life of Saint Francis, 16 prints; a Last Judgment, folio; Monilium, Bullarum, Inauriumque Artificiosissimæ Icones, 10 prints, 1581; The Dead Christ in his Mother's Lap; Marcus Curtius; Moses Striking the Rock, and The Resurrection of Lazarus, after Lambert Lombard; the Fathers of the Desert; and Biblia Sacra and the History of the Church, after Rubens.

COLLÉ, Charles (1709–1783), dramatist and song-writer, was the son of a notary, and was born at Paris. At a very early age he began to study the writings of Marot and La Fontaine, of Chapelle and Molière, to take delight in the theatre, and to be specially interested in the rhymes of Jean Heguanier, then the most famous maker of couplets in Paris. From a notary's office Collé, who seems to have had little taste for legal studies, was transferred to that of M. de Meulan, the receiver-general of finance. When about seventeen, however, he made the acquaintance of Piron, and afterwards, through Gallet, of Panard. The example of these three masters of the vaudeville, while determining his vocation, made him diffident; and for some time he composed nothing but *amphigouris*—verses whose merit was measured by their unintelligibility. The friendship of the younger Crébillon, however, diverted him from this byway of art, and the establishment in 1729 of the famous "Caveau" gave him a field for the display of his fine talent for popular song. In 1739 the Society of the Caveau, which numbered among its members Helvetius, Duclos, Gentil-Bernard, Boucher, Rameau, Piron, and the two Crébillons, was dissolved, and was not reconstituted till twenty years afterwards. Meanwhile, the Regent Orleans, who was an excellent comic actor, particularly in representations of low life, and who had been looking out for an author to write suitable parts for him, made Collé his secretary. It was for the duke and his associates that Collé composed the greater part of his *Théâtre de Société.* Based on the stories of the younger Crébillon and La Fontaine, all the pieces in this collection, while remarkable for ease and gaiety, in point of delicacy are such as might be expected from their source and their avowed object. In 1763, however, Collé, whose jestings the duke had rewarded with a place under Government, produced at the Théâtre Français *Dupuis et Desronais,* a sentimental comedy, which met with a decided success, and which was followed in 1771 by *La Veuve,* an attempt in the same direction, and a complete failure. In 1774 appeared *La Partie de Chasse de Henri Quatre* (partly taken from Dodsley's *King and the Miller of Mansfield*), Collé's last and best play. From 1758 to 1782, besides these and a multitude of songs, Collé was writing his *Journal Historique,* a curious collection of literary and personal strictures and animadversions on his boon companions as well as on their enemies, on Piron as on Voltaire, on La Harpe as on Corneille. In 1783, having outlived the greater part of his old friends, and grieving for the loss of his wife, to whom he was greatly attached, Collé died. He is best remembered by his lyrics, which form an important link in the chain of style through which the *chanson,* that peculiarly French form of the song, has passed. They are frank and jovial, though often licentious, and are remarkable for wit and amiability no less than for the artistic management of the refrain and for their popular attractions. The subjects are love and wine; occasionally, however, as in the famous lyric (1756) on the capture of Port Mahon, for which the author received a pension of 600 livres, the note of patriotism is struck with no unskilful hand, while in many others Collé shows himself possessed of considerable epigrammatic force. See Grimm's *Correspondance;* and Taillefer's *Tableau Historique de l'Esprit et du Caractère des Littératures Françaises.*

COLLE, Rafaelle del, painter, was born at Colle, near Borgo San Sepolcro, in Tuscany, about 1490. A pupil of Raphael, whom he is held to have assisted in the Farnesina and the Vatican, Colle, after his master's death, was the assistant of his chief scholar, Giulio Romano, at Rome and afterwards at Mantua. In 1536, on the occasion of the entry of Charles V. into Florence, he took service in that city under Vasari, whose written works are many degrees superior to his paintings. In his later years Colle resided at Borgo San Sepolcro, where he kept a school of design; among his many pupils of note may be mentioned Gherardi and Vecchi. His works, which are yet to be found at Urbino, at Perugia, at Pesaro, and at Gubbio, are fine examples of the Roman school of Raphael. The best are a painting of the Almighty supported by angels, a Resurrection, and an Assumption, all preserved in churches at Borgo San Sepolcro.

COLLEGE (*Collegium*), in Roman law signified a number of persons associated together by the possession of common functions,—a body of colleagues. Its later meaning applied to any union of persons, and *Collegium* was the equivalent of *ἑταιρεία.* In many respects, *e.g.,* in the distinction between the responsibilities and rights of the society and those of individual members thereof, the collegium was what we should now call a corporation (see Corporation). Collegia might exist for purposes of trade like our guilds, or for religious purposes (*e.g.,* the college of augurs, of pontifices, &c.), or for political purposes, *e.g.,* tribunorum plebis collegia. By the Roman law a collegium must have at least three members. The name is now usually applied to educational corporations, the most important of which are the colleges of Oxford and Cambridge. In the numerous statutes relating to colleges the colleges of Winchester and Eton are usually associated with those of Oxford and Cambridge.

These colleges are in the eye of the law eleemosynary corporations. In some of the earlier statutes of Queen Elizabeth they are spoken of as having an ecclesiastical character, but the doctrine of the common law since the Reformation has been that they are purely lay corporations, notwithstanding that most or all of their members may be persons in priest's orders. This is said to have been settled by Patrick's case (see Raymond's *Reports*).

Colleges appear to have grown out of the voluntary association of students and teachers at the university. According to some accounts these must at one time have been numerous and flourishing beyond anything we are now acquainted with. We are told, for example, of 300 halls or societies at Oxford, and 30,000 students. Into the truth of these statements, or into the causes which led to the reduction in the number of scholars, we need not now enter. In early times there seems to have been a strong desire to confine the scholars to certain licensed houses, beyond the influence of the townspeople. Men of wealth and culture, and notably the political bishops and chancellors of England, obtained charters from the Crown for the incorporation of societies of scholars, and these in time became exclusively the places of abode for students attending the university. At the same time the corporations thus founded were not necessarily attached to the locality of the university. The early statutes of Merton College, for example, allow the residence of the college to be shifted as occasion required; and the foundations of Wolsey at Oxford and Ipswich seem to have been the same in intention. In later times the university and the colleges became coextensive; every member of the university had to attach himself to some college or hall, and every person admitted to a college or hall was obliged to matriculate himself in the university.

In Ayliffe's *Ancient and Present State of the University of Oxford* it is stated that a college must be "made up of three persons (at least) joined in community. And the reason of this almost seems to speak its own necessity, without the help of any express law to countenance it; because among two persons only there cannot be, in fact, a major part; and then if any disagreement should happen to arise between them it cannot be, in fact, brought to a conclusion by such a number alone in case both the parties should firmly adhere to their dissenting opinions; and thus it is declared by the civil law. But by the canon law it is known to be otherwise; for by that law two persons in number may make and constitute a college, forasmuch as according to this law two persons make and constitute an assembly or congregation. The common law of England, or rather the constant usage of our princes in erecting aggregate bodies, which has established this rule among us as a law, has been herein agreeable to the method and doctrine of the civil law, for that in all their grants and charters of incorporation of colleges they have not framed any aggregate body consisting of less than three in number." Another principle, apparently derived from the civil law, is that a man cannot be a fellow in two colleges at the same time. The law of England steadily resisted any attempt to introduce the principle of inequality into colleges. An Act of Henry VIII. (33, c. 27), reciting that divers founders of colleges have given in their statutes a power of veto to individual members, enacts that every statute made by any such founder, whereby the grant or election of the governor or ruler with the assent of the most part of such corporation should be in any wise hindered by any one or more being the lesser number (contrary to the common law), shall be void.

The corporation consists of a head or master, fellows, and scholars. Students, not being on the foundation, residing in the college, are not considered to be members of the corporation. The governing body in all cases is the head and fellows.

It is considered essential to corporations of an ecclesiastical or educational character that they should have a visitor whose duty it is to see that the statutes of the founder are obeyed. The duties of this officer have been ascertained by the courts of law in a great variety of decided cases. Subject to such restrictions as may be imposed on him by the statutes of the college, his duties are generally to interpret the statutes of the college in disputed cases, and to enforce them where they have been violated. For this purpose he is empowered to "visit" the society—usually at certain stated intervals. In questions within his jurisdiction his judgment is conclusive, but his jurisdiction does not extend to any cases under the common laws of the country, or to trusts attached to the college. Generally the visitorship resides in the founder and his heirs unless he has otherwise appointed, and in default of him in the Crown.

The fellowships, scholarships, &c., of colleges were until a comparatively recent date subject to various restrictions. Birth in a particular county, education at a particular school, relationship to the founder, and holy orders, are amongst the most usual of the conditions giving a preferential or conclusive claim to the emoluments. Most of these restrictions have been or are being swept away. See Universities.

The colleges of the English universities are large landowners. A royal commission in 1874 reported the external income of the colleges of Oxford to be £307,369, 17s. 2d., and of Cambridge £264,256, 17s. 10½d. These sums are mainly derived from landed property, and are exclusive of the revenues of the universities. By several Acts of Parliament colleges are allowed to sell their real property with the consent of the copyhold commissioners, who take care that the purchase-money is laid out in other real property. In college and other corporation property a system of letting land under beneficial leases—*i.e.*, at less than the full yearly rent, and recoverable every seven years on payment of a fine—has long prevailed, and is believed to be responsible for the alleged inferior condition of land belonging to corporations. The system is now being superseded by leases at rack-rent.

At Oxford, in addition to the colleges, there are four or five halls, which differ from colleges mainly in not being corporate bodies. Their property is held in trust for them by the university.

In England the colleges have through their tutors and lecturers supplied nearly all the teaching of the universities—the lectures of the professors being either supernumerary or merely ornamental. Of late years colleges have combined their forces for the purpose of establishing common systems of lectures, and there has been a strong desire to reconstitute the teaching power of the universities. Commissions are now being proposed for Oxford and Cambridge, which will have to settle these and other problems of the higher education.

Most of the colleges of Oxford and Cambridge are old foundations—only a few dating from times posterior to the Reformation. Among recent foundations are Downing College at Cambridge, Keble College at Oxford (which is governed by a board or council of trustees), and the restoration of Magdalen Hall at Oxford, now endowed and incorporated under the name of Hertford College.

Among educational corporations under the same title elsewhere, Phillimore (*Ecclesiastical Law*) mentions King's College and University College, London, Sion College, St Bees, St David's, Lampeter, &c. The distinction between college and university is found also at St Andrews, and in the more recently founded university of Durham and the Queen's University in Ireland.

COLLIER, Arthur (1680–1732), metaphysician and divine, was born at the rectory of Langford Magna, near Sarum, on 12th October 1680. There is no account of his childhood and early youth; but it is probable that, after receiving some rudimentary instruction at home, he went to one of the grammar schools at Salisbury. He entered at Pembroke College, Oxford, in July 1697, and remained there till October in the following year, when he and his brother William became members of Balliol together. His father died in 1697, and as the family owned the advowson of Langford Magna, it was arranged, after some difficulties raised by Burnet, then bishop of Salisbury, that the benefice should be held by a clergyman until Arthur was old enough to be inducted. He was accordingly presented to the benefice in 1704, and continued in it till his death in 1732. Although a bold speculator in theology, his sermons intended for his parish show no traces of his peculiar notions, and he seems to have been faithful in the discharge of his duty. He was often in pecuniary difficulties, from which at last he was obliged to free himself by selling the reversion of Langford rectory to Corpus Christi College, Oxford, a misfortune which his biographer attributes to his "habits of abstruse speculation, which seem to have unfitted him for all considerations of worldly prudence." Collier's philosophical opinions took shape early in his mind. They grew out of a diligent study of the writings of Descartes and Malebranche. Norris of Bemerton, a neighbouring clergyman, also strongly influenced him by his *Essay on the Ideal World*. It is remarkable that Collier makes no reference to Locke, nor shows the least sign of having any knowledge of his works. As early as 1703 Collier seems to have become convinced of the non-existence of an external world. There is among his MSS., under date January 1708, an outline of an essay in three chapters on the question whether the visible world is external or not. In 1712 he wrote two essays, which are still in manuscript, one on substance and accident, and the other termed *Clavis Philosophica*. The work on which his philosophical reputation depends appeared in 1713, under the title *Clavis Universalis, or a New Inquiry after Truth, being a Demonstration of the Non-Existence or Impossibility of an External World*. It has been favourably mentioned by Reid, Stewart, and others, was frequently referred to by the Leibnitzians, and was translated into German by Professor Eschenbach in 1756. Berkeley's *Principles of Knowledge* and his *Theory of Vision* preceded it by three and four years respectively. Although there is no evidence that they were known to Collier before the publication of his book, a passage in a letter written by him in March 1713–14 proves that he was acquainted in some measure with Berkeley's opinions at that date. In this letter and other four, which are given in Benson's *Memoirs of Collier* (1837), there are some further remarks in defence of his philosophical views; but they are merely a repetition of the arguments in the *Clavis*. These are grounded on two presuppositions—first, the utter aversion of common sense to any theory of representative perception; and second, the opinion which Collier held in common with Berkeley, and Hume afterwards, that the difference between imagination and sense perception is only one of degree. The former is the basis of the negative part of his argument;

the latter supplies him with all the positive account he has to give, and that is meagre enough. The *Clavis* consists of two parts. After some introductory remarks, in which he explains that he will use the term "external world" in the sense of absolute, self-existent, independent matter, and fences the position he is to occupy against sundry possible misinterpretations, he attempts in the first part to prove that the visible world is not external, by showing—first, that the seeming externeity of a visible object is no proof of real externeity, and second, that a visible object, as such, is not external. The image of a centaur seems as much external to the mind as any object of sense; and since the difference between imagination and perception is only one of degree, God could so act upon the mind of a person imagining a centaur, that he would perceive it as vividly as any object can be seen. Descartes and his school affirm that certain objects of sense, as sounds, smells, &c., exist only in their respective faculties, although no one can doubt that they *seem* to exist altogether without them. The same philosophers agree that light and colours, which are allowed to be objects properly visible, are not external. Still they seem to be so. The delusions of the insane and the visions of inspired men are further instances of seeming externality which is not real. So is the familiar case of objects seen in a looking-glass. A number of similar illustrations are used to prove the second proposition, that a visible object, as such, is not external. If we assume, for instance, that there is an external moon, it cannot be the same as the visible moon, for this is ever-changing and is never bigger than a trencher; but the real moon is some thousands of miles in diameter. Berkeley uses the same argument in his *Alciphron* (1732). Then, too, the Aristotelian and the Cartesian forms of representative perception agree in holding that the true object of vision is not the external reality. The author concludes his first part by replying to objections based on the universal consent of men, on the assurance given by touch of the extra existence of the visible world, and on the truth and goodness of God (Descartes), which would be impugned if our senses deceived us. Collier argues naively that if universal consent means the consent of those who have considered the subject, it may be claimed for his view. He thinks with Berkeley that objects of sight are quite distinct from those of touch, and that the one therefore cannot give any assurance of the other; and he asks the Cartesians to consider how far God's truth and goodness are called in question by their denial of the externality of the secondary qualities. The second part of the book is taken up with a number of metaphysical arguments to prove the impossibility of an external world. The pivot of this part is the logical principle of contradiction. From the hypothesis of an external world a series of antinomies are deduced, such as that the world is both finite and infinite, is movable and immovable, &c.; and finally, Aristotle and various other philosophers are quoted, to show that the external matter they dealt with, as mere potentiality, is just nothing at all. Among other uses and consequences of his treatise, Collier thinks it furnishes an easy refutation of the Romish doctrine of transubstantiation. If there is no external world, the distinction between substance and accidents vanishes, and these become the sole essence of material objects, so that there is no room for any change whilst they remain as before. Sir William Hamilton thinks that the logically necessary advance from the old theory of representative perception to idealism was stayed by anxiety to save this miracle of the church; and he gives Collier credit for being the first to make the discovery.[1] Professor Ueberweg, on the other hand, is of opinion that idealism and the miracle of the eucharist may be reconciled by regarding substance not as substrate supporting the accidents, but as intelligible essence; so that when in the religious act the body and blood of Christ are conjoined with the bread and wine, these cease to be essential and become accidents, and a different substance is present.[2] But in that form of idealism which recognizes an intelligible essence there must be such a necessary connection between essence and phenomenon as would require the presence of new phenomena along with the new essence. Still it must have been some deeper cause than concern for the church dogma that retarded idealism. Until philosophers could be brought to reflect on the meaning of such notions as externality, cause, &c., it was inevitable that they should continue striving to justify the belief in an external material world. Collier's blank denial would not have turned the stream. It needed a more subtle thinker to divert it into the course which it afterwards followed.

Collier's book possesses an interest for the student of philosophy on account of the resemblance between his views and those of his contemporary Berkeley. Both were impelled to philosophize by their dissatisfaction with the theory of representative perception. Both have the feeling that it is inconsistent with the common sense of mankind, which will insist that the very object perceived is the sole reality, and both claim to substitute for the theory held in favour, and vainly sought to be demonstrated by their predecessors, another that will meet the demands of common sense. They equally affirm that the so-called representative image is the sole reality, and discard the unperceiving material cause of the philosophers as an unthinkable monstrosity. Of objects of sense, they say, their *esse* is *percipi*. But Collier never got beyond a bald assertion of the fact, while Berkeley addressed himself to an explanation of it, which gave him ever profounder matter for philosophical reflection all his days. The thought of a distinction between direct and indirect perception never dawned upon Collier's mind. He could only meet the doctrine of the representationists, therefore, with a flat negation. To the question how all matter exists in dependence on percipient mind he could only reply, "Just how my reader pleases, provided it be somehow." As cause of our sensations and ground of our belief in externality, he substituted for an unintelligible material substance an equally unintelligible operation of divine power. But his illustrious contemporary gave a fresh start to philosophy by his exposition of the association between visual and tactual sensations; and his glimpses, faint at first, gradually grew more distinct of an intelligible order in the universe. Collier's book exhibits no traces of a scientific development. In the first part, which may be compared with Berkeley's *Theory of Vision*, he merely brings together a few instances of visual experience, which throw discredit upon the popular opinion. The most that can be said about him is that he was an intelligent student of Descartes and Malebranche, and had the ability to apply the results of his reading to the facts of his experience. He starts no original conception, contributes nothing to the development of philosophy. The latter half of his book reads like the ingenious quibbling of the schoolmen. In philosophy he is a curiosity, and nothing more. His biographer tries to make out that the *Clavis* fell flat on the English public in comparison with the reception accorded to Berkeley's writings, on account of its inferiority in point of style. No doubt it is immensely inferior in that respect; but the crudeness of Collier's thought had quite as much to do with his failure to gain a hearing. Hamilton[3] allows greater sagacity to Collier than to Berkeley, for not vainly attempting to enlist men's natural belief against the hypothetical realism of the philosophers. But Collier did so as far as his light enabled him. He appealed to the popular conviction that the proper object of sense is the sole reality, although he despaired of getting men to give up their belief in its externality. He moreover distinctly asserted that nothing but prejudice prevented them from doing so; and there is little doubt that if it had ever occurred to him, as it did to Berkeley, to explain the genesis of the notion of externality, he would have been more hopeful of commending his theory to the popular mind. What Collier simply denied Berkeley tried to explain, and therein lies that real difference between the two writers which accounts for the comparative oblivion that has been the fate of the one, and justifies the place assigned to the other in the history of philosophy.

In a curious discourse on Genesis i. 1, which Collier published in 1730, under the modest title, *A Specimen of a True Philosophy*, we have a jumble of his theological views and his philosophical opinions. Inasmuch as we are often told in Scripture that God created all

things in and by the Son, the $\dot{\alpha}\rho\chi\dot{\eta}$ of the passage commented on must refer to the only begotten Son of God. If then we exist in God, because we are made by Him, as St Paul says, "in him we live, and move, and have our being," we must believe that we exist more immediately in the Son, being told, as in the text, that God made us and all things by and in His Son. Christ, the $\dot{\alpha}\rho\chi\dot{\eta}$ of the whole creation, must needs be in some sense the subject or object of all that is called science. Things, however, do not exist immediately in Christ, but at various distances and projections from Him. Everything in particular is in its own proper or immediate $\dot{\alpha}\rho\chi\dot{\eta}$ or substance; but all these terminate in one, the Son of God, the substance of the whole creation. This interpretation of the passage is corroborated by the conclusion reached in the *Clavis Universalis;* for it is there proved that the visible or material world exists immediately in the mind of the percipient, and hence the meaning of the text must be that mind or spirit is the $\dot{\alpha}\rho\chi\dot{\eta}$ in which God created the heaven and the earth. As the objects of sense exist immediately in the mind, so the mind exists immediately in the Son of God; and thus the ladder of being is completed in this *Specimen of a True Philosophy.*

The Logology, or a Treatise on the Logos, in Seven Sermons on John i. 1, 2, 3, and 14, was published in 1732, the year of Collier's death. It further applies his theory of inexistence to the Son, who is said to be in the Father, as men are in Him, and material objects are in them. The Son is the "mean proportional" between God and us. Collier was heterodox in regard to the incarnation, as well as the Trinity, maintaining "that the pre-existent Word, or Son of God, was not united to a created human soul or spirit, but was himself the man called Jesus and the Christ."

COLLIER, Jeremy (1650–1726), a learned English nonjuring divine, born at Stow-cum-Quy, Cambridgeshire, in 1650, and was educated at Caius College, Cambridge. His first appointment was to the small rectory of Ampton, near Bury St Edmunds, which, after six years, he resigned in order to proceed to London, where in 1685 he was made lecturer of Gray's Inn. The change of Government at the Revolution, however, soon rendered the public exercise of his function impracticable. He was committed to Newgate for writing in favour of the dethroned monarch, and again on a charge of carrying on a treasonable correspondence with the enemies of the popular movement; but he was released on both occasions without trial, by the intervention of his friends. So far did he carry his scruples at this period, that he submitted to confinement rather than make a tacit acknowledgment of the jurisdiction of the court by accepting his liberty upon bail. In the two following years he continued to harass the Government by his publications; but for his boldness in granting absolution at their execution to Sir John Friend and Sir William Perkins, who had attempted the assassination of William, he was obliged to flee, and for the rest of his life continued under sentence of outlawry. When the storm had blown over he returned to London, and employed his leisure in literary works, which were less political in their tone. In 1697 appeared the first volume of his *Essays on Several Moral Subjects,* to which a second was added in 1705, and a third in 1709. All three series enjoyed great popularity at the time of their appearance. It was in 1798, however, that Collier produced the book by which he is best known, and for which he has been most justly praised, the famous *Short View of the Immorality and Profaneness of the English Stage.* Its publication involved him in a lengthened controversy with Congreve, Vanbrugh, and the other wits of the day. The book abounds in hypercriticism and in useless display of learning, neither intrinsically valuable nor conducive to the argument. Yet, in the words of Macaulay, who gives an admirable account of the discussion in his essay on the Comic Dramatists of the Restoration, "when all deductions have been made, great merit must be allowed to the work. There is hardly any book of that time from which it would be possible to select specimens of writing so excellent and so various." The *Short View* was followed by a *Defence,* a *Second Defence,* and a *Farther Vindication,* and in 1703 by *Mr Collier's Dissuasive from the Playhouse, in a Letter to a Person of Quality.* The fight lasted in all some ten years; but Collier had right on his side, and triumphed; and the reformation of the English stage, so greatly needed, may be said to date from the publication of the *Short View.* From 1701 to 1721 Collier was employed in the translation and publication (in six volumes folio) of Moreri's *Dictionnaire Historique,* and in the compilation and issue of the two volumes folio of his own *Ecclesiastical History of Great Britain.* The latter work was attacked by Burnet and others, but the author showed himself as keen a controversialist as ever. Many attempts were made to shake his fidelity to the lost cause of the Stuarts, but he continued indomitable to the end. His last work was a volume of *Practical Discourses,* published in 1725. He died April 26, 1726.

COLLINGWOOD, Cuthbert (1750–1810), the first Baron Collingwood, a celebrated naval commander, was born at Newcastle-upon-Tyne, on the 26th of September 1750. He was early sent to school; and when only eleven years of age he was put on board the "Shannon," then under the command of Captain (afterwards Admiral) Brathwaite, a relative of his own, to whose care and attention he was in a great measure indebted for that nautical knowledge which shone forth so conspicuously in his subsequent career. After serving under Captain Brathwaite for some years, and also under Admiral Roddam, he went in 1774 to Boston with Admiral Graves, who in the year following presented him with a lieutenancy. In 1779 he was made commander of the "Badger," and shortly afterwards post-captain of the "Hinchinbroke," a small frigate. In the spring of 1780 that vessel, under the command of Nelson, was employed upon an expedition to the Spanish Main, where it was proposed to pass into the Pacific by navigating boats along the River San Juan and the Lakes Nicaragua and Leon. The attempt failed, and most of those engaged in it became victims to the deadly influence of the climate. Nelson was promoted to a larger vessel, and Collingwood succeeded him in the command. It is a fact worthy of record that the latter succeeded the former very frequently from the time when they first became acquainted, until the star of Nelson set at Trafalgar—giving place to that of Collingwood, less brilliant certainly, but not less steady in its lustre.

After commanding in another small frigate, Collingwood was promoted to the "Sampson" of sixty-four guns; and in 1783 he was appointed to the "Mediator," destined for the West Indies, where, with Nelson, who had a command on that station, he remained till the end of 1786. With Nelson he warmly co-operated in carrying into execution the provisions of the navigation laws, which had been infringed by the United States, whose ships, notwithstanding the separation of the countries, continued to trade to the West Indies, although that privilege was by law exclusively confined to British vessels. In 1786 Collingwood returned to England, where, with the exception of a voyage to the West Indies, he remained until 1793, in which year he was appointed captain of the "Prince," the flag-ship of Rear-Admiral Bowyer. About two years previous to this event he had married Miss Sarah Roddam—a fortunate alliance, which continued to be a solace to him amidst the privations to which the life of a seaman must ever be subject.

As captain of the "Barfleur," Collingwood was present at the celebrated naval engagement which was fought on the 1st of June 1794; and on that occasion he displayed equal judgment and courage. On board the "Excellent" he shared in the victory of the 14th of February 1797, when Sir John Jarvis humbled the Spanish fleet off Cape St Vincent. His conduct in this engagement was the theme of universal admiration throughout the fleet, and greatly advanced his fame as a naval officer. After blockading Cadiz for some time, he returned for a few weeks to Portsmouth to repair. In the beginning of 1799 Collingwood was raised to the rank of vice-admiral, and hoisting his flag in the "Triumph," he joined the Channel Fleet, with which he proceeded to the Mediterranean, where the principal naval forces of France and Spain were assembled. Collingwood continued actively employed in watching the enemy, until the peace of Amiens restored him once more to the bosom of his family.

The domestic repose, however, which he so highly relished, was cut short by the recommencement of hostilities with France, and in the spring of 1803 he quitted the home to which he was never again to return. The duty upon which he was employed was that of watching the French fleet off Brest, and in the discharge of it he displayed the most unwearied vigilance. Nearly two years were spent in this employment; but Napoleon had at length matured his plans and equipped his armament, and the grand struggle which was to decide the fate of Europe and the dominion of the sea was close at hand. The enemy's fleet having sailed from Toulon, Admiral Collingwood was appointed to the command of a squadron, with orders to pursue them. The combined fleets of France and Spain, after spreading terror throughout the West Indies, returned to Cadiz. On their way thither they bore down upon Admiral Collingwood, who had only three vessels with him; but he succeeded in eluding the pursuit, although chased by sixteen ships of the line. Ere one half of the enemy had entered the harbour he drew up before it and resumed the blockade, at the same time employing an ingenious artifice to conceal the inferiority of his force. But the combined fleet was at last compelled to quit Cadiz; and the battle of Trafalgar immediately followed. The brilliant conduct of Admiral Collingwood upon this occasion has been much and justly applauded. The French admiral drew up his fleet in the form of a crescent, and in a double line, every alternate ship being about a cable's length to windward of her second, both ahead and astern. The British fleet bore down upon this formidable and skilfully arranged armament in two separate lines, the one led by Nelson in the "Victory," and the other by Collingwood in the "Royal Sovereign." The latter vessel was the swifter sailer, and having shot considerably ahead of the rest of the fleet, was the first engaged. "See," said Nelson, pointing to the "Royal Sovereign" as she penetrated the centre of the enemy's line, "see how that noble fellow Collingwood carries his ship into action!" Probably it was at the same instant that Collingwood, as if in response to the observation of his great commander, remarked to his captain, "What would Nelson give to be here?" The consummate valour and skill evinced by Collingwood had a powerful moral influence upon both fleets. It was with the Spanish admiral's ship that the "Royal Sovereign" closed; and with such rapidity and precision did she pour in her broadsides upon the "Santa Anna," that the latter was on the eve of striking in the midst of thirty-three sail of the line, and almost before another British ship had fired a gun. Several other vessels, however, seeing the imminent peril of the Spanish flag-ship, came to her assistance, and hemmed in the "Royal Sovereign" on all sides; but the latter, after suffering severely, was relieved by the arrival of the rest of the British squadron; and not long afterwards the "Santa Anna" struck her colours. The result of the battle of Trafalgar, and the expense at which it was purchased, are well known. On the death of Nelson, Collingwood assumed the supreme command; and by his skill and judgment greatly contributed to the preservation of the British ships, as well as of those which were captured from the enemy. He was raised to the peerage, as Baron Collingwood of Coldburne and Heathpool, and received the thanks of both Houses of Parliament, with a pension of £2000 per annum.

From this period until the death of Lord Collingwood no great naval action was fought; but he was much occupied in important political transactions, in which he displayed remarkable tact and judgment. Being appointed to the command of the Mediterranean fleet, he continued to cruise about, keeping a watchful eye upon the movements of the enemy. His health, however, which had begun to decline previously to the action of Trafalgar in 1805, seemed entirely to give way, and he repeatedly requested Government to be relieved of his command, that he might return home; but he was urgently requested to remain, on the ground that his country could not dispense with his services. This conduct has been regarded as harsh; but the good sense and political sagacity which he displayed afford some palliation of the conduct of the Government; and the high estimation in which he was held is proved by the circumstance that among the many able admirals, equal in rank and duration of service, none stood so prominently forward as to command the confidence of ministers and of the country to the same extent as he did. After many fruitless attempts to induce the enemy to put to sea, as well as to fall in with them when they had done so (which circumstance materially contributed to hasten his death), he expired on board the "Ville de Paris," then lying off Port Mahon, on the 7th of March 1810.

Lord Collingwood's merits as a naval officer were in every respect of the first order. In original genius and romantic daring he was inferior to Nelson, who indeed had no equal in an age fertile in great commanders. In seamanship, in general talent, and in reasoning upon the probability of events from a number of conflicting and ambiguous statements, Collingwood was equal to the hero of the Nile; indeed, many who were familiar with both give him the palm of superiority. His political penetration was remarkable; and so high was the opinion generally entertained of his judgment, that he was consulted in all quarters, and on all occasions, upon questions of general policy, of regulation, and even of trade. He was distinguished for benevolence and generosity; his acts of charity were frequent and bountiful, and the petition of real distress was never rejected by him. He was an enemy to impressment and to flogging; and so kind was he to his crew, that he obtained amongst them the honourable name of father. Between Nelson and Collingwood a close intimacy subsisted, from their first acquaintance in early life till the fall of the former at Trafalgar; and they lie side by side in the cathedral of St Paul's. The selections from the public and private correspondence of Lord Collingwood, published in 2 vols., 8vo, in 1828, contain some of the best specimens of letter-writing in our language. See also *A Fine Old English Gentleman exemplified in the Life and Character of Lord Collingwood, a Biographical Study*, by William Davies, London, 1875.

COLLINS, Anthony (1676–1729), an English writer on theology and philosophy, born at Heston, near Hounslow in Middlesex, on the 21st June 1676, was the son of a country gentleman of good fortune. After being educated at Eton, and at King's College, Cambridge, he was entered at the Middle Temple, but he did not pursue the profession of the law. The most interesting episode of his life was his intimacy with Locke, who in his letters speaks of him with the most affectionate regard. During a visit to Holland, made, it is said, in order to escape the storm raised by the *Discourse of Freethinking*, he also made the acquaintance of Leclerc and several other Dutch scholars. In 1715 he settled in Essex; and he was in that county appointed to the offices of justice of the peace and deputy-lieutenant, which he had before held in Middlesex. His open expression of his opinions, with all its freedom, was, as he owns, carefully kept "within the bounds of doing himself no harm;" he always published anonymously, though the authorship of his books never appears to have been long a secret; and the independence of his position, together with his pure and genial character, saved him from all personal annoyance. The only attack reported to have been made upon him, otherwise than by means of the press, was the fruitless petition presented by Whiston, while smarting under his criticism, praying that he might be removed from the commission of the peace. Collins died at his house in Harley Street, London, on December 13, 1729, at the age of fifty-three.

The first work of note published by Collins was his *Essay concerning the Use of Reason in Propositions the Evidence whereof depends on Human Testimony* (1707). He demands that the revelation of God should be conformable to man's natural ideas of God, but draws a distinction between what is contrary to reason and what is merely contrary to our experience.

Six years later appeared his most famous work, *A Discourse of Freethinking, occasioned by the Rise and Growth of a Sect called Freethinkers* (1713). Notwithstanding the ambiguity of its title, and though it attacks the priests of all churches without moderation, it contends for the most part, at least explicitly, for no more than must be admitted by every Protestant, or than is maintained in such works as Taylor's *Liberty of Prophesying;* and it points out forcibly that the first introduction of Christianity, and the success of all missionary enterprise, involve free-thinking (in its etymological sense) on the part of those converted. In England this essay, which was regarded and treated as a plea for deism, made a great sensation, calling forth several replies, among others from Whiston, Bishop Hare, Bishop Hoadly, and Richard Bentley, who, under the signature of *Phileleutherus Lipsiensis*, roughly handles certain arguments carelessly expressed by Collins, but triumphs chiefly by an attack on his scholarship. Swift also, being satirically referred to in the book, made it the subject of a caricature. In France, where it was answered by Crousaz, it produced a still deeper impression.

In 1724 Collins published his extraordinary *Discourse on the Grounds and Reasons of the Christian Religion*, with *An Apology for Free Debate and Liberty of Writing* prefixed. Ostensibly it is written in opposition to Whiston's attempt to show that the passages of the Old Testament prophecies quoted in the New had since the time of Christ been corrupted by the Jews, and with the object of proving that the fulfilment of prophecy by the events of Christ's life is all "secondary, secret, allegorical, and mystical," since the original and literal reference is always to some other fact. To explain this "allegorical" reading, he quotes from the Dutch Hebraist Surenhusius ten methods according to which the authors of the *Gemara* and other allegorical writers among the Jews interpret difficult parts of the Scriptures, and which are asserted to have been used in the New Testament. Of these methods the gentlest is altering the points, and the most severe is "changing the order of words, adding words, and retrenching words, which is a method often used by Paul;" and the true purpose of the book would appear to have been to show, in a veiled satire, that the fulfilment of prophecy in the New Testament is of the same kind as that contrived by the rabbis. And further, as he strives to prove that the fulfilment of prophecy is the only valid proof of Christianity, he thus secretly aims a blow at Christianity as a revelation. The canonicity of the New Testament he ventures openly to deny, on the ground that the canon could only be fixed by men who were inspired. No less than thirty-five answers were directed against this book, the most noteworthy of which were those of Bishop Edward Chandler, Arthur Sykes, Clarke, and Sherlock. To these, but with special reference to the work of Chandler, which maintained that a number of prophecies were literally fulfilled in Christ, Collins replied by his *Scheme of Literal Prophecy Considered*, 1727. An appendix contends against Whiston that the book of Daniel was forged in the time of Antiochus Epiphanes.

In philosophy, Collins takes a foremost place as a defender of Necessitarianism. His brief *Inquiry Concerning Human Liberty* (1715) gives, in a remarkably clear and concise form, all the important arguments in favour of his theory, with able and suggestive replies to the chief objections that have been urged against it. Little, in fact, of moment has been added by modern determinists. One of his arguments, however, calls for special criticism,—his assertion that it is self-evident that nothing that has a beginning can be without a cause is an unwarranted assumption of the very point at issue. Collins's position was attacked in an elaborate treatise by Samuel Clarke, in whose system the freedom of the will is made essential to religion and morality. During Clarke's lifetime, fearing perhaps (as has been suggested) to be branded as an enemy of religion and morality, Collins gave no reply, but in 1729 he published an answer, entitled *Liberty and Necessity*.

The other of Collins's two purely philosophical treatises is *A Letter to Mr Dodwell*. A controversy was then being carried on between Clarke, who asserted the natural immortality of the soul, and Dodwell, who held that the soul is mortal till baptism confers immortality upon it; and Collins entered the lists to suggest other possibilities. Adopting Locke's suggestion, he maintained that it is conceivable that the soul may be material; and, secondly, that if the soul be immaterial it does not follow, as Clarke had contended, that it is immortal; indeed in no way, he argues, can philosophy prove its immortality.

Two of Collins's early works yet remain to be mentioned—his *Vindication of the Divine Attributes*, in which he attacks a sermon of King, archbishop of Dublin, and maintains that from our knowledge of human qualities we can attain to a true, if limited, knowledge of the divine attributes; and his *Priestcraft in Perfection, or a Detection of the Fraud of inserting and continuing the Clause, "The Church hath power to decree Rites and Ceremonies and Authority in Controversies of Faith," in the Twentieth Article of the Church of England* (1709), to which—as the question excited a very active controversy—he added, early in the next year, a second pamphlet on the same subject. (T. M. W.)

COLLINS, MORTIMER (1827–1876), novelist and writer of lyrics, was born at Plymouth, and was educated at a private school. After some years spent in tuition and some contributions in verse to the Bristol newspapers, he repaired to London, and devoted himself to journalism in the Conservative interest. In 1855 he published a volume of verse; and in 1865 appeared his first story, *Who is the Heir?* A second volume of lyrics, *The Inn of Strange Meetings*, was issued in 1871; and in 1872 he produced his longest and best sustained poem, *The British Birds, a communication from the Ghost of Aristophanes.* He wrote profusely for journals and magazines—the *Owl*, the *Globe*, *Punch*, *Temple Bar*, *Belgravia*, the *World*, &c.—and produced, besides, several novels, the most readable of which, perhaps, is *Sweet Anne Page* (1868). As novels merely, these works are not greatly to be commended; as the work of a clever man of pronounced opinions, they are often interesting enough. Their author's great claim to remembrance, however, is based upon his lyrics; some of these, in their light grace, their sparkling wit, their airy philosophy, are equal to anything of their kind in modern English.

COLLINS, William (1721–1759), who divides with Gray the glory of being the greatest English lyrist of the 18th century, was born on the 25th of December, 1721, at Chichester, of which city his father, a rich hatter, was the mayor. After some childish studies in his native town, he was sent, in January 1733, to Winchester College, where Whitehead and Joseph Warton were his schoolfellows. When he had been nine months at the school, Pope paid Winchester a visit and proposed a subject for a prize poem; it is legitimate matter or fancy to suppose that the lofty forehead, the brisk dark eyes, and gracious oval of the childish face, as we know it in the only portrait existing of Collins, did not escape the great man's notice, then not a little occupied with the composition of the *Essay on Man*. In 1734 it is supposed that the young poet published his first verses, on *The Royal Nuptials*, of which, however, no copy has come down to us; another poem, probably satiric, called *The Battle of the Schoolbooks*, was written about this time, and has also been lost. Fired by his poetic fellows to further feats in verse, Collins produced, in his seventeenth year, those *Persian Eclogues* which were the only writings of his that were valued by the world during his own lifetime. They were not printed for some years, and meanwhile Collins sent, in January and October 1739, some verses to the *Gentleman's Magazine*, which attracted the notice and admiration of Johnson, then still young and uninfluential. In March 1740 he was admitted a commoner of Queen's College, Oxford, but did not go up to Oxford until July 1741, when he entered Magdalen College. At Oxford he continued his affectionate intimacy with the Wartons, and gained the friendship of Gilbert White. Early in 1742 the *Persian Eclogues* appeared in London. They were four in number, and formed a modest pamphlet of not more than 300 lines in all. Those pieces may be compared with Victor Hugo's *Les Orientales*, to which, of course, they are greatly inferior. Considered with regard to the time at which they were produced, they are more than meritorious, even brilliant, and one at least —the second—can be read with enjoyment at the present day. The rest, perhaps, will be found somewhat artificial and effete. In November 1743 Collins was made bachelor of arts, and a few days after taking his degree published his second work, an *Epistle to Sir Thomas Hanmer*. This poem, written in heroic couplets, shows a great advance in individuality, and resembles, in its habit of impersonifying qualities of the mind, the riper lyrics of its author. For the rest, it is an enthusiastic review of poetry, culminating in a laudation of Shakespeare. It is supposed that he left Oxford abruptly in the summer of 1744 to attend his mother's death-bed, and did not return. His indolence, which had been no less marked at the university than his genius, combined with a fatal irresolution to make it extremely difficult to choose for him a path in life. The army and the church were successively suggested and rejected; and he finally arrived in London, bent on enjoying a small property as an independent man about town. He made the acquaintance of Johnson and others, and was urged by those friends to undertake various important writings—a *History of the Revival of Learning*, several tragedies, and a version of Aristotle's *Poetics*, among others —all of which he commenced and lacked force of will to continue. He soon squandered his means, plunged, with most disastrous effects, into profligate excesses, and sowed the seed of his untimely misfortune. It was at this time, however, that he composed his matchless odes, which appeared on the 20th of December 1746, dated 1747. The origiual project was to have combined them with the odes of Joseph Warton, but the latter, now forgotten, proved at that time to be the more marketable article. Collins's little volume fell dead from the press, but it won him the admiration and friendship of Thomson, with whom, until the death of the latter in 1748, he lived on terms of affectionate intimacy. The *Odes*, in the volume of that name, were twelve in number; to their contents we shall presently return. In 1749 Collins was raised beyond the fear of poverty by the death of his uncle; and he left London to settle in his native city. He had hardly begun to taste the sweets of a life devoted to literature and quiet, before the weakness of his will began to develop in the direction of insanity, and he hurried abroad to attempt to dispel the gathering gloom by travel. In the interval he had published two short pieces of consummate grace and beauty—the *Elegy on Thomson*, in 1749, and the *Dirge in Cymbeline*, later in the same year. In the beginning of 1750 he composed the *Ode on the Popular Superstitions of the Highlands*, which was dedicated to the author of *Douglas*, and not printed till long after the death of Collins, and an *Ode on the Music of the Grecian Theatre*, which no longer exists, and in which our literature probably has sustained a severe loss. With this poem his literary career closes, although he lingered in great misery for nearly nine years. From Gilbert White we learn that his madness was occasionally violent, and that he was confined for a time in an asylum at Oxford. But for the most part he resided at Chichester, suffering from extreme debility of body when the mind was clear, and incapable of any regular occupation. Music affected him in a singular manner, and it is recorded that he was wont to slip out into the cathedral cloisters during the services, and moan and howl in horrible accordance with the choir. In this miserable condition he passed out of sight of all his friends, and in 1756 it was supposed, even by Johnson, that he was dead; in point of fact, however, his sufferings did not cease until the 12th of June 1759. No journal or magazine recorded the death of the forgotten poet, though Goldsmith, only two months before, had commenced the laudation which was soon to become universal.

No English poet so great as Collins has left behind him so small a bulk of writings. Not more than 1500 lines of his have been handed down to us, but among these not one is slovenly, and few are poor. His odes are the most sculpturesque and faultless in the language. They lack fire, but in charm and precision of diction, exquisite propriety of form, and lofty poetic suggestion they stand unrivalled. That one named *The Passions* is the most popular; that *To Evening* is the greatest favourite with imaginative persons. In reading this, and the *Ode to Simplicity*, one seems to be handling an antique vase of matchless delicacy and elegance. Distinction may be said to be the crowning grace of the style of Collins; its leading peculiarity is the incessant impersonification of some quality of the character. In the *Ode on Popular Superstitions* he produced a still nobler work; this poem, the most considerable in size which has been preserved, contains passages which are beyond question unrivalled for rich melancholy fulness in our literature between Milton and Keats. The life of Collins was written by Dr Johnson, he found an enthusiastic admirer in Dr Langhorne; and more recently a kindly biographer in Mr Moy Thomas. (E. W. G.)

COLLINS, William (1787–1847), painter, was the son of an Irish picture dealer and man of letters, the author of a *Life of George Morland*, and was born in London. He studied under Etty in 1807, and in 1809 exhibited his first pictures of repute—Boys at Breakfast, and Boys with a Bird's Nest. In 1815 he was made associate of the Royal Academy, and was elected R.A. in 1820. For the next sixteen years he was a constant exhibitor; his fishermen, shrimp-catchers, boats and nets, stretches of coast and sand, and, above all, his rustic children were universally popular. Then, however, he went abroad on the advice of Wilkie, and for two years (1837–1838) studied the life, manners, and scenery of Italy. In 1839 he exhibited the first fruits of this journey; and in 1840, in which year he was appointed librarian to the Academy, he made his first appearance as a painter of history. In 1842 he returned to his early manner and choice of subject, and during the last years of life enjoyed greater popularity than ever. As a painter Collins is entitled to high praise. He was a good colourist and an excellent draughtsman; he was also conscientious exceedingly, and an ardent lover and student of nature. His earlier pictures are deficient in breadth and force,—are feeble, in fact, from excess of care and finish; but his later work, though also carefully executed, is rich in effects of tone and in broadly painted masses. His biography, *Life of William Collins, R.A.*, 2 vols., by his son Wilkie Collins, the well-known novelist, appeared in 1848.

COLLODION (from κόλλα, glue), a colourless, viscid fluid, made by dissolving gun-cotton and the other varieties of pyroxylin, or cellulotrinitrin, $C_6H_7O_2(NO_3)_3$, in a mixture of alcohol and ether. It was discovered in 1848 by Maynard in Boston. The quality of collodion differs according to the proportions of alcohol and ether and the nature of the pyroxylin it contains. Collodion in which there is a great excess of ether gives by its evaporation a very tough film; the film left by collodion containing a large quantity of alcohol is soft and easily torn; but in hot climates the presence of an excess of alcohol is an advantage, as it prevents the rapid evaporation of the ether. Pyroxylin for the making of collodion for photographic purposes is prepared by immersing cotton-wool ten minutes in a mixture of nitric and sulphuric acids at a temperature of 140° Fahr. When tolerably strong acids at a low temperature are employed, the nitric acid being in by far the larger quantity, the pyroxylin made requires an amount of alcohol equal to only about $\frac{1}{8}$th or $\frac{1}{12}$th that of the ether in bulk. According to M. Miallie, the most explosive kinds of gun-cotton are not the best adapted for the preparation of collodion; a pyroxylin very soluble in ether is in his process made from 2 parts by weight of carded cotton to 40 parts of nitre and 60 of concentrated sulphuric acid. Under the microscope, the film produced by collodion of good quality appears translucent and colourless, the cotton being perfectly dissolved; old collodion that does not give good photographic impressions sufficiently quickly exhibits liquid globules of modified ether. The film from collodion which is too alcoholic has the microscopic appearance of cellular tissue; and when water has been present, the fibrillæ of the cotton become apparent as amorphous flocks. To preserve collodion it should be kept cool, and out of the action of the light; iodized collodion that has been discoloured by the development of free iodine may be purified by the immersion in it of a strip of silver foil. For the iodizing of collodion, ammonium bromide and iodide and the iodides of calcium and cadmium are the agents employed. The first to suggest the use of collodion in photography was M. le Grey, in Paris; Mr F. S. Archer, in February 1851, recommended iodized collodion instead of paper for the taking of photographs (*The Chemist*, New. Ser., vol. ii. No. xix. p. 257, March 1851). In surgery collodion is used in its usual condition, or combined with elastic and other substances, for the protection of inflamed surfaces, as in erysipelas and smallpox. When poured upon the skin, it forms a thin film which contracts as it dries. *Flexible collodion*, which, as it does not crack in drying, is preferable for surgical purposes to the ordinary preparation, is made from collodion 6 oz., Canada balsam 120 grs., castor-oil one fluid drachm. *Vesicating* or *Blistering Collodion* contains cantharidin as one of its constituents. The styptic colloid of Richardson is a strong solution of tannin in gun-cotton collodion. Small balloons are manufactured from collodion by coating the interior of glass-globes with the liquid; the film when dry is removed from the glass by applying suction to the mouth of the vessel. M. E. Gripon has found (*Compt. Rend.*, April 5, 1875) that collodion membranes, like glass, reflect light and polarize it both by transmission and reflection; they also transmit a very much larger proportion of radiant heat, for the study of which they are preferable to mica. See PHOTOGRAPHY.

COLLOT D'HERBOIS, JEAN MARIE (1750–1796), a prominent actor in the French Revolution, was a Parisian actor. After figuring for some years at the principal provincial theatres of France and Holland, he became director of the playhouse at Geneva. He had from the first a share in the revolutionary tumult; but it was not until 1791 that he became a figure of importance. Then, however, by the publication of *L'Almanach du Père Gérard*, a tract designed to set forth, in homely style, the advantages of a constitutional government, he suddenly acquired great popularity. His renown was soon increased by his active interference on behalf of the Swiss of the Château-Vieux Regiment, condemned to the galleys for mutiny at Nancy. His efforts resulted in their liberation; he went himself to Brest in search of them; and a civic feast was decreed on his behalf and theirs, which gave occasion for one of the few poems published during his life by André Chénier. He next endeavoured to obtain the office of minister of justice, but was disappointed. The Tenth of August, however, placed him in the municipality of Paris. There he attached himself to Billaud-Varenne, and had with him a large share in bringing about the September Massacres. Having been elected a deputy for Paris to the Convention, he was among the first to demand the abolition of royalty; and from Nice, whither he had gone on an embassy, he voted the death of Louis XVI.—"*sans sursis.*" In the struggle between the Mountain and the Girondists he displayed great energy; and after the *coup d'état* of May 31 (1793) he made himself conspicuous by his pitiless pursuit of the defeated party. In June he was made president of the Convention; and in September, with Billaud-Varenne, he was admitted to the Committee of Public Safety. He voted loudly and persistently for all the bloodiest and sternest measures. In November, after the Lyonese insurrection, he was sent with Fouché to punish the rebellious city, where, it is said, he had once been hissed as an actor. This he effected by putting about 1500 persons to death in one day. In May 1794 an attempt was made to assassinate Collot; but it only increased his popularity. In the struggle for mastery between Robespierre and Tallien, Collot took the part of the latter In spite, however, of his fierce attack on Robespierre he was expelled from the Committee of Public Safety, and was denounced in form by Lecointre. He defended himself, and was acquitted, but only to be denounced anew by Merlin, and to be condemned, with Billaud-Varenne, to transportation to Cayenne, where he died of fever a few months after his arrival.

Colbot d'Herbois wrote and adapted from the English and Spanish many plays, one of which, *Le Paysan Magistrat*, kept the stage for several years. *L'Almanach du Père Gérard* was reprinted (1792) under the title of *Étrennes aux Amis de la Constitution Française, ou Entretiens du Père Gérard avec ses Conciloyens*, Paris, 12mo.

COLMAN, GEORGE (1733–1794), essayist and dramatist, usually called the Elder, and sometimes George the First, to distinguish him from his son, was born at Florence, where his father was stationed as resident at the court of the grand duke of Tuscany. After a preliminary course of study at a private academy in Marylebone, he was sent to Westminster School, which he left in due course for Christ Church, Oxford. Here he made the acquaintance of Bonnel Thornton, the parodist, and together they founded *The Connoisseur* (1754–1756), a periodical which reached its 140th number, and which, Johnson said, "wanted weight." In 1758 he took the degree of Master of Arts, came to London soon afterwards, was entered at Lincoln's Inn, and was duly called to the bar; and in 1760 he produced his first play, *Polly Honeycomb*, which met with great success. In 1761 he brought out *The Jealous Wife*, a comedy rich in borrowed excellences; in 1764 the death of Lord Bath placed him in possession of an annuity; in 1765 appeared his brilliant metrical translation of the plays of Terence; and in 1766 he produced *The Clandestine Marriage*, jointly with Garrick, whose Lord Ogleby was one of his finest impersonations. In 1767 he succeeded to a second annuity, on the death of General Pulteney, purchased a fourth share in Covent Garden Theatre, and was appointed acting manager. In 1768 he was elected into the famous Literary Club, then nominally consisting of twelve members; in 1774, after seven years of managership, he sold his share in the great playhouse to Leake; and in 1777 he purchased of Foote, then broken in health and spirits, and near his end, the Little Theatre in the Haymarket. In 1778 he published an edition of Beaumont and Fletcher; and in 1783 appeared his translation of Horace's Epistle *De Arte Poetica*, with notes and a commentary. He was attacked with palsy in 1785; in 1789 his brain became affected, and he lapsed gradually into idiocy. Besides the works already cited, Colman was author of some 35 plays, of an excellent translation from the *Mercator* of Plautus for Bonnell Thornton's edition (1769–1772), and of many parodies and occasional pieces. An incomplete edition of his dramatic works was published in 1777, in four volumes. See also *Prose on Several Occasions, with some Pieces in Verse, by George Colman*, London, 1787, 3 vols.; and *Some Particulars of the Life of the Late George Colman, Written by Himself*, London, 1795.

COLMAN, George (1762–1836), the Younger, son of the preceding, passed from Westminster School to Christ Church, Oxford, and King's College, Aberdeen, and was finally entered as a student of law at the Temple, London. While at Aberdeen he published a poem in honour of Charles James Fox, called *The Man of the People*; and in 1782 he produced, at his father's playhouse in the Haymarket, his first play, *The Female Dramatists*, for which *Roderick Random* supplied the materials. It was unanimously condemned, but his next attempt, *Two to One*, was entirely successful, and the young Templar's vocation was decided on. The failing health of the elder Colman obliging him to relinquish the management of the Haymarket theatre, the younger George succeeded him, at a yearly salary of £600. On the death of the father the patent was continued to the son; but difficulties arose in his way, lawsuits and pamphlets accumulated round him, and he was forced to take sanctuary within the Rules of the King's Bench. Here he resided for many years. Released at last through the kindness of George IV., who had appointed him exon of the Yeomen of the Guard, a dignity disposed of by Colman to the highest bidder, he was made examiner of plays by the duke of Montrose, then lord chamberlain. This office, to the disgust of all contemporary dramatists, to whose MSS. he was as illiberal as severe, he held till his death. Colman's comedies, which have never been collected, are a curious mixture of genuine comic force and platitudinous sentimentality. Several of them are yet acted; but their popularity is rather to be attributed to the humour of the actors who adopt them as vehicles for display than to any intrinsic vitality. The best of them are *John Bull* (1805), for which the author received the largest sum of money that had till then been paid for any single play, *The Poor Gentleman*, and *The Heir-at-Law*. Colman, whose conversational powers were remarkable, as Byron has recorded, was also the author of a great deal of so-called humorous poetry (mostly coarse, though much of it was popular)—*My Night Gown and Slippers* (1797), *Broad Grins* (1802), and *Poetical Vagaries* (1812). Some of his writings were published under the assumed name of Arthur Griffinhood of Turnham Green. See *Random Records*, London, 1830, 2 vols., and R. B. Peake, *Memoirs of the Colman Family*, London, 1842, 2 vols.

COLMAR, or Kolmar, till 1870 the chief town of the department of Haut Rhin in France, but now of the district of Upper Alsace, in the German empire, is situated on the Lauch and the Fecht, tributaries of the Ill. It communicates by a canal with the Rhine, and has a station on the railway from Basel to Strasburg, being about 40 miles S.S.W. of the latter city. It is the seat of the administrative offices for Upper Alsace, an imperial court of appeal for Alsace-Lorraine, a commercial court, an imperial lyceum, a Protestant normal college, a literary, an agricultural, and a natural history society. The last, founded in 1861, maintains a valuable museum in the old convent of Unterlinden, and publishes valuable contributions to local science. There is another museum, named after the old painter Schongau, for the preservation of works of art; the town library contains 50,000 volumes, and the archives of Upper Alsace reach back to the 7th century. The most remarkable edifices in the town are the so-called cathedral, or St Martin's church, a Gothic structure built in 1363, the prefecture or administrational buildings, and the town-house; and there are also civil and military hospitals, barracks, a theatre, and a deaf-mute institution. The manufactures of the town comprise cotton goods of various sorts, packing-cloth, hosiery, starch, silk thread, iron and copper wares, engines, sewing-machines, bricks, matches, and leather; and there are eight breweries, a dye-work, and several printing and lithographic establishments. The domestic trade of the country is centred in the city, and large transactions are effected in wine and hops. Colmar grew up round a royal residence called Columbaria, which is first mentioned in the 8th century. It obtained a charter of incorporation in 1226, and was afterwards made a free imperial city by the Emperor Frederick II. It was taken after a six weeks' siege by Adolphus of Nassau in 1293, invested by Duke Otto of Austria in 1330, occupied by Duke Rudolf in 1358, seized by the Swedes in 1632, and finally dismantled by the French after the siege of 1673.

COLNE, a market town of England, in the county of Lancaster, 26 miles north of Manchester, on a small affluent of the Calder, near the Liverpool and Leeds Canal, with a station on a branch of the Midland line. It is a place of great antiquity, and many Roman coins have been found on the site. As early as the 14th century it was the seat of a woollen manufacture; but its principal manufactures now are printed calicoes and mousselines-de-laine. The chief buildings are the parish church of St Bartholomew, an ancient edifice which has been frequently restored, and the cloth or piece-hall, in the Elizabethan style. The grammar school is interesting as the place where Archbishop Tillotson received his early education. In the neighbourhood are several limestone and slate quarries. Population in 1851, 6644; in 1871, 7335.

COLOCYNTH, Coloquintida, or Bitter Apple, *Citrullus* or *Cucumis Colocynthis*, a plant of the natural order *Cucurbitaceæ* or Gourds. The flowers are unisexual; the male blossoms have five stamens and sinuous anthers, the female have reniform stigmas, and a 3 to 6 celled ovary. The fruit is round, and about the size of an orange; it has a thick yellowish rind, and a light, spongy, and very bitter pulp, which furnishes the colocynth of druggists. The seeds, which number from 200 to 300, and are disposed in vertical rows on the three parietal placentæ of the fruit, are flat and ovoid, and dark-brown; they are used as food by some of the tribes of the Sahara, and a coarse oil may be expressed from them. The foliage resembles that of the cucumber, and the root is perennial. The plant has a wide range, being found in Ceylon, India, Persia, Arabia, Syria, North Africa, the Grecian Archipelago, the Cape Verd Islands, and the south-east of Spain. The term *pakkuoth*, translated "wild gourds" in 2 Kings iv. 39, is thought to refer to the fruit of the colocynth; but, according to Celsius, it signifies a plant known as the squirting cucumber, *Ecbalium purgans*. The commercial colocynth consists of the peeled and dried fruits, which are imported from Aleppo, Smyrna, Mogador, Spain, and other localities. In the preparation of the drug, the seeds are always removed from the pulp. Its active principle is an intensely bitter glucoside, *colocynthin*, $C_{56}H_{84}O_{23}$, soluble in water, ether, and alcohol, and decomposable by acids into glucose and a resin, *colocynthein*, $C_{40}H_{54}O_{13}$ Colocynth is a drastic purgative, and in large doses the powdered drug or its decoction has an inflammatory action on the intestines, and may produce fatal effects. It is administered in combination with aloes, scammony, cardamoms, and potassium sulphate, also with henbane. Colocynth was known to the ancient Greek, Roman, and Arabic physicians; and in a herbal of the 11th century, written in Saxon (Cockayne, *Leechdoms*, &c., vol. i. p. 325, Lond., 1864), the following directions are given as to its use:—"For stirring of the inwards, take the inward neshness of the fruit, without the kernels, by weight of two pennies; give it, pounded in lithe beer to be drunk; it stirreth the inwards."

COLOGNA, a town of Italy, in the province of Verona, 20 miles south-east of the city of that name on the Frasana Canal. It has a cathedral, and carries on an extensive trade in hemp, silk, wine, grain, and almonds. Population, 7000.

COLOGNE, German KÖLN or CÖLN, the chief city of Rhenish Prussia, and a fortress of the first rank, capital of a government of the same name, is situated in the form of a half circle on the left bank of the Rhine, 45 miles N.N.W. of Coblentz, in 50° 56′ 29″ N. lat., 6° 57′ 52″ E. long. It is connected with the suburb of Deutz, on the opposite side of the Rhine, by a bridge of boats nearly 1400 feet long, and by a handsome iron bridge which serves both for railway and street traffic. Although when viewed from a distance the city has a picturesque aspect, it is very irregularly built, and the older streets are narrow, crooked, and dirty. The most important squares are the Heumarkt, Neumarkt, Altmarkt, and Waidmarkt. There are two railway stations, the Central, near the cathedral, and the Pantaleon. There are also two stations in Deutz. The cathedral or Dom, the principal edifice and chief object of interest in Cologne, is one of the finest and purest monuments of Gothic architecture in Europe. It stands on the site of a cathedral commenced about the beginning of the 9th century by Hildebold, metropolitan of Cologne, and finished under Willibert in 873. This structure was ruined by the Normans, was rebuilt, but in 1248 was almost wholly destroyed by fire. The foundation of the present cathedral was then laid by Conrad of Hochstaden. The original plan of the building has been attributed to Gerhard von Rile. In 1322 the new choir was consecrated, and the bones of the three kings were removed to it from the place they had occupied in the former cathedral. After Conrad's death the work of building advanced but slowly, and at the time of the Reformation it ceased entirely. In the early part of the 19th century the repairing of the cathedral was taken in hand, and in 1842 the building of fresh portions necessary for the completion of the whole structure was commenced. The cathedral, which is in the form of a cross, has a length of 480, a breadth of 282 feet; the height of the central aisle is 154 feet; that of each of the towers, when completed, will be upwards of 500 feet. The heaviest of the six bells weighs 11 tons. In the choir the heart of Mary de' Medici is buried; and in the adjoining side-chapels are monuments of the founder and other archbishops of Cologne, and the shrine of the three kings, which is adorned with gold and precious stones. The very numerous and richly-coloured windows, presented at various times to the cathedral, add greatly to the imposing effect of the interior. (See ARCHITECTURE, vol. ii p. 431.) Many of the churches of Cologne are of interest both for their age and for the monuments and works of art they contain. In St Peter's are the famous altar-piece by Rubens, representing the Crucifixion of St Peter several other works by Lucas of Leyden, and some old German glass-paintings. St Martin's, built between the 10th and 12th centuries, has a fine bapistery, and paintings by Du Bois and Honthorst; St Gereon's, built in the 11th century on the site of a Roman rotunda, is noted for its mosaics

Plan of Cologne.

1. St Cunibert's Church.
2. Civil Jail.
3. St Ursula's Church.
4. St Gereon's Church.
5. Archbishop's Palace
6. Government Palace.
7. Palace of Justice.
8. St Andreas's Church.
9. Jesuits' Church.
10. Cathedral.
11. Diorama.
12. Post Office.
13. Church of the Minorites.
14. Museum of Paintings.
15. Rathhaus (Town Hall).
16. St Martin's Church.
17. Synagogue.
18. Church of the Apostles.
19. Bank.
20. Civil Hospital.
21. Casino.
22. St Maria's Church.
23. Gürzenich (Merchant's Hall)
24. St Mauritius's Church.
25. St Peter's Church.
26. Tempelhaus (Exchange)
27. Gymnasium
28. St Pantaleon Church.
29. Garrison Lazaretto.
30. St Severin Church.

and glass and oil paintings; the Minorite church, commenced in the same year as the cathedral, contains the tomb of Duns Scotus. Besides these may be mentioned the Pantaleon church, a 12th century structure, with a monument to Theophania, wife of Otto II.,; St Cunibert, in the Byzantine-Moorish style, completed in 1248; St Maria im Capitol, the oldest church in Cologne, dedicated in 1049 by Pope Leo IX., noted for its crypt, organ, and paintings; St Cecilia, St Ursula, and St George. Other public buildings are the Gürzenich, the former meeting-place of the diets of the German empire, built between 1441 and 1474, the great hall of which is capable of accommodating 3000 persons; the Rathhaus, which dates from the 13th century; the Tempelhaus, built partly in the 12th century; the Museum Wallraf-Richartz, in which is a collection of paintings by old Italian and Dutch masters, together with some works by modern artists; the Zeughaus or arsenal, situated on Roman foundations; the Government buildings, erected by Bircher in 1830; the archbishop's palace, three gymnasia, several normal and commercial schools and literary and scientific institutions, and three theatres. The university, founded in 1388, was suppressed by the French during their occupation of the country. The walls which surround the city are about seven miles in circuit. Outside the walls, to the north side, are the Zoological and the Botanical Gardens. Cologne has a considerable trade in corn, wines, hides, and rape-seed with Holland, Belgium, and other countries; and steamers ply regularly between the city and the ports on the Rhine. The principal manufactures are cotton yarn and stuffs, hosiery, woollens, silks, tobacco, sugar, soap, wax-lights, starch, malt, dyes, white-lead, porcelain, carpets, brandy and spirits, eau-de-cologne, and leathern and metal wares. In 1815 the population of Cologne was 47,000; in 1871 it amounted to 129,233, or, if that of Deutz be included, about 141,000.

Cologne occupies the site of *Oppidum Ubiorum*, the chief town of the Ubii, and there in 51 A.D. a Roman colony was planted by the Emperor Claudius, at the request of his wife Agrippina, who was born in the place. After her it was named Colonia Agrippina or Agrippinensis. Cologne rose to be the chief town of Germania Secunda, and had the privilege of the Jus Italicum. Both Vitellius and Trajan were at Cologne when they became emperors. Statues, sarcophagi, and other Roman remains, and portions of the old Roman walls have been found at Cologne. About 330 the city was taken by the Franks, and in 475 it became the residence of the French king Childeric. In 870 it was annexed to the empire. The bishopric was founded in 314, the archbishopric about the end of the 8th century; in the 14th century the archbishops were made electors of the German empire. The last elector, Maximilian, died in 1801. Cologne was besieged by Emperor Henry V. in 1160, and by Philip of Swabia in 1201. From 1452 to 1474, having taken part with England, it was excluded from the Hanseatic League, of which it was one of the most important and wealthy cities. The intolerance of its magistrates in expelling Jews and Protestants, and the closing of the Rhine navigation in the 16th century by the Dutch, contributed to its decline. This last restriction having been removed in 1837, the trade of Cologne has greatly improved. In 1794 Cologne was taken by the French; it was ceded to them by the Treaty of Lunéville in 1801, and from that time till 1814, when it was restored to the Prussians, it was the capital of the department of the Roer.

COLOMBIA, or, according to the official title, the Republic of the United States of Colombia, is a modern confederation in South America, consisting of the nine states of Antioquia, Bolivar, Boyacá, Cauca, Cundinamarca, Magdalena, Panamá, Santander, and Tolima, and comprising a considerable portion of the territory of the old Spanish vice-royalty of New Granada. It is bounded on the N. by the Caribbean Sea, on the E. by Venezuela, on the S. by Ecuador and Brazil, and on the W. by the Pacific. It thus extends from 12° 20′ N. to 2° 30′ S. lat., and from 65° 50′ to 83° 5′ W. long.,—its total area being roundly estimated at 500,000 square miles, or more than double that of Spain and Portugal. About four-fifths lies to the north of the equator.

On the Atlantic it possesses a coast line of upwards of 1000 miles, richly furnished with bays and natural harbours. Proceeding westward from Calabozo Creek, in the Gulf of Maracaibo, the first inlet of real importance which we discover is the Bahia Honda, which is well protected from the strong winds of the east and north, but is rendered unsuitable for the establishment of a port by its lack of drinkable water. Passing by the Bay of El Portete, we next reach the ports of Riohacha and Dibulla, of which the former is of considerable commercial importance as a centre of exportation, though it is greatly surpassed by that of Santa Marta, which is the next to break the coast-line. Santa Marta is situated at the side of the Cienega Lagoon, which stretches 25 miles from south to north, with a breadth of 11 from east to west, has communication with the lakes of Pajaral and Cuatro Bocas, and, though rather shallow, can be navigated by flat-bottomed steamboats. At the mouth of the Magdalena lies the port of Barranquilla, and a short distance to the west that of Sabanilla, one of the most active along the whole coast. After these comes the splendid Bay of Carthagena, known for centuries to all navigators of the Caribbean; and still further to the west the coast is broken by the port of Zapote, the Bay of Zispata, the Gulf of Morrosquillo, and finally by the noble Gulf of Darien, with the estuary of the Atrato and the ports of Turbo, Guacuba, Candelaria, &c. Along the isthmus are the Mandinga Creek; the Bay of Portobello, so famous in the history of Spanish America; the modern port of Colon, or Aspinwall, at the entrance of Navy Bay; and the now decadent port of Chagres. The coast-line of the Pacific is hardly so important as that of the Atlantic, except along the isthmus, where it forms the great Bay of Panamá, with the subordinate inlets of Parita Bay on the west and the Gulf of San Miguel on the east. Along the remainder of the line are Cupica, San Francisco, Solano, Palmar, and Charambira (the last obstructed by a bar), the large Bay of Malaga, protected by the Isla de Palmas, with the harbours of Guapi and Izcuandé, the Bay of Pasa Caballos, the harbour of Tumaco, and in the Island of Gorgona the fine harbour of Trinidad. Coast

The western part of Colombia is one of the most mountainous districts in the world; its eastern extension belongs to the great plains of the Orinoco and the Amazon. The mountains are all more or less directly portions of the system of the Andes. Entering at the south from the territory of Ecuador, they form an extensive plateau from which a large number of rivers take their rise. The portion known as the *paramo* of Cruz Verde has, according to Steinheil, an elevation of 10,975 old Paris feet, or about 11,695 English feet. From this table-land the system breaks up into three ranges, which stretch north through nearly the whole length of the country, with a general parallelism of direction least maintained by the eastern portion. Of these ranges the loftiest at first is the Central, or the Cordillera of Quindiu, which contains the snow-peaks of Huila, Ruiz, and Tolima, the culminating peak of the Andes north of the equator; but in 5° 5′ N. lat., where this range sinks down, the Eastern rises to the snow limit, and is the most elevated of the three Cordilleras. The Eastern Cordillera, or the Cordillera de la Suma Paz, runs north-east to the paramos of Pamplona, from which it sends out a branch to meet the *massif* of the Sierra Nevada of Santa Marta. In its passage through the state of Santander it attains in the Alto de el Viejo an altitude of 12,965 feet, in Alto de el Trio of 9965, and in the Boca del Monte of 12,735. The Sierra Nevada is said to reach a height of 23,779 feet, and it is certainly covered with perpetual snow over a large part of its summit. The Surface

Western Cordillera, or Cordillera de Choco, is the least remarkable of the three, and has been worn down in many places into what are comparatively mere rounded hills with easy passages between; it continues northward, however, much further than the central chain, and in fact extends right through the Isthmus of Panamá.

The *llanos* or plains of the Orinoco extend eastward from the slopes of the Cordillera de la Suma Paz. As far south as the Vichada they form an almost complete level, destitute of trees, and affording abundant pasturage; while further south they are covered with forests, display considerable irregularity of surface, and are not unfrequently broken by steep rocks rising to a height of from 300 to 600 feet.

The fundamental formations throughout Colombia are igneous and metamorphic, the great masses of the Cordilleras consisting of gneiss, granite, porphyry, and basalt. In many places the Carboniferous strata have attained considerable development, though they have been thrown into strange confusion by some unknown disturbance. Volcanic forces are still at work, as is shown by occasional earthquakes, and also by such phenomena as those at Batan near Sogamoso where the subterranean heat is great enough to affect the local climate. Glaciers are still extant in the Paramo del Ruiz, and possibly in some of the other snow-clad heights. The slopes of the various Cordilleras are frequently covered with deep beds of gravel; and the valleys are full of alluvial deposits of very various periods. The rivers have in many instances cut remarkable passages for themselves through the mountains; and, according to Codazzi, the Sogamoso has at one time been the outlet of a vast series of lakes which he believed to have occupied the highlands of Bogotá, Tunja, and Velez.

The rivers of Colombia belong almost entirely to the great Atlantic versant; but they are distributed by the principal water-shed in very various directions. The two most important are the Magdalena or Rio Grande and the Cauca, which both flow from south to north through nearly the entire length of the country,—the former occupying the valley between the Eastern and the Central Cordilleras, and the latter that between the Central and the Western. They unite about 130 miles before reaching the sea, but they so long maintain an independent course that neither can fairly be regarded as a mere tributary of the other. The Magdalena takes its rise in a small lake called the Laguna del Buey or Ox Lake, situated in the plateau of Las Papas. It receives from the right hand the Suaza, the Rio Neiva, the Cabrera, the Prado, the Fuzagasanga, famous for the falls of Tequendama, the Bogotá, the Carare, the Opon, the Sagamoso, itself a considerable stream, and the Rio Cesar, a fine river from the Sierra Nevada; and from the left the La Plata, the Paez, the Saldana, the Cuello, the Guali, the Samana, or Miel, the Nare or Rio Negro, and various minor tributaries. The Magdalena is one of the most important water highways of the country, in spite of the fact that its current is so rapid as to make the upward voyage both difficult and tedious. From Honda, where the progress is interrupted by rapids, a native boat takes only about three days to reach the sea, while no fewer than six weeks are spent, even when the water is low, in returning against the stream Steamers of from 50 to 200 tons burden, however, have plied regularly since 1833 between Honda Barranquilla. The Honda rapids can be surmounted by haulage, and steamers descend them in safety, though there is a fall of 20 feet in two miles, and of 16 feet in the first. Above this point the channel is clear about half-way to the source, and though the traffic is still mainly carried on by native boats and rafts, a German named Alexander Weckbecker succeeded, in 1875, in taking a large steamboat—the "Moltke"—three times to the town of Neiva. The Cauca rises to the west of the source of the Magdalena, in the Lake of Santiago, in the paramo of Guanacas. In the upper part of its course it flows through a volcanic region, and its waters are so impregnated with sulphuric and other acids that they are destructive of fish. These acids are mainly contributed by the headstream of the Rio Vinagre or Vinegar River, which rises in the Purace volcano. The principal tributaries are the Piendamó, the Ovejas, the Palo, the Amaime, and the La Vieja, from the Central Cordillera; and the Jamundi and a large number of minor streams from the Western. After the junction of the Cauca and the Magdalena the united stream attains an imposing breadth; but it breaks up into several channels before it falls into the sea. The River Atrato, which disembogues in the Gulf of Darien and separates the main branch of the Eastern Cordillera from the isthmian ranges, is of high importance, not only in itself as an actual means of communication, but as affording, in the opinion of many engineers, one of the most feasible means of forming an interoceanic canal. So important was it regarded by Philip II. that its navigation was forbidden in 1730 on pain of death; and the prohibition was not removed for a considerable period. The account, however, so frequently repeated, of the possibility of passing from the Atlantic to the Pacific versant by means of a canal, excavated about 1788 in the Raspadura ravine by some enterprising monk, seems to have little or no foundation. The Atrato rises in the slopes of the Western Cordillera, has a course of about 300 miles, and a breadth, during the last 96 miles, of from 750 to 1000 feet. Its depth in this lower part of its passage varies from 40 to 70 feet or even more. At Quibdó, 220 miles from the embouchure, it is still 850 feet wide and 8 to 20 feet deep; and as the fall of the river is only about 3 inches to a mile, steamboats can pass as far as the confluence of the San Pablo and Certigui, 32 miles above Quibdó.

Of those rivers that belong to the Orinoco system the most important are the Guaviare, the Meta, and the Vichada. The first is formed of the Guayavero and the Iriwida, which flows from the mountains of Tunahí; and the principal tributaries of the second are the Chire, the Casanare, and the Lipa. Of those that belong to the Amazon are several tributaries of the Rio Negro branch, and the Caquita, or Japura. This last rises in the eastern slopes of the same table-land which gives birth to the Magdalena and the Cauca; and its principal affluents are the Pescado, the Caguan, and the Apoponi. Though belonging to Colombia only by its head waters, there is another tributary of the Amazon which bids fair to be of great importance to the country as a means of communication with Brazil. This river, the Rio Iça or Potumayo rises in the Andes in the province of Pasto, under 2° N. lat., has a total length from its source to its confluence of 932 miles, receives in its course 36 affluents, of which several would afford passage for steamboats, and waters a region that abounds in gum elastic, sarsaparilla, cocoa, nut-wood, Pasto resin, gold, and other means of wealth. Its depth is from 7 to 34 feet during low water, and twice as great during flood; at some places it has a breadth of 1300 feet, and its current is from 3 to 4 nautical miles an hour. A steamer only takes 10 days to pass from the confluence with the Amazon to the mouth of the Guamuéa; and this place is only 80 or 90 miles from the province of Pasto. The opening up of this route is due to Raphael Reyes, a full account of whose exploration will be found in Petermann's *Mittheilungen* for 1876. The only rivers that remain to be noted are those of the isthmus; and these are chiefly of importance for their bearing on the question of interoceanic communication. The principal are the Chagres, disemboguing in the Atlantic, and the Tuyra, the Chepa or Bayanos, and the Chiriqui, which find their way to the Pacific.

Many of the Colombian rivers take their rise in mountain lakes, and several of them fill considerable basins in their course; but throughout the country there are very few of those extensive sheets of water that form so usual a feature in most mountainous regions The River Cesar flows through the lakes of Zipatosa and Adentro; between the Cauca and the Nechi lies Lake Caceres, as well as several others of less importance; the district of Tunja still preserves the Lake of Tota; and in Bogotá is the famous Guatavita, where the Muiscas are reputed to have sunk their treasures.

Colombia is distinctively a mineral country, and the list of its productions in this department includes gold, silver, platinum, copper, lead, iron, mercury, and antimony, limestone, potash, soda, magnesia, alum, and salt, coal and asphalt, emeralds, amethysts, and amber. Many of the most important deposits are as yet untouched, owing mainly to the defective state of internal communication, and even those that have been worked have proved much less remunerative from the same cause. Gold especially is very widely diffused; it was freely used by the natives before the arrival of Europeans, and formed a valuable source of revenue to the Spanish Government, who employed thousands of negroes and Indians in the task of collection. It is principally obtained from alluvial deposits; and in some districts there is hardly a stream that would not furnish its quota. Hydraulic appliances were introduced about 1870 in some of the workings; and a more systematic treatment is being gradually adopted. Antioquia is the most important gold-producing state in the confederation; the total value of gold and silver exported from the capital in 1875 was 2,403,241 dollars; there were upwards of eighty lode mines at work in 1875; and 15,000 men and women are employed in the mining. The silver frequently occurs in very rich lodes; but, owing it would seem to various economical causes, many of the mining operations have been unsuccessful. The "Santa Anna" mines in Tolima, which were worked from 1826 to 1873 (for some years under the direction of Mr Robert Stephenson, the railway engineer), yielded during that period about £700,000 worth of ore, but ultimately proved a failure. The "Frias" silver mine, belonging to the Tolima Mining Company of London, yielded in 1875 300 tons of ore valued at £100 per ton. The emerald mines are remarkable as being the only known source of the genuine stone. They are situated at Muzo, in the state of Boyacá, in the Central Cordillera, to the north of Bogotá. Soon after the Spanish Conquest they were worked on a large scale by the Government; but towards the close of the 18th century it was found that it cost 6500 pesos to extract 1000 pesos worth of emerald, and they were consequently abandoned (see Ezpeleto's report in *Relac. de los Vireyes*, p. 347). After the war of independence the mines were appropriated by the republic, from which a French company obtained a monopoly from 1864 to 1874. During this period the stones found a ready market in Paris, where green was the imperial colour. Since the expiry of the contract the mines have been demonopolized. The emeralds are found in two distinct layers of calcareous bitumen, the upper of which is black and friable, and the under compact. In the upper the emeralds occur in "nests," in the lower in veins, and usually in the neighbourhood of bands of fluor-spar. The finest stones may be worked up to a value of £20 a carat; the worst sorts are only worth about 5s. Coal is pretty generally distributed throughout the republic, and the great bed of Cali probably extends to the Pacific. Rock-salt is obtained in the table-lands of Bogotá, Tunja, and Pamplona, and forms an important Government monopoly.

Though Colombia is situated within the tropics, and, in fact, as we have seen, is crossed by the equator in its southern limits, its great irregularity of surface and its extensive coast-lines develop a great variety of climatic conditions. A comparatively short journey transports the traveller from the sultry valley of the Magdalena, where the water grows tepid and the stones burning hot in the sun's rays, to the summits of a mountain where the snow lies cold from year to year. In the table-lands and valleys of the Eastern and Western Cordilleras, at a height of 800 to 9500 feet above the level of the sea, there are two dry seasons and two rainy, the former commencing at the solstices and the latter at the equinoxes, while in the lowlands both of the Pacific and the Atlantic seaboard there is only one dry and one rainy of six months each. In the Gulf of Darien and the Isthmus of Panamá there is no such distinction, and rain occurs in any part of the year. The greatest mean temperature in the country is about 86° Fahr., and the lowest in the inhabited parts of the Cordilleras is about 44°. At Honda, which is about 1000 feet above sea-level, the daily range of the thermometer is only from 8° to 12°, and the annual not more than 20°. "The hottest place," says Mosquera, to whom we are largely indebted, "which I have found in New Granada, is the port of Ocaña, where I have on several occasions seen the thermometer in the shade at 104° Fahr." In the *llanos* of the Orinoco the mean annual temperature is about 80° Fahr., while in the forest district to the south the average is about 8° higher. In the latter the rain is distributed throughout the year, while in the former the seasons are distinctly marked, and from November till April the rains fall in torrents accompanied with dreadful thunderstorms.

Plants.

In keeping with this variety of climate the Colombian flora ranges from purely tropical forms in the lowlands up to purely Alpine or boreal types in the mountains. The tree limit on Tolima, in the Central chain, is 10,360 feet. The country abounds with extensive forests, in which timber of gigantic proportions waits for the settler's axe. Besides several of the common species of palm trees which are found as high as 2500 feet above the sea, there are two remarkable species, the *Ceroxylon andicola*, Palma de Cera, or Wax-palm, and the *Oreodoxa regia*, or Palmita del Azufral, which in company with the oak, frequently clothe the Cordilleras to a height of 6000 or 8000 feet. They are both of extreme beauty, and the former shoots up to about 180 or 200 feet. From the Sierra Nevada and other districts are obtained logwood, Brazil-wood, and fustic; and the *Myroxylon toluifera*, from which the balsam of Tolu is collected, grows luxuriantly on the banks of the Rio Negro. Excellent Indian-rubber is obtained from the *Castilloa elastica*, a lofty and luxuriant tree, which occurs in considerable abundance in Panamá, Cauca, and other states. The quantity and quality of the material might be greatly increased and improved, as the collection is still in the hands of a very rude and careless class of men. Under the superintendence of Mr Cross the tree is being introduced into British India. Cinchona of six or seven different varieties is common throughout the country,—the elevation most favourable for its growth being between 7800 and 9000 feet above the sea. Of other medicinal plants there may be mentioned the aloe, the sarsaparilla, the albataque, and the vine of the cross. The cotton plant grows wild in many parts and yields an excellent fibre; indigo is indigenous; and an almost endless variety of fruits are found throughout the country.

The fauna is perhaps hardly so rich as the flora, but it does not fall far behind. Of monkeys there are at least seventeen distinct species; the feline race is represented by seven or eight, including the puma and the jaguar; there are two species of bears; the alligator swarms in the Magdalena and some of the other rivers; deer are common at various elevations; the sloth, the armadillo, the guagua (*Cœlogenus subniger*), the opossum, and the cavy prevail in the forests; and the tapir or danta wanders in the higher regions. Among the birds may be mentioned the condor and ten other birds of prey, several species of swallows, numerous varieties of parrots, paroquets, lories, and cockatoos, cranes and storks, the pleasant-singing tropial, and the strangely-coloured sol-y-lune, which takes its name from the figure of the sun and moon on its wings. The boa constrictor, the yaruma, the cascabel, and various other serpents are frequent enough in the warmer regions, but are not met with at a greater height than 5400 feet above the sea. Insects are abundantly represented, the most important practically being the ants, which in some districts, as for instance the isthmus, are almost a plague. Turtle abounds on the coasts; and pearl-oysters are the object of a very considerable fishery.

Agriculture holds the first place among the industries of Colombia; but the methods employed are still of a very rude description. Maize, wheat, and other cereals are cultivated on the elevated plains; rice, cotton, tobacco, sugar, coffee, cocoa, yams, arracacha, and bananas in the coast region. Tobacco is especially successful in Ambalema, Carmen, Palmira, Jiron, and Morales, and it forms an important export. In the plains of the Orinoco and the undulating savannahs of Panamá the breeding of cattle and horses is largely carried on by the creole inhabitants, and several of the Indian tribes are also in possession of valuable herds. Beyond such common (almost domestic) trades as hand-weaving, dyeing, tanning, and basket-making, there is almost no manufacturing industry in the country, though the basis for future development has been laid by the establishment in Bogotá of glass-works, distilleries, a cigar-factory, and a sulphuric acid factory. One product of the domestic industry alone finds its place in the list of exports—namely, straw hats, usually known as jipijapa or Panamá hats. The raw produce, however, is largely exported; the principal articles being cinchona bark, indigo, coffee, cotton, tobacco, silver ore, hides, and the minor items—ivory-nuts, ipecacuanha, and balsam of Tolu. The relation between the exports and imports and the variations of amount from year to year will be seen by the following table:—

	Imports.	Exports.
1869	7,255,092 dollars.	8,137,000 dollars.
1870	5,843,451	8,077,153
1871	5,862,711	8,247,817
1872	8,427,175	8,253,806
1873	12,500,000	10,500,000

The national government of Colombia is republican,—the main basis of the constitution being a scheme drawn up in 1863 after the model of the United States of North America. The executive power is exercised by the president and four ministers or *secretarios*. The presidential elections recur every two years; the choice is determined by a majority of the states; and the new president enters on office on the 1st of April. The secretaries have charge respectively of the four departments of Home and Foreign Affairs, Finance and Public Works, Treasury and Credit, and War and Marine. The legislative power of the federation is divided between a house of representatives elected by universal suffrage, and a senate of 27 members, or three from each state. The number of the representatives depends on the size of the state-population,—one being allowed for every 50,000 inhabitants, and one for the remainder if it reaches 20,000. In 1875 there were in all 61 representatives. There is a supreme court at Bogotá, conducted by a president, four judges, and a procurator-general; the judges are elected by the legislative houses of the nine states. There is no state church, and full religious liberty prevails. The predominant profession, however, is the Roman Catholic, and an archbishop is established at Bogotá. The national income is very small; but it has been steadily increasing for a number of years. In 1869-70 it was 2,883,758 pesos (about 4s. value); in 1870-71, 3,573,570; in 1871-72, 3,178,446; in 1872-73, 4,000,000. The taxes are very light,—by far the greater part of the revenue accruing from the custom-houses established at Buenaventura, Carlosama, Cartagena, Cucuta, Rio Hacha, Sabanilla, Santa Marta, Jumaco, and Turbo. In 1872-73 the various receipts were—customs, 2,775,450 pesos; salt monopoly, 799,213; Panamá railway, 250,000; postal service, 67,609; telegraphs, 10,627; mint, 18,000; national property, 72,595; ecclesiastical property, 6506. The customs would yield a still greater return were it not for smuggling, which prevails largely, especially at Cartagena. The tariff hitherto in use divides articles into classes, which pay so much per kilogramme; and thus the burden of the duty falls most on inferior goods. The salt works yielded, in 1869-70, 136,568 cwts., of which 81 per cent. was obtained from Cundinamarca, 18 per cent. from Boyacá, and 1 per cent. from the territory of San Martin. The postal service is still in a very backward state, and the charges are very high; but this cannot be otherwise till the road system of the country has been developed. Rapid progress, however, is being made by several of the states in this preliminary undertaking. In April 1875 there were upwards of 1000 miles of telegraph, the principal lines stretching from Honda to Bogotá, and from Ambalema to Manizales. In 1873 the total number of telegraphic messages amounted to 500,000. In the less populous districts the maintenance of the lines is very costly, as not only are the wires stolen by thieves, but they are frequently damaged by the monkeys, who use them for gymnastic purposes. The only two railways actually in operation are the Panamá line (46 miles), and the line between Sabanilla and Barranquilla (17 miles); but great efforts are being made, both by the central Government and by the separate states, to construct lines throughout the country, and contracts have already been made for some of the most important. The national property consists mainly of waste lands, which are allotted to applicants on very liberal terms. A great deal of the church property confiscated by the republic has been sold; some of it is rented out; and many of the convents are used for public offices. The public debt amounted, in 1875, to 10,105,500 dollars, of which 10,000,000 are the old debts of the war of independence, which pay an interest of 4½ per cent. The English debt of 1863 has been cleared off. There is no national navy, and the armed force in time of peace only amounts to 1420 men; in time of war the states have to furnish 1 per cent. of their population. The separate states have their own constitutions and governors, and they differ considerably in their political tendencies.

The educational condition of Colombia has hitherto been very low; but, by a law published in 1870, the management of public instruction was taken from the hands of the clergy and intrusted to the state, a complete reform of the school system was effected, teachers were introduced from Europe, and compulsory education was adopted. In this last point Colombia has taken the lead in the New World. In Antioquia 486 schools were in operation in 1873, with an attendance of about 21,500; in Bolivar, 44; in Boyacá, 208 (public schools), with 9000 pupils; in Cauca, 229, with 9925; in Cundinamarca, 338, with 16,489; in Magdalena, 100, with 2968; in Santander, 300, with 11,974; in Tolima, 100 schools and 3640 scholars. In Panamá the state of education is not so good, but public schools are being established there also. The expense is borne partly by the special states and partly by the national treasury, which devotes 317,120 dollars annually to this purpose, assigning 200,000 to subsidize the states, and 117,120 to the institutions for the higher education. These include the national university, the Vasquez academy, and schools of engineering, natural science, &c., established in the federal capital, state colleges, and normal schools. Education.

It can hardly be said that Colombia possesses a national literature, the writing and printing hitherto effected serving mainly the immediate purpose of the day. Its inheritance of the Spanish language, however, leaves it in vital contact with one of the older literatures of Europe, and frees it from the painful, though, it might be, fruitful necessity of working its way through confusion of dialects to a recognized national speech. Such intellect as the country has spared from war and political activity has mainly been directed to the natural sciences, which found their first footing on Colombian soil through the labours of the celebrated Don José Celestino Mutis. Of those who have attained a greater or less degree of fame in this department, it is sufficient to mention Zea, Cabal, Caldas, Pombo, Cespedes, Camacho, Lozano, and Codazzi; Restrepo and Mosquera have contributed to the history of their country. In several of the more important cities journalism is pretty well represented, and the Government is about to establish a magazine for the purpose of diffusing a knowlege of Colombian affairs.

The population of the territory of the present republic at the time of the Spanish Conquest consisted of a large number of independent tribes of very various degrees of civilization. Of these several have totally disappeared as separate unities; others have been in large measure Hispanicized both in language and in habits; many still retain their separate dialects, organization, and customs, and some are even now as opposed to the European movement as they were when the nrst white foot left its print on their shores. According to Uricoechea there are at least twenty-seven native languages spoken in the western part of Colombia, fourteen in Tolima, thirteen in the region of the Caquitá, twelve in Panamá, Bolivar, and Magdalena, ten in Bogotá and Cundinamarca, and thirty-four in the region of the Meta, while twelve have died out in the course of the last century The tribes of the Atlantic seaboard, from Chiriqui to Goahira, attach themselves to the great Carib stock; those of the Eastern portion of the country show affinities with the contiguous Brazilian race; those of the Tuquerus district are of the Peruvian type; while the tribes of Antioqula, Cauca, Popayan, and Neiva preserve characteristics more akin to those of the Aztecs than to any other race.

At the time of the Spanish Conquest the most important of all the tribes was the Miuscas or Chibchas, who had attained a considerable degree of civilization, and established their authority over the table-lands of Bogotá and Tunja. They are now represented by some bands that wander about the Meta; their ancient language is partly preserved by the labours of Gonzalo Bermudez, José Dadei, and Bernardo de Lugo; and they have been the subject of a special study by Uricoechea in his *Gramatica, Vocabulario, &c., de la Lengua Chibcha*, Paris, 1871. The Chibchas, says this author, were divided into three independent nations and several caciqneships; three chiefs exercised supreme power—the *Zipa*, who resided in Muequetá (the present Funza), the *Zaque*, resident at Hunaa (now Tunja), and the *Jeque*, or chief of Iraca, who held the office of pontiff, was regarded as the successor of the god Nemtereqneteba, and had his residence at the city of Suamoz or Sogamoso.

Another remarkable tribe, which has now totally disappeared, was the Tayronas, of the Sierra Nevada of Santamarta. They likewise were well advanced in civilization, as is proved not only by the reports of their conqnerors, but also by such remains of their skill as the gold ornaments which are found from time to time in their territory, and the well-made roads by which it is still traversed. The most important of the tribes that still retain their savage state are the Mesayas, the Caquetas, the Mocoas, the Amarizanos, the Guipanabis, and the Andaquies in the eastern part of the republic; the Goahiros, the Motilonea, the Guainetas, and the Cocinas, in the districts of Rio Hacha, Upar, and Santamarta; and the Dariens, the Cunacunas, and the Chocos, on the banks of the Atrato and its affluents. These tribes have all along been a thorn in the side of the country. In the 18th century we have in the viceregal reports continued complaints of the raids of the Chimilas, the Goahiros, the Andaquies, and the Motilones, who defied equally the military and the ecclesiastical method of reduction. The missionaries who were scattered through the country had a hard time of it with their converts, who even after they were baptized and instructed, "take advantage of their knowledge to elude and assail us." To the present day the settlement and Christianization of this part of the population is one of the political problems of Colombia, and as recently as 1874 a bill was brought in for the purpose. The exact nnmber of the nncivilized Indians is hardly ascertained; it was roughly calculated by Mosquera as ranging from 108,000 to 120,000. The rest of the population is composed mainly of Spanish Creoles, Negroes, and mixed races. According to Samper it was divided in 1858 as follows:—1,527,000 whites and white crossbreeds, 447,000 crossbreeds in which the Indian blood is more distinctly present, 90,000 Africans, and 446,000 crossbreeds in which the Negro or Indian blood is plainly predominant. According to a communication supplied to Behm and Wagner's *Bevölkerung der Erde*, 1874, the distribution of the population, exclusive of the nncivilized Indians, was in 1871 as it appears in the following table:—

	Area in sq. miles.	Males.	Females.	Capitals.	Pop. of Capitals.
Antioquia.....	22,790	181,492	184,482	Medellin,	30,000
Bolivar........	27,027	114,306	125,042	Cartagena,	7,800
Boyacá.........	33,349	232,727	250,147	Tunja,	8,000
Canca..........	257,451	210,363	224,715	Popayan,	16,000
Cundinamarca	79,845	196,843	212,759	Bogotá,	50,000
Magdalena....	26,950	40,682	44,573	Santamarta,	3,500
Panamá........	31,921	113,009	107,533	Panamá,	18,378
Santander.....	16,293	204,551	220,876	Socorro,	20,000
Tolima.........	18,476	110,791	120,100	Guamo,	7,000

Owing to the discordant claims of Colombia, Venezuela, and Brazil, the area of the frontier states is very variously given according to the limits selected, and the calculation of the population is open to the same irregularity.

History.—The coast of Colombia was one of the first parts of the American continent visited by the Spanish navigators. Alonso de Ojeda touched at several points in 1499 and 1501; and Columbus himself visited Veragua, Portobello, and other places in his last voyage in 1502. In 1508 Ojeda obtained from the Spanish Crown a grant of the district from Cape Vela westward to the Gulf of Darien, while the rest of the country from the Gulf of Darien to Capo Gracias-a-Dios was bestowed on his fellow-adventurer Nicuessa. The two territories designated respectively Nueva Andalucia and Castella de Oro were united in 1514 into the province of Tierra-firma, and entrusted to Pedro Arias de Avila. By the middle of the century the Spanish power was fairly established, and flourishing communities arose along the coasts, and in the table-lands of Cundinamarca formerly occupied by the Muiscas. For the better government of the colony the Spanish monarch erected a presidency of New Granada, which continued till 1718, when it was raised to the rank of a viceroyalty. In the following year, however, the second viceroy, D. Jorge Villalonga, Count de la Cueva, expressing his opinion that the maintenance of this dignity was too great a burden on the settlers, the viceroyalty gave place to a simple presidency. In 1740 it was restored, and it continued as long as the Spanish authority, including within its limits not only the present Colombia, but also Venezuela and Ecuador. An insurrection against the home Government was formally commenced in 1811, and an incessant war against the Spanish forces was waged till 1824. In 1819 the great national hero, Bolivar (see BOLIVAR), effected a union between the three divisions of the country, to which was given the title of the Republic of Colombia; but in 1829 Venezuela withdrew, and in 1830 Quito or Ecuador followed her example. The Republic of New Granada was founded November 21, 1831; and in 1832 a constitution was promulgated, and the territory divided into eighteen provinces, each of which was to have control of its local affairs. The president was to hold office for four years; and the first on whom the dignity was bestowed was General Santauder. His position, however, was far from enviable; for the country was full of all the elements of unrest and contention. One of his measures, by which New Granada became responsible for the half of the debts of the defunct republic of Colombia, gave serious offence to a large party, and he was consequently succeeded not, as he desired, by José Maria Obando, but by a member of the opposition, José Ignacio de Marquez. This gave rise to a civil war, which lasted till 1841, and not only left the country weak and miserable, but afforded an evil precedent which has since been too frequently followed. The contest terminated in favour of Marquez, and he was succeeded in May 1841 by Pedro Alcantara Herran, who had assisted to obtain the victory. In 1840 the province of Cartagena had seceded, and the new president had hardly taken office before Panamá and Veragua also declared themselves independent, under the title of the State of the Isthmus of Panamá. Their restoration was, however, soon effected; the constitution was reformed in 1843; education was fostered, and a treaty concluded with the English creditors of the republic. Further progress was made under General Mosquera from 1845 to 1848; a large part of the domestic debt was cleared off, immigration was encouraged, and free trade permitted in gold and tobacco. The petty war with Ecuador, conclnded by the peace of Santa Rosa de Carchi, is hardly worthy of mention. From 1849 to 1852 the reins were in the hands of General Lopez, a member of the democratic party, and under him various changes were effected of a liberal tendency. In January 1852 slavery was entirely abolished. The next president was José Maria Obando, but his term of office had to be completed by vice-presidents Obaldia and Mallarino. In 1853 an important alteration of the constitution took place, by which the right was granted to every province to declare itself independent, and to enter into merely federal connection with the central republic. In 1856 and 1857 Antioquia and Panamá took advantage of the permission. The Conservative party carried their candidate in 1857, Mariano Ospino, a lawyer by profession; but an insurrection broke out in 1859, which was fostered by the ex-president Mosquera, and finally took the form of a regular civil war. Bogotá was captured by the democrats in July 1861, and Mosquera assumed the chief power. A congress at Bogotá established a republic, with the name of the United States of Colombia, adopted a new federal constitution, and made Mosquera dictator. Meanwhile the opposite party was victorious in the west; and their leader, Arboleda, formed an alliance with Don Garcia Moreno, the president of Ecnador. He was assassinated, however, in 1862; and his successor, Canal, came to terms with Mosquera at Cali. The dictatorship was resigned into the hands of a convention at Rio Negro, in Antioquia; a provisional government was appointed, a constitution was drawn up, and Mosquera elected president till 1864. An unsuccessful attempt was also made to restore the union between the three republics of the former federation. The presidency of Mannel Murillo Toro (1864–66) was disturbed by various rebellions, and even Mosquera, who next came to the helm, found matters in such a disorganized condition that he offered to retire. On the refusal of his resignation, he entered into a struggle with the majority in the congress, and ultimately resorted to an adjournment and the unconstitutional arrest of 68 of the senators and representatives. To the decree of impeachment published by the congress he replied by a notice of dissolution and a declaration of war; but he soon found that the real power was with his opponents, who effected his arrest, and condemned him first to two years' imprisonment, but afterwards by commutation to two years' exile. The presidency of Santos Gutierrez (1868-70) was disturbed by insurrections in different parts of the republic, the most important of which was that in Panamá, where the most absolute disorganization prevailed. Under his successor, General E. Salgar, a Liberal candidate elected in opposition to General Herran, a treaty was finally concluded with the United States in connection with an interoceanic canal, a bank was established at Bogotá, and educational reforms instituted. Manuel Murillo Toro (1872-74) and Santiago Perez (1874-76) have seen the country apparently acquiring constitutional equilibrium, and turning its energies to the development of its matchless resources. There has been no war with foreign states for several years; and though the question of the boundary lines frequently causes dispute between Colombia and her eastern neighbours, Venezuela and Brazil, it is to be hoped it will be peaceably settled. The election for the presidential term 1876-78 resulted in favour of Aquileo Parra.

Caulin, *Hist. corografica de la nueva Andalucia*, &c., Madrid, 1779; Restrepo, *Historia de la revolucion de Colombia*, Paris, 1827; Acosta, *Compendio del descubrimiento y colonisacion de la Neuva Granada*, Paris, 1848, and "Sur la Sierra Nevada de Sainte Marthe," in *Bulletin de la Soc. Géol. de France*, 1851-2; Karsten, *Ueber die geognostischen Verhältnisse der Westl. Colombia*, Vienna, 1856; Albert Berg, *Physiognomie der Trop. Vegetation Süd Amerikas*, 1856 (the views in this fine folio are almost exclusively Colombian); Samper, *Ensayo sobre las revoluciones pol. y la condicion de las republicas Colombianas*, Paris, 1861; E. Reclus, *Voyage à la Sierra Nevada de Sainte Marthe*, Paris, 1861; Wagner in Petermann's *Mittheilungen*, 1861 and 1862; Powles, *New Granada: its Internal Resources*, London, 1863; Mosquera, *Memoria sobre la geografia de la Nueva Granada*, New York, 1852, and his *Compendio de geografia dos statos unidos de Colombia*, London, 1866; Garcia y Garcia, *Relaciones de los Vireyes del Nuevo Reino de Granada*, New York, 1869; Codazzi, *Atlas de los estados unidos de Colombia*; Reiss and Stübel, *Alturas tomadas en la republ. de Colombia*, Quito, 1872 (reproduced in *XII. Jahresbericht des Vereins für Erdk. zu Dresden, Wissensch. Theil*); Steinheil, "Barometrische Höhenbestimmungen in Colombia," and "Reisen in Colombien," in Petermann's *Mittheil.*, 1876. The literature of the various canal projects is itself very extensive; it is sufficient to mention the works of Kelly, Puydt, and Selfridge. (H. A. W.)

COLOMBO, the capital and principal seaport town of Ceylon, on the west coast of the island, in 6° 55′ N. lat. and 79° 45′ E. long. The municipal limits include an area of 6415 acres, which is divided into the nine wards of The Fort and Galle Face, Pettah, St Sebastian's, St Paul's, Cottanchina, New Bazaar, Marandana, Slave Island, and Colpetty. The fortified part of the town is about a mile and a half in circuit, and occupies a rocky promontory of but slight elevation, surrounded on three sides by the sea, and protected on the land side by a lake, a moat, and drawbridges. The Galle Face affords a favourite promenade for the European population; Pettah is mainly inhabited by natives and half castes; and Colpetty is a beautiful suburb. Most of the streets are finely shaded with a species of *Hibiscus* planted by the Dutch; and the most of the older European houses bear the marks of Dutch occupation. Colombo contains the Government offices and courts, and is the residence of the civil and military authorities, the seat of a Church of England bishop, and a centre for Roman Catholic, Wesleyan, Baptist, and other missionary organizations. The principal buildings are the Government or Queen's House, the court-house, the town-hall, the lunatic asylum, the lazaretto, the military barracks and hospitals at Galle Face, Wellicadde jail, and Wolfendahl church; among the public institutions may be mentioned St Thomas's college and collegiate school, founded by Bishop Chapman in 1821; Wesley college; the industrial school; the medical school, established in 1870, with six scholarships attached; a branch of the Royal Asiatic Society, with a museum; the United Service library; the military-medical and the colonial-medical libraries and museums; the Pettah library, established in 1829; the agri-horticultural society; and the model farm inaugurated by Prince Alfred. The cinnamon gardens and the circular walk are pleasant places of resort; the former date from the Dutch occupation, and were long celebrated for their beauty and luxuriance. The town is supplied with gas and water by a company incorporated under Acts passed in 1862 and 1867. The principal articles of manufacture in Colombo are coffee, oil, and coir; the first of these especially keeps a large number of mills in operation. There are also a good many saw-mills in the town and neighbourhood, and the Government maintains a foundry and ironworks. The supply of ice is in the hands of a company. The harbour is small, and the roadstead is safe only during the south-east monsoon, but various improvements now in progress promise to make Colombo one of the chief ports of Southern India. The first stone of a great breakwater was laid by the Prince of Wales in 1875. The population of Colombo is of very various origin:—Sinhalese, Parsees, Chinese, Malabars, Arabs, Persians, Kaffirs, Afghans, descendants of Portuguese and Dutch, and half castes of all colours. In 1874 the total number of inhabitants was given as 97,129, of whom 42,160 were Sinhalese, 22,389 Moors, 20,633 Tamils and Chatties, and 1765 Europeans. Colombo was originally known as the Kalantotta or Kalany ferry. By the Arabs the name was changed to Kalambu, and the town is mentioned by Ibn Batuta about 1340 as the largest and finest in Serendib. In 1517 the Portuguese effected a settlement, and in 1520 they fortified their port and bade defiance to the native besiegers. In 1586 the town was again invested by Raja Singh, but without success. On its capture by the Dutch in 1656 it was a flourishing colony with convents of five religious orders, churches, and public offices, inhabited by no fewer than 900 noble families and 1500 families dependant on mercantile or political occupations. In 1796 it was surrendered to the British.

COLON. See ASPINWALL, vol. ii. p. 716.

COLONNA, GIOVANNI PAOLO, chapel-master of St Petronio at Bologna, and president of the Philharmonic Academy there, was born at Brescia about the middle of the 17th century. The music-school which he established at Bologna produced many good musicians, among them Clari. Most of Colonna's works are for the church, and are among the most remarkable compositions of the 17th century. They included settings of the psalms for three, four, five, and eight voices, and several masses and motetts. He also composed an opera, under the title *Amilcare*, and an oratorio, *La Profezia d'Eliseo*. Boyce considered Colonna as Handel's model for choruses accompanied with instrumental parts different from the vocal. The same practice, however, was adopted by several of Colonna's contemporaries.

COLONNA, VITTORIA (1490-1547), the daughter of Fabrizio Colonna, grand constable of the kingdom of Naples, and of Anna da Montefeltre, daughter of the "Good Duke" Frederick of Urbino, was born at Marino, a Roman fief of her father's house. Betrothed when four years old, at the instance of Ferdinand of Aragon, to Francisco D'Avalos, son of the marquis of Pescara, she received the highest education, and gave early proof of a love of letters. Her hand was sought, among other suitors, by the dukes of Savoy and Bragança, but at seventeen, as she ardently desired, her marriage with D'Avalos took place. The couple resided on the islet of Ischia till 1511, when the husband offered his sword to the Holy League, in whose service he was taken at Ravenna (1512), and carried to France. During the months of exile and the long years of campaigning that followed this mishap, they corresponded in most passionate terms, in prose and verse. They saw each other but seldom, for Pescara was one of Charles V.'s most brilliant and active captains; but Vittoria's influence over him was sufficient to keep him, after Pavia

(1525), from joining the projected league against the emperor, and to make him refuse the crown of Naples that was offered him as the price of his treason. The same year he died of wounds at Milan. Vittoria, who was hastening to tend him, received the news of his death at Viterbo. She halted, and turned off to Rome, whence, after a brief stay, she departed for Naples. There she remained for about ten years. She refused several suitors, and began to produce those *Rime Spirituali* that form so distinct a feature in her works. In 1536 she left Naples for Ferrara, calling at Rome, where she was visited by Charles V., and whither in 1538 she came to take up her abode. In Rome, besides winning the esteem of Reginald Pole and Cardinal Contarini, she became the object of a passionate friendship on the part of Michelangelo, then in his sixty-fourth year. The great artist wrote for her some of his finest sonnets, made drawings for her, and spent long hours in her society. Her removal from Rome to Orvieto (1541), on the occasion of her brother Ascanio Colonna's revolt against Paul III., and her subsequent residence in Viterbo (1541–45), where Reginald Pole was governor and legate, produced no change in their relations; they visited and corresponded as before. She returned to Rome in 1546, and died there about the end of February 1547.

The amatory and elegiac poems of Vittoria Colonna, which are the production of a delicate and sympathetic imitativeness rather than of a vigorous and original talent, were printed at Parma in 1538; a second edition appeared in the following year; a third, containing sixteen of the *Rime Spirituali*, was published at Florence soon afterwards; and a fourth, including a still larger proportion of the religious element, was issued at Venice in 1544.

COLONY. The term colony, often loosely applied, is most commonly used to denote a settlement of the subjects of a sovereign state in lands beyond its boundaries, owning no allegiance to any foreign power, and retaining a greater or less degree of dependence on the mother country. The founding and the growth of such communities furnish matter for an interesting chapter in the history as well of ancient as of modern civilization; and the regulation of the relations between the parent state and its dependencies abroad gives rise to important problems alike in national policy and in international economics.

It was mainly the spirit of commercial enterprise that led the Phœnicians to plant their colonies upon the islands and along the southern coast of the Mediterranean; and even beyond the Pillars of Hercules this earliest great colonizing race left enduring traces of its maritime supremacy. Carthage, indeed, chief of the Phœnician settlements, sent forth colonies to defend her conquests and strengthen her military power; and these sub-colonies naturally remained in strict subjection to her power, whereas the other young Phœnician states assumed and asserted entire independence.

In this latter respect the Greek colonies resembled those of the Phœnicians. From a very early period the little civic communities of Greece had sent forth numerous colonizing streams. At points so far asunder as the Tauric Chersonese, Cyrene, and Massilia were found prosperous centres of Greek commercial energy; but the regions most thickly peopled by settlers of Greek descent were the western seaboard of Asia Minor, Sicily, and the southern parts of the Italian peninsula. Nor were the least prosperous communities those which were sprung from earlier colonies. The causes that led to the foundation of the Greek colonies were very various. As in Phœnicia, pressure created by the narrow limits of the home country coincided with an adventurous desire to seek new sources of wealth beyond seas; but very many Greek emigrations were caused by the expulsion of the inhabitants of conquered cities, or by the intolerable domination of a hated but triumphant faction within the native state. The polity of the new community, often founded in defiance of the home authorities, might either be a copy of that just left behind or be its direct political antithesis. But wherever they went, and whether, as apparently in Asia Minor, Greek blood was kept free from barbaric mixture, or whether, as in Magna Græcia and Sicily, it was mingled with that of the aboriginal races, the Greek emigrants carried with them the Hellenic spirit and the Hellenic tongue; and the colonies fostered, not infrequently more rapidly and more brilliantly than at home, Greek literature, Greek art, and Greek speculation. The relation to be preserved towards the mother states was seldom or never definitely arranged. But filial feeling and established custom secured a measure of kindly sympathy, shown by precedence yielded at public games, and by the almost invariable abstinence of the colony from a hostile share in wars in which the mother city was engaged.

The relation of Rome to her colonies was altogether different. No Roman colony started without the sanction and direction of the public authority; and while the *Colonia Romana* differed from the *Colonia Latina* in that the former permitted its members to retain their political rights intact, the colony, whether planted within the bounds of Italy or in provinces such as Gaul or Britain, remained an integral part of the Roman state. In the earlier colonies, the state allotted to proposing emigrants from amongst the needy or discontented class of citizens portions of such lands as, on the subjection of a hostile people, the state took into its possession as public property. At a later time, especially after the days of Sulla, the distribution of the territories of a vanquished Roman party was employed by the victorious generals as an easy means of satisfying the claims of the soldiery by whose help they had triumphed. The Roman colonies were thus not merely valuable as *propugnacula* of the state, as permanent supports to Roman garrisons and armies, but they proved a most effective means of extending over wide bounds the language and the laws of Rome, and of inoculating the inhabitants of the provinces with more than the rudiments of Roman civilization.

The occupation of the fairest provinces of the Roman empire by the northern barbarians had little in common with colonization. The Germanic invaders came from no settled state; they maintained loosely, and but for a short while, any form of brotherhood with the allied tribes. A nearer parallel to Greek colonization may be found in Iceland, whither the adherents of the old Norse polity fled from the usurpation of Harold Haarfager; and the early history of the English pale in Ireland shows, though not in orderliness and prosperity, several points of resemblance to the Roman colonial system.

Though both Genoese and Venetians in their day of power planted numerous trading posts on various portions of the Mediterranean shores, of which some almost deserve the name of colonies, the history of modern colonization on a great scale opens with the Spanish conquests in America. The first Spanish adventurers came, not to colonize, but to satisfy as rapidly as possible and by the labour of the enslaved aborigines, their thirst for silver and gold. Their conquests were rapid, but the extension of their permanent settlements was gradual and slow. The terrible cruelty at first exercised on the natives was restrained, not merely by the zeal of the missionaries, but by effective official measures; and ultimately home-born Spaniards and Creoles lived on terms of comparative fairness with the Indians and with the half-breed population. Till the general and successful revolt of her American colonies, Spain maintained and employed the latter directly and solely for what she conceived to be her own advantage. Her commercial policy was one of most irrational and intolerable restriction and repression; and till the end of Spanish rule on the American continent, the whole political power was retained by the court at Madrid, and administered in the colonies by an oligarchy of home-bred Spaniar[ds].

The Portuguese colonization in America, in most respects resembling that of Spain, is remarkable for the development there given to an institution sadly prominent in the history of the European colonies. The nearness of Brazil to the coast of Africa made it easy for the Portuguese to supply the growing lack of native labour by the wholesale importation of purchased or kidnapped Africans.

Of the French it is admitted that in their colonial possessions they displayed an unusual faculty for conciliating the prejudices of native races, and even for assimilating themselves to the latter. But neither this nor the genius of successive governors and commanders succeeded in preserving for France her once extensive colonies in Canada or her great influence in India. In Algeria the French Government has not merely found a practical training school for her own soldiers, but by opening a recruiting field amongst the native tribes it has added an available contingent to the French army.

The Dutch took early a leading share in the carrying trade of the various European colonies. They have still extensive plantations in the East Indian Archipelago; and though their settlement at the Cape passed into British hands, a republic of Dutch-speaking boers maintains a precarious existence northward from the British possessions. The Danish and Swedish dependencies in the Antilles are but trifling in extent or importance.

It is the English-speaking race that has shown an unexampled energy and capacity for colonization. The English settlements in Virginia, New England, Maryland, and Pennsylvania had, between the second decade of the 17th and the seventh decade of the 18th century, developed into a new nation that was soon able to take rank with the most powerful of European states. Promoted in great measure by the desire to escape from the political or religious oppression of the English court, the transatlantic settlements were, though remaining under governors appointed by England, permitted to arrange their civil polity—necessarily assuming a democratic shape—very much as they chose; and, at first, troubles at home, and later, their distance, saved the colonies from much political interference on the part of successive English Governments. Though by the "Navigation Laws" and other enactments, England had always undertaken to regulate, in her own interest, the commercial relations between herself and her American colonists, encroachment, in the matter of taxation, on the immunity till then enjoyed provoked the spirit that in 1776 "solemnly published and declared that these United Colonies are, and of right ought to be, free and independent States." The vast unoccupied territories of the United States relieve her citizens and the immigrants who join them from seeking scope for their enterprize beyond the recognized limits of the Republic; but the method according to which the United States Government provides for the continuous westward advance of new settlements is essentially a system of colonization. The newly occupied lands are governed as a "territory" by the Federal Government, till the population reaches a fixed limit high enough to justify a demand to be admitted to the Union on an equal footing with the other States. The "American Colonization Society" has made an interesting philanthropic experiment for the establishment of negro freedmen in Africa; the result is the existing independent Republic of Liberia.

It is estimated that the existing colonies and dependencies of Great Britain cover about one-sixth of the land-surface of the globe, and nearly the same proportion of its population. The various origin of these colonial possessions, and their different relations to the Crown of Great Britain, suggest the question, How the foreign dependencies of a sovereign state may best be classified?

It is clear that the ultimate constitution of a colony depends but little on the manner in which the territory for settling was originally acquired. Whether it was by conquest or by formal cession from a foreign power, the new population, even if, as in the case of Canada, it at first consisted largely of people alien in blood and language to the colonizing country, may soon obtain a constitution and relations to the ruling state identical with those of lands originally acquired from thinly-scattered and wandering savages merely by the occupancy of citizen emigrants. Of almost equal unimportance for the future organization of the colony are the motives which led the earliest settlers to emigrate. The caprice of mere adventurers, the desperate desire of broken men to repair their fortunes, and the stern determination of public-spirited men to escape for ever some unendurable civil or religious grievance at home, have in their turn given rise to colonies now hardly distinguishable in their general features. Whether the emigration be purely voluntary and undertaken with or without official sanction, or systematically promoted by a Government for the furtherance of national commerce or in order to relieve itself of over-population; whether the new lands be handed over under a royal charter to a company, or granted, as proprietary, to an individual, the traces of the initiatory conditions may speedily disappear. And around a military outpost, a mere trading factory, or the prison walls of a penal settlement, a numerous and enterprizing population may soon be tending increasing herds or engaged in the steady and profitable tillage of the soil.

The circumstances whereon the characteristic development and permanent constitution of the colony depend are the physical conditions of the territory—its climate and its products. A colony in the fullest sense of our usage of the term can arise only where the European colonist may look on his adopted habitation as his permanent home, where he can found a family and rear his children in robust health, where his and their growing patriotism may come to regard their interests as bound up with the well-being of the community of which they form a part. Here alone can "daughter lands" hope to establish a polity that, without wholly severing the bond that unites them to the parent country, shall secure for them the self-government which the British emigrant regards as his birthright. New nations of the European stock can arise only where the cereals thrive, where the settler can without physical harm undergo the fatigue of rearing and tending his flocks, and where the line that divides master from servant is narrow and easily passed—that is, in a temperate climate. On these conditions it depends whether a foreign settlement shall be, on the one hand, an *agricultural* or *pastoral* colony, or, on the other, a *plantation* colony merely. In the plantation the European is a cultivator too, and may from year to year superintend his crops of sugar, coffee, or tobacco; but his relation to the soil on which he lives is comparatively a loose and transitory one. The difficulty of maintaining health undeteriorated by the tropical climate for more than a few years, and the impossibility of rearing a family in physical vigour, compel the planter to regard Europe as his home, even though his interests in the plantation pass to sons bred in a northern climate. They in their turn go abroad only to hasten home as soon as their views of what constitutes a competency admit. The number of European residents remains small; and the necessity of employing negro or coolie labour must divide the population into two castes,—one of masters and one of servants. And thus results the impossibility of that equal distribution of privileges and of responsibilities wherein lies the advantage of local self-government. Into one or other of the two classes of colonies thus distinguished those sometimes technically termed *mining* and *trading* colonies are, according to circumstances, likely to pass. The trading colony, so long as it is a mere factory or emporium of commodities, differs but little from the settlements of Europeans within the bounds of foreign states such as China, sometimes loosely spoken of as colonies of Europeans. The term *internal colonization* is occasionally used of schemes for promoting the prosperity of thinly-peopled and unfertile areas in some European states. The *military colonies* planted by Austria along her southern frontier serve a useful and very obvious purpose.

The *Colonial Office List* arranges British dependencies under three heads, according to their governmental relations with the English Crown. Officially, British "colonial possessions" are either:—1. "Crown colonies, in which the Crown has the entire control of legislation, while the administration is carried on by public officers under the control of the Home Government; 2. Colonies possessing representative institutions but not responsible government, in which the Crown has no more than a veto on legislation, but the Home Government retains the control of public officers; 3. Colonies possessing representative institutions and responsible government, in which the Crown has only a veto on legislation, and the Home Government has no control over any officer except the governor. . . . Under responsible government the executive councillors are appointed by the governor alone with reference to the exigencies of representative government, the other public officers by the governor on the advice of the Executive Council. In no appointment is the concurrence of the Home Government requisite." Some of the dependencies ranked here as Crown colonies can be called colonies only in a very loose sense. Military stations, such as Gibraltar, Malta, Aden, are convenient both to the navy and the commercial marine as coaling stations or ports for repair and for provisioning. The distinction between classes 2 and 3 is manifestly temporary, in most cases at least; there being, for example, no reason why an agricultural colony like that at the Cape, at present without "responsible government," should not ere long possess that privilege. India, a "Crown colony" in the list, is rarely spoken of under that name; the enormous numerical disparity between the handful of resident Europeans and the millions of civilized natives makes it seem incongruous to put India under the same category as Canada or Victoria, and to some extent justifies the recent adoption of the title "Empress of India" by the Queen.

It is rather the force of circumstances than the consistent maintenance of any definite policy that has shaped the relation of England to her various dependencies. But the colonial policy of the future has of late been largely debated, and with widely divergent issues. The "colonial system" so long maintained by England, as well as by all other powers, has been finally abandoned. No one now claims that the mother country has the right, still less that in self-defence she is bound, to restrict and hamper the trade of the colony for her own benefit; nor are there now found many to advocate the differential duties in favour of colonial produce, which that ancient system rendered all but necessary. Many, indeed, go to an opposite extreme, and argue that for both sides it would be better that the interdependent relation should be totally sundered, and each colony, as soon as possible, left to shift for itself. The trade of neither party, it is alleged, gains anything by the maintenance of the connection; the European state is exposed to needless risk in time of war by her responsibility to her scattered dependencies, and to additional expense in providing against that risk; while the colonies are liable to be dragged into wars with which they have no concern. The good-will arising from the sense of common origin would, it is said, amply maintain all the mutual advantages enjoyed under the present system, and would secure a virtual confederacy. The democratic experiments some of our colonies have been freely permitted to carry out, and their trade legislation, divergent from that of England, the incorporative federation of contiguous colonies, and the withdrawal of royal troops from the most developed colonial communities, are by many regarded as actual steps taken in the direction of an eventual separation. To another class of theorizers it appears that a "personal union," the entire legislative independence of the colonies with allegiance to the sovereign of the old country, would better secure the well-being of the several parts of the empire thus constituted; while again others contend that the interests of England and of her possessions abroad, and the cause of freedom and civilization throughout the world, would gain if the bonds of relation were yet more closely drawn together, and if provision could be made for the representation of the colonies in the imperial parliament. Meanwhile, that parliament is supreme over the whole British empire; all the proceedings in the colonial legislatures are liable to be annulled by the Crown. The Crown appoints all governors, is the supreme fountain of justice, and has the sole right of declaring peace and war save in so far as that power is, under certain conditions, delegated to the Governor-general of India; while the admitted aim of colonial policy is to develop the colonies socially, politically, and commercially quite as much as if their ultimate independence were the end contemplated.

Whether European Governments systematically encourage or repress emigration, it is clear that the overgrowth of population in the more densely-peopled centres of the old civilization must continue to send forth emigrants and to increase the already rapid growth of the existing colonies. It is significant for the future of European colonization that, of available territory in the temperate regions of America and Australasia (the temperate portions of Central Asia being, as inaccessible, ill adapted for European settlements), eighty per cent. is calculated to belong to the Anglo-Saxon race; and while the colonies of the English-speaking race have welcomed industrious men of all nationalities, tongues, and religious and political prepossessions, the colonial institutions, even where they differ most widely in their administration from those of England, bear an unmistakably English stamp, and have been manifestly moulded by an English spirit.

See Heeren, *Geschichte d. Europ. Staatensystems u. seiner Colonien*, 1809; H. Merivale, *Lectures on Colonization and the Colonies*, 1839–41, new edition, 1861; Arthur Mills, *Colonial Constitutions*, 1856; Sir E. Creasy, *Imperial and Colonial Constitution of the Britannic Empire*, 1872; W. E. Forster, *Our Colonial Empire*, 1875.

The following table, which is based on the latest returns and estimates, indicates the extent and population of the colonial possessions of the various European countries, but does not include any colony that was settled before the 15th century:—

COLOPHON. an ancient city of Asia Minor, situated a short distance from the coast, and about eight miles north of Ephesus. It was founded by the Ionians, but did not take part in the great political festival of the Apaturia. The principal facts in its history are its capture by the Persians and its depopulation by Lysimachus. At a later date the name was not unfrequently applied to the contiguous city of Notium. which continued to flourish till the time of Cicero at least. The site of Colophon is easily determined. but there are hardly any traces of its buildings. It claimed to be the birthplace of Homer, and, besides various lesser names, it numbered among its celebrities Mimnermus the elegiac poet, and Nicander the author of the *Theriaca*. Its name was given to a resin obtained from the pines on the neighbouring Mount Gallesus, and is still recognizable in "colophony," and in the French *colophane*. The ancient proverb, τὸν Κολοφῶνα ἐπέθηκεν (he has put the Colophon to the matter), has likewise left its trace in the modern languages, and more particularly in the vocabulary of bibliography, where the word "colophon" is employed to designate the concluding lines of early printed works, containing the title. date, &c. The adage is said to have arisen either from the decisive influence of the Colophonian cavalry in a contest, or from the fact that the citizens had the casting vote in the great Ionian assembly.

COLORADO. one of the United States of North America. Boundaries: N., Wyoming and Nebraska; E., Nebraska and Kansas; S., the Indian Territory and New Mexico; and W., Utah. Latitude, between 37° and 41° N.; longitude, from 102° to 109° W. Breadth N. to S. about 280 miles, length E. to W. about 380. Area estimated at 106,500 square miles, or 68,160,000 acres. Population, 120,000.

Mountains.—This territory is traversed from north to south by the great continental chain of the Rocky Mountains, and according to its orographical configuration may be divided into a mountain district, a hill district, and a plain district. The principal range of these mountains bears the name of the Sawatch Range. It consists of a solid mass of granite, has an average elevation of 13,500 feet, presents a broad and massive outline, and has a mean breadth of from fifteen to twenty miles. It is really a prolongation of the Sierra Madre of Mexico, and up to about 40° N. lat. it forms the dividing line between the Atlantic and the Pacific versants. Beginning at the south we have the following peaks:—Mount Bowles, 14,106 feet; twelve miles northward, Mount Howard, 14,208; eleven miles to the north-east, La Plata Mount, 14,126; seven miles from La Plata, Grizzly Peak, 13,786, and Mount Elbert, 14,150; and six miles from Mount Elbert, Massive Mountain, 14,192. For about eighteen miles north of this last elevation the range is comparatively low, but it rises again in the great terminal peak of the Holy Cross, which attains a height of 13,478 feet, and owes its name to the figure emblazoned on its summit by the white lines of its snow-filled ravines. Second only in importance to the Sawatch range are the Elk Mountains, which strike off from it in a south-west direction, and extend for a distance of upwards of thirty miles. They are geologically interesting for the almost unexampled displacement of the strata of which they are composed, and the apparent confusion which has thence arisen. Among the most remarkable of its separate summits are Italian Mountain, 13,431 feet in height, so called because it displays the red, white, and green of the Italian national colours; Whiterock Mountain, 13,847 feet; Teocalli Mountain, 13,274; Crested Butte, 12,014; Gothic Mountain, 12,491; Snow Mass, 13,961; Maroon Mountain, 14,000; Castlepeak, 14,106; Capitol, 13,992, and Sopris Peak, 12,972. Of less importance, but still distinct and well defined, are the Wet Mountains in the south-east, the Raton Mountains in the south, and the Uncompahgre Mountains in the south-west. The eastern series of elevations which abut on the region of the plains are known as the Front Range, and present a fine bold outline, broken by several peaks of about 14,000 feet or upwards in height. One of the most remarkable features of the orography of Colorado is the unusual development of its upland valleys, or "parks," to use the term that has become distinctively their own. The four most extensive are known respectively as the North, the Middle, the South, and the San Luis; the last is by far the finest of the four. They stretch almost in a line from the southern to the northern boundary of the State, just on the western side of the Front Range, and occupy an average breadth of 50 miles. The San Luis Park is, as it were, an "immense elliptical bowl" with an area of 9400 square miles, bounded on the E. by the Wet Mountains and the Sangre de Cristo range, and on the W. by the Sierra de San Juan, which is part of the great Sierra Miembres. Its surface is nearly as flat as a lake, and it almost certainly was at one time the bed of a great inland sea. The centre of the northern part, which bears the distinctive title of the Rincon, is still occupied by a considerable sheet of water, fed by nineteen mountain streams, and accustomed in the winter to overflow a large stretch of the neighbouring savannah. The southern part, which continues onwards into New Mexico, is traversed by the Rio del Norte and several of its tributaries.

Rivers.—Of the rivers of the Atlantic versant, the most important are the South Platte, the Arkansas, and the Rio Grande del Norte; those of the Pacific are all members of the great Colorado River. The South Platte has its head waters in Buckskin Mountain, and its earlier tributaries flow from the slopes of the northern part of the Front Range. At its source at Montgomery it has a height above the sea of 11,176 feet; at its exit from the upper cañon it is still 7623, but by the time it reaches Denver it is only 5176. The Arkansas rises in the same district, at a height of 10,176 above the sea, in Tennessee Pass, but as it leaves Chalk Creek has come down to 7877. In the upper part of its course it passes through a cañon from 1000 to 1500 feet in depth. The Rio Grande del Norte has its head waters in the Sawatch range and the Sangre de Cristo range, and flows south through the valley San Luis Park. The river which gives its name to the State belongs to the territory only by some of its most important tributaries, of which it is sufficient to mention the Bear River, and the Gunnison and Grand River, which unite before they pass into the territory of Utah. The numerous minor "creeks" which feed the main streams must not be forgotten in forming an idea of the main features of the country.

Minerals.—Colorado is pre-eminently a mineral district, and to this fact it owes its colonization. It possesses extensive deposits of gold and silver ore, and between the years 1859 and 1872 it furnished to the United States mint upwards of $20,000,000 worth of the former metal and $1,114,542 of the latter. Iron is pretty widely diffused, and zinc and copper occur in many of the mines. Coal is also found extensively on both sides of the main range of mountains; the area occupied by the Tertiary deposits being no less than 7200 square miles, and the annual yield about 200,000 tons. The mining districts are five in number, and are distinguished as the district of the northern mines, the mines of the eastern base, the Conejos county mines, the southern mines, and the mines of Summit County. At Murphy's mine, about twelve miles from Denver, the stratum is about 16 feet thick, and the percentage of fixed carbon is found to be 55·31.

The *climate* of Colorado is remarkable for its regularity and salubrity. During the day the thermometer not unfrequently rises to 90° in summer, but the nights are always cool and dewless. In winter the weather is generally mild,—the lowest thermometric marking being only 7° below zero, in Middle Park 15°, and in Denver 13°. Snow often lies deep in the higher inhabited districts, but in the lowlands it is never more than 10 or 12 inches, and it disappears again almost immediately. All through the year the atmosphere is so dry and light that butcher meat can be preserved by the simplest process of desiccation. Between July and October there is very little rain, day after day bringing a bright and cloudless sky. "An air more delicious to breathe," says Bayard Taylor, "cannot anywhere be found; it is neither too sedative nor too exciting, but has that pure, sweet, flexible quality which seems to support all one's happiest and healthiest moods." For asthmatic and consumptive patients it exercises a restorative influence which cannot be disputed; and the State consequently promises to become an extensive sanatorium for the eastern districts of the continent. The only flaw in the climate of Colorado is its violent storms of wind, and in some parts of the country heavy falls of hail. It would seem, however, that the humidity is on the increase; and whatever be its cause, the change is quite perceptible since the colonization of the territory. The Cache à la Poudre, for instance, is said to be yearly increasing in volume, and streams which formerly dried up in the summer now maintain a continuous flow. Among the secondary hygienic advantages of which Colorado can boast, the mineral wells hold an important place. They occur in various parts of the country, and belong to different classes. Chalybeate waters are found at Manitou, Carlisle, and Red Creek; soda springs at Manitou, Trinidad, and Cañon City; sulphur springs at Fairplay, on the Navajo River, and at Idaho springs; and thermal springs, partly sulphur and partly soda, exist at Pagosa, in the Middle Park, in Seguache County, at Wagon Wheel Gap, and at Del Norte. Manitou is already becoming a fashionable watering-place; the fountains and the surrounding land were purchased by a company in 1870; and in 1873 there were already six large hotels and numerous private residences erected round the spot. In the lowland districts water for drinking is very scarce; but supplies can frequently be obtained by the sinking of Artesian wells.

Vegetation.—The mountains of Colorado were, till a comparatively recent date, richly clothed with forest; but owing partly to natural causes, and still more to the lavish consumption and reckless destruction of the early settlers, the quantity of growing timber in the State is exceedingly small, and before long, if restorative measures are not adopted, the Colorado demand for wood will require to be supplied from without. Whole mountain sides often present the appearance of monstrous cheavaux-de-frise, the dead trunks of the wind-thrown pines being tossed about in all directions. The principal trees, after the pine, are the so-called hemlock and cedar, the cotton wood, and the aspen (or *Populus tremuloides*). The minor flora of the country is exceedingly rich; and especially in the plain region the abundance of flowers is amazing. "The colour of the landscape," says Dilke, "is in summer green and flowers; in fall time yellow and flowers; but flowers ever."

Agriculture.—Wherever irrigation can be obtained the soil of eastern Colorado is well fitted for agriculture. Wheat, oats, and barley afford heavy crops; potatoes succeed except in the extreme south, and owing to the dryness of the atmosphere are easily kept; onions vie in size and flavour with any in the continent; beans might be grown more extensively, but they suffer from the attacks of a small insect, possibly a species of *Haltica;* and almost all the garden products of the same latitude in Europe can be satisfactorily cultivated. The wheat affords a very white dry flour, and competes with the finest in the markets of the world. The yield often reaches forty or fifty bushels per acre, and in exceptional cases considerably exceeds this amount. In the higher districts—the parks and the mountain-valleys—a greater proportion of ground is devoted to pasture either of sheep or cattle. The native grasses are of excellent quality as fodder; and during the winter the natural hay that has withered where it grew is preferred by the cattle to the best that can be furnished by the labours of the husbandman. In certain districts the pastoral departments of husbandry have had to be abandoned, owing to the presence of poisonous plants, the most important of which seems to be *Oxytropis Lamberti;* but these districts are of very limited extent. The cost of pasturing is merely nominal, as the cattle can be driven over extensive districts, under the charge of Mexican or Indian herdsmen. Wool can be produced for ten cents per lb., and a four-year-old steer for ten dollars. The chief plague of the agriculturist is the locust, or grasshopper, as it is called in America. This insect is usually hatched in the month of June, when the cereals are well advanced; but occasionally in dryer and warmer seasons it appears as early as April and does great damage to the young crops. Another insect, the *Doryphora decemlineata*, popularly known as the Colorado Beetle (see p. 134 of the present volume), has recently become famous for its attacks on the potato, not only in this State but as far east as Ohio. It appears formerly to have fed on the *Solanum rostratum*, but to have found the new tuber a better habitat.

History.—Recent explorations have shown that the western parts, at least, of the Colorado territory were at one time inhabited by a native American race of considerable civilization, who were perhaps connected or even identical with the Moquis of the regions further south. The first important European mission was that of Vasquez Coronado, despatched from Mexico in 1540. In 1821 the Rocky Mountains were visited by S. T. Long, the American engineer; and part of the northern district was pretty fully explored by Captain J. C. Fremont during the great expedition of 1843. It was not till 1858 that the Indian tribes were disturbed in their sparsely-peopled hunting grounds; but in that year the discovery of gold by W. G. Russell, a Georgian, on the banks of the River Platte, near the present city of Denver, attracted general attention, and bands of pioneers poured in from Kansas, Nebraska, and Missouri. During 1860, 1861, and 1862, there was a continuous stream of immigration; Denver, Black Hawk, Golden City, Central City, Mount Vernon, and Nevada city were all founded in 1859; next year saw the rise of Breckenridge, Empire, and Gold Hill; George Town and Mill City were added in 1861, and Ward District was settled in 1862. In 1861 the region was organized as a territory in accordance with the wish of the inhabitants, who had held a convention at Denver in 1859; its area was declared to include 47,657,000 acres previously assigned to the territories of Utah and Kansas, 10,262,400 from that of Nebraska, and 8,960,000 from New Mexico, making a total of 66,880,000. The first governor was William Gilpin, a Pennsylvanian by birth and a Quaker in religion, who has done a great deal for the development of the territory, and was the originator of the scheme by which it was made to include part of both slopes of the Sierra. From 1862 to 1865 the natural progress of immigrational movement was checked, partly by the great national struggle, and partly by the local Indian war which broke out in 1864, and for a time rendered the routes extremely unsafe, and even threatened the existence of the new settlements. Many of the sites, indeed, were deserted, and large numbers of the miners left the country. In this way Empire greatly decayed, and Gold Dirt and Bakerville absolutely disappeared. Happily it was only the Indians of the plains who took part in the attacks, and though they numbered from 10,000 to 15,000, they were quickly quelled. In 1865 the immigration again flowed on; and it was found that at the census of 1870 the population was 39,864 citizens, distributed into 9358 families, and inhabiting 10,009 houses. The proportion of males to females was 24,820 to 15,044. Since that date the population has very rapidly increased, and it was estimated at 120,000 in 1874. Colorado was received into the Union as a State in 1877.

See Fremont, *Narrative of Exploring Expedition*, 1846; Capt. Stansbury, *Expedition to the Valley of the Great Salt Lake*, 1852; Edward Bliss, *The Gold Mines of Colorado;* Hollister, *Flying Trip to the Silver Mines of Colorado;* Bayard Taylor, *A Summer Trip to Colorado*, 1867; Bowles, *Summer Vacations in the Parks and Mountains of Colorado*, 1869; W. Blackmore, *Colorado: its Resources and Prospects*, 1869; Greatorex, *Summer Etchings in Colorado*, 1874; Porter and Coulter, *Synopsis of the Flora of Colorado*, 1874; and as the main source of all topographical, geological, and botanical details regarding the State, the *Reports of the United States Geological and Geographical Survey*, which have been published from time to time by the Government.

COLORADO RIVER, or Rio Colorado, a large river of North America, which rises in the Rocky Mountains and falls into the Gulf of California. The main stream, known as the Green River, has its source in Fremont's Peak on the western borders of Wyoming, so that the whole extent of its course must be upwards of 2000 miles. After receiving the waters of the Yampuh and the White River, it flows south for about 150 miles without any important augmentation till it meets with the great rival stream of the Grand River, which by means of its numerous confluents drains so large a portion of the western versant in the State of Colorado. The united stream continues to force its way south, till at its junction with the Colorado Chiquito, or Little Colorado, which takes its rise in the Sierra Madre of New Mexico, it turns almost due west, and cuts right athwart the line of the mountain ranges. Its southern direction is resumed after the confluence of the Virgen from the Wahsatch Mountains, and it only receives one other tributary of real magnitude, the River Gila, before it reaches the sea. The enormous canons or ravines through which the Colorado and several of its confluents force their way, render this one of the most remarkable river systems of the world. The Grand Cañon alone extends for a distance of about 200 miles westward from the junction of the Colorado Chiquito, and its walls rise almost sheer from the water's edge to a height of from 4000 to as much as 7000 feet. Further down is Black Cañon which, with a length of 25 miles and a height of 1000 or 1500 feet, would be considered a magnificent phenomenon, were it not so completely thrown into insignificance by its more stupendous neighbour. These very features which give the river its uniqueness prevent it from being of much use as a means of navigation; but steamers can proceed upwards as far as Callville, about 612 miles from the mouth.

The discovery of the Colorado is due to Fernando Alascon in 1540; but it was not till Lieutenant Ives's expedition in 1857 that even the lower part of its course was properly explored. The mysteries of the Great Cañon were first invaded by an unlucky "prospector," James White, who along with a companion thought it safer to trust himself to the river than to the Indians. In 1869 the whole course from the head-waters in Wyoming to the town of Callville was traversed by a party of explorers, commissioned by the United States Government and commanded by Professor J. W. Powell. Since that date the river and its basin have been the object of systematic survey under the same auspices, and the results of the gigantic undertaking have been published by Professor Powell in his *Exploration of the Colorado River of the West and its Tributaries, explored in* 1869, 1870, 1871, and 1872 (Washington, 1875).

COLOSSÆ, a once large and important city of Asia Minor, in Phrygia Major, on the Lycus, a branch of the Mæander. The notices of Colossæ in ancient history are few and brief. Xerxes passed through it on his way to Greece, 481 B.C., and at the close of the same century it was visited by Cyrus the younger. It is described by Xenophon in the *Anabasis* as being at that period a large and flourishing city. Like Laodicea, and other cities in that part of Phrygia, Colossæ carried on an extensive trade in wool, and derived a large revenue from the skill of its inhabitants in dyeing that article. After the time of Cyrus the city seems to have gradually decayed, till in the Middle Ages it disappeared altogether. Near its ruins there sprang up another town called Chonæ, the birthplace of the Byzantine historian, Nicetas Choniates, now represented by the town of Khonas. Excavations made in the neighbourhood of this place have brought to light the ruins of a large city, which is believed, with good reason, to be Colossæ. The Epistle to the Colossians (see below) is addressed to the inhabitants of this city, in which one of the earliest of the Christian churches in Asia was planted.

COLOSSEUM. See AMPHITHEATRE, vol. i. p. 774; ARCHITECTURE, vol. ii. p. 419; and ROME.

COLOSSIANS, THE EPISTLE TO THE, belongs to the third of the four groups under which the Pauline epistles may be chronologically arranged,—a group which occupies a midway position between the letters sent to Corinth, Galatia, and Rome, in the apostle's third missionary journey, and the letters known as the Pastoral Epistles. By similarity of language and matter the epistle to the Colossians is intimately connected with that to the Ephesians; and the notices of St Paul's companions, and of Onesimus and Archippus, which occur in the epistle to Philemon, show that this last epistle was also written and sent at the same time as the other two. The epistle to the Philippians belongs to the same group, and the most probable view is that it was from Rome that all four were written by Paul, "the prisoner of Jesus Christ" (comp. Philem. 1; Col. iv. 10, 18; Eph. iii. 1, iv. 1, vi. 20; Phil. i. 13, 14, iv. 22). Some critics—among whom may be mentioned Schulz, Böttger, Thiersch, Meyer, and Reuss, whose opinion is strongly advocated by De Pressensé in his *Histoire des Trois Premiers Siècles*—contend that at least three of the epistles were written from Cæsarea; but the traditional view that all four were written from Rome is supported by most modern writers, and is freest from difficulties. The date of the epistle to the Colossians may be placed about 62 or 63 A.D. Assuming for the present its genuineness, we may gather from the contents of the epistle itself its occasion and object. Epaphras, who is spoken of in high terms by the apostle, and may with some probability be considered the founder of the church at Colossæ (i. 7), has brought tidings to St Paul which make him anxious concerning the Christians in Colossæ and its neighbourhood (ii. 1, iv. 13). False teachers are there endeavouring to beguile them with plausible talk (ii. 4), and Paul, as a minister of the gospel earnestly labouring in the cause of proclaiming Christ to the nations (i. 24–29), feels his heart called out towards those whose faith is being insidiously assailed, although he is absent from them, and has never personally visited Colossæ or Laodicea (ii. 1). He accordingly writes an epistle the polemical purport of which is patent. Paul's polemic, however, is no mere negative protest. He sets up, as against the "false philosophy" which he so strenuously repudiates (ii. 8), a "theological conception of the person of Christ," which strikes at the root of all vain speculations concerning the unseen world, and shows that the work of reconciliation effected by Christ is complete, so that in Him Christians are to see the one Mediator through whom God is to be known, approached, served. The latter part of the epistle consists of various practical exhortations, both general and specific; and it closes with several notices of a personal character. Tychicus was the bearer of this letter (iv. 7), as he was also of that known as the epistle to the Ephesians, which by some critics is identified with "the letter from Laodicea" (iv. 16).

But are these letters genuine? There is no historical ground for doubting the Pauline authorship, or for the theory which has been advanced that the two epistles are inventions of a later age, or for the supposition that, whilst one of them is genuine, the other is made up of materials derived from that one which was really written by St Paul. The fact that opponents of the genuineness of the letters do not agree as to which was the original is significant. Mayerhoff thinks, indeed, both epistles to be spurious, but considers that the epistle to the Colossians was compiled from that to the Ephesians; while De Wette holds the epistle to the Ephesians to be a "verbose enlargement" of that to the Colossians, and advocates the genuineness of the latter. The opponents of the Pauline authorship rest mainly on three lines of argument, *viz.*, the similarity of the two epistles, the peculiarity of their contents, and peculiarities of style.

The objection founded on the similarity of the language and matter of the two epistles is one that cannot be substantiated. For whilst there are striking resemblances, there are no less striking differences; and whilst the resemblances can be very naturally accounted for by the contemporaneousness of the letters, the differences are so markedly in accordance with the apparent designs of the separate letters,—that to the Colossians being primarily polemic, and that to the Ephesians being of a mystic and devotional character,—that we may fairly use of each epistle the words applied by Meyer to the epistle to the Colossians,—"The supposed forgery of such an epistle would be far more marvellous and inexplicable than its genuineness."

Another objection brought forward is that in these epistles we have sentiments that savour of heresies later than the apostolic age. This objection seems to be based upon very superficial grounds, and to spring from prejudice rather than from research. What definite ground is there for asserting that "Gnostic and Montanist" sentiments are to be found in these epistles? While certain false teachings and tendencies are alluded to, which evidently go beyond the more naked Pharisaic Judaism controverted in the epistle to the Galatians, nothing can be produced to show that the heretical teaching animadverted upon in the epistle to the Colossians, or even in the later epistles of Paul to Timothy and Titus, is *Gnosticism* in the sense in which that term is applied to later systematic theosophies and cosmologies, such as those of Basilides and Valentinus. And would it not be natural, as Neander points out, to postulate, even if we had no records to testify to the fact, the existence of certain transitional links between the *gnosis* of the 2d century and the earlier stages of the apostolic preaching? Such links are found in the *incipient* Gnosticism, if so it is to be called, of which we have traces in the epistles of the imprisonment and the subsequent Pastoral Epistles.

A third objection has been made to the genuineness of the epistle to the Colossians, as well as to the Ephesian epistle, on the ground of the peculiarity of their style and of certain terms used in them, some of which are asserted to be technical terms, as *æon*, *pleroma*, *&c.*, and others are words not elsewhere used in the Pauline writings. The answer to this objection is that the peculiar terms are not used in the sense which they acquired in heretical writings of a later period, and that the unusual words are to be attributed partly to the nature of the subject and partly to the disposition of the writer's mind at the time. If, indeed, we are to condemn any writing of an author for containing peculiarities not exhibited in other writings of the same author, the questions arise, whence are we to take our standard of judgment, or how are we to know in what cases we should apply so vague a critical canon? Bleek says, sensibly enough, in view of this line of objection, "We do not for a moment deny that the epistle to the Colossians contains much which is peculiar to itself; but its contents, such as they are, do not tell against its coming from the same author as the other epistles of St Paul, for even those which Baur allows to be genuine contain much that is distinctive and peculiar, *e.g.*, the Galatians as compared with the Corinthians, and 2 Corinthians as compared with 1 Corinthians." The fact is that in the Tübingen school "subjective criticism" has run to riot. The phenomena to be investigated are interpreted according to a preconceived theory, rather than fairly looked at, examined, and explained. The testimony of the early church to the Colossian and Ephesian letters is unexceptionable. In the case of the epistle to the Colossians, there are indications of its recognition in allusions by Justin Martyr and Theophilus of Antioch; it occurs in the Muratorian canon (*circ.* 170 A.D); it is cited by Irenæus, Clement of Alexandria, Tertullian, and Origen; Eusebius places it among the "acknowledged" books of the apostolical writings; and it occurs in Marcion's list, as given by Epiphanius. Nor is there anything in the epistle itself that is out of accordance with the circumstances of the apostle Paul, or the condition of the Asiatic churches in the seventh decade of the 1st century.

We must now briefly notice the character of the teaching against which St Paul directed the controversial portion of the epistle to the Colossians (ii. 4–23). His warnings are against a philosophy which is vain and fallacious; against a system of multiplied religious observances and distinctions of meats; against an arbitrary system of angel-worship; and against certain rigorous rules of asceticism. The basis of this alien teaching was unmistakably Judaic, but the Judaizing effort was of a mystic and ascetic type; and it is not unreasonable to see in the theosophical speculations and ascetic ordinances, indicated in St Paul's picture of the dangers which beset the Colossian Christians, an admixture of Jewish and Oriental elements. Professor Lightfoot has shown that Oriental notions concerning the evil of matter and the need of rigid abstinence, together with "an esoteric doctrine relating to angelic beings" and a tendency to sun worship, appear in Essenism, which he suggests might be called Gnostic Judaism. The Essene side of Judaism was doubtless represented among the Jews who were settled in, or journeyed to and from, various places in Asia Minor; and all mystic and ascetic ideas would find a congenial soil in Phrygia. The teaching and tendencies alluded to in the epistle to the Colossians, and subsequently in the Pastoral Epistles, form the intermediate link between the "Gnostic Judaism" of the Essenes and teachers allied to them and the "Judaizing Gnosticism" of the 2d century.

The question whether Paul himself planted the church at Colossæ is one of minor importance, which has been much discussed by commentators. Lardner argues elaborately in favour of a visit by Paul to Colossæ and Laodicea. He bases his view upon a passage cited from Theodoret, in which ch. ii. 1 is interpreted so as to distinguish between the Colossians and Laodiceans on the one side and the "as many as had not seen Paul's face" on the other. This view has been controverted in detail by Davidson, but is advocated by Wordsworth. Bleek mentions Schulz, Wiggers, and others as following Theodoret, but he takes the contrary view himself, as do also Alford, Conybeare and Howson, and Lightfoot. The last-named commentator says that Theodoret's interpretation is "opposed alike to grammatical and logical considerations."

Another disputable though not very important point is whether the Ephesian or the Colossian letter was written first. Critics are divided, and it is somewhat difficult to gather from a comparison of the epistles which view is most probable. We are inclined to favour the view that the briefer, more controversial, and in some respects more vigorous letter was written first, and was followed by the fuller and more mystic one. It has been said that this epistle is characterized by a "ruggedness of expression and want of finish that borders on obscurity" (Lightfoot), and it has been suggested that the absence of personal connection on St Paul's part with the Colossian church might partially account for "the diminished fluency of this letter," as compared with other and earlier ones. We do not think this explanation a satisfactory one. The "ruggedness" should rather be attributed to the intensity of feeling wherewith the apostle, confined as he was in his far-off place of imprisonment, threw himself into the controversy with the false teachers,—persons whom he must have regarded as among the "grievous wolves," of whom he had forewarned the elders at Miletus some few years previously (Acts xx. 29, 30), men who should "arise out of the Christian community itself, and speak perverse things to draw men after them." This explanation is somewhat corroborated by what Alford points out, viz., that the majority of peculiar expressions in the epistle occur in the second chapter. And Professor Lightfoot himself adds—"No epistle of St Paul is more vigorous in conception or more instinct with meaning. It is the very compression of thoughts which creates the difficulty. If there is a want of fluency there is no want of force. Feebleness is the last charge which can be brought against this epistle."

The value of this epistle to the church historian, to the Christian theologian, and to any one who wishes fairly to estimate the "philosophic" bearings of Christian dogma is very great. A commentator of the 17th century, H. Suicer, mentioned by Walch in his *Bibliotheca Theologica*, calls the epistle to the Colossians *theologiæ Christianæ compendium*.

Authorities for what has been said, and references to further literature upon the subject, may be found in "Introductions," such as those by Davidson and Bleek, and in "Prolegomena" of commentators, *e.g.*, Alford, Wordsworth, and Braune in Lange's *Bibelwerk*, a treasury of information made accessible to English readers in Dr Schaff's edition, published by T. & T. Clark. Frequent reference has been made in the course of this article to the recent very valuable commentary of Professor Lightfoot. In addition to the exegetical notes, he gives us thorough dissertations on "the churches of the Lycus," the "Colossian heresy," and "the Essenes." There is also a digest of the principal various readings, containing an ingenious conjecture as to the original reading in chap. ii. 18. Attention is drawn to the fact that the epistles to the Ephesians and the Colossians, alone among the Pauline epistles, are exposed to those "harmonizing tendencies" in transcribers which have had such an influence on the text of the gospels. Professor Lightfoot deals, also, in a most exhaustive manner, with the subject of the apocryphal letter to the Laodiceans (connected with Col. iv. 16), which appears in a considerable number of MSS. of the New Testament, and shows it to be "a cento of Pauline phrases strung together without any definite connection or any clear object." Paley, in his *Horæ Paulinæ*, has a very satisfactory section on the similarity of the epistles to the Ephesians and the Colossians. On the character of the heretical tendencies in Asia Minor the general reader will find all requisite information in Neander, *History of the Planting, &c., of Christianity*, and Pressensé, *Histoire des Trois Premiers Siècles de l'Église Chrétienne*. Mansel, in his *Gnostic Heresies*, has a chapter devoted to Notices of Gnosticism in the New Testament. Both Neander and Pressensé draw attention to the arbitrary and unsound theorizing of the Tübingen school in respect to the group to which the epistle to the Colossians belongs. (W. S. S.)

COLOSSUS, in antiquity, a term applied generally to statues of great size, and in particular to the bronze statue of Helios, in Rhodes, which for its size came to be reckoned among the wonders of the world. It was made from the spoils left by Demetrius Poliorcetes when he raised the prolonged siege of Rhodes. The sculptor was Chares, a native of Lindus, and of the school of Lysippus, under whose influence the art of sculpture was led to the production of colossal figures by preference. The work occupied him twelve years, it is said, and the finished statue stood 70 cubits high. It stood near the harbour (ἐπὶ λίμενι), but at what point is not certain. When, and from what grounds, the belief arose that it had stood across the entrance to the harbour, with a beacon light in its hand and ships passing between its legs, is not known, but the belief was current as early as the 16th century. M. Benndorf has recently endeavoured to trace it to a mistaken reading of a Greek epigram on the Colossus, and his conjecture seems probable (*Mittheilungen des deutschen Instituts in Athen*, part 1, p. 45). The statue was thrown down by an earthquake about the year 224 B.C., that is about 56 years after its erection. Then, after lying broken for nearly 1000 years, it is said, the pieces were bought by a Jew, and probably reconverted into instruments of war.

COLOUR. See LIGHT and OPTICS.

COLSTON, EDWARD (1639–1721), was the son of William Colston, a Bristol merchant of good position. He is generally understood to have spent some years of his youth and manhood as a factor in Spain, with which country his family was long connected commercially, and whence, by means of a trade in wines and oil, great part of his own vast fortune was to come. On his return he seems to have settled in London, and to have bent himself resolutely to the task of making money. In 1681, the date of his father's decease, he appears as a governor of Christ's Hospital, to which noble foundation he afterwards gave frequently and largely. In the same year he probably began to take an active interest in the affairs of Bristol, where he is found about this time embarked in a sugar refinery; and during the remainder of his life he seems to have divided his attention pretty equally between the city of his birth and that of his adoption. In 1682 he appears in the records of the great western port as advancing a sum of £1800 to its needy corporation; in 1683 as "a free burgess and *meire* (St Kitts) merchant" he was made a member of the Merchant's Hall; and in 1684 he was appointed one of a committee for managing the affairs of Clifton. In 1685 he again appears as the city's creditor for about £2000, repayment of which he is found insisting on in 1686. In 1689 he was chosen auditor by the Vestry at Mortlake, where he was residing in an old house once the abode of Ireton and Cromwell. In 1691, on St Michael's Hill, Bristol, at a cost of £8000, he founded an almshouse for the reception of 24 poor men and women, and endowed with accommodation for "Six Saylors," at a cost of £600, the Merchant's Almshouses in King Street. In 1696, at a cost of £8000, he endowed a foundation for clothing and teaching 40 boys (the books employed were to have in them "no tincture of Whiggism"); and six years afterwards he expended a further sum of £1500 in rebuilding the school-house. In 1708, at a cost of £41,200, he built and endowed his great foundation on Saint Augustine's Back, for the instruction, clothing, maintaining, and apprenticing of 100 boys; and in time of scarcity, during this and next year, he transmitted "by a private hand" some £20,000 to the London committee. In 1710, after a poll of four days, he was sent to Parliament, to represent, on strictest Tory principles, his native city of Bristol; and in 1713, after three years of silent political life, he resigned this charge. He died in 1721, having nearly completed his eighty-fifth year; his remains were conveyed, with all the funereal magnificence his own solemn fastidiousness could suggest, from his house at Mortlake to Bristol, where he was buried in All Saints' Church. Colston, who was in the habit of bestowing large sums yearly for the release of poor debtors and the relief of indigent age and sickness, and who gave (1711) no less than £6000 to increase Queen Anne's Bounty Fund for the augmentation of small livings, was always keenly interested in the organization and management of his foundations; the rules and regulations were all drawn up by his hand, and the minutest details of their constitution and economy were dictated by him. A high churchman and Tory, with a genuine intolerance of dissent and dissenters, his name and example have served as excuses for the formation of several politic benevolent societies—the "Anchor," the "Dolphin," the "Grateful,"—whose rivalry has been perhaps as instrumental in keeping their patron's memory green as have the splendid charities with which he enriched his native city. See Garrard, *Edward Colston, the Philanthropist*, 4to, Bristol, 1852; and Pryce, *A Popular History of Bristol*, 1861.

COLT, SAMUEL (1814–1862), the inventor of the revolver, was born at Hartford, Connecticut, where his father possessed a manufactory of silks and woollens. At ten years old he left school for the factory, and at fourteen he made a runaway voyage to India, during which he made a wooden model, yet existing, of what was afterwards to be the revolver. On his return he learned chemistry from his father's bleaching and dyeing manager, and travelled over the United States and Canada lecturing on that science. The profits of two years of this work enabled him to continue his researches and experiments. In 1835 he visited Europe, and patented his inventions in London and Paris, securing the American right on his return; and the same year he founded the Patent Arms Company, for the manufacture of his revolvers only. The scheme did not succeed; some use was indeed made of the arms, but they were not generally appreciated; and in 1842 the company became insolvent. No revolvers were made for five years; and none were to be had when Taylor sent from Mexico for a supply. The Government ordered 1000 from the inventor; but before these could be produced he had to construct a new model, for a pistol of the company's make could nowhere be found. This commission was the beginning of an immense success. The little armoury at Whitneyville (New Haven, Connecticut), where the order for Mexico was executed, was soon exchanged for larger workshops at Hartford, the inventor's birthplace. These in their turn gave place (1852) to the enormous factory, doubled in 1861, on the banks of the Connecticut River, whence so many millions of revolvers, with all their appendages, have issued, and whence was sent, for the Russian and English Governments, to Tula and Enfield, the whole of the elaborate machinery devised by Colt for the manufacture of his pistols.

COLUMBA, St, was born on the 7th of December 521, and the place of his birth is supposed to have been Gartan, in the county of Donegal. Both on the father's and on the mother's side he was descended from princely families in Ireland, and Conal, king of the Scots in Northern Britain, was his kinsman. Some writers are of opinion that his original name was Crimthan, and that he received the surname of Columba from the dove-like simplicity of his character, but it is more probable that the latter was his baptismal name. He was afterwards known as Columbkille, or Columba of the Churches, to distinguish him from others of the same name. Ireland was already famous for the learned men who taught in its numerous monasteries; and Columba studied for some time under one of the most distinguished of these, St Finian of Moville. Almost as a matter of course, under such circumstances, he embraced the monastic life. He was ordained deacon while at Moville, and afterwards, when about thirty years of age, was raised to the priesthood. During his residence in Ireland he founded two famous monasteries, one named Dair Calgach, on the banks of Lough Foyle, the other Dair-magh in Leinster, better known by their modern names of Derry and Durrow.

When upwards of forty years of age he left his native island, accompanied by twelve disciples, and went on a mission to Northern Britain. Argyll and the neighbouring islands were at this time portions of the Christian kingdom of the Scots, and from its sovereign Conal he received the Island of Hy, or Iona, where he fixed his residence. His first task was to erect a church and monastery—humble structures of timber and reeds, according to the fashion of the country and the age. Having spent some years in preparation, he began the great work of his life,—the conversion of the heathen kingdom of the Northern Picts. Crossing over to the mainland he proceeded to the residence, on the banks of the Ness, of Brude, king of the Picts. By his preaching, his holy life, and, as his earliest biographers assert, by the performance of miracles, he converted the king and many of his subjects. The precise details, except in a few cases, are unknown, or obscured by exaggeration and fiction; but it is certain that the whole of northern Scotland was converted by the labours of Columba and his disciples, and the religious instruction of the people provided for by the erection of numerous monasteries.

The monastery of Iona was reverenced as the mother house of all these foundations, and its abbots were obeyed as the chief ecclesiastical rulers of the whole nation of the Northern Picts. There were then neither dioceses nor parishes in Ireland and Celtic Scotland; and by the Columbite rule the bishops themselves, although they ordained the clergy, were subject to the jurisdiction of the abbots of Iona, who, like the founder of the order, were only presbyters. The controversies connected with this subject are well known to the students of ecclesiastical history, and need not here be farther adverted to. Similar disputes have existed regarding the doctrines of Columba and his followers. This point also is beyond the range of the present article. It may be sufficient to mention that there is no real difficulty as to their belief in its general features. It was the same as that of the Western Church on the Continent, with which also their ritual agreed except in a few unimportant particulars, such as the precise time of keeping Easter. The confusion in these matters has been chiefly owing to the careless and incorrect identification of the Columbites with the clergy afterwards known by the name of Culdees.

Columba was honoured by his countrymen, the Scots of Britain and Ireland, as much as by his Pictish converts, and in his character of chief ecclesiastical ruler or primate he gave formal benediction and inauguration to Aidan, the successor of Conal, as king of the Scots. He accompanied that prince to Ireland in 590, and took a leading part in a council held at Drumceat in Ulster, where a controversy was settled which had existed between the king of Ireland and the sovereign of the British Scots. The last years of Columba's life appear to have been spent at Iona. There he was already revered as a saint, and whatever credit may be given to some portions of the narratives of his biographers, there can be no doubt as to the wonderful influence which he exercised, as to the holiness of his life, and as to the love which he uniformly manifested to God and to his neighbour.

In the summer of 597 he knew that his end was approaching. On Saturday the 8th of June he was able, with the help of one of his monks, to ascend a little hill above the monastery and to give it his farewell blessing. Returning to his cell he continued a labour in which he had been engaged, the transcription of the Psalter. Having finished the verse of the 34th Psalm where it is written, "They who seek the Lord shall want no manner of thing that is good," he said, "Here I must stop:—what follows let Baithen write;" indicating, as was believed, his wish that Baithen should succeed him as abbot. He was present at evening in the church, and when the midnight bell sounded for the nocturnal office early on Sunday morning he again went thither unsupported, but sank down before the altar and passed away as in a gentle sleep.

The original materials for a life of St Columba are unusually full. The earliest biography was written by one of his successors, Cuminius, who became abbot of Iona in 657. Much more important is the enlargement of that work by Adamnan, who became abbot of Iona in 679. These narratives are supplemented by the brief but most valuable notices given by the Venerable Bede. The first modern writers who discussed the life and actions of Columba, with any approach to critical accuracy, were two learned clergymen of the Roman communion,—Thomas Innes, the Scottish antiquary, and Dr John Lanigan, the ecclesiastical historian of Ireland. In 1857 Dr Reeves, now dean of Armagh, published his edition of Adamnan's *Life*, enriched with notes and dissertations which throw light on all the events of the saint's personal history and on everything connected with the state of Celtic Britain at the time. Later still we have an account of Columba by Count Montalembert, who, in his third volume of the *Monks of the West*, gives us, to use Gibbon's well-known words about Pope's Homer, "a portrait endowed with every merit excepting that of likeness to the original." (G. G.)

COLUMBANUS (*c.* 550-615), an Irish monk, was born in Leinster about the year 550, and was educated in the monastery of Bangor. He left the monastery in 590, together with twelve youths whom he was training, and established himself in the Vosges, among the ruins of an ancient town called Anagratis. Crowds quickly flocked round them, and the monasteries of Luxeuil and Fontenay were erected. But the enemies of Columbanus accused him before a synod of French bishops (602) for keeping Easter according to the old British and now unorthodox way, while a more powerful conspiracy was organized against him at the court, for boldly and haughtily rebuking for their crimes both the king of Burgundy, Thierry II., and the queen-mother Brunehaut. In consequence of this he was banished, but he proudly refused to stir. He was at length removed from his monastery by force, and, with St Gall and others of the monks, he withdrew into Switzerland, where he preached with no great success to the Suevi and Alemanni. Being again compelled to flee, he retired to Italy, and founded the monastery of Bobbio, in which he remained till his death. His writings, which include some Latin poems, prove him a man of learning, and he appears to have been acquainted not only with the Latin classics, but also with Greek, and even Hebrew. His works were published at Louvain in 1667. His *Regula Cœnobitalis cum Pœnitentiali* is to be found in the *Codex Regularum* (Paris, 1638). The order of the Columbans merged in that of the Benedictines in the beginning of the 8th century.

COLUMBIA, the capital of South Carolina, United States of North America, is a city of nearly 10,000 inhabitants. It lies on the east bank of the Congaree River, just below its junction with the Broad and Saluda, and is 124 miles N.N.W. of Charleston, the principal seaport of the State. It is noted for its salubrity and the natural beauty of its site and surroundings. As the capital and political centre of the State, it has held a position second only in importance to Charleston, and has been the home of many distinguished men. Several public institutions enhance its dignity. Among these are the South Carolina College, founded in 1804, with which the late Professor Francis Lieber was long officially connected, the asylum for the insane, a theological school, the State-house, court-house, &c. It is the terminus of three railroads which connect it with Charleston and the sea-coast, and with points west and north, and is also the head of steamboat navigation on the River Congaree. A fertile agricultural region surrounds it, and it enjoys a fair degree of commercial prosperity. Near the close of the civil war (1865), the Union army of General Sherman entered the city, being feebly opposed by the Confederates. During the Federal occupation, fires were set—whether by invaders or defenders has never been determined beyond doubt—by which many buildings and a large amount of property were destroyed.

COLUMBIA, District of, a territory of the United States of America, originally erected under a law of Congress of July 1790, for the establishment of a permanent seat of government. This law authorized the acquisition by the United States of a territory not exceeding ten miles square, at the confluence of the Potomac and its eastern branch. A part of the territory thus designated was ceded to the United States by Virginia, and included the city of Alexandria, and a part by Maryland including the city of Georgetown. Outside of these cities the territory was occupied by planters and farmers, as it had been from the latter part of the 17th century. By a law of Congress of July 1846, that portion of the district which had been ceded to the United States by Virginia was ceded back to that State. The present area of the district is 64 square miles. Under the law of 1790, three commissioners were appointed to receive the cession of the district, and to lay out the city of Washington and erect the public buildings for the reception of the Federal Government. The corner-stone of the Capitol was laid by Washington, September 18, 1793. On the first Monday of December 1800, the removal of the Government from Philadelphia was effected.

The surface of the district is diversified by hill and dale, is well wooded with oak, maple, chestnut, hickory, and other trees, is productive when well cultivated, and affords at several points extended and beautiful views of the valley of the Potomac. The scenery of Rock Creek, an affluent of the Potomac, is also celebrated for its romantic beauty. The climate is temperate and healthy. In the autumn bilious fevers are sometimes prevalent on the low grounds. The staple product before 1800 was tobacco, the culture of which has of late years been abandoned for grain, Indian corn, hay, fruit, and vegetables, all of which are produced in great abundance, and sold at remunerative prices in the markets of Washington and Georgetown. The shad and herring fisheries of the Potomac yield a large revenue.

The population of the district at each census since its organization is thus stated :—

	White.	Coloured.	Total.
1800	5,672	2,472	8,144
1810	10,345	5,126	15,471
1820	16,058	7,278	23,336
1830	21,152	9,109	30,261
1840	23,926	9,819	33,745
1850	37,941	13,746	51,687
1860	60,763	14,316	75,080
1870	88,278	43,404	131,700

The native-born population in 1870 was 115,446 ; the foreign-born, 16,254. The number of dwellings was 23,308; persons to a dwelling, 5·65 ; valuation of real and personal estate, $126,873,618; value of farms, $3,800,000 ; of farm productions, $319,000. The number of manufacturing establishments was 952 ; steam-engines, 54 ; water-wheels, 15; hands employed, 4685; capital, $5,021,925 ; products, $9,292,173,—consisting mainly of flour, building materials, furniture, clothing, and iron. The debt of the district, mainly incurred since 1872 in the construction of sewers and the paving of streets in Washington and Georgetown, is about $25,000,000.

The district is under the control of Congress, and its municipal affairs are regulated by three commissioners appointed by the president and Senate, by virtue of a law of 1874. The courts are constituted by Act of Congress, and the judges appointed by the president and Senate. By the law of 1874, the municipalities of Georgetown and Washington were abolished, and the elective franchise throughout the district suppressed. It has no representative in Congress.

The Chesapeake and Ohio Canal connects Georgetown, the head of tide-water on the Potomac, with Cumberland, the centre of the bituminous coal region of the State of Maryland. It is 180 miles in length, and transports 1,000,000 tons of coal per annum. The district is intersected by the Washington and Metropolitan branches of the Baltimore and Ohio Railway, and by the Baltimore and Potomac Railway, and is connected with the south by rail to Alexandria, the northern terminus of the Virginia railway system. There are well-managed lines of steamboats running to Norfolk, Baltimore, and New York, the last freighted mainly with flour from the district mills. The coal tonnage of the Potomac exceeds 600,000 tons annually from the port of Georgetown, which is the port of entry for the district of Columbia.

Since 1793 the United States Government has expended $60,000,000 in the erection of public buildings and improvement of public grounds in the district. For each of the years 1873, 1874, and 1875, Congress appropriated over $2,000,000 as its share of the expenses of the district government. The free schools of the district are maintained at an annual cost of $400,000. The Columbian university, established by the Baptists in 1821, is a well-endowed and flourishing institution. The Howard university, established for the education of the freedmen, is also well patronized. There are 120 church edifices in the district, of which the Baptists have 25, the Methodists 42, the Roman Catholics 14, the Episcopalians 20, the Presbyterians 14, and the Lutherans 8. The United States navy yard in Washington is one of the most complete in its appointments of all the dock-yards in the country.

COLUMBIA, BRITISH, the first of the Canadian provinces organized on the Pacific, was admitted into the Dominion in 1871. Including Vancouver's Island, it embraces an area of 233,000 square miles, of bold sea-coast, lofty mountain ranges, and rugged picturesque river courses, as well as rich fertile valleys. Unlike the great river system to the east of the Rocky Mountains, the rivers of British Columbia make their way by abrupt rapids and falls, in their comparatively brief courses from the Rocky Mountains to the sea.

British Columbia owes its rise to the status of a province of Canada to the sudden influx of gold-diggers in 1856 and following years. The bed of the Fraser River had been discovered to be a rich auriferous deposit; and all who preferred the lottery-like chances of the diggings to the more laborious but certain fruits of patient industry hastened to this new Eldorado. In a semi-official publication of 1864, it is stated that, in 1860, "Antler, the most important creek, yielded at one time, at the lowest estimate, gold to the value of $10,000 per day. On one claim $1,000 worth was taken out of the sluice-boxes as the result of a single day's work." But it was not till 1862 that the unsystematic process of mere surface diggings and washings of nomad adventurers was superseded by sinking shafts and carrying on a regulated system of mining under the direction of experienced engineers. Companies were formed; large capital was invested; and an official report of 1870 states the yield of gold for that year from the mines of Cariboo, Silionet, Lilloet, Columbia, Yale, and Lytton at $1,333,745, in addition to the large quantities of the precious metal carried out of the province by private adventurers. It appears from authentic returns that from 1862 to 1871 gold to the value of $16,650,036 was shipped from British Columbia by the banks, and so registered and put on record; while the estimated value of that which was carried out of the country by miners themselves during the same period is probably not over-estimated at $6,000,000. Nor is this a mere temporary supply derived from surface-washings. Extensive tracts of gold-bearing quartz rocks constitute an important element in the permanent mineral resources of the country. According to the *Tables of the Trade and Navigation of the Dominion of Canada*, printed at Ottawa in 1875, the export of gold in dust and bars from the province of British Columbia during the previous year is valued at $1,072,422.

As explorations and surveys are carried further into the interior the auriferous regions prove to be widely extended, and rich in their promised yield. Gold has been found over an area of not less than 200 miles, and is readily obtained by the simple processes of the adventurous gold-washer, in the beds of the Fraser, the Thompson, the Peace, and Ominica Rivers, or the creeks and tributaries flowing into them. Stickeen River, towards the Alaska frontier, the most recent gold-field, has been successfully worked since 1875, and continues to yield an abundant return. But though the rumour of river-beds of golden sand is the readiest of all stimulants to emigration, a rush of gold-diggers is not the most satisfactory addition to the population of a young colony; nor is wealth thus easily acquired generally turned to good account. The immigrant population included bands of lawless adventurers, Texans, Mexicans, Spaniards, Californian, Australian, American, and Chinese gold-diggers, with a heterogeneous gathering of reckless fortune-hunters from all parts of the world. The necessity for some regularly-organized form of government to control such a population made the organization of the territory beyond the Rocky Mountains into a province of the Dominion all the more welcome to the industrious settlers who were there seeking a permanent home.

Under the new orderly rule the crowd of gold-seekers was speedily followed by emigrants in pursuit of more settled industry. Agricultural labourers soon found that the golden harvest could be secured to themselves by providing for the miners the fruits of the soil. It is probably no exaggeration to estimate the worth of the gold carried out of the province from 1856 to 1875 as not less than $36,000,000. Much of this might be considered as productive of no direct benefit to the country. Indirectly, however, it has largely contributed to the opening up of the new province, and making its many attractions known. It led to the construction of roads, developed the mining districts, encouraged agricultural and general trade, and stimulated the growth of permanent settlements. In 1841 the "Vincennes" ship of the American exploring expedition entered the Straits of De Fuca; and Dr Pickering has preserved a vivid picture of the forbidding aspect of rudest savage life which then met his eye. Contrasting the then strange uncultivated scenes of that wild coast with the familiar centres of American civilization on the opposite shores of the same continent, he says, "Scarcely two centuries ago our New England shores presented only scenes like that before me: and what is to be the lapse of the third?" Within less than twenty years thereafter the town of Victoria was rising on Vancouver's Island, and that of New Westminster on the neighbouring mainland. The printing press was in full operation. The *British Colonist*, the *New Westminster Times*, and other newspapers were in circulation, where so recently the Indian trail and wigwam were the sole evidence of the presence of man. The produce and manufactures of the province exported during the year ending June 1874 are valued in *The Trade and Navigation Returns* for the year at $2,120,624; the customs receipts are being chiefly expended on public works, and the varied resources of the country have been rapidly developed and turned to the best account.

Minerals.—The mineral products of British Columbia still occupy the foremost place in its exports. They are valued in 1874 at $1,351,145. But it is important for the future progress of the young province on the Pacific that its minerals include coal. Mr Horetsky, in his *Canada on the Pacific*, describes the shipping of coal at Vancouver Island for the San Francisco market, where it sells at $12 per ton; and Mr Grant, in his *Ocean to Ocean*, reports his visit to Nanaimo, with a population of seven or eight hundred, all depending on the neighbouring Douglas mine. "The manager," he says, "informed us that they would probably ship 50,000 tons this season, and that next year they would be in a position to ship 100,000 or more. The coal measures which the few seams now worked represent extend over the whole eastern coast of Vancouver Island." Fine anthracite coal is also found near the coast, and in vast quantities, of superior quality, on Queen Charlotte's Island; and about 160 miles in the interior, on the River Nicholas, 50,671 tons of coal were exported in 1874 to the United States and Mexico, the value of which was $278,213.

When the census was taken in 1870, the population of the little capital of Victoria amounted only to 3,270, including 211 Chinese, but exclusive of Indians. Already it exceeds 5,000 souls, of very diverse character and nationality, but with abundant energy, and an assurance of progress. The Government of the Dominion is extending its aid to the young province with a liberal hand. In the fiscal year 1872–3, the total receipts to the Dominion from all sources in British Columbia amounted to $417,409; while the expenditure,—apart from railway surveys,—was $639,037. The same spirit still prevails. Buildings are in progress in Victoria for a post-office, savings bank, Government and Indian department; plans have also been prepared for a custom house and revenue office; and the efficient organization of courts of law and a system of police is being followed up by the erection of a penitentiary.

Fisheries.—Attention is now being energetically directed to the treasures of the ocean, the value of which has long been familiar to the native tribes. Mr J. W. Powell, Indian commissioner, in a report to the minister of the interior, dated at Victoria, February 4, 1875, after a general survey of the condition of the Indians of the province of British Columbia, and the results of efforts to encourage their attention to agriculture, thus proceeds :—

"Fish is the great staple product of all the coast Indians, and owing to the numerous lakes and rivers with which British Columbia is most bountifully supplied, affords the chief means of subsistence to almost all of the interior tribes. All kinds of fish are found in great abundance in the Northern Pacific waters; but the salmon, of which there are some six varieties, is the most constant and appreciated article of diet. The fish is now forming one of the most important exports of this province. The dog-fish is caught in large quantities for the oil contained in the liver, which not only forms a common article of barter between Indians themselves, but is sold to and exported as one of the chief products of the country by the Whites.

"The exports of fish, fish-oil, and furs (the two latter being almost solely obtained by Indians) for the fiscal year ended June 1874 were :—

	1874.	July 20, 1870 to June 30, 1871.
Fish	$69,665 00	
Fish Oil	44,453 00	27,638 00
Furs	307,625 00	200,407 00
Total	$421,743 00	$228,045 00"

All this, it has to be borne in remembrance, is the produce of native Indian enterprize, under the stimulus supplied by the White traders. The co-operation indeed extends to other industries besides those of the hunter and the fisher. The fur-bearing animals of the province include the bear, beaver, land and sea otters, fur and hair seals, martens, minks, racoons, fishers, wolverines, wolves, foxes, lynx, ermines, skunks, and pumas. Besides the produce resulting from the hunting and trapping of those fur-bearing animals, and the fruits of native industry in the fisheries of the rivers and the coasts, the Indian commissioner also notes the collection of cranberries as another productive resource of native industry. The export of cranberries from British Columbia varies according to favourable or less productive seasons. In the year 1874, which was regarded as a poor season, cranberries, gathered by the Indians, were exported to the value of $2011.

With such results from the unregulated labours of rude Indian tribes, it is manifest how great must be the resources of the country, not only in the furs which have long been an object of trade, but in the unheeded fisheries of the ocean and rivers. The whale still frequents the coast, and is pursued with success by the Clallums, Macaws, and other coast tribes. Now regular companies are being formed for its capture. In 1871 the "British Columbia Whaling Company" had produced 20,000 gallons of oil ; and the results continue on a progressive scale. The dog-fish also, which has long been an object of special favour among the Indians, is now taken in large quantities by the Whites for its oil. In 1870 the produce of this fishery alone yielded 50,000 gallons of oil ; and the price which it commanded in California has since proved a sufficient stimulus to increased zeal in prosecuting the fisheries. Cod, halibut, haddock, salmon, sturgeon, smelt, and sardines, all abound along the coasts, or in the straits and estuaries, and with the growing population and wealth both in the provinces and in the neighbouring States of the Pacific, the value of this branch of industry must rapidly increase. The riches of the sea must, indeed, in the end, far outrival all the produce of the gold mines, and may yet rival the fisheries of Nova Scotia and Newfoundland. Even now, with a sparse population, and trade in its infancy, the exports of the fisheries for 1874 are valued at $114,118.

The province of British Columbia has the same advantage over the neighbouring States of the Pacific, owing to climate and favourable geographical position, which the eastern provinces enjoy in comparison with the States on the Atlantic. This is specially manifest in the value of its timber ; and this must go on increasing with the wealth of the surrounding States. Already the value of the produce of the forest has amounted in the year 1874 to $260,116 ; and in its various forms of planks, spars, laths, and shingles, it is being exported not only to the neighbouring States and to South America, but to Australia and China, as well as to Great Britain. The white and yellow pine and the valuable Douglas pine abound. Cedar and hemlock attain to a great size ; fine oak and maple are also abundant ; and the rivers and the natural harbours afford every facility for a lumber trade for which the countries on both sides of the Pacific will supply as ready a market as the Eastern States and the ports of Europe afford to the lumberers of the provinces of Eastern Canada.

Already railway enterprize is abundantly stimulated by the development of the resources of this young province ; and now the great question of the future is the route of the projected Pacific Railway, and its terminus on the Pacific coast. The disputes between the Provincial Government and that of the Dominion relative to its immediate construction have been the cause of much local irritation. In the summer of 1876, the Earl of Dufferin, as Governor-General of the Dominion, made a tour through British Columbia, and greatly contributed to a more reasonable feeling by his conciliatory mediation. The construction of a railway through the province is attended with more than the usual difficulties. In contrast to the vast level ranges of prairie to the east of the Rocky Mountains, its surface is extremely irregular; and the selection of a railway route is controlled by the necessity of finding both a pass through the Rocky Mountains and a suitable access to the seaboard. Yellow Head Pass affords what appears to be the most advantageous route, at an elevation of about 3700 feet above the level of the sea. Immediately to the west of this an irregular plateau extends to within less than 100 miles of the coast, where the Cascade Range is reached. From this the descent to the coast is abrupt ; the rivers have furrowed deep channels, or directed their courses into the natural cañons of this rugged coast line, and much difficulty has been experienced in selecting an available route. From the mouth of the Columbia River, for 700 miles northward, the coast is indented with numerous inlets which cut deep into the land, and are comparable to the rugged fiords of Norway. Bute Inlet, which was first selected as the terminus of a proposed route through the Homathco Valley, is of this character. It is an exposed sound, walled by lofty cliffs, and with its waters of great depth, so that no suitable roadstead or anchorage is available. The latest surveys (1876) indicate that the line must pass by the Fraser River to New Westminster, where suitable natural harbourage can be found. The chief objection to this route is its vicinity to the frontier, so that it very partially opens up the interior of the country. But Dean Inlet, which has been advocated as a preferable terminus, lies too far to the north. The project of an interoceanic railway through British American territory is, under any circumstances, a bold one ; and the way in which it is being pressed onward to practical realization abundantly illustrates the enterprize of this young country, which only requires the increased population which such facilities would supply to develop its inexhaustible resources.

Altogether, evidence enough has already been disclosed to show the great future which is in store for the Canadian provinces on the Pacific. The next decennial census will embrace British Columbia, and furnish more definite statistics as to its industrial progress and natural resources. A steady influx of emigration of the best quality is its first great need. The present population, apart from the native Indian and half-breed, is of a very miscellaneous character, including British, Canadian, American, French, German, and Chinese settlers, with as yet a large preponderance of the male sex.

In the *Tables of the Trade and Navigation of the Dominion for* 1874, the province of British Columbia not only exceeds in the value of its exports both the provinces of Prince Edward Island and Manitoba, but it exhibits the exceptionably favourable contrast of an excess in value of exports over imports. The total value of all goods imported for the year 1874 amounted to $2,048,336, while the value of its exports during the same period was $2,120,624.

Under the principles of confederation, the full rights of self-government and representative institutions both in its own local parliament and in that of the Dominion have been accorded to this young province. It has its own lieutenant-governor and Legislative Assembly, and is represented at Ottawa by three senators and six members of the House of Commons in the Dominion Parliament. (D. W.)

COLUMBUS, a city of the United States of America, capital of the State of Ohio, in Franklin county, is situated on the Scioto, a tributary of the Ohio, about 100 miles north-east of Cincinnati. It is well laid out on a level site in the midst of an extensive plain, and possesses very broad and handsome streets pleasantly shaded with elm-trees. High Street is its principal thoroughfare, and Capitol Square one of the most spacious of its open areas; while Broad Street, 120 feet wide, is laid out for a stretch of two miles. As the capital of the State it contains the usual public buildings, which are of a higher character than are to be found in other cities of the Union. The Capitol is an imposing edifice built of grey limestone, with a rotunda 150 feet high. It covers an area of 55,936 square feet, and its internal accommodation is most complete. There are also in and around the city the penitentiary, extending over more than 10 acres of ground, and accommodating upwards of 1000 prisoners ; the new lunatic asylum, capable of containing 600 patients; the blind asylum, the idiot asylum, the deaf and dumb asylum, the United States arsenal, various hospitals and charitable institutions, a city hall, a county court-house, a county infirmary, the Starling medical college, the Lutheran university, an agricultural and mechanical college, the odd-fellows' hall, and the opera-house. The city possesses a fine park of about 40 acres, named in honour of its donor, Dr Lincoln Goodale, and another of equal extent called the City Park. The grounds of the Franklin County Agricultural Society occupy 83 acres, and the gardens of the Columbus Horticultural Society 10. The manufactures of the city are rather miscellaneous, and none of them have as yet developed to any great proportions; flour-mills, engineering works, and factories for agricultural implements, brushes, carriages, harness, files, and furniture are among the chief establishments. Railways radiate from Columbus in all directions; and it has water-communication by means of a branch of the Ohio Canal. The first settlement of Columbus dates from 1812; its borough charter was bestowed in 1816, when it also became the seat of the State Government; it was made the capital of the county in 1824, and ten years after was raised to the rank of a city. The population in 1830 was 2437; in 1850, 17,882; and in 1870, 31,274.

COLUMBUS, a city of the United States, capital of Muscogee county, in Georgia, is situated on the east bank of the Chattahoochee, opposite the town of Girard 84 miles southwest of Macon. The river, which here separates the States of Georgia and Alabama, is navigable from Columbus to the Gulf of Mexico, a distance of 300 miles, and affords ready communication with the neighboring cotton-growing districts. A change in the level of the river at this place furnishes a strong head of water, which has been turned to practical use by the construction of a dam and other hydraulic contrivances. The town which occupies a pretty extensive area, is regularly laid out, and its streets are of a good breadth. It contains a court-house, a temperance hall, and several churches. Its chief industry is connected with the cotton trade, but there are also some flour-mills and other works. The town dates from 1828, when it was laid out on the Coweta Reserve. Population in 1850, 5042, and in 1870, 7401, of whom 3204 were colored.

COLUMBUS, Christopher (c. 1436–1506), was the eldest son of Dominico Colombo and Suzanna Fontanarossa, and was born at Genoa in 1435 or 1436, the exact date being uncertain. His father was a wool-comber, of some small means, who was yet living two years after the discovery of the West Indies, and who removed his business from Genoa to Savona in 1469. His eldest boy was sent to the university of Pavia, where he devoted himself to the mathematical and natural sciences, and where he probably received instruction in nautical astronomy from Antonio da Terzago and Stefano di Faenza. On his removal from the university it appears that he worked for some months at his father's trade; but on reaching his fifteenth year he made his choice of life, and became a sailor.

Of his apprenticeship, and the first years of his career, no records exist. The whole of his earlier life, indeed, is dubious and conjectural, founded as it is on the half dozen dark and evasive chapters devoted by Fernando, his son and biographer, to the first half century of his father's times. It seems certain, however, that these unknown years were stormy, laborious, and eventful; "wherever ship has sailed," he writes, "there have I journeyed." He is known, among other places, to have visited England, "Ultima Thule" (Iceland), the Guinea coast, and the Greek Isles; and he appears to have been some time in the service of René of Provence, for whom he is recorded to have intercepted and seized a Venetian galley with great bravery and audacity. According to his son, too, he sailed with Colombo el Mozo, a bold sea captain and privateer; and a sea fight under this commander was the means of bringing him ashore in Portugal. Meanwhile, however, he was preparing himself for greater achievements by reading and meditating on the works of Ptolemy and Marinus, of Nearchus and Pliny, the *Cosmographia* of Cardinal Aliaco, the travels of Marco Polo and Mandeville. He mastered all the sciences essential to his calling, learned to draw charts and construct spheres, and thus fitted himself to become a consummate practical seaman and navigator.

In 1470 he arrived at Lisbon, after being wrecked in a sea fight that began off Cape St Vincent, and escaping to land on a plank. In Portugal he married Felipa Munnis Perestrello, daughter of a captain in the service of Prince Henry, called the Navigator, one of the early colonists and the first governor of Porto Santo, an island off Madeira. Columbus visited the island, and employed his time in making maps and charts for a livelihood, while he pored over the logs and papers of his deceased father-in-law, and talked with old seamen of their voyages, and of the mystery of the western seas. About this time, too, he seems to have arrived at the conclusion that much of the world remained undiscovered, and step by step to have conceived that design of reaching Asia by sailing west which was to result in the discovery of America. In 1474 we find him expounding his views to Paolo Toscanelli, the Florentine physician and cosmographer, and receiving the heartiest encouragement.

These views he supported with three different arguments, derived from natural reasons, from the theories of geographers, and from the reports and traditions of mariners. "He believed the world to be a sphere," says Helps; "he under-estimated its size; he over-estimated the size of the Asiatic continent. The farther that continent extended to the east, the nearer it came round towards Spain." And he had but to turn from the marvellous propositions of Mandeville and Aliaco to become the recipient of confidences more marvellous still. The air was full of rumours, and the weird imaginings of many generations of mediæval navigators had taken shape and substance, and appeared bodily to men's eyes. Martin Vicente, a Portuguese pilot, had found, 400 leagues to the westward of Cape St Vincent, and after a westerly gale of many days' duration, a piece of strange wood, wrought, but not with iron; Pedro Correa, his own brother-in-law, had seen another such waif at Porto Santo, with great canes capable of holding four quarts of wine between joint and joint, and had heard of two men being washed up at Flores, "very broad-faced, and differing in aspect from Christians." West of the Azores now and then there hove in sight the mysterious islands of St Brandam; and 200 leagues west of the Canaries lay somewhere the lost Island of the Seven Cities, that two valiant Genoese had vainly endeavoured to discover. In his northern journey, too, some vague and formless traditions may have reached his ear, of the voyages of Biorn and Leif, and of the pleasant coasts of Helleland and Vinland that lay towards the setting sun. All were hints and rumours to bid the bold mariner sail westward, and this he at length determined to do.

The concurrence of some state or sovereign, however, was necessary for the success of this design. The Senate of Genoa had the honour to receive the first offer, and the responsibility of refusing it. Rejected by his native city, the projector turned next to John II. of Portugal. This king had already an open field for discovery and enterprise along the African coast; but he listened to the Genoese, and referred him to a Committee of Council for Geographical Affairs. The council's report was altogether adverse; but the king, who was yet inclined to favour the theory of Columbus, assented to the suggestion of the bishop of Ceuta that the plan should be carried out in secret and without Columbus's knowledge by means of a caravel or light frigate. The caravel was dispatched, but it returned after a brief absence, the sailors having lost heart, and having refused to venture farther. Upon discovering this dishonourable transaction Columbus felt so outraged and indignant that he sent off his brother Bartholomew to England with letters for Henry VII., to whom he had communicated his ideas. He himself left Lisbon for Spain (1484), taking with him his son Diego, the only issue of his marriage with Felipa Munnis, who was by this time dead. He departed secretly,—according to some writers, to give the slip to King John, according to others, to escape his creditors. Three years after (20th March 1488) a letter was sent by the king to "Christopher Colon, our especial friend," inviting him to return, and assuring him against arrest and proceedings of any kind; but it was then too late.

Columbus next betook himself to the south of Spain, and seems to have proposed his plan first to the duke of Medina Sidonia (who was at first attracted by it, but finally threw it up as visionary and impracticable), and next to the duke of Medina Celi. The latter gave him great encouragement, entertained him for two years, and even determined to furnish him with the three or four caravals. Finally, however, being deterred by the consideration that the enterprize was too vast for a subject, he turned his guest from the determination he had come to of making instant application at the court of France, by writing on his behalf to queen Isabella; and Columbus repaired to the court at Cordova at her bidding.

It was an ill moment for the navigator's fortune. Castile and Leon were in the thick of that struggle which resulted in the final defeat of the Moors; and neither Ferdinand nor Isabella had time to listen. The adventurer was indeed kindly received; he was handed over to the care of Alonso de Quintanilla, whom he speedily converted into an enthusiastic supporter of his theory. He made many other friends, and here met with Beatriz Enriquez, the mother of his second son Fernando.

From Cordova Columbus followed the court to Salamanca, where he was introduced to the notice of the grand cardinal, Pedro Gonzalez de Mendoza, "the third king of Spain." The cardinal, while approving the project, thought that it savoured strongly of heterodoxy; but an interview with the projector brought him over, and through his influence Columbus at last got audience of the king. The matter was finally referred, however, to Fernando de Talavera, who in 1487 summoned a junta of astronomers and cosmographers to confer with Columbus, and examine his design and the arguments by which he supported it. The Dominicans of San Estebán in Salamanca entertained Columbus during the conference. The júrors, who were most of them ecclesiastics, were by no means unprejudiced, nor were they disposed to abandon their pretensions to knowledge without a struggle. Columbus argued his point, but was overwhelmed with Biblical texts, with quotations from the great divines, with theological objections; and in a short time the junta was adjourned. In 1489 Columbus, who had been following the court from place to place (billeted in towns as an officer of the king's, and gratified from time to time with sums of money toward his expenses), was present at the siege of Malaga. In 1490 the junta decided that his project was vain and impracticable, and that it did not become their highnesses to have anything to do with it; and this was confirmed, with some reservation, by their highnesses themselves, at Seville.

Columbus was now in despair. He at once betook himself to Huelva, where his brother-in-law resided, with the intention of taking ship for France. He halted, however, at Palos, a little maritime town in Andalusia. At the monastery of La Rabida he knocked and asked for bread and water for his boy Diego, and presently got into conversation with Juan Perez de Marchena, the guardian, who invited him to take up his quarters in the monastery, and introduced him to Garci Fernandez, a physician and an ardent student of geography. To these good men did Columbus propound his theory and explain his plan. Juan Perez had been the queen's confessor; he wrote to her, and was summoned to her presence; and money was sent to Columbus, to bring him once more to court. He reached Granada in time to witness the surrender of the city; and negotiations were resumed. Columbus believed in his mission, and stood out for high terms; he asked the rank of Admiral at once, the vice-royalty of all he should discover, and a tenth of all the gain, by conquest or by trade. These conditions were rejected, and the negotiations were again interrupted. An interview with Mendoza appears to have followed; but nothing came of it, and in January 1492 Columbus actually set out for France. At length, however, on the entreaty of Luis de Santangel, receiver of the ecclesiastical revenues of the crown of Aragon, Isabella was induced to determine on the expedition. A messenger was sent after Columbus, and overtook him at the Bridge of Pines, about two leagues from Granada. He returned to the camp at Santa Fé; and on 17th April 1492, the agreement between him and their Catholic majesties was signed and sealed.

His aims were nothing less than the discovery of the marvellous province of Cipango and the conversion to Christianity of the Grand Khan, to whom he received a royal letter of introduction. The town of Palos was ordered to find him two ships, and these were soon placed at his disposal. But no crews could be got together, in spite of the indemnity offered to all criminals and broken men who would serve on the expedition; and had not Juan Perez succeeded in interesting Martin Alonso Pinzon and Vicente Yañez Pinzon in the cause, Columbus's departure had been long delayed. At last, however, men, ships, and stores were ready. The expedition consisted of the "Santa Maria," a decked ship, with a crew of 50 men, commanded by the Admiral in person; and of two caravels, the "Pinta," with 30 men, under Martin Pinzon, and the "Niña," with 24 men, under his brother Vicente Yañez, afterwards (1499) the first to cross the line in the American Atlantic. The adventurers numbered 120 souls; and on Friday, 3d August 1492, at eight in the morning, the little fleet weighed anchor, and stood out for the Canary Islands.

An abstract of the Admiral's diary made by the Bishop Las Casas is yet extant; and from it many particulars may be gleaned concerning this first voyage. Three days after the ships had set sail the "Pinta" lost her rudder, the Admiral was in some alarm, but comforted himself with the reflection that Martin Pinzon was energetic and ready-witted; they had, however, to put in (August 9) at Teneriffe, to refit the caravel. On 6th September they weighed anchor once more with all haste, Columbus having been informed that three Portuguese caravels were on the look-out for him. On 13th September the variations of the magnetic needle were for the first time observed; on the 15th a wonderful meteor fell into the sea at four or five leagues distance. On the 16th they arrived at those vast plains of seaweed called the Sargasso Sea; and thenceforward, writes the Admiral, they had most temperate breezes, the sweetness of the mornings being most delightful, the weather like an Andalusian April, and only the song of the nightingale wanting. On the 17th the men began to murmur; they were frightened by the strange phenomena of the variations of the compass, but the explanation Columbus gave restored their tranquillity. On the 18th they saw many birds, and a great ridge of low-lying cloud; and they expected to see land. On the 20th they saw two pelicans, and were sure the land must be near. In this, however, they were disappointed, and the men began to be afraid and discontented; and thenceforth Columbus, who was keeping all the while a double reckoning, one for the crew and one for himself, had great difficulty in restraining the men from the excesses which they meditated. On the 25th Alonso Pinzon raised the cry of land, but it proved a false alarm; as did the rumour to the same effect of the 7th October, when the "Niña" hoisted a flag and fired a gun. On the 11th the "Pinta" fished up a cane, a log of wood, a stick wrought with iron, and a board, and the "Niña" sighted a stake covered with dog-roses; "and with these signs all of them breathed, and were glad." At ten o'clock on that night Columbus perceived and pointed out a light ahead; and at two in the morning of Friday, the 12th October, 1492, Rodrigo de Triana, a sailor aboard the "Niña," announced the appearance of what proved to be the New World. The land sighted was an island, called by the Indians Guanahani, and named by Columbus San Salvador.[1]

The same morning Columbus landed, richly clad, and bearing the royal banner of Spain. He was accompanied by the brothers Pinzon, bearing banners of the Green Cross, a device of his own, and by great part of the crew. When they all had "given thanks to God, kneeling upon the shore, and kissed the ground with tears of joy, for the great mercy received," the Admiral named the island, and took solemn possession of it for their Catholic majesties of Castile and Leon. At the same time such of the crews as had shown themselves doubtful and mutinous sought his pardon weeping, and prostrated themselves at his feet.

Into the detail of this voyage, of highest interest as it is, it is impossible to go farther. It will be enough to say that it resulted in the discovery of the islands of Santa Maria del Concepcion, Exuma, Isabella, Juanna or Cuba, Bohio, the Cuban Archipelago (named by its finder the Jardin del Rey), the island of Santa Catalina, and that of Hispaniola, now called Haiti, or San Domingo. Off the last of these the "Santa Maria" went aground, owing to the carelessness of the steersman. No lives were lost, but the ship had to be unloaded and abandoned; and Columbus, who was anxious to return to Europe with the news of his achievement, resolved to plant a colony on the island, to build a fort out of the material of the stranded hulk, and to leave the crew. The fort was called La Navidad; 43 Europeans were placed in charge; and on 16th January 1493, Columbus, who had lost sight of Martin Pinzon, set sail alone in the "Niña" for the east; and four days afterwards the "Pinta" joined her sister-ship off Monte Christo. A storm, however, separated the vessels, and a long battle with the trade winds caused great delay; and it was not until the 18th February that Columbus reached the Island of Santa Maria in the Azores. Here he was threatened with capture by the Portuguese governor, who could not for some time be brought to recognize his commission. On 24th February, however, he was allowed to proceed; and on 4th March the "Niña" dropped anchor off Lisbon. The king of Portugal received the Admiral with the highest honours; and on 13th March the "Niña" put out from the Tagus, and two days afterwards, Friday, 15th March, dropped anchor off Palos.

The court was at Barcelona; and thither, after despatching a letter announcing his arrival, Columbus proceeded in person. He entered the city in a sort of triumphal procession, was received by their majesties in full court, and, seated in their presence, related the story of his wanderings, exhibiting the "rich and strange" spoils of the new-found lands,—the gold, the cotton, the parrots, the curious arms, the mysterious plants, the unknown birds and beasts, and the nine Indians he had brought with him for baptism. All his honours and privileges were confirmed to him; the title of Don was conferred on himself and his brothers; he rode at the king's bridle; he was served and saluted as a grandee of Spain. And, greatest honour of all, a new and magnificent scutcheon was blazoned for him (4th May 1493), whereon the royal castle and lion of Castile and Leon were combined with the four anchors of his own old coat of arms. Nor were their Catholic highnesses less busy on their own account than on that of their servant. On 3d and 4th May Alexander VI. granted bulls confirming to the crowns of Castile and Leon all the lands discovered,[2] or to be discovered, beyond a certain line of demarcation, on the same terms as those on which the Portuguese held their colonies along the African coast. A new expedition was got in readiness with all possible dispatch, to secure and extend the discoveries already made.

After several delays the fleet weighed anchor on 25th September and steered westwards. It consisted of three great carracks (galleons), and fourteen caravels (light frigates), having on board about 1500 men, besides the animals and material necessary for colonization. Twelve missionaries accompanied the expedition, under the orders of Bernardo Buil, a Benedictine friar; and Columbus had been directed (29th May 1493) to endeavour by all means in his power to Christianize the inhabitants of the islands, to make them presents, and to "honour them much," while all under him were commanded to treat them "well and lovingly," under pain of severe punishment. On 13th October the ships which had put in at the Canaries, left Ferro; and so early as Sunday, 3d November, after a single storm, "by the goodness of God and the wise management of the Admiral" land was sighted to the west, which was named Dominica. Northwards from this new found island the isles of Maria Galante and Guadaloupe were discovered and named; and on the north-western course to La Navidad those of Montserrat, Antigua, San Martin, and Santa Cruz were sighted, and the island now called Porto Rico was touched at, hurriedly explored, and named San Juan. On 22d November Columbus came in sight of Hispaniola, and sailing eastward to La Navidad, found the fort burned and the colony dispersed. He decided on building a second fort; and coasting on forty miles east of Cape Haytien, he pitched on a spot where he founded the city and settlement of Isabella.

Second voyage.

The character in which Columbus had appeared had till now been that of the greatest of mariners; but from this point forward his claims to supremacy are embarrassed and complicated with the long series of failures, vexations, miseries, insults, that have rendered his career as a planter of colonies and as a ruler of men most pitiful and remarkable.

The climate of Navidad proved unhealthy; the colonists were greedy of gold, impatient of control, and as proud, ignorant, and mutinous as Spaniards could be; and Columbus, whose inclinations drew him westward, was doubtless glad to escape the worry and anxiety of his post, and to avail himself of the instructions of his sovereigns as to further discoveries. In January 1494 he sent home, by Antonio de Torres, that dispatch to their Catholic highnesses by which he may be said to have founded

[1] Helps refers to the island as "one of the Bahamas." It has been variously identified—with Turk's Island, by Navarrete (1825); with Cat Island, by Irving (1828) and Humboldt (1836); with Mayaguarra, by Varnhagen (1864); and finally, with greatest shew of probability, with Watling Island, by Munoz (1798), supported by Becher (1856), Peschel (1857), and Major (1871).

[2] "The countries which he had discovered were considered as a part of India. In consequence of this notion, the name of Indies is given to them by Ferdinand and Isabella in a ratification of their former agreement which was granted to Columbus after his return."—Robertson's *History of America.*

the West Indian slave trade. He founded the mining camp of San Tomaso in the gold country; and on 24th April 1494, having nominated a council of regency under his brother Diego, and appointed Pedro de Margarite his captain-general, he put again to sea. After following the southern shore of Cuba for some days, he steered southwards, and discovered the island of Jamaica, which he named Santiago. He then resumed his exploration of the Cuban coast, threaded his way through a labyrinth of islets supposed to be the Morant Keys, which he named the Garden of the Queen; and after coasting westwards for many days, he became convinced that he had discovered continous land, and caused Perez de Luna, the notary, to draw up a document attesting his discovery (12th June 1494), which was afterwards taken round and signed, in presence of four witnesses, by the masters, mariners, and seamen of his three caravels, the "Niña," the "Cardera," and the "San Juan." He then stood to the south-east, and sighted the island of Evangelita; and after many days of difficulties and anxieties, he touched it and named the island La Mona. Thence he had intended to sail eastwards, and complete the survey of the Caribbean Archipelago. But he was exhausted by the terrible tear and wear of mind and body he had undergone (he says himself that on this expedition he was three and thirty days almost without any sleep), and on the day following his departure from La Mona, he fell into a lethargy, that deprived him of sense and memory, and had well nigh proved fatal to life. At last, on 29th September, the little fleet dropped anchor off Isabella, and in his new city the great Admiral lay sick for five months.

The colony was in a sad plight. Every one was discontented, and many were sick, for the climate was unhealthy and there was nothing to eat. Margarite and Buil had quitted Hispaniola for Spain; but ere his departure, the former, in his capacity of captain-general, had done much to outrage and alienate the Indians. The strongest measures were necessary to undo this mischief; and backed by his brother Bartholomew, a bold and skilful mariner, and a soldier of courage and resource, who had been with Diaz in his voyage round the Cape of Good Hope, Columbus proceeded to reduce the natives under Spanish sway. Alonso de Ojeda succeeded by a brilliant *coup de main* in capturing the cacique Caonabo, and the rest submitted. Five ship loads of Indians were sent on to Seville (24th June 1495) to be sold as slaves; and a tribute was imposed upon their fellows, which must be looked upon as the origin of that system of *repartimientos* or *encomiendas* which was afterwards to work such cruel mischief among the conquered. But the tide of court favour seemed to have turned against Columbus. In October 1495 Juan Aguado arrived at Isabella, with an open commission from their Catholic majesties, to inquire into the circumstances of his rule; and much contest and recrimination followed. Columbus found that there was no time to be lost in returning home; he appointed his brother Bartholomew "adelantado" of the Island; and on 10th March 1496 he quitted Hispaniola in the "Niña." The vessel, after a protracted and perilous voyage, reached Cadiz on 11th June 1496. The Admiral landed in great dejection, wearing the costume of a Franciscan. Reassured, however, by the reception of his sovereigns, he asked at once for eight ships more, two to be sent to the colony with supplies, and six to be put under his orders for new discoveries. The request was not immediately granted, as the Spanish exchequer was not then well supplied. But principally owing to the interest of the queen, an agreement was come to similar to that of 1492, which was now confirmed. By this royal patent, moreover, a tract of land in Hispaniola, of 50 leagues by 20, was made over to him. He was offered a dukedom or a marquisate at his pleasure; for three years he was to receive an eighth of the gross and a tenth of the net profits on each voyage; the right of creating a mayorazgo or perpetual entail of titles and estates was granted him; and on 24th June his two sons were received into Isabella's service as pages. Meanwhile, however, the preparing of the fleet proceeded slowly; and it was not till the 30th May 1498 that he and his six ships set sail.

From San Lucar he steered for Gomera, in the Canaries, and thence dispatched three of his ships to San Domingo He next proceeded to the Cape Verd Islands, which he quitted on 4th July. On the 31st of the same month, being greatly in need of water, and fearing that no land lay westwards as they had hoped, Columbus had turned his ship's head north, when Alonso Perez, a mariner of Huelva, saw land about 15 leagues to the south-west. It was crowned with three hill-tops, and so when the sailors had sung the *Salve Regina*, the Admiral named it Trinidad which name it yet bears. On Wednesday, 1st August, he beheld for the first time, in the mainland of South America, the continent he had sought so long. It seemed to him but an insignificant island, and he called it Zeta. Sailing westwards, next day he saw the Gulf of Paria, which was named by him the Golfo de la Balena, and was borne into it at immense risk on the ridge of waters formed by the meeting with the sea of the great rivers that empty themselves, all swollen with rain, into the ocean. For many days he coasted the continent, esteeming as islands the several projections he saw, and naming them accordingly; nor was it until he had looked on and considered the immense volume of fresh water poured out through the embouchures of the river now called the Orinoco, that he concluded that the so-called archipelago must be in very deed a great continent.

Unfortunately at this time he was suffering intolerably from gout and opthalmia; his ships were crazy; and he was anxious to inspect the infant colony whence he had been absent so long. And so, after touching at and naming the island of Margarita, he bore away to the north-east, and on 30th August the fleet dropped anchor off Isabella.

He found that affairs had not prospered well in his absence. By the vigour and activity of the adelantado, the whole island had been reduced under Spanish sway, but at the expense of the colonists. Under the leadership of a certain Roldan, a bold and unprincipled adventurer, they had risen in revolt, and Columbus had to compromise matters in order to restore peace. Roldan retained his office; such of his followers as chose to remain on the island were gratified with *repartimientos* of land and labour; and some fifteen, choosing to return to Spain, were enriched with a number of slaves, and sent home in two ships which sailed in the early part of October 1499.

Five ship-loads of Indians had been deported to Spain some little time before. On the arrival of these living cargoes at Seville, the queen, the stanch and steady friend of Columbus, was moved with compassion and indignation. No one, she declared, had authorized him to dispose of her vassals in any such manner; and proclamations at Seville, Granada, and other chief places ordered (20th June 1499) the instant liberation and return of all the last gang of Indians. In addition to this the ex-colonists had become incensed against Columbus and his brothers. They were wont to parade their grievances in the very court-yards of the Alhambra, to surround the king, when he came forth, with complaints and reclamations, to insult the discoverer's young sons with shouts and jeers. There was no doubt that the colony itself, whatever the cause, had not prospered so well as might have been desired. And, on the whole, it is not surprising that Ferdinand, whose support to Columbus had never been very hearty, should about this time have determined to suspend him. Accordingly on March 21, 1499, Francisco de Bobadilla was ordered "to ascertain what persons had raised themselves against justice in the island of Hispaniola, and to proceed against them according to law." On May 21st the government of the island was conferred on him, and he was accredited with an order that all arms and fortresses should be handed over to him; and on May 26 he received a letter for delivery to Columbus, stating that the bearer would "speak certain things to him" on the part of their highnesses, and praying him "to give faith and credence, and to act accordingly." Bobadilla left Spain in July 1500, and landed in Hispaniola in October.

Columbus, meanwhile, had restored such tranquillity as was possible in his government. With Roldan's help he had beaten off an attempt on the island of the adventurer Ojeda, his old lieutenant; the Indians were being collected into villages and Christianized. Gold-mining was actively and profitably pursued; in three years, he calculated, the royal revenues might be raised to an average of 60,000,000 reals. The arrival of Bobadilla, however, speedily changed this state of affairs into a greater and more pitiable confusion than the island had ever before witnessed. On landing, he took possession of the Admiral's house and summoned him and his brothers before him. Accusations of severity, of injustice, of venality even, were poured down on their heads, and Columbus anticipated nothing less than a shameful death. Bobadilla put all three in irons, and shipped them off to Spain.

Alonso de Villejo, captain of the caravel in which the illustrious prisoners sailed, still retained a proper sense of the honour and respect due to Columbus, and would have removed the fetters; but to this Columbus would not consent. He would wear them, he said, until their highnesses, by whose order they had been affixed, should order their removal; and he would keep them afterwards "as relics and as memorials of the reward of his services." He did so. His son Fernando "saw them always hanging in his cabinet, and he requested that when he died they might be buried with him." Whether this last wish was complied with is not known.

A heart-broken and indignant letter from Columbus to Doña Juana de la Torre, the governess of the infante Don Juan, arrived at court before the despatch of Bobadilla. It was read to the queen, and its tidings were confirmed by communications from Alonso de Villejo, and the alcaide of Cadiz. There was a great movement of indignation; the tide of popular and royal feeling turned once more in the Admiral's favour. He received a large sum to defray his expenses; and when he appeared at court, on 17th December, he was no longer in irons and disgrace, but richly apparelled and surrounded with friends. He was received with all honour and distinction. The queen is said to have been moved to tears by the narration of his story. Their majesties not only repudiated Bobadilla's proceedings, but declined to inquire into the charges that he at the same time brought against his prisoners, and promised Columbus compensation for his losses and satisfaction for his wrongs. A new governor, Nicolas de Ovando, was appointed in Bobadilla's room, and left San Lucar on 18th February 1502, with a fleet of 30 ships. The latter was to be impeached and sent home; the Admiral's property was to be restored, and a fresh start was to be made in the conduct of colonial affairs. Thus ended Columbus's history as viceroy and governor of the new Indies which he had presented to the country of his adoption.

His hour of rest, however, was not yet come. Ever anxious to serve their Catholic highnesses, "and particularly the queen," he had determined to find a strait through which he might penetrate westwards into Portuguese Asia. After the usual inevitable delays his prayers were granted, and on 9th May 1502, with four caravels and 150 men, he weighed anchor from Cadiz, and sailed on his fourth and last great voyage. He first betook himself to the relief of the Portuguese fort of Arzilla, which had been besieged by the Moors, but the siege had been raised voluntarily before he arrived. He put to sea westwards once more, and on 13th June discovered the island of Martinique. He had received positive instructions from his sovereigns on no account to touch at Hispaniola; but his largest caravel was greatly in need of repairs, and he had no choice but to abandon her or disobey orders. He preferred the latter alternative, and sent a boat ashore to Ovando, asking for a new ship and for permission to enter the harbour to weather a hurricane which he saw was coming on. But his requests were refused, and he coasted the island, casting anchor under lee of the land. Here he weathered the storm, which drove the other caravels out to sea, and annihilated the homeward-bound fleet, the richest that had till then been sent from Hispaniola. Roldan and Bobadilla perished with others of the Admiral's enemies; and Fernando Colon, who accompanied his father on this voyage, wrote long years afterwards, "I am satisfied it was the hand of God, for had they arrived in Spain they had never been punished as their crimes deserved, but rather been favoured and preferred."

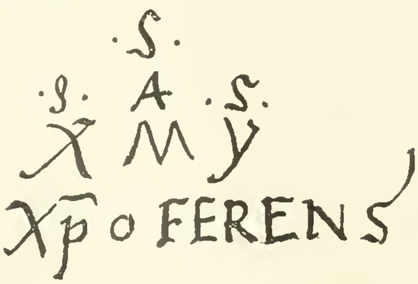
After recruiting his flotilla at Azua, Columbus put in at Jaquimo and refitted his four vessels; and on 14th July 1502 he steered for Jamaica. For nine weeks the ships wandered painfully among the keys and shoals he had named the Garden of the Queen, and only an opportune easterly wind prevented the crews from open mutiny. The first land sighted was the islet of Guanaja, about forty miles east of the coast of Honduras. Here he got news from an old Indian of a rich and vast country lying to the eastward, which he at once concluded must be the long sought for empire of the Grand Khan. Steering along the coast of Honduras, great hardships were endured, but nothing approaching his ideal was discovered. On 12th September Cape Gracias-á-Dios was sighted. The men had become clamorous and insubordinate; not until the 5th December, however, would he tack about, and retrace his course. It now became his intention to plant a colony on the river Veragua, which was afterwards to give his descendants a title of nobility; but he had hardly put about when he was caught in a storm, which lasted eight days, wrenched and strained his crazy, worm-eaten ships severely, and finally, on the Epiphany, blew him into an embouchure which he named Bethlehem. Gold was very plentiful in this place, and here he determined to found his settlement. By the end of March 1503 a number of huts had been run up, and in these the adelantado with 80 men was to remain, while Columbus returned to Spain for men and supplies. Quarrels, however, arose with the natives; the adelantado made an attempt to seize on the person of the cacique, and failed; and before Columbus could leave the coast he had to abandon a caravel, to take the settlers on board, and to relinquish the enterprize. Steering eastwards, he left a second caravel at Porto Bello; and on May 31st he bore northwards for Cuba, where he obtained supplies from the natives. From Cuba he bore up for Jamaica, and there, in the harbour of Santa Gloria, now St Anne's Bay, he ran his ships aground in a small inlet still called Don Christopher's Cove.

The expedition was received with the greatest kindness by the natives, and here Columbus remained upwards of a year awaiting the return of his lieutenant Diego Mendez, whom he had dispatched to Ovando for assistance. During his critical sojourn here, the admiral suffered much from disease and from the lawlessness of his followers.

whose misconduct had alienated the natives, and provoked them to withhold their accustomed supplies, until he dexterously worked upon their superstitions by prognosticating an eclipse. Two vessels having at last arrived for their relief from Mendez and Ovando, Columbus set sail for Spain, and after a tempestuous voyage he landed once more at Seville on 7th September 1504.

As he was too ill to go to court, his son Diego was sent thither in his place, to look after his interests and transact his business. Letter after letter followed the young man from Seville,—one by the hands of Amerigo Vespucci. A licence to ride on muleback was granted him on 23d February 1505; and in the following May he was removed to the court at Segovia, and thence again to Valladolid. On the landing of Philip and Juana at Coruña (25th April 1506) although "much oppressed with the gout and troubled to see himself put by his rights," he is known to have sent off the adelantado to pay them his duty and to assure them that he was yet able to do them extraordinary service. The last documentary note of him is contained in a final codicil to the will of 1498, made at Valladolid on 19th May 1506. By this the old will is confirmed; the mayorazgo is bequeathed to his son Diego, and his heirs male, failing these to Fernando, his second son, and failing these to the heirs male of Bartholomew; only in case of the extinction of the male line, direct or collateral, is it to descend to the females of the family; and those into whose hands it may fall are never to diminish it, but always to increase and ennoble it by all means possible. The head of the house is to sign himself The Admiral." A tenth of the annual income is to be set aside yearly for distribution among the poor relations of the house. A chapel is founded and endowed for the saying of masses. Beatriz Enriquez is left to the care of the young admiral in most grateful terms. Among other legacies is one of "half a mark of silver to a Jew who used to live at the gate of the Jewry, in Lisbon." The codicil was written and signed with the Admiral's own hand. Next day (20th May 1506) he died.

He was buried at Valladolid; but his remains were soon after transferred thence to the Carthusian monastery of Las Cuevas, Seville, where the bones of Diego, the second Admiral, were also laid. Exhumed in 1536, the bodies of both father and son were taken over sea to Hispaniola (San Domingo), and interred in the cathedral. In 1795–96, on the cession of that island to the French, the august relics were re-exhumed, and were transferred with great state and solemnity to the cathedral of the Havana, where they yet remain. The male issue of the Admiral became extinct with the third generation, and the estates and titles passed by marriage to a scion of the house of Bragança.



Columbus's Cipher.

The interpretation of the seven-lettered cipher accepting the smaller letters of the second line as the final ones of the words, seems to be—*Servate-me, Xristūs, Maria, Yosephus.* The name *Christopher* appears in the last line.

In person Columbus was tall and shapely, long-faced and aquiline, white-eyed and auburn-haired, and beautifully complexioned. At thirty his hair was quite grey. He was temperate in eating, drinking, and dress; and "so strict in religious matters, that for fasting and saying all the divine office, he might be thought professed in some religious order." His piety, as his son has noted, was earnest and unwavering; it entered into and coloured alike his action and his speech; he tries his pen in a Latin distich of prayer; his signature is a mystical pictistic device. He was pre-eminently fitted for the task he created for himself. Through deceit and opprobrium and disdain he pushed on towards the consummation of his desire; and when the hour for action came the man was not found wanting.

COLUMELLA, Lucius Junius Moderatus, the author of the most complete classical treatise on agricultural affairs, was born at Gades (Cadiz), and belongs to the 1st century A.D., being contemporary with Seneca. He possessed an estate called Ceretanum, perhaps near the Pyrenees, perhaps in Sardinia, and he also travelled extensively, but he principally resided at Rome. His extant works treat with great fulness, and in a diffuse but not inelegant style which well represents the silver age, of the cultivation of all kinds of corn and garden vegetables, trees, flowers, the vine, the olive, and other fruits, and of the rearing of all the domestic animals. They consist of the 12 books of the *De Re Rustica*, that which treats of gardening being in dactylic hexameters, and of a book *De Arboribus*, which is the only part we possess of a work treating of the same subjects as *De Re Rustica*, but earlier and less elaborate. The *editio princeps* was published by Jenson at Venice in 1472, in the *Rei Rusticæ Scriptores Varii*. A good edition is contained in the *Rei Rusticæ Scriptores Veteres Latini* of Gesner (Leipsic, 1735, again edited and collated with a newly discovered MS. by Ernesti, 1773); and the best is that given in the *Scriptores Rei Rusticæ* by Schneider (Leipsic, 1794). There are translations in English (1745), French (1551), Italian (1554–57–59 and 1808), and German (1769).

COLZA OIL is a non-drying oil obtained from the seeds of *Brassica Napus*, var. *oleifera*, a variety of the plant which produces Swedish turnips. Colza is extensively cultivated in France, Belgium, Holland, and Germany; and, especially in the first-named country, the expression of the oil is an important industry. In commerce colza is classed with rape oil, to which both in source and properties it is very closely allied. It is a comparatively inodorous oil of a yellow colour, having a specific gravity at 60° Fahr. of 0·9128; and it solidifies at 22° Fahr. The cake left after expression of the oil is a valuable feeding substance for cattle. Colza oil is extensively used as a lubricant for machinery, and for burning in lamps. It was for many years employed in British light-houses, having been favourably reported on for that purpose in 1845 by Professor Faraday, but mineral oils are now more generally used.

COMACCHIO, a town of Italy, in the province of Ferrara, at the head of a circondario, is situated on a long island near the seaward side of an extensive lagoon in the Adriatic, known as the Valli di Comacchio, in 44° 41′ 36″ N. lat. and 29° 51′ 23″ E. long. It is the seat of a bishop, and possesses a Capuchin convent and several fine churches. It was at one time strongly fortified, and still has remains of the citadel, which, in accordance with the treaty of Vienna, was held by the Austrians till 1859. The inhabitants are mainly engaged in the manufacture of salt and the prosecution of the fisheries in the lagoon, which, with its shallow area of 41,600 acres, affords a rich feeding ground for eels and grey mullets. The seaward entrance is carefully guarded by a system of nets, so that the fish, once within the lagoon, cannot find their way out again. The eels are exported to all parts of Italy, sometimes alive, but more usually in a pickle; and they are greatly esteemed for their delicate flavour. The average annual production is 1,800,000 lb, and the value about £40,000. Population, 8900

COMANA (frequently called CHRYSE, or AUREA, *i.e.*, the golden, to distinguish it from Comana in Pontus), a city of Cappadocia, in a deep valley of the Anti-Taurus range, through which the River Sarus (Sihun) flows. This city was celebrated in ancient times as the place where the rites of the goddess Mā, the Greek *Enyo*, were celebrated with much solemnity. The service was carried on in a sumptuous temple and with great magnificence. To defray expenses, large estates had been set apart, which yielded a more than royal revenue. The city of Comana, which was a mere apanage of the temple, was governed immediately by the chief priest, who was always a member of the reigning family, and took rank next to the king. The number of persons engaged in the service of the temple, even in Strabo's time, was upwards of 6000. Under Caracalla, Comana became a Roman colony. Its site has not been identified.

COMANA, an ancient city of Pontus in Asia Minor, said to have been colonized from Comana in Cappadocia. It stood on the River Iris (or Tocat-su), not far from its source, and from its central position was a favourite emporium of the Armenian and other merchants. The moon-goddess was worshipped in the city with a pomp and ceremony in all respects analogous to those employed in the Cappadocian city. Large multitudes were attracted to the place by the great annual processions, and the permanent population was increased by the influx of devotees. The slaves attached to the temple alone numbered not less than 6000. Remains of Comana are still to be seen near a village called Gumenek on the Tocat-su, seven miles from the city of Tocat. "They consist," says Van Lennep, "of a low hill upon which are scattered fragments of brick and hewn-stone, with here and there the remains of a wall or a partly fallen vault." The bridge that crosses the river at the spot is largely composed of fragments of ancient structures, and several sepulchral inscriptions can be deciphered on the blocks beneath the arches. Still nearer the modern village of Gumenek than these ruins lies a large boulder of marble in which tombs or cells have been excavated. One of these is reputed to have been the abode of Chrysostom during his first exile from Constantinople.

COMANCHES, a tribe of North American Indians, so called by the Spaniards, but known to the French as Padouques, and among themselves as Naiini. They belong to the Shohone family, and when first met by Europeans occupied the regions between the upper waters of the Brazos and Colorado on the one hand and the Arkansas and Missouri on the other. They were brought to nominal submission in 1783 by the Spanish general Anza, who killed thirty of their chiefs; but they again became troublesome, and continued to harass the district of Texas till they were settled in a reservation in the Indian Territory. In 1872 a portion of the tribe, called the Quanhada or Staked Plain Comanches, had to be reduced by military measures. Their total numbers, estimated by President Burnet in 1847 as 10,000 or 12,000, are now reduced to little more than 3000 or 4000.

COMAYAGUA, a city of Central America, capital of the republic of Honduras, and of the department of Comayagua, is situated in 14° 28′ N. lat. and 87° 39′ W. long., about half way between the Pacific and the Atlantic, on the right bank of the Humuya or Ulua River, and near the southern edge of a wide and fertile valley to which it gives its name. It lies 2060 feet above the level of the sea; and the valley is shut in by mountains varying in height from 5000 to 6000 feet, so that it enjoys a comparatively temperate and equable climate. It is the residence of the president and the seat of the only bishop in Honduras; but the political disturbances of the country have reduced it to a very poor condition. The houses are mainly of one story and built of sun-dried bricks; and the fine fountains, monuments, and public buildings, of which it once could boast, have for the most part fallen into ruins or decay. Of those still left the principal is the cathedral, a rather imposing building, with cupolas and towers dating from the beginning of the 18th century. The university, founded in 1678, and more than once nominally restored in the present century, does not practically exist. The trade of the city is very small, in spite of the fertility of the neighbouring district; but a railway is in course of construction, which will put it in direct communication with both sides of the continent. In the neighbourhood, Mr Squier informs us, "hardly a step can be taken without encountering evidences of aboriginal occupation; but the only relic mentioned in the city itself is a dog-shaped figure built into the walls of the church of Our Lady of Dolores." The present city, originally designated Valladolid la Nueva, was founded in 1540 by Alonzo Caceres, who had been instructed to find out an eligible site for a town midway between the oceans. In 1557 it received the rights of a city, and in 1561 was made a bishop's see. Its prosperity is shown by the fact that at the great revolution of 1827 it had about 18,000 inhabitants. Burned in that year by the monarchical party of Guatemala, it has since suffered during successive contests, more especially in 1872, when it witnessed the defeat of General Medina's army by the allied forces of San Salvador and Guatemala, and in 1873, when it was besieged for about two months. In 1854 Scherzer estimated the population at only 2000; but it is believed now to number between 7000 and 8000.

COMB, a toothed implement for arranging and dressing hair and other fibrous substances. Worsted wools, waste silk, and other long fibres are dressed and prepared for spinning by a process called combing, performed formerly by hand-combs, but now by an elaborate combing machine. This process of combing will be described in connection with the manufactures to which it belongs. Here we have only to do with the implement so well known in domestic economy. Comb-making is necessarily a prominent and extensive industry, in which a considerable variety of materials are employed, the most common being the horns and hoofs of cattle, tortoise-shell, ivory, boxwood, vulcanite or hardened Indian-rubber, and to a small extent German silver and other metals. Of these materials horn is by far the most extensively employed, and the working of that substance illustrates all the peculiarities of the craft. The industry is one still extensively prosecuted on a small scale, with all the disadvantages of manual labour and wasteful and tedious processes; but in several large factories very ingenious labour and material-saving machinery is brought into operation, as in the extensive and complete works of Messrs Stewart & Co. of Aberdeen. In Messrs Stewart's factory the raw material annually consumed averages 3,500,000 horns, about 1,000,000 hoofs, nearly 600 lb of tortoise-shell and 20 tons of vulcanite, out of which more than 10,000,000 combs are manufactured. The British supply of horn is very limited, and altogether inadequate to the demand. The sources whence this raw material is drawn are chiefly South America and Australia, whence ox and cow horns are procured, and India, China, and Siam, which supply buffalo horns. When the horn is brought into the factory it is first assorted into sizes, preparatory to being cut up into pieces. From an ordinary horn two cross sections are taken for comb-making, called, first, the head or root cut, and, second, the screw or tip cut. The solid tips remaining are disposed of either for button-making or for being formed into knife and other handles. Other scraps and cuttings are of great value to makers of prussiate of potash and for artificial manure. The sections to be used for combs are taken to the opening department, where they are wetted in water and heated over an open fire till the horny substance becomes quite soft. The head cut is slit longitudinally once, or if it is a large horn it may be slit into two. The screw cut is so termed on account of the peculiar spiral direction in which it is slit, the cut being so directed that the piece when opened out may form an oblong rectangular plate with as little waste of horn as practicable. After slitting, the cuts are opened out between tongs, and inserted between screw plates where they are pressed quite flat. Plates which are intended for staining in imitation of tortoise-shell are at this stage inserted in strong iron frames between heated and oiled iron plates, in which they are submitted for some time to enormous pressure. After this pressure the plates are found to have a translucent appearance and a uniform greenish hue. The pressure, however, operates injuriously on the fibre or grain of the horn, rendering it liable to split. When, therefore, the horn is of good natural colour, it is preferred to finish it in that condition. The prepared plates of horn are laid aside to dry in a room where a high temperature is maintained by steam-pipes. Subsequently they are squared and trimmed on circular saw benches, and assorted into sizes suitable for the various kinds of combs manufactured.

In the manufacture of ordinary dressing-combs two distinct processes of tooth-cutting are followed. The first method, which is applied to all fine combs, consists in cutting out the teeth by means of circular saws; and this is the only process applicable to the preparation of small toothed combs and all combs made of ivory and boxwood. Saw-cutting is, moreover, the only process formerly adopted, but instead of a circular saw, the comb-maker used a gauged hand-saw called a *stadda* or *steady*. The saws now employed are of small diameter; and, according to the work they have to perform, they are fine-toothed and thin, some of them being constructed to cut from 70 to 80 teeth per lineal inch. The saws are mounted on a spindle which revolves with great rapidity, and the plate or plates of horn to be toothed are clamped up in a holder, which by a cam motion is alternately raised and depressed, bringing the horn each time against the saw, which cuts out one tooth to its full depth. After each cut an automatic arrangement moves the horn forward the breadth of a tooth, the gearing being so mounted that the teeth may be cut fine or coarse at pleasure. The second method of cutting the teeth is known as twinning, from the fact that a pair of combs are cut out of a single plate. The process of twinning consists in so cutting a plate of horn that the whole material is utilized, what is removed to form the teeth of one comb being exactly sufficient for the teeth of a corresponding opposite comb. When the cutting of twinned combs is complete the plate presents the appearance of a pair of combs with their teeth exactly inosculating or dovetailing into each other. The twinning machine, by which this is accomplished, is a complex and beautiful piece of mechanism. The plates of horn to be twinned are softened by heat, and secured in a bed-plate which travels under a pair of cutting chisels, fast or slow, as the teeth are to be cut coarse or fine. The chisels, having cutting edges equal to the length of the teeth to be formed, descend alternately and cut through the plate, but as their cutting edges are at a small angle in relation to each other, the cuts are wedge-formed or tapering, and thus the pointed ends of one comb are taken out of the roots or head of another. With the aid of this apparatus a man and boy can cut more than 2000 combs per day, while an old-fashioned comb-maker working with his hand-saw can only cut from two to three dozen combs daily, and that with almost double the material required in the twinning process.

After the combs are formed either by circle saw or by twinning, they are next thinned or tapered to their outer edges on grindstones. They then pass to the "grailing" department, where by means of special forms of files or rasps, known as grails and topers, the individual teeth are rounded or bevelled, tapered, and smoothed. If the combs are to be finished in their natural colours, they are then smoothed with sand-paper, buffed on leather wheels, and polished on wheels built up of discs of soft calico. If, as is frequently the case, the combs are to be finished as imitation tortoise-shell, they are, in the translucent state before alluded to, treated with dilute nitric acid, which communicates a light yellow tinge like the ground colour of tortoise-shell. The deep semi-opaque orange spotting is next produced by dropping over the surface spots of a composition containing caustic soda, litharge, and dragon's blood. After some time this composition is washed off, and the parts to which it was applied are found to be a little swollen up and stained a deep orange tinge. The combs are then polished as above stated.

The elaborate pierced patterns of ornamental back combs are cut out by small ribbon saws; and the work is generally finished by hand-carving with proper tools. Plainer and less artistic work is done by embossing in heated dies and ordinary pierced work is also produced by cutting dies. Formerly the wide set teeth of back combs were frequently stamped out.

In order to economize tortoise-shell, and to obtain large and thick combs out of the comparatively small and thin plates in which that substance usually occurs, a process of cementing or soldering is resorted to. The joining of two plates of tortoise-shell is very perfectly accomplished by first carefully scraping and cleaning the surfaces to be united. They are then applied to each other, heated, and strongly pressed between pincers,—this being sufficient to cause a perfect amalgamation of the two surfaces. After cementation tortoise-shell is treated in every respect as a piece of fine white or buffalo horn. (J. PA.)

COMBACONUM, a town of Southern India, in the district of Tanjore, 20 miles from the city of that name and 30 miles from the sea, in 10° 58′ N. lat. and 79° 26′ E. long. It is a large town with wide and airy streets, and is adorned with pagodas, gateways, and other buildings of considerable pretension. The great gopura, or gate-pyramid, is one of the most imposing buildings of the kind,—rising in twelve stories to a height of upwards of 100 feet, and ornamented with a bewildering profusion of figures of men and animals formed in stucco. One of the water-tanks in the town is popularly reputed to be filled with water admitted from the Ganges every twelve years by a subterranean passage 1200 miles long; and it consequently forms a centre of attraction for large numbers of devotees. A considerable trade is carried on in the town, and weaving is one of its chief industries. The bazaar occupies a long and wide street, and is well supplied with provisions. The city is historically interesting as the capital of the Chola race, one of the oldest Hindu dynasties of which any traces remain, and from which the whole coast of Coromandel, or more properly Cholamundel, derives its name. Population about 40,000.

COMBE, ANDREW, M.D. (1797-1847), was born in Edinburgh, 27th October 1797. His name holds an honoured place in the roll of sanitary reformers. Instead of waiting till disease was developed, he sought its prevention by the adoption of a careful system of hygiene. He served an apprenticeship in a surgery, and in 1817 passed at Surgeons' Hall. He proceeded to Paris to complete his medical studies, and whilst there he investigated phrenology on anatomical principles. He became convinced of the truth of the new science, and, as he acquired much skill in the dissection of the brain, he subsequently gave additional interest to the lectures of his brother George, by his practical demonstrations of the convolutions. He returned to Edinburgh in 1819 with the intention of beginning practice; but being attacked by the first symptoms of pulmonary disease, he was obliged to seek health in the south of France and in Italy during the two following winters. He began to practise in 1823, and by careful adherence to the laws of health he was enabled to fulfil the duties of his profession for nine years. During that period he assisted in editing the *Phrenological Journal* and contributed a number of articles to it, defended phrenology before the Royal Medical Society of Edinburgh, published his *Observations on Mental Derangement* (1831), and prepared the greater portion of his *Principles of Physiology Applied to Health*. The latter work was issued in 1834, and immediately obtained extensive public favour. In 1836 he was appointed physician to Leopold I., king of the Belgians, and removed to Brussels. He had only been there a few months, however, when another severe attack of hæmoptysis warned him that the climate was unsuitable, and would speedily render him unequal to the duties of his position. Scrupulously conscientious in everything, he at once resigned. The king and Baron Stockmar persuaded him to remain a few weeks longer in the hope that he might recover; but they were disappointed. He continued, however, to hold the position of consulting physician to his majesty. In Edinburgh he proceeded to work with renewed energy; he published his *Physiology of Digestion*, and resumed practice as a consulting physician, his advice being eagerly sought by old and new patients and by his professional brethren. In 1838 he was appointed one of the physicians extraordinary to the queen in Scotland. Two years later he completed his *Physiological and Moral Management of Infancy*, which he believed to be his best work, and it was his last. He suffered at intervals from extreme weakness, and in 1842 the symptoms became alarming. His latter years were mostly occupied in seeking at various health resorts some alleviation of his disease; he spent two winters in Madeira, and tried a voyage to the United States, but was compelled to return within a few weeks of the date of his landing at New York. He went on a visit to a nephew at Gorgie, near Edinburgh, and there he died on the 9th August 1847. His last literary effort was a paper on ship-fever, which was published in the *Times* after his death; its principal suggestions have been carried out by the Act 12 and 13 Vict. c. 23. His biography, written by George Combe, was published in 1850.

COMBE, GEORGE (1788-1858), was born in Edinburgh, 21st October 1788. As the first advocate in this country of the phrenological doctrines of Gall and Spurzheim, and as the author of *The Constitution of Man Considered in Relation to External Objects*, he attracted much attention in Britain, on the Continent, and in America. His father was a brewer,—a man of shrewd business qualities, and of a benevolent disposition, and a strict observer of Calvinistic practices; and his children—nine daughters and eight sons—were placed under a rigid system of religious instruction. In a fragment of autobiography written by Combe shortly before his death, he complains of the irksomeness of the Sunday observances and tasks imposed on his father's household. His frame was feeble; the Sunday tasks followed weeks of severe mental labour at school, and, so far from cultivating in him a religious spirit, they rendered the church, Sunday, and the Catechism sources of weariness and terror to him. His character was earnest and thoughtful even as a child; and feelings of despondency thus engendered were intensified by the weakness of his constitution. His mind became largely occupied with the current theological theories and, in time, with doubts of their truth. He attended the High School for five years, and then proceeded to the university. In 1804 he entered a lawyer's office as an apprentice, and applied himself diligently to the acquirement of the details of his profession. At the same time he assisted his younger brothers and sisters in their studies, and read philosophy, history, and general literature; philosophical works, however, had most attraction for him. In 1812 he obtained his commission as writer to the signet, and, soon after, that of notary public. His shrewdness and conscientiousness in dealing with clients speedily obtained for him a degree of practice which exceeded his expectations. Meanwhile, in private, he had vague yearnings to accomplish something which might benefit mankind. In 1815 the *Edinburgh Review* contained an article on Gall and Spurzheim's system of "craniology," which the reviewer denounced as "a piece of thorough quackery from beginning to end." Combe laughed like others at the absurdities of this so-called new theory of the brain, and thought that it must be finally exploded after such an exposure; and when Dr Spurzheim delivered lectures in Edinburgh, in refutation of the statements of his critic, Combe considered the subject unworthy of serious attention. He was, however, invited to a friend's house where he saw Spurzheim dissect the brain, and he was so far impressed by the demonstration that he attended the second course of lectures. Proceeding to investigate the subject for himself, he became satisfied, after two years of study and observation, that the fundamental principles of phrenology were true—namely "that the brain is the organ of mind; that the brain is an aggregate of several parts, each subserving a distinct mental faculty; and that the size of the cerebral organ is, *cæteris paribus*, an index of power or energy of function." He had moved slowly at first; he now pursued his investigations with enthusiasm. He compared the known characteristics of friends with their phrenological developments; he studied anatomy; he visited schools, prisons, and large manufactories; and he became more and more satisfied that he was approaching a truth which would be of great value to humanity. He requested his brother Dr Andrew Combe—who was at that time a medical student in Paris—to give particular attention to the dissection of the brain, in order to be prepared to support or to condemn the new theories on anatomical principles. In 1817 his first essay on phrenology was published in the *Scots Magazine*; and a series of papers on the same subject appeared soon afterwards in the *Literary and Statistical Magazine*; these were collected and published in 1819 in book form as *Essays on Phrenology*. His friends became alarmed by his public advocacy of a cause which was the laughing-stock of all men of reputation, and warned him that it would be the ruin of his professional prospects. He was not diverted from his course, and he had the satisfaction of finding his business increase; for the many who laughed at his hobby or regretted it still recognized his assiduity in attending to the affairs of his clients. The *Essays* gave an extraordinary impetus to the new science; friends and foes became numerous; a phrenological society was founded; the *Phrenological Journal* was established, and was published quarterly for twenty years; a volume of *Phrenological Transactions* was issued; and Combe's first work developed into *A System of Phrenology* in two large volumes, of which five editions have been published. By his lectures and writings he attracted public attention to the subject on the Continent and in America, as well as at home; and a long discussion with Sir William Hamilton in 1827–28 excited general interest.

The publication of his most popular work, *The Constitution of Man*, was determined upon after serious deliberation. He had circulated private copies amongst his friends, several of whom regarded the principles of the essay as dangerous to society and urged him to suppress it. The principle on which he based his argument was that all the laws of nature were in harmony with each other, and that man would best fulfil God's will, and attain the greatest happiness for himself, by discovering those laws and obeying them. He saw nothing irreligious in this principle; he believed that on the contrary it supplied a philosophic basis to religion. When the book was published in 1828, he was charged by the church party with being a materialist and an atheist; but, on the other hand, he received from near and distant quarters grateful thanks for the new light his work had shed upon religion, and for the satisfaction it afforded to doubting minds. As one indication of the estimation which the work obtained, it is notable that amongst many editions in America there was one for the blind. From this date the current of Combe's public life broadened; he became strong in his own convictions of the truth, and consequently more resolute in carrying them to practical issues. He might hesitate at first, doubting himself; but once satisfied that he was right, he never faltered. He saw everything by the light of phrenology, and the light rendered him patient of the opposition of others, and guided him to the most earnest efforts to benefit his fellow-creatures, morally and socially. He gave time, labour, and money to help forward the education of the poorer classes; he established the first infant school in Edinburgh under the direction of Mr Wilderspin; and he originated a series of evening lectures on chemistry, physiology, history, and moral philosophy—the lectures on the latter subject being delivered by himself. He studied the criminal classes, and tried to solve the problem how to reform as well as to punish them; and he strove to introduce into lunatic asylums a humane system of treatment. In 1836 he offered himself as a candidate for the chair of logic in the Edinburgh University, and the testimonials submitted on his behalf on that occasion show that he was held in high esteem by men of very opposite opinions. As he had expected, he was rejected by the town council in favour of Sir William Hamilton.

Having received numerous invitations to visit America, he proceeded thither in 1838, and about two years were occupied in lecturing in the principal States on phrenology, education, and the treatment of the criminal classes. On his return in 1840 he published his *Moral Philosophy*, and in the following year his *Notes on the United States of North America*. In 1842 he delivered, in German, a course of twenty-two lectures in the university of Heidelberg—being the first Englishman who had ventured to lecture there in the national language. But the effort resulted in an illness which prostrated him for some time. He continued to travel much on the Continent—inquiring into the management of schools, prisons, and asylums. The commercial crisis of 1855 elicited his remarkable pamphlet on *The Currency Question*. The culmination of the religious thought and experience of his life is contained in his work *On the Relation between Science and Religion*, first publicly issued in 1857, and now in its fifth edition. Writing pamphlets, contributing to periodicals, lecturing, and correcting the new editions of his works rendered his days busy to the last. He was engaged in revising the ninth edition of the *Constitution of Man* when he died at Moor Park, Farnham, 14th August 1858. He had married in 1833 Cecilia Siddons, a daughter of the great actress. She had been the companion of all his travels, and she was with him at the end. Apart from his position as a phrenologist he earned distinction by his efforts on behalf of education, and by his courage in promulgating certain philosophic truths, which at the time were regarded as subversive of everything good, but are now accepted so entirely as matters of course that his share in obtaining recognition for them is apt to be forgotten. (C. G.)

COMBE, WILLIAM (1741–1823), an anonymous hack writer of great fertility and of some merit, was born at Bristol in 1751. The circumstances of his birth and parentage are somewhat doubtful, and it is questioned whether his father was a rich Bristol merchant, or a certain William Alexander, a London alderman, who died in 1763. Be this as it may, it is certain that Combe was educated at Eton, with Fox, Lyttelton, and William Beckford; that Alexander bequeathed him some £2000—a little fortune that soon disappeared in a course of splendid extravagance, which gained him the nickname of Count Combe; and that he finally fixed his residence in London (about 1771), as a law student and bookseller's hack. In 1775 he published *The Philosopher in Bristol*, a series of essays of merely local interest; and in 1776 he made his first success in London with *The Diaboliad*, a satire full of bitter personalities. Four years afterwards (1780) he became an inmate of the King's Bench; and much of his subsequent life was spent in prison. He appears to have written a correspondence between Sterne and Eliza Draper, and also the *Letters of the Late Lord Lyttelton* (1780). Periodical literature of all sorts—pamphlets, satires, burlesques, "two thousand columns for the papers," "two hundred biographies," *The Origin of Commerce*—filled up the next years, and about 1789 Combe was receiving £200 yearly from Pitt. Six volumes of a *Devil on Two Sticks in England* caused him to be saluted as "the English Le Sage;" in 1794–96 he wrote the text for Boydell's *History of the River Thames*; in 1803, he was placed on *The Times*. In 1807 *All the Talents*, a satire, appeared; it ran through twenty editions and is generally attributed to Combe. In 1809–11 he wrote for Ackermann's *Political Magazine* the famous *Three Tours of Dr Syntax*, which, owing greatly to Rowlandson's designs, had an immense success. Then came poems in illustration of drawings by Princess Elizabeth, *The Military Adventures of Johnny Newcome* (1815), *The English Dance of Death* (1815–16), *The Dance of Life* (1816–17), *The Adventures of Johnny Quæ Genus* (1822)—all written for Rowlandson's caricatures; together with *Histories* of Oxford and Cambridge, *Picturesque Tours* along the Rhine and other rivers, *Histories of Madeira*, *Antiquities of York*, texts for *Turner's Southern Coast Views*, and contributions innumerable to the *Literary Repository*. In his later years, notwithstanding a by no means unsullied character, Combe was courted for the sake of his charming conversation and inexhaustible stock of anecdote. He is said to have written and burned his autobiography; but it does not appear that the loss of this memorial is to be regretted. He died in London in 1823.

Brief obituary memoirs of Combe appeared in Ackermann's *Literary Repository* and in the *Gentleman's Magazine* for August 1823; and in May 1859 a list of his works, drawn up by his own hand, was printed in the latter periodical. See also *Diary of H. Crabb Robinson*, *Notes and Queries* for 1869, and a paper in the *Churchman's Shilling Magazine* for the same year.

COMBERMERE, Stapleton Cotton, First Viscount (1773–1865), was the second son of Sir Robert Salusbury Cotton of Combermere Abbey, Cheshire, and was born, 14th November 1773, at one of the family estates in Denbighshire. As a boy he was distinguished for his vivacity, courage, and fondness of field sports. He was educated at Westminster School, and when only sixteen, obtained through his father a second lieutenancy in the 23d Regiment, or Royal Welsh Fusiliers. A few years afterwards (1793) he became by purchase captain of the 6th Dragoon Guards, accompanying them during the disastrous expedition to Flanders against the French. Subsequently, and while yet in his twentieth year, he joined the 25th Light Dragoons as lieutenant-colonel, and, while in attendance with his regiment on George III. at Weymouth, he became a great favourite of the king's. In 1796 he went with his regiment to India, and in 1799, under Lord Harris and along with Colonel Wellesley, he distinguished himself in the war with Tippoo Saib, and at the storming of Seringapatam. In 1808, being now major-general, he was sent to the seat of war in Portugal, where he shortly rose to the position of commander-in-chief of cavalry under Wellington, and it was here that he most displayed that personal courage, swiftness of action, and judgment which won for him his fame as a cavalry officer. His share in the battle of Salamanca (July 22, 1812) was especially marked, and received the personal thanks of Wellington. The day after, he was accidentally wounded in the left arm by a shot from one of the Portuguese allies. On the conclusion of peace in 1814, General Cotton was raised to the peerage under the style of Baron Combermere. He was not present at Waterloo, the command which he expected, and bitterly regretted not receiving, having been given to Lord Uxbridge. In 1817 he was appointed governor of Barbados and commander of the West Indian forces. His active military life was concluded in India (1826), where he besieged and took Bhartpur—a fort which twenty-two years previously had defied the genius of Lake, and was deemed impregnable. For this service he was created Viscount Combermere. A long period of peace and honour still remained to him at home. In 1834 he was sworn a privy councillor, and in 1852 he succeeded his old chief as constable of the Tower and lord lieutenant of the Tower Hamlets. In 1855 he received a marshal's baton, and was made G.C.B. He discharged his duties to the last, and died at Clifton in his ninety-second year. An equestrian statue in bronze, the work of Baron Marochetti, has been raised in his honour by the inhabitants of Chester. In private life Lord Combermere was most exemplary, and the means by which he attained health and longevity (as detailed in the memoir by Viscountess Combermere and Captain Knollys, 2 vols., 1866,) afford an interesting illustration of what can be done by the exercise of a strict control over appetite and by a regular regimen:—

"On the 14th November, 1863, Lord Combermere had reached his ninetieth year, still in the full possession of his mental faculties, and with his usual activity very little impaired; indeed, the only infirmities which afflicted him were deafness and occasional weakness of the limbs, arising as much from slight rheumatism as a failure of general strength. He still rode three hours daily, and walked short distances with his usual alert step and upright carriage. His voice was as strong, his hand as steady as ever, and he wrote clearly and rapidly without spectacles, which he never used except by candle-light. The wonderful memory for which he had always been remarkable never failed, and while it recalled long past events with surprising accuracy, registered and reproduced those of more recent date with equal exactness. No one could detect any failure in his quick perception or ready conclusions, nor did he betray even the most trifling of those mental deficiencies often attendant on a lesser age than his. When eighty-seven, he had danced a quadrille at a rural fête as lightly as his grandchildren, and at eighty could climb over a hurdle with ease. All these immunities from disease and decrepitude were secured by the invariable moderation which, in spite of service in various climates, left his naturally vigorous constitution unimpaired up to the very end. He rose very early in summer, and the last few years of his life rode an hour before breakfast. This meal was always very simple, and without meat of any kind. At half-past one a small luncheon and half a glass of wine satisfied him until dinner. This last was his largest meal, at which he partook plentifully of meat, and drank, for the last fifteen years, one pint of light sherry. Tea or coffee he never touched in early life, afterwards seldom indulging at breakfast in the former, usually drinking instead cocoa, as the most wholesome beverage. Plain meat, bread, and potatoes constituted his dinners, and he never for twenty-six years once transgressed the rule which he had determined to observe, of eating only what was wholesome, and avoiding fruit, vegetables, beer, champagne, salt meat, condiments, and every other article proscribed by the most rigid dietetics. Besides carefully rejecting all unwholesome food, he made it a practice to eat so slowly that he was always longer than any one else at meals. Few could resist as he did the temptation of a well-supplied table, which he wished to be luxurious for others, while he contented himself with simple fare, enjoying only the sight of the fine fruits furnished from his productive houses and well-cultivated gardens.

"Such abstinence would to many be impracticable; but Lord Combermere possessed a power of self-control which few can compass. As an instance of this, after having long indulged in the habit of taking snuff incessantly, he relinquished it suddenly and entirely. Continual smoking had equally been a practice of his earlier life, until, becoming aware of its evil effects on his health, he restricted himself to two small cigars nightly."

COMBINATIONS among workmen for the purpose of raising their wages, or otherwise altering the terms of their service, were for a long time expressly prohibited by statute. While the state attempted to interfere in the regulation of wages, any combination to defeat the statutory rate would naturally be looked upon with disfavour; and we need hardly be surprised to find that in 1425 a statute was actually passed, making it felony for masons to confederate together to raise their wages above the amount fixed for them by the law. The spirit of such legislation survived to times in which economical principles might be supposed to have been better understood. The Act of 39 and 40 Geo. III. c. 106 (repealing an Act of the previous session on the same subject) made illegal all contracts for obtaining advance of wages or for altering the hours of work, except contracts made between masters and men; and every workman entering into any such contract was liable to be committed to the common jail for three months on conviction before two justices of the peace. The same punishment was reserved for workmen entering into any combination for the same purpose. For the more effectual suppression of combinations among workmen, it was enacted that persons attending any meeting for the furtherance of such contracts and combinations, or persuading or intimidating persons into attending such meetings, or collecting subscriptions for such purposes, should also be liable to be sent to jail for three months by two justices. A law so severe and so one-sided had its natural effect in promoting secret combinations and provoking acts of violence. In 1825, after an inquiry by a committee of the House of Commons, the 6 Geo. IV. c. 129 (repealing an Act on the same subject in the previous session) was passed, whereby a vast number of recited statutes relating to masters and workmen, and generally all enactments relative to combinations of workmen, were repealed. Combinations among workmen were thus relieved from the oppressive statutes specially directed against them. The

Trade Unions Act, 1871, further enacted that the purposes of any trade union shall, not by reason merely that they are in restraint of trade, be unlawful so as to render a member liable to prosecution for conspiracy or otherwise, or to render void or voidable any agreement or trust. The Act specifies certain agreements which may not be enforced in the courts, but which are still not to be regarded as unlawful. It also provides for the registration of trade unions. Their legal position under the criminal law, and the results of recent legislation on the subject, will be discussed under the heading CONSPIRACY. For an account of their history and economical relations see the article on TRADES UNIONS.

COMEDY. See DRAMA.

COMENIUS, or KOMENSKY, JOHANN AMOS (1592–1671), a famous writer on education, and the last bishop of the old church of the Moravian and Bohemian Brethren, was born at Comna, or, according to another account, at Niwnitz, in Moravia, of poor parents belonging to the sect of the Moravian Brethren. Having studied at Herborn and Heidelberg, and travelled in Holland and England, he became rector of a school at Preran, and after that pastor and rector of a school at Fulnek. In 1621 the Spanish invasion and persecution of the Protestants robbed him of all he possessed, and drove him into Poland. Soon after he was made bishop of the church of the Brethren. He supported himself by teaching Latin at Lissa, and it was here that he published his *Pansophiæ Prodromus* (1630), a work on education, and his *Janua Linguarum Reserata* (1631), the latter of which gained for him a great and wide-spread reputation, being produced in twelve European languages, and also in Arabic, Persian, and Turkish. He subsequently published several other works of a similar kind, as the *Eruditionis Scholasticæ Janua* and the *Janua Linguarum Trilinguis*. His method of teaching languages, which he seems to have been the first to adopt, consisted in giving, in parallel columns, sentences conveying useful information, in the vernacular and the languages intended to be taught (*i.e.*, in Comenius's works, Latin and sometimes Greek). In some of his books, as the *Orbis Sensualium Pictus* (1658), pictures are added; this work is, indeed, the first children's picture-book. In 1638 Comenius was requested by the Government of Sweden to draw up a scheme for the management of the schools of that country; and a few years after he was invited to join the commission that the English Parliament then intended to appoint, in order to reform the system of education. He visited England in 1641, but the disturbed state of politics prevented the appointment of the commission, and Comenius passed over to Sweden in August 1642. The great Swedish minister, Oxenstiern, obtained for him a pension, and a commission to furnish a plan for regulating the Swedish schools according to his own method. Devoting himself to the elaboration of his scheme, Comenius settled first at Elbing, and then at Lissa; but, at the burning of the latter city by the Poles, he lost nearly all his manuscripts, and he finally removed to Amsterdam, where he died in 1671.

As a theologian, Comenius was greatly influenced by Boehme. In his *Synopsis Physicæ ad Lumen Divinum Reformatæ* he gives a physical theory of his own, said to be taken from the book of Genesis. He was also famous for his prophecies, and the support he gave to visionaries. In his *Lux in Tenebris* he published the visions of Kotterus, Dabricius, and Christina Poniatovia. Attempting to interpret the book of Revelation, he promised the millennium in 1672, and guaranteed miraculous assistance to those who would undertake the destruction of the Pope and the house of Austria, even venturing to prophesy that Cromwell, Gustavus Adolphus, and Ragotski, prince of Transylvania, would perform the task. He also wrote to Louis XIV., informing him that the empire of the world should be his reward if he would overthrow the enemies of God.

Comenius also wrote against the Socinians, and published three historical works—*Ratio Disciplinæ Ordinisque in Unitate Fratrum Bohemorum*, which was republished with remarks by Buddæus, *Historia Persecutionum Ecclesiæ Bohemicæ* (1648), and *Martyrologium Bohemicum*. See Raumer's *Geschichte der Pädagogik*, and Carpzov's *Religionsuntersuchung der Böhmischen und Mährischen Brüder*.

COMET

IN the present article it is proposed to exhibit formulæ by means of which the orbital elements of a comet may be determined from three observations, assuming the comet to move in a parabola, an hypothesis upon which the apparent paths of the great majority of these bodies may be closely represented, appending thereto a fully worked example of the practical application of the formulæ; also to put the reader in possession of methods now employed for calculating ephemerides of the apparent positions of a comet, to assist in observation. The limits within which we are confined will necessitate reference to other works for demonstration of our formulæ, but care will be taken to name those authorities, which are not only most accessible, but by which the subject has been most clearly treated.

A list of comets of short or moderate period, so far as known at present, a class which offers particular interest to the student of this branch of astronomy, will likewise be included.

The method of calculating a parabolic orbit from three observations which we shall follow is the comparatively expeditious one proposed by Olbers, and demonstrated in his *Abhandlung über die leichteste und bequemste Methode die Bahn eines Cometen zu berechnen*, first published at Weimar in 1797, and since twice reprinted with considerable modifications and additions. The method is founded upon the principle that, if $a\,c$ be the chord between the extreme positions of the comet in its orbit, and $A\,C$ the similar chord of the earth's path, the radii-vectores at the middle position cut $a\,c$ and $A\,C$ proportionally to the times occupied in describing the arcs, a supposition which, though not mathematically exact, is but little in error if the intervals between the observations are pretty nearly equal, and the arcs described small.

It may be convenient if the notation employed in the subsequent formulæ be given here, at least as regards the principal quantities entering into our calculations.

t .... Time of observation (in decimals of a day).
R. A. .... Right Ascension.
δ .... Declination; $+$N, $-$S.
α .... Geocentric longitude.
β .... ,, latitude.
Δ .... True distance of comet from the earth.
$\rho = \Delta \cos\beta$ ... Curtate distance of comet from the earth.
θ .... Comet's heliocentric longitude, on the ecliptic.
λ .... ,, ,, latitude.
r .... ,, radius-vector.
A .... Sun's true longitude.
R .... Earth's radius-vector.
u .... The argument of latitude or distance of the comet from the ascending node.
T .... The epoch of perihelion passage, expressed in the same manner as t.
π .... The longitude of the perihelion, reckoned on the ecliptic to the node and thence on the orbit.

☊ ....The longitude of the ascending node.
i.................The inclination of the comet's orbit to the ecliptic.
q... ....The perihelion distance, expressed, like other distances in astronomical calculations, in parts of the earth's mean distance from the sun.
v................The comet's true anomaly.

We suppose that the observations furnish three complete positions of the comet referred as usual to the equator, or expressed in right ascension and declination, with the mean times of observation at the respective places.

The first step will be to convert the observed right ascensions and declinations into longitudes (α) and latitudes (β). thus :—

$$\text{Put tan. N} = \frac{\text{tan. }\delta}{\text{sin. R.A.}}.\ \text{Then, tan. }\alpha = \frac{\text{cos. }(\text{N}-\epsilon)}{\text{cos. N}}.\ \text{tan R.A.}$$

$$\text{And tan. }\beta = \text{tan. }(\text{N}-\epsilon).\ \text{sin. }\alpha \qquad \epsilon\ldots\left\{\begin{array}{l}\text{the obliquity of the eclip-}\\ \text{tic at date, from the}\\ \textit{Nautical Almanac.}\end{array}\right.$$

Thus we find α', α'', α''', and β', β'', β''', where the quantities with *one* accent apply to the *first* observation, those with *two* accents to the *second* place, and with *three* accents, to the *last* observation. *This is to be understood throughout our formulæ for the calculation of the orbit.*

Now reduce the times of observation to the meridian of Greenwich by applying the longitude of the place of observation with its proper sign, and convert the times so reduced into decimals of a day; thus we have t', t'', t'''.

For each of these times interpolate from monthly page iii., in the *Nautical Almanac*, the sun's longitude (A) and the logarithm of the earth's radius-vector (R); the sun's longitude in the Almanac being *apparent*, the amount of aberration ($20''\cdot42 \div \text{R}$), which is given in another part of the ephemeris, must be *added* to the *apparent* longitude, to obtain the *true* longitude required in the calculation. We have then A′, A″, A‴ and the logarithms of R′, R″, R‴, and are ready to proceed with the application of Olbers's method.

We commence by calculating M or $\frac{\rho'''}{\rho'}$, the ratio of the comet's curtate distances from the earth at the first and third observations from

$$\text{M} = \frac{\text{tan. }\beta''.\ \text{sin. }(\alpha'-\text{A}'') - \text{tan. }\beta'.\ \text{sin. }(\alpha''-\text{A}'')}{\text{tan. }\beta'''.\ \text{sin. }(\alpha''-\text{A}'') - \text{tan. }\beta''.\ \text{sin. }(\alpha'''-\text{A}'')} \cdot \frac{t'''-t''}{t''-t'} \Big\} \quad \text{(I.)}$$

or rather more conveniently, by putting $m = \frac{\text{tan. }\beta''}{\text{sin. }(\alpha''-\text{A}'')}$, from

$$\text{M} = \frac{m.\ \text{sin. }(\alpha'-\text{A}'') - \text{tan. }\beta'}{\text{tan. }\beta''' - m.\ \text{sin. }(\alpha'''-\text{A}'')} \cdot \frac{t'''-t''}{t''-t'} \Big\} \ ; \quad . \quad . \quad \text{(II.)}$$

The following equations must then be formed (k is the chord of the comet-orbit between the extreme observations):

$$\left.\begin{array}{l}
r'^2 = \text{R}'^2 - 2\text{R}'.\ \text{cos. }(\alpha'-\text{A}').\ \rho' + \text{sec. }\beta'^2.\rho'^2 \\
r'''^2 = \text{R}'''^2 - 2\text{R}'''.\ \text{M. cos. }(\alpha'''-\text{A}''')\rho' + \text{sec. }\beta'''^2.\ \text{M}^2.\ \rho'^2 \\
k^2 = (r'^2 + r'''^2) - 2\text{R}'.\ \text{R}'''.\ \text{cos. }(\text{A}'''-\text{A}') \\
\quad + 2\text{R}'''.\ \text{cos. }(\alpha'-\text{A}''')\rho' + 2\text{R}'.\ \text{M. cos. }(\alpha'''-\text{A}').\ \rho' \\
\quad - 2\text{M. cos. }(\alpha'''-\alpha')\rho'^2 - 2\text{M. tan. }\beta'.\ \text{tan. }\beta'''.\ \rho'^2
\end{array}\right\} \text{(III.)}$$

If $(t'''-t')$ be the interval of time between the first and third observations we have, by Lambert's theorem.

$$t'''-t' = \frac{\left(\frac{r'+r'''+k}{2}\right)^{\frac{3}{2}} - \left(\frac{r'+r'''-k}{2}\right)^{\frac{3}{2}}}{3m.\ \sqrt{2}}$$

With an assumed value for ρ' we calculate r, r''', and k, and then t''' for comparison with the observed interval between the first and third observations, and vary ρ' in successive trials until the observed and calculated values agree. In this solution of the above equations by the method of trial and error, a first approximate value of ρ' may be inferred as follows :—

Writing the equation for k^2

$$k^2 = \text{F} + \text{G}.\ \rho' + \text{H}\rho'^2,$$

$$\text{assume tan. }\psi = \frac{2\text{H}}{\text{G}}\sqrt{\frac{\text{F}}{\text{H}}}\ ;\ \text{then }\rho = \text{tan. }\tfrac{1}{2}\psi.\ \sqrt{\frac{\text{F}}{\text{H}}} \quad \text{(IV.)}$$

The amount and direction of the error of interval between the extreme times of observation, resulting from this first value of ρ', will, after a little experience, guide the computer to another value nearer to the true one; and the error of the second assumption, compared with that of the first, again leads to a much closer value for the third approximation, and so on till the assumed value of ρ' produces an agreement between the calculated and observed intervals. In practice we have not found any great advantage on adopting one or other of the devices suggested for obtaining successive values of ρ' by use of tables or otherwise—the simple method of continued approximation, by deducing a new value of the curtate distance proportional to the errors in the two preceding assumptions, will be found in the great majority of cases sufficiently expeditious and as little troublesome as any other.

In working Lambert's equation, proceed as follows :—

$$\text{Put} \quad \text{B} = \frac{r + r''' + k}{2} \qquad \text{D} = \frac{r + r'' - k}{2} \quad . \quad . \quad . \quad . \quad \text{(V.)}$$

$$\log.\ z' = \log.\ \text{B} + \tfrac{1}{2}\log.\ 3 + 1.4378117$$
$$\log.\ z'' = \log.\ \text{D} + \tfrac{1}{2}\log.\ \text{D} + 1.4378117$$

$z' - z''$ = the time of describing the chord, expressed in days and decimals.

The approximations to ρ' may be continued until $z' - z''$ agrees with $(t'''-t')$, within 2 or 3 in the fifth place of decimals, though if the computer has only rough observations at command, a larger error may be tolerated.

The comet's curtate distance from the earth at the third observation is given by

$$\rho''' = \text{M}\rho'$$

With the final values of r', r''', ρ' and ρ''', the direct calculation of the elements of the orbit commences.

The heliocentric longitudes θ', θ''', and latitudes λ', λ''', are obtained from

$$\left.\begin{array}{ll}
& r'.\ \text{cos. }\lambda.\ \text{sin. }(\theta'-\text{A}) = \rho.\ \text{sin. }(\alpha-\text{A}) \\
& r'.\ \text{cos. }\lambda'.\ \text{cos. }(\theta'-\text{A}') = \rho'.\ \text{cos. }(\alpha'-\text{A}) - \text{R}' \\
& r'.\ \text{sin. }\lambda' = \rho'.\ \text{tan. }\beta' \\
\text{and} & \\
& r'''.\ \text{cos. }\lambda'''.\ \text{sin. }(\theta'''-\text{A}''') = \rho'''.\ \text{sin. }(\alpha'''-\text{A}''') \\
& r'''\ \text{cos. }\lambda'''.\ \text{cos. }(\theta'''-\text{A}''') = \rho'''.\ \text{cos. }(\alpha'''-\text{A}''') - \text{R}''' \\
& r'''.\ \text{sin. }\lambda''' = \rho'''.\ \text{tan. }\beta'''
\end{array}\right\} \text{(VI.)}$$

in which equations the right-hand quantities are known.

The values of r' and r''', resulting from these equations, should agree with the preceding ones if the calculations have been correctly performed. This agreement forms the first verification of the work.

If θ''' is in advance of θ', the motion in the orbit is *direct*; if the contrary be the case, the motion is *retrograde*.

Then, if the motion be *direct*, the longitude of the ascending node (☊) and inclination of the orbit to the ecliptic (i) will be found from

$$\left.\begin{array}{l}
\text{tan. }i.\ \text{sin. }(\theta'-☊) = \text{tan. }\lambda' \\
\text{tan. }i.\ \text{cos. }(\theta'-☊) = \dfrac{\text{tan. }\lambda''' - \text{tan. }\lambda'.\ \text{cos. }(\theta'''-\theta')}{\text{sin. }(\theta'''-\theta')}
\end{array}\right\} \text{(VII.)}$$

and if the motion be *retrograde* from

$$\text{tan. }i.\ \text{sin. }(☊-\theta') = \text{tan. }\lambda'$$
$$\text{tan. }i.\ \text{sin. }(☊-\theta') = \frac{\text{tan. }\lambda''' - \text{tan. }\lambda'.\ \text{cos. }(\theta'-\theta''')}{\text{sin. }(\theta'-\theta''}.$$

The distances of the comet from the ascending node reckoned upon the orbit, at the first and third observations (u', u'''), are given in the case of *direct* motion by

$$\text{tan. }u' = \frac{\text{tan. }(\theta'-☊)}{\text{cos. }i} \qquad \text{tan. }u''' = \frac{\text{tan. }(\theta'''-☊)}{\text{cos. }i} \Big\} \text{(VIII}$$

or, if the motion be *retrograde*, by

$$\text{tan. }u' = \frac{\text{tan. }(☊-\theta')}{\text{cos. }i} \qquad \text{tan. }u''' = \frac{\text{tan. }(☊-\theta''')}{\text{cos. }i}.$$

The arc $u''' - u'$ is equal to the difference of true anomalies, and the true anomaly at the first observation (v') will be obtained from

$$\tan.\ \tfrac{1}{2}v' = \mathrm{cotan.}\ \tfrac{1}{2}(u''' - u') - \frac{\sqrt{\dfrac{r'}{r'''}}}{\sin.\ \frac{1}{2}(u''' - u')} \quad . \quad . \quad \text{(IX.)}$$

or from

$$\tan.\ \tfrac{1}{2}v' = \frac{\sqrt{r'''}.\ \cos.^2\tfrac{1}{2}(u''' - u') - \sqrt{r'}}{\sqrt{r'''}.\ \sin.\ \tfrac{1}{2}(u''' - u')} \qquad v''' = v' + u''' - u'$$

The perihelion distance $(q) = r'.\ \cos.^2\tfrac{1}{2}v' = r'''.\ \cos.^2\tfrac{1}{2}v'''$.

The longitude of the perihelion, reckoned on the ecliptic to the node and thence on the orbit, is given by

$$\left.\begin{array}{l} \pi = \Omega + u' - v'\ .\ .\ \text{for } \textit{direct} \text{ motion} \\ \pi = \Omega + v' - u'\ .\ .\ \text{for } \textit{retrograde} \text{ motion} \end{array}\right\} \quad . \quad \text{(X.)}$$

As a further verification of the calculations, we have—

$$k^2 = r'^2 + r'''^2 - 2r'.\ r'''.\ \cos.\ (u''' - u'), \quad . \quad . \quad . \quad \text{(XI.)}$$

which should give the former value of k.

We have now only to determine the time of perihelion passage (T), by finding the interval between the first observation and the perihelion (τ) from v' and q, by means of the equation—

$$\left.\begin{array}{l} \tau = \dfrac{(2q)^{\frac{3}{2}}}{2k}\left(\tan.\ \tfrac{1}{2}v' + \tfrac{1}{3}\tan.^3\tfrac{1}{2}v\right) \quad \begin{array}{r} k \text{ being the Gaussian} \\ \text{constant } [8{\cdot}2355814] \end{array} \\ = \dfrac{(2q)^{\frac{3}{2}}}{[8,5366114]}\cdot\ (\tan.\ \tfrac{1}{2}v' + [9,5228787]\ \tan.^3\tfrac{1}{2}v.) \end{array}\right\} \text{(XII.)}$$

Similarly we may find the interval from the third observation to perihelion by substituting v''' for v'; the times thus separately determined should agree, and this agreement will afford a third check upon the accuracy of our work.

Thus the whole of the elements of the parabolic orbit are found, and it is always desirable to ascertain how the geocentric place calculated from these elements for the time of the second observation agrees with the position observed; the first and third places are necessarily represented.

In the computation of a geocentric position from parabolic elements we may proceed thus :—

Find the interval from perihelion passage to the time for which we require to compute $(t - \mathrm{T})$, in days and decimals.

$$\left.\begin{array}{l} \text{Put cotan. } 2\,\nu = 3k\,(2q)^{-\frac{3}{2}}\,(t - \mathrm{T}) \\ \quad\ \ \text{cotan. } \xi \quad = \sqrt[3]{\text{cotan. } \nu} \\ \text{then tan. } \tfrac{1}{2}v = 2 \text{ cotan. } 2\,\xi \qquad r = \dfrac{q}{\cos.^2\frac{1}{2}v}. \end{array}\right\} \quad . \quad . \quad \text{(XIII.)}$$

We have thus the true anomaly and radius-vector. Then, if the motion be *direct*,—

$$\left.\begin{array}{l} \cos.\ \lambda\ .\ \cos.\ (\theta - \Omega) = \cos.\ (v + \pi - \Omega) \\ \cos.\ \lambda\ .\ \sin.\ (\theta - \Omega) = \sin.\ (v + \pi - \Omega)\ .\ \cos.\ i \\ \sin.\ \lambda \qquad\qquad\qquad\ \ = \sin.\ (v + \pi - \Omega)\ .\ \sin.\ i \end{array}\right\} \quad . \quad . \quad \text{(XIV.)}$$

or, if the motion be retrograde,—

$$\left.\begin{array}{l} \cos.\ \lambda\ .\ \cos.\ (\Omega - \theta) = \cos.\ (v - \pi + \Omega) \\ \cos.\ \lambda\ .\ \sin.\ (\Omega - \theta) = \sin.\ (v - \pi + \Omega)\ .\ \cos.\ i \\ \sin.\ \lambda \qquad\qquad\qquad\ \ = \sin.\ (v - \pi + \Omega)\ .\ \sin.\ i \end{array}\right\} \quad . \quad . \quad . \quad \text{(XV.)}$$

—equations which give the heliocentric longitude and latitude (θ, λ). The geocentric longitude and latitude (α, β) and the true distance from the earth (Δ) are then obtained from—

$$\left.\begin{array}{l} \Delta\ .\ \cos.\ \beta\ .\ \sin.\ (\alpha - \mathrm{A}) = r\ .\ \cos.\ \lambda\ .\ \sin.\ (\theta - \mathrm{A}) \\ \Delta\ .\ \cos.\ \beta\ .\ \cos.\ (\alpha - \mathrm{A}) = r\ .\ \cos.\ \lambda\ .\ \cos.\ (\theta - \mathrm{A}) + \mathrm{R} \\ \Delta\ .\ \sin.\ \beta \qquad\qquad\qquad\quad = r\ .\ \sin.\ \lambda \end{array}\right\} \quad \text{(XVI.)}$$

If the position of the comet as referred to the equator is required,—

$$\text{Put tan. N} = \left.\frac{\tan.\ \beta}{\sin.\ \alpha}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad \text{(XVII.)}$$

Then

$$\tan.\ \mathrm{R.A.} = \frac{\cos.\ (\mathrm{N} + \epsilon)}{\cos.\ \mathrm{N}}\ .\ \tan.\ \alpha \qquad \tan.\ \mathrm{Decl.} = \tan.\ (\mathrm{N} + \epsilon).\sin.\ \mathrm{R.A.}$$

As an example of the calculation of the orbit of a comet by Olbers's method, we will compute the elements of the comet discovered at the Observatory of Marseilles by M. Borrelly on the 6th of December 1874, employing three observations taken at that Observatory on December 7, 16, and 26, viz. :—

1874.	Mean Time at Marseilles. H.	M.	S.	Comet's Right Ascension. H.	M.	S.	Comet's Declination. °	′	″
Dec. 7......	6	40	52	16	0	24·52	+36	38	50
,, 16......	16	43	31	16	11	5·82	+45	37	37
,, 26......	6	18	0	16	24	58·97	+55	34	12

Converting the right ascensions into *arc*, and the times into decimals of a day, after subtracting $21^{m}\ 35^{s}$ from them, for reduction to the meridian of Greenwich, we have—

	Greenwich Mean Times.	Right Ascension (arc). °	′	″	Declination. °	′	″
Dec.	7·26339	240	6	8	+36	38	50
,,	16·68190	242	46	27	+45	37	37
,,	26·24751	246	14	45	+55	34	12

The obliquity of the ecliptic, from the *Nautical Almanac*, was 23° 27′ 28″, and hence, by the formulæ p. 183, we find the following positions referred to the plane of the ecliptic, and interpolating for the above times from the same ephemeris the corresponding longitudes of the sun and log. radii-vectores of the earth, correcting the sun's longitudes for aberration, and reducing all to mean equinox of 1875·0.

	°	′	″		°	′	″
α'	225	2	30	β'	+55	31	52
α''	221	47	16	β''	+64	35	27
α'''	212	44	3	β'''	+74	17	30
A′	255	32	49	Log. R′	9·9933590		
A″	265	7	46	,, R″	9·9929263		
A‴	274	52	15	,, R‴	9·9926916		

The right ascension and declination are thus converted into longitude and latitude for the first observation :—

R.A......	240° 6′ 8″	Log. sin. α......	−9·8497775
δ......	+ 36 38 50	Log.tan.(N − ϵ)	−0·3135946
Log. tan. δ......	+9·8715409	Log. tan. β......	+0·1633721
Log. sin. R.A......	−9·9379771		° ′ ″
Log. tan. N......	−9.9335638	β......	+55 31 52
N......	139 21 56		
ϵ......	23 27 28		″
N − ϵ......	115 54 28	Precession to 1875·0	+3·3

	225° 2′ 19″		
Correction......	+11		
Long. M. Eq. 1875·0...	225 2 30		

And so for the second and third positions.

The interpolation of the sun's longitudes and the log radii-vectores of the earth from monthly page iii. of the *Nautical Almanac* requires no illustration.

We now form the angles $\alpha' - \mathrm{A}''$, $\alpha'' - \mathrm{A}''$, $\alpha''' - \mathrm{A}''$, &c., and take out the sines and cosines required; and it is always convenient to have these functions and other of the principal quantities copied in plain figures on a paper separate from the calculations. Thus we have,—

	°	′	″	Sine.	Cosine.
$\alpha' - \mathrm{A}''$	319	54	44	−9·8088592	....
$\alpha'' - \mathrm{A}''$	316	39	30	−9·8365440	....
$\alpha''' - \mathrm{A}''$	307	36	17	−9·8988564	....
$\alpha' - \mathrm{A}'$	329	29	41	−9·7055368	+9·9352968
$\alpha''' - \mathrm{A}'''$	297	51	48	−9·9464841	+9·6696554
$\alpha' - \mathrm{A}'''$	310	10	15	....	+9·8096060
$\alpha''' - \mathrm{A}'$	317	11	14	....	+9·8654465
$\mathrm{A}''' - \mathrm{A}'$	19	19	26	....	+9.9748170
$\alpha''' - \alpha'$	347	41	33	....	+9·9899024

We have—

$$t'' - t' = 9{\cdot}41851 \text{ days}; \quad t''' - t'' = 9{\cdot}56561 \text{ days},$$
$$t''' - t' = 18{\cdot}98413 \text{ days}.$$

The calculation of $M = \frac{\rho'''}{\rho'}$, is as follows, by (II.):—

Log. tan. β''...	+0·3232781
Log. sin. $(\alpha''-A'')$...	−9·8365440
Log. m...	−0·4867341
Log. sin. $(\alpha'-A'')$...	−9·8088592
	+0·2955933
No. 1 ...	+1·975119
Log. tan. β'...	+0·1633710

Log. $(t'''-t'')$...	0·9807127
Log. $(t''-t')$...	0·9739822
Log. $\left(\frac{t''-t''}{t''-t'}\right)$...	0·0067305

Next, we form the equations (III.) for the determination of r'^2, r'''^2, and k^2 by successive assumptions for the value of ρ',—

Log. R'	9·9933590
Log. R'^2... ..	9·9867180
R'^2......	0·969880
Log. 2	0·3010300
Log. R'	9·9933590
Log. cos. $(\alpha'-A')$...	9·9352968
	0·2296858
No....	1·697015
Log. sec. β'	0·2472153
Log. sec. β'^2......	0·4944306
No...............	+3·121983

Log. R'''	9·9926916
Log. R'''^2......	9·9853832
R'''^2......	0·966903
Log. 2	0.3010300
Log. R'''......	9·9926916
Log. M	9·6699800
Log. cos. $(\alpha'''-A''')$..	9·6696554
	9·6333570
No.	0·429890
Log. sec. β'''	0·5674468
Log. sec. β'''^2......	1·1348936
M^2......	9·3399600
	0·4748536
No...............	+2·984376

Therefore the equations for r'^2 and r'''^2 are—

$$r'^2 = 0·969880 - 1·697015.\rho' + 3·121983.\rho'^2$$
$$r'''^2 = 0·966903 - 0·429890.\rho' + 2·984376.\rho'^2$$
$$r'^2+r'''^2 = 1·936783 - 2·126905.\rho' + 6·106359.\rho'^2$$

Log. 2	0·3010300
Log. R'	9·9933590
Log. R'''......	9·9926916
Log. cos. $(A'''-A')$..	+9·9748170
	+0·2618976
No. 5...............	+1·827669

No. 6 + No. 7.....	+1·944404

Log. 2	0·3010300
Log. M	9·6699800
Log. cos. $(\alpha'''-\alpha')$...	+9·9899024
	+9·9609124
No. 8...............	+0·913929
Log. 2	0·3010300
Log. M	9·6699800
Log. tan. β'	+0·1633710
Log. tan. β'''......	+0·5509163
	+0·6852973
No. 9...............	+4·845039
No. 8 + No. 9.....	+5·758968

So that the equation for k^2 is thus formed,—

$$r'^2 + r'''^2 = 1·936783 - 2·126905.\rho' + 6·106359.\rho'^2$$
$$1·827669 + 1·944404.\rho' - 5·758968.\rho'^2$$
$$k^2 = 0·109114 - 0·182501.\rho' + 0·347391.\rho'^2$$

And thus substituting logarithms in the factors for ρ' and ρ'^2, our equations stand thus, in the form for proceeding with the work—

$$r'^2 = 0·969880 - [0·2296858].\rho' + [0·4944306]\rho'^2$$
$$r'''^2 = 0·966903 - [9·6333570].\rho' + [0·4748536]\rho'^2$$
$$k^2 = 0·109114 - [9·2612653].\rho' + [9·5408186]\rho'^2$$

We have now to find the value of ρ' by trial and error. Here, if $k^2 = F + G.\rho' + H\rho'^2$, we have—

$F = 0·10911$, $\log. G = -9·26127$, $\log. H = +9·54082$.

And for a first approximate value of ρ', by (IV.),—

Log. F... =	9·03788
Log. H... =	9·54082
	9·49706
Log. $\sqrt{\frac{F}{H}}$...	9·74856
Log. tan. $\frac{1}{2}\psi$...	0·06370
Log. ρ'...	9·81226
ρ' ..	0·649

Log. 2 ... =	0·30103
Log. H... =	+9·54082
Log. 2H... =	+9·84185
Log. G...	−9·26127
	−0·58058
Log. $\sqrt{\frac{F}{H}}$...	+9·74856
tan. ψ...	−0·83202
ψ...	98° 22',5
$\frac{1}{2}\psi$...	49° 11',25

In the earlier approximations we may use *five-figure* logarithms. With $\rho' = 0·649$, the work proceeds thus—

Log. ρ'......	9·81224

If for a second approximation we take $\rho' = 0·7139$, and calculate $z'-z''$ precisely as before, the error in the interval from the first to the third observation, or $(t'''-t')$, is found to be $-0^d·3606$, which, compared with the error of the first assumption ($-2^d·0488$), shows a change of $+1^d·6882$ for an increase of 0·0649 in ρ', or of $\frac{1}{10}$th part, and by mere proportion we have $\rho' = 0·72776$, for a third approximation, giving the error in interval $= +0^d·0222$, so that we are now approaching the true value, and with

$\rho' = 0{\cdot}7269562$, obtained from the errors of the second and third trial in the same way that the third value of ρ' was inferred, we may substitute seven-figure logarithms and work more closely; it will thus be found that the error in interval correspónding to the fourth assumption for ρ' is reduced to $+0^{d}{\cdot}00167$, or less than $2\frac{1}{2}$ minutes, and if we are only seeking an approximate knowledge of the orbit, the direct calculation of the elements might proceed with this fourth value of ρ'. However, to make the computation in this example a little more complete, we work out two further hypotheses, and finally adopt for the correct value of ρ'...0·7268994, with which the calculation is as follows:—

	−0·2296858		+0·4944306	R'^2....	0·969880

so that our first verification is complete.

The comet's heliocentric longitude at the third observation (θ''') being less than that at the first observation (θ'), the motion in the orbit is *retrograde* or contrary to the order of the signs, and we therefore proceed to determine the longitude of the ascending node (☊) and the inclination (i) by the second set of equations in (VII.): thus—

θ' ...	121° 22′ 10″·4
θ'''...	114° 54′ 5″·8
$\theta'-\theta'''$...	6° 28′ 4″·6

Log. cos. $(\theta'-\theta''')$...	+9·9972269		
Log. tan. λ'...	+0·3134658	....	+0·3134658
(1.)...	+0·3106927	sin. (☊ − θ')...	+9·5160651
No. to (1.)...	+2·0449972	tan. i....	0·7974007
Nat. tan. λ'''...	+1·3776038	i....	80° 56′ 27″·5
Nat. tan. λ''' − No. (1.)...	−0·6673934		

Log...	−9·8243819
Log. sin. $(\theta'+\theta''')$...	+9·0517209
	−0·7726610
Log. tan. λ'...	+0·3134658
Log. tan. (☊ − θ')...	−9·5408048
☊ − θ'...	160° 50′ 37″·7
Add θ'...	121° 22′ 10″·4
☊...	282° 12′ 48″·1

☊...	282° 12′ 4
θ'''...	114 54 5·8
☊ − θ'''.	167° 18′ 42″·3

Then for the arguments of latitude at first and third observations (u', u''')—

Log. tan. (☊ − θ')...	−9·5408048	Log. tan. (☊ − θ''')...	−9·3524609
Log. cos. i...	9·1971480	Log. cos. i...	9·1971480
Log. tan. u'...	−0·3436568	Log. tan. u'''...	−0·1553129
u'...	114° 22′ 57″·6	u'''...	124° 57′ 59″·6

∴ $u'''-u' = 10°\ 35'\ 2''{\cdot}0$, and $\frac{1}{2}(u'''-u') = 5°\ 17'\ 31''{\cdot}0$.

We have now to calculate the true anomaly at the first observation from the radii-vectores r', r''' and the included angle $u'''-u'$, which is $=v'''-v'$, and for this purpose will employ both expressions for tan. $\frac{1}{2}v$ in (IX.)—

By the first formula.

Log. cotan. $\frac{1}{2}(u'''-u')$	$+1{\cdot}0332699$
No (1.) = (Nat. cotan. $\frac{1}{2}(u'''-u')$)	$+10{\cdot}796174$
Log. r'	$0{\cdot}0708694$
Log. r'''	$0{\cdot}1742799$
Log. $\left(\frac{r'}{r'''}\right)$	$-9{\cdot}896585$
$\sqrt{\frac{r'}{r'''}}$	$9{\cdot}9482948$
Log. sin. $\frac{1}{2}(u'''-u')$	$+8{\cdot}9648750$
	$+0{\cdot}9834198$
No. 2.	$+9{\cdot}625422$
No. (1.) - No. (2) = Nat. tan. $\frac{1}{2}v'$	$+1{\cdot}170752$
Log. tan. $\frac{1}{2}v'$	$+0{\cdot}0684649$
$\frac{1}{2}v'$	$+49°\ 29'\ 51''{\cdot}5$
∴ v'	$98°\ 59'\ 43''{\cdot}0$

By the second formula.

Log. $\sqrt{r'''}$	$0{\cdot}0871400$
Log. cos. $\frac{1}{2}(u'''-u')$	$+9{\cdot}9681449$
	$0{\cdot}0852849$
No. 1.	$+1{\cdot}2169840$
Log. $\sqrt{r'}$	$0{\cdot}0354347$
No. 2.	$+1{\cdot}0850125$
No. 1 – No. 2.	$+0{\cdot}1319715$
Log.	$+9{\cdot}1204801$
Log. (sin. $\frac{1}{2}(u'''-u')\sqrt{r'''}$)	$+9{\cdot}0520150$
Log. tan. $\frac{1}{2}v'$	$+0{\cdot}0684651$
$\frac{1}{2}v'$	$+49°\ 29'\ 51''{\cdot}5$

The parihelion distance $(q) = r'.\cos.^2 \frac{1}{2}v'$, or

Log. cos. $\frac{1}{2}v'$	$9{\cdot}8125654$
Log. cos.^{2} $\frac{1}{2}v'$	$9{\cdot}6251308$
Log. r'	$0{\cdot}0708694$
Log. q	$9{\cdot}6960002$
q	$0{\cdot}4969525$

The longitude of the perihelion (π)—

$$= \Omega - v' - u'$$
$$= 282°\ 12'\ 48''{\cdot}1 + 98°\ 59'\ 43''{\cdot}0 - 114°\ 22'\ 57''{\cdot}6$$
$$= 266°\ 49'\ 33''{\cdot}5$$

It remains only to determine the time of perihelion from (XII.), computing both from v' and $v''' = v' + (u''' - u') = 109°\ 34'\ 45''{\cdot}0$, so as to have the final verification of the work—

$\frac{1}{2}v' = 49°\ 29'\ 51''{\cdot}4$

Log. tan. $\frac{1}{2}v'$ =	$+0{\cdot}0684649$
Log. tan.^{3} $\frac{1}{2}v'$ =	$+0{\cdot}2053947$
Log. ($\frac{1}{3}$)	$9{\cdot}5228787$
	$+9{\cdot}7282734$
No.	$+0{\cdot}534901$

x	$2{\cdot}365523$
Log. x	$0{\cdot}3739272$
Log. $\left(\frac{(2q)^{\frac{3}{2}}}{2k}\right)$	$1{\cdot}4589339$
	$1{\cdot}8328611$
No. = days from 3d obs. to perihelion	$68^d{\cdot}05517$
Date of 3d observation,	December $26{\cdot}24751$
Perihelion passage,	October $19{\cdot}19234$

We have now the whole of the elements of the parabolic orbit, viz., as usually written and entered in catalogues,—

Perihelion Passage, 1874, *October* 19·1924, *Greenwich Mean Time*.

π	$266°\ 49'\ 33''{\cdot}5$	Mean equinox 1875·0
Ω	$282°\ 12'\ 48''{\cdot}1$	
i	$80°\ 56'\ 27''{\cdot}5$	
Log. q	$9{\cdot}6960002$	

Motion retrograde.

As already remarked, it is always desirable to ascertain how the comet's geocentric position, calculated from the elements thus obtained, agrees with the observed position. A close agreement where good observations have been employed, of course, indicates that the real path of the comet in space does not much differ from a parabola, while a considerable difference, *i.e.*, one exceeding the probable error of the observation, may be due to the ellipticity of the orbit, and the comet may prove to be one of no long period. We will, therefore, proceed to compute the longitude and latitude from the above elements for the time of the second observation.

Perihelion passage (T), October	$19{\cdot}19240$
Date of second observation (t''), December	$16{\cdot}68190$
$t''-$T	$+58{\cdot}48950$

Instead of using Barker's table, we will compute the true anomaly directly by the formulæ (XIII.); thus,

Log. $(3k)$	$8{\cdot}7127027$
Log. $(t''-$T$)$	$+1{\cdot}7670779$
	$+0{\cdot}4797806$
Log. $(2q)^{\frac{3}{2}}$	$9{\cdot}9955453$
Log. cotan. 2ν	$+0{\cdot}4842353$
2ν	$18°\ 9'\ 18''{\cdot}8$
ν	$9°\ 4'\ 39''{\cdot}4$
Log. cos. $\frac{1}{2}v''$	$=9{\cdot}7850693$
Log. cos.$^2\frac{1}{2}v''$	$9{\cdot}5701386$
Log. q	$9{\cdot}6960002$
Log. r''	$0{\cdot}1258616$

Log. cotan. ν	$0{\cdot}7964958$
Log. cotan. ξ = Log. $\sqrt[3]{\text{cotan. }\nu}$	$0{\cdot}2654986$
ξ	$28°\ 29'\ 7''{\cdot}6$
2ξ	$56°\ 58'\ 15''{\cdot}2$
Log. cotan. 2ξ	$9{\cdot}8130004$
Log. 2	0.3010004
tan. $\frac{1}{2}v''$	$0{\cdot}1140304$
$\frac{1}{2}v''$	$+\ 52°\ 26'\ 13''{\cdot}0$
v''	$+104°\ 52'\ 26''{\cdot}0$

We then obtain the comet's heliocentric longitude on the ecliptic (θ'') and heliocentric latitude (λ''), the motion in the orbit being *retrograde*, from equations (XV.) :—

Ω	$282°\ 12'\ 48''{\cdot}1$	
v''	$104\ \ 52\ \ 26{\cdot}0$	
	$27\ \ 5\ \ 14{\cdot}1$	
π	$266\ \ 49\ \ 33{\cdot}5$	
$v''+\Omega-\pi$	$120\ \ 15\ \ 40{\cdot}6$	
Log. sin. $(v''+\Omega-\pi)$	$+9{\cdot}9363812$	$+9{\cdot}9363812$
Log. cos. i / Log. sin. i	$+9{\cdot}1971480$	$9{\cdot}9945489$
	$+9{\cdot}1335292$	Log. sin. λ'' $+9{\cdot}9309301$

So that the errors of elements for the second observation may be expressed in transcription thus:—

$$d\alpha''. \cos. \beta'' = -8''·7$$
$$d\beta'' = +24''·5$$

These errors are not greater than may be looked for, in a computation upon the method we have adopted.

We have computed the true distance of the comet from the earth at the second observation Δ''. If the true distances at the first and third observations are desired, we have $\Delta' = \dfrac{\rho'}{\cos. \beta'}$, $\Delta''' = \dfrac{\rho'''}{\cos. \beta'''}$, or, in the present case, $\Delta' = 1·28437$, $\Delta''' = 1·24574$, so that the comet was slowly approaching the earth during the interval over which the observations extend.

If it be preferred to compare with the observed right ascension and declination, the formulæ (XVII.) have yet to be applied, the calculation, as will be seen, being very similar to that in the conversion of right ascension and declination into longitude and latitude.

[The formation of the equations for the determination of ρ', ρ''', and k will perhaps be found the most slippery part of the computation by the beginner, and we add therefore two or three sets of data from observation and the ephemeris, with the resulting equations, which may be verified for the sake of obtaining a better acquaintance with this part of the work.

Comet 1870. (*Coggia, August* 28.)

	t	α	β	A	Log. R
Aug.	28·5356	46° 7′·0	−11° 22′·1	155 27′·4	0·00411

$$r'''^2 = 1·020559 - [0·1391891]\,\rho' + [0·2602010]\,\rho'^2$$
$$k^2 = 0·139596 + [8·5723285]\,\rho' + [8·0795842]\,\rho'^2$$

It will be remarked that the apparent motion of this comet was very slow during the interval we have taken; it afforded a case where the orbit could only be improved by increased length of observation.]

We may correct the elements thus obtained for the main effect of the error due to the assumption made on commencing our calculation, by the following process, also suggested by Olbers, and applicable to the same observations.

There are already found r', r''', v', v''', and ρ'.

Put $p = \dfrac{r'''. \sin. (v''' - v'')}{r'. \sin. (v'' - v')} - \dfrac{(t''' - t'')}{(t'' - t')}$ and $q = \dfrac{R'''. \sin. (A''' - A'')}{R'. \sin. (A'' - A')} - \dfrac{(t''' - t'')}{(t'' - t')}$. $m = \dfrac{\tan. \beta''}{\sin. (\alpha'' - A'')}$, as in the calculation of the ratio of the curtate distances $\dfrac{\rho'''}{\rho'}$ or M.

Then compute N from

$$N = \frac{R'. \sin. (A'' - A')(q - p). m}{\rho'(m. \sin. (A'' - \alpha') - \tan. \beta')} \cdot \frac{(t'' - t')}{(t''' - t'')}$$
$$H = 1 + \frac{(t'' - t')}{(t''' - t'')} \cdot p + N$$

Multiply those terms in the equations for ρ'''^2 and k^2 which contain M by H, and the term in the equation for ρ'''^2 which contains M^2 by H^2; the equation for ρ'^2 not containing M or M^2 remains unchanged. With this new system of equations we find corrected values of ρ' and of r' and r''', and the elements of the orbit therefrom as before. ρ''' is now M . H . ρ'.

To apply the above formulæ to our preceding example we have

	° ′ ″		° ′ ″

With this corrected value of log. M, we might recalculate the co-efficients of ρ' and ρ'^2 in the equations for r'''^2 and k^2, and complete the calculation of the orbit, but as the method of procedure is precisely that already illustrated by an example, it is unnecessary to occupy space here by so doing.

In the majority of cases in practice, the first elements of a comet's orbit are calculated from a much shorter interval of observation than has been taken in the preceding example,—not infrequently from observations on consecutive nights, and in such cases our elements may be open to considerable correction, though the natural desire of the astronomer to learn something of a new comet's position in the system, its track in the heavens, or possible identity with a comet already calculated, induces as speedy a determination of the orbit, however approximate, as practicable.

If the observations used in the first computations are near together, or the geocentric motion is slow, it will be preferable to wait for later positions, rather than occupy time in attempting a closer representation of the middle place. When later observations are available, the orbit may be re-calculated, M or $\frac{\rho'''}{\rho'}$, being determined by Olbers's formulæ of correction, employing r', r''', ρ', &c., as deduced from the first orbit. But the following general method of correcting approximate elements of a parabolic orbit, which has been widely used, will be found as satisfactory, though requiring great care in working. It is generally known as the method of variation of curtate distances.

We select three good observations at as wide intervals as practicable. These observations should be corrected for the effects of parallax and aberration by means of distances from the earth (Δ) calculated from approximate elements.

The aberration will be most conveniently taken into account by subtracting $497^{s}\cdot8 \times \Delta$ from the time of observation, and interpolating the values of A and Log. R from the *Nautical Almanac* for the time thus reduced.

Then, introducing the observed longitude and latitude and the value of ρ, calculated from the approximate orbit, find θ, λ, and r at the first and third observations from—

$$
\begin{aligned}
r.\cos.\ \lambda.\sin.\ (\theta-a) &= \mathrm{R}.\sin.\ (\mathrm{A}-a) \\
r.\cos.\ \lambda.\cos.\ (\theta-a) &= \mathrm{R}.\cos.\ (\mathrm{A}-a)+\rho \\
r.\sin.\ \lambda &= \rho.\tan.\ \beta
\end{aligned}
$$

From θ', λ', r', and θ''', λ''', r''', we compute the elements in the same manner as before, and thence the geocentric longitude for the time of the second observation, which call a_1. (The geocentric latitude may be substituted for the longitude, if it be changing more rapidly.) Also find the time by these elements between the first and third observations, which call t_1. Now vary ρ' by a small quantity, as 0·01 or 0·005 ($=m$), and find θ', λ', r' again, and with these new values, combined with the previous ones for θ''', λ''', r''', compute the elements, and compare again with the second longitude, and call the difference from the longitude first computed r; also find the interval between the first and third observations, and call the difference in this case p. Next, with the *first values* of ρ', θ', λ', r', combine θ''', λ''', r''' calculated from a similar slightly changed value of ρ''', $(\rho'''+n)$, and, completing the elements, compare again with the longitude at the second observation obtained with the unvaried ρ', ρ''', and also with the corresponding interval between the extreme observations, and call the differeuces from the longitude and interval with unvaried curtate distances s and q. We have thus in the three calculations,—

$$
\begin{gathered}
a_1\ ,\ a_1+r\ ,\ a_1+s \\
t_1\ ,\ t_1+p\ ,\ t_1+q
\end{gathered}
$$

The three hypotheses and corrected values of ρ', ρ''' are then—

	Hyp. I.	Hyp. II.	Hyp. III.	True orbit.
Assumed ρ'	ρ'	$\rho'+m$	ρ'	$\rho'+x$
ρ'''	ρ'''	ρ'''	$\rho'''+n$	$\rho'''+y$
Interval between extreme observations.........	t	$t+p$	$t+q$	(t) observed interval.
Second longitude	a_1	a_1+r	a_1+s	(a) do. longitude.

And we have—

$$(t)-t = \frac{p.x}{m} + \frac{q.y}{n}$$

$$(a)-a_1 = \frac{r.x}{m} + \frac{s.y}{n}$$

$$x = \frac{[(t)-t]\,s.m-[(a)-a_1]\,q.m}{s.p-r.q} \qquad y = \frac{[(t)-t]\,r.n-[(a)-a_1]\,p.n}{r.q-s.p}$$

If the resulting corrections of the curtate distances are small, the true, or rather corrected, elements may be obtained by interpolation between the values obtained on the different hypotheses. When x and y are large, it is occasionally necessary to repeat the work, to have a close agreement between the middle longitude calculated from the corrected orbit and the longitude observed.

To make our article rather more complete, we may now refer to the calculation of ephemerides of the geocentric places of a comet from the parabolic elements, which are required during its visibility to facilitate observations. If a few places only are required, the right ascensions and declinations may be found in the manner already described; but if the comet is likely to continue visible any length of time, it is more convenient to work by rectangular equatorial co-ordinates, introducing the X, Y, Z, depending on the sun's position. which are now given with much detail in the *Nautical Almanac*. Before proceeding further, however, it will be desirable to explain the use of Barker's Table, to which reference has already been made, in the calculation of the true anomalies, as it dispenses with the longer computation introduced above, with the view to render our example independent of any other publication. The table had appeared from time to time, in one form or another, in various astronomical works; but in 1847 it was re-computed with extreme precision by Dr Luther, and printed in Encke's edition of Olbers's *Abhandlung über die leichteste und bequemste Methode die Bahn eines Cometen zu berechnen.* It is much too extensive to be reproduced here.

The true anomaly in the parabola is related to the time from perihelion by the equation—

$$\frac{75\,k\,(t-\mathrm{T})}{q^{\frac{3}{2}}\sqrt{2}} = 75 \tan.\tfrac{1}{2}v + 25 \tan.^3 \tfrac{1}{2}v$$

where k is the Gaussian constant [log. = 8·2355814], and q as before the perihelion distance. In the table—

$$\mathrm{M} = 75 \tan.\tfrac{1}{2}v + 25.\tan.^3\tfrac{1}{2}v$$

$$\text{or } \mathrm{M} = \frac{75.k.(t-\mathrm{T})}{q^{\frac{3}{2}}\sqrt{2}},$$

an equation, which, when q is known, allows either of $(t-\mathrm{T})$ being found from M, and consequently from v, or when $(t-\mathrm{T})$ is known, gives M, and then, by means of the table, the corresponding v.

Put $\mathrm{C}=\frac{75k}{\sqrt{2}}$; C is therefore a constant and log. C = 9·9601277.

If, then, there be calculated for any comet the quantity—

$$m=\frac{\mathrm{C}}{q^{\frac{3}{2}}}$$

we shall have—

$$\mathrm{M}=m(t-\mathrm{T})=75 \tan.\tfrac{1}{2}v+25.\tan.^3\tfrac{1}{2}v.$$

To afford the reader a clearer idea of the great assistance which a table of this kind renders in cometary calculations, we will apply Luther's table in the two cases where we have used direct formulæ in our example,—

(1.) To obtain $(t'-\mathrm{T})$ from $v'=98°\ 59'\ 43''\cdot0$.

Log. q	9·6960002
$\frac{1}{2}$ Log. q	9·8480001
Log. $q^{\frac{3}{2}}$	9·5440003
Log. C	9·9601277
Log. m	0·4161274

The table, of which the argument is the true anomaly (v), with interval 100″, furnishes these values of log. M, near the above value of v—

v °	′	″	Log. M.	Diff. for 1″.
98	58	20	2·1066640	34·69
99	0	0	2·1070109	

Wherefore, by simple interpolation, we find 98° 59′ 43″·0 corresponds to log. M...2·1069519; from this value of log. M subtract log. m, as found above, and we have 1·6908245 for the logarithm of the time (in days and decimals) from perihelion, corresponding to 49ᵈ·07096, as before.

(2.) In the reverse process, the determination of v, when $(t-\mathrm{T})$ is given, we have in our example, as referring to the second observation with which the elements were compared—

$(t''-\mathrm{T})$	+58·48950
Log. $(t''-\mathrm{T})$	1·7670779
Log. m	0·4161274
Log. M	2·1832053

Near this value of M the table gives us—

v °	′	″	Log. M.	Diff. for 1″.
104	51	40	2·1830332	37·50
104	53	20	2·183[illegible]	

Whence, again by simple proportion, we find log. M = 2·1832053, which corresponds to 104° 52′ 25·9″, differing only 0″·1 from the value found in the example.

The student should procure the last edition of the work above-named for the sake of this table, and for the extensive catalogue of orbits of comets, coming down to 1864, and by far the most complete and reliable yet published.

It has been remarked that, where an ephemeris of geocentric positions (right ascension and declination) for any length of time is required, it is convenient to calculate with rectangular equatorial co-ordinates, instead of by the process we have followed in comparing the orbit with the middle observation.

For this purpose we compute what may be termed *co-ordinate constants*, from the elements π, ☊, and i, and obliquity of ecliptic (ϵ), by the following formulæ:—

$$\mathrm{P}=\cos.\ ☊ \qquad \mathrm{P}'=\sin.\ ☊\ \cos.\ \omega \qquad \mathrm{P}''=\sin.\ ☊\ \sin.\ \omega$$

$$\mathrm{Q}=-\sin.\ ☊ .\cos.\ i \qquad \tan.\psi=\frac{\tan.\ i}{\cos.\ ☊}, \qquad \mathrm{Q}''=s.\sin.(\psi+\epsilon)$$

$$\frac{\mathrm{P}}{\mathrm{Q}}=\tan.\ \mathrm{A} \qquad s=\frac{\sin.\ i}{\sin.\ \psi} \qquad \frac{\mathrm{P}''}{\mathrm{Q}''}=\tan.\ \mathrm{C}$$

$$\frac{\mathrm{P}}{\sin.\mathrm{A}}=\sin.\ a \qquad \mathrm{Q}'=s..\cos.(\psi+\epsilon) \qquad \frac{\mathrm{P}''}{\sin.\ \mathrm{C}''}=\sin.\ c$$

$$\mathrm{A}'=\mathrm{A}+(\pi-☊) \qquad \frac{\mathrm{P}'}{\mathrm{Q}'}=\tan.\mathrm{B} \qquad \mathrm{C}'=\mathrm{C}+(\pi-☊)$$

$$\frac{\mathrm{P}'}{\sin.\ \mathrm{B}}=\sin.\ b$$

$$\mathrm{B}'=\mathrm{B}+(\pi-☊)$$

As a partial check upon the calculation, we have—

$$\tan.\ i=\frac{\sin.\ b.\sin.\ c.\sin.\ (\mathrm{C}'-\mathrm{B}')}{\sin.\ a.\ \cos.\ \mathrm{A}}$$

The angle ψ is to be taken in the *first* quadrant with its proper sign, and when the comet's motion is retrograde, i must be used with a negative sign. The heliocentric co-ordinates of the comet (x, y, z) will then be obtained from—

$$\left.\begin{aligned} x &= r.\sin.\ a.\sin.\ (\mathrm{A}'+v) \\ y &= r.\sin.\ b.\sin.\ (\mathrm{B}'+v) \\ z &= r.\sin.\ c.\sin.\ (\mathrm{C}'+v), \end{aligned}\right.$$

x being measured in the direction of the first point of Aries, from the sun as origin of co-ordinates, y towards 90° of Right Ascension, and z from the plane of the equator, *positive* to the *north*.

Similar co-ordinates of the sun, X, Y, Z, with the earth as origin, are found in the *Nautical Almanac* for Greenwich noon and midnight.

The Right Ascension and Declination are given by

$$\tan \mathrm{R.A.}=\frac{\mathrm{Y}+y}{\mathrm{X}+x} \qquad \tan\delta=\frac{\mathrm{Z}+z}{\mathrm{X}+x}.\cos \mathrm{R.A.}$$

The true distance of the comet from the earth $(\Delta)=\frac{\mathrm{Z}+z}{\sin.\delta}$.

As an example of this calculation we will find the co-ordinate constants applying to the elements of Borrelly's comet in this article.

Here ☊ = 282° 12′ 48″·1 π − ☊ = 344° 36′ 45″·4.
i = 80° 56′ 27″·5 (the motion being retrograde).
The mean obliquity of ecliptic, 1875·0 = 23° 27′ 19″·9.

P = Log. cos. ☊	+9·3254186

$\frac{P''}{\text{Log. sin. C}}$ = log. sin. c...	9·9884500
C = C + (π − ☊).....	188° 9′ 37″·3

We thus have, as the expressions are usually written,

$x = r.\ [9{\cdot}4176428] \sin(\ 38°\ 34'\ 46''{\cdot}5 + v)$
$y = r.\ [9{\cdot}9963572] \sin(279\ \ 54\ \ 8{\cdot}8 + v)$...
$z = r.\ [9{\cdot}9884500] \sin(188\ \ 9\ \ 37{\cdot}3 + v)$

{All quantities being of course logarithmic.

The true anomaly reckoned from 0° to 180°, in a *direct* orbit, is to be applied to A′, B′, and C′, with a *negative* sign if the time for which we are calculating be before the perihelion passage, and with a positive sign if the time be subsequent thereto. In a *retrograde* orbit the contrary rule is to be observed.

In our comparison of the elements of Borrelly's comet with the second observation we found $v = 104°52'26''{\cdot}0$, and log. $r = 0{\cdot}1258616$; the calculation of the heliocentric co-ordinates and geocentric place with these values stands thus:—

For the demonstration of the method of determining a parabolic orbit, which has been here adopted, the reader may consult Olbers's work, already mentioned, and for various modifications and refinements he is referred to Encke's treatise, *Ueber die Olbers'-sche Methode zur Bestimmung der Cometenbahnen*, in the appendix to the *Berliner Astronomisches Jahrbuch* for 1833; he will obtain much additional information from the treatise on *Theoretical Astronomy*, by Prof. Watson of Ann Arbor, U.S., and from Prof. Oppölzer's work, *Bahnbestimmung der Kometen und Planeten*, Leipsic, 1870.

On the solution of Lambert's equation, we may refer him to a paper by Mr Marth in *Astronomische Nachrichten*, vol. lxv., Nos. 1557–60, which he will find accompanied by elaborately constructed tables. To obviate extending this article to inconvenient length, the introduction of tables has been avoided throughout; and should it fall under the notice of any one practised in such calculations, we must beg him to attribute any deviation from general rules to the wish to make the article complete in itself, so that the student may compute parabolic elements of any new comet, and its apparent track in the heavens therefrom, without extraneous assistance.

For the method of calculating elliptical orbits, when decided deviation from the parabola is indicated, the reader is referred to Gauss's classical work, *Theoria Motus Corporum Cœlestium*, originally published in 1809, a translation of which, by Commander Davis, U.S.N., was printed at Boston in 1857; in this volume he will also find the demonstration of the formulæ employed in calculating geocentric places from the elements of the orbit.

In presenting elements of comets of short period we shall include in Group A the comets for which periods of less than fifteen years are either established or have been assigned with greater or less degree of probability, and in Group B comets of longer periods, but not exceeding eighty years. We take the comets in order of length of period.

Group A.

I. *Encke's Comet.*

T.....1875, April 13·0682

a... 2·21105 (the semi-axis major).
Period 3·288 years.
Direct.

T is expressed in Greenwich mean time.

The revolution of this comet in about 3⅓ years was discovered by Encke on its appearance in 1818–19, when it was detected by Pons. Encke, having calculated the effect of perturbation by the planet Jupiter, showed that the comet had been previously observed in 1786, 1795, and 1805, though missed at the intervening returns. It has been observed, with more or less success, at every appearance since 1819. Encke's investigations soon led him to infer that the comet's period had slightly diminished since 1795, and that this diminution might be owing to the effect of a resisting medium. The late researches of Dr von Asten of Pulkowa indicate that it is only in certain revolutions that an effect of this nature can be suspected, so that great doubt is thrown upon the validity of Encke's theory.

II. *Blanpain's Comet.* 1819, IV.

These elements were calculated by Encke, who had ascertained that the motion of the comet could not be represented by a parabolic orbit. Clausen thought the comet was identical with one observed in 1743, which also exhibited a deviation from the parabola, and Olbers favoured his view, but no elliptical elements have yet been deduced directly from the observations of 1743. Elements which appear in some of the catalogues of comet-orbits with Clausen's name attached, were merely inferred from an assumed semi-axis major of 3·10, founded upon the hypothesis of identity with Blanpain's comet of 1819. The latter has not been observed since that appearance.

III. *Burckhardt's Comet.* 1766, II.

T.........1766, April 26·9581

a.........2·93368.
Period...5·025 years.
Direct.

Though there is great probability of the identity of this comet with Winnecke's comet (No. VII.), it is preferable at present to treat of these bodies separately. The comet of 1766 was undoubtedly moving in an elliptical orbit of no long period, as was established by Burckhardt after a great amount of computation, but the observations were not sufficiently precise to allow of the length of revolution being found with exactness.

IV. *Tempel's Comet.* 1873, II.

T......1873, June 25·3777		e.........0·544156

i............ 12 43 20		

Discovered by Tempel at Milan, 1873, July 3. The marked deviation from a parabolic orbit was soon independently noticed in England and on the Continent. It does not appear that there is any record of this comet having been observed prior to the year 1873.

V. *De Vico's Comet.* 1844, I.

T..... 1844, September 2·4779		e.........0·617372
		a.........3·10045
π............342° 30′ 48″	1844,	Period..5·459 years.
☊ 63 49 38	Sept. 1.	Direct.
i............ 2 54 46		

Discovered by De Vico at Rome, 1844, August 22. Notwithstanding the elaborate calculation of the orbit by Professor Brünnow, the comet has not been detected since 1844. The researches of M. Leverrier make it highly probable that this body is identical with the comet observed by Lahire at Paris in 1678, though it was not detected at any one of the many returns to perihelion which must have taken place in the interim.

VI. *Brorsen's Comet.* 1846, III.

T......1873, October 10·2694		e ....0·808560
		a.........3·10556
π............116° 2′ 50″	1870·0	Period..5·473 years.
☊ 101 12 38		Direct.
i............ 29 24 13		

Discovered by Brorsen at Kiel, 1846, February 26, and since observed at several returns, including the last in 1873, to which year, it will be seen, the above elements apply. The comet appears to have been detected at its first passage of the perihelion in the present orbit, the form of which is evidently due to a very near approach to the planet Jupiter in May 1842. A first approximation to the elements previous to this encounter with Jupiter has been given by the late Professor D'Arrest.

VII. *Winnecke's Comet.* 1858, II (=1819, III. =1766, II. ?)

T......1875, March 12·1765.		e... .....0·741013
		a.........3·20081
π............276° 37′ 51″	1875·0	Period..5·727 years.
☊ 111 29 43		Direct.
i............ 11 17 4		

A comet discovered by Professor Winnecke, 1858, March 8, was soon found to be moving in an elliptical orbit of short period, and to be identical with the third comet of 1819, to which Encke had assigned a revolution of 5·62 years. The two appearances of 1819 and 1858 have since been connected, from calculation of the perturbations produced by the planet Jupiter, by Clausen, so that there is no possible doubt of the identity of the comets of these years. According to Clausen's computation, the intermediate perihelion passages took place, 1825, February 5; 1830, August 21; 1836, March 3; 1841, September 18; 1847, March 29; and 1852, October 11, the comet being missed at every return. Our elements are for the last appearance in 1875. (See No. III.)

VIII. *Pigott's Comet.* 1783.

T......1783, November 19·9304		e.........0·552456
		a.........3·26066
π............50° 17′ 25″	1783·0	Period...5·888 years.
☊ 55 40 31		Direct.
i..... .. ...45 6 54		

Certainly a comet which, at the time it was detected by Pigott (of variable-star celebrity) at York, 1783, November 19, was moving in an orbit with short period of revolution. This was first established by Burckhardt about the year 1819, but the most accurate orbit will be that of Professor Peters of Clinton Observatory, New York, who has used improved solar places. His orbit is given above. The comet has not been observed since 1783, but Peters has pointed out that with a major axis differing very little from that he had found, the comet might have encountered the planet Jupiter at some one of the aphelion passages subsequent to 1783, and thus have undergone an entire change of orbital elements.

Discovered by Tempel in April 1867; the periodicity established at the same appearance. We have here given orbits both for that year and for the next return in 1873, on account of the heavy perturbations which the elements suffered from the attraction of Jupiter, near to which the comet passed about the aphelion passage. It will be seen that the node was thereby thrown back more than 22°, the inclination increased 3½°, and the revolution lengthened upwards of three months. The least distance between the planet and comet was about 0·32, the earth's mean distance being taken as unity.

X. *Biela's Comet.*

The periodicity of this comet was ascertained on its discovery in February 1826 by Biela, at Josephstadt, Bohemia, and independently by Gambart at Marseilles about ten days later. Both discoverers remarked the similarity of elements to those of the comets of 1772 imperfectly observed by Montaigne at Limoges, and the first comet of 1806. Clausen's calculations showed that the period of revolution between 1772 and 1826 had been about 6¾ years, the comet having escaped observation at the intermediate returns, excepting that of 1806, when it was detected by Pons. Professor Santini of Padua has principally occupied himself with the investigation of the motions of this comet, and more recently the late Professor Hubbard of Washington. The comet was observed at its re-appearance in 1832, but missed in 1839, from proximity to the sun's place. At the next return in 1845–6 it was again found, and at this appearance a remarkable separation into two distinct nebulosities took place under the eyes of astronomers. In 1852 both components were re-observed, and were found to have considerably widened their distance from one another. At the return to perihelion in 1859, there was no possibility of observations from unfavourable position in the heavens; but in 1866, according to calculation, which involved accurate determination of the planetary perturbations, its track seemed likely to favour observation, yet, notwithstanding long and minute search, the comet was not found, nor was anything seen of it as a comet in 1872. In this year, however, there occurred an extraordinary shower of meteors at the end of November, which beyond doubt were moving in the orbit almost identical with that of Biela when last observed. Subjoined are the elements of the two nebulosities forming the comet at the last appearance in 1852:—

Discovered by D'Arrest at Leipsic, 1851, June 27; he suspected a marked deviation of the orbit from a parabola as early as July 8, and elliptical elements were very fairly determined at this first observed visit. MM. Villarceau and Leveau of Paris have principally occupied themselves with the motions of this body, which, like others of the group, approaches very near to the orbit of Jupiter, thereby at times undergoing considerable perturbation. This was the case in 1861, when the distance between the two bodies was only 0·36, so that the elements we have given above for 1877 are materially different from what they were in 1851; the period of revolution is now about 100 days longer than when the comet was discovered. It was observed in 1857–58 and in 1870, but missed at the intermediate return.

i............ 11 21 50		

Discovered by M. Faye at Paris, 1843, Nov. 22, and period determined at this appearance. M. Leverrier has made very extensive researches respecting the previous motions of this comet, which he considers to have been revolving in an orbit of the above limited dimensions since the year 1747, when it may have passed so near to the planet Jupiter as to have its orbit completely changed. The calculations relating to this comet have for many years been in the hands of Dr Axel-Moller of Lund, the results of whose masterly computation of the perturbations will be found in various volumes of the *Astronomiche Nachrichten*. Observations have been made at every return to perihelion since 1843.

XIII. *Peters's Comet.* 1846 (V.)

T .....1846, June 1·2124			e .... 0·721339
			a.......... 5·48558
π.............240° 7′ 35″	1846·0		Period...12·85 years.

i............. 30 24 24			

Discovered at Naples by Dr Peters, now director of the Observatory of Clinton, U.S., 1846, June 26, and not observed elsewhere, except at Rome on July 2. The period of revolution is uncertain to ±1·6 years, according to Peters's last discussion of the observations of 1846, since which year the comet has not been found, though there appears to be no doubt of the great deviation of the orbit from a parabola.

XIV. *Tuttle's Comet.*

T......1871, December 1·7974.		e.......... 0·821054

☊ 269 17 12		Direct.
i 54 17 0		

Periodicity discovered in 1858, when the comet was detected by Mr Tuttle at Cambridge, U.S. (January 4). It was soon found to present a great similarity of elements to those of the second comet of 1790, which was found by Mechain at Paris on January 9, and further investigation established the identity of the comets, five revolutions having been performed between 1790 and 1858. The two appearances have been connected by the calculation of the perturbations in the interval by Clausen and Tischler.

GROUP B.

I. *Comet* 1866 I. (Tempel.)

T......1866, January 11·1339		e .... 0·905420
		a.........10·32479
π .... 60° 28′ 5″	1866·0	Period...33·18 years.
☊......... .231 26 3		Retrograde.
i............ 17 18 5		

This body is widely known as the "comet of the November meteors," which have been found to move in an orbit that is almost identical. It was discovered by Tempel, 1865, Dec. 19; the best determination of the elliptical elements is due to Prof. Oppölzer. The ensuing return to perihelion will be looked for in 1899, in which year a repetition of the grand meteoric display of 1866 may also be expected.

II. *Stephan's Comet.* 1867, I.

T......1867, January 19·8606		e.............. 0·849055
		a..........10·41762
π........ ....75° 52′ 16″	1867·0	Period....33·62 years.
☊..............78 35 45		Direct.
i.... ....18 12 35		

Discovered by Stephan at Marseilles, 1867, Jan. 27. The elliptical orbit which represents the whole course of observation very closely is due to Mr Searle of Cambridge, U.S. This comet appears to make a very close approach to the orbits of Mars and Uranus, and it is likely the actual form of orbit may be owing to an encounter with the latter planet near the aphelion.

III. *Westphal's Comet.* 1852.

T......1852, Oct. 12·7628		e .... 0·918463
		a ....15·3315
π......... 43° 14′ 8″	1852·0	Period....60·03 years.
☊ 346 9 49		Direct.
i 40 54 28		

Discovered by Westphal at Göttingen, 1852, July 24. The elliptical character of the orbit was first established by Marth in the same year. Elements, in the calculation of which the effect of planetary attraction during the period of observation is included, have been published both by the discoverer and by Dr Axel Möller, whose elaborate investigations relating to Faye's comet have been already mentioned.

IV. *Pons's Comet.* 1812.

T......1812, Sept. 15·3136		e............ 0·954541
		a.. ....17·0955
π............ 92° 18′ 44″	1812	Period.....70·69 years.
☊ 253 1 2		Direct.
i...... ..... 73 57 3		

Detected by Pons at Marseilles, 1812, July 20, and independently at a later date by Wisniewsky at Novo-Tcherkask. To Encke is due the discovery of the periodicity, but it is doubtful if the length of revolution can be inferred from the observations, within several months, so that although another perihelion passage is approaching, no reliable prediction of the track in the heavens is at present practicable.

V. *De Vico's Comet.* 1846, III.

T......1846, March 5·5454		e........... 0·962089
		a............17·5072
π ....90° 27′ 0″	1846·0	Period.....73·25 years.
☊ 77 33 33		Direct.
i ... .85 5 42		

Discovered by De Vico at Rome, 1846, Feb. 20, and in a few weeks recognized as a periodical comet, ellipses having been calculated by Breen, Hind, and Peirce. The most reliable orbit, which is given above, is by Van Galen. This comet makes a near approach to the orbit of the planet Venus.

VI. *Olbers's Comet.* 1815.

T......1815, April 25·9922		e............ 0·931220
		a............ 17·6338
π ....149° 1′ 56″	1815	Period .....74·05 years.
☊ 83 28 54		Direct.
i... .... 44 29 55		

Discovered by Olbers at Bremen 1815, March 6. The elements transcribed were calculated by Bessel upon the whole course of observation; very similar ellipses were also found by Gauss, Nicolai, and Nicollet. Bessel computed the effect of planetary attraction upon the motion of the comet in the actual revolution, and assigned the next perihelion passage to 1887, Feb. 9; but unfortunately this date is not to be relied upon within anything like narrow limits.

VII. *Brorsen's Comet.* 1847, V.

T......1847, Sept. 9·5427		e............ 0·972560
		a ....17·7795
π .... 79° 12′ 6″	1847	Period.....74·97 years.
☊ 309 48 49		Direct.
i... .... 19 8 25		

Discovered by Brorsen at Altona, 1847, July 20. While there appears to be no doubt of the ellipticity, the period is yet open to considerable uncertainty, Dr Gould (the present director of the Observatory of Cordova) having inferred a revolution of 81·05 years. It is one of those comets which yet require a more minute calculation.

VIII. *Halley's Comet.*

In the case of this celebrated body we shall content ourselves with reproducing the elements for the appearance of 1835–36, as elaborately worked out by Westphalen, and the elements assigned for the next return in the year 1910 by the late Count de Pontécoulant.

i............ 17 46 51		

It would be useless to attempt to present a history of Halley's comet within the space to which this article must be limited. With regard to its history previous to the year 1456, the earliest visit known to Halley, the reader may refer to a paper on "The Past History of the Comet of Halley," Hind in *Monthly Notices of the Royal Astronomical Society*, vol. x., in which the appearances of the comet are traced back with a greater or less degree of probability to the year B.C. 12, chiefly by aid of the details preserved to us in the Chinese annals; also to a remarkable memoir by the late Dr Angström of Upsala, *Sur deux inégalités d'une grandeur remarquable dans les apparitions de la comète de Halley*, Upsala, 1862, which is corroborative of the conclusions in the first-mentioned paper. (J. R. H.)

COMINES, a town of France, in the department of Nord and the arrondissement of Lille, on the River Lys, which there divides Belgium from France. It is a thriving manufacturing town, with breweries, linen and tape factories, bleachfields, and oil-works. The principal building is the collegiate church of St Peter's. It was in this place that Comines, the French chronicler, was born. Population in 1872, 4020 in the town, and 6353 in the commune.

COMINES, PHILIPPE DE (1445–1509), called the father of modern history, was born at the castle of Comines. He lost both father and mother in his earliest years. In 1463 his godfather, Philip of Burgundy, summoned him to court, and soon after transferred him to the household of his son, afterwards known as Charles the Bold. He speedily acquired considerable influence over the mind of Charles, and in 1468 was appointed chamberlain and councillor; consequently when in the same year Louis XI. entrapped himself at Peronne, Comines was able both to soften the passion of the duke and to give useful advice to the king, whose life he did much to save. Three years later he was charged with an embassy to Louis, who gained him over to himself by many brilliant promises. In 1472 he left Burgundy for the court of France. He was at once made chamberlain and councillor; a pension of 6000 livres was bestowed on him; he received the principality of Talmont, the confiscated property of the family of La Tremville; and many other dignities and presents of land were conferred on him by the king. He was employed to carry out the intrigues of Louis in Burgundy, and spent several months as envoy in Italy. On his return he was received with the utmost favour, and in 1479 obtained a decree confirming him in possession of his principality.

On the death of Louis a suit was commenced against Comines by the family of La Tremville, and he was cast in heavy damages. He plotted against the regent, Anne de Beaujeu, and joined the party of Orleans. Having attempted to carry off the king, and so free him from the tutelage of his sister, he was arrested, and put in one of his old master's iron cages at Loches. In 1489 he was banished to one of his own estates for ten years, and made to give bail to the amount of 10,000 crowns of gold for his good behaviour. Recalled to the council in 1492, he strenuously opposed the Italian expedition of Charles VIII., in which, however, he took part, notably as representing the king in the negotiations which resulted in the treaty of Vercelli. During the rest of his life, notwithstanding the accession of Louis XII., whom he had served as duke of Orleans, he held no position of importance; and his last days were disturbed by law-suits. He died at Argenton in 1509.

The *Memoirs*, to which Comines owes his reputation as a statesman and man of letters, were written during his latter years; the first six books are assigned to 1488–94, and the next two to 1497–1501. Hallam says of them that they "almost make an epoch in historical literature;" and Saint-Beuve, after speaking of Comines as being in date the first truly modern writer, and comparing him with Montaigne, says that his history remains the definitive history of his time, and that from it all political history took its rise. None of this applause is undeserved, for the pages of Comines abound with excellences. He analyzes motives and pictures manners, he delineates men and describes events; his reflections are pregnant with suggestiveness, his conclusions strong with the logic of facts.

The *Memoirs* remained in MS. till 1524, when part of them were printed by Galliot du Pré, the remainder first seeing light in 1525. Subsequent editions were put forth by Denys Sauvage in 1552, by Denys Godefroy in 1649, and by Lenglet Dufresnoy in 1747. That of Mademoiselle Dupont (1841–48) is the best. Various translations of Comines into English have appeared, from that of T. Danett in 1596 to that, based on the Dupont edition, which was printed in Bohn's series in 1855.

COMITAN, or COMITLAN, a town of Mexico, in the state of Chiapas, on the River Grijalva, a tributary of the Tabasco, about forty miles south-east of San Cristobal, the capital of the state. It has a superb church, and a convent dedicated to St Domingo, from which it takes the more precise designation of San Domingo Comitan. The inhabitants derive their subsistence in great measure from agriculture; but they also carry on a smuggling trade with Belize and Guatemala. Population about 10,000.

COMITIA, derived from *con* and *ire*, was employed by the Romans to denote an assembly of the people, called for the purpose of accepting or rejecting some proposition submitted to them by the heads of the state. It was a fundamental principle of the Roman constitution that the supreme power was inherent in the citizens, though it might be delegated by them to hereditary or to elected magistrates. All important matters, however, had to be brought before the sovereign people, who could either ratify or reject, but without discussion, the proposals made to them. Such, at least in theory, and, during the best days of the republic, in practice also, was the function of these popular assemblies.

As may be readily understood, different elements had the ascendency among the Roman people at different periods in their history. So far as it was possible for a state exposed to so many and such various influences to be conservative of its political traditions, Rome, whether monarchical, republican, or imperial, was essentially so. But under the force of circumstances innovations were introduced from time to time, which materially altered the position of the two political parties—the patricians and the plebeians—into which the state was early divided, and by whose dissensions it was long distracted. And in none of her institutions can the progress of the struggle between these rival factions be more clearly traced, than in the nature and powers of those assemblies or comitia, by which the supreme authority at Rome was in succession wielded.

It is usual to describe the Roman comitia as of three kinds, named from the mode in which the people were organized and in which they voted—the comitia curiata, or assembly of the curiæ; the comitia centuriata, or assembly of the centuries; and the comitia tributa, or assembly of the tribes. To these some add a fourth,—the comitia calata (from *calare*, to call); but as this assembly had neither political functions nor a separate organization, it is unnecessary to do more than mention the name.

1. *Comitia Curiata.* The assembly of the curiæ is believed to have been coeval with the rise of Rome itself, and its origin is therefore rightly ascribed by tradition to the mythical founder of the city. The system seems to have been an essential part of the constitution of the early Latin communities, of which Rome was originally only one. Its primary object cannot now be satisfactorily determined; but the purpose for which it came to be employed is sufficiently clear. From a very early period, the Roman curiæ, or "wardships," as they may be called, numbered thirty, being ten for each of the three once independent communities—the Ramnians, Tities, and Luceres—from whose amalgamation the Roman people sprang. At first these curiæ were probably made up exclusively of the freeholders, or patricians, as the latter were afterwards designated, on whom devolved exclusively the right and duty of bearing arms. It has been maintained by some that the class of dependents called by Roman writers clients as well as the burgesses or citizens had a right to vote in the assembly of the curiæ. No direct evidence, however, can be brought forward in support of this supposition, which in the nature of the case is highly improbable; and, if allowed to be present at all, they were likely nothing more than spectators,

or, as their name is said to imply, "listeners." In an assembly each curia had one vote, which was determined by the majority of the individual votes in the different curiæ. As the number of the latter was even, and no provision was made for deciding the matter in the case of their being equally divided on any question, it would seem as if this function had not been thought of in fixing the number of the curiæ, or had been subordinated to some other consideration.

2. *Comitia Centuriata.* By the operation of causes sufficiently obvious, a great increase soon took place in the numbers and influence of the dependent members of the Roman commonwealth. As a natural consequence, the way was paved for a reform of the constitution, though we may well conceive that the step was hastened by the gradual thinning of the ranks of the old freeholders in the incessant wars in which Rome found herself involved with her neighbours. Thus in the course of time a new class, the plebeians of history, arose out of the clients, preponderating in numbers and by no means destitute of wealth. If this class was allowed no rights as citizens, it was exempt from service in the field; and while their political inferiority must have been galling to its members, their immunity from the chances of war can hardly have been looked upon with equanimity by the ruling faction. It was to redress this twofold grievance that the reform ascribed to King Servius Tullius is generally believed to have been effected. But the whole scheme was one skilfully devised, so as to assign to the plebeians duties rather than to bestow upon them rights, and it was evidently the work of a statesman who was in the interest of the patricians. Our chief authorities for the details of the arrangement are Livy and Dionysius, whose accounts, though they differ in some particulars, agree in the main. We must bear in mind, however, that both of them describe the assembly of the centuries rather as it existed in their own day than as it was at first constituted.

According to the authors just named, the whole body of free Romans, burgesses and non-burgesses, was divided into a certain number of classes (*i.e.*, "summonings," probably from *calare*), numbered according to the amount of fortune possessed by each citizen. The class of each man was ascertained by means of a register, drawn up every five years by officers appointed for the purpose, in which were set forth in detail the age of the citizen, the amount of his property, and other particulars. The first class comprised all whose fortune was estimated at not less than 100,000 asses or pounds of copper, sub-divided into 40 centuries of "juniors," who could be called upon for active service, and 40 centuries of "seniors," who in time of war were to do garrison duty at home. In the second class were enrolled those who had property valued at not less than 75,000 asses, with 10 centuries of juniors, 10 of seniors, and 2 of artificers. The third, fourth, and fifth classes included those who possessed not less than 50,000, 25,000, and 12,500 (according to Livy, 11,000) asses respectively, sub-divided into centuries in a similar manner. Those who had not a sufficient money qualification are included by Livy in the fifth class, and made to form a single century, but are reckoned by Dionysius as a sixth class. In addition, there were 18 centuries of equites, or cavalry, who always voted first, made up of the most wealthy members of the landholder class, the actual possession of land being apparently regarded as a necessary qualification for this, the favourite branch of the service. Livy gives the whole number of the centuries as 194; Dionysius makes them 193. The voting in the assembly was by centuries, each century possessing a collective vote exactly as in the case of the curiæ. It was so arranged that the 18 centuries of equites and the 80 centuries of the first class voted first. If they were agreed on the question at issue, the other classes were not called upon to vote at all. As the centuries, though nominally "hundreds," might and probably did contain fewer in the first class, and certainly many times more than that number in some of the other classes, it is plain that in the assembly by far the largest share of power was retained in the hands of the wealthy, of whom the original burgess element would long form the main portion. How far we have in this scheme merely a modification of an earlier arrangement there are no means of determining. As Mommsen remarks, it is more than probable that the assessments were originally laid on land. Be this as it may, the Servian reform was originally a new military rather than a new political organization, its author intending that the privileges of the patricians, assembled in their curiæ, should remain as before. But its results were different from what had been anticipated. By a process easily understood, the rights of the curiæ gradually passed to the centuries. The assembly of the former continued indeed to meet, but the assembly of the latter became thenceforth the chief guardian of the rights of the Roman people.

3. *Comitia Tributa.* The further growth and development of the democratic element in the Roman constitution, consequent on the change just described, soon led to a demand for greater changes in the same direction. The tribunes of the people, now the acknowledged leaders of the democracy, took advantage of an ancient division of the original territory of Rome into tribes, to give greater prominence to this element than it had yet possessed. These tribes, 30 and afterwards 35 in number, which, as is supposed by some, had already supplied a basis for the arrangement into curiæ as well as classes, seem to have at first existed for purely local purposes. But the leaders of the people succeeded at length in forming them into a political union entitled to exercise certain functions, chief among which was the election of the inferior magistrates, and the approval or rejection of such legislative measures as affected the interests of the plebeians as a class. Whether the assembly of the tribes was composed of plebeians only, or of all, whether patrician or plebeian, living within certain limits, has not been ascertained, the balance of opinion inclining to the hypothesis that makes it to have consisted of plebeians alone. After the rise of this new power, it became a matter of great difficulty to determine what questions were to be submitted to the tribes and what to the centuries, each claiming to be the real representatives of the whole body of the people. A solution appears to have been sought for and found in some combination of the two rival assemblies. At what times this change took place, and what was its exact nature, are matters that must ever remain involved in the greatest obscurity. All that can be said is this; either by means of their own assembly, or by their using it somehow for the purpose of counterbalancing the power of the patricians in the assembly of the centuries, the plebeians ultimately gained what they had so long aimed at—a position of supreme importance in the republic. When the wealthier classes found their influence thus neutralized, they ceased to attend the comitia altogether, and the popular will was represented by the lower classes alone. A period of moral and political corruption followed, ending in the military despotism of the Cæsars. Under the first emperors, the form of calling the assemblies together was still observed, but the people met no longer to control their chief ruler, but simply to receive information as to what he had done. Even this form was by and by discontinued, and in the last days of the empire the comitia was an institution known only as one of the traditions of the past greatness of Rome. (J. M'D.)

COMMERCE

COMMERCE, in its general acceptation, is the international traffic in goods, or what constitutes the foreign trade of all countries as distinct from their domestic trade, and it will be convenient in this place to treat it chiefly under this aspect

The same causes which give rise to exchange of commodities in a limited field call it into operation over more extended territories, and the same effects which flow from it in the smaller flow from it in the larger sphere. There are the same phenomena in either case, but in proportion as trade extends beyond the narrow boundaries of a tribe or a nation, the greater are the obstacles it has to encounter, not only in physical distance, and the practicable transit of commodities, but in computation, in gauging the capacity and course of markets, in the risk of making wrong adventures, in the rivalry and exclusiveness, the wars and revolutions of states; and consequently the more liable it becomes to complications, partly native and partly foreign to itself, by which its advantages have been obscured and its progress has been impeded in all ages.

Exchange of commodities implies not only a division of labour, but a development of natural resources where most abundant and accessible. As long as mankind live in scattered and isolated families, each supplying its own wants directly by its own labour, there can be little or no commerce; and as long as there is no commerce every local habitation of man must depend on its natural resources, however poor, unvaried, or difficult to utilize. Division of labour and exchange may be said to be of twin birth, since the existence of the one cannot be conceived without the other; and as they grow up from the simplest embryo, they act and react on each other, giving always wider scope to their mutual operation, and preparing a certain density of population in central places, or markets, where the traffickers meet and artificers find it their interest to settle, whether in the desert where caravans converge in their various routes from one region to another, or at the confluence of navigable rivers, or in secure bays of inland seas, commanding an extensive coast line, or some interoceanic passage, and thus laying the foundation of towns and cities, to become, it may be, as they have become in many instances, the seats of rule and empire. The direct result of these primitive human instincts, as they may be called, of division and exchange of the products of labour was to extend among mankind a material and social comity, apart from all tribal or political relations, from which sprung, as on a solid base or framework, the fair but often frail fabric of civilization, arts, sciences, letters, philosophy, religion—all that gives grace and dignity to humanity. The special office of commerce, in the material part of the economy, is to organize places, soils, climates, all local conveniences of land or sea, and superior natural resources of various countries, as that of the division of labour is to organize the talent, handiness, and aptitude of individuals.

The formative and developing power of this function of commerce is much more conspicuous in the phenomena of ancient history and in contemporary results than may at first sight appear It were easy, judging from local qualities alone, to explain why the metropolis of the United Kingdom should be on the Thames where London now is; how rival ports arose along the western coast of Britain, on the Severn, the Mersey, and the Clyde; why Lancashire should have become the great centre of the cotton manufacture; why Dundee, from a small beginning in flax from the adjacent Baltic, should have become a great emporium of flaxen and cognate fabrics; why there should be a Hull on the Humber, a Newcastle on the Tyne, and a rapidly rising Middlesborough on the Tees; why the Thames should maintain, after many centuries of change and amidst many rivals, its pristine supremacy, and yet the western coast of our island be much more brilliant commercially than the eastern. But the same principle may be no less a guide to our understanding why the earliest records we have of great seats of population should be on the Euphrates, the Nile, the Ganges, and the Blue and Yellow Rivers of China; how Palmyra, the ancient grandeur of which has been discovered in its modern ruins, should have been built in the middle of a desert; how the cradle of navigation and maritime commerce should be so indelibly couched along the coasts and round the numerous islands of the Mediterranean Sea; how international trade, seeking an outlet from its dreary prison of overland desert, war, and rapine, should have found it for a time by the Mediterranean to the Red Sea and the Indian Ocean, only to be diverted by a bold navigation round the cape of Africa, and should now be returning under more secure conditions to the shorter route again. The tendency of commerce to connect one seat of population with another, to open roads, to seize on every physical advantage of transit between them, to create new centres of industry and traffic on the lines of communication, and by the union, not only of human labour and capacities, but of almost boundlessly diversified territorial resources thus effected, to increase the production and circulation of commodities, is too obvious to require illustration. This is what has been called by economists "the territorial division of labour," but the term scarcely reaches a full expression of the effect of commerce. There is not only a territorial extension of the division of labour in the sense of being spread over a larger area and a greatly more numerous population, but the physical resources, the natural agents of wealth themselves, as found in various countries and places, are brought into the general organization as they could be by no other means, and made to yield in due harmony with each other all their special and relative superiorities.

A consideration of this action of international traffic in commodities is sufficient to dispel many false views that have at various times been propounded with much authority—such as that commerce, being an exchange of value for value, can add nothing to the general wealth; or that the profit of one party to an exchange is the loss of the other party; or that the only profit of commerce consists of the balance accruing in the precious metals; and similar crudities of conception. The substratum of the whole system of international traffic is that commodities after bearing the cost of transit, are of more value in one place than in another. Commodities are often so abundant, or capable of being produced so abundantly in some places, as to be superfluities, and absolutely valueless in such places, and yet are of much value in other places. As this relation is mutual, there is nothing inconsistent in an exchange of commodities of more value in one place than in another with a gain of value on both sides of the exchange; and this becomes all the more apparent when, in addition to the profit of the merchants or agents employed in the transaction, there is taken into account the gain arising to the communities in their industry, and in the profits of their industry.

Exchange of commodities must have been coeval with human society. However self depending on their own labour men may have been in the social state, they must soon have had some commodities to exchange with each other, and as stock increased the process would rapidly extend. The liability to failure of crops and to famine must have led to storing of corn in seasons of plenty, and to occasional traffic in the first necessary of life.

The earliest records of commerce on an international scale are to be found in the Hebrew Scriptures. Such a transaction as that of Abraham, for example, weighing down "four hundred shekels of silver, *current with the merchant*," for the field of Ephron, is suggestive of a group of facts and ideas indicating an advanced condition of commercial intercourse,—property in land, sale of land, arts of mining and purifying metals, the use of silver of recognized purity as a common medium of exchange, and merchandize an established profession, or division of labour. That other passage in which we read of Joseph being sold by his brethren for twenty pieces of silver to "a company of Ishmeelites, coming from Gilead, with their camels bearing spicery, balm, and myrrh to Egypt," extends our vision still farther, and shows us the populous and fertile Egypt in commercial relationship with Chaldea, and Arabians, foreign to both, as intermediaries in their traffic, generations before the Hebrew commonwealth was founded. The allusions in Homer and other ancient writings do not bespeak so advanced a state of trade as those in Genesis. There would seem to have been brass coins among the warriors engaged at the siege of Troy; and the shields of Homeric heroes cost, some nine oxen, some more splendid a hundred oxen, implying much rude magnificence in the form of barter; and yet probably not such barter, pure and simple, as is seen in the present day at Kiakhta and Maimatchin, on the Chinese borders of Russia, where chests of tea are exchanged in bulk for Muscovite manufactures of cotton or wool. One might fairly infer, from such archaic touches of the Greek bard, that he had in view an agricultural and pastoral state of society, in which oxen, from their more ready power of purchase than any other commodity, had become a rough standard of value; but oxen could not in any state of society be a general medium of exchange, and the history of circulating media, by which exchanges were effected in ancient times, is curiously illustrative of the transition of real into symbolic value. It may be doubted whether the hundred *kesitas* paid by Jacob for a field in Shalem were lambs or pieces of money having lambs as their insignia. The leather-money of Carthage, which appears to have been symbolic, was probably much more valuable than the iron money of Sparta, which had an intrinsic worth. Any commodity of the first rank in a public mart might become in small circulable pieces the symbol of so much of that commodity to be delivered to order, and from the constancy of that particular exchange, might be relied upon for the purchase of other commodities. But, generally speaking, the use of gold and silver as instruments of exchange betokens a much higher commercial development than where commodities are priced by a number of oxen, or by rings of brass or iron; and it is on record that the precious metals were thus employed in Arabia and Syria, some 2000 years B.C., as they, no doubt, had been much anterior to that date both in Egypt on the one hand and in the rich and populous plains of the Tigris and Euphrates on the other.

The first foreign merchants of whom we read, carrying goods and bags of silver from one distant region to another, were the Southern Arabs, reputed descendants of Ishmael and Esau. Touching in their territory on the south the Red Sea and the right bank of the Nile, and on the north and east the most densely inhabited tracts of Asia, and accustomed in their own interior economy to a free and nomadic life, it may have occurred to the more intelligent and enterprizing of these people to enter on this new and adventurous course. Their traffic could only have small beginnings, but they were pioneers of foreign trade, and showed to their richer neighbours that the desert could be pierced. On the other hand, the first navigators and maritime carriers of goods of whom we read were the Phœnicians, the *débris* of the Canaanites overthrown by the conquering Hebrews, who, intent on the plain of the Jordan, the hilly slopes of Judea, and the sacred Mount Moriah—the long "promised land,"—allowed the dispossessed to settle on a narrow strip of territory along the coast of the Mediterranean. As the clearance proceeded the number of refugees increased, and this outcast race, with one foot on the sea and the other barely on the land, soon outstripped the Edomites and the Ishmaelites in the career of commerce. They founded Tyre and Sidon, of whose opulence there are abundant proofs both in sacred and in profane history. Launching their oared barks on the wave, and steering close along the shore so as to be able to take shelter in the nearest harbourage from a storm, they established a securer and cheaper passage between Egypt and Syria than had before been known. The corn and ivory of the Nile and the oil, silk, dyes, and spices of Western Asia flowed into their hands. From carriers they became merchants, and to merchandize they added manufactures. They enlarged their ships, grew bolder in navigation, and hoisted sails. In the days of Solomon their vessels had penetrated the Red Sea, and brought back to the great king the wealth of Ophir; but that this land of gold was in India, and that the Phœnician craft crossed the Indian Ocean are conclusions unsupported by evidence. It is certain that they traversed thoroughly the shores of the Mediterranean, both continental and insular, established settlements and colonies in many of the islands of the Greek Archipelago, and, greatest of all, founded Carthage, one of the most noted, and probably the most lamented in its fall, of the commercial cities and empires of the ancient world. The kings of Tyre and Sidon, though often involved in the wars and troubles of the Hebrew monarchy, remained for the most part in friendly alliance with Judah and Israel, to whom they were the most valuable of allies both in a commercial and defensive point of view; and it was their adhesion to the cause of Zedekiah, king of Judah, that brought upon the Tyrians the terrible and all but fatal revenge of Nebuchadnezzar, king of Babylon, 3416 A.M. But while their old city on the shore was being reduced to ashes by a thirteen years' siege, the portion of inhabitants who clung to the defence built a new city on an adjacent island, and thus took a new lease of life from the sea—a process which was destined to be almost identically repeated by Venice many centuries afterwards, when the Roman empire was falling under the blows of the barbarians. But Phœnicia never fully recovered her former power, and the *coup de grace* was given to this famous commercial republic in the capture of Tyre by Alexander the Great, 250 years after the struggle with Nebuchadnezzar. The whole inhabitants of the once proud city, who had not saved themselves by flight, were either put to the sword, crucified, or sold into slavery. After this event the name of the Phœnicians disappeared from history, or was soon absorbed in the rising splendour of the commercial cities of Greece—Athens, Corinth, Argos, and their colonies; of Carthage, still in full fame; and of the great seaport named after its founder Alexander, and built in a spot so well chosen that the city retains its importance to the present hour.

In the commerce of the ante-Christian ages the Jews do not appear to have performed any conspicuous part. Both the agricultural and the theocratic constitution of their society were unfavourable to a vigorous prosecution of foreign trade. In such traffic as they had with other nations they were served on their eastern borders by Arabian merchants, and on the west and south by the Phœnician shippers.

The abundance of gold, silver, and other precious commodities gathered from distant parts, of which we read in the days of greatest Hebrew prosperity, has more the character of spoils of war and tributes of dependent states than the conquest by free exchange of their domestic produce and manufactures. The varied merchandize of Tyre and Sidon must have passed over the roads of Palestine, and helped to enrich the Jewish treasury. Tadmor, built by Solomon in the Syrian desert, where there were wells of water, can only be supposed to have been designed as a post for the service of this traffic; and it became not only a resting-place for traffickers and their camels, but a great centre of commerce and political power, under the later name of Palmyra. But it was not until the Jews were scattered by foreign invasions, and finally cast into the world by the destruction of Jerusalem, that they began to develop those commercial qualities for which they have since been so famous. A similar remark may be made of the more ancient nation of Egypt, of whom there is scarce a trace to be found as pioneers of foreign trade. When famine visited adjacent tracts of country corn was usually to be obtained on the Nile, but those in want had to go for it, and the Phœnicians at one period, and the Greeks at another, became the corn merchants of Egypt, while Rome for some centuries drew large supplies to order of her Government. One can readily believe the great wealth, industry, and resources of empires of which such cities as Nineveh and Babylon were the capitals; but the habit of Eastern potentates to drain to their central treasuries the riches of the most distant provinces, and the boundless power by which millions of people were doomed to servitude, are calculated to weaken the impression that such emblems of grandeur as may still remain in ruins are to be ascribed to anything which in the present age could be dignified with the name of commerce.

Such being the general spirit and economy of the ancient nations of the East of which we have historic records, it may be more easily conceived how dense populations might grow up on the great plain of Hindustan and the still greater plain of China; have their own wars, revolutions, and social changes; develop much wealth and varied riches, much art and science, much literary and philosophical refinement; have much internal traffic, with little or no commerce beyond their own widely-extended and impassable frontiers; and yet be so unknown to the rest of the world that the Persians, even in the days of Xerxes, appear to have had scarce a conjecture that there was such an empire as China in existence; that Alexander, on conquering Persia and watering his horses in the Indus, should dream that he was master of all Asia—"weep," as the romantic version runs, "that there was no more world to conquer;" and that, in short, over the growth of these ancient civilizations of Eastern Asia, surviving to the present day and embracing about a half of the human race, the curtain of history should drop as blankly as if they belonged to another planet, or could be seen only through a haze of fable and mystical tradition.

There are three conditions as essential to extensive international traffic as diversity of natural resources, division of labour, accumulation of stock, or any other primal element—(1) means of transport, (2) freedom of labour and exchange, and (3) security; and in all these conditions the ancient world was signally deficient.

The great rivers, which became the first seats of population and empire, must have been of much utility as channels of transport, and hence the course of human power of which they are the geographical delineation, and probably the idolatry with which they were sometimes honoured. Nor were the ancient rulers insensible of the importance of opening roads through their dominions, and establishing posts and lines of communication, which, though primarily for official and military purposes, must have been useful to traffickers and to the general population. But the free navigable area of great rivers is limited, and when diversion of traffic had to be made to roads and tracks through deserts, there remained the slow and costly carriage of beasts of burden, by which only articles of small bulk and the rarest value could be conveyed with any hope of profit. Corn, though of the first necessity, could only be thus transported in famines, when beyond price to those who were in want, and under this extreme pressure could only be drawn from within a narrow sphere, and in quantity sufficient to the sustenance of but a small number of people. The routes of ancient commerce were thus interrupted and cut asunder by barriers of transport, and the farther they were extended became the more impassable to any considerable quantity or weight of commodities. As long as navigation was confined to rivers and the shores of inland gulfs and seas, the oceans were a *terra incognita*, contributing nothing to the facility or security of transport from one part of the world to another, and leaving even one populous part of Asia as unapproachable from another as if they had been in different hemispheres. The various routes of trade from Europe and North-Western Asia to India, which have been often referred to, are to be regarded more as speculations of future development than as realities of ancient history. It is not improbable that the ancient traffic of the Red Sea may have been extended along the shores of the Arabian Sea to some parts of Hindustan, but that vessels braved the Indian Ocean and passed round Cape Comorin into the Bay of Bengal, 2000 or even 1000 years before mariners had learned to double the Cape of Good Hope, is scarcely to be believed. The route by the Euxine and the Caspian Sea has probably never in any age reached India. That by the Euphrates and the Persian Gulf is shorter, and was besides the more likely from passing through tracts of country which in the most remote times were seats of great population. There may have been merchants many, who traded on all these various routes, but that commodities were passed in bulk over great distances is inconceivable. It may be doubted whether in the ante-Christian ages there was any heavy transport over even 500 miles, save for warlike or other purposes, which engaged the public resources of imperial states, and in which the idea of commerce, as now understood, is in a great measure lost.

The advantage which absolute power gave to ancient nations in their warlike enterprises, and in the execution of public works of more or less utility, or of mere ostentation and monumental magnificence, was dearly purchased by the sacrifice of individual freedom, the right to labour, produce, and exchange under the steady operation of natural economic principles, which more than any other cause vitalizes the individual and social energies, and multiplies the commercial resource of communities. Commerce in all periods and countries has obtained a certain freedom and hospitality from the fact that the foreign merchant has something desirable to offer; but the action of trading is reciprocal, and requires multitudes of producers and merchants, as free agents, on both sides, searching out by patient experiment wants more advantageously supplied by exchange than by direct production, before it can attain either permanence or magnitude, or can become a vital element of national life. The ancient polities offered much resistance to this development, and in their absolute power over the liberty, industry, and property of the masses of their subjects raised barriers to the extension of commerce scarcely less formidable than the want of means of communication itself. The conditions of security under which foreign trade can alone flourish equally exceeded the resources of ancient civilization. Such roads as exist must be protected from robbers, the rivers and seas from pirates; goods must have safe passage and safe storage, must be held in a manner sacred in the territories through which they pass, be insured against accidents, be respected even in the madness of hostilities; the laws of nations must give a guarantee on which traders can proceed in their operations with reasonable confidence; and the Governments, while protecting the commerce of their subjects with foreigners as if it were their own enterprise, must in their fiscal policy, and in all their acts, be enduced with the highest spirit of commercial honour. Every great breach of this security stops the continuous circulation, which is the life of traffic and of the industries to which it ministers. But in the ancient records we see commerce exposed to great risks, subject to constant pillage, hunted down in peace, and utterly extinguished in war. Hence it became necessary that foreign trade should itself be an armed force in the world; and though the states of purely commercial origin soon fell into the same arts and wiles as the powers to which they were opposed, yet their history exhibits clearly enough the necessity out of which they arose. Once organized, it was inevitable that they should meet intrigue with intrigue, and force with force. The political empires, while but imperfectly developing industry and traffic within their own territories, had little sympathy with any means of prosperity from without. Their sole policy was either to absorb under their own spirit and conditions of rule, or to destroy, whatever was rich or great beyond their borders.

Nothing is more marked in the past history of the world than this struggle of commerce to establish conditions of security and means of communication with distant parts. When almost driven from the land, it often found both on the sea; and often, when its success had become brilliant and renowned, it perished under the assault of stronger powers, only to rise again in new centres and to find new channels of intercourse.

While Rome was giving laws and order to the half-civilized tribes of Italy, Carthage, operating on a different base, and by other methods, was opening trade with less accessible parts of Europe. The strength of Rome was in her legions, that of Carthage in her ships; and her ships could cover ground where the legions were powerless. Her mariners had passed the mythical straits into the Atlantic, and established the port of Cadiz. Within the Mediterranean itself they founded Carthagena and Barcelona on the same Iberian peninsula, and ahead of the Roman legions had depots and traders on the shores of Gaul. After the destruction of Tyre, Carthage became the greatest power in the Mediterranean, and inherited the trade of her Phœnician ancestors with Egypt, Greece, and Asia Minor, as well as her own settlements in Sicily and on the European coasts. An antagonism between the great naval and the great military power, whose interests crossed each other at so many points, was sure to occur; and in the three Punic wars Carthage measured her strength with that of Rome both on sea and land with no unequal success. But a commercial state impelled into a series of great wars has departed from its own proper base; and in the year 146 B.C. Carthage was so totally destroyed by the Romans that of the great city, more than 20 miles in circumference, and containing at one period near a million of inhabitants, only a few thousands were found within its ruined walls. In the same year Corinth, one of the greatest of the Greek capitals and seaports, was captured, plundered of vast wealth, and given to the flames by a Roman consul. Athens and her magnificent harbour of the Piræus fell into the same hands 60 years later. It may be presumed that trade went on under the Roman conquests in some degree as before; but these were grave events to occur within a brief period, and the spirit of the seat of trade in every case having been broken, and its means and resources more or less plundered, and dissipated—in some cases, as in that of Carthage, irreparably the most necessary commerce could only proceed with feeble and languid interest under the military, consular, and proconsular licence of Rome at that period. It may be remarked that Tyre, the great seaport of Palestine, having been destroyed by Alexander the Great, Palmyra, the great inland centre of Syrian trade, was visited with a still more complete annihilation by the Roman Emperor Aurelian within little more than half a century after the capture and spoliation of Athens. The walls were razed to their foundations; the population—men, women, children, and the rustics round the city—were all either massacred or dispersed; and the queen Zenobia was carried captive to Rome. Palmyra had for centuries, as a centre of commercial intercourse and transit, been of great service to her neighbours, east and west. In the wars of the Romans and Parthians she was respected by both as an asylum of common interests which it would have been simple barbarity to invade or injure; and when the Parthians were subdued, and Palmyra became a Roman *annexe*, she continued to flourish as before. Her relations with Rome were more than friendly; they became enthusiastic and heroic; and her citizens, in a most brave expedition, having inflicted signal chastisement on the king of Persia for the imprisonment of the emperor Valerian, the admiration of this conduct at Rome was so great that their spirited leader Odenathus, the husband of Zenobia, was proclaimed Augustus, and became co-emperor with Gallienus. But the Palmyrians, on receiving this exalted honour from the Roman senate and people, might have said, "Timeo Danaos dona ferentes," for it introduced into their secure, palm-covered, and lucrative groves of commerce the bane of imperial politics and ambition; and it was the passionate impulse of Palmyra and her widowed queen to erect an empire of their own that brought down upon them the terrible and enduring retribution of Aurelian. It is obvious that the destruction of Palmyra must not only have doomed Palestine, already bereft of her seaports, to greater poverty and commercial isolation than had been known in long preceding ages, but have also rendered it more difficult to Rome herself to hold or turn to any profitable account her conquests in Asia; and, being an example of the policy of Rome to the seats of trade over nearly the whole ancient world, it may be said to contain in graphic characters a presage of what came to be the actual event—the collapse and fall of the Roman empire itself.

The repeated invasions of Italy by the Goths and Huns gave rise to a seat of trade in the Adriatic, which was to sustain during more than a thousand years a history of unusual splendour. The Veneti cultivated fertile lands on the Po, and built several towns, of which Padua was the chief. They appear from the earliest note of them in history to have been both an agricultural and trading people; and they offered a rich prey to the barbarian hordes when these broke through every barrier into the plains of Italy. Thirty years before Attila razed the neighbouring city of Aquileia, the consuls and senate of Padua, oppressed and terrified by the prior ravages of Alaric passed a decree for erecting Rialto, the largest of the numerous islets at the mouth of the Po, into a chief town and port, not more as a convenience to the islanders than as a security for themselves and their goods. But every fresh incursion, every new act of spoliation by the dreaded enemies, increased the flight of the rich and the industrious to the islands, and thus gradually arose the second Venice, whose glory was so greatly to exceed that of the first. Approachable from the mainland only by boats, through river passes easily defended by practised sailors against barbarians who had never plied an oar, the Venetian refugees could look in peace on the desolation which swept over Italy; their warehouses, their markets, their treasures were safe from plunder; and stretching their hands over the sea, they found in it fish and salt, and in the rich possessions of trade and territory which it opened to them, more than compensation for the fat lands and inland towns which had long been their home. The Venetians traded with Constantinople, Greece, Syria, and Egypt. They became lords of the Morea, and of Candia, Cyprus, and other islands of the Levant. The trade of Venice with India, though spoken of, was probably never great. But the crusades of the 12th and 13th centuries against the Saracens in Palestine extended her repute more widely east and west, and increased both her naval and her commercial resources. It is enough, indeed, to account for the grandeur of Venice that in course of centuries, from the security of her position, the growth and energy of her population, and the regularity of her government at a period when these sources of prosperity were rare, she became the great emporium of the Mediterranean—all that Carthage, Corinth, and Athens had been in a former age on a scene the most remarkable in the world for its fertility and facilities of traffic,—and that as Italy and other parts of the Western empire became again more settled her commerce found always a wider range. The political history of the Venetian Republic is deeply interesting, were this the proper place to do more than glance at the fortune of commerce and the circumstances and conditions under which it attains its grandest success. The bridge built from the largest of the islands to the opposite bank became the "Rialto," or famous exchange of Venice, whose transactions reached farther, and assumed a more consolidated form, than had been known before. There it was where the first public bank was organized; that bills of exchange were first negotiated, and funded debt became transferable; that finance became a science, and book-keeping an art. Nor must the effect of the example of Venice on other cities of Italy be left out of account. Genoa, following her steps, rose into great prosperity and power at the foot of the Maritime Alps, and became her rival, and finally her enemy. Naples, Gaeta, Florence, many other towns of Italy, and Rome herself, long after her fall, were encouraged to struggle for the preservation of their municipal freedom, and to foster trade, arts, and navigation, by the brilliant success set before them on the Adriatic; but Venice, from the early start she had made, and her command of the sea, had the commercial pre-eminence.

The state of things which arose on the collapse of the Roman empire presents two concurrent facts, deeply affecting the course of trade—(1) the ancient seats of industry and civilisation were undergoing constant decay, while (2) the energetic races of Europe were rising into more civilized forms and manifold vigour and copiousness of life. The fall of the Eastern division of the empire prolonged the effect of the fall of the Western empire; and the advance of the Saracens over Asia Minor, Syria, Greece, Egypt, over Cyprus and other possessions of Venice in the Mediterranean, over the richest provinces of Spain, and finally across the Hellespont into the Danubian provinces of Europe, was a new irruption of barbarians from another point of the compass, and revived the calamities and disorders inflicted by the successive invasions of Goths, Huns, and other Northern tribes. For more than ten centuries the naked power of the sword was vivid and terrible as flashes of lightning over all the seats of commerce, whether of ancient or more modern origin. The feudal system of Europe, in organizing the open country under military leaders and defenders subordinated in possession and service under a legal system to each other and to the sovereign power, must have been well adapted to the necessity of the times in which it spread so rapidly; but it would be impossible to say that the feudal system was favourable to trade, or the extension of trade. The commercial spirit in the feudal, as in preceding ages, had to find for itself places of security, and it could only find them in towns, armed with powers of self-regulation and defence, and prepared, like the feudal barons themselves, to resist violence from whatever quarter it might come. Rome, in her best days, had founded the municipal system, and when this system was more than ever necessary as the bulwark of arts and manufactures, its extension became an essential element of the whole European civilization. Towns formed themselves into leagues for mutual protection, and out of leagues not infrequently arose commercial republics. The Hanseatic League, founded as early as 1241, gave the first note of an increasing traffic between countries on the Baltic and in northern Germany, which a century or two before were sunk in isolated barbarism. From Lubeck and Hamburg, commanding the navigation of the Elbe, it gradually spread over 85 towns, including Amsterdam, Cologne, and Frankfort in the south, and Dantzic, Königsberg, and Riga in the north. The last trace of this league, long of much service in protecting trade, and as a means of political mediation, passed away the other year in the erection of the new German empire, but only from the same cause that had brought about its gradual dissolution—the formation of powerful and legal governments—which, while leaving to the free cities their municipal rights, were well capable of protecting their mercantile interests. The towns of Holland found lasting strength and security from other causes. Their foundations were laid as literally in the sea as those of Venice had been. They were not easily attacked whether by sea or land, and if attacked had formidable means of defence. The Zuyder Zee, which had been opened to the German Ocean in 1282, carried into the docks and canals of Amsterdam the traffic of the ports of the Baltic, of the English Channel, and of the south of Europe, and what the seas did for Amsterdam from without the Rhine and the Maese did for Dort and Rotterdam from the interior. By the Union of Utrecht in 1579 Holland became an independent republic, and for long after, as it had been for some time before, was the greatest centre of maritime traffic in Europe. The rise of the Dutch power in a low country, exposed to the most destructive inundations, difficult to cultivate or even to inhabit, affords a striking illustration of those conditions which in all times have been found specially favourable to commercial development, and which are not indistinctly reflected in the mercantile history of England, preserved by its insular position from hostile invasions, and capable by its fleets and arms to protect its goods on the seas and the rights of its subjects in foreign lands.

The progress of trade and productive arts in the Middle Ages, though not rising to much international exchange, was very considerable both in quality and extent. The republics of Italy, which had no claim to rival Venice or Genoa in maritime power or traffic, developed a degree of art, opulence, and refinement commanding the admiration of modern times; and if any historian of trans-Alpine Europe, when Venice had already attained some greatness, could have seen it 500 years afterwards, the many strong towns of France, Germany, and the Low Countries, the great number of their artizans, the products of their looms and anvils, and their various cunning workmanship might have added many a brilliant page to his annals. Two centuries before England had discovered any manufacturing quality, or knew even how to utilize her most valuable raw materials, and was importing goods from the Continent for the production of which she was soon to be found to have special resources, the Flemings were selling their woollen and linen fabrics, and the French their wines, silks, and laces in all the richer parts of the British Islands. It is more commonly, indeed, when commerce is somewhat still, and men, finding their means resting within limited bounds, learn to delight in labour and invention for their own sake apart from their immediate profits, that the quality of work is improved, and a vantage ground is established for more extended operations, than when commerce is in full career, everything buoyant, saleable, and rising in value, and the lust of gain has taken possession of the human spirit. The Middle Ages may be said to have had this result on a large scale. They placed the barbarous populations of Europe under a severe discipline, trained them in the most varied branches of industry, and developed an amount of handicraft and ingenuity which became an always more solid basis for the future. But trade was too walled in, too much clad in armour, and too incessantly disturbed by wars and tumults, and violations of common right and interest, to exert its full influence over the general society, or even to realize its most direct advantages. It wanted especially the freedom and mobility essential to much international increase, and these it was now to receive from a series of the most pregnant events.

The mariner's compass had become familiar in the European ports about the beginning of the 14th century, and the seamen of Italy, Portugal, France, Holland, and England entered upon a more enlightened and adventurous course of navigation. The Canary Islands were sighted by a French vessel in 1330, and colonized in 1418 by the Portuguese, who two years later landed on Madeira. In 1431 the Azores were discovered by a shipmaster of Bruges. The Atlantic was being gradually explored. In 1486, Diaz, a Portuguese, steering his course almost unwittingly along the coast of Africa, came upon the land's-end of that continent; and nine years afterwards Vasco de Gama, of the same nation, not only doubled the Cape of Good Hope, but reached Zanzibar. About the same period a Portuguese traveller penetrated to India by the old time-honoured way of Suez; and a land, which tradition and imagination had invested with almost fabulous wealth and splendour, was becoming more real to the European world at the moment when the expedition of Vasco de Gama had made an oceanic route to its shores distinctly visible. One can hardly now realize the impression made by these discoveries in an age when the minds of men were awakening out of a long sleep, when the printing press was disseminating the ancient classical and sacred literature, and when geography and astronomy were subjects of eager study in the seats both of traffic and of learning. But their practical effect was seen in swiftly-succeeding events. Before the end of the century Columbus had thrice crossed the Atlantic, touched at San Salvador, discovered Jamaica, Porto Rico, and the Isthmus of Darien, and had seen the waters of the Orinoco in South America. Meanwhile Cabot, sent out by England, had discovered Newfoundland, planted the English flag on Labrador, Nova Scotia, and Virginia, and made known the existence of an expanse of land now known as Canada. This tide of discovery by navigators flowed on without intermission. But the opening of a maritime route to India and the discovery of America, surprising as these events must have been at the time, were slow in producing the results of which they were a sure prognostic. The Portuguese established at Goa the first European factory in India a few years after Vasco de Gama's expedition, and other maritime nations of Europe traced a similar course. But it was not till 1600 the English East India Company was established, and the opening of the first factory of the Company in India must be dated some ten or eleven years later. So also it was one thing to discover the two Americas, and another, in any real sense, to possess or colonize them, or to bring their productions into the general traffic and use of the world. Spain, following the stroke of the valiant oar of Columbus, found in Mexico and Peru remarkable remains of an ancient though feeble civilization, and a wealth of gold and silver mines, which to Europeans of that period was fascinating from the rarity of the precious metals in their own realms, and consequently gave to the Spanish colonizations and conquests in South America an extraordinary but unsolid prosperity. The value of the precious metals in Europe was found to fall as soon as they began to be more widely distributed, a process in itself at that period of no small tediousness; and it was discovered further, after a century or two, that the production of gold and silver is much like the production of other commodities for which they exchange, viz., limited, and only increased in quantity at a heavier cost, that is only reduced again by greater art and science in the process of production. Many difficulties, in short, had to be overcome, many wars to be waged, and many deplorable errors to be committed, in turning the new advantages to account. But given a maritime route to India and the discovery of a new world of continent and islands in the richest tropical and subtropical latitudes, it could not be difficult to foresee that the course of trade was to be wholly changed as well as vastly extended.

The substantial advantage of the oceanic passage to India by the Cape of Good Hope, as seen at the time, was to enable European trade with the East to escape from the Moors, Algerines, and Turks who now swarmed round the shores of the Mediterranean, and waged a predatory war on ships and cargoes which would have been a formidable obstacle even if traffic, after running this danger, had not to be further lost, or filtered into the smallest proportions, in the sands of the Isthmus, and among the Arabs who commanded the navigation of the Red and Arabian Seas. Venice had already begun to decline in her wars with the Turks, and could inadequately protect her own trade in the Mediterranean. Armed vessels sent out in strength from the Western ports often fared badly at the hands of the pirates. European trade with India can scarcely be said, indeed, to have yet come into existence. The maritime route was round about, and it lay on the hitherto almost untrodden ocean, but the ocean was a safer element than inland seas and deserts infested by the lawlessness and ferocity of hostile tribes of men. In short, the maritime route enabled European traders to see India for themselves, to examine what were its products and its wants, and by what means a profitable exchange on both sides could be established; and on this basis of knowledge, ships could leave the ports of their owners in Europe with a reasonable hope, *via* the Cape, of reaching the places to which they were destined without transshipment or other intermediary obstacle. This is the explanation to be given of the joy with which the Cape of Good Hope route was received in one age, as well as the immense influence it exerted on the future course and extension of trade, and of the no less apparent satisfaction with which it has been to some extent discarded in favour of the ancient line, *via* the Mediterranean, Isthmus of Suez, and the Red Sea in our own time.

The maritime route to India was the discovery to the European nations of a "new world" quite as much as the discovery of North and South America and their central isthmus and islands. The one was the far, populous Eastern world, heard of from time immemorial, but with which there had been no patent lines of communication. The other was a vast and comparatively unpeopled solitude, yet full of material resources, and capable in a high degree of European colonization. America offered less resistance to the action of Europe than India, China, and Japan; but on the other hand this new populous Eastern world held out much attraction to trade. These two great terrestrial discoveries were contemporaneous; and it would be difficult to name any conjuncture of material events bearing so importantly on the history of the world. The Atlantic Ocean was the medium of both; and the waves of the Atlantic beat into all the bays and tidal rivers of Western Europe. The centre of commercial activity was thus physically changed; and the formative power of trade over human affairs was seen in the subsequent phenomena, —the rise of great seaports on the Atlantic seaboard, and the ceaseless activity of geographical exploration, manufactures, shipping, and emigration, of which they became the outlets.

The Portuguese are entitled to the first place in utilizing the new sources of wealth and commerce. They obtained Macao as a settlement from the Chinese as early as 1537, and their trading operations followed close on the discoveries of their navigators on the coast of Africa, in India, and in the Indian Archipelago. Spain spread her dominion over Central and South America, and forced the labour of the subject natives into the gold and silver mines, which seemed in that age the chief prize of her conquests. France introduced her trade in both the East and West Indies, and was the first to colonize Canada and the Lower Mississippi. The Dutch founded New York in 1621; and England, which in boldness of naval and commercial enterprize had attained high rank in the reign of Elizabeth, established the thirteen colonies which became the United States, and otherwise had a full share in all the operations which were transforming the state of the world. The original disposition of affairs was destined to be much changed by the fortune of war; and success in foreign trade and colonization, indeed, called into play other qualities besides those of naval and military prowess. The products of so many new countries—tissues, dyes, metals, articles of food, chemical substances—greatly extended the range of European manufacture. But in addition to the mercantile faculty of discovering how they were to be exchanged and wrought into a profitable trade, their use in arts and manufactures required skill, invention, and aptitude for manufacturing labour, and these again, in many cases, were found to depend on abundant possession of natural materials, such as coal and iron. In old and populous countries, like India and China, modern manufacture had to meet and contend with ancient manufacture, and had at once to learn from and improve economically on the established models, before an opening could be made for its extension. In many parts of the New World there were vast tracts of country, without population or with native races too wild and savage to be reclaimed to habits of industry, whose resources could only be developed by the introduction of colonies of Europeans; and innumerable experiments disclosed great variety of qualification among the European nations for the adventure, hardship, and perseverance of colonial life. There were countries which, whatever their fertility of soil or favour of climate, produced nothing for which a market could be found; and products such as the sugar-cane and the seed of the cotton plant had to be carried from regions where they were indigenous to other regions where they might be successfully cultivated, and the art of planting had to pass through an ordeal of risk and speculation. There were also countries where no European could labour; and the ominous work of transporting African negroes as slaves into the colonies—begun by Spain in the first decade of the 16th century, followed up by Portugal, and introduced by England in 1562 into the West Indies, at a later period into New England and the Southern States, and finally domiciled by royal privilege of trade in the Thames and three or more outports of the kingdom,—after being done on an elaborate scale, and made the basis of an immense superstructure of labour, property, and mercantile interest over nearly three centuries, had, under a more just and ennobling view of humanity, to be as elaborately undone at a future time. These are some of the difficulties that had to be encountered in utilizing the great maritime and geographical conquests of the new epoch. But one cannot leave out of view the obstacles, arising from other sources, to what might be dreamed to be the regular and easy course of affairs. Commerce, though an undying and prevailing interest of civilized countries, is but one of the forces acting on the policy of states, and has often to yield the pace to other elements of national life. It were needless to say what injury the great but vain and purposeless wars of Louis XIV. of France inflicted on that country, or how largely the fruitful and heroic energies of England were absorbed in the civil wars between Charles and the Parliament, to what poverty Scotland was reduced, or in what distraction and savagery Ireland was kept by the same course of events. The grandeur of Spain in the preceding century was due partly to the claim of her kings to be Holy Roman Emperors, in which imperial capacity they entailed intolerable mischief on the Low Countries and on the commercial civilization of Europe, and partly to their command of the gold and silver mines of Mexico and Peru, in an eager lust of whose produce they brought cruel calamities on a newly-discovered continent where there were many traces of antique life, the records of which perished in their hands or under their feet. These ephemeral causes of greatness removed, the hollowness of the situation was exposed; and Spain, though rich in her own natural resources, was found to be actually poor—poor in number of people, poor in roads, in industrial art, and in all the primary conditions of interior development. An examination of the foreign trade of Europe two centuries after the opening of the maritime route to India and the discovery of America would probably give more reason to be surprised at the smallness than the magnitude of the use that had been made of these events.

Mr David Macpherson, who published his elaborate *Annals of Commerce* in 1805, states that in 1764 the total imports of Great Britain amounted in official value to £11,250,660, and the total exports to £17,446,306.[1] He found from the Custom House books that in 1800 the imports had increased to £30,570,004, and the exports to £43,152,019, which he deemed an encouraging amount of progress, as, in view of the events, then deemed peculiarly disastrous, that had occurred in the interval—the loss of the American colonies, the French Revolution, and the wars of Bonaparte—it may, no doubt, be held to be. Of the exports in 1800 £24,304,283 were British, and £18,847,735 foreign and colonial merchandize. The proportion of the latter shows to what extent this country had become the medium of trade between Europe and the East and West Indies; but as these re-exports must be deducted from the total imports, there is left only £11,722,269 of imports to

[1] The imports and exports of Ireland at this period, and till the Union, formed a separate account, but the great bulk of them were in her trade with England and Scotland. In 1799 the imports of Ireland from all other ports than Great Britain were £1,263,595, and her exports £759,692; while her imports from Great Britain were £4,011,468, and her exports to Great Britain £4,891,161. Foreign markets were found for Irish manufactures through the British ports, and Ireland was supplied with foreign and colonial merchandize through the same channels. In 1771 the exports of British linen from England were 4,411,040 yards, and of Irish linen 3,450,224 yards. In the same year the exports of linen from Scotland included 701,012 yards of Irish manufacture.

Great Britain for her own purposes of manufacture and consumption. At the beginning of the century two-thirds of the foreign commerce of England was through London, and was largely in the hands of privileged companies. The commercial towns of the provinces and of Scotland had only begun to make some figure. In 1787 Liverpool was a small seaport, having only 445 vessels of 72,731 aggregate tonnage, and clearing inward and outward in foreign trade less than double the amount of her own tonnage. At the same period Glasgow, enriched though she had been by the trade with America, had only 46,000 inhabitants; and Manchester, though a place of considerable manufacture, was still waiting the great impulse to be given to her industry by liberal supplies of cotton, and by the inventions of Arkwright and Crompton.

It may be said, however, that in three eventful centuries the world had been well explored. Colonies had been planted on every coast; great nations had sprung up in vast solitudes or in countries inhabited only by savage or decadent races of men; the most haughty and exclusive of ancient nations had opened their ports to foreign merchantmen; and all parts of the world been brought into habitual commercial intercourse. The seas, subdued by the progress of navigation to the service of man, had begun to yield their own riches in great abundance; and the whale, seal, herring, cod, and other fisheries, prosecuted with ample capital and hardy seamanship, had become the source of no small traffic in themselves. The lists of imports and exports and of the places from which they flowed to and from the centres of trade, as they swelled in bulk from time to time, show how busily and steadily the threads of commerce had been weaving together the labour and interests of mankind, and extending a security and bounty of existence unknown in former ages.

Tariffs. Apart from wars, which commerce directly tends to avert, but which often spring from forces more powerful for the time than commercial interest, there remained little more by which a rapid extension of international trade could be impeded, save causes arising from ignorance or impolicy; and among these deserves chiefly to be noticed the prevailing practice of nations, in promoting their own several industries and trade, to wage a subtle war in times of peace on the industries and trade of each other. That foreign imports, and even domestic exports, should contribute some quota to the public revenue is in itself a reasonable proposition. The custom-house, which has to register goods coming in and going out, and to exercise an official regulation in the ports, should defray at the least its own expense, like any other necessary mercantile function. The convenience of raising public revenue by duties on imports and exports is amply evinced by the universal adoption of this expedient; and the convenience will always be materially modified by the more or less crude or scientific form which the system of taxation has assumed, by the financial exigency of states, and by the degree in which other objects than those of revenue have been permitted to enter into the general policy. It has been argued with much plausibility that there are certain stages and conditions of some branches of industry, in which it is politic to protect them against unequal competition in their own markets with the more advanced arts and appliances of foreign countries, until they have by this means acquired ability to stand upon their own merits; and this being once admitted, the transition is easy to the general doctrine that, since every nation always finds that there are commodities which other nations can produce much better and cheaper than it can produce them for itself, it is wise and expedient to place the admission of nearly all foreign goods and produce under a custom duty protective of the native industry. The interest of the public revenue is here lost in another line of policy, because protective duties carry the consequence that several parts of a nation have to pay to several other parts more of their own means for what they need than they should have had to pay to the foreigner, and under a system of this kind the sources of public revenue, so far from being increased, are certain of being impaired. On the other hand, there are imports so entirely of foreign origin, and so free from considerations of competition with domestic industry, that a large revenue may be raised upon them in the custom-house, without disturbing the freedom or equity of international trade. The immense customs revenue of the United Kingdom from duties on tea, coffee, and tobacco (duties on wines and foreign spirits may be excluded since they are set off by excise duties on native liquors) is a remarkable example of the power of levying public revenue in the ports without infringing any commercial or economic principle. The question of tariffs thus appears to be capable of reasonable solution as long as it is kept within the circle of what is permanently expedient to the public revenue. When it passes beyond these bounds it launches into a sea of complicated errors. The idea or self-interest that has force to discourage the imports of foreign commodities by protective duties passes naturally onward to bounties on the export of some favoured articles of domestic produce, under which the same practical result is conversely produced, and one part of the nation has to pay in taxes to the state some proportion of the price necessary to effect a sale abroad of the produce of another part of the nation. When bounties are given, they have to be accompanied with a series of compensations or "drawbacks;" and the confusion has often become so great, as when the export bounty is on the manufactured article and the protective duty on the imported raw material, or as, say, when there is a duty on foreign wool, and woollen goods on export are entitled to a drawback, that the state has been reduced to a dilemma, and anything it did seemed only to make the condition worse. This medley of cross-purposes is increased by the means adopted by parent states on one hand to bolster, on another to monopolize to themselves, the trade of their colonies, and by the elaborate rules of preference and exclusion by which maritime nations have attempted to favour their own ships in the carrying trade of the seas.

All the mischief of the protective and prohibitory system was exhibited by the Orders in Council of the British Government, and the Berlin and Milan decrees of Bonaparte, fulminated in the passion and fury of war; and if these high acts of power were seen to be not only futile and sublimely ridiculous, but in their aim and effects destructive of all commercial civilization, it would argue little reason on the part of nations to carry out the same objects through the more calm, systematic, and insidious operation of mutually hostile tariffs. Though nothing dies more slowly than the spirit of monopoly in trade, yet from many signs it may be hoped that this obstacle to commerce will gradually disappear like others.

The present century has witnessed an extension of the commercial relations of mankind of which there is no parallel in previous history. The facts are so well known that it is unnecessary to reproduce them in any detail; and yet it may be useful to indicate, however lightly, the principal phenomena. The heavy debts and taxes, and the currency complications in which the close of the Napoleonic wars left the European nations, as well as the fall of prices which was the necessary effect of the sudden closure of a vast war expenditure and absorption of labour, had a crippling effect for many years on trading energies. Yet even under such circumstances commerce is usually found, on its well-established modern basis, to make steady progress from one series of years to another. The powers of production had been greatly increased by a brilliant development of mechanical arts and inventions. The United States had grown into a commercial nation of the first rank. The European colonies and settlements were being extended, and assiduously cultivated, and were opening larger and more varied markets for manufactures. In 1819 the first steamboat crossed the Atlantic from New York to Liverpool, and a similar adventure was accomplished from England to India in 1825—events in themselves the harbingers of a new era in trade. There began also to be signs, in the general prominence given to the study of economic principles, and in the policy of Mr Huskisson in England, of a growing public opinion in favour of greater freedom of trade; and China, after many efforts, was opened under treaty to an intercourse with foreign nations which was soon to attain surprising dimensions. These various causes supported the activity of commerce in the first four decades; but the great movement which has made the century so remarkable was chiefly disclosed in practical results from about 1840.

It has been seen above what the amount of the foreign trade of Great Britain was in the first year of the century. In 1839 the total value of British produce and manufactures exported, then including under the Legislative Union of the Kingdoms Irish produce and manufactures, was £53,233,580; and the total value of imports was £62,048,000, of which £12,796,000 was exported to other countries. The number of vessels belonging to the British empire in 1839, while the navigation laws were still in force, was 27,745, of an aggregate tonnage of 3,068,433, and 191,283 men. In 1850 the exports of home produce and manufactures had increased to £71,368,000, and the imports to £100,469,000, of which £21,874,000, was exported. In 1873, which may be taken as the close of the period under review, the declared value of exports of British and Irish produce and manufactures reached the enormous total of £255,073,336, and the imports the still more astonishing total of £370,380,742. In the returns for 1873 the exports of foreign and colonial merchandize are given only in quantities, but in the two succeeding years the value of this branch of export trade is given as £10,251,220 in 1874, when the total imports were £370,054,834, and £12,103,732 in 1875, when the total imports were £373,941,125—much less than in 1800, when the official value of re-exports is given as £18,847,735, on a total import of only £30,570,004, indicating, on the one hand, how greatly direct import from the countries of origin to the countries of use must have increased during the century, and, on the other hand, in how much larger proportion our imports of foreign and colonial merchandize had been entered for home consumption. The shipping in 1873, not of the British empire as in 1839, but of the United Kingdom alone, had increased, under repeal of the navigation laws, to 21,581 vessels, 5,748,097 tons, and 202,239 men.

The total value of British and Irish exports in 1873, as compared with 1839, shows an increase of 379 per cent., and of imports an increase of 496 per cent.—an expansion of trade within the third of a century wholly without example. In the years from 1800 to 1839 the increase of domestic exports had been only 119 per cent., and of imports 102 per cent. A larger progressive increase of imports than of exports has been a feature of British commerce for the last twenty years, and would seem to bear out the opinion of economists that this is the result of all prosperous foreign trade, though an excess of imports over exports so large as £120,000,000 per annum cannot possibly be due to the cause which they have usually assigned for it, viz., the profit accruing from the exchange of goods less valuable for goods more valuable in the respective countries, and is probably only accounted for by the large investments of British capital of late years abroad, the interest of which has for the most part to be paid in merchandize.[1]

An increase of the foreign trade of the United Kingdom from £115,281,580 to £625,454,078, in the course of thirty-four years, presents a vaster theme than can be easily grasped, and it may be enough here simply to supply some concise information—(1) as to the commodities which entered into so large a commerce, and (2) as to the distribution of the movement in the various quarters of the world. In the *Parliamentary Account of Revenue, Population, and Commerce for* 1839, a summary is given of the principal articles of British and Irish export, and their respective values; and by placing these in juxtaposition with the same articles of export from the Board of Trade returns for 1873, as in the following table, a pretty comprehensive view may be obtained of the impulse given to our various manufacturing industries:—

	1839.		1873.
Apparel and Haberdashery...	£1,332,427	....	£10,032,483
Brass and Copper Manufactures	1,250,606	....	8,820,568
		Copper Unwrought...	1,207,411
Coal	542,609	....	13,205,618
Cotton Manufactures	16,378,445	....	61,447,357
" Twist and Yarn	6,858,193	....	15,876,363
Earthenware	771,173	....	2,062,533
Glass	357,315	....	1,344,694
Hardware and Cutlery	1,828,521	....	4,938,[illegible]2
Iron and Steel, Wrought and Unwrought	2,719,824	....	37,779,[illegible]6
Linen Manufactures	3,292,220	....	7,295,121
" Yarn	818,485	....	1,975,738
		Jute Manufacture ...	1,591,581
		" Yarn	206,525
Machinery and Mill Work ...	236,482	....	9,994,169
Silk Manufactures	868,118	....	1,876,313
		Thrown, Twist, and Yarn	1,567,837
Woollen Manufactures—			
By Piece	5,800,869	....	25,279,235
By Yard	620,247		
Woollen and Worsted Yarn ...	423,320	....	5,403,983

These figures speak largely for themselves. The British export of cotton manufactures in 1839 was so great as to cast into the shade every other export, and, though its increase since that period has been wonderful, yet it is gratifying to observe, in the progress of other branches, the greater breadth and variety which the manufacturing industry of the United Kingdom has assumed. The export of cotton goods and yarns in 1839 was nearly a half of our whole export of produce and manufactures. In 1873 they were less than a third. Indeed, if coal and iron, and iron and steel manufactures be put together, they

[1] The difference between *official* and *real* value in the returns, over the periods here referred to, vitiates in some measure the figures, not only as regards the old and discarded criterion of "the balance of trade," but as a means of exact comparison of one period with another; while, at the same time, they hold valid enough as regards the relative value of the several branches of import and export trade. Official valuation, the rates of which were fixed as far back as 1698, was long applied both to imports and exports, till at the close of last century the real or declared value of domestic exports began to be given along with the official value, and the discrepancy of the two—the official value increasing, and the real value declining in proportion to the quantities—gave rise to an opinion that we were always selling more of the products of our industry for less value in exchange, whereas it was the result of the cheapening of production by machines and steam-power, and anything but a proof either of industrial or mercantile loss. The official valuation of imports was much longer adhered to than in the case of exports, till of late years the practice has been to give the real or declared value in both branches of the commerce. It must be admitted, however, to Mr M'Culloch and other authorities, that these returns of value, however near the mark, can never show a balance of trade in the sense once supposed. The value given in the ports cannot exactly correspond with the value realized, since the whole system of trade proceeds on the fact that certain goods and produce are of more value in one country than in another. It was remarked as long ago as 1800 that the export of coffee was much overvalued in the official returns, and if coffee, one would say tea, and

will be found much to exceed in export value the cotton industry, though it must be added that to the extension of the latter there are yet no apparent limits. Many articles of export, which in 1839 were too inconsiderable to be included in a summary of principal articles, and not a few which had not then appeared in the export list, have since risen to a value much exceeding that of some principal articles in 1839; as for example, in 1873 alkali and chemical products, £4,676,861; beer and ale, £2,419,575; books, £912,534; herrings, £1,027,121; paper manufactures, £973,899; painters' colours and materials, £1,016,975; stationery other than paper, £672,970; telegraphic wire and apparatus, £2,359,563; and iron, steam, and sailing ships, made to foreign order, of which there is no record in the Board of Trade returns whatever. The imports of the United Kingdom in 1873, besides many new commodities of great aggregate value, such as esparto, guano, gutta-percha, hops, jute, oil-seed and oil-seed cakes, petroleum, pyrites, and various chemical substances, present a general increase over the whole range of foreign and colonial merchandize, most marked in raw materials and provisions, of which the chiefly notable example, since they may fitly be embraced in the same category, includes wheat, corn, flour, rice, cattle, sheep, pigs, bacon, butter, cheese, eggs, poultry, potatoes, all manner of farm and dairy produce, the import value of which in 1873 is found to have amounted to £85,036,365.

This, however marvellous, is indeed but the commerce of our kingdom, but it contains the main current of the commerce of the whole world, and is consequently an example, though a strong and concentrated example, of what has been passing in other mercantile communities. The exports of all nations have not been computed at more than £800,000,000 to £850,000,000. Deducting from the larger sum the British and Irish exports, it follows that more than two-thirds of the exports of all other parts of the world are imported into the United Kingdom. Any permanent increase of trade in so large a centre is impossible without an increase throughout the general sphere, though this increase may be variously distributed. The following statistical results of Professor Levi exhibit in the briefest form where the chief movement has been in the remarkable epoch under consideration, so far as it can be seen through the trade of the United Kingdom.[1]

Relation of Whole Trade of United Kingdom.

	1840.	1870.
With Europe	41	40 per cent.
,, Asia	13	18 ,,
,, Africa	5	8 ,,
,, America	37	29 ,,
,, Australia	4	5 ,,

most other foreign and colonial produce; but the import of these articles having been valued on the same official scale, this could not affect the proportion either in quantity or value between the re-export and the total import of foreign and colonial merchandize. What is shown by the above figures to have been this proportion then, and what has occurred since so greatly to change the relation of imports and exports, is consistent with what might be predicated on grounds of general reason. It was certain that when Britain was supporting a great war on the Continent, and paying heavy subsidies to European Governments, she should have to send large quantities both of her own produce and her foreign and colonial imports to the countries where she was spending her capital so freely and continuously. It was equally certain that, when this burden was thrown off, when her great debt had been consolidated, and its interest was being paid out of her own resources, and a surplus capital was once more developed, she would use her foreign and colonial merchandize more largely in her own arts, manufactures, and consumption, and that in any lengthened course of such prosperity her imports would begin to exceed her exports instead of the reverse. The excess of British imports over exports, including exports of foreign and colonial merchandize, began to appear in the Board of Trade returns about 1850; and this is coincident with the period within which we have to date an increasing investment of British capital in foreign and colonial securities.

All countries	39	90	46

It is always critical to assign specific causes for commercial results on so vast a scale and over so wide a theatre, for in such cases there must not only have been a long antecedent preparation of means to enable such rapid and gigantic efforts to be made, but it is certain that many economic causes will be found to have been in concurrent operation, effects themselves becoming causes in turn, and though in apparent conflict, one checking the excess of the other, yet in reality extending and sustaining the general impulse. But three grand characteristics of the period have been adduced with almost common consent as affording an explanation of the phenomena—(1) the adoption of free trade by Great Britain, (2) the Californian and Australian gold discoveries, and (3) steam navigation, railways, telegraphs;—and these may obviously be accepted as the most powerful forces ever brought to bear on the extension of trade in any one age.

The measures by which Sir Robert Peel introduced this great change in the policy of the United Kingdom were marked by four general objects, merging by practical sequence in the absolute principle of freedom of trade—1st, to remove from the tariff all prohibitions of foreign import, among the chief of which were agricultural live stock, while retaining for a limited period some protective regulation; 2d, to place hundreds of articles of the nature of raw materials of manufacture, and others of less importance, yet useful in the arts, on a footing of entire freedom from customs duty; 3d, to reduce the duties on foreign manufactures which came into competition with home manufactures; and 4th, to repeal the corn laws, admitting foreign grain on a nominal fixed duty, which last involved an equally complete relief to provisions, live stock, agricultural produce of every kind, and to foreign manufactures. When the landlords and farmers were placed in full and direct competition with the world, no class of manufacturers had any excuse left for the slightest shred of protection. All these measures had the appearance more of liberal concessions to foreign nations than of any advantage to home producers; and this is, no doubt, the reason why free trade was so long resisted, and many were unable to see, until the problem was visibly demonstrated, that in liberating commerce, even in developing foreign resources, the most powerful impulse may be given to all the springs of domestic prosperity. The immediate effects in increasing the public revenue—even the customs revenue, which seemed endangered by the abolition of so many duties—in reviving British trade and manufactures, and imparting new life to agriculture itself, were so great that the free trade policy was speedily carried up to its highest points of triumph. The differential duties on foreign and colonial, slave and free labour sugar were removed; and the navigation laws, in favour of which the greatest prejudice had long existed, were fully conformed to the new policy. The expected influence of so successful an illustration of free trade on other nations has not yet been realized to any considerable extent. A more liberal system of trade with France and other European countries has only been effected by treaty, which, however mutually advantageous in its results, is in its temporary and provisional character more or less unsatisfactory. It was not enough that Great Britain could say to her neighbours that free trade had worked well not only for herself but for them. There was always the ready retort of the protected interests in the respective countries that what was good for England in her somewhat exceptional condition, might not be good, or might even be impossible, for them; and here the controversy has rested. But it must be allowed to argue a vast deal for the power of free trade that Great Britain, in the face of so many unreciprocal tariffs, has been able to open an effective market in her ports for amounts of foreign goods and produce which thirty years ago would have been deemed fabulous, while at the same time circulating her own commodities in such increasing quantities to all parts of the world. There can be little question that the free commercial policy of this country has been one of the leading springs of the late marvellous extension of international trade.

The effect of the Californian and Australian gold mines has been compared to that of the silver mines of South America at two periods—when their treasures began to be distributed in Europe, and again when the abundance and cheapness of quicksilver increased their productiveness; —but there is one difference at least, viz., that under the greatly more active life of the present age, as compared with the 16th and 17th centuries, the results of the Californian and Australian gold discoveries were much more rapidly developed than in the other case, and may be said to have passed and been exhausted under the eyes of a single generation. We should thus be better able to judge the effect of sudden, though, as they prove, always temporary increases of the supplies of the precious metals.

The two events in question were almost coincident, and they came when a general extension of trade had already been ten years in progress. The first effect was to produce a great emigration to the countries in which the gold-fields were situated, and this was followed by large exports of goods to the same quarters, which, as usually happens when business falls under speculative impulses out of the ordinary mercantile course, were much overdone, and ended eventually in heavy loss to the shippers. Abundance of labour had been supplied to the gold-fields with unwonted celerity, and as the labour was not unremunerative, and in many cases was even rewarded by large findings of gold, the commotion in emigration, traffic, and shipping was sustained for a considerable time. The coffers of the banks of England and France were soon filled with the new supplies of gold, and these imparted increased confidence to banking operations by which they were as soon redistributed. All this was calculated to give additional impulse and extension to the commercial forces already in motion. There was a new increase of demand for goods; much labour had been transferred from old seats of industry to new fields; and there was rise of wages, and rise of prices. But whether the effects would have been different whatever other produce than gold had been the impelling cause may be much doubted. The effect of increased supplies of the precious metals *per se* on prices is difficult to trace, and is seldom detected by the keenest analysis, more especially in a period of extending trade and industry, for the precious metals are then more quickly absorbed, and many causes, of which their increased supply is but one and the least, are operating on the value of goods. The Californian and Australian mines remain productive, though in much diminished amount, and their most permanent effect on commerce will probably be found to be that they helped materially to build California into a populous State, which has become one of the largest granaries of wheat in the world, and to make the Australian colonies a growing empire, of such varied resources that its foreign trade, greatly as it had increased in the first ten years of the gold discoveries, continued to increase in the subsequent ten years, when its produce of gold had declined into a subordinate interest.

Immensely important as the creative and stimulating effect of the free trade of Britain and the Californian and Australian gold discoveries had been, they pale before a mighty service that remains to be noticed, and which, in the prolific force of a world aroused to commerce, they had all the while been carrying forward in their train.

There is little need of remark in this place on steam ships, railways, and telegraphs—equally marvellous in their power of facilitating commerce and in the rapidity of their construction to this end—beyond a simple indication. The words alone convey what an age we have been living in, and what the international progress in commerce must have been. In 1839 the ocean steamers in the world, if any, could have been counted on one's fingers. In the United Kingdom alone there are now 1597 steam vessels, of nearly 1000 average tonnage, wholly employed in foreign trade. All the greater maritime states have lines of ocean steamers, and there is scarce any part of the world to which goods and passengers are not carried with the speed, regularity, and capacity which steam-power has given to navigation. That goods might be hauled overland by steam was only deemed possible when George Stephenson opened the first short railway in England in 1825. There are now 17,000 miles of railway in the United Kingdom, or one mile of steam-road to every seven square miles of area, carrying both goods and passengers with the ease and celerity of this new system. A similar work has been done in other civilized nations, and over many thousands of miles of comparatively desert tracts of country. The only densely-peopled quarter of the world unknown to railway enterprize is China, and in China a short railway has just been opened from Shanghai to Woosung, amid the curiosity and welcome of the populace. The rapid development of telegraphy is more wonderful even than that of steam ships or railways. Difficult problems of pure science, of science applied to art, and of material manufacture, had to be solved and tested at every step, and all this had to be done with the slightest attractions to capital on the stock exchange. Yet the telegraph wires have been laid successfully under the Atlantic, the Pacific, and the Eastern Seas, and there remain now but few parts of the commercial world to which messages may not be sent and answers received within a few hours. These wondrous and wondrously combined powers of science and mechanism have realized, in the highest form conceivable to the practical mind, the facility of transport and the means of rapid communication and intelligence which commerce had been seeking at infinite distance from the beginning of time, but seeking in vain. Their influence on the interior economy of commonwealths has been no less marked than on the exterior distribution of their products. They are the work of less than half a century, and yet to form them has cost tens of thousands of millions sterling of capital. On whatever side the question is considered, nothing less than marvels are presented to our reason. For supposing these achievements possible, the science, art, and labour prepared and ready, where was the wealth to be found to accomplish them? It may be said that steam ships, railways, and telegraphs have been called into existence by the rising energy and resources of commerce, and it may also be said that at every stage they have created the traffic by which alone they could be sustained and extended.

The international lending of capital has attained such magnitude, and is so often lost sight of in the study of more visible imports and exports, as to require careful consideration, not only on the part of the immediate lenders and borrowers, but of all who are engaged in foreign trade.[1]

[1] The amount of foreign loans and securities, of a public character, held in the United Kingdom has been variously estimated at from 1000 to 1500 millions sterling.

Capital, in its monetary form of transfer, is as much a commodity as the more usual articles of trade; and when a country lends large sums to another country, the same effects are produced on the rates of exchange for the time being, and more protractedly on the general course of import and export, as would be produced by an equivalent amount of goods exported by the borrowing country. The imports of the borrower, during the period of expenditure of the loans, will increase; and the exports, though they may not diminish, will lose in some measure their previous proportion to the imports. These are consequences worthy of observation in the general conduct of mercantile business, but they also go farther. The free lending of money from country to country, with its incidents of higher rates of interest, and a certain degree of speculative adventure, is legitimate. By this means the richer parts of the world help to develop the poorer, as well as to increase their own prosperity; and when the debts thus contracted become valid and transferable securities, they are an important element in equalizing exchange where temporarily disturbed. But the extreme looseness with which this branch of commerce is conducted almost exceeds belief. The proceedings of the recent Committee on Foreign Loans have thrown some light on the subject. As long as bankers and financiers of repute put loans on the market without care as to their objects or security, or an exercise of the least mercantile judgment as to the probable effect of the loans on the value of requisite materials, and with the view simply of making some large immediate profit to themselves, and dropping the whole charge and risks, often by deceptive means, into the hands of a helpless public of investors, the most deplorable consequences must ensue. It is scarcely an exaggeration to say that in the years 1869–72 the foreign railway and other undertakings thus launched were such as there were not materials in the markets of the whole world to carry through, without an enhancement of values that should not only render the undertakings themselves hopeless, but seriously cripple much well-established trade. In the more solid class of foreign loans, bearing the security of not unprosperous states, it has frequently happened that nearly the whole revenue of the state was derived from customs duties. While the borrowing proceeded, the imports of the state increased, and the revenue flourished, giving a guarantee to the creditors. When the loan had been expended, and the return interest and redemptions had to be paid, the imports suddenly declined, and the revenue security on which the money had been lent disappeared, throwing the states themselves into much commercial embarrassment, in some cases into political convulsions. This subject cannot here be further pursued, but its bearings on trade are sufficiently apparent.

It may be said, in conclusion, that commerce has acquired a security and extension, in all its most essential conditions, of which it was void in any previous age. It can hardly ever again exhibit that wandering course from route to route, and from one solitary centre to another, which is so characteristic of its ancient history, because it is established in every quarter of the globe, and all the seas and ways are open to it on terms fair and equal to every nation. Wherever there is population, industry, resource, art, and skill, there will be international trade. Commerce will have many centres, and one may relatively rise or relatively fall; but such decay and ruin as have smitten many once proud seats of wealth into dust cannot again occur without such cataclysms of war, violence, and disorder as the growing civilization and reason of mankind, and the power of law, right, and common interest forbid us to anticipate. But, with all these advantages, it must not be supposed that the future course of trade is free of difficulty. The very magnitude of commerce now suggests what serious work devolves on all who are engaged in it. If in the older times it was thought that a foreign merchant required to be not only a good man of business, but even a statesman, it is evident that all the higher faculties of the mercantile profession must still more be called into request when imports and exports are reckoned by hundreds instead of fives or tens of millions, when the markets are so much larger and more numerous, the competition so much more keen and varied, the problems to be solved in every course of transaction so much more complex, the whole range of affairs to be overseen so immensely widened. It is not a company of merchants, having a monopoly, and doing whatever they please, whether right or wrong, that now hold the commerce of the world in their hands, but large communities of free merchants in all parts of the world, affiliated to manufacturers and producers equally free, each under strong temptation to do what may be wrong in the pursuit of his own interest, and the only security of doing right being to follow steady lights of information and economic science common to all. The triumphs of commerce and its auxiliaries have been exhibited in the present article. Easy transport of goods by land and sea, prompt intelligence from every point of the compass, general prevalence of mercantile law and safety, have all been accomplished; and the world is opened to trade. But intellectual grasp of principles and details, and the moral integrity which is the root of all commercial success, have to be severely tested in this vaster sphere. (R. SO.)

COMMERCY, a town of France in the department of Meuse, at the head of an arrondissement, on the left bank of the Meuse, twenty miles east of Bar-le Duc. It possesses a castle built in 1708 and now used as cavalry barracks, a Benedictine convent occupied by the prefecture, a hospital rebuilt in the 18th century, and a cloth-market. Its public walks are very fine, and lead out in various directions to pleasant suburban villages. The industrial establishments include foundries, lime-kilns, and a cotton factory; and the trade runs mainly on cattle, grain, wood, and basket-work. Population, 4191.

Commercy dates back to the 9th century, and at that time its lords were dependent on the bishop of Metz. In 1544 it was besieged by Charles V. in person. For some time the lordship was in the hands of Cardinal de Retz, who lived in the town for a number of years, and there composed his memoirs. From him it was purchased by Charles IV., duke of Lorraine, who bestowed it on his daughter Anne on her marriage with the prince of Ile-Bonne. In the beginning of the 18th century it formed a principality under the prince of Vaudemont; and in 1744 it became the residence of Stanislas, king of Poland, who spent a great deal of care on the embellishment of the town and neighbourhood. A description of his improvements is given in the *Journal des Savants* for 1752.

COMMODUS, LUCIUS AURELIUS (161–192), emperor of Rome from 180 to 192, was born at Lanuvium in 161, and was the son of the philosopher-emperor M. Aurelius, and of the younger Faustina. His teachers were carefully selected; but all the pains bestowed on his education did not prevent him from choosing the society and the pursuits of profligate favourites and common gladiators. Blind to his faults, however, his father gave him the title of emperor when not more than fifteen years of age; and at sixteen he shared the imperial power in every department except the chief pontificate. On the death of Aurelius, whom he had accompanied in the war against the Germans, Commodus hastily concluded peace, and hurried back to the pleasures of the capital (180). From the first he gave himself up to unbounded licence; but for some years his vices were all private. In 183, however, he was attacked, at the instigation of his sister Lucilla, by an assassin, who declared that he struck in the name of the senate; and the nobility paid the penalty by the murder of any of that rank who afterwards aroused the slightest suspicion in the mind of the emperor. At the same time the vulgar vanity of Commodus manifested itself in a manner that exposed him to the scorn of the meanest citizen. No longer content with showing his strength and dexterity to a little group of favourites in the palace, he presented himself as a spectacle in the arena, and, carefully protected from serious danger, displayed his skill by shooting hundreds of wild animals, and by meeting in fight hundreds of gladiators. He called himself the Roman Hercules, and commanded that he should be worshipped as such. Plots against his life naturally began to spring up. That of his favourite Perennis was discovered in time. The next danger was from the people, who were infuriated by the dearth of corn. The mob repelled the prætorian guard, but the execution of the hated minister, Cleander, quieted the tumult. The attempt also of the daring highwayman Maternus to seize the empire was betrayed; but at last Eclectus the emperor's chamberlain, Lætus the prefect of the prætorians, and his mistress Marcia, finding their names on the list of those doomed to death, united to destroy him. He was poisoned, and then strangled by a wrestler named Narcissus, on the 31st December 192, in the thirty-second year of his age. It was said that he had intended to disgrace the office of consul by taking the auspices at the commencement of a new year of office, not in the consular robe but in the garb of a secutor, and surrounded not by the senate, but by a band of gladiators. His guards alone, accustomed to his lavish bounty, regretted his death; and Pertinax, being chosen by the conspirators, was allowed quietly to succeed him.

COMMON LAW, like civil law, is a phrase with many shades of meaning, and it is probably safest to define it with reference to the various things to which it is opposed. It is contrasted with statute law, as law not promulgated by the sovereign body; with equity, as the law prevailing between man and man, unless when the Court of Chancery assumes jurisdiction; and with local or customary law, as the general law for the whole realm, tolerating variations in certain districts and under certain conditions. It is also sometimes contrasted with civil, or canon, or international law, which are foreign systems recognized in certain special courts only and within limits defined by the common law. As against all these contrasted kinds of law, it may be described broadly as the universal law of the realm, which applies wherever they have not been introduced, and which is supposed to have a principle for every possible case. Occasionally, it would appear to be used in a sense which would exclude the law developed by at all events the more recent decisions of the courts.

Blackstone divides the civil law of England into *lex scripta*, or statute law, and *lex non scripta*, or common law. The latter, he says, consists of (1) general customs, which are the common law strictly so called, (2) particular customs prevailing in certain districts, and (3) laws used in particular courts. The first is the law by which "proceedings and determinations in the king's ordinary courts of justice are guided and directed." That the eldest son alone is heir to his ancestor, that a deed is of no validity unless sealed and delivered, that wills shall be construed more favourably and deeds more strictly, are examples of common law doctrines, "not set down in any written statute or ordinance, but depending on immemorial usage for their support." The validity of these usages is to be determined by the judges—"the depositaries of the law, the living oracles who must decide in all cases of doubt, and who are bound by an oath to decide according to the law of the land." Their judgments are preserved as records, and "it is an established rule to abide by former precedents where the same points come again in litigation." The extraordinary deference paid to precedents is the source of the most striking peculiarities of the English common law. There can be little doubt that it was the rigid adherence of the common law courts to established precedent which caused the rise of an independent tribunal administering justice on more equitable principles—the tribunal of the chancellor, the Court of Chancery. And the common law courts—the Queen's Bench, Common Pleas, and Exchequer—have always, as compared with the Court of Chancery, been distinguished for a certain narrowness and technicality of reasoning. At the same time the common law has never been a fixed or rigid system. In the application of old precedents to the changing circumstances of society, and in the development of new principles to meet new cases, the common law courts have displayed an immense amount of subtlety and ingenuity and a great deal of sound sense. The continuity of the system is not less remarkable than its elasticity. Two great defects of form disfigure the English law. The first is the separation of common law and equity. The second is the overwhelming mass of precedents in which the law is embedded. The recent Judicature Act is an attempt to remedy the first by merging the jurisdiction of all the courts in one supreme court, and causing equitable principles to prevail over those of the common law where they differ. The second can only be removed by some well-conceived scheme of the nature of a code or digest (see CODE). The English common law may be described as a pre-eminently national system. Based on Saxon customs, moulded by Norman lawyers, and jealous of foreign systems, it is, as Bacon says, as mixed as our language and as truly national.

COMMON PLEAS, COURT OF (*Communia Placita*), was one of the three common law courts at Westminster—the other two being the Queen's Bench and Exchequer. The jurisdiction of all three, together with that of the Court of Chancery, the Court of Probate and Matrimonial Causes, and the Court of Bankruptcy, is vested in the new High Court of Justice, established by the Judicature Act, 1873. One division of that court is called the Common Pleas division, and there all the business which before the Act was "within the exclusive cognizance of the Court of Common Pleas" must still be transacted.

COMMON PRAYER. See LITURGY.

COMMONS. It is a well-known result of the application of the historical method to laws and institutions, that it has reversed many of our leading conceptions of the natural or original forms of property. That the primitive form of property in land was not severalty but commonalty, that land was held not by individuals but by communities, and that individual ownership was slowly evolved out of common ownership, are propositions as nearly as possible the opposite of our *a priori* ideas on the subject. The existence of rights of common is one of the traces of the ancient system still remaining in our law, but its real significance was for a long time obscured by the feudal theories on which the law of real property is based.

There seems to be good reason to believe that among the English, as among other Teutonic nations, the system of land-holding by village communities prevailed. For an account of that system reference may be made to Sir H. Maine's lectures, or to the short essay by Professor Nasse, a translation of which has been published by the Cobden Club (*On the Agricultural Community of the Middle Ages*). It may be sufficient to state here the bare outlines of the system. The "mark," or territory occupied by the community, was divided into the following parts :—(1) The township, where were the houses held by heads of families in severalty; (2) The arable land, divided into several plots, but subject to regulations as to common cultivation—the most usual of which is the three-field system; the land was to be fallow every third year, and the whole community had rights of pasturage on the fallow portion, and on the stubble of the fields under crop at certain portions of the year between harvest and seed-time; (3) The meadow-land, which in like manner was common for a period after the hay harvest, and was afterwards fenced off in separate allotments for the new crop; (4) The common or waste land, not appropriated for cultivation, and over which the community had rights of pasturage, wood-cutting, &c. After the Conquest we find the mark superseded by the manor, and although it has long been the fashion to find the absolute beginning of the latter system in the Conquest, there seems to be good reason to believe that its leading elements—the ideas of lordship and tenure—had been developed among the Anglo-Saxons themselves (see Digby's *Introduction to the History of the Law of Real Property*). At all events, the manorial system became defined and fixed under the Norman lawyers, and remains still the legal basis of property in land. All land is regarded as being held of the king, and the king's tenants might have tenants of their own. The practice of sub-infeudation, as it was called, was stopped by the statute *Quid Emptores*, 1290, which enacted that, when a lord alienated a portion of his land, the alienee, instead of being tenant of the alienor, should take his place as tenant to the lord next above him. Since this statute, therefore, no new manors could be created. All lands were supposed to be traceable originally to a grant from the king. Out of the lands so granted to him, the lord would grant certain portions to free tenants on certain rents and services, and these are the freeholders of the manor. His own portion would be cultivated by *villains*, or *serfs*, attached to the soil, and these ultimately developed into the important class of copyholders. There remains the uncultivated and unappropriated land, over which the freeholders had certain rights of common supposed to be incident to their original grant. Within the manor were certain courts (Court Leet, Court Baron, Customary Court), the most important of which is the Court Baron, or assembly of the freeholders, partly judicial and partly administrative. It is regarded by the common law as the inseparable concomitant of a manor, so that if there be no Court Baron there is no manor. The historical investigations to which we have referred point to the identity of the Court Baron with the assembly of the village community. The lord's waste in like manner represents the common waste of the community not appropriated in severalty, and used by all in common for pasturage, &c. The legal theory, however, supposes that the whole organization is created by grant; the lord is the owner of the soil, and the rights of tenants are merely such as he has granted to them out of consideration for rents and services reserved. Whatever has not been so granted belongs as a matter of course to the lord. The rights of common come to be regarded as of the nature of servitudes—*jura in alieno solo*—exceptional privileges granted over land by its real owner to his tenants.

Rights of common enjoyed by the freeholders of the manor as incident to their tenure are said to be *appendant*, or attached to their holdings. Rights of common not coeval with the original grant, or enjoyed by strangers in respect of land not belonging to the manor at all, are said to be *appurtenant*. Rights claimed irrespectively of land altogether are called rights of common *in gross*. Similar rights in copyholders depend on the *custom* of the manor.

The most important right of common is *Common of Pasture*, which if *appendant* can only be claimed for beasts useful for tillage—such as horses, oxen, and sheep,—and in respect of arable land only (for manure); if *appurtenant*, it may extend to swine, goats, and geese, &c., and is not confined to arable land; if *in gross*, it is subject to no restriction as to the species of beasts. The claim must be for some number limited and defined, and where no number is fixed, it is restricted to beasts *levant* and *couchant*—a phrase which, according to judicial interpretation, means such cattle as the winter eatage of the tenement, together with the hay, &c., obtained from it in summer, could support. Some lands are subject to this common of pasture during certain portions of the year only—*e.g.*, in the case of lammas-lands from the 1st of August, for eight months after which they are held in severalty. This arrangement may be compared with what is said of the village community above. Such lands are said to be *commonable*.

Common of Piscary is a right of fishing in a particular stream.

Common of Estovers is the right of cutting wood on another's estate.

Common of Turbary is the right of cutting turfs, and must be claimed in respect of land on which a house has been built, as "turves are only wanted to burn in a house."

In some manors there is a right of digging and taking coals, minerals, &c. Subject to these rights, everything belongs to the lord of the manor, and a custom to exclude him from all manner of profit would be held void as being unreasonable.

In our earliest legislation on the subject of commons, the rights of the commoner appear to have a firmer footing than the theory which derives them from the grant of the lord would lead us to expect. The Statute of Merton (1235) gives relief to the lords whose efforts to improve their wastes have been frustrated by commoners bringing an assize of novel disseisin for their pasture, and the lord in such cases was to be held blameless if sufficient pasture, with ingress and egress, had been provided. It only applied, as we learn from the criticism of Bracton, to *common appendant*, and to cases where the right is expressly limited in number or kind. The Statute of Westminster the second (1285) extended it to rights *appurtenant*. Under these statutes inclosures can be made on the following conditions only :—

1. It must be proved that sufficient pasturage has been left for the commoners.
2. If there is common of pasture in gross, inclosure cannot be made.
3. The statutes do not authorize inclosures which would infringe upon any other common rights, as turbary, piscary, &c.
4. They do not affect copyholders.

(See *Six Essays on the Preservation of Commons*).

It will be observed that, in relation to the rights described, the lord and the commoners are the only parties recognized by the law. The public in general have no rights. It has been alleged, indeed, that the immemorial use of open spaces near large towns by the inhabitants for exercise and recreation raises the presumption of a dedication—a question we need not discuss here. It is chiefly, however, in connection with the needs of the public, especially of the inhabitants of large towns, that the law of commons is still a subject of some practical importance. Until quite recently the inclosure of commons was regarded as a matter affecting the lord alone, or at most the lord and the commoners. Of late, the interest of the public at large in preserving the commons uninclosed has been strenuously asserted, and as we shall see has been recognized in legislation.

At common law, in spite of the predominance given to the rights of the lord, there was no means of converting the common or any portion of it into the severalty of the lord, unless to a comparatively small extent, under the Statutes of Merton and Westminster the second. The increase of population and the growing need for food-producing land made it the interest of the lord, and it may be considered of the public also, that much of the common ground should be brought under cultivation. Down to the year 1800 this was effected by private Inclosure Acts, of which there were as many as 1600 or 1700. The provisions which it had been customary to insert in these special Acts were in 1801, after the manner of which we have so many examples, consolidated in Sir John Sinclair's Inclosure Act, 41 Geo. III. c. 109. At this time the inclosure and cultivation of common lands were looked forward to as a means of increasing the national wealth. It is not till 1836 that we find any recognition of the desirability, on public grounds, of preventing inclosures under certain circumstances, viz., in the 6 and 7 Will. IV. c. 115, for facilitating the inclosure of open and arable fields (which applied to what have been called commonable lands and not to manorial wastes). The 55th section forbids inclosures within ten miles of London, or within corresponding distances of smaller towns. Subject to the provisions of these Acts about 2000 private Inclosure Acts had been passed, when in 1845 came the General Inclosure Act, 8 and 9 Vict. c. 148. Its object is stated to be to facilitate the inclosure and improvement of commons and other lands, now subject to rights of property, which obstruct cultivation and the productive employment of labour, &c. Commissioners are to be appointed who shall judge of the expedience of an inclosure and superintend its execution. All common lands are brought within the scope of the Act, but manorial wastes are not to be inclosed without the previous sanction of Parliament, which was also made necessary for inclosures within fifteen miles of London, or within two miles of any city of 10,000 inhabitants, or within two and a half miles of any city of 20,000 inhabitants, and so on. (A later Act, 15 and 16 Vict. c. 79, made the consent of parliament necessary in all cases under this Act.) Village greens are not to be inclosed, and by § 30 the commissioners are authorized to require, as one of the conditions of the inclosure, the appropriation of an allotment for the exercise and recreation of the neighbourhood on the following scale :—In a parish of 10,000 inhabitants not more than 10 acres; between 5000 and 10,000 inhabitants not more than 8 acres; between 2000 and 5000 not more than 5 acres; and under 2000 not more than 4. Allotments might also be made for the labouring poor. Under this Act inclosures proceeded apace, and the commissioners have been accused of unduly favouring inclosure, and neglecting the powers with which they were intrusted for the protection of the public. Alluding to this feeling the Home Secretary (Mr Cross), in proposing the Bill which afterwards became the Act of 1876, stated that of 414,000 acres which had been inclosed under the Act less than 4000 had been dedicated to purposes of recreation and exercise, and he admitted that, whereas inclosures had formerly been treated as a private estate improvement to which the owner was entitled, a great change of opinion had taken place as to the rights of the public. This feeling found expression in the Metropolitan Commons Act, 1866, which absolutely prohibits all further inclosure of metropolitan commons, and facilitates schemes for the management and improvement of such commons for the benefit of the public, due compensation being made for beneficial interests affected thereby. This, it will be observed, is a complete change of attitude. Whereas the lord was formerly treated as the real owner, and allowed to buy off partial interests, the public is now placed in that position, and the lord becomes an encumbrancer, to be bought off like any other.

The revival of public interest in commons led to resistance being offered in courts of law to the unauthorized inclosure of commons by lords of the manor. One of the most important of these cases is that of Warrick *v.* Queen's College, Oxford (6 *Chancery Appeals*, 716), in which the plaintiff, as a freeholder of the manor of Plumstead, obtained a decree against the defendants, who had inclosed a portion of the common of the manor. The judgment of the Lord Chancellor (Hatherley) on that occasion contains a statement of the view now taken by the courts of claims to rights of common. In the Commissioners of Sewers *v.* Glasse, the Corporation of London defeated attempted inclosures in Epping Forest.

In 1869, a committee of the House of Commons presented a report on metropolitan commons, and many of their recommendations have been embodied in the Inclosure Act 1876, of which the following are the chief provisions. The preamble of the Commons Act 1876 states that, under the Inclosure Acts 1845 to 1868, the commissioners are empowered to authorize, by provisional orders subject to assent of Parliament, the inclosure of commons, provided the inclosure is made on such terms as may be necessary for the protection of public interests, and provided they are of opinion that such inclosure is expedient, having regard to the benefit of the neighbourhood; and that it is desirable that circumstances bearing on the expediency of the proposed inclosure should be more fully brought under the notice of the commissioners, and that inclosure of commons in severalty should not be made unless the commissioners are satisfied that it would be of benefit to the neighbourhood as well as to private interests, and that further effect ought to be given to the provisions relating to allotments for purposes of exercise and recreation. The commissioners may entertain applications either for (1) the regulation or (2) the inclosure of a common. The regulation includes the adjustment of rights and the improvement of a common; and the latter comprises (1) draining, manuring, and levelling the common, (2) planting trees, or otherwise beautifying it, (3) making bye-laws, (4) general management, and (5) appointment of conservators. In case of "inclosure," as well as "regulation," the commissioners may insert provisions for the benefit of the neighbourhood, *e.g.*, the securing free access to particular points of view, preserving trees or historical objects, reserving playing-grounds, making roads, &c. In the case of suburban commons (*i.e.*, situated within six miles of any town) the sanitary authority shall be represented. The commissioners are directed to require evidence as to the benefit of the neighbourhood, and, in the case of inclosure, information as to the advantages of inclosure as compared with regulation. Rules are provided for inspecting the common, holding meetings, &c. The provisional order shall contain all the statutory provisions for the benefit of the neighbourhood that are applicable to the case, and, where the common to be inclosed is waste land of a manor, a description of the allotments for recreation ground. Compensation must be provided for private interests affected by the order. Two-thirds of the persons whose interests are affected must assent to the order, and in the case of a manorial waste the lord must consent, or his representative in interest, before the commissioners can certify the expediency of the order. When the freemen of a town have interests in the common, the consent of two-thirds of them must be obtained. The Inclosure Acts are amended by certain sections relating to field-gardens and recreation-grounds. Encroachments on or inclosure of village-greens are to be deemed a public nuisance. Illegal inclosures on commons settled under this Act are within the jurisdiction of the county court. Persons intending to inclose a common otherwise than under this Act must give three months' notice of their intention by advertisement. The section of the Inclosure Act 1845 which fixes a limit to allotments for recreation-grounds is repealed. The Act does not apply to metropolitan commons. (E. R.)

COMMONS, House of. See Parliament.

COMMUNE, the smallest administrative division of France, corresponding in its main features to the municipal borough of England. Communes constitute legal corporations of elaborate organization, capable of holding property, contracting debts, and appearing as persons in court. The chief magistrate of a commune is the *maire*, who is assisted by one or more *adjoints*, and a deliberative assembly, called the *conseil municipal*, or municipal council. As an agent of the national Government, he is charged with the local promulgation and execution of the general laws and decrees of the country; and as a member of the municipality he has to attend to the police, the revenue, and the public works of the commune, and, in general, to act as representative of the corporation. In communes that either rank as the administrative centres of a department, arrondissement, or canton, or have a population of more than 3000, the *maire* is nominated by the central Government; in those which are not thus distinguished, the appointment lies with the prefect of the department. Suspension from office may be inflicted by the prefect; but deposition can only proceed from the Government. An *adjoint* may be intrusted by the *maire* with the discharge of any of his functions; and as the *maire's* representative he may preside over the *conseil municipal* even if he be not otherwise a member of the body. The councillors are elected by the votes of the communal electors; and like the *maire* and the *adjoints*, they hold office for a term of five years. The decisions of the council in regard to the local budget and various other matters are subject to revision and amendment by the prefect of the department.

COMMUNISM is the name that has been given to the schemes of social innovation which have for their starting-point the attempted overthrow of the institution of private property. It is not to be wondered at that so stupendous an undertaking should have failed, except in a very few instances, in its immediate object. The principle of private property has been called by one who was by no means a blind worshipper of the social condition which has been built upon it, "that primary and fundamental institution on which, unless in some exceptional and very limited cases, the economical arrangements of society have always rested." To attack this primary and fundamental institution indicates a mind so bold as well as so imaginative that it might well be thought that the assaults upon it would be few and far between, limited to a single country or to a single age, or at least to a class of individuals rendered desperate by having nothing to lose by a general social revolution. The opinion that a communist is a man who has no property to lose and who therefore advocates a general redistribution of wealth is very wide-spread and popular. It is embodied in the well-known lines of the corn-law rhymer:—

> "What is a Communist? One who hath yearnings
> For equal division of unequal earnings.
> Idler or bungler, or both, he is willing
> To fork out his penny and pocket your shilling."

The facts connected with the history of communism show that the movements against the institution of private property have taken place in nearly every country, and in almost every age. They have originated with men of such divergent intellectual rank as Plato and Robert Owen, as widely sundered in respect of time, country, and social surroundings as the Essenes, Sir Thomas More, Saint Simon, and Father Rapp. The mere mention of these names goes some way towards the refutation of the popular conception of a communist as a needy adventurer seeking a means to possess himself of the property of others. There may have been some so-called communists attracted to the movement by the hope of being enabled to live on the labour and industry of their neighbours; but such men have never originated any socialistic movement, and their motives have generally been quickly detected by the genuine communists, who have not infrequently adopted very vigorous means to expel such black sheep from their flock. Among the modern leaders of communistic movements who have actually reduced to practice the theoretical schemes of *The Republic* and *Utopia* have been men who have devoted great wealth and rare organizing faculties to the carrying out of their plans for the reconstruction of society. It has been estimated that Robert Owen, during the course of his long life, devoted no less a sum than £60,000 from his own private fortune to the promotion of communistic schemes; what he sacrificed indirectly to his views on social reform cannot be easily estimated. His faculty for the successful conduct of business was so remarkable that at the early age of twenty-six, without a shilling of capital of his own, he was appointed manager of the mills of the Chorlton Company with a salary of £1000 a year, besides one-ninth of the profits realized by the company. There can be no doubt that Owen had the personal qualities which would have enabled him to amass a colossal fortune if his ambition had lain in that direction. The immense pecuniary and personal sacrifices which he made to the cause of communism show that he at least was animated by motives the direct opposite of the selfishness and sloth generally attributed to the advocates of that system. Another leading communist, Saint Simon, was the representative of one of the most ancient families of the French nobility. A career in the army was open to him in which he might easily have satisfied the usual ambition of the class to which he belonged. As a young man he served with distinction through five campaigns.

Many other instances might be given of the disinterestedness of the leaders of communistic schemes. Among American associations one of the most successful as to the number and material prosperity of its members is the society known as the Perfectionists of Oneida and Wallingford. Their founder, John Humphrey Noyes, is the son of a banker, and a man fitted by education and natural gifts to have succeeded in any of the ordinary careers of professional or commercial activity. Whether we look at communism as depicted in the pages of Plato's *Republic* and Sir Thomas More's *Utopia*, or in the practical efforts made to realize these philosophical speculations by such men as Owen and Noyes, we find no justification for the assumption that the movement is one for enabling "idlers and bunglers" to live on the industry and talents of their more energetic and skilful neighbours.

As we are here saying what communism is not, rather than endeavouring to define what it is, this is perhaps the right place to state that communism, meaning thereby community of goods and the abolition of private property, has no connection with the doings of the *Commune* of Paris which was overthrown in May 1871. The French word *Commune* is a household word in France for "Township" or "Corporation." Every town and village in France has its *Commune* or municipality. In nearly every town and village there is corporate property called *Les Biens Communaux*, and this property is vested in the corporation or *Commune*. The similarity, however, of the French word for corporation to ours for expressing the doctrine of community of goods, has led to a great amount of misconception and confusion, even among writers who are generally careful and well informed. The revolution of the *Commune* was entirely political; it propounded no new economic theories. It arose from a joint effort of many sections of extreme politicians who were agreed in nothing but in demanding the establishment of (1) a democratic republic, and (2) the communal (or corporate) independence of Paris. Only about seven out of the seventy members of the Communal Government were communists in the economic sense, and these seven were among the most thoughtful and least violent of the party to which they belonged. They never had an opportunity of giving any official sanction to their communistic views, and they were gradually thrust on one side by their more violent and unscrupulous comrades. This is therefore not the place to attempt anything like an account of the brief reign of the *Commune*, which indeed belongs to the history of Paris. It is sufficient to state that its doings were not even tinged with communism in the economic sense of the word.

Communistic schemes have found advocates in almost every age and in many different countries. The foremost men both of thought and action have from time to time been attracted by them. They have been so various in scope, and the amount of detail with which they are described by their authors is so considerable, that it is difficult to get at the underlying principle which is common to them all. It must be remembered that the philosophic communism of Plato and More has been adapted to the wants of actual daily life by rough German peasants and Lancashire operatives: and though of course the actual has differed a good deal from the ideal commune, yet their resemblance is, under the circumstances, very much more striking than their divergence. The one thing that is shared by all communists, whether speculative or practical, is deep dissatisfaction with the economic conditions by which they are surrounded. In Plato's *Republic* the dissatisfaction is not limited to merely economic conditions. In his examination of the body politic there is hardly any part which he can pronounce to be healthy. He would alter the life of the citizens of his state from the very moment of birth. Children are to be taken away from their parents and nurtured under the supervision of the state. The old nursery tales, "the blasphemous nonsense with which mothers fool the manhood out of their children," are to be suppressed. Dramatic and imitative poetry are not to be allowed. Education, marriage, the number of births, the occupations of the citizens are to be controlled by the guardians or heads of the state. The most perfect equality of conditions and careers is to be preserved; the women are to have similar training with the men, no careers and no ambition are to be forbidden to them; the inequalities and rivalries between rich and poor are to cease, because all will be provided for by the state. Other cities are divided against themselves. "Any ordinary city, however small, is in fact two cities, one the city of the poor, the other of the rich, at war with one another" (*Republic*, bk. iv. p. 249, Jowett's translation). But this ideal state is to be a perfect unit; although the citizens are divided into classes according to their capacity and ability, there is none of the exclusiveness of birth, and no inequality is to break the accord which binds all the citizens, both male and female, together into one harmonious whole. The marvellous comprehensiveness of the scheme for the government of this ideal state makes it belong as much to the modern as to the ancient world. Many of the social problems to which Plato draws attention are yet unsolved, and some are in process of solution in the direction indicated by him. He is not appalled by the immensity of the task which he has sketched out for himself and his followers. He admits that there are difficulties to be overcome, but he says in a sort of parenthesis, "Nothing great is easy." He refuses to be satisfied with half measures and patchwork reforms. "Enough, my friend! but what is enough while anything remains wanting?" These sentences indicate the spirit in which philosophical as distinguished from practical communists from the time of Plato till to-day have undertaken to reconstruct human society.

Sir Thomas More's *Utopia* has very many of the characteristics of *The Republic*. There is in it the same wonderful power of shaking off the prejudices of the place and time in which it was written. The government of Utopia is described as founded on popular election; community of goods prevailed, the magistrates distributed the instruments of production among the inhabitants, and the wealth resulting from their industry was shared by all. The use of money and all outward ostentation of wealth were forbidden. All meals were taken in common, and they were rendered attractive by the accompaniment of sweet strains of music, while the air was filled by the scent of the most delicate perfumes. More's ideal state differs in one important respect from Plato's. There was no community of wives in Utopia. The sacredness of the family relation and fidelity to the marriage contract were recognized by More as indispensable to the well-being of modern society. Plato, notwithstanding all the extraordinary originality with which he advocated the emancipation of women, was not able to free himself from the theory and practice of regarding the wife as part and parcel of the property of her husband. The fact, therefore, that he advocated community of property led him also to advocate community of wives. He speaks of "the *possession and use* of women and children," and proceeds to show how this possession and use must be regulated in his ideal state. Monogamy was to him mere exclusive possession on the part of one man of a piece of property which ought to be for the benefit of the public. The circumstance that he could not think of wives otherwise than as the property of their husbands only makes it the more remarkable that he claimed for women absolute equality of training and careers. The circumstance that communists have so frequently wrecked their projects by attacking marriage and advocating promiscuous intercourse between the sexes may probably be traced to the notion which regards a wife as being a mere item among the goods and chattels of her husband. It is not difficult to find evidence of the survival of this ancient habit of mind. "I will be master of what is mine own," says Petruchio. "She is my goods, my chattels."

The Perfectionists of Oneida, a well-known communistic society in the United States which has put into practice community of wives, or, as they call it, complex marriage, justify their extraordinary social system by affirming that there is "no intrinsic difference between property in persons and property in things; and that the same spirit which abolished exclusiveness in regard to money would abolish, if circumstances allowed full scope to it, exclusiveness in regard to women and children" (Nordoff's *Communistic Societies of the United States*, pp. 271–2). It is this notion of a wife as property that is responsible for the wild opinions communists have often held in favour of a community of wives and the break-up of family relations. If they could shake off this notion and take hold of the conception of marriage as a contract, there is no reason why their views on the community of property should lead them to think that this contract should not include mutual fidelity and remain in force during the life of the contracting parties. It was probably not this conception of the marriage relation so much as the influence of Christianity which led More to discountenance community of wives in Utopia. It is strange that the same influence did not make him include the absence of slavery as one of the characteristics of his ideal state. On the contrary, however, we find in Utopia the anomaly of slavery existing side by side with institutions which otherwise embody the most absolute personal, political, and religious freedom. The presence of slaves in Utopia is made use of to get rid of one of the practical difficulties of communism, viz., the performance of disagreeable work. In a society where one man is as good as another, and the means of subsistence are guaranteed to all alike, it is easy to imagine that it would be difficult to ensure the performance of the more laborious, dangerous, and offensive kinds of labour. In Utopia, therefore, we are expressly told that "all the uneasy and sordid services" are performed by slaves. The institution of slavery was also made supplementary to the criminal system of Utopia, as the slaves were for the most part men who had been convicted of crime; slavery for life was made a substitute for capital punishment.

In many respects, however, More's views on the labour question were vastly in advance of his own time, and indeed of ours. He repeats the indignant protest of the *Republic* that existing society is a warfare between rich and poor. "The rich," he says, "devise every means by which they may in the first place secure to themselves what they have amassed by wrong, and then take to their own use and profit, at the lowest possible price, the work and labour of the poor. And so soon as the rich decide on adopting these devices in the name of the public, then they become law." One might imagine these words had been quoted from the programme of the International Society, so completely is their tone in sympathy with the hardships of the poor in all ages. More shared to the full the keen sympathy with the hopeless misery of the poor which has been the strong motive power of nearly all speculative communism. The life of the poor as he saw it was so wretched that he said, "Even a beast's life seems enviable!" Besides community of goods and equality of conditions, More advocated other means of ameliorating the condition of the people. Although the hours of labour were limited to six a day there was no scarcity, for in Utopia every one worked; there was no idle class, no idle individual even. The importance of this from an economic point of view is insisted on by More in a passage remarkable for the importance which he attaches to the industrial condition of women. "And this you will easily apprehend," he says, "if you consider how great a part of all other nations is quite idle. First, women generally do little, who are the half of mankind." Translated into modern language his proposals comprise universal compulsory education, a reduction of the hours of labour to six a day, the most modern principles of sanitary reform, a complete revision of criminal legislation, and the most absolute religious toleration. The romantic form which Sir Thomas More gave to his dream of a new social order found many imitators. The *Utopia* may be regarded as the prototype of Campanella's *City of the Sun*, Harrington's *Oceana*, Bacon's *Nova Atlantis*, Defoe's *Essay of Projects*, Fénelon's *Voyage dans l'Ile des Plaisirs*, and other works of minor importance.

It is remarkable that all communists have made a great point of the importance of universal education. All ideal communes have been provided by their authors with a perfect machinery for securing the education of every child. One of the first things done in every attempt to carry communistic theories into practice, has been to establish a good school and guarantee education to every child. The first impulse to national education in the present century probably sprang from the very marked success of Robert Owen's schools in connection with the cotton mills at New Lanark. At a time (1806) when popular education was in the lowest possible condition, Owen, as manager and part owner of the New Lanark Mills, proposed to his partners to spend £5000 upon new schools. They not unnaturally objected to an expenditure at that time quite unprecedented; whereupon Owen bought his partners out for £84,000, and took his own course upon the educational system he had brought forward. It is to be observed that communists have seldom or never relied on their peculiar system alone for the regeneration of society. Community of goods has indeed been their central idea, but they have almost invariably supported it by other projects of less questionable utility. Compulsory education, free trade, and law reform, the various movements connected with the improvement of the condition of women, have found their earliest advocates among theoretical and practical communists. The communists denounce the evils of the present state of society; the hopeless poverty of the poor, side by side with the self-regarding luxury of the rich, seems to them to cry aloud to Heaven for the creation of a new social organization. They proclaim the necessity of sweeping away the institution of private property, and insist that this great revolution, accompanied by universal education, free trade, a perfect administration of justice, and a due limitation of the numbers of the community, would put an end to half the self-made distresses of humanity. Has it never occurred to them that a similarly happy result might be attained if all these subsidiary reforms were carried out, leaving the principles of private property and competition to their old predominance in the economic world? If the principles of communism and of private property are to be fairly compared, the comparison must not be between communism as it might be and private property as it is. Communism to be successful requires to be accompanied by important reforms, towards which existing society founded on private property is gradually finding its way. The power which society, as at present constituted, has shown of adapting itself to altered circumstances, and of assimilating by slow degrees the more valuable concomitants of the most revolutionary theories, is strong proof that it does not deserve to be dealt with in the summary manner advocated by the communists.

We find in many socialistic writings of thirty or forty years ago the assumption expressed or implied that, in society as it is, the most valuable and essential reforms are impracticable. M. Louis Blanc, for instance, in his book called *L'Organisation du Travail*, first published in 1839, says that in the existing order of society the spread of education among the masses would be dangerous,—would, in fact, be impossible. This, if true, would be the strongest possible indictment against the existing order of society. But how have events falsified the assumptions made in the following passage? "On a vu pourquoi, dans le système actuel, l'éducation des enfants du peuple était impossible. . . . . Beaucoup d'esprits sérieux pensent qu'il serait dangereux aujourd'hui de répandre l'instruction dans les rangs du peuple, et ils ont raison. Mais comment ne s'aperçoivent-ils pas que ce danger de l'éducation est une preuve accablante de l'absurdité de notre ordre social? Dans cet ordre social, tout est faux: le travail n'y est pas en honneur; les professions les plus utiles y sont dédaignées; un laboureur y est tout au plus un objet de compassion, et on n'a pas assez de couronnes pour une danseuse. Voilà, voilà pourquoi l'éducation du peuple est un danger!" (p. 100). Hence, he concludes, a social revolution ought to be attempted; a new system of society ought to be introduced; the old system of society is, he says, so "full of iniquities" that it cannot co-exist with a diffusion of education among the people. Even at the time when these words were written there was much to show that they were not true. Since they were written the spread of education has been most general in those countries in which the old social order, founded on private property and competition, is unshaken.

Germany, Scotland, and America have an educated people, and they are distinguished among other countries for possessing a peaceful, law-abiding, and order-loving population. So far from education being a danger to the institution of private property, nearly every one has been convinced by events that it is much more seriously threatened by ignorance and the helpless desperation ignorance brings; and the old order of society has recognized the necessity of protecting itself by the diffusion of education.

L'Organisation du Travail furnishes another example of the mistake communists often make in thinking it is necessary to turn the world upside down in order to bring about some desirable economic change. M. Louis Blanc is describing the organization necessary for the establishment of his "ateliers nationaux," which became so famous nine years later when the eloquent author of *L'Organisation du Travail* was a member of the Government of 1848. He is speaking of the place occupied by the credit and banking system in the existing economical order of society. "Que doit être le crédit? Un moyen de fournir des instruments de travail au travailleur. Aujourd'hui, nous l'avons montré ailleurs" (in an article in the *Revue de Progrès* called "Question des Banques") "le crédit est tout autre chose. Les banques ne prêtent qu'au riche. Voulussent-elles prêter au pauvre, elles ne le pourraient pas sans courir aux abîmes. Les banques constitutées au point de vue individuel ne sauraient donc jamais être, quoi qu'on fasse, qu'un procédé admirablement imaginé pour rendre les riches plus riches et les puissants plus puissants. Toujours le monopole sous les dehors de la liberté, toujours la tyrannie sous les apparences du progrès! *L'Organisation* proposée" (that of the national workshops) "couperait court à tant d'iniquités. Cette portion de bénéfices, specialement et invariablement consacrée à l'agrandissement de l'atelier social par le recrutement des travailleurs, voilà le crédit. Maintenant, qu'avez vous besoin des banques? Supprimez-les" (pp. 97–8). This passage is a striking instance of the way in which communistic writers are inclined to treat social and economic problems. M. Louis Blanc observed that the banking system at the time in which he wrote was in some respects defective. From the nature of their business and the security they were obliged from motives of self-preservation to demand, the banks lent only to those who were able to give them that security, *i.e.*, to the rich. Even this statement requires some modification unless in the expression "the rich" is included every struggling farmer or tradesman who is helped over a time of pecuniary difficulty by the credit afforded to him by his banker. The fact remains, however, that the banks did not give credit to the labouring classes. Credit, urges M. Louis Blanc, which ought to be a means of furnishing the instruments of production to the labourer, is in reality no such thing. What is the remedy which he suggests for this deficiency in the credit system? An entire reorganization of the industrial world, in which every labourer will be supplied by the state with the tools and raw materials which his work requires. If this proposed reorganization were adopted there would no longer be any scarcity of credit, and as for banks, he cries triumphantly, they would no longer be necessary, let them be put down.

It is not M. Louis Blanc only who observed that the ordinary banking system cannot, from want of security, afford to make advances to the labouring classes. Herr Schulze-Delitzsch noted the same fact, but the remedy which he suggested, and which has been carried out with such great success in Germany, is very different from the heroic treatment recommended in the passage we have quoted from M. Blanc. The Schulze-Delitzsch credit banks which began to be established in Germany in the year 1851 are associations of artizans formed for the purpose of enabling the members to obtain by means of credit the capital necessary to production. These associations are entirely self-supporting; they have supplanted nothing, they have up-rooted nothing. Their success, so far from weakening the ordinary banking system, has strengthened it by supplying one of its deficiencies. The individual workman cannot obtain an advance of capital upon credit because he cannot give adequate security that it will be repaid. But the credit banks are associations of workmen who are jointly and severally responsible for the repayment of loans made to any one of their number. A member of one of these associations can through its means obtain a loan on favourable terms, because the principle of the unlimited liability of each of the members for the repayment of a loan made to any one of them affords the means of offering to the lender most ample and sufficient security. The fact that the principle of unlimited liability is strictly maintained is really the essential characteristic of the security which the association is able to give to those who advance capital to it. If this principle were relaxed it is more than doubtful whether the security offered by the association would be sufficiently good to ensure advances of capital being made to its members on remunerative terms. The unlimited liability of each for the debts of all necessitates great caution before a new member can be elected into one of these associations. The circumstances and previous career of candidates for membership are most carefully inquired into. They must give satisfactory evidence as to their previous character and industry, and they are required to give substantial proof that they are in a position to share the pecuniary responsibilities of the association by becoming shareholders in it. Care, however, is taken to elect no one who is not a *bona fide* workman. The capital required for making loans is partly obtained from the subscriptions of members, but the principal part of it is obtained in the open market, where the association, being able to offer good security, can obtain money on reasonable terms.

The success of these associations has been most striking. In 1865 there were 961 credit banks in existence in Germany. Of these 498 sent in a report of their financial condition to the central bureau, and their accounts showed that they then possessed nearly 170,000 members, and that the money annually advanced was equal to £10,000,000 sterling. As ten years have passed since the time when these reports were sent in, and the prosperity of the associations has during the interval been uninterrupted, there is every reason to believe that the number of members and the amount of the loans would at the present time show a very considerable increase. The very remarkable success of the credit banks is an instance of what great things can be done by self-help and without initiating any attack on the existing order of economic life. It is one of the least pleasing aspects of communism that communists not only do not attempt themselves to bring about by similar means an amelioration in the economic condition of society, but they have often gone out of their way to pour contempt and ridicule on such reforms as that introduced by Herr Schulze-Delitzsch. The establishment of the credit banks was looked on with great disfavour by the German communists. Their leader, Ferdinand Lassalle, published a book, said to be the most important of his economic writings, in which he bitterly attacked the credit banks and the co-operative system generally (*Herr Schulze-Delitzsch, Der ökonomische Julian, oder Kapital und Arbeit*, Berlin, 1864; *Dem deutschen Arbeitsstande und den deutschen Bourgeoisie gewidmet*). Co-operation, he saw, made no attack on the principles of private property and competition; and it was these principles which he had set himself to destroy. The good achieved by an amelioration of the condition of the people did not appear to him to outweigh the evils which he believed to be associated with every circumstance that favoured the accumulation of capital in private hands. Co-operation, he urges, is only improved capitalism, and the very improvement by making it more formidable seemed only to make it more hateful to him.

In the same spirit of bitter hostility to all means of improving the existing condition of society without changing the basis on which it rests, communists have often shown great contempt for political liberalism. The changes proposed and carried out by political liberals are condemned by the communists as a mere patching up of an essentially worthless fabric which must be got rid of before anything better can be substituted in its place. At the time when the agitation for the Reform Bill carried in 1832 was uppermost in the minds of all English politicians, Robert Owen took an opportunity of proclaiming in public his belief in the utter futility of all political reform. The German communists, or socialists as they are often called, have, generally speaking, been very emphatic in expressing themselves in a similar strain. The following passage, taken from the writings of Karl Marx, a member of the International Society, is scarcely an exaggeration of the views of the German school of communism on the value and results of political liberalism :—

"Although the liberals have not carried out their principles in any land as yet completely, still the attempts which have been made are sufficient to prove the uselessness of their efforts. They endeavoured to free labour, but only succeeded in subjecting it more completely under the yoke of capital; they aimed at setting at liberty all labour powers, and only riveted the chains of misery which held them bound; they wanted to release the bondman from the clod, and deprived him of the soil on which he stood by buying up the land; they yearned for a happy condition of society, and only created superfluity on one hand and dire want on the other; they desired to secure for merit its own honourable reward, and only made it the slave of wealth; they wanted to abolish all monopolies, and placed in their stead the monster monopoly, capital; they wanted to do away with all wars between nation and nation, and kindled the flames of civil war; they tried to get rid of the state, and yet have multiplied its burdens; they wanted to make education the common property of all, and made it the privilege of the rich; they aimed at the greatest moral improvement of society, and have only left it in a state of rotten immorality; they wanted, to say all in a word, unbounded liberty, and have produced the meanest servitude; they wanted the reverse of all which they actually obtained, and have thus given a proof that liberalism in all its ramifications is nothing but a perfect Utopia."

The condition of England is often pointed at triumphantly by communists of other countries as a complete condemnation of the principles of private property, capitalism, and competition. Lassalle, Marx, Louis Blanc, and others quote passages from bluebooks, speeches of English statesmen, and writings of our public men in which the condition of the English poor is painted in the darkest colours. In England, they say, for the last half century you have had liberalism in the ascendant; you have had free trade, you have had an energetic and industrious people; the amount of capital eager for employment is practically unlimited; competition has had in nearly every branch of trade the most unrestricted development. In England, if anywhere, we may surely look for the nearest approach to perfection of which the present economic condition of society is capable. Then they proceed to quote passages from parliamentary speeches and official reports, and from English writers on political economy, all bearing witness to the terrible poverty and squalor in which a large proportion of the labouring class in this country spend their lives. M. Louis Blanc, in the book already referred to, quoted from Lord Lytton's *England and the English* a passage showing that the amount and quality of nutriment consumed by the inmates of our jails and workhouses were at that time far in excess of what could be obtained by the wages of the frugal and industrious working-man. Marx cites the following passage from Dr Hunter's report to the Privy Council (1862–3) on the domiciliary condition of the agricultural labourer :—"The means of existence of the hind are fixed at the very lowest possible scale. What he gets in wages and domicile is not at all commensurate with the profit produced by his work. His means of subsistence are always treated as a fixed quantity; as for any further reduction of his income he may say *nihil habeo, nihil curo.* He is not afraid of the future; he has reached zero, a point from which dates the farmer's calculation. Come what may he takes no interest in either fortune or misfortune."

Whatever may be the value of the remedy which communism suggests for so melancholy a condition as that here described, it is surely useful that the attention of people who have "much goods laid up for many years" should be forcibly arrested, and that they should be made to consider why it is that in the richest country in the world the condition of a large proportion of the labouring classes is so bad that it can hardly be made worse. But at present there is a general conviction that the remedy proposed by communists is one which it would be overwhelmingly difficult to apply, and it is also believed that even if it were applied it would be of doubtful efficacy. Some of the most obvious difficulties associated with the practical adoption of communism have been already adverted to. The social, political, and industrial edifice which is the outcome of centuries of effort and sacrifice would be destroyed by the adoption of communism; it would be necessary to reconstruct society from its very foundations; and society, like a constitution, is one of those things which cannot be made—it must grow. Then also the efficacy of communism as a remedy for the miserable condition of the poor is, to say the least, doubtful. To what cause may be assigned most of the pauperism, misery, and squalor which hang like a cloud over the lives of so many of the labouring classes? What was the principal agency which brought about calamities like the Irish and the Orissa famines? There can be but one answer to these questions,—the pressure of population on the means of subsistence. Many communistic writers have passionately denied this, and have denounced with all the fervour of emotional natures the doctrine laid down by Malthus that population tends to increase faster than subsistence is capable of being increased. No one, however, has attempted to throw doubt on the main fact on which the Malthusian doctrine rests, that everywhere, except in very new countries with a large extent of unoccupied fertile land, checks on population are in active operation. These checks must exist everywhere where population does not increase at its greatest possible speed. Under favourable conditions population sometimes has doubled itself in 20 years. Professor Cairnes has stated that in Ireland the population more than doubled itself in the 38 years between 1767 and 1805. At the rate of increase of the ten years ending 1870, the population of England would double itself in 63 years, that of France in 265 years. In France and England, therefore, checks on population are, in a varying degree, in active operation; and the same may be said of all old countries. It is important, however, to inquire into the nature of the checks on population in actual operation. They may be divided into two classes, the first carrying with it nothing but misery and degradation, the second implying a high degree of self-restraint, independence, and foresight. In the first class may be placed war, pestilence, famine, and all the diseases incident to insufficient food and overcrowding. In the second class may be placed prudential restraints on marriage and on the number of births to each marriage, and emigration. Every circumstance which weakens the efficiency of the checks on population comprised in the second class necessarily adds to the force of the checks which we have placed in the first class. In other words, any circumstance which relaxes the force of the prudential checks on population tends to produce the miseries of famine, scarcity, and "starvation diseases." What would be the effect of communism on the population question? Would it strengthen or weaken the motives which promote a prudential limitation of numbers? Nearly all communists, whether theoretical or practical, have faced in one way or another the population question. The solutions they have offered differ widely. Let us first see what the greatest of theoretical communists have had to say on the subject.

Plato seems to have thought the matter an easy one, and says that the guardians of his state must control the number of births. In Utopia the age at which men and women were allowed to marry was fixed by the state, and all irregularities in defiance of this rule were to be severely punished. The population was also to be kept within certain limits by means of migration, emigration, or colonization. But the theoretical communists of modern times have hardly found words strong enough to express their detestation of the principle that any limitation is desirable to the possible number of births. The writings of Malthus are spoken of as "an outrage on household life." His language, it is said, "brutalized the purest feelings of domesticity." M. Louis Blanc inveighs against the doctrines of political economists, and protests that they are blaspheming God when they say that the prosperity of the poor would be promoted by a limitation of the population. Why are you not logical? he cries. If you were you would recommend that the children of the poor should be put to death! And in another place he speaks of "cette économie politique sans entrailles dont Ricardo a si complaisament posé les prémisses, et dont Malthus a tiré avec tant de sang-froid l'horrible conclusion. Cette économie politique portait en elle même un vice qui devait la rendre fatale à l'Angleterre et au monde" (*L'Organisation du Travail*, p. 71). Practical communists have not, however, met the population question in the spirit indicated by these quotations. Several of the most successful realizations of communistic life have maintained the strictest celibacy among their members. The Essenes, who practised community of goods before the Christian era, were a sect composed entirely of men, who lived in seclusion from the world and were in many important respects the prototypes of Christian hermits or monks.

Two of the most important communistic societies of the United States have also made celibacy an essential feature of their system. The "Economites" and "the Shakers," the societies to which reference is made, have existed since 1805 and 1792 respectively. They are strictly celibate, their numbers being recruited by converts from the outside world and to a slight extent by the adoption of pauper children and orphans from neighbouring towns. Other communistic societies maintain the authority of the heads of the society to limit the number of marriages. The Spartan Government, which in many important respects was communistic, exercised the most absolute control over the increase of population. Among the Moravians marriage is not permitted to take place without the consent of the heads of the society, who furnish the newly married couples with a suitable marriage portion. The Separatists, an American community of German origin, established in 1817, favour celibacy although they do not enforce it. No marriage can take place without the consent of the trustees of the society; and they further discourage marriage by entering among the articles of their religion a declaration of their belief that celibacy is more in accordance with the divine will than marriage. The Amana community also, a German society in the United States, which dates its origin from early in the last century, discourages marriage among its members. No man is allowed to marry before he is twenty-four years of age. Mr Nordhoff relates that the reason for this rule was explained to him by one of the elders of the Amana Society in these words,—"They" (the young men) "have few cares in life, and would marry too early for their own good—food and lodging being secured them—if there were not a rule upon the subject." The religious tone of the community is also set against marriage. "In the Amana Church there are three classes, orders, or grades, the highest consisting of those members who have manifested in their lives the greatest spirituality and piety. Now if the newly-married couple should have belonged for years to this highest class, their wedding would put them down into the lowest, or the 'children's order,' for a year or two until they had won their slow way back by deepening piety" (Nordhoff's *Communistic Societies of the United States*, pp. 36–7). Even the Perfectionists, whose extraordinary system of "complex marriage" has been already referred to, take many precautions against a superabundant population. The number of births is controlled by the heads of the society. The founder of the community writes as follows: "Previous to about two and a half years ago, we refrained from the usual rate of child-bearing, for several reasons—financial and otherwise." Even when the number of births was increased it was stated that they were purposely kept within such limits that "judicious moral and spiritual care, with the advantage of a liberal education," could be guaranteed to every child (Nordhoff, p. 276). The practical answer made by communists to the population question, even in so wealthy a country as America, in which unoccupied fertile land can be easily and cheaply obtained, is that a strict limitation of numbers is absolutely essential to their social and industrial well-being. As a matter of fact the population of nearly all the American communistic societies has not increased at all, but has greatly declined during the last fifty years. The number of Shakers, for instance, in 1823 was 3800; their number in 1874 was 2415. The Icarians, the only American community which makes marriage compulsory, have declined in twenty-five years from 1500 to 65.

It would, however, be rash to conclude from these facts that the general adoption of communism would tend to strengthen the prudential checks on population. We have seen that modern communists, when freed from the trammels of actual experience of the daily working of the system they advocate, have vigorously denounced the theory and practice of Malthusianism. The American communities have declined in numbers partly in consequence of the adoption in two of them of celibacy as a religious principle. It is also impossible to avoid the conclusion that their numbers have fallen off partly in consequence of the unattractive conditions of communistic life. The young members of these societies not unfrequently leave them when they arrive at manhood and womanhood. The routine and absence of spontaneity of a communistic life is a weight to young and active minds that is not counterbalanced by security from want, or what has been called a bread-and-butter prosperity. The numbers of marriages and of births have been controlled in other of these societies in virtue of the absolute despotism which is vested in their chiefs; individual liberty is entirely suspended; the smallest minutiæ of the daily life of their members is regulated from headquarters. A government which decides at what hour its subjects shall go to bed at night and rise in the morning; which prescribes the colour, shape, and material of the dresses worn, the time of meals, the quality of the food consumed, the daily task apportioned to each member; which enforces a rule that each of its subjects shall leave every morning a notice stating at what exact spot he or she will be found during each hour of the day; a government which can do all these things will find no great difficulty in controlling the number of marriages and births. Mr Nordhoff states that "the fundamental principle of communal life is the subordination of the individual's will to the general interest or the general will; practically this takes the shape of unquestioning obedience by the members towards the elders or chiefs of their society." If, however, communism were adopted throughout a whole nation, the minute despotism which now distinguishes the government of existing communistic societies, and which furnishes them with an effectual control over the growth of population, would cease to be possible; or if, indeed, it should ever become possible it would be through the careful suppression of individual liberty, and through the strenuous encouragement of everything which tended to destroy self-reliance on the part of the people and to build up the absolute power of the state. A people who purchased material prosperity at the price of their liberty would strike a bad bargain, especially when it is remembered that the limitation of the number of marriages and births which is enforced by the central authority in a communistic society can be effected by voluntary self-control in a society based on private property and competition. The difference, therefore, so far as the population question is concerned, between communism and private property is whether the necessary restraint upon the possible number of births shall proceed from the direct intervention of the state, or whether it shall proceed from the combined motives of self-interest, self-control, and parental obligation on the part of the people themselves. It should be remembered that what communism professes to be able to do is to ensure to every member of a communistic society an ample supply of the necessaries and conveniences of life. If the population question is pressing now when the workhouse and parochial relief are the only refuge of those who cannot maintain themselves, would it not become much more pressing if a man could obtain freely, and without fulfilling any disagreeable conditions, food, house, and clothing for himself, and as many children as he chose to bring into existence? It is this consideration which has forced upon the government of communistic societies the control of the marriages and births of their members. Even where the principles of communism are adopted in so very materially modified a form as they are in our poor law system, legislative control over population has been enforced. The regulation which separates man and wife in the workhouse is a practical recognition of the principle that, where the State guarantees a maintenance, it must, in self-protection, exercise control over the numbers of those dependent on it for support. Self-help brings with it self-control; state-help makes state-control indispensable. In the present economic condition of society the solution of the population question is not to be found in placing in the hands of the state, as communism has done, absolute control over domestic life. The solution of the problem must be sought in education, in an improved standard of comfort and a determination on the part of the people not to sink below it, and in a reform of the most communistic portion of our poor law system,—the lavish distribution of out-door relief.

There are some charges made against communism which may be brought with at least equal force against the economic and industrial arrangements which now prevail. One of these is that communism does not avail itself sufficiently of the motive of self-interest in order to obtain from each labourer the best and most conscientious work of which he is capable. If, it is urged, the result of a man's industry belongs not to himself solely but to the whole community of which he is a member, he will not throw the same energy and zeal into his work as he will if everything which he produces belongs solely to himself. There can be no doubt of the truth of this statement; self-interest is a force on which industrial machinery chiefly relies for motive power. But it is remarkable that the prevailing system of working for fixed weekly wages checks the play of self-interest in the workman much more completely than it is checked in a communistic society by the fact that the results of the labour of each are shared by all. A workman who is in receipt of fixed weekly wages has no motive to reach any higher standard of excellence or expedition in his work than such as will prevent him from being discharged for bad work or laziness. It is a complaint constantly heard among employers of labour that the only ambition of the men seems to be to see how little work they can do for their wages. The actual existence of this feeling among workmen is proved by many of the rules of trades' unions,—such as that which limits the number of bricks which a hod-man is allowed to carry, and which in one case forbade the use of wheel barrows in taking bricks from one spot to another. Mr Thornton's book *On Labour* gives several examples of the rules adopted by trades' unions to check the tendency which is sometimes found in a workman to exert himself to do his best and thus show his superiority over his fellows. "'Not besting one's mates' has by several unions been made the subject of special enactment. . . . . The Manchester Bricklayers' Association has a rule providing that 'any man found running or working beyond a regular speed shall be fined 2s. 6d. for the first offence, 5s. for the second, 10s. for the third, and if still persisting shall be dealt with as the committee think proper.'" It was urged by the trade unionists in the textile manufactures of Lancashire and Yorkshire as a serious argument for placing impediments in the way of the employment of women in these industries that they were apt to take a pride and pleasure in the excellence and rapidity of their work, and that their vanity was such that a word of praise or encouragement from the overlooker would cause them to redouble their exertions (Report of Dr Bridges and Mr Holmes on the condition of women and children employed in Textile Industries, 1873).

These examples are more than sufficient evidence that the present industrial system does not bring into play the motive force of direct self-interest in stimulating the exertions of the labourers. In this respect communism would seem at first sight to compare favourably with mere wages-receiving industry; for in a communistic society every man and woman has some direct share, however small, in the results of his or her labour. If more is produced, there will be more to receive; and instead of a trades' union, every member of which is pledged, under penalties, to work slowly and to watch that his fellow-workmen do the same, communism gives to each labourer a direct interest not only in working well himself, but in watching to see that honest and steady work is done by his neighbours. As a matter of fact, the American communistic societies have found no difficulty in enforcing the habit of careful and regular industry on their members. The American communists do not as a rule work hard; for they find that they can provide for all the wants of the community without excessive or exhausting toil. But there are no idle members, and every member works well and steadily while he is working. That the quality of their work is good is proved by the fact that their commercial reputation stands very high. The garden seeds, the production of which is the staple trade among the Shakers, have been celebrated for their excellence for more than seventy years all over the United States. "The Oneida Perfectionists established the reputation of their silk twist in the market by giving accurate weight and sound material; the woollen stuffs of Amana command a constant market, because they are well and honestly made; and in general I have found that the communists have a reputation for honesty and fair dealing among their neighbours, wherever their products are bought and sold" (Nordhoff).

It must, however, be remembered that a few small communities, such as those which exist in America, afford no fair test of what would be the effect of a general adoption of communism on industrial activity and efficiency. The communists in the United States only number about 5000, including children; and though there are eight different societies, these are divided into 72 separate communities, the Shakers alone having 58. On an average, therefore, each community consists of less than 70 persons. The elaborate despotism of communistic government, together with the minute surveillance which the small size of these communities renders possible, makes it easy for the leaders of these societies to exact from each member his quota of toil; idleness would be at once detected and would not be suffered to exist, as the power of expelling an idle member would be resorted to if the voice of public opinion were not sufficient to induce him to mend his ways. Similar means of detecting and preventing idleness would be completely absent if communism were generally adopted. There would, of course, in this case be no power of expelling an idle member, and the difficulty of detecting and proving to the central authorities a disposition on the part of any of the members to avoid a fair share of work would increase *pari passu* with the size of the community. The motive of self-interest in promoting good work is much more powerful in a small communistic society than in a large one. A man can appreciate the value of his own industry much more clearly if the resulting product is shared between 60 or 70 persons, every one of whom is well known to him, than he can if it is thrown into the common stock of 20,000 people. The weakening of the motives of self-interest which is inherent in communism is reduced to a minimum in small communities, but it would act with fatal results to industrial activity if there should ever be an attempt to make communism universal. For, much as the present system falls short of making the most of the great engine of self-interest among those who merely work for wages, there is no such failure among the other industrial classes. Capitalists, landowners, inventors, Cornish tributers, and members of co-operative productive societies and copartnerships are all brought under the stimulating influence of self-interest, and thus devote themselves to industrial projects with a zeal completely and necessarily unknown among those who work for wages or those who are members of communistic societies. It is the special feature of co-operation that it brings the motive of self-interest into activity among manual labourers. Without attempting, as communism does, to overthrow all existing economic institutions, it takes these as they are, and men and women as they are, and suggests a means by which the labourer, no less than the capitalist, can be stimulated by direct self-interest to throw some energy and enthusiasm into his work.

We referred above to the melancholy picture drawn by Karl Marx, Louis Blanc, and others of the condition of the English poor. Since they wrote, co-operation has in some parts of England done much to brighten the social and industrial condition of the working classes. The *Times* of 18th August 1875 gives an account of the co-operative manufactures in the town of Oldham. In this one town there are 80 joint-stock co-operative mills; in the county of Lancashire there are 150. The bulk of the shareholders are artizans, who labour in the mills, and who therefore have a direct and immediate interest in the results of their industry. Cotton-spinning and weaving are the principal businesses carried on in these mills. The principle of self-interest has had the effect of producing, not mere activity on the part of the labourer, but thoroughly sound and honest work. We are told by the *Times* that these mills possess a high reputation for probity of manufacture. They are worked partly with capital subscribed by the shareholders, in £5 or £10 shares, and partly with borrowed capital which bears a fixed rate of interest. Many of the mills pay a dividend of 10 per cent. on their share capital; the ledgers and account-books of each society are open to all the shareholders, who also exercise the power of electing in open meeting the managers and officers of the association. The shareholders frequently invest money on loan to the societies of which they are members, so that the interests of the lenders and of the shareholders are identified in the most absolute manner possible. The most important of these associations is perhaps the Industrial Co-operative Society of Oldham founded in the year 1850–1. From very small beginnings it has gradually extended its operations until in the year 1874 it divided a dividend of £40,000 among its shareholders in four quarterly instalments of £10,000 each. The total turnover of this society is £250,000 a year. It forms, as it were, a kind of bank to the other co-operative societies. At Christmas 1874 it had out on loan to these associations a number of sums varying from £11,732 downwards, making a total of £45,437. The Sun Mill Company, another of the Oldham co-operative associations, has a share capital of £100,000. It is stated in a parliamentary return published in 1874 that there are in England and Wales 790 co-operative societies, with 340,930 members, a share capital of £3,334,104, and a loan capital of £431,808. Their net profits for the year 1873 were £958,721, of which £861,964 was distributed as dividends among the members of the society, and £18,555 was paid away as interest to non-members. There can be no doubt that co-operation was to a great extent originated in England by communists. It is an outcome of the communistic movement, for it was in the first instance mainly promoted by social reformers who had proved by many failures the futility of communism as an engine of social regeneration. Notwithstanding its origin, there is, however, no movement more distinctly non-communistic than co-operation. It strengthens the principles of capital and private property by making every co-operator a capitalist, and thus personally interesting him in the maintenance of the present economic condition of society.

When the really great results of co-operation in this country are compared with the very limited success of nearly a century of communism in America, the conclusion is inevitable that co-operation is much more effectual than communism in producing a radical improvement in the condition and status of labour, that it is easier to graft upon existing institutions, and that its working is unaccompanied by the despotism, the crushing of individuality, and the discouragement of self-help, which are the admitted dangers and drawbacks of communism. The state banks and national workshops of M. Louis Blanc's economic dreams were realized in 1848–50 in a manner that must have caused the severest disappointment to their philanthropic author; failure and discredit were their only practical results. The

Social Democrats of Germany with Lassalle at their head, have left nothing tangible which can be said to have advanced their cause. The Schulze-Delitzsch credit banks, which they assailed as an improved form of capitalism, have done and are doing more for labour in Germany than the whole Social Democratic party has ever done.

In France the names of Saint Simon, Fourier, Bazard, and Enfantin suggest chiefly a series of tragic failures. In England Owen's name recalls the brief existence of Harmony Hall and Orbiston, the establishment of the Labour Exchange and the issue of Labour Notes, and a number of other schemes which raised great hopes and expectations that were doomed to a speedy disappointment. In America the success of communism, such as it is, is hardly more encouraging than its failure in Europe. The measure of material prosperity achieved is not very considerable, bearing in mind the length of time most of the societies have existed and the ease and cheapness with which unoccupied land can be obtained in the United States. Mr Nordhoff estimates the capitalized wealth of the 72 American communes at twelve millions of dollars, or about £2,400,000 sterling. They own between 150,000 and 180,000 acres of land, or on an average about 36 acres a head—a comparatively small holding for America. The 72 communes are spread over 13 States; they possess some of the most fertile land in the world; one of the Shaker villages owns a magnificent estate of 4500 acres lying in the famous Miami bottom, a soil much of which is so fertile that after sixty years of cropping it will still yield from 60 to 70 bushels of corn to the acre without manuring. The material condition of the inhabitants of the communistic villages compares favourably, no doubt, with that of the German peasants by whom the majority of American communes were originally started; but the monotony, the personal submission, the impossibility of privacy or temporary seclusion, the absence of anything like intellectual activity in these societies, would render the life well-nigh unbearable to people who had been previously accustomed to a higher standard of happiness than that at present within the reach of the ordinary day-labourer. Many communistic experiments in America have been unsuccessful. Mr J. H. Noyes, in his book on "American Socialisms," gives a short history of no fewer than forty-seven of these failures. Comparing the history of those societies which have died a natural death with that of those which still continue to exist, it is found that the successful societies had no advantage either in the wealth of their members or the intellectual ability of their leaders. Most of the successful societies began poor; most of the unsuccessful societies began with what were believed to be sufficient means to achieve success. Many of the unsuccessful societies were founded by high-minded, highly-cultivated men and women, and their members were distinguished for their education and intellectual attainments. From these facts and with ample means through personal experience for forming a correct opinion, Mr Nordhoff draws the conclusion that in a communistic experiment success depends upon a feeling among all the members "of the unbearableness of the circumstances" in which their lives were originally cast. They must have suffered from wrong and oppression, as well as from want, before communism can appear as a welcome change in their manner of life. Hence the poorer and more narrow and miserable the condition of the people who start a communistic experiment the more likely is it under judicious leaders to succeed. People are easily satisfied when almost any change in their lives must be for the better. It would be most undesirable to detract from the achievement of the American communes in raising the poorest and most miserable peasants to a degree of material prosperity, which compares with that of the well-to-do small farmer in England or America. This is no small feat; and they have also proved the possibility of putting communism into a practical form, at any rate on a small scale, and under exceptionally favourable economic conditions. But it is impossible to doubt that their principal value to the world has been in illustrating the limitations and drawbacks of the system. As long as communism remained an unexplored region given over to the dreamers of dreams and the seers of visions, it was impossible to prove that it did not possess all the marvellous perfection they fondly attributed to it. The American societies offer a life which is confessedly attractive only to those whose original circumstances are exceptionally unfortunate; to these communism can give, together with a congenial religious atmosphere, material prosperity of a humble type, accompanied by the sacrifice of individuality, liberty, privacy, and intellectual development. It can hardly be denied that these experiments prove that, even were communism on a large scale practically possible, it could never satisfy the aspirations of those who look for a time when increased material prosperity among the working-classes shall be accompanied by a corresponding increase of intellectual activity, political responsibility, and personal independence. The old form of society would seem to be more favourable than communism to the growth of these qualities; and it is probable that the American experiments may help to establish the conviction among economic revolutionists that more can be accomplished by grafting new institutions, such as co-operation, on the old plant of private property than can be achieved by rooting it up altogether, and planting the seedling of communism in its stead.

F.)

COMO, a city of Italy, capital of the province of its own name, at the south-west corner of the Lake of Como, in a beautiful valley surrounded by richly-clad mountains. It lies in 45° 48′ 26″ N. lat. and 9° 4′ 45″ E. long., and is distant twenty-eight miles by rail from Milan. The city proper is still surrounded by its ancient walls and towers; but two pretty extensive suburbs, known as Vico and St Agostino, have grown up outside—the former containing a large number of fine villas, and the latter devoted specially to manufacturing purposes. The principal buildings are the cathedral, the broletto or town hall, the churches of St Fedele and St Abondio, the *Palazzo Giovio*, with its library and collection of antiquities, the Gallio College, and the theatre. The cathedral, erected by the voluntary contributions of the citizens, is a structure of various dates and styles of architecture,—the earliest portions being by Lorenzo de' Spazi of the end of the 14th century, while the cupola is the work of Guvara, an architect of the first half of the 18th. The most interesting, perhaps, of the monuments which it preserves, is that of Benedetto Giovio, an early historian of the city. The broletto dates from 1215, and is built of alternate courses of black and white marble; but of still greater value as an artistic effort is the church of St Abondio, a small but exquisite structure of the 11th century, built, it would seem, in the lower portions of Roman remains, and remarkable for an "apse of extraordinary height and richness rising between two tall campaniles." There are extensive factories in Como for the spinning and weaving of silk; it also manufactures woollens, cotton, and soap; and there are iron-works in the immediate vicinity. To its position on the lake and its command of the Splügen and St Gotthard lines of communication, it is indebted for a considerable trade by way of transit and distribution. About a mile to the south of the town is the tower of Baradello, famous as the place where the Torriani of Milan were confined in cages by the Visconti party, over whom they had previously tyrannized. The population of Como is 24,350.

Como is readily identified with the ancient *Comum*, a city of Gallic origin, situated within the territory of the Galli Insubres. Though from an early period a flourishing and important centre, it never played a very conspicuous part in ancient history. Soon after the beginning of the 2d century B.C., the people of Comum joined the Insubres in an attack on the Romans; but they were defeated, and their city fell into the hands of the conquerors, and became a Roman colony. The first colonists, however, were unable to maintain themselves against the inroads of the Rhætian Gauls; and additional settlers were sent down from time to time. Julius Cæsar, in particular, introduced 5000, of whom a tenth were Greeks; and the colony assumed for a short time the name of Novum Comum. On the accession of Cæsar to supreme power, Comum obtained the complete right of citizenship; but though it was at this time at the height of its prosperity, it never took rank higher than a municipal town. In the early part of the Middle Ages it formed for a time, like many of the towns of Italy, an independent republic; but after a considerable struggle it had to submit to Milan. Its deliverance was effected in 1158 by Frederick I. of Germany, to whom its citizens had appealed; but in the 15th century it again succumbed before the Milanese nobles. In 1520 it was captured by Charles V. During the Roman period the Pliny family were connected with the city; and in more modern times it numbers among its celebrities Paulus Jovius, Piazzi the astronomer, and Volta the electrician. See Cantu, *Storia di Como*, 1829; and Monti, *Storia di Como*, 1829.

COMO, Lake of, or, in Italian, *Lago di Como*, known to the Romans as *Lacus Larius*, is, from the beauty of its scenery and the mildness of its climate, one of the most celebrated of all the Italian lakes. It is situated in the province of Como, in that part of the country which belonged to the kingdom of Lombardy; and it occupies the bottom of a great valley, which, stretching south from the neighbourhood of Chiavenna at the foot of the Splügen, breaks up at Bellaggio into two branches which run respectively south-east and south-west. The lake is thus divided into three basins, of which the south-western is known more particularly as the Lago di Como, and the south-eastern as the Lago di Lecco. The northern part of the original basin has been silted up by the debris brought down from the valleys of San Giacomo and Bregaglia by the River Mera; and not only has the Adda, which enters from the east, filled up the branch that in all probability once extended up the Valtelline as far as Morbegno, but it has also, by its delta, or cone of ejection, cut off from the main body of the lake the part now known as the Lago di Mezzola. Of the real form of the bed of the lake there was hardly any knowledge till 1865, when a survey was undertaken by Signor Gentilli and MM. Casella and Bernasconi. The results obtained were published by Gentilli in the second volume of the Memoirs of the *Società Italiana di Scienze Naturali*, and by his coadjutors in a separate pamphlet entitled *Cenni Orografici sul Lago di Como*. It appears that the greatest depth is 1341 feet, which was registered in a section of the Lago di Como from Torrigia to Como. From the northern extremity of the lake the basin gradually grows deeper as we advance southwards, till it shallows towards the promontory of Bellaggio; in the south-western branch it grows rapidly deeper again, while in the south-eastern it shallows to 390 or 290 feet. This difference of the two branches is easily explained by the fact that the Lago di Como is a closed basin except at its junction with the main body of the lake, and throughout a coast line of upwards of forty miles receives only two unimportant torrents, while the Lago di Lecco is in the direct course of the Adda, which makes its exit by the southern extremity. The total length of the lake, from Como to its northern extremity, is about thirty miles, and its greatest width, between Menaggio and Varenna, about two miles and a half. The shores of the lake are studded with ancient castles, flourishing hamlets, and the villas of wealthy proprietors. On the eastern side the principal places are Colico-piano, Dervio, Bellano, Varenna, Mandello, and Lecco; and along the western Gravedona, Dongo, Menaggio, Cadenabbia, Argegno, Moltrasio, and Cernobbio. Bellaggio, as already mentioned, is situated at the promontory where the lake bifurcates southwards. The Villa Vigorni, near Menaggio, formerly the property of Mylius of Frankfort, contains sculptures of Thorwaldsen, Marchesi, and Argenti; the Villa Giulia, near Bellaggio, belongs to the king of the Belgians; the Villa Carlotta or Sommariva, near Cadenabbia, took its name from Charlotte of Prussia, wife of the duke of Saxe-Meiningen; the Villa d'Este, near Cernobbio, was at one time the residence of Queen Caroline of England. The Villa Raimondi or Odescalchi, is the largest of all.

For further details, besides the publications already referred to, see Cantu, *Como e il suo lago* (last edition, 1872); Leonhardi, *Der Comersee und seine Umgebungen*, Leipsic, 1862; P. A. Curti, *Il lago di Como e il pian d'Erba*, 1872; and an article by John Ball in the eighth volume of the *Geol. Mag.*

COMONFORT, Ignacio (1812–1863), a Mexican soldier and politician, who, after occupying a variety of civil and military posts, was in December 1855 made provisional president by Alvarez, and from December 1857 was for a few weeks constitutional president. See Mexico.

COMORES or Comoro Islands, a group in the Mozambique Channel, between Madagascar and Cape Delgado, on the east coast of Africa, discovered by Houtman in 1598, and consisting of the four main islands of Angaziya, Angazecha, or Great Comoro, Anzuan or Johanna, Mohilla, and Mayotta, and a considerable number of diminutive islets. 1. *Comoro*, the largest, has a length of about thirty-five miles, with a width of about twelve, and a population of 35,000. Near its southern extremity it rises into a fine dome-shaped mountain, which has a height of upwards of 8500 feet, and is visible for more than 100 miles. Eruptions are recorded for the years 1830, 1855, and 1858; and traces of the last of these commotions are still very distinct. The island is politically divided into various petty principalities, and maintains its own petty feuds. The natives are tall of stature and well-formed, and appear to be mainly of Arabic descent, with a mixture of Malagasy blood. The chief towns are Maroni, Itzanda, and Mouchamouli; the first, situated at the head of a bay in 11° 40′ 44″ S. lat., being the seat of the principal sultan in the island. 2. *Johanna*, next in size, rises in a succession of richly wooded heights till it culminates in a central peak, upwards of 5000 feet above the sea, in 12° 14′ 17″ S. lat. and 44° 27′ 34″ E. long. The whole island is under one sultan, who resides at the town of Johanna on the north side. The natives are hospitable to foreigners, and especially to Englishmen. Domestic slavery exists, but of a very mild description. The capital, which is sometimes called Moussamondou, is substantially built of stone, surrounded by a wall, and commanded by a dilapidated citadel; it is the seat of an English consul, and carries on a considerable trade in supplying ships with provisions. There is a small but safe anchorage at Pomony, where coal is kept for H.M. ships in the Mozambique Channel. The population amounts to about 12,000. 3. *Mayotta*, about 21 miles long by 6 or 7 miles in breadth, is surrounded by an extensive and dangerous coral-reef. The principal heights on its extremely irregular surface are Mavegani Mountain, which rises in two peaks to a maximum of 2164 feet, and Uchongin, which only falls below it by about 60 feet. The island belongs to the French since 1843, and they have established small military and naval colony on the contiguous islet of Zaudzi, which lies within the reef in 12° 46′ 48″ S. lat.

and 45° 20′ 14″ E. long. There are substantial Government buildings and store-houses; the garrison numbers about 100 soldiers; and a number of sugar estates have been formed, especially on the eastern side of the island. Before the French acquisition Mayotta was subject to Dansulu, king of the Sacalavas, who had been expelled from the north-west coast of Madagascar by the conquests of Radama, king of the Ovahs. Population, 12,000. 4. *Mohilla*, the smallest, is 15 miles in length, and 7 or 8 miles at its maximum breadth, with a population of 6000. Unlike the other three it has no peaks, but rises gradually to a central ridge about 1900 feet in height. It is governed by an independent sovereign resident at Douany, a walled town close to the coast, in 12° 17′ S. lat. and 43° 46′ E. The most important town besides the capital is Numa-Choa.

All the islands possess a very fertile soil; they produce cocoa-nuts, rice, maize, sweet-potatoes, yams, sugar, coffee, cotton, indigo, and various tropical fruits. A large number of cattle and sheep, the former similar to the small species at Aden, are reared by the natives; turtle is caught in abundance along the coasts, and forms an article of export, and the fauna is comparatively rich for the size of the area. Population of the group, 65,000.

See T. S. Leigh, "Mayotta and the Comoro Islands," in *Jour. Roy. Geog. Soc.*, 1849; De Horsey, "On the Comoro Islands," in *Jour. Roy. Geog. Soc.*, 1864.

COMPANY is one of the many words used to denote the association of individuals in the pursuit of some common purpose. Partnership, union, society, club, corporation, and company, all have this shade of meaning in common, although they differ from each other in many particulars. The suggested derivation of the word company (from *cum panis*) may be compared with the original meaning of *gild.* A gild was a feast, and the first associations named gilds, like the first associations named companies, had for their object the furtherance of a common entertainment. Corporation, unlike the other words of similar meaning, has in law a very definite signification. It applies only to an association which has been endowed with a fictitious personality, enabling it to sue and be sued, to acquire rights and incur obligations, without the individual members thereof being implicated. Company, on the other hand, may be used generally to describe almost any kind of association In practice, however, it is confined to two classes of associations. The first are those joint-stock companies whose vast proportions and wide ramifications are among the most striking features of modern industrial life. The other are the livery or city companies, which still retain the name and the constitution, while they have long abandoned the objects of the gilds of the Middle Ages. See CORPORATIONS.

Joint Stock Companies.—Commercial companies are a comparatively modern creation in English law. The common law appears to have recognized no privileged associations except those which were incorporated by charter, or statute, or prescription. All other associations, no matter what their numbers or purpose, were mere assemblages of individuals. A trading association was at the best only a partnership, and between large partnerships and small partnerships there was no legal difference whatever. Each of the members was responsible for all the debts of the association, and all the members had to unite in instituting or defending any process of law. The inconvenience of such disabilities must have increased with the growth of trade. On the other hand, if the society applied to the Crown for a charter, and succeeded, it became a corporation, and the members were rendered irresponsible for its debts. What was wanted for trade was a society which might sue and be sued like a corporation, while its members remained personally liable for its debts. Joint-stock companies were regarded at first with great disfavour by the Legislature. In 1719 was passed the Bubble Act (6 Geo. I. c. 18). The first part of the Act, reciting the utility of the practice of assuring ships and lending money on bottomry, empowers the king to create by charter two corporations to deal in such ventures; and all assuring of ships, or lending of money on bottomry by any other corporation, partnership, or society, is made illegal. Private persons, acting for themselves, may still continue to underwrite policies and lend money. The Act then recites the growth of dangerous and mischievous undertakings and projects, wherein the undertakers and subscribers have presumed to act as if they were corporate bodies, and have pretended to make their shares transferable, and enacts that "all and every the undertakings and attempts described as aforesaid, and all other public undertakings and attempts tending to the common grievance, prejudice, and inconvenience of his Majesty's subjects, or great numbers of them, in their trade, commerce, or other lawful affairs; and all public subscriptions, receipts, payments, assignments, transfers, pretended assignments and transfers; and all other matters and things whatsoever, for furthering, countenancing, or proceeding in any such undertaking or attempt; and more particularly, the acting or presuming to act as a corporate body or bodies, the raising or pretending to raise transferable stock or stocks, the transferring or pretending to transfer or assign any share or shares in such stock or stocks, without legal authority, either by Act of Parliament or by any charter from the Crown, to warrant such acting as a body corporate, or to raise such transferable stock or stocks, or to transfer shares therein; and all acting, or pretending to act, under any charter formerly granted from the Crown for particular or special purposes therein expressed, by persons who do or shall use, or endeavour to use, the same charters for raising a capital stock, or for making transfers or assignments, or pretended transfers or assignments, of such stock, not intended or designed by such charter to be raised or transferred; and all acting or pretending to act under any obsolete charter, become void by non-user or abuser, or for want of making lawful elections which were necessary to continue the corporations thereby intended, shall (as to all or any such acts, matters, and things, as shall be acted, done, attempted, endeavoured, or proceeded upon after the said 24th day of June 1720) for ever be deemed to be illegal or void, and shall not be practised or in wise put in execution." And all such undertakings are to be deemed public nuisances. Although wholly powerless to prevent the growth of joint-stock companies, the Bubble Act was not repealed till 1825. The Bubble Act is supposed to have been passed in the interest of the famous South Sea Company. By 9 Anne c. 21 the Crown was empowered to incorporate the persons interested in the public debt, with certain privileges of trade on the South Seas. By 6 Geo. I. c. 4 the company thus created was authorized to increase its stock. The supposed advantages of the company turned out to be a delusion. In the meantime numberless other speculations of a similar character were started, and in many cases pretended to act under charters which were either obsolete or insufficient for the purpose. The South Sea Company prosecuted these adventurers under the Bubble Act, but while it succeeded in exposing their real character it also helped thereby to weaken public confidence in its own. For a period of nearly ninety years the Bubble Act remained inoperative, but at the end of that period several cases under it were brought into court (Collyer *On Partnership*). At the same time, by 6 Geo. IV. c. 91 the Crown was enabled to grant charters of incorporation under which members might be made responsible for the corporation's debts. In 1834 the Crown was empowered to grant to companies by letters patent, without incorporation, the privilege of suing and being sued by a public officer. When a charter could not be obtained, companies might be incorporated, or empowered to plead by public officers, under special Acts of Parliament. For such corporate or quasi-corporate privileges application had to be made either to the Crown or Parliament. In 1826 banking companies were allowed to obtain the privilege of suing by public officer on complying with certain rules. In 1844, all companies (with some exceptions) were enabled to obtain a certificate of incorporation without applying for a charter or a special Act. Banking companies, however, were required to apply to the Crown for a charter. Members of companies thus created were still responsible, to the whole extent of their fortune, for the debts of the companies. In 1855 limited liability was introduced by 18 and 19 Vict. c. 133, shareholders being made responsible to the extent only of the amount of their shares. Companies with this privilege must use the word "limited" after their names. The dissolution and winding-up of insolvent companies remained to be simplified, and from 1846 to 1850 various measures were introduced, enabling different classes of companies to be wound up, without the usual process by bill to which the shareholders, as partners, necessarily had to appear. The legislative history of companies, thus briefly traced, exhibits their development out of simple partnerships in a not uninstructive manner. Partnerships in the eye of the law, they are looked upon by the Legislature as false pretenders to the character of corporations; they are at first denounced as nuisances, then tolerated, and gradually relieved one by one from those legal incidents of partnership which impede their functions in the organization of commerce. In 1862 a consolidation of the numerous Acts relating to companies was effected by the Act for the incorporation, regulation, and winding-up of trading companies and other associations, which gave to the Court of Chancery exclusive jurisdiction in winding-up. The following are a few of the chief provisions of this important Act. It prohibits the formation of any company, association, or partnership, of more than ten persons for the business of banking, and of more than twenty persons for any business having for its object the acquisition of gain, unless it is registered under this Act. Companies, formed by Act of Parliament or letters patent, or engaged in mining within the jurisdiction of the stannaries, are exceptions. Or, as it may be otherwise stated, all associations for the acquisition of gain, other than those last mentioned, and excluding banking partnerships of fewer than ten, or other trading societies of fewer than twenty members, will be illegal unless registered under this Act. Any seven or more persons, joining together for the pursuit of any lawful object, may form an incorporated company by subscribing a memorandum of association and registering. The liability of members may be unlimited, or it may be limited to the amount unpaid of the nominal value of their shares, or to sums guaranteed. The memorandum of association must contain particulars as to the name, object, &c., of the proposed company; and companies limited by share or guarantee must use the word "limited" after their names. Companies limited by shares may, and other companies, whether limited by guarantee or unlimited, must also send articles of association, containing regulations for the management of the company. The Act contains in a schedule a table of regulations which may be adopted in such companies, and in the case of companies limited by shares will be held to apply, unless expressly modified or excluded by the articles. The memorandum and articles of association are sent to the registrar, who issues a certificate of incorporation, and the subscribers and persons joining them thereupon become a corporate body with perpetual succession, and a common seal, and power to hold lands, but with liability on the part of members to contribute to the assets of the company in the manner prescribed by the Act. Companies, not intended for the pursuit of gain, may not hold more than 2 acres of land without a licence from the Board of Trade. Part II. deals with the distribution of capital and liabilities of members of companies and associations under this Act. When a company is wound up, every present and past member shall be liable to contribute to the assets of the company, with the following (among other) qualifications:—No past member shall be liable, if he has ceased to be a member for a year before the winding-up, nor shall he be liable for any debt contracted by the company after he has ceased to be a member, nor unless present members are unable to satisfy the contributions required. Part III. contains provisions for the protection of creditors and of members. Part IV. treats of the winding-up of companies, which may be either by the court or voluntary. A company may be wound up by the court (*i.e.*, the Court of Chancery in England and Ireland, and Court of Session in Scotland) in the following cases, viz., when a special resolution of the company has been passed requiring it; when the company does not begin business within a year from its incorporation, or suspends business for a year; when the members are reduced to less than seven; when it is unable to pay its debts; and when the court thinks it ought to be wound up. Where a voluntary winding-up has been begun, the court may order it to be continued, subject to the supervision of the court. Part V. constitutes a registration office. Part VI. applies the Act to companies registered under the various Joint-Stock Companies Acts. Part VII. defines the companies "authorized to register under this Act." Part VIII. applies the Act to unregistered companies. Part IX. contains a repealing clause and some temporary provisions. After five years' experience of the original Act an amending Act was published in 1867, and the two are to be construed together. The Companies Act 1867 contains provisions facilitating changes in the constitution of companies. A limited company may have directors with unlimited liability. A company limited by shares may under certain conditions reduce its capital, or divide its capital or part thereof into shares of smaller amount than is fixed by the memorandum of association. Associations not intended for gain may have the privileges of limited liability without being compelled to use the word "limited" after their names. A company may have some shares fully paid and others not. A limited company may issue warrants for shares fully paid up, in name of bearer. There are several sections dealing with contracts made on behalf of a company, and one important section, the 38th, enacts that any prospectus not specifying such contracts shall be deemed fraudulent on the part of the promoters, &c., issuing the same, as regards any person taking shares in the company on the faith of such prospectus. This section was drawn to meet the practice of concealing from investors contracts which would be binding on the intended company when formed, and its somewhat ambiguous phraseology has been the subject of much discussion in the law courts. See, for example, *in re* Coal Economizing Gas Company—Lover's Case, *Law Reports* 1, Chancery Division 182.

The objects of certain trading companies, as, for example, railways, involve an interference with the rights of private persons, which requires the direct authority of the Legislature. Such undertakings are therefore authorized by special Acts of Parliament, which begin as private bills before one or other of the two Houses, and pass through both, and receive the assent of the sovereign in the same manner as public bills (see BILL). The principles on which state interference with private rights is thus granted have so far been ascertained and fixed by the practice of many parliaments, that the procedure in private bills has tended to assimilate itself more and more to an ordinary litigation. The committees are tribunals acknowledging certain rules of policy, and hearing evidence from witnesses and arguments from professional advocates. An important point in the history of this kind of legislation is marked by the three Consolidation Acts of 1845 (8 and 9 Vict.) The Companies Clauses Consolidation Act consolidates sundry provisions relating to the constitution and management of joint-stock companies, usually introduced into Acts of Parliament authorizing the execution of undertakings of a public nature by such companies. The Lands Clauses Consolidation Act applies to undertakings authorized by special Act to take or purchase land. The Railways Clauses Consolidation Act applies to Acts authorizing the construction of railways. The clauses of the Consolidation Acts are to be taken as incorporated in a special Act of the class in question, unless they are expressly varied or excepted thereby. A further development of the same tendency may be observed in proposals which have been made from time to time to hand over the authority of Parliament, in relation to such companies, to a permanent tribunal.

Livery Companies.—These societies, now chiefly remarkable as a feature in the municipal organization of London, belong to a class of institutions which at one time were universally prevalent in Europe. In most other countries they have disappeared; in England, while their functions have wholly changed, the organization remains. The origin of the city companies is to be found in the craftgilds of the Middle Ages. The absence of a strong central authority, such as we are now accustomed to, doubtless accounts for the tendency to confederation in the beginning of modern societies. Artificial groups, formed in imitation of the family, discharged the duties which the family was no longer able, and which the state was not yet able, to undertake. The inhabitants of towns were forced by external pressure into the societies known as gild-merchants, which in course of time monopolized the municipal government, became exclusive, and so caused the growth of similar societies among their excluded citizens. The craftgilds were such societies, composed of handicraftsmen, which entered upon a severe struggle for power with the earlier gilds and finally defeated them. The circumstances and results of the struggle are stated to have been of much the same character in England and on the Continent. In London the victory of the crafts is decisively marked by the ordinance of the time of Edward II., which required every citizen to be a member of some trade or mystery, and by another ordinance in the 49th of Edw. III., which transferred the right of election of corporate officers (including members of Parliament) from the ward-representatives to the trading companies. Henceforward, and for many years, the companies engrossed political and municipal power in the city of London.

The trading fraternities assumed generally the character of corporations in the reign of Edward III. Many of them had been chartered before, but their privileges, hitherto exercised only on sufferance and by payment of their terms, were now confirmed by letters patent. Edward III. himself became a member of the fraternity of Linen Armourers, or Merchant Taylors, and other distinguished persons followed his example. From this time forward they are called livery companies, "from now generally assuming a distinctive dress or livery." The origin of the Grocers' Company is thus described:—"Twenty-two persons, carrying on the business of pepperers in Soper's Lane, Cheapside, agree to meet together, to a dinner, at the Abbot of Bury's, St Mary Axe, and commit the particulars of their formation into a trading society to writing. They elect after dinner two persons of the company so assembled—Roger Osekyn and Lawrence de Hallwell—as their first governors or wardens, appointing, at the same time, in conformity with the pious custom of the age, a priest or chaplain to celebrate divine offices for their souls" (Heath's "Account of the Grocers' Company," quoted in Herbert's *Twelve Great Livery Companies*, vol. i. p. 43). The religious observances and the common feasts were characteristic features of those institutions. They were therefore not merely trade unions in the current meaning of that phrase, but may rather be described as forms of industrial self-government, the basis of union being the membership of a common trade, and the authority of the society extending to the general welfare, spiritual and temporal, of its members. It must be remembered that they flourished at a time when the separate interests of master and servant had not yet been created; and indeed, when that fundamental division of interests arose, the companies gradually lost their functions in the regulation of industry. The fact that the craftsmen were a homogeneous order will account for the wide authority claimed by their societies, and the important public powers which were conceded to them. Their regulations, says Herbert, "chiefly regarded the qualifications of members, keeping of their trade secrets, the regulations of apprenticeship and of the company's peculiar concerns, the domestic management of the fraternity and its funds, and the uniting together of it in brotherly love and affection. To these may be added, as forming a prominent feature in all the ancient communities, the regulation of their religious and other ceremonies." In the regulation of trade they possessed extensive powers. They required every one carrying on the trade to join the company. In the 37th of Edward III., in answer to a remonstrance against the mischief caused by "the merchants called grocers who engrossed all manner of merchandize vendable, and who suddenly raised the prices of such merchandize within the realm," it was enacted "that all artificers and people of mysteries shall each choose his own mystery before next Candlemas, and that, having so chosen it, he shall henceforth use no other." Dr Brentano (*On Gilds*) holds that it is wrong to represent such regulations as monopolistic, inasmuch as there was no question whatever of a monopoly in that time nor until the degeneration of the craftgilds into limited corporations of capitalists. In the regulation of trade the right of search was an important instrument. The wardens of the grocers are to "assayen weights, powders, confeccions, platers, oyntments, and all other things belonging to the same crafte." The goldsmiths had the assay of metals, the fishmongers the oversight of fish, the vintners of the tasting of wine, &c. The companies enforced their regulations on their members by force. Many of their ordinances looked to the domestic affairs and private conduct of the members. The grocers ordain "that no man of the fraternite take his neyghbor's house y[t] is of the same fraternite, or enhaunce the rent against the will of the foresaid neyghbor." Perjury is to be punished by the wardens and society with such correction as that other men of the fellowship may be warned thereby. Members reduced to poverty by adventures on the sea, increased price of goods, borrowing and pledging, or any other misfortune, are to be assisted "out of the common money, according to his situation, if he could not do without."

Following what appears to be the natural law of their being, the companies gradually lost their industrial character. The course of decay would seem to have been the following. The capitalists gradually assumed the lead in the various societies, and the richer members engrossed the power, and the companies tended to become hereditary and exclusive. Persons might be members who had nothing to do with the craft, and the rise of great capitalists and the development of competition in trade made the regulation of industry by means of companies no longer possible. For an account of the "degeneration of craftgilds" a general reference may be made to Brentano *On Gilds*, c. iv. The usurpation of power on the part of the richer members was not always effected without opposition. Brentano refers to a pamphlet on the Clothworkers' Company, published in 1649, which asserts that "the commonalty" in the old charters meant, not the whole gild, but only the masters, wardens, and assistants. Herbert records a most interesting dispute in the Goldsmiths' Company in 1529. The mode of electing officers, and the system of management generally, was challenged by three members who called themselves "artificers, poor men of the craft of goldsmiths." The company, or rather the wardens, the assistants, and livery, presented a petition to the lord mayor, which was answered by the discontented craftsmen. The dispute was carried into the Court of Chancery and the Star Chamber. The artificers accused the company of subverting their grants, misappropriating the funds, and changing the constitution of the society, and they complain of this being done by the usurpation of persons who "were but merchant goldsmiths, and had but little knowledge in the science." In 1531 the three complainants were summarily expelled from the company, and then the dispute seems to have ended. In the last stage of the companies the members have ceased to have any connection with the trades, and in most cases their regulative functions have disappeared. The one characteristic which has clung to them throughout is that of owners of property and managers of charitable trusts. The connection between the companies and the municipality is shortly as follows. The ordinance of Edward II. required freemen of the city to be members of one or other of the companies. By the ordinance of 49 Edw. III. the trading companies were to nominate the members of common council, and the persons so nominated alone were to attend both at common councils and at elections. An ordinance in 7 Richard II. restored the elections of common councilmen to the wards, but corporate officers and representatives in Parliament were elected by a convention summoned by the lord mayor from the nominees of the companies. An Act of Common Council in 7 Edw. IV. appointed the election of mayor, sheriffs, &c., to be in the common council, together with the masters and wardens of the companies By 15 Edw. IV. masters and wardens were ordered to associate with themselves the honest men of their mysteries, and come in their best liveries to the elections; that is to say, the franchise was restricted to the "liverymen" of the companies. At this time the corporation exercised supreme control over the companies, and the companies were still genuine associations of the traders and householders of the city. The delegation of the franchise to the liverymen was thus, in point of fact, the selection of a superior class of householders to represent the rest. When the corporation lost its control over the companies, and the members of the companies ceased to be traders and householders, the liverymen were no longer a representative class, and some change in the system became necessary. The Act 11 Geo. II. c. 18, and the Reform Acts of 1832 and 1867, reformed the representation in several particulars. The liverymen of the companies, being freemen of the city, have still, however, the exclusive power of electing the lord mayor, sheriffs, chamberlain, and other corporate officers.

The contributions made by the companies to the public purposes of the state and the city are interesting points in their early history. Their wealth and their representative character made them a most appropriate instrument for the enforcement of irregular taxation. The loan of £21,263, 6s. 8d. to Henry VIII. for his wars in Scotland, in 1544, is believed by Herbert to be the first instance of a pecuniary grant to the Crown, but the practice rapidly gained ground. The confiscation of ecclesiastical property at the time of the Reformation affected many of the trusts of the companies; and they were compelled to make returns of their property devoted to religious uses, and to pay over the rents to the Crown. In course of time the taxation of the companies became "a regular source of supply to Government." The historians of the city have for the most part described these as unjust and tyrannical exactions, but, looking at the representative and municipal character of the companies and the purposes to which their contributions were applied, we may regard them as a rough but not unfair mode of taxation. The Government, when money was wanted for public works, informed the lord mayor, who apportioned the sums required among the various societies, and issued precepts for its payment. Contributions towards setting the poor to work, erecting the Royal Exchange, cleansing the city ditch, discovering new countries, furnishing military and naval armaments, for men, arms, and ammuniton for the defence of the city, are among what Herbert calls the sponging expedients of the Government. The Crown occasionally interfered in a more unjustifiable manner with the companies in the exercise of their patronage. The Stuarts made strenuous efforts to get the control of the companies. Terrified by the proceedings in the *quo warranto* case, most of the companies surrendered their charters to the Crown, but such surrenders were annulled by the Act of 2 William and Mary reversing the judgment in *quo warranto* against the city. The livery companies now in existence are the following:—

Apothecaries.
Armourers and Braziers.
Bakers.
Barbers.
Basket Makers.
Blacksmiths
Bowyers.
Brewers.
Broderers.
Butchers.
Carmen.
Carpenters.
Clockmakers.
Clothworkers.
Coach and Coach-harness Makers.
Cooks.
Coopers.
Cordwainers.
Curriers.
Cutlers.
Distillers.
Drapers.
Dyers.
Fan Makers.
Farriers.
Fellowship Porters.
Felt Makers.
Fishmongers.
Fletchers.
Founders.
Framework Knitters.
Fruiterers.
Girdlers.
Glass-sellers.
Glaziers.
Glovers.
Gold and Silver Wire-drawers.
Goldsmiths.
Grocers.
Gunmakers.
Haberdashers.
Horners.
Innholders.
Ironmongers.
Joiners.
Leathersellers.
Loriners.
Makers of Playing Cards.
Masons.
Mercers.
Merchant Taylors.
Musicians.
Needlemakers.
Painter Stainers.
Parish Clerks.
Pattern Makers.
Pewterers.
Plasterers.
Plumbers.
Poulterers.
Saddlers.
Salters.
Scriveners.
Shipwrights.
Silkthrowsters.
Skinners.
Spectacle Makers.
Stationers.
Tallow Chandlers.
Tilers and Bricklayers.
Tinplate Workers.
Turners.
Upholsterers.
Vintners.
Watermen.
Wax Chandlers.
Weavers.
Wheelwrights.
Woolmen.

The following are the twelve great companies:—Mercers, Grocers, Drapers, Fishmongers, Goldsmiths, Skinners, Merchant Taylors, Haberdashers, Salters, Ironmongers, Vintners, Cloth-workers. The "Irish Society" was incorporated in the 11 James I. as "the governor and assistants of the new plantation in Ulster, within the realm of Ireland." The twelve companies contributed in equal portions the sum of £60,000 for the new scheme, by which it was intended to settle a Protestant colony in the lands forfeited by the Irish rebels. The companies divided the settlement into twelve nearly equal parts, assigning one to each, but the separate estates are still held to be under the paramount jurisdiction of the Irish Society. The charter of the society was revoked by the Court of Star Chamber in the reign of Charles I., but a new one was granted by Charles II., under which the society still acts.

Most of the companies administer charities of large but unascertained value. Many of them are governors of important schools, *e.g.*, the Skinners have the Tonbridge Grammar School; the Mercers, St Paul's School; the Merchant Taylors, the school bearing their name, &c. There is no exact information to be had as to the value of these trusts, or the manner in which they are administered. The *History of the Twelve Great Livery Companies*, by W. Herbert (London, 1837), may be referred to on this subject.

Admission to the companies is now subject to the payment of considerable fees. For example, in the Merchant Taylors the fees are—Upon taking up the freedom, by patrimony or servitude, £1, 3s. 4d., by redemption, £84; on admission to the livery, £80, 8s.; on election to the Court of Assistants, £115, 10s. The hospitality of the companies is well-known. The advantages of being a member, still more of being a liveryman or assistant, of one of the rich companies are doubtless considerable. There are indications that the position of the city companies is likely to be for some time to come the subject of political discussion. It may be briefly said that they are being threatened on two sides—on one side by those who desire to see extensive reforms in the municipal organization of the metropolis; and on the other by those who wish to carry forward the process of inspection and revision of endowments, which has already overtaken the universities, schools, and other charities. (E. R.)

COMPARATIVE ANATOMY is the term employed to express that branch of anatomy in which the construction, form, and structure of two or more animals are compared with each other, so as to bring out their features of similarity or dissimilarity. It is sometimes used, in contrast with the term human anatomy, to signify the anatomy of the lower animals, but this is an imperfect and inexact use of the term, as the anatomy of man may be made comparative when it is examined in comparison with that of animals. The study of comparative anatomy is of especial importance to the physiologist, the embryologist, the veterinarian, and the zoologist. To the physiologist because, from the comparison of the bodies of different animals with each other, modifications in the size, form, and structure of any particular organ can be traced, and conclusions can be drawn on the importance of the function of the organ in the economy. Moreover, with a knowledge of comparative anatomy, the physiologist can conduct experiments on animals which have organs similar in structure to those of man, and determine their function more precisely than would be possible in the human body. To the veterinarian a knowledge of the comparative anatomy of the domestic animals is essential to the study of their diseases. To the embryologist, a knowledge of the anatomy of different animals throws light on the signification of the structural changes which the body of any particular animal passes through in the course of its development. To the zoologist, a knowledge not only of the external form but of the internal structure of animals is essential in order that he may frame a precise system of classification. In the present work the anatomy of the different great classes and some of the more important orders of the animal kingdom is arranged under special heads—that of the amphibia under AMPHIBIA, of birds under BIRDS, of monkeys under APES, &c. See also ANATOMY, vol. i. pp. 799 and 818.

COMPASS, THE MARINER'S, consists of three principal parts,—the card, the needle on its lower surface, and the case. The whole is enclosed in the compass-box, or binnacle. The term compass is said to have been applied to the instrument because the card involves or compasses the whole plane of the horizon, or because the needle indicates the whole circle of possible variations of direction. The surface of the card is divided by radiating lines into 32 parts, each containing 11° 15′; these constitute the 32 points or rhumbs; the half-points and quarters are subdivisions of the same. The north pole is denoted on the card by a *fleur-de-lis*[1]; and the line which joins the north and south poles passes through the axis of the needle. The points are named according to their proximity to the four cardinal points; for instance, the point mid-way between N. and N.E. is called north-north-east, being nearer north than east, and is marked N.N.E; the point mid-way between N. and N.N.E. is termed north by east, and is marked N. by E. The circumference of the card is sometimes divided into 360°. The divisions of the card are shown in the accompanying figure. The card is directed by the needle,

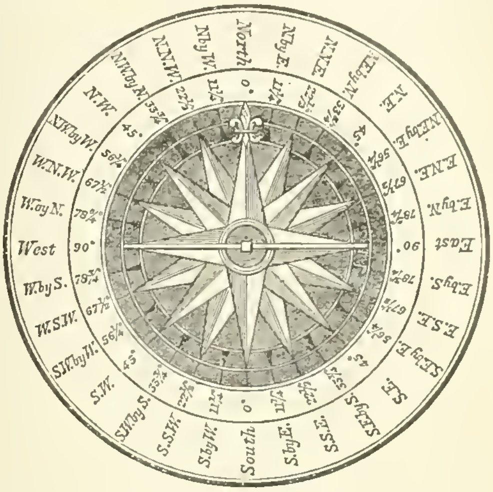

FIG. 1.—Compass Card.

which, with it, is pivoted on a vertical axis. With a little variation, the needle points nearly to the geographical north, and hence the mode of steering by the compass. Four or more parallel magnets, with like poles pointing in like directions, may be combined to form the needle; and by this arrangement the magnetic moment is increased for a given weight of steel. The needle is usually suspended on a central cap of ruby or agate, the point of suspension being of a similar hard material. On the inside of the compass-box is a vertical line known as lubber's point; and since this and the pivot of the card are in the same plane with the ship's keel, the point on the circumference of the card opposite to lubber's point shows the angle the ship's course makes with the magnetic meridian. The compass is kept horizontal by the use of a gimbal, or ring moving freely on an axis, within which it swings on an axis at right angles. In the azimuth compass the circumference of the card is divided into degrees and parts by a vernier, and is fitted up with sight-vanes to take amplitudes and azimuths, for the purpose of determining the variation of the compass by observation. The variation is applied to the magnetic course shown by the steering compass, and thus the true course with respect to the meridian becomes known.

The conditions that chiefly affect the use of the mariner's compass are those of the magnetic declination and deviation. The declination is the angle contained between the geographical or true and the magnetic meridian; or, as Barlowe defines it, the swerving of the pointing of the magnetical needle in the horizon from the meridian line there. The angle of declination varies according to locality, and must be ascertained at sea by means of the

[1] According to Mr T. S. Davies, this may originally have been an ornamented cross.

azimuth compass. The discovery of the variation of declination was made by Stephen Burrowes when voyaging between the north cape of Finmark and Vaigatch (Vaygates), and was afterwards determined by Gillebrand, professor of geometry at Gresham College. In 1683, in a communication to the Royal Society (*Phil. Trans.*, June 16, p. 214), Dr E. Halley shows that the irregularity observed in the variations of the compass at sea is not due to the attraction of the land, and comes to the conclusion that the whole globe of the earth is one great magnet, having four magnetical poles or points of direction. The declination for any place is subject to secular variations: thus, at Paris in 1681, it was 2° 30′ to the W., in 1865 it was 18° 44′ W. Halley, in a paper entitled "Account of the Cause of the Change of the Variation of the Magnetical Needle" (*Phil. Trans.*, Oct. 19, 1692, pp. 563-578), points out, with other instances of secular variation, that between 1580 and 1692 the direction of the needle at London changed from 11° 15′ E. to 6° W., or more than 17°, and demonstrates that the direction is in no place fixed or constant, though in some places it changes faster than in others. Besides the secular, there are annual and diurnal variations of small amount. The existence of the latter was discovered by Mr Graham about 1719. The deviation of the compass is the departure of the north and south line from the magnetic meridian, owing to the magnetism of the ship itself, or that induced in it by the earth's magnetic force. It was first observed during 1772-74 by Mr Wales, the astronomer of Captain Cook. When surveying along the coast of New Holland in 1801 and 1802, Captain Matthew Flinders made the discovery that there was a difference in the direction of the magnetic needle, according as his ship's head pointed to the E. or W.—westerly in the former, easterly in the latter case. When the ship's head was N. or S. the needle took the same direction, or nearly so, that it would on shore, and showed a variation from the true meridian which was about a medium between that given by it when east and when west. He found, also, that the error in variation was nearly proportionate to the number of points which the ship's head was from the north or south. (*Phil. Trans.*, 1805, p. 186.) The deviation in wooden ships can be practically obviated, but in iron ships it has to be partly allowed for, partly compensated. Barlow used a correcting plate of iron to overcome the directive action on the compass due to the magnetism of wooden vessels. On Professor Airy's method, the permanent magnetism of ships is compensated by a steel magnet placed at a given distance below the compass; it is, however, liable to changes of intensity, occasioned by shocks, vibration, unequal heating, and other causes, a fact which led the late Dr Scoresby to propose the employment of a compass aloft, out of the region of the ship's influence. The induced magnetism of ships can be only imperfectly compensated, since it varies according to the ship's bearing, and as she rolls and pitches; but corrections can be made for the heeling error. The discovery of the dip of the magnetic needle is ascribed by Gilbert to Robert Norman, a nautical instrument maker at Wapping, who, about 1590, introduced the employment of a sliding weight on the needle for the correction of the dip at different points of the earth's surface.

The earliest references to the use of the compass are to be found in Chinese history, from which we learn how, in the sixty-fourth year of the reign of Ho-ang-ti (2634 B.C.), the emperor Hiuan-yuan, or Ho-ang-ti, attacked one Tchi-yeou, on the plains of Tchou-lou, and finding his army embarrassed by a thick fog raised by the enemy, constructed a chariot (Tchi-nan) for indicating the south, so as to distinguish the four cardinal points, and was thus enabled to pursue Tchi-yeou, and take him prisoner. (Klaproth, *Lettre à M. le Baron Humboldt sur l'invention de la Boussole*, Paris, 1834. See also Mailla, *Histoire générale de la Chine*, tom i. p. 316. Paris, 1777.) Several other allusions to the compass are contained in early Chinese records. The power of the loadstone to communicate polarity to iron is said to be for the first time explicitly mentioned in a Chinese dictionary, finished in 121 A.D., where the loadstone is defined as "a stone with which an attraction can be given to the needle." The first mention of the use of the compass for the purpose of navigation—an art that has apparently retrograded rather than advanced among the Chinese—occurs in the Chinese encyclopædia, *Poei-wen-yun-fou*, in which it is stated that under the Tsin dynasty, or between 265 and 419 A.D., "there were ships directed to the south by the needle." The Chinese, Mr Davis informs us, once navigated as far as India, but their most distant voyages at present extend not further than Java and the Malay Islands to the south (*The Chinese*, vol. iii. p. 11, London, 1844). According to an Arabic manuscript, a translation of which was published by Eusebius Renaudot (Paris, 1718), they traded in ships to the Persian Gulf and Red Sea in the 9th century. Staunton, in vol. i. of his *Embassy to China* (London, 1797), after referring to the early acquaintance of the Chinese with the property of the magnet to point southwards, remarks (p. 445), "The nature and the cause of the qualities of the magnet have at all times been subjects of contemplation among the Chinese. The Chinese name for the compass is *ting-nan-ching*, or needle pointing to the south; and a distinguishing mark is fixed on the magnet's southern pole, as in European compasses upon the northern one." "The sphere of Chinese navigation," he tells us (p. 447), "is too limited to have afforded experience and observation for forming any system of laws supposed to govern the variation of the needle. . . . The Chinese had soon occasion to perceive how much more essential the perfection of the compass was to the superior navigators of Europe than to themselves, as the commanders of the 'Lion' and 'Hindostan,' trusting to that instrument, stood out directly from the land into the sea." The number of points of the compass, according to the Chinese, is twenty-four, which are reckoned from the south pole; the form also of the instrument they employ is different from that familiar to Europeans. The needle is peculiarly poised, with its point of suspension a little below its centre of gravity, and is exceedingly sensitive; it is seldom more than an inch in length, and is less than a line in thickness. It appears thus sufficiently evident that the Chinese are not indebted to Western nations for their knowledge of the use of the compass. "It may be urged," writes Mr T. S. Davies, "that the different manner of constructing the needle amongst the Chinese and European navigators shows the independence of the Chinese of us, as theirs is the *worse* method, and had they copied from us, they would have used the better one" (Thomson's *British Annual*, 1837, p. 291). On the other hand, it does not seem improbable that a knowledge of the mariner's compass was communicated by them directly or indirectly to the early Arabs, and through the latter was introduced into Europe. Sismondi has remarked (*Literature of Europe*, vol i.) that it is peculiarly characteristic of all the pretended discoveries of the Middle Ages that when the historians mention them for the first time they treat them as things in general use. Gunpowder, the compass, the Arabic numerals, and paper, are nowhere spoken of as discoveries, and yet they must have wrought a total change in war, in navigation, in science, and in education. Tiraboschi (*Storia della Letteratura Italiana*, tom. iv. lib. ii. p. 204, *et seq.*, ed. 2., 1788), in support of the conjecture that the compass was introduced into Europe by the Arabs, adduces their superiority in scientific learning, and their early skill in navigation. He quotes a passage on the polarity of the loadstone from a treatise translated by Albertus Magnus, attributed by the latter to Aristotle, but apparently only an Arabic compilation from the works of various philosophers. As the terms *Zoron* and *Aphron*, used there to signify the south and north poles, are neither Latin nor Greek, Tiraboschi suggests that they may be of Arabian origin, and that the whole passage concerning the loadstone may have been added to the original treatise by the Arabian translators.

Dr W. Robertson asserts (*Historical Disquisition concerning Ancient India*, p. 227) that the Arabs, Turks, and Persians have no original name for the compass, it being called by them *Bossola*, the Italian name, which shows that the thing signified is foreign to them as well as the word. The Rev. G. P. Badger has, however, pointed out (*Travels of Ludovico di Varthema*, trans., J. W. Jones, ed. G. P. Badger, Haklnyt Soc., 1863, note, pp. 31 and 32) that the name of Bushla or Busba, from the Italian *Bussola*, though common among Arab sailors in the Mediterranean, is very seldom used in the Eastern seas,—*Dairah* and *Beit el-Ibrah* (the Circle, or House of the Needle) being the ordinary appellatives in the Red Sea, whilst in the Persian Gulf *Kiblah-nâmeh* is in more general use. Robertson quotes Sir J. Chardin as boldly asserting "that the Asiatics are beholden to us for this wonderful instrument, which they had from Europe a long time before the Portuguese conquests. For, first, their compasses are exactly like ours, and they buy them of Europeans as much as they can, scarce daring to meddle with their needles themselves. Secondly, it is certain that the old navigators only coasted it along, which I impute to their want of this instrument to guide and instruct them in the middle of the ocean. . . . I have nothing but argument to offer touching this matter, having never met with any person in Persia or the Indies to inform me when the compass was first known among them, though I made inquiry of the most learned men in both countries. I have sailed from the Indics to Persia in Indian ships, when no European has been aboard but myself. The pilots were all Indians, and they used the forestaff and quadrant for their observations. These instruments they have from us, and made by our artists, and they do not in the least vary from ours, except that the characters are Arabic. The Arabs are the most skilful navigators of all the Asiatics or Africans; but neither they nor the Indians make use of charts, and they do not much want them; some they have, but they are copied from ours, for they are altogether ignorant of perspective." The observations of Chardin, who flourished between 1643 and 1713, cannot be said to receive support from the testimony of some earlier authorities. That the Arabs must have been acquainted with the compass, and with the construction and use of charts, at a period nearly two centuries previous to Chardin's first voyage to the East, may be gathered from the description given by Barros of a map of all the coast of India, shown to Vasco da Gama by a Moor of Guzerat (about the 15th July 1498), in which the bearings were laid down "after the manner of the Moors," or "with meridians and parallels very small (or close together), without other bearings of the compass; because, as the squares of these meridians and parallels were very small, the coast was laid down by these two bearings of N. and S., and E. and W., with great certainty, without that multiplication of bearings of the points of the compass usual in our maps, which serves as the root of the others." Further, we learn from Osorio that the Arabs at the time of Gama "were instructed in so many of the arts of navigation, that they did not yield much to the Portuguese mariners in the science and practice of maritime matters." (See *The Three Voyages of Vasco da Gama*, Hakluyt Soc., 1869; note to chap. xv. by the Hon. H. E. J. Stanley, p. 138.) Also the Arabs that navigated the Red Sea at the same period are shown by Varthema to have used the mariner's chart and compass (*Travels*, p. 31).

Again, it appears that compasses of a primitive description, which can hardly be supposed to have been brought from Europe, were employed in the East Indies certainly as early as several years previous to the close of the 16th century. In William Barlowe's *Navigator's Supply*, published in 1597, we read:—"Some fewe yeeres since, it so fell out that I had severall conferences with two East Indians which were brought into England by master Candish [Thomas Cavendish], and had learned our language: The one of them was of Mamillia [Manilla] in the Isle of Luzon, the other of Miaco in Japan. I questioned with them concerning their shipping and manner of sayling. They described all things farre different from ours, and shewed, that in steade of our Compas, they use a magneticall needle of sixe ynches long, and longer, upon a pinne in a dish of white *China* earth filled with water; In the bottome whereof they have two crosse lines, for the foure principall windes; the rest of the divisions being reserved to the skill of their Pilots." Bailak Kibdjaki, also, an Arabian writer, shows in his *Merchant's Treasure*, a work given to the world in 1282, that the magnetized needle, floated on water by means of a splinter of wood or a reed, was employed on the Syrian seas at the time of his voyage from Tripoli to Alexandria (1242), and adds:—"They say that the captains who navigate the Indian seas use, instead of the needle and splinter, a sort of fish made out of hollow iron, which, when thrown into the water, swims upon the surface, and points out the north and south with its head and tail" (Klaproth, *Lettre*, p. 57). Furthermore, although the sailors in the Indian vessels in which Niccola de'Conti traversed the Indian seas in 1420 are stated to have had no compass, still, on board the ship in which Varthema, less than a century later, sailed from Borneo to Java, both the mariner's chart and compass were used; it has been questioned, however, whether in this case the compass was of Eastern manufacture (*Travels of Varthema*, Introd. xciv., and p. 249). We have already seen that the Chinese as late as the end of the 18th century made voyages with compasses on which but little reliance could be placed; and it may perhaps be assumed that the compasses early used in the East were mostly too imperfect to be of much assistance to navigators, and were therefore often dispensed with on customary routes. The simple water-compass is said to have been used by the Coreans so late as the middle of the 18th century; and Dr T. Smith, writing in the *Philosophical Transactions* for 1683–4, says of the Turks (p. 439), "They have no genius for Sea-voyages, and consequently are very raw and unexperienced in the art of Navigation, scarce venturing to sail out of sight of land. I speak of the natural *Turks*, who trade either into the *black Sea* or some part of the *Morea*, or between *Constantinople* and *Alexandria*, and not of the Pyrats of *Barbary*, who are for the most part Renegado's, and learnt their skill in Christendom. . . . . . The Turkish compass consists but of 8 points, the four Cardinal and the four Collateral." That the value of the compass was thus, even in the latter part of the 17th century, so imperfectly recognized in the East may serve to explain how in earlier times that instrument, long after the first discovery of its properties, may have been generally neglected by navigators.

The Saracen geographer, Edrisi, who lived about 1100, is said by Boucher to give an account, though in a confused manner, of the polarity of the magnet (Hallam, *Mid. Ages*, vol. iii. chap. 9, part 2); but the earliest definite mention as yet known of the use of the mariner's compass in the Middle Ages occurs in a treatise entitled *De Utensilibus*, written by Alexander Neckam in the 12th century. He speaks there of a needle carried on board ship which, being placed on a pivot, and allowed to take its own position of repose, shows mariners their course when the polar star is hidden. In another work, *De Naturis Rerum*, lib. ii. c. 89, he writes,—"Mariners at sea, when, through cloudy weather in the day which hides the sun, or through the darkness of the night, they lose the knowledge of the quarter of the world to which they are sailing, touch a needle with the magnet, which will turn round till, on its motion ceasing, its point will be directed towards the north" (W. Chappell, *Nature*, No. 346, June 15, 1876). The magnetical needle, and its suspension on a stick or straw in water, are clearly described in *La Bible Guiot*, a poem probably of the 13th century, by Guiot de Provins, wherein we are told that through the magnet (*la manette* or *l'amanière*), an ugly brown stone to which iron turns of its own accord, mariners possess an art that cannot fail them. A needle touched by it, and floated by a stick on water, turns its point towards the pole-star, and a light being placed near the needle on dark nights, the proper course is known (*Hist. littéraire de la France*, tom. ix. p. 199; Barbazan, *Fabliaux*, tom. ii. p. 328). Cardinal Jacques de Vitry, bishop of Acon in Palestine, in his *History* (cap. 89), written about the year 1218, speaks of the magnetic needle as "most necessary for such as sail the sea;"[1] and another French crusader, his contemporary, Vincent de Beauvais, states that the adamant (loadstone) is found in Arabia, and mentions a method of using a needle magnetized by it which is similar to that described by Kibdjaki. From quotations given by Antonio Capmany (*Questiones Criticas*) from the *De Contemplatione* of Raymond Lully, of the date 1272, it appears that the latter was well acquainted with the use of the magnet at sea;[2] and before the middle of the 13th century Gauthier d'Espinois alludes to its polarity, as if generally known, in the lines:—

"Tous autresi comme l'aimant decoit [detourne,
L'aiguillette par force de vertu,
A ma dame tot le mont [monde] retenue
Qui sa beauté connoit et aperçoit."

Guido Guinizzelli, a poet of the same period, writes:—"In those parts under the north are the mountains of loadstone, which give the virtue to the air of attracting iron; but because it [the loadstone] is far off, [it] wishes to have the help of a similar stone to make it [the virtue] work, and to direct the needle towards the star."[3] Brunetto Latini also makes reference to the compass in his encyclopædia *Livres dou trésor*, composed about 1260; and a letter written in 1269, attributed to Peter Adsiger, shows that the declination of the needle had already been observed at that date. From Torfæus we learn that the compass, fitted into a box, was already in use among the Norwegians about the middle of the 13th century (*Hist. Rer. Norvegicarum*, iv. c. 4, p. 345, Hafniæ, 1711); and it is probable that the use of the magnet at sea was known in Scotland at or shortly subsequent to that time, though King Robert, in crossing from Arran to Carrick in 1306, as Barbour writing in 1375 informs us, "na nedill had na stane," but steered by a fire on the shore.

From the above it will have been evident that, as Barlowe remarks concerning the compass, "the lame tale of one Flavius at Amelphus, in the kingdome of Naples [Flavio Gioja of Amalphi, cir. 1307], for to have devised it, is of very slender probabilitie;" and as regards the assertion of Dr Gilbert, of Colchester (*De Magnete*, p. 4, 1600), that Marco Polo introduced the compass into Italy from the East in 1260,[4] we need only quote the words of Col. Yule (*Book of Marco Polo*):—"Respecting the mariner's compass and gunpowder, I shall say nothing, as no one now, I believe, imagines Marco to have had anything to do with their introduction."

When and by whom the card was added are still matters of conjecture; but the thirty-two points or rhumbs into which it is divided were recognized at least as early as the time of Chaucer, who, in 1391, wrote, "Now is thin Orisonte departed in xxiiii partiez by thi azymutz, in significacion of xxiiii partiez of the world; al be it so that ship men rikne thilke partiez in xxxii" (*Treatise on the Astrolabe*, ed. Skeat, Early Eng. Text Soc., Lond. 1872).

The improvement of the compass has been but a slow process. *The Libel of English Policie*, a poem of the first half of the 15th century, says with reference to Iceland (chap. x.)—

---

[1] Adamas in India reperitur . . . . . Ferrum occulta quadam natura ad se trahit. Acus ferrea postquam adamantem contigerit, ad stellam septentrionalem . . . . . semper convertitur, unde valde necessarius est navigantibus in mari.

[2] Sicut acus per naturam vertitur ad septentrionem dum sit tacta a magnete.—Sicut acus nautica dirigit marinarios in sua navigatione.

[3] Ginguené, *Hist. lit. de l'Italie*, t. i. p. 413.

[4] "According to all the texts he returned to Venice in 1295 or, as is more probable, in 1296."—Yule.

"Out of Bristowe, and costes many one,
Men haue practised by nedle and by stone
Thider wardes within a litle while."
Hakluyt, *Principal Navigations*, p. 201, Lond. 1599.

From this it would seem that the compasses used at that time by English mariners were of a very primitive description. Barlowe, in his treatise *Magnetical Advertisements*, printed in 1616 (p. 66), complains that "the Compasse needle, being the most admirable and usefull instrument of the whole world, is both amongst ours and other nations for the most part, so bungerly and absurdly contrived, as nothing more." The form he recommends for the needle is that of "a true circle, having his Axis going out beyond the circle, at each end narrow and narrower, unto a reasonable sharpe point, and being pure steele as the circle it selfe is, having in the middest a convenient receptacle to place the capitell in." In 1750 Dr Gowan Knight found that the needles of merchant-ships were made of two pieces of steel bent in the middle and united in the shape of a rhombus, and proposed to substitute straight steel bars of small breadth, suspended edgewise, and hardened throughout. He also showed that the Chinese mode of suspending the needle conduces most to sensibility. In 1820 Prof. Barlow reported to the Admiralty that half the compasses in the Royal Navy were mere lumber, and ought to be destroyed. Since then many improved varieties of ships' compasses have been introduced, of which may be mentioned those of Pope, Preston, Walker, Dent, Stebbing, Gowland, Gray, Duchemin, and Harris. In the last the needle turns upon a point which is the centre of a doubly-curved bar of copper, fixed as a diameter to a ring of the same metal. In the Admiralty compass the bowl is of copper, the card of mica; and compound magnetic bars, as proposed by Scoresby, are employed.

The most remarkable and, as shown by trial, most satisfactory form of the compass is that patented in 1876 by Sir William Thomson (see fig. 2). The card consists of a central boss and an

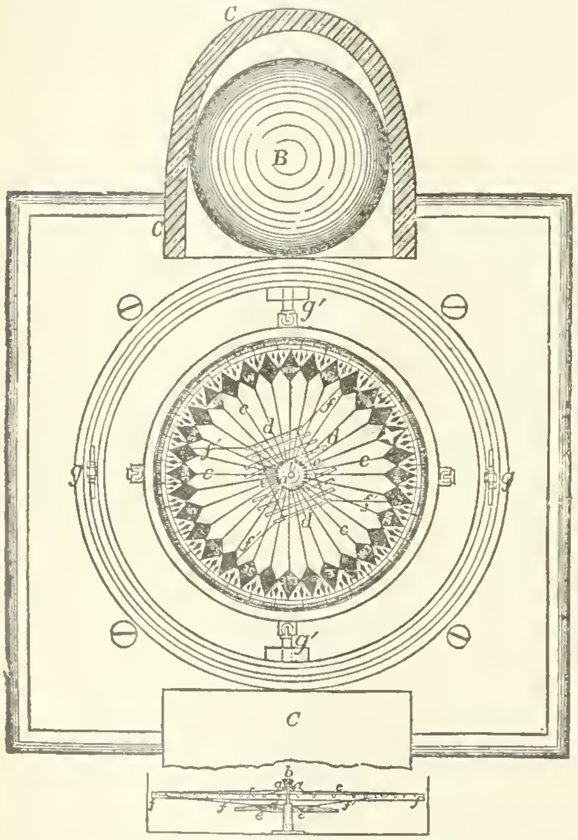

Fig. 2.—Plan and Transverse Section of Sir William Thomson's Compass-card.

B, Corrector for quadrantal error; C, Box for corrector; *g*, Aluminium boss; *b*, Central cap of sapphire; *c*, Cords connecting rim and boss; *d*, Magnets; *e*, Threads connecting magnets; *f*, Aluminium rim; *f*, Cords supporting magnets; *g*,*g′*, Knife edges for gimbals.

outer rim, both of aluminium, connected together by fine silk cords. Eight or twelve small magnets, 2 to 3 inches long, having their corresponding ends tied together by threads of equal lengths, are suspended by silk cords from the rim, to which is attached thin paper marked with the points of the compass and degrees. The concentration, in this wise, of the greater part of the weight in the rim gives a long period of free oscillation, and consequently great steadiness; and as the card of a 10-inch compass, with its suspended needle and sapphire, weighs only 178 grains, the frictional error is very slight. Owing to the smallness of the needles, a perfect correction for all latitudes of a quadrantal error of 5 or 6 degrees for a 10-inch, and of 11 or 12 degrees for a 7-inch compass can be effected by means of a couple of iron globes not more than 6 inches in diameter, fixed on opposite sides of the binnacle. The thwart-ship and the fore-and-aft components of the ship's magnetic force are neutralized by two adjustable correctors placed one over the other, and so arranged that in their zero position the middle line of both is vertically under the centre of the compass. Each corrector consists of two bar magnets movable round a common horizontal axis perpendicular to their lengths. To correct the heeling error, an adjustable magnet is applied below the compass in a line through its centre perpendicular to the deck. For taking bearings, a new instrument, the azimuth mirror, is provided, whereby the image of the object reflected from a plane mirror is thrown, as in a camera lucida, on the graduated circle of the compass card, and is seen through a convex lens. Another improvement is the use of knife edges instead of journals for supporting the gimbals. A hemispherical space below the compass-case, nearly filled with castor-oil, serves to calm the vibrations of the bowl.

COMPIÈGNE, a town of France, at the head of an arrondissement, in the department of Oise, situated on the left bank of the Oise, which is there crossed by a handsome bridge of three arches, 36 miles east of Beauvais, on the railway between Paris and St Quentin, in 49° 25′ 4″ N. lat. and 2° 49′ 35″ E. long. It is famous as the occasional residence of the French kings from a very early period; and it possesses a considerable number of fine edifices. Among these may be mentioned the church of St Jacques, of the 13th century; Saint Antoine, of the 15th and 16th; the town-house, a picturesque building of the late Gothic style, dating from the 16th; the theatre; and the royal palace, which is one of the most extensive and magnificent structures of the kind in France. It was erected mainly under Louis XV. and XVI., but large additions have been made in more recent times. The gardens are beautifully laid out, and in the neighbourhood is the famous forest of Compiègne, which covers an area of 30,000 acres, and includes the site of the camp constructed by Cæsar in his campaign against the Bellovaci. The town is the seat of a civil and a commercial tribunal, and has a communal college, a public library, and a museum in the town-hall. The principal manufactures are hosiery, muslins, ropes, and wooden wares; and there is a fair trade in corn and wood. Population in 1872, 11,859 in the town, and 12,281 in the commune.

Compiègne, or, as it is called in the Latin chronicles, Compendium, seems originally to have been a hunting-lodge of the early Frankish kings. It was enriched by Charles the Bald with two castles, and a Benedictine abbey dedicated to Saint Corneille, the monks of which retained down to the 18th century the privilege of acting for three days as lords of Compiègne, with full power to release prisoners, condemn the guilty, and even inflict sentence of death. It was in Compiègne that Louis the Debonnaire was deposed in 833; and at the siege of the town in 1430, Joan of Arc was taken prisoner by the English. The abbey church received the dust of Louis II., Louis V., and Hugh the Great; and for a long time it had the distinction of possessing the oldest organ in France, a gift from Constantine Copronymus to Pepin the Short. In 1624 the town gave its name to a treaty of alliance concluded by Richelieu with the Dutch; and it was in the palace that Louis XV. gave welcome to Marie Antoinette, that Napoleon I. received Marie Louise of Austria, that Louis XVIII. entertained the Emperor Alexander of Russia, and that Leopold king of the Belgians was married to the Princess Louise. Under Napoleon III. it was the annual resort of the court during the hunting season, and thus became the scene of many a remarkable assembly. In 1871 the town was an important post of communication between France and Germany.

COMPOSTELLA, a city of Spain in the Galician province of Coruña, more frequently called Santiago, in honour of its patron saint, St James, whose shrine was long one of the principal places of pilgrimage in Christendom. It gives its name to one of the four military orders of Spain which rank as follows:—Compostella, Calatrava, Alcantara, and Manresa. See SANTIAGO.

COMPTON HENRY (1632–1713), bishop of London, was the youngest son of the earl of Northampton. After the restoration of Charles II. he became cornet in a regiment of horse, but he soon quitted the army for the church. He was made bishop of Oxford in 1674, and in the following year was translated to the see of London. He was also appointed a member of the Privy Council, and intrusted with the education of the two princesses—Mary and Anne. Compton showed a liberality most unusual at the time to Protestant dissenters, whom he wished to reunite with the established church. He held several conferences on the subject with the clergy of his diocese; and in the hope of influencing candid minds by means of the opinions of unbiassed foreigners, he obtained letters treating of the question (since printed at the end of Stillingfleet's *Unreasonableness of Separation*), from Le Moyne, professor of divinity at Leyden, and the famous French Protestant divine, Claude. But to Roman Catholicism he was strongly opposed. On the accession of James II. he consequently lost his seat in the council and his deanery in the Chapel Royal; and for his firmness in refusing to suspend Dr Sharpe, whose writings against Popery had rendered him obnoxious to the king, he was himself suspended. At the Revolution, Compton embraced the cause of William and Mary; he performed the ceremony of their coronation; his old position was restored to him; and, among other appointments, he was chosen as one of the commissioners for revising the liturgy. During the reign of Anne he remained a member of the Privy Council, and he was one of the commissioners appointed to arrange the terms of the union of England and Scotland; but, to his bitter disappointment, his claims to the primacy were twice passed over.

He published, besides several theological works, *A Translation from the Italian of the Life of Donna Olympia Maladichini, who governed the Church during the time of Pope Innocent X., which was from the year* 1644 *to* 1655 (1667), and *A Translation from the French of the Jesuits' Intrigues* (1669).

COMTE, AUGUSTE, the most eminent and important of that interesting group of thinkers whom the overthrow of old institutions in France turned towards social speculation. Vastly superior as he was to men like De Maistre on the one hand, and to men like Saint Simon or Fourier on the other, as well in scientific acquisitions as in mental capacity, still the aim and interest of all his thinking was also theirs, namely, the renovation of the conditions of the social union. If, however, we classify him, not thus according to aim, but according to method, then he takes rank among men of a very different type from these. What distinguishes him in method from his contemporaries is his discernment that the social order cannot be transformed until all the theoretic conceptions that belong to it have been rehandled in a scientific spirit, and maturely gathered up into a systematic whole along with the rest of our knowledge. This presiding doctrine connects Comte with the social thinkers of the 18th century,—indirectly with Montesquieu, directly with Turgot, and more closely than either with Condorcet, of whom he was accustomed to speak as his philosophic father.

Isidore-Auguste-Marie-François-Xavier Comte was born in January 1798, at Montpellier, where his father was a receiver-general of taxes for the district. He was sent for his earliest instruction to the school of the town, and in 1814 was admitted to the École Polytechnique. His youth was marked by a constant willingness to rebel against merely official authority; to genuine excellence, whether moral or intellectual, he was always ready to pay unbounded deference. That strenuous application which was one of his most remarkable gifts in manhood showed itself in his youth, and his application was backed or inspired by superior intelligence and aptness. After he had been two years at the École Polytechnique he took a foremost part in a mutinous demonstration against one of the masters; the school was broken up, and Comte like the other scholars was sent home. To the great dissatisfaction of his parents, he resolved to return to Paris (1816), and to earn his living there by giving lessons in mathematics. Benjamin Franklin was the youth's idol at this moment. "I seek to imitate the modern Socrates," he wrote to a school friend, "not in talents, but in way of living. You know that at five and twenty he formed the design of becoming perfectly wise, and that he fulfilled his design. I have dared to undertake the same thing, though I am not yet twenty." Though Comte's character and aims were as far removed as possible from Franklin's type, neither Franklin nor any man that ever lived could surpass him in the heroic tenacity with which, in the face of a thousand obstacles, he pursued his own ideal of a vocation.

For a moment circumstances led him to think of seeking a career in America, but a friend who preceded him thither warned him of the purely practical spirit that prevailed in the new country. "If Lagrange were to come to the United States, he could only earn his livelihood by turning land surveyor." So Comte remained in Paris, living as he best could on something less than £80 a year, and hoping, when he took the trouble to break his meditations upon greater things by hopes about himself, that he might by-and-by obtain an appointment as mathematical master in a school. A friend procured him a situation as tutor in the house of Casimir Périer. The salary was good, but the duties were too miscellaneous, and what was still worse, there was an end of the delicious liberty of the garret. After a short experience of three weeks Comte returned to neediness and contentment. He was not altogether without the young man's appetite for pleasure; yet when he was only nineteen we find him wondering, amid the gaieties of the carnival of 1817, how a gavotte or a minuet could make people forget that thirty thousand human beings around them had barely a morsel to eat. Hardship in youth has many drawbacks, but it has the immense advantage over academic ease of making the student's interest in men real, and not merely literary.

Influence of Saint Simon

Towards 1818 Comte became associated as friend and disciple with a man who was destined to exercise a very decisive influence upon the turn of his speculation. Henry, count of Saint Simon, was second cousin of the famous duke of Saint Simon, the friend of the Regent, and author of the most important set of memoirs in a language that is so incomparably rich in memoirs. He was now nearly sixty, and if he had not gained a serious reputation, he had at least excited the curiosity and interest of his contemporaries by the social eccentricities of his life by the multitude of his schemes and devices, and by the fantastic ingenuity of his political ideas. Saint Simon's most characteristic faculty was an exuberant imagination, working in the sphere of real things. Scientific discipline did nothing for him; he had never undergone it, and he never felt its value. He was an artist in social construction; and if right ideas, or the suggestion of right ideas, sometimes came into his head, about history, about human progress, about a stable polity, such ideas were not the products of trains of ordered reasoning; they were the intuitional glimpses of the poet, and consequently as they professed to be in real matter, even the right ideas were as often as not accompanied by wrong ones.

The young Comte, now twenty, was enchanted by the philosophic veteran. In after-years he so far forgot himself as to write of Saint Simon as a depraved quack, and to deplore his connection with him as purely mischievous. While the connection lasted he thought very differently. Saint Simon is described as the most estimable and lovable of men, and the most delightful in his relations; he is the worthiest of philosophers. Even after the association had come to an end, and at the very moment when Comte was congratulating himself on having thrown off the yoke, he honestly admits that Saint Simon's influence has been of powerful service in his philosophic education. "I certainly," he writes to his most intimate friend, "am under great personal obligations to Saint Simon; that is to say, he helped in a powerful degree to launch me in the philosophical direction that I have now definitely marked out for myself, and that I shall follow without looking back for the rest of my life." Even if there were no such unmistakable expressions as these, the most cursory glance into Saint Simon's writings is enough to reveal the thread of connection between the ingenious visionary and the systematic thinker. We see the debt, and we also see that when it is stated at the highest possible, nothing has really been taken either from Comte's claims as a powerful original thinker, or from his immeasurable pre-eminence over Saint Simon in intellectual grasp and vigour and coherence. As high a degree of originality may be shown in transformation as in invention, as Molière and Shakespeare have proved in the region of dramatic art. In philosophy the conditions are not different. *Il faut prendre son bien où on le trouve.*

It is no detriment to Comte's fame that some of the ideas which he recombined and incorporated in a great philosophic structure had their origin in ideas that were produced almost at random in the incessant fermentation of Saint Simon's brain. Comte is in no true sense a follower of Saint Simon, but it was undoubtedly Saint Simon who launched him, to take Comte's own word, by suggesting to his strong and penetrating mind the two starting points of what grew into the Comtist system—first, that political phenomena are as capable of being grouped under laws as other phenomena; and second, that the true destination of philosophy must be social, and the true object of the thinker must be the reorganization of the moral, religious, and political systems. We can readily see what an impulse these far-reaching conceptions would give to Comte's meditations. There were conceptions of less importance than these, in which it is impossible not to feel that it was Saint Simon's wrong or imperfect idea that put his young admirer on the track to a right and perfected idea. The subject is not worthy of further discussion. That Comte would have performed some great intellectual achievement, if Saint Simon had never been born, is certain. It is hardly less certain that the great achievement which he did actually perform was originally set in motion by Saint Simon's conversation, though it was afterwards directly filiated with the fertile speculations of Turgot and Condorcet. Comte thought almost as meanly of Plato as he did of Saint Simon, and he considered Aristotle the prince of all true thinkers; yet their vital difference about Ideas did not prevent Aristotle from calling Plato master.

After six years the differences between the old and the young philosopher grew too marked for friendship. Comte began to fret under Saint Simon's pretensions to be his director. Saint Simon, on the other hand, perhaps began to feel uncomfortably conscious of the superiority of his disciple. The occasion of the breach between them (1824) was an attempt on Saint Simon's part to print a production of Comte's as if it were in some sort connected with Saint Simon's schemes of social reorganization. Comte was never a man to quarrel by halves, and not only was the breach not repaired, but long afterwards Comte, as we have said, with painful ungraciousness took to calling the encourager of his youth by very hard names.

In 1825 Comte married. His marriage was one of those of which "magnanimity owes no account to prudence," and it did not turn out prosperously. His family were strongly Catholic and royalist, and they were outraged by his refusal to have the marriage performed other than civilly. They consented, however, to receive his wife, and the pair went on a visit to Montpellier. Madame Comte conceived a dislike to the circle she found there, and this was the too early beginning of disputes which lasted for the remainder of their union. In the year of his marriage we find Comte writing to the most intimate of his correspondents:—"I have nothing left but to concentrate my whole moral existence in my intellectual work, a precious but inadequate compensation; and so I must give up, if not the most dazzling, still the sweetest part of my happiness." We cannot help admiring the heroism which cherishes great ideas in the midst of petty miseries, and intrepidly throws all squalid interruptions into the background which is their true place. Still, we may well suppose that the sordid cares that come with want of money made a harmonious life none the more easy. Comte tried to find pupils to board with him, but only one pupil came, and he was soon sent away for lack of companions. "I would rather spend an evening," wrote the needy enthusiast, "in solving a difficult question, than in running after some empty-headed and consequential millionaire in search of a pupil." A little money was earned by an occasional article in *Le Producteur*, in which he began to expound the philosophic ideas that were now maturing in his mind. He announced a course of lectures (1826), which it was hoped would bring money as well as fame, and which were to be the first dogmatic exposition of the Positive Philosophy. A friend had said to him, "You talk too freely, your ideas are getting abroad, and other people use them without giving you the credit; put your ownership on record." The lectures were intended to do this among other things, and they attracted hearers so eminent as Humboldt the cosmologist, as Poinsot the geometer, as Blainville the physiologist.

Serious illness.

Unhappily, after the third lecture of the course, Comte had a severe attack of cerebral derangement, brought on by intense and prolonged meditation, acting on a system that was already irritated by the chagrin of domestic failure. He did not recover his health for more than a year, and as soon as convalescence set in he was seized by so profound a melancholy at the disaster which had thus overtaken him, that he threw himself into the Seine. Fortunately he was rescued, and the shock did not stay his return to mental soundness. One incident of this painful episode is worth mentioning. Lamennais, then in the height of his Catholic exaltation, persuaded Comte's mother to insist on her son being married with the religious ceremony, and as the younger Madame Comte apparently did not resist, the rite was duly performed, in spite of the fact that the unfortunate man was at the time neither more nor less than raving mad. To such shocking conspiracies against common sense and decency does ecclesiastical zealotry bring even good men like Lamennais. On the other hand, philosophic assailants of Comtism have not always resisted the temptation to recall the circumstance that its founder was once out of his mind,—an unworthy and irrelevant device, that cannot be excused even by the provocation of Comte's own occasional acerbity. As has been justly said, if Newton once suffered a cerebral attack without on that account forfeiting our veneration for the

Principia, Comte may have suffered in the same way, and still not have forfeited our respect for what is good in the systems of Positive Philosophy and Positive Polity.

In 1828 the lectures were renewed, and in 1830 was published the first volume of the *Course of Positive Philosophy*. The sketch and ground plan of this great undertaking had appeared in 1826. The sixth and last volume was published in 1842. The twelve years covering the publication of the first of Comte's two elaborate works were years of indefatigable toil, and they were the only portion of his life in which he enjoyed a certain measure, and that a very modest measure, of material prosperity. In 1833 he was appointed examiner of the boys in the various provincial schools who aspired to enter the École Polytechnique at Paris. This and two other engagements as a teacher of mathematics secured him an income of some £400 a year. He made M. Guizot, then Louis Philippe's minister, the important proposal to establish a chair of general history of the sciences. If there are four chairs, he argued, devoted to the history of philosophy, that is to say, the minute study of all sorts of dreams and aberrations through the ages, surely there ought to be at least one to explain the formation and progress of our real knowledge? This wise suggestion, which still remains to be acted upon, was at first welcomed, according to Comte's own account, by Guizot's philosophic instinct, and then repulsed by his "metaphysical rancour."

Meanwhile Comte did his official work conscientiously, sorely as he grudged the time which it took from the execution of the great object of his thoughts. We cannot forbear to transcribe one delightful and touching trait in connection with this part of Comte's life. "I hardly know if even to you," he writes in the expansion of domestic confidence to his wife, "I dare disclose the sweet and softened feeling that comes over me when I find a young man whose examination is thoroughly satisfactory. Yes, though you may smile, the emotion would easily stir me to tears if I were not carefully on my guard." Such sympathy with youthful hope, in union with the industry and intelligence that are the only means of bringing the hope to fulfilment, shows that Comte's dry and austere manner veiled the fires of a generous social emotion. It was this which made the over-worked student take upon himself the burden of delivering every year from 1831 to 1848 a course of gratuitous lectures on astronomy for a popular audience. The social feeling that inspired this disinterested act showed itself in other ways. He suffered the penalty of imprisonment rather than serve in the national guard; his position was that though he would not take arms against the new monarchy of July, yet being a republican he would take no oath to defend it. The only amusement that Comte permitted himself was a visit to the opera. In his youth he had been a play-goer, but he shortly came to the conclusion that tragedy is a stilted and bombastic art, and after a time comedy interested him no more than tragedy. For the opera he had a genuine passion, which he gratified as often as he could, until his means became too narrow to afford even that single relaxation.

Of his manner and personal appearance we have the following account from one who was his pupil:—"Daily as the clock struck eight on the horologe of the Luxembourg, while the ringing hammer on the bell was yet audible, the door of my room opened, and there entered a man, short, rather stout, almost what one might call sleek, freshly shaven, without vestige of whisker or moustache. He was invariably dressed in a suit of the most spotless black, as if going to a dinner party; his white neck-cloth was fresh from the laundress's hands, and his hat shining like a racer's coat. He advanced to the arm-chair prepared for him in the centre of the writing-table, laid his hat on the left-hand corner; his snuff-box was deposited on the same side beside the quire of paper placed in readiness for his use, and dipping the pen twice into the ink-bottle, then bringing it to within an inch of his nose, to make sure it was properly filled, he broke silence: 'We have said that the chord AB,' &c. For three quarters of an hour he continued his demonstration, making short notes as he went on, to guide the listener in repeating the problem alone; then, taking up another cahier which lay beside him, he went over the written repetition of the former lesson. He explained, corrected, or commented till the clock struck nine; then, with the little finger of the right hand brushing from his coat and waistcoat the shower of superfluous snuff which had fallen on them, he pocketed his snuff-box, and resuming his hat, he as silently as when he came in made his exit by the door which I rushed to open for him."

Completion of Positive Philosophy

In 1842, as we have said, the last volume of the *Positive Philosophy* was given to the public. Instead of that contentment which we like to picture as the reward of twelve years of meritorious toil devoted to the erection of a high philosophic edifice, the author of this great contribution found himself in the midst of a very sea of small troubles. And they were troubles of that uncompensated kind that harass without elevating, and waste a man's spirit without softening or enlarging it. First, the jar of temperament between Comte and his wife had become so unbearable that they separated (1842). It is not expedient for strangers to attempt to allot blame in such cases, for it is impossible for strangers to know all the deciding circumstances. We need only say that in spite of one or two disadvantageous facts in her career which do not concern the public, Madame Comte seems to have uniformly comported herself towards her husband with an honourable solicitude for his well-being. Comte made her an annual allowance, and for some years after the separation they corresponded on friendly terms. Next in the list of the vexations that greeted Comte on emerging from the long tunnel of philosophizing, was a lawsuit with his publisher. The publisher had impertinently inserted in the sixth volume a protest against a certain foot-note, in which Comte had used some hard words about M. Arago. Comte threw himself into the suit with an energy worthy of Voltaire, and he won it. Third, and worst of all, he had prefixed a preface to the sixth volume, in which he deliberately went out of his way to rouse the active enmity of the very men on whom depended his annual re-election to the post of examiner for the Polytechnic School. The result of this perversity was that by-and-by he lost the appointment, and with it one-half of his very modest income. This was the occasion of an episode, which is of more than merely personal interest.

Before 1842 Comte had been in correspondence with our distinguished countryman, J. S. Mill. Mr Mill had been greatly impressed by Comte's philosophic ideas; he admits that his own *System of Logic* owes many valuable thoughts to Comte, and that, in the portion of that work which treats of the logic of the moral sciences, a radical improvement in the conceptions of logical method was derived from the *Positive Philosophy*. Their correspondence, which was extremely full and copious, and which we may hope will one day be made accessible to the public, turned principally upon the two great questions of the equality between men and women, and of the expediency and constitution of a sacerdotal or spiritual order. When Comte found himself straitened, he confided the entire circumstances to his English friend. As might be supposed by those who know the affectionate anxiety with which Mr Mill regarded the welfare of any one whom he believed to be doing good work in the world, he at once took pains to have Comte's loss of income made up to him, until Comte should have had time to repair that loss by his own endeavour. Mr Mill persuaded Grote, Molesworth, and Raikes Currie to advance the sum of £240. At the end of the year (that is in 1845) Comte had taken no steps to enable himself to dispense with the aid of the three Englishmen. Mr Mill applied to them again, but with the exception of Grote, who sent a small sum, they gave Comte to understand that they expected him to earn his own living. Mr Mill had suggested to Comte that he should write articles for the English periodicals, and expressed his own willingness to translate any such articles from the French. Comte at first fell in with the plan, but he speedily surprised and disconcerted Mr Mill by boldly taking up the position of "high moral magistrate," and accusing the three defaulting contributors of a scandalous falling away from righteousness and a high mind. Mr Mill was chilled by these pretensions; they struck him as savouring of a totally unexpected charlatanry; and the correspondence came to an end. For Comte's position in the argument one feels that there is much to be said. If you have good reason for believing that a given thinker is doing work that will destroy the official system of science or philosophy, and if you desire its destruction, then you may fairly be asked to help to provide for him the same kind of material freedom that is secured to the professors and propagators of the official system by the state or by the universities. And if it is a fine thing for a man to leave money behind him in the shape of an endowment for the support of a scientific teacher of whom he has never heard, why should it not be just as natural and as laudable to give money, while he is yet alive, to a teacher whom he both knows and approves of? On the other hand, Grote and Molesworth might say that, for anything they could tell, they would find themselves to be helping the construction of a system of which they utterly disapproved. And, as things turned out, they would have been perfectly justified in this serious apprehension. To have done anything to make the production of the *Positive Polity* easier would have been no ground for anything but remorse to any of the three. It is just to Comte to remark that he always assumed that the contributors to the support of a thinker should be in all essentials of method and doctrine that thinker's disciples; aid from indifferent persons he counted irrational and humiliating. But is an endowment ever a blessing to the man who receives it? The question is difficult to answer generally; in Comte's case there is reason in the doubts felt by Madame Comte as to the expediency of relieving the philosopher from the necessity of being in plain and business-like relations with indifferent persons for a certain number of hours in the week. Such relations do as much as a doctrine to keep egoism within decent bounds, and they must be not only a relief, but a wholesome corrective to the tendencies of concentrated thinking on abstract subjects.

What finally happened was this. From 1845 to 1848 Comte lived as best he could, as well as made his wife her allowance, on an income of £200 a year. We need scarcely say that he was rigorously thrifty. His little account books of income and outlay, with every item entered down to a few hours before his death, are accurate and neat enough to have satisfied an ancient Roman householder. In 1848, through no fault of his own, his salary was reduced to £80. M. Littré and others, with Comte's approval, published an appeal for subscriptions, and on the money thus contributed Comte subsisted for the remaining nine years of his life. By 1852 the subsidy produced as much as £200 a year. It is worth noticing, after the story we have told, that Mr Mill was one of the subscribers, and that M. Littré continued his assistance after he had been driven from Comte's society by his high pontifical airs. We are sorry not to be able to record any similar trait of magnanimity on Comte's part. His character, admirable as it is for firmness, for intensity, for inexorable will, for iron devotion to what he thought the service of mankind, yet offers few of those softening qualities that make us love good men and pity bad ones. He is of the type of Brutus or of Cato—a model of austere fixity of purpose, but ungracious, domineering, and not quite free from petty bitterness.

If you seek to place yourself in sympathy with Comte it is best to think of him only as the intellectual worker, pursuing in uncomforted obscurity the laborious and absorbing task to which he had given up his whole life. His singularly conscientious fashion of elaborating his ideas made the mental strain more intense than even so exhausting a work as the abstract exposition of the principles of positive science need have been, if he had followed a more self-indulgent plan. He did not write down a word until he had first composed the whole matter in his mind. When he had thoroughly meditated every sentence, he sat down to write, and then, such was the grip of his memory, the exact order of his thoughts came back to him as if without an effort; and he wrote down precisely what he had intended to write, without the aid of a note or a memorandum, and without check or pause. For example, he began and completed in about six weeks a chapter in the *Positive Philosophy* (vol. v. ch. 55), which would fill forty of the large pages of this *Encyclopædia*. Even if his subject had been merely narrative or descriptive, this would be a very satisfactory piece of continuous production. When we reflect that the chapter in question is not narrative, but an abstract exposition of the guiding principles of the movements of several centuries, with many threads of complex thought running along side by side all through the speculation, then the circumstances under which it was reduced to literary form are really astonishing. It is hardly possible for a critic to share the admiration expressed by some of Comte's disciples for his style. We are not so unreasonable as to blame him for failing to make his pages picturesque or thrilling; we do not want sunsets and stars and roses and ecstasy; but there is a certain standard for the most serious and abstract subjects. When compared with such philosophic writing as Hume's, Diderot's, Berkeley's, then Comte's manner is heavy, laboured, monotonous, without relief, and without light. There is now and then an energetic phrase, but as a whole the vocabulary is jejune; the sentences are overloaded; the pitch is flat. A scrupulous insistence on making his meaning clear led to an iteration of certain adjectives and adverbs, which at length deaden the effect beyond the endurance of all but the most resolute students. Only the profound and stimulating interest of much of the matter prevents one from thinking of Rivarol's ill-natured remark upon Condorcet, that he wrote with opium on a page of lead. The general effect is impressive, not by any virtues of style, for we do not discern one, but by reason of the magnitude and importance of the undertaking, and the visible conscientiousness and the grasp with which it is executed. It is by sheer strength of thought, by the vigorous perspicacity with which he strikes the lines of cleavage of his subject, that he makes his way into the mind of the reader; in the presence of gifts of this power we need not quarrel with an ungainly style.

Hygiène cérébrale

Comte pursued one practice which ought to be mentioned in connection with his personal history, the practice of what he styled *hygiène cérébrale*. After he had acquired what he considered to be a sufficient stock of material, and this happened before he had completed the *Positive Philosophy*, he abstained deliberately and scrupulously from reading newspapers, reviews, scientific transactions, and everything else whatever, except two or three poets (notably Dante) and the *Imitatio Christi.* It is true that his friends kept him informed of what was going on in the scientific world. Still this partial divorce of himself from the record of the social and scientific activity of his time, though it may save a thinker from the deplorable evils of dispersion, moral and intellectual, accounts in no small measure for the exaggerated egoism, and the absence of all feeling for reality, which marked Comte's later days.

Only one important incident in Comte's life now remains to be spoken of. In 1845 he made the acquaintance of Madame Clotilde de Vaux, a lady whose husband had been sent to the galleys for life, and who was therefore, in all but the legal incidents of her position, a widow. Very little is known about her qualities. She wrote a little piece which Comte rated so preposterously as to talk about George Sand in the same sentence; it is in truth a flimsy performance, though it contains one or two gracious thoughts. There is true beauty in the saying—"*It is unworthy of a noble nature to diffuse its pain.*" Madame de Vaux's letters speak well for her good sense and good feeling, and it would have been better for Comte's later work if she had survived to exert a wholesome restraint on his exaltation. Their friendship had only lasted a year when she died (1846), but the period was long enough to give her memory a supreme ascendency in Comte's mind. Condillac, Joubert, Mill, and other eminent men have shown what the intellectual ascendency of a woman can be. Comte was as inconsolable after Madame de Vaux's death as D'Alembert after the death of Mademoiselle L'Espinasse. Every Wednesday afternoon he made a reverential pilgrimage to her tomb, and three times every day he invoked her memory in words of passionate expansion. His disciples believe that in time the world will reverence Comte's sentiment about Clotilde de Vaux, as it reveres Dante's adoration of Beatrice—a parallel that Comte himself was the first to hit upon. It is no doubt the worst kind of cynicism to make a mock in a realistic vein of any personality that has set in motion the idealizing thaumaturgy of the affections. Yet we cannot help feeling that it is a grotesque and unseemly anachronism to apply in grave prose, addressed to the whole world, those terms of saint and angel which are touching and in their place amid the trouble and passion of the great mystic poet. Only an energetic and beautiful imagination, together with a mastery of the rhythm and swell of impassioned speech, can prevent an invitation to the public to hearken to the raptures of intense personal attachment from seeming ludicrous and almost indecent. Whatever other gifts Comte may have had—and he had many of the rarest kind,—poetic imagination was not among them, any more than poetic or emotional expression was among them. His was one of those natures whose faculty of deep feeling is unhappily doomed to be inarticulate, and to pass away without the magic power of transmitting itself.

Comte lost no time, after the completion of his *Course of Positive Philosophy*, in proceeding with the *System of Positive Polity*, to which the earlier work was designed to be a foundation. The first volume was published in 1851, and the fourth and last in 1854. In 1848, when the political air was charged with stimulating elements, he founded the Positive Society, with the expectation that it might grow into a reunion as powerful over the new revolution as the Jacobin Club had been in the revolution of 1789. The hope was not fulfilled, but a certain number of philosophic disciples gathered round Comte, and eventually formed themselves, under the guidance of the new ideas of the latter half of his life, into a kind of church. In the years 1849, 1850, and 1851, Comte gave three courses of lectures at the Palais Royal. They were gratuitous and popular, and in them he boldly advanced the whole of his doctrine, as well as the direct and immediate pretensions of himself and his system. The third course ended in the following uncompromising terms—"In the name of the Past and of the Future, the servants of Humanity—both its philosophical and its practical servants—come forward to claim as their due the general direction of this world. Their object is to constitute at length a real Providence in all departments,—moral, intellectual, and material. Consequently they exclude once for all from political supremacy all the different servants of God—Catholic, Protestant, or Deist—as being at once behindhand, and a cause of disturbance." A few weeks after this invitation, a very different person stepped forward to constitute himself a real Providence.

In 1852 Comte published the *Catechism of Positivism.* In the preface to it he took occasion to express his approval of Louis Napoleon's *coup d'état* of the second of December, —"a fortunate crisis which has set aside the parliamentary system, and instituted a dictatorial republic." Whatever we may think of the political sagacity of such a judgment, it is due to Comte to say that he did not expect to see his dictatorial republic transformed into a dynastic empire, and, next, that he did expect from the Man of December freedom of the press and of public meeting. His later hero was the Emperor Nicholas, "the only statesman in Christendom,"—as unlucky a judgment as that which placed Dr Francia in the Comtist Calendar.

In 1857 he was attacked by cancer, and died peaceably on the 5th of September of that year. The anniversary is always celebrated by ceremonial gatherings of his French and English followers, who then commemorate the name and the services of the founder of their religion. Comte was under sixty when he died. We cannot help reflecting that one of the worst of all the evils connected with the shortness of human life is the impatience which it breeds in some of the most ardent and enlightened minds to hurry on the execution of projects, for which neither the time nor the spirit of their author is fully ripe.

In proceeding to give an outline of Comte's system, we shall consider the *Positive Polity* as the more or less legitimate sequel of the *Positive Philosophy*, notwithstanding the deep gulf which so eminent a critic as Mr Mill insisted upon fixing between the earlier and the later work. There may be, as we think there is, the greatest difference in their value, and the temper is not the same, nor the method. But the two are quite capable of being regarded, and for the purposes of an account of Comte's career ought to be regarded, as an integral whole. His letters when he was a young man of one-and-twenty, and before he had published a word, show how strongly present the social motive was in his mind, and in what little account he should hold his scientific works, if he did not perpetually think of their utility for the species. "I feel," he wrote, "that such scientific reputation as I might acquire would give more value, more weight, more useful influence to my political sermons." In 1822 he published a *Plan of the Scientific Works necessary to Reorganize Society.* In this opuscule he points out that modern society is passing through a great crisis, due to the conflict of two opposing movements,—the first, a disorganizing movement owing to the break-up of old institutions and beliefs; the second, a movement towards a definite social state, in which all means of human prosperity will receive their most complete development and most direct application. How is this crisis to be dealt with? What are the undertakings necessary in order to pass successfully through it towards an organic state? The answer to this is that there are two series of works. The first is theoretic or spiritual, aiming at the development of a new principle of co-ordinating social relations, and the formation of the system of general ideas which are destined to guide society. The second work is practical or temporal; it settles the distribution of power, and the institutions that are most conformable to the spirit of the system which has previously been thought out in the course of the theoretic work. As the practical work depends on the conclusions of the theoretical, the latter must obviously come first in order of execution.

In 1826 this was pushed further in a most remarkable piece called *Considerations on the Spiritual Power*—the main object of which is to demonstrate the necessity of instituting a spiritual power, distinct from the temporal power and independent of it. In examining the conditions of a spiritual power proper for modern times, he indicates in so many terms the presence in his mind of a direct analogy between his proposed spiritual power and the functions of the Catholic clergy at the time of its greatest vigour and most complete independence,—that is to say, from about the middle of the 11th century until towards the end of the 13th. He refers to De Maistre's memorable book, *Du Pape*, as the most profound, accurate, and methodical account of the old spiritual organization, and starts from that as the model to be adapted to the changed intellectual and social conditions of the modern time. In the *Positive Philosophy*, again (vol. v. p. 344), he distinctly says that Catholicism, reconstituted as a system on new intellectual foundations, would finally preside over the spiritual reorganization of modern society. Much else could easily be quoted to the same effect. If unity of career, then, means that Comte from the beginning designed the institution of a spiritual power, and the systematic reorganization of life, it is difficult to deny him whatever credit that unity may be worth, and the credit is perhaps not particularly great. Even the re-adaptation of the Catholic system to a scientific doctrine was plainly in his mind thirty years before the final execution of the *Positive Polity*, though it is difficult to believe that he foresaw the religious mysticism in which the task was to land him. A great analysis was to precede a great synthesis, but it was the synthesis on which Comte's vision was centred from the first. Let us first sketch the nature of the analysis. Society is to be reorganized on the base of knowledge. What is the sum and significance of knowledge? That is the question which Comte's first masterwork professes to answer.

The *Positive Philosophy* opens with the statement of a certain law of which Comte was the discoverer, and which has always been treated both by disciples and dissidents as the key to his system. This is the Law of the Three States. It is as follows. Each of our leading conceptions, each branch of our knowledge, passes successively through three different phases; there are three different ways in which the human mind explains phenomena, each way following the other in order. These three stages are the Theological, the Metaphysical, and the Positive. Knowledge, or a branch of knowledge, is in the Theological state, when it supposes the phenomena under consideration to be due to immediate volition, either in the object or in some supernatural being. In the Metaphysical state, for volition is substituted abstract force residing in the object, yet existing independently of the object; the phenomena are viewed as if apart from the bodies manifesting them; and the properties of each substance have attributed to them an existence distinct from that substance. In the Positive state, inherent volition or external volition and inherent force or abstraction personified have both disappeared from men's minds, and the explanation of a phenomenon means a reference of it, by way of succession or resemblance, to some other phenomenon,—means the establishment of a relation between the given fact and some more general fact. In the Theological and Metaphysical state men seek a cause or an essence; in the Positive they are content with a law. To borrow an illustration from an able English disciple of Comte:—"Take the phenomenon of the sleep produced by opium. The Arabs are content to attribute it to the 'will of God.' Molière's medical student accounts for it by a *soporific principle* contained in the opium. The modern physiologist knows that he cannot account for it at all. He can simply observe, analyze, and experiment upon the phenomena attending the action of the drug, and classify it with other agents analogous in character."—(*Dr Bridges.*)

The first and greatest aim of the Positive Philosophy is to advance the study of society into the third of the three stages,—to remove social phenomena from the sphere of theological and metaphysical conceptions, and to introduce among them the same scientific observation of their laws which has given us physics, chemistry, physiology. Social physics will consist of the conditions and relations of the facts of society, and will have two departments,—one, statical, containing the laws of order; the other dynamical, containing the laws of progress. While men's minds were in the theological state, political events, for example, were explained by the will of the gods, and political authority based on divine right. In the metaphysical state of mind, then, to retain our instance, political authority was based on the sovereignty of the people, and social facts were explained by the figment of a falling away from a state of nature. When the positive method has been finally extended to society, as it has been to chemistry and physiology, these social facts will be resolved, as their ultimate analysis, into relations with one another, and instead of seeking causes in the old sense of the word, men will only examine the conditions of social existence. When that stage has been reached, not merely the greater part, but the whole, of our knowledge will be impressed with one character, the character, namely, of positivity or scientificalness; and all our conceptions in every part of knowledge will be thoroughly homogeneous. The gains of such a change are enormous. The new philosophical unity will now in its turn regenerate all the elements that went to its own formation. The mind will pursue knowledge without the wasteful jar and friction of conflicting methods and mutually hostile conceptions; education will be regenerated; and society will reorganize itself on the only possible solid base—a homogeneous philosophy.

Classification of sciences.

The *Positive Philosophy* has another object besides the demonstration of the necessity and propriety of a science of society. This object is to show the sciences as branches from a single trunk,—is to give to science the ensemble or spirit of generality hitherto confined to philosophy, and to give to philosophy the rigour and solidity of science. Comte's special object is a study of social physics, a science that before his advent was still to be formed; his second object is a review of the methods and leading generalities of all the positive sciences already formed, so that we may know both what system of inquiry to follow in our new science, and also where the new science will stand in relation to other knowledge.

The first step in this direction is to arrange scientific method and positive knowledge in order, and this brings us to another cardinal element in the Comtist system, the classification of the sciences. In the front of the inquiry lies one main division, that, namely, between speculative and practical knowledge. With the latter we have no concern. Speculative or theoretic knowledge is divided into abstract and concrete. The former is concerned with the laws that regulate phenomena in all conceivable cases;

the latter is concerned with the application of these laws. Concrete science relates to objects or beings; abstract science to events. The former is particular or descriptive; the latter is general. Thus, physiology is an abstract science; but zoology is concrete. Chemistry is abstract; mineralogy is concrete. It is the method and knowledge of the abstract sciences that the Positive Philosophy has to reorganize in a great whole.

Comte's principle of classification is that the dependence and order of scientific study follows the dependence of the phenomena. Thus, as has been said, it represents both the objective dependence of the phenomena and the subjective dependence of our means of knowing them. The more particular and complex phenomena depend upon the simpler and more general. The latter are the more easy to study. Therefore science will begin with those attributes of objects which are most general, and pass on gradually to other attributes that are combined in greater complexity. Thus, too, each science rests on the truths of the sciences that precede it, while it adds to them the truths by which it is itself constituted. Comte's series or hierarchy is arranged as follows:—(1) Mathematics (that is, number, geometry, and mechanics), (2) Astronomy, (3) Physics, (4) Chemistry, (5) Biology, (6) Sociology. Each of the members of this series is one degree more special than the member before it, and depends upon the facts of all the members preceding it, and cannot be fully understood without them. It follows that the crowning science of the hierarchy, dealing with the phenomena of human society, will remain longest under the influence of theological dogmas and abstract figments, and will be the last to pass into the positive stage. You cannot discover the relations of the facts of human society without reference to the conditions of animal life; you cannot understand the conditions of animal life without the laws of chemistry; and so with the rest.

This arrangement of the sciences, and the Law of the Three States, are together explanatory of the course of human thought and knowledge. They are thus the double key of Comte's systematization of the philosophy of all the sciences from mathematics to physiology, and his analysis of social evolution, which is the base of sociology. Each science contributes its philosophy. The co-ordination of all these partial philosophies produces the general Positive Philosophy. "Thousands had cultivated science, and with splendid success; not one had conceived the philosophy which the sciences when organized would naturally evolve. A few had seen the necessity of extending the scientific method to all inquiries, but no one had seen how this was to be effected. . . . . The Positive Philosophy is novel as a philosophy, not as a collection of truths never before suspected. Its novelty is the organization of existing elements. Its very principle implies the absorption of all that great thinkers had achieved; while incorporating their results it extended their methods. . . . . What tradition brought was the results; what Comte brought was the organization of these results. He always claimed to be the founder of the Positive Philosophy. That he had every right to such a title is demonstrable to all who distinguish between the positive sciences and the philosophy which co-ordinated the truths and methods of these sciences into a doctrine."—(*G. H. Lewes.*)

We may interrupt our short exposition here to remark that Comte's classification of the sciences has been subjected to a vigorous criticism by Mr Herbert Spencer. Mr Spencer's two chief points are these:—(1) He denies that the principle of the development of the sciences is the principle of decreasing generality; he asserts that there are as many examples of the advent of a science being determined by increasing generality as by increasing speciality. (2) He holds that any grouping of the sciences in a succession gives a radically wrong idea of their genesis and their interdependence; no true filiation exists; no science develops itself in isolation; no one is independent, either logically or historically. M. Littré, by far the most eminent of the scientific followers of Comte, concedes a certain force to Mr Spencer's objections, and makes certain secondary modifications in the hierarchy in consequence, while still cherishing his faith in the Comtist theory of the sciences. Mr Mill, while admitting the objections as good, if Comte's arrangement pretended to be the only one possible, still holds that arrangement as tenable for the purpose with which it was devised. Mr Lewes asserts against Mr Spencer that the arrangement in a series is necessary, on grounds similar to those which require that the various truths constituting a science should be systematically co-ordinated, although in nature the phenomena are intermingled.

The first three volumes of the *Positive Philosophy* contain an exposition of the partial philosophies of the five sciences that precede sociology in the hierarchy. Their value has usually been placed very low by the special followers of the sciences concerned; they say that the knowledge is second-hand, is not coherent, and is too confidently taken for final. The Comtist replies that the task is philosophic, and is not to be judged by the minute accuracies of science. In these three volumes Comte took the sciences roughly as he found them. His eminence as a man of science must be measured by his only original work in that department,—the construction, namely, of the new science of society. This work is accomplished in the last three volumes of the *Positive Philosophy*, and the second and third volumes of the *Positive Polity*. The Comtist maintains that even if these five volumes together fail in laying down correctly and finally the lines of the new science, still they are the first solution of a great problem hitherto unattempted. "Modern biology has got beyond Aristotle's conception; but in the construction of the biological science, not even the most unphilosophical biologist would fail to recognize the value of Aristotle's attempt. So for sociology. Subsequent sociologists may have conceivably to remodel the whole science, yet not the less will they recognize the merit of the first work which has facilitated their labours."—(*Congreve.*)

Sociological conceptions.

We shall now briefly describe Comte's principal conceptions in sociology, his position in respect to which is held by himself, and by others, to raise him to the level of Descartes or Leibnitz. Of course the first step was to approach the phenomena of human character and social existence with the expectation of finding them as reducible to general laws as the other phenomena of the universe, and with the hope of exploring these laws by the same instruments of observation and verification as had done such triumphant work in the case of the latter. Comte separates the collective facts of society and history from the individual phenomena of biology; then he withdraws these collective facts from the region of external volition, and places them in the region of law. The facts of history must be explained, not by providential interventions, but by referring them to conditions inherent in the successive stages of social existence. This conception makes a science of society possible. What is the method? It comprises, besides observation and experiment (which is, in fact, only the observation of abnormal social states), a certain peculiarity of verification. We begin by deducing every well-known historical situation from the series of its antecedents. Thus we acquire a body of empirical generalizations as to social phenomena, and then we connect the generalizations with the positive theory of human nature. A sociological demonstration lies in the establishment of an accordance between the conclusions of historical analysis and the preparatory conceptions of biological theory. As Mr Mill puts it:—"If a sociological theory, collected from historical evidence, contradicts the established general laws of human nature; if (to use M. Comte's instances) it implies, in the mass of mankind, any very decided natural bent, either in a good or in a bad direction; if it supposes that the reason, in average human beings, predominates over the desires, or the disinterested desires over the personal,—we may know that history has been misinterpreted, and that the theory is false. On the other hand, if laws of social phenomena, empirically generalized from history, can, when once suggested, be affiliated to the known laws of human nature; if the direction actually taken by the developments and changes of human society, can be seen to be such as the properties of man and of his dwelling-place made antecedently probable, the empirical generalizations are raised into positive laws, and sociology becomes a science." The result of this method is an exhibition of the events of human experience in co-ordinated series that manifest their own graduated connection.

Next, as all investigation proceeds from that which is known best to that which is unknown or less well known, and as, in social states, it is the collective phenomenon that is more easy of access to the observer than its parts, therefore we must consider and pursue all the elements of a given social state together and in common. The social organization must be viewed and explored as a whole. There is a nexus between each leading group of social phenomena and other leading groups; if there is a change in one of them, that change is accompanied by a corresponding modification of all the rest. "Not only must political institutions and social manners, on the one hand, and manners and ideas, on the other, be always mutually connected; but further, this consolidated whole must be always connected by its nature with the corresponding state of the integral development of humanity, considered in all its aspects of intellectual, moral, and physical activity."—(*Comte.*)

Decisive importance of intellectual development.

Is there any one element which communicates the decisive impulse to all the rest,—any predominating agency in the course of social evolution? The answer is that all the other parts of social existence are associated with, and drawn along by, the contemporary condition of intellectual development. The Reason is the superior and preponderant element which settles the direction in which all the other faculties shall expand. "It is only through the more and more marked influence of the reason over the general conduct of man and of society, that the gradual march of our race has attained that regularity and persevering continuity which distinguish it so radically from the desultory and barren expansion of even the highest animal orders, which share, and with enhanced strength, the appetites, the passions, and even the primary sentiments of man." The history of intellectual development, therefore, is the key to social evolution, and the key to the history of intellectual development is the Law of the Three States.

Among other central thoughts in Comte's explanation of history are these:—The displacement of theological by positive conceptions has been accompanied by a gradual rise of an industrial régime out of the military régime;—the great permanent contribution of Catholicism was the separation which it set up between the temporal and the spiritual powers;—the progress of the race consists in the increasing preponderance of the distinctively human elements over the animal elements;—the absolute tendency of ordinary social theories will be replaced by an unfailing adherence to the relative point of view, and from this it follows that the social state, regarded as a whole, has been as perfect in each period as the co-existing condition of humanity and its environment would allow.

The elaboration of these ideas in relation to the history of the civilization of the most advanced portion of the human race occupies two of the volumes of the *Positive Philosophy*, and has been accepted by competent persons of very different schools as a master-piece of rich, luminous, and far-reaching suggestion. Whatever additions it may receive, and whatever corrections it may require, this analysis of social evolution will continue to be regarded as one of the great achievements of human intellect. The demand for the first of Comte's two works has gone on increasing in a significant degree. It was completed, as we have said, in 1842. A second edition was published in 1864; a third some years afterwards; and while we write (1876) a fourth is in the press. Three editions within twelve years of a work of abstract philosophy in six considerable volumes are the measure of a very striking influence. On the whole, we may suspect that no part of Comte's works has had so much to do with this marked success as his survey and review of the course of history.

Social dynamics in the *Positive Polity*.

The third volume of the later work, the *Positive Polity*, treats of social dynamics, and takes us again over the ground of historic evolution. It abounds with remarks of extraordinary fertility and comprehensiveness; but it is often arbitrary; its views of the past are strained into coherence with the statical views of the preceding volume; and so far as concerns the period to which the present writer happens to have given special attention, it is usually slight and sometimes random. As it was composed in rather less than six months, and as the author honestly warns us that he has given all his attention to a more profound co-ordination, instead of working out the special explanations more fully, as he had promised, we need not be surprised if the result is disappointing to those who had mastered the corresponding portion of the *Positive Philosophy*. Comte explains the difference between his two works. In the first his "chief object was to discover and demonstrate the laws of progress, and to exhibit in one unbroken sequence the collective destinies of mankind, till then invariably regarded as a series of events wholly beyond the reach of explanation, and almost depending on arbitrary will. The present work, on the contrary, is addressed to those who are already sufficiently convinced of the certain existence of social laws, and desire only to have them reduced to a true and conclusive system."

The Positivist system.

What that system is it would take far more space than we can afford to sketch even in outline. All we can do is to enumerate some of its main positions. They are to be drawn not only from the *Positive Polity*, but from two other works,—the *Positivist Catechism: a Summary Exposition of the Universal Religion, in Twelve Dialogues between a Woman and a Priest of Humanity*; and, second, *The Subjective Synthesis* (1856), which is the first and only volume of a work upon mathematics announced at the end of the *Positive Philosophy*. The system for which the *Positive Philosophy* is alleged to have been the scientific preparation contains a Polity and a Religion; a complete arrangement of life in all its aspects, giving a wider sphere to Intellect, Energy, and Feeling than could be found in any of the previous organic types,—Greek, Roman, or Catholic-feudal. Comte's immense superiority over such præ-Revolutionary utopians as the Abbé Saint Pierre, no less than over the group of post-revolutionary utopians, is especially visible in his firm grasp of the cardinal truth that the improvement of the social organism can only be effected by a moral development, and never by any changes in mere political mechanism, or any violences in the way of an artificial redistribution of wealth. A moral transformation must precede any real advance. The aim, both in public and private life, is to secure to the utmost possible extent the victory of the social feeling over self-love, or

Altruism over Egoism. This is the key to the regeneration of social existence, as it is the key to that unity of individual life which makes all our energies converge freely and without wasteful friction towards a common end. What are the instruments for securing the preponderance of Altruism? Clearly they must work from the strongest element in human nature, and this element is Feeling or the Heart. Under the Catholic system the supremacy of Feeling was abused, and the Intellect was made its slave. Then followed a revolt of Intellect against Sentiment. The business of the new system will be to bring back the Intellect into a condition not of slavery, but of willing ministry to the Feelings. The subordination never was, and never will be, effected except by means of a religion, and a religion, to be final, must include a harmonious synthesis of all our conceptions of the external order of the universe. The characteristic basis of a religion is the existence of a Power without us, so superior to ourselves as to command the complete submission of our whole life. This basis is to be found in the Positive stage, in Humanity, past, present, and to come, conceived as the Great Being.

The Great Being

"A deeper study of the great universal order reveals to us at length the ruling power within it of the true Great Being, whose destiny it is to bring that order continually to perfection by constantly conforming to its laws, and which thus best represents to us that system as a whole. This undeniable Providence, the supreme dispenser of our destinies, becomes in the natural course the common centre of our affections, our thoughts, and our actions. Although this Great Being evidently exceeds the utmost strength of any, even of any collective, human force, its necessary constitution and its peculiar function endow it with the truest sympathy towards all its servants. The least amongst us can and ought constantly to aspire to maintain and even to improve this Being. This natural object of all our activity, both public and private, determines the true general character of the rest of our existence, whether in feeling or in thought; which must be devoted to love, and to know, in order rightly to serve, our Providence, by a wise use of all the means which it furnishes to us. Reciprocally this continued service, whilst strengthening our true unity, renders us at once both happier and better."

Central to the religion.

The exaltation of Humanity into the throne occupied by the Supreme Being under monotheistic systems made all the rest of Comte's construction easy enough. Utility remains the test of every institution, impulse, act; his fabric becomes substantially an arch of utilitarian propositions, with an artificial Great Being inserted at the top to keep them in their place. The Comtist system is utilitarianism crowned by a fantastic decoration. Translated into the plainest English, the position is as follows: "Society can only be regenerated by the greater subordination of politics to morals, by the moralization of capital, by the renovation of the family, by a higher conception of marriage, and so on. These ends can only be reached by a heartier development of the sympathetic instincts. The sympathetic instincts can only be developed by the Religion of Humanity." Looking at the problem in this way, even a moralist who does not expect theology to be the instrument of social revival, might still ask whether the sympathetic instincts will not necessarily be already developed to their highest point, before people will be persuaded to accept the religion, which is at bottom hardly more than sympathy under a more imposing name. However that may be, the whole battle—into which we shall not enter—as to the legitimateness of Comtism as a religion turns upon this erection of Humanity into a Being. The various hypotheses, dogmas, proposals, as to the family, to capital, &c., are merely propositions measurable by considerations of utility and a balance of expediencies. Many of these proposals are of the highest interest, and many of them are actually available; but there does not seem to be one of them of an available kind, which could not equally well be approached from other sides, and even incorporated in some radically antagonistic system. Adoption, for example, as a practice for improving the happiness of families and the welfare of society, is capable of being weighed, and can in truth only be weighed, by utilitarian considerations, and has been commended by men to whom the Comtist religion is naught. The singularity of Comte's construction, and the test by which it must be tried, is the transfer of the worship and discipline of Catholicism to a system in which "the conception of God is superseded" by the abstract idea of Humanity, conceived as a kind of Personality.

And when all is said, the invention does not help us. We have still to settle what *is* for the good of Humanity, and we can only do that in the old-fashioned way. There is no guidance in the conception. No effective unity can follow from it, because you can only find out the right and wrong of a given course by summing up the advantages and disadvantages, and striking a balance, and there is nothing in the Religion of Humanity to force two men to find the balance on the same side. The Comtists are no better off than other utilitarians in judging policy, events, conduct.

The worship and discipline

The particularities of the worship, its minute and truly ingenious re-adaptations of sacraments, prayers, reverent signs, down even to the invocation of a new Trinity, need not detain us. They are said, though it is not easy to believe, to have been elaborated by way of Utopia. If so, no Utopia has ever yet been presented in a style so little calculated to stir the imagination, to warm the feelings, to soothe the insurgency of the reason. It is a mistake to present a great body of hypotheses—if Comte meant them for hypotheses—in the most dogmatic and peremptory form to which language can lend itself. And there is no more extraordinary thing in the history of opinion than the perversity with which Comte has succeeded in clothing a philosophic doctrine, so intrinsically conciliatory as his, in a shape that excites so little sympathy and gives so much provocation. An enemy defined Comtism as Catholicism *minus* Christianity, to which an able champion retorted by calling it Catholicism *plus* Science. Hitherto Comte's Utopia has pleased the followers of the Catholic, just as little as those of the scientific, spirit.

The priesthood

The elaborate and minute systematization of life, proper to the religion of Humanity, is to be directed by a priesthood. The priests are to possess neither wealth nor material power; they are not to command, but to counsel; their authority is to rest on persuasion, not on force. When religion has become positive, and society industrial, then the influence of the church upon the state becomes really free and independent, which was not the case in the Middle Age. The power of the priesthood rests upon special knowledge of man and nature; but to this intellectual eminence must also be added moral power and a certain greatness of character, without which force of intellect and completeness of attainment will not receive the confidence they ought to inspire. The functions of the priesthood are of this kind:—To exercise a systematic direction over education; to hold a consultative influence over all the important acts of actual life, public and private; to arbitrate in cases of practical conflict; to preach sermons recalling those principles of generality and universal harmony which our special activities dispose us to ignore; to order the due classification of society; to perform the various ceremonies appointed by the founder of the religion. The authority of the priesthood is to rest wholly on voluntary adhesion, and there is to be perfect freedom of speech and discussion; though, by the way, we cannot forget Comte's detestable congratulations to the Czar Nicholas on the "wise vigilance" with which he kept watch over the importation of Western books.

From his earliest manhood Comte had been powerfully impressed by the necessity of elevating the condition of women. (See remarkable passage in his letters to M. Valat, pp. 84–7.) His friendship with Madame de Vaux had deepened the impression, and in the reconstructed society women are to play a highly important part. They are to be carefully excluded from public action, but they are to do many more important things than things political. To fit them for their functions, they are to be raised above material cares, and they are to be thoroughly educated. The family, which is so important an element of the Comtist scheme of things, exists to carry the influence of woman over man to the highest point of cultivation. Through affection she purifies the activity of man. "Superior in power of affection, more able to keep both the intellectual and the active powers in continual subordination to feeling, women are formed as the natural intermediaries between Humanity and man. The Great Being confides specially to them its moral Providence, maintaining through them the direct and constant cultivation of universal affection, in the midst of all the distractions of thought or action, which are for ever withdrawing men from its influence. . . . . . Beside the uniform influence of every woman on every man, to attach him to Humanity, such is the importance and the difficulty of this ministry that each of us should be placed under the special guidance of one of these angels, to answer for him, as it were, to the Great Being. This moral guardianship may assume three types,—the mother, the wife, and the daughter; each having several modifications, as shown in the concluding volume. Together they form the three simple modes of solidarity, or unity with contemporaries,—obedience, union, and protection,—as well as the three degrees of continuity between ages, by uniting us with the past, the present, and the future. In accordance with my theory of the brain, each corresponds with one of our three altruistic instincts,—veneration, attachment, and benevolence."

How the positive method of observation and verification of real facts has landed us in this, and much else of the same kind, is extremely hard to guess. Seriously to examine an encyclopædic system, that touches life, society, and knowledge at every point, is evidently beyond the compass of such an article as this. There is in every chapter a whole group of speculative suggestions, each of which would need a long chapter to itself to elaborate or to discuss. There is at least one biological speculation of astounding audacity, that could be examined in nothing less than a treatise. Perhaps we have said enough to show that after performing a great and real service to thought, Comte almost sacrificed his claims to gratitude by the invention of a system that, as such, and independently of detached suggestions, is markedly retrograde. But the world has strong self-protecting qualities. It will take what is available in Comte, while forgetting that in his work which is as irrational in one way as Hegel is in another.

The English reader is specially well placed for satisfying such curiosity as he may have about Comte's philosophy. Miss Martineau condensed the six volumes of the *Philosophie Positive* into two volumes of excellent English (1853); Comte himself gave them a place in the Positivist Library. The *Catechism* was translated by Dr Congreve in 1858. The *Politique Positive* has been reproduced in English (Longmans, 1875-7) by the conscientious labour of Comte's London followers. This translation is accompanied by a careful running analysis and explanatory summary of contents, which make the work more readily intelligible than the original. For criticisms, the reader may be referred to Mr Mill's *Auguste Comte and Positivism;* Dr Bridges's reply to Mr Mill, *The Unity of Comte's Life and Doctrines* (1866); Mr Herbert Spencer's essay on the *Genesis of Science*, and pamphlet on *The Classification of the Sciences;* Professor Huxley's "Scientific Aspects of Positivism," in his *Lay Sermons;* Dr Congreve's *Essays Political, Social, and Religious* (1874); Mr Fiske's *Outlines of Cosmic Philosophy* (1874); Mr Lewes's *History of Philosophy*, vol. ii. (J. MO.)

COMUS (from κῶμος, revel, or a company of revellers) was, in the later mythology of the Greeks, the god of festive mirth. In classic mythology the personification does not exist; but Comus appears in the Εἰκόνες, or *Descriptions of Pictures*, of Philostratus, a writer of the 3d century A.D., as a winged youth, slumbering in a standing attitude, his legs crossed, his countenance flushed with wine, his head—which is sunk upon his breast—crowned with dewy flowers, his left hand feebly grasping a hunting spear, his right an inverted torch. Ben Jonson introduces Comus, in his masque entitled *Pleasure reconciled to Virtue* (1619), as the portly jovial patron of good cheer, "First father of sauce and deviser of jelly." In the *Comus, sive Phagesiposia Cimmeria: Somnium* (1608, and at Oxford, 1634), a moral allegory by a Dutch author, Hendrik van der Putten, or Erycius Puteanus, the conception is more nearly akin to Milton's, and Comus is a being whose enticements are more disguised and delicate than those of Jonson's deity. But Milton's Comus is a creation of his own. His story is one

> "Which never yet was heard in tale or song
> From old or modern bard, in hall or bower."

Born from the loves of Bacchus and Circe, he is "much like his father, but his mother more"—a sorcerer, like her, who gives to travellers a magic draught that changes their human face into the "brutal form of some wild beast," and, hiding from them their own foul disfigurement, makes them forget all the pure ties of life, "to roll with pleasure in a sensual sty."

CONCA, SEBASTIANO (1676–1764), a painter of the Florentine school, was born at Gaeta, and studied at Naples under Francesco Solimena. In 1706, along with his brother Giovanni, who acted as his assistant, he settled at Rome, where for several years he worked in chalk only, to improve his drawing. He was patronized by the Cardinal Ottoboni, who introduced him to Clement XI.; and a Jeremiah painted in the church of St John Lateran, was rewarded by the Pope with knighthood and by the cardinal with a diamond cross. His fame grew quickly, and by-and-by he received the patronage of most of the crowned heads of Europe. He painted on till near the day of his death, and left behind him an immense number of pictures, mostly of a brilliant and showy kind, which are distributed among the churches of Italy. Of these the Probatica, or Pool of Siloam, in the hospital of Santa Maria della Scala, at Siena, is considered the finest.

CONCAN, or KONCAN, a maritime tract of Western India, situated within the limits of the Presidency of Bombay, and extending from the Portuguese settlement of Goa on the S. to the territory of Damán, belonging to the same nation, on the N. On the E. it is bounded by the Ghâts, and on the W. by the Indian Ocean. This tract comprises the two British districts of Tannah and Ratnagiri, and may be estimated at 300 miles in length, with an average breadth of about 40. From the mountains on its eastern frontier, which in one place attain a height of 4700 feet, the surface, marked by a succession of irregular hilly spurs from the Ghâts, slopes to the westward, where the mean elevation of the coast is not more than 100 feet above the level of the sea. Several mountain streams, but none of any magnitude, traverse the country in the same direction. One of the most striking characteristics of the climate is the violence of the monsoon rains—the mean annual fall at Mahábleshwar amounting to 239 inches. It is believed that the abundant moisture borne along from the Indian Ocean by this aerial current, becomes arrested and condensed by the mountain barrier of the Ghâts, and in this manner accounts for the excessive rains which deluge the Concan. The products of this country are the same as those of

Malabar; and the hemp raised is said to be of a stronger quality than that grown above the Ghâts. The coast has a straight general outline, but is much broken into small bays and harbours. This, with the uninterrupted view along the shore, and the land and sea breezes, which force vessels steering along the coast to be always within sight of it, rendered this country from time immemorial the seat of piracy; and so formidable had the pirates become in the 18th century, that all ships suffered which did not receive a pass from the chiefs of the pirates. The Great Mogul maintained a fleet for the express purpose of checking them, and they were frequently attacked by the Portuguese. British commerce was protected by occasional expeditions from Bombay, commencing about 1756; but the piratical system was not finally extinguished until 1812.

According to ancient traditions, this country was inhabited by a tribe of savages, till they were conquered by the Hindus, who gave it to a tribe of Brahmans; and it was held by them until it was taken possession of by the Mahometan kings of Bíjapúr. It was conquered in the 17th century by Siváji, the founder of the Mahratta empire. Towards the close of the same century Konaji Angria established a kingdom on this coast, extending 120 miles from Tannah to Bankut, together with the inland country as far back as the mountains. The dominion of this prince and his family over a portion of the tract continued till the line became extinct, and the territory lapsed to the paramount power. The remainder of the Concan had been already incorporated with the British dominions since the fall of the Peshwa in 1818.

CONCEPCION, a city of Chili, the capital of the province of the same name. Founded by Pedro de Valdivia, it was originally situated where the small village of Penco now stands, on the Bay of Talcahuano; but having been first pillaged and destroyed by the Araucanians, and in 1730 levelled to the ground by an earthquake, the town was removed to its present site, 36° 49′ S. lat., 72° 50′ W. long., in a fertile plain on the north side of the Bio-Bio, about five miles from the sea and 270 miles south-west of Santiago. In the year 1835 it was again laid in ruins by an earthquake, which so terrified the inhabitants that for a long time the place remained partly unoccupied. Afterwards, however, the streets were rebuilt, and the area occupied by the town has been greatly extended. The main streets and squares are broad and spacious; the dwelling-houses (mostly of only one floor) are among the best planned and constructed in Chili; and the cathedral, churches, and public buildings are handsome edifices. Powerful flour mills are in the town and neighbourhood, as well as immense cellars (bodegas) for the storage of wheat and wine. It is connected by rail with its two ports—Tomé and Talcahuano, and with all the important towns of the interior. Population, 19,200.

CONCLAVE. The word conclave is used to signify any company of persons gathered together in consultation; its proper meaning is any such gathering of persons *locked up together* (*con*, collective pronoun, and *clavis*, a key); and the technical meaning, which has superseded all other uses of the word, save where some other significance is specially indicated, is the meeting of the members of the Sacred College of Cardinals for the purpose of electing a Pope.

The Pope, who is simply the bishop of Rome, was originally chosen by the entire body of the people constituting the church at Rome. Gradually, and by a process of encroachment, the several steps of which are, as might be expected, very obscure, the right of nomination was confined to the clergy, the people still retaining a right of objection, exercised very much in the same manner as the forbidding banns of marriage is now exercised. The grasping tyranny of the clergy combined with the lawless turbulence of the laity, consisting no longer, as originally, of a select body of religious men, but of the entire population, to cause this participation of the laity also to fall into disuse. The next step was to allow the privilege of the vote only to the chief among the clergy—*cardinales*—the cardinal clergy, so called as the principal virtues were called cardinal virtues (see CARDINAL). During some centuries the emperor was understood to have a controlling voice in the election, in such sort that his approbation was necessary for the validity of it. But the practice varied much in this respect, according as the emperor was or was not strong, near at hand, or interested in the election. The history of this part of the subject is exceedingly obscure; but it is certain that at least one Pope provided that the consent of the emperor should be necessary for the election of his successor, and on the other hand that other elections were made about the same period without the emperor's participation.

It was not till many years after the right of election had been abusively confined to the cardinals, that the practice of shutting up those dignitaries for the purpose of exercising that right was resorted to. And in the earliest instances the "conclave" seems to have been an involuntary imprisonment imposed on them *ab extra*. In 1216 the Perugians constrained the nineteen cardinals who elected Honorius III. to enter into conclave the day after the death of Innocent III., who died at Perugia, keeping them imprisoned till the election should be completed. Gregory IX. was similarly elected at Rome in 1227, the cardinals having been shut up against their will by the senators and people of Rome. In 1272 Gregory X. was elected at Viterbo by seventeen cardinals, who had not only been shut up against their will, but from over whose heads the roof of the building in which the conclave was held was removed by the citizens in order to hasten their deliberations.

This Gregory, in a council held at Lyons in 1274, promulgated a code of law for the conducting of the Papal election, comprised in fifteen rules. And these rules, though modified by subsequent pontiffs in some respects, and supplemented by a vast number of more minute regulations, remain to the present day the foundation and origin of all the law and practice of Papal elections. The text of this code is too lengthy to be given here. It may be read in the original Latin in the *Life of Gregory X.*, by Pagi, as in many other works,—the *Notes to Platina* by Panvinius, &c.;—or in English, slightly abbreviated, in a volume on the Papal conclaves by T. A. Trollope (p. 64). The substance of some of the more important provisions may be given summarily, as follows. Cardinals to go into conclave on the tenth day after the Pope's death, attended by one person only, unless in a case of evident need, when two may be permitted. Cardinals to live in conclave in common without separation between bed and bed by wall, curtain, or veil (modified by subsequent rules to the present practice of a wooden cell for each cardinal). No access to conclave to be permitted. An opening to be left for food to be passed in. No vote shall be given save in conclave. Cardinals who quit the conclave by reason of sickness cannot vote. Those who arrive after the closing of it may enter and vote. Cardinals who may have been censured or excommunicated cannot be excluded from conclave. An election can only be made by a two-thirds majority of those present. Any man, lay or ecclesiastic, not a heretic and not canonically incapacitated, may be elected Pope. No entreaties or promises to be made by one cardinal to another with a view of influencing the vote. All bargains, agreements, undertakings, even though corroborated by an oath, having such an object to be of no validity; and "let him that breaks such be deemed worthy of praise rather than of the blame of perjury."

Very many popes have sought to enforce and make yet more stringent this last all-important rule, by reiterated fulminations of excommunication *ipso facto*, in any and every case of its contravention. The most solemn forms of oath that language can devise have been prescribed. The Bulls condemning all simoniacal bargainings have been ordered to be invariably read with every circumstance of solemnity in every conclave before the business of the meeting is entered on. And the result of all these multiplied precautions, precepts, prohibitions, and menaces has been that a study of the history of the Papal conclaves leaves the student with the conviction that no election untainted by simony has ever yet been made, while in a great number of instances the simony practised in the conclave has been of the grossest, most shameless, and most overt kind

The form of oath, as practised at the present day, which the cardinal pronounces in the act of delivering his vote, is as follows: "Testor Christum Dominum, qui me judicaturus est, me eligere quem secundum Deum judico eligi debere"—"I call to witness Christ our Lord, who shall be my judge, that I am electing him who before God I think ought to be elected." The words seem at first sight to have been chosen and put together with the view of rendering them as solemn and as binding on the conscience of the elector as possible. Yet a little examination of them will show that they are well adapted to afford room for a whole host of equivocations. And, in fact, volumes of subtle casuistry have been written on the exact sense of the terms of the cardinal's oath, and on the degree of literalness in which it must be assumed to be binding on the conscience; *e.g.*, it is the opinion of conclave tacticians that an elector may often injure the final chance of success of a candidate by voting for him at those first scrutinies, which are not intended really to result in any election, but are a mere exploring of the ground and trial of strength. Is an elector, then, to injure the chance of the man he deems the fittest to be elected by voting for him at such times? Again a man may, doubtless often does, conscientiously believe himself to be the fittest man to be elected. Must he invalidate his own election by voting for himself? Or must he vote for some other, whom he does *not* think the fittest man? It has been asked, may a man vote for a candidate whom he does not think the fittest man, when it is clear that that candidate will be elected? The answer has been in the affirmative, "because it is fitting that an election be made with concord and without giving rise to evil passions." In fact, it is well-nigh certain that if every elector at every scrutiny voted for the man whom he thought fittest to be elected, there could not be any election by a two-thirds majority at all,—so absolutely and necessarily a matter of compromise is every election!

The present practice is for such cardinals as are present in Rome to enter conclave on the tenth day after the Pope's death. Each cardinal finds a boarded cell constructed in the Quirinal or Vatican,—recently the Quirinal, henceforward necessarily the Vatican,—assigned to him by lot. Every morning and every evening they proceed to a scrutiny, *i.e.*, to a solemn voting by specially prepared voting papers (which conceal the name of the voter, to be opened only in the case of an election being made at that scrutiny) in the Sistine or in the Paoline Chapel. After each scrutiny an "accessit" takes place;—*i.e.*, after the number of the votes for each candidate has been declared, it is open to every voter to declare by a similar secret vote that he "accedes" to such or such a candidate. If no election is thus arrived at, the same process is repeated every morning and every evening, till some cardinal is found to have the requisite majority of two-thirds of those who are present, *plus* one, the candidate's own vote being subtracted. Thereupon the "adoration" immediately takes place, and the *Habemus Pontificem* is proclaimed "*Urbi et Orbi.*" (T. A. T.)

CONCORD, a city of the United States of America, capital of New Hampshire, is situated near the centre of the State, on the Merrimack River, 42 miles N.W. of Portsmouth and 75 miles N.N.W. of Boston by railroad. It is pleasantly laid out, for the most part on the west side of the river; and its principal streets are lined with trees. The State-house, which is a handsome edifice built of granite, occupies an open space ornamented with elms and maple trees. The town contains also a city hall and three public libraries; while in the neighbourhood there is the State asylum for the insane, with a farm attached for the employment of the inmates. Concord is well supplied with water, and, having both railroad and canal communication, is advantageously situated for the development of its manufactures. These consist chiefly of carriages, dry goods, leather goods, and furniture. Granite of a superior quality is also quarried in the neighbourhood; and a large trade is carried on in dressed and undressed blocks. The site of the town was first occupied by settlers in 1725; it was known as Rumford until 1765, when it received its present name. It was incorporated as a city in 1853, and is now the seat of the courts formerly held in Portsmouth. Population in 1870, 12,241.

CONCORD, a town of the United States, in Middlesex county, Massachusetts, is 20 miles north-west of Boston by railroad. It is a quiet place of 2400 inhabitants, containing a good public library. The interest attached to the town arises from the prominent part its citizens took in the early revolutionary war. It was here, on the 19th April 1775, that the first blood was shed in the War of Independence (concurrent with the battle of Lexington), when an English detachment was driven from the town by Colonel Barrett at the head of some militia and "minutemen." A granite obelisk, 25 feet in height, was erected in 1835 on the spot where the first English soldiers fell.

CONCORDANCE, a verbal index, in which all the leading words used by an author are alphabetically arranged, with a reference to the place where each occurs. The want of such a work first made itself felt in the department of biblical interpretation, and the earliest concordances were those of the Scriptures. Hence the application of the term has been generally limited to a Biblical index. The first of these was compiled under the direction of Cardinal Hugo de St Caro, who died about 1262. This concordance was formed from the Vulgate translation, and it is said that nearly 500 Dominican monks were employed on it. The earliest Hebrew concordance, called *The Light of the Way*, was produced by Rabbi Mordecai Nathan (1438–48), and published at Venice in 1523. This was followed by the much more complete and accurate work of Marius de Calasio, a Franciscan friar, whose concordance, based on that of Nathan, was published at Rome in 1621. Buxtorf's is the next Hebrew concordance that deserves mention—a work marked by much care and scholarship, but following the Masoretic divisions of the Old Testament, and so less likely to be of use to the general student. It was published at Basel in 1632, and abridged by Ravius, under the title *Fount of Zion* (Berlin, 1677). In 1754, Dr John Taylor of Norwich published his *Hebrew Concordance, Adapted to the English Bible, Disposed after the Manner of Buxtorf*. This held the first place among works of the kind, until the appearance of Dr Julius Fürst's *Hebrew and Chaldee Concordance*. Of Greek concordances to the Septuagint, the best is that compiled by Abraham Trommius, minister of Groningen, which was published at Amsterdam in 1718. This is a work distinguished by great industry and erudition; it forms a complete index and lexicon to the Septuagint, all save the book of Daniel, which was not at that time included in the Septuagint version. Among Greek concordances to the New Testament, the principal place is held by that of Erasmus Schmid (1638), reprinted in a corrected form at Gotha in 1717. An abridged edition of this valuable work is published by Messrs Bagster, in their *Polymicrian Series.* The first of English concordances was one to the New Testament, published at London, before 1540. The earliest concordance to the entire Bible, in English, was formed by Marbeck (London, 1550). This work is very imperfect, and refers only to chapters, not to verses. It was followed by various others, among which may be noted the *Cambridge Concordance* (1689). The *Englishman's Concordance*, designed for the use of students who are acquainted only with the vernacular, is valuable for purposes of exegesis, and the comparison of different English translations of the same Greek and Hebrew words. But all of these were thrown into the shade by the full and trustworthy work of Alexander Cruden. This is entitled *A Complete Concordance to the Holy Scriptures of the Old and New Testament*, and was published in 1737. It has been frequently re-edited, and still retains its place as an authority. Besides concordances to the entire Bible, verbal indexes to separate portions of it have been prepared. There is a *Concordance of the Proverbs of Solomon, and of his Sentences in Ecclesiastes;* a *Concordance of the Metrical Psalms and Paraphrases* (Edin., 1856); and a *Concordance of the Prayer-Book Version of the Psalms.* There is also a *Concordance of the Apocrypha.* Concordances to other works than the Scriptures are of more recent date. The very earliest is a *Concordance of Feudal Law*, compiled at the end of the 17th century. Twiss and Ayscough each prepared a concordance to the works of Shakespeare, but these were both incomplete and incorrect. Mrs M. Cowden Clarke, in 1847, supplied the deficiency by her elaborate *Concordance to Shakespeare.* A *Concordance to Milton* was published in 1867. The latest works of this class are the *Concordance to the Works of Alfred Tennyson, D.C.L.*, by D. B. Brightwell (1869), and that to the works of Alex. Pope by Edwin Abbott (1875).

CONCORDAT is an agreement between the Pope, as representing the Catholic Church, and a temporal sovereign, with reference to the rights of the church within the territory of the latter. It must be borne in mind that the pretensions of Hildebrandism (1074 to 1300 A.D.) were very great; they included a power of absolving sovereigns and subjects from their oaths, a large feudal revenue collected abroad, a peculiar status for the Catholic clergy. Against these, temporal sovereigns claimed what were called *jura majestatis circa sacra*,—viz., *jus advocatiæ* (Schutzrecht), or the supreme patronage of the national church; *jus cavendi* (Recht der Versorge), or right of considering whether ecclesiastical regulations conflict with civil duties; and *jus inspiciendi*, or general right of superintending the morals of the church and the administration of its property. The great historical assertions of Papal supremacy were made in the Decretals:—"*Venerabilem,*" sent in 1197 by Innocent III. to the majority of the imperial electors who had chosen Philip of Swabia; "*Ad Apostolicæ,*" by which Innocent IV. in 1245 deposed Frederick II. from the imperial throne on the ground of perjury, sacrilege, and heresy; "*Clericis Laicos*" and "*Unam Sanctam*" (1296 and 1302), which dealt with the taxation of church property, and laid down the principle "oportet autem gládium esse sub gladio." The same claims appear in the Extravagant "*De Consuetudine,*" issued by John XXII. in 1322, and in the frequently published Bull "*In Cœna Domini*" (1773). The Encyclical Letter "*Quanta Cura,*" and relative Syllabus of 1864, and the *Costituzione* "*Pastor Æternus*" of 1870 contain the latest expression by the Pope of his international functions. It was after the empire had, by the decree of Frankfort (1338), declared that Papal confirmation and coronation were unnecessary, and the reformatory councils of Constance and Basel had increased the controlling power of the whole church, and diminished the appeals and *annates* which caused so much discontent, that pragmatic sanctions and concordats began to be used to regulate the relations between the different European powers and the Papacy. The French Pragmatic of 1268, which defended the local jurisdictions and rights of presentation, and prohibited Papal imports except for pious, rational, and urgent causes, and the Pragmatic Sanction which in 1438 at the Council of Bruges the French clergy composed in imitation of the Basel decrees, were largely modified in favour of Rome by the concordat entered into in 1510 between Francis I. and Leo X. This arrangement left the nomination of bishops with the Crown, which had before merely given a *congé d'élire* for the election by chapter, but assigned no term within which the Pope must institute. The consequence was that whenever it suited his purpose the Pope delayed institution. After a long period of irritating dispute the French clergy, led by Le Pellier and Bossuet, in their famous declaration of 1682, formally asserted what are now called Cismontane or national church principles. Louis XIV. had considerably enlarged the Crown right of *Régale*, which included the revenues of vacant churches, but he was now (1693) ignominiously compelled to write a letter to Innocent XI., in which he undertook not to enforce the edict of 1682. The suppression of the Jesuits, in 1773, was a heavy blow to the temporal influence of Rome. It was mainly brought about by the behaviour of Clement XIII. The duke of Parma had prohibited appeals from his territory to Rome in questions about the benefices of Parma, and had also republished the principle, familiar in the common law of Europe, that no Papal rescript should take effect in Parma without receiving the ducal *exequatur.* Clement then fired off the "Monitorio di Parma," excommunicating in terms of the Bull "*In Cœna*" all concerned in the Parmesan edict. The indignant reaction which followed in all the courts of Catholic Europe decided the triumph of Ganganelli and the Regalisti party, who were opposed at the Vatican by the Ultramontane party of Zelanti. Under the civil constitution which the French Church received from the Revolution, the bishops received institution from their metropolitan. In 1801, a concordat was arranged between Napoleon as first consul and Pius VII. Under this the consul nominated and the Pope appointed bishops, who were all required to swear allegiance to the republic[1]. The much more important matters of the verification of Bulls by *Exequatur, Placitum*, or Letters of *Pareatis*, the position of the delegates of the church, the effect to be given to the decrees of councils held out of France, and the *Appel comme d'Abus*, were all settled by the "Regulations of the Gallican Church," better known as the Organic Articles, with regard to which the Pope was not consulted. Shortly afterwards Napoleon, by the decree of Schönbrunn (1809), annexed the Papal dominions to France, and imprisoned the Pope at Fontainebleau, where the "false" concordat of 1813 was signed. The main provision of this was to devolve the right of institution on the metropolitan bishop, if not exercised by the Pope within six months. In 1817 the Bourbons tried to negotiate a retrograde concordat, but the attempt was fortunately frustrated. The political attitude of Guizot and Napoleon III. towards Gregory XVI. and Pius IX. was friendly, but in 1870 the Prussian victories brought to an

[1] Several bishops, who refused this oath, were driven from France, and formed in England La Petite Eglise, which existed for some time (see *The Guardian*, 4 Feb. 1852).

end the French occupation of the Papal States which had begun in the intervention of 1849, and had been continuous from 1864. By the Italian statute of guarantees (13th May 1871) personal inviolability and the honours of a sovereign are secured to the Pope. He has also a large income and several residences, and a private postal and telegraphic service; and he is allowed to receive diplomatic agents from foreign states. The same statute gives complete freedom to the church, but deprives it of coercive jurisdiction. The royal *Placet* is relinquished as unnecessary, but a stringent penal law (7th June 1871) is directed against seditious words, writings, or acts of the clergy.

In the empire the earliest concordat is the Concordatum Calixtinum of 1122, between Henry V. and Pope Calixtus II. The benefits of the Basel Decrees were in great measure lost by the concordat entered into in 1448 between Frederick III. and Nicholas V. The political position of the Pope was much altered by the Treaty of Westphalia, which, without his consent, and even against his protests, conceded the right to certain nations of freely exercising the Protestant religion.

Early in the 18th century the cause of the national church in Austria, and of the immediate divine right of Episcopacy, was placed on solid foundations of learning and argument by the writings of Van Espen *(Jus ecclesiasticum universum hodiernæ disciplinæ*, Cologne, 1702; *Tractatus de promulgatione legum ecclesiasticarum)*. The abuses of the permanent *Nuntiatura*, maintained by the Pope, called forth the *Punctation* of the four archbishops who met at Ems, 25th August 1786. Joseph II. had already carried out large reforms, but these episcopal resolutions recommended still further changes in the "Recursus ad Principem," or prohibition of appeals to Rome, the power of dispensation and of granting faculties, the administration of conventual property and charitable funds, the reservation of benefices and their transmission by inheritance, the exaction of *annates* and *pallium* money, &c. Under the decrees of Joseph II. in 1781, no Papal Bulls or rescripts were allowed to be published, except such as had received the Placitum Regium, and had been effected through the intervention of the imperial and royal agency at Rome. In 1850, however, both the bishops and the faithful under their charge were allowed to have recourse to the Pope in spiritual matters, and to receive the decisions of his Holiness without the previous consent of the secular authorities. With the exception of the three archbishoprics of Olmütz, Salzburg, and Breslau, where the archbishop is elected by the chapter, the practice was, on a bishopric becoming vacant, for the emperor to propose three candidates from whom the Pope selects one—a selection subsequently ratified by the emperor. The same decree of 1850, proceeding on the anti-revolutionary imperial patent of 4th March 1849 (§ 2), permits Catholic bishops to issue admonitions and ordinances, without consent of the civil power, to decree ecclesiastical punishments which do not affect purely civil rights, to suspend and remove from ecclesiastical office, and to declare emoluments forfeited, and to control education in primary and intermediate schools and in the universities. This arrangement was sealed by the concordat of 18th August 1855 (printed fully in *Times*, 20th November 1855), which, however, was repealed by the series of Church Acts passed by Prince Auersperg in 1874, in imitation of the Falk legislation of Prussia.

The relations of Belgium with Rome were of course at one time determined by the decree of the French National Assembly (1791), and the concordat between Pius VII. and Napoleon (1801). On 18th June 1827, William I., Protestant king of the Netherlands, entered into a concordat with Pope Leo XII., which confirmed and extended the provisions of the earlier concordat relating to the institution of bishops by letters apostolic. The power which the Crown then reserved of striking out objectionable names from the list of candidates prepared by the chapter was entirely renounced by the 16th Article of the Belgian Constitution of 1830, which declares that the state has no right to interfere with the nomination or installation of any religious ministers, or to prevent them from corresponding with their superiors or from publishing their Acts. But then the Government has this indirect control, that all the salaries of the Catholic clergy are voted in the annual budget, and do not belong to the church. The concordat of 1827 was never in force in Holland, where the fundamental law of 1848 (§ 65) declares that no Dutchman can accept titles without the permission of the king, and where public opinion has prevented the creation of Catholic bishops.

Spain, although the most Catholic of powers, has, at least since the accession of the Austrian dynasty, zealously defended its national church rights against the Pope. In 1568, Philip II. claimed as royal prerogative the right to present to all Spanish bishoprics, and created a Board, "Supremo Consejo de la Camara," to preserve the royal jurisdiction, to protect the canons, and to watch over the external policy in ecclesiastical matters. The Pope having sided with Austria in the Succession War, the breach between Spain and Rome widened during the 18th century. The principles that no causes should be carried before a judge outside the kingdom, that benefices should be conferred only on natives, that sovereigns are not subject to interdict or spiritual censure, that all Bulls should, before publication, be subject to the royal *Cedula*, were loudly and angrily proclaimed; and in 1805 the king attacked the secret influences of the *Curia* by directing that all applications to Rome for grants and dispensation should receive the *Visto Bueno* of the royal agent at Rome. The estrangement continued in the 19th century, when till 1848 the Pope refused to recognize the succession of Isabella II. under the Pragmatic Sanction of 1830. From 1753 to 1851, matters had stood on a concordat which the eminent statesman, De Carbajal, persuaded Ferdinand VI. to negotiate with Clement XII. It gave the king the right of presentation to vacant bishoprics (patronatos), and to the Pope 22,000,000 reales as compensation for the loss of *annates* and fees on briefs. The concordats of 1851 and 1859 are more favourable to Rome; but the attempt of Canovas del Castillo and the Cardinal Simeoni to procure a recognition of the 1851 concordat, in 1875, was defeated by General Jovellar.

In non-Roman Catholic states, of course, no valid concordat could be framed. Accordingly, as in the cases of Prussia (1821) and Hanover (1824), edicts relating to the adjustment of dioceses, or other matters not purely spiritual, were issued by the Pope under the name of Bullæ Circumscriptionis. These were formally sanctioned by the Home Government, and directed to be printed in the collection of laws.

The most important sources of information on this subject are the reports presented to Parliament in 1816 and 1851, on the "Regulation of Roman Catholic Subjects in Foreign Countries," which have been summarized in the 2d volume of Sir R. Phillimore's *Commentaries on International Law.* The works of Van Espen and the *Euchiridion Juris Ecclesiastici* of George Rechberger (1809) are standard works. The French concordats have been elaborately discussed by M. de Pradt, at one time archbishop of Malines, in *Les Quatres Concordats*, 3 vols., Brussels, 1815, and *Suite des Quatre Concordats*, 1 vol., Paris, 1820. The works of the eminent jurist Portalis, who took an active part in the discussion of the latter French concordats, may also be consulted,—*Discours, Rapports, et Travaux inédits sur le Concordat de* 1801, *les Articles Organiques*, &c. (W. C. S.)

CONCORDIA, the goddess of concord, a Roman divinity, in whose honour several temples were erected at Rome. The most ancient of these was that built on the declivity of the Capitol by Camillus, 367 B.C. In this temple the senate sometimes assembled. It was restored by Livia, the wife of Augustus, and consecrated by Tiberius, 9 A.D. In the time of Constantine and Maxentius it was destroyed by fire, but was again restored. The second temple was erected close to that of Vulcan by Cn. Flavius; and there was a third built by L. Manlius, on the Capitoline Hill. Concordia was represented as a matron holding in her right hand a patera, or an olive branch, and in her left a cornucopia. Her symbols were two hands joined together, and two serpents entwined about a caduceus, or herald's staff.

CONCORDIA, a village of Italy in the province of Venice, 35 miles N.E. of the city of that name, and in the immediate neighbourhood of the town of Portogruaro, of importance as preserving the name and marking the site of a famous Roman city of the later empire. It was probably founded by Augustus, on the pacification of his dominions, and consequently bears the full title of Colonia Julia Concordia. Its rapidly growing prosperity, well attested even by the fragmentary remains of its buildings, was suddenly crushed by Attila in 452 A.D.; but its continued existence throughout the Middle Ages is proved both by history and by archæology. The baptistry still extant is in the style of the 9th century, and an inscription preserves the memory of a bishop Regimpotus of the 10th. The place has been brought again into notice by the discovery, in 1873, of the old Christian cemetery which has furnished upwards of 160 stone coffins, in several cases distinguished by inscriptions of considerable import to the historian.—See *Bullettino dell' Instituto di Corr. Arch.* 1874.

CONCRETE, an artificial conglomerate or rubble masonry, consisting of a mixture of coarse pieces of stone, gravel, shingle, broken brick, or crushed slag with sand and Portland or other cement. It is employed for laying the foundations of bridges and of buildings on soft or wet ground, as also in the construction of moles and breakwaters, and of houses and churches; for the backing of wharves, of the abutments of arches, and of masonry generally where heavy walls are required; for the substance of fire-proof doors; for the making of sewer-pipes; and as a paving for streets and floors. It soon hardens after use, becoming a stony mass little permeated by moisture. In the shape of blocks, sometimes weighing very many tons, it has been found of great value for the formation of harbours and sea-walls in places to which stone could not have been transported. The foundations of the breakwater pier at Douglas, Isle of Man, were made by laying down concrete within frames resting on submarine rock. The quay walls of Stobcross Docks, Glasgow, are supported on triple groups of concrete cylinders, 27½ feet in length and resting on iron shoes. Each cylinder is formed by sinking in the soil a column of eleven rings of concrete; this, after being cleared of the sand and gravel it contains, is filled with Portland cement concrete. Walls are made of concrete either by allowing it to harden in mass between two faces of boarding, or by making it into blocks and building as with bricks. Concrete was employed by the Romans, by whom the term *signinum* was applied to a kind of plaster composed of powdered tiles and mortar; and Smeaton gained the idea of applying it to the construction of river-works from an inspection of the ruins of Corfe Castle in Dorsetshire, a Saxon structure. In the Middle Ages it was much used in the making of fortifications.

The composition of concrete necessarily depends to some extent upon the nature and qualities of the materials most available for making it. The béton aggloméré of M. F. Coignet is composed of about 180 parts of sand, 44 of slaked lime, 33 of Portland cement, and 20 of water. A mixture of the cement with the sand and lime is first made, with the addition of small quantities of water; the mass is then incorporated with the requisite amount of water in a cylindrical machine, from the bottom of which it is delivered ready for compression in moulds. This composition can be formed into blocks of any desired bulk; and these, after exposure to the weather for a few weeks, acquire a hardness equal to that of good building stone. A good concrete can be made from 60 parts of coarse pebbles, 25 of rough sand, and 15 of lime. Semple recommends a mixture of 8 parts of pebbles, 4 of sharp river sand, and 1 of lime. The proportions given by Treussart are unslaked hydraulic lime 30 parts by measure, trass of Andernach 30, sand 30, gravel 20, broken stone or hard limestone 40 parts; and for another concrete, hydraulic lime 33 parts, pozzuolana 45, sand 22, broken stone and gravel 60 parts; the former is used as soon as made, the latter should be exposed about 12 hours after preparation. Burnt clay and pounded brick may be used in the same proportions as the trass, but are best not employed in sea-water. The quantity of natural or artificial pozzuolanas is increased, and that of the gravel or stone decreased, if rich limes are used (Burnell, *Limes, &c*). Excellent concrete is made from Thames or other river ballast mingled with ⅐th or ⅛th its bulk of lime; in setting it contracts by about one-fifth of its volume, a cubic yard of the concrete requiring 30 cubic feet of ballast and 3½ cubic feet of lime. Hydraulic concrete must contain a sufficiency of mortar to aggregate the whole mass of rubbly material, and the lime or cement should be thoroughly slaked before the immersion of the concrete. For the breakwater at Dover Mr Lee employed 16 foot cubes of concrete made in moulds, composed of Portland cement, Portland stone chippings, sand, and shingle. The blocks at the mole, Marseilles, were formed from 5 parts of sand, 2 of broken stone, and 3 of Theil lime. The concrete used at the extension of the London docks consisted of 1 part of blue Lias lime to 6 of gravel and sand; and that made by M. Vicat for the bridge at Souillac, on the Dordogne, contained, with 26 parts of hydraulic lime, 39 of granitic sand, and 66 of gravel. The composition for the Copenhagen sea-forts was 1 part of Portland cement, 4 of sand, and 16 of fragments of stone.

Austin's artificial stone is a concrete of sand and other materials cemented by lime. *Ransome's concrete stone* is made by subjecting a mixture of sodium silicate and clean pit sand, to which between 5 and 10 per cent. of chalk has been added, to the action of a solution of calcium chloride, whereby insoluble calcium silicate and soluble sodium chloride, or common salt, are produced, the former acting as a cementing material for the particles of sand. The stone is made non-absorbent by giving the face of it a wash with sodium silicate, and then a second application of the calcium chloride. (See H. Reid, *A Practical Treatise on Concrete*, London, 1869.)

CONCUBINAGE, the state of a man and woman cohabiting as married persons without the sanction of a legal marriage. In a scriptural sense, it denotes cohabiting lawfully with a wife of second rank, who enjoyed no other conjugal right but that of cohabitation, and whom the husband could repudiate and dismiss with a small present (Gen. xxi.) In like manner he could, by means of presents, exclude his children by her from the heritage (Gen. xxv.) To judge from the conjugal histories of Abraham and Jacob, the immediate cause of concubinage was the barrenness of the lawful wife, who in that case introduced her maid-servant to her husband, for the sake of having children. This resembles the singular practice authorized not only in Israel (Deut. xxv.), and anciently in Athens and Sparta, but by the laws of Menu, that a brother, or some other person, should be substituted when the married couple had been unable to produce offspring. In process of time, however, concubinage appears to have degenerated into a regular custom among the Jews; and the institutions of Moses were directed to prevent excess and abuse in that respect.

The Roman *concubinatus* differed from *justæ nuptiæ* in not giving the father the *potestas* over his children, and from *contubernium*, which was the concubinage of slaves. It was a permanent monogamous relation, free from some of the restrictions imposed by the civil law upon marriages. Although the married woman had a more dignified position, concubinage was thought the appropriate union for persons of different ranks, as a *patronus* and *liberta*. By imperial legislation, *naturales liberi* and concubines were gradually admitted to limited rights of succession; and the legitimation *per subsequens matrimonium* completed their status.

Concubinage is also used to signify a marriage with a woman of inferior condition, to whom the husband does not convey his rank. Such concubinage was beneath marriage both as to dignity and civil rights, yet concubine was a reputable title, and very different from that of "mistress" among us. The concubine also might be accused of adultery in the same manner as a wife. By French law the presence of a concubine in the house entitles the wife to a divorce. This kind of concubinage is still in use in some countries, particularly in Germany, under the title of *halbehe* (half-marriage), or left-hand marriage, in allusion to the manner of its being contracted, namely, by the man giving the woman his left hand instead of the right. This is a real marriage, though without the usual solemnity; and the parties are both bound to each other for ever, though the female cannot bear the husband's name and title. Neither spouse has any right of succession to the other, but the children take a third of the father's estate, if he leaves no lawful children.

Du Cange observes that one may gather from several passages in the epistles of the popes that they anciently allowed of such connections. The seventeenth canon of the first Council of Toledo (400 A.D.) declares that he who with a faithful wife keeps a concubine is excommunicated; but that if the concubine serve him as a wife, so that he has only one woman, under the title of concubine, he shall not be rejected from communion. This applied not only to laymen, but to inferior priests, who were then allowed to marry. The latter councils extend the name concubine to disreputable women not kept in the house. That is also the meaning of the word in the 8th rubric of the concordat of 1517 between Leo X. and Francis I. The Council of Nicæa refers to a class of secret concubines, *superinductæ*, and St Augustine denounces all irregular relations.

It is certain the patriarchs had a great number of wives, and that these did not all hold the same rank,—some being inferior to the principal wife. Solomon had 700 wives and 300 concubines. Q. Curtius observes that Darius was followed in his army by 365 concubines, all in the equipage of queens.

In most Mahometan and other polygamous countries, female slaves are used as concubines and enjoy a certain status. Under the ancient *Fueros*, which succeeded the *Lex Visigothorum* in Spain, concubinage was recognized by the name of *barragania*. The parties entered into a contract (*carta de mancebia e campanera*), by which the man took the concubine *por todos los dios que yo visquiere*, and she received right to bread, table, and knife (*a pan, mesa, e cuchello*). Apart from contract, some *Fueros* gave the faithful concubine a right of succession to one-half of the man's acquired property. The Council of Valladolid (1228) reproved the *barragania* of priests. Similarly the *Gragas*, or ancient law of Iceland, recognized the *frilla*, or concubine, alongside of the *husfreyia*, or lawful wife, though the two were not permitted to dwell in the same house. According to the Danish *hand vesten*, the concubine who had publicly lived with a man and partaken his meals for three winters became a lawful wife. The Celtic handfast marriage may also be referred to. (W. C. S.)

CONDAMINE, CHARLES MARIE DE LA. See LA CONDAMINE.

CONDÉ, a town of France, in the department of Nord, arrondissement of Valenciennes, is situated at the confluence of the Scheldt and the Haine, and at the terminus of the Mons canal, two miles from the Belgian frontier. It contains a hôtel de ville and an arsenal, a church and a hospital. Brewing is carried on to a small extent, as well as the manufacture of oil and salt, and there is a large trade in coal. The place is of considerable antiquity, dating at least from the later Roman period. Taken in 1676 by Louis XIV., it definitely passed into the possession of France by the Treaty of Nimeguen two years later, and was afterwards fortified by Vauban. During the revolutionary war it was attacked and taken by the Austrians (1794); and in 1815 it again fell to the Allies. Condé gives its name to a distinguished branch of the Bourbon family. Population of the town in 1872, 3748; of the commune, 4964.

CONDÉ SUR NOIREAU, a town of France, in the department of Calvados, and arrondissement of Vire, is situated at the confluence of the Noireau and the Drouance, 28 miles south of Caen. The town is the seat of a civil tribunal, and its manufactures are not unimportant, comprising cotton and woollen weaving, dyeing, and tanning. The two old churches of St Sauveur and St Martin are worthy of remark, the latter possessing a very fine stained-glass window representing our Lord's Passion. A statue has been erected here to Dumont d' Urville, the traveller, a native of the town. Condé formerly belonged to the countship of Mortain; and it owes its origin to a fort which is said to have been constructed by the Romans. It fell into the hands of the English in 1418, but was retaken by Charles VII. in 1449. Much interest was shown by the inhabitants in the Reformation movement, and a provincial synod was held in the town in 1674 At the Revolution it lost its name of Condé, and during that period was known only as Noireau. Population of the town in 1872, 6445.

CONDÉ, PRINCES OF. The title of prince of Condé (assumed from the ancient town of Condé, noticed above) was borne by a branch of the House of Bourbon. The first who assumed it was the famous Huguenot leader, Louis de Bourbon, the fifth son of Charles de Bourbon, duke of Vendôme (see next article). His son, Henry, prince of Condé (1552–1588), also belonged to the Huguenot party. Fleeing to Germany, he raised a small army, with which in 1575 he joined Alençon. He became leader of the Huguenots, but after several years' fighting was taken prisoner of war. Not long after he died of poison, administered, according to the belief of his contemporaries, by his wife, Catherine de la Trémouille. This event, among others, awoke strong suspicions as to the legitimacy of his heir and namesake, Henry, prince of Condé (1588–1646). King Henry IV., however, did not take advantage of the scandal. In 1609 he caused the prince of Condé to marry Charlotte de Montmorency, whom shortly after Condé was obliged to save from the king's persistent gallantry by a hasty flight, first to Spain and then to Italy. On the death of Henry, Condé returned to France, and intrigued against the regent, Mary de' Medici; but he was seized, and imprisoned for three years.

There was at that time before the court a plea for his divorce from his wife, but she now devoted herself to enliven his captivity at the cost of her own liberty. During the rest of his life Condé was a faithful servant of the king. He strove to blot out the memory of the Huguenot connections of his house by affecting the greatest zeal against Protestants. His old ambition changed into a desire for the safe aggrandizement of his family, which he magnificently achieved, and with that end he bowed before Richelieu, whose niece he forced his son to marry. His son Louis, the great Condé, is separately noticed below. The next in succession was Henry Jules, prince of Condé (1643–1709), the son of the great Condé and of Clémence de Maillé, niece of Richelieu. He fought with distinction under his father in Franche-Comté and the Low Countries; but he was heartless, avaricious, and undoubtedly insane. The end of his life was marked by singular hypochondriacal fancies. He believed at one time that he was dead, and refused to eat till some of his attendants dressed in sheets set him the example. His grandson, Louis Henry, duke of Bourbon (1692–1740), who did not assume the title of prince of Condé which belonged to him, was member of the council of regency which ruled during the minority of Louis XV., and first minister from the death of the duke of Orleans in 1723 to 1726, when he was superseded by Cardinal de Fleury. He greatly enriched his family and his mistress, De Prie, by taking every advantage of his position; but he made himself unpopular by the weight of taxes which he imposed. The son of the duke of Bourbon, Louis Joseph, prince of Condé (1736–1818), after receiving a good education, distinguished himself in the Seven Years' War, and most of all by his victory at Johannisberg. As governor of Burgundy he did much to improve the industries and means of communication of that province. At the Revolution he took up arms in behalf of the king, became commander of the "army of Condé," and fought in conjunction with the Austrians till the peace of Campo Formio in 1797, being during the last year in the pay of England. He then served the emperor of Russia in Poland, and after that (1800) returned into the pay of England, and fought in Bavaria. In 1800 Condé arrived in England, where he resided for several years. On the restoration of Louis XVIII. he returned to France. He died at Paris in 1818. He wrote *Essai sur la Vie du grand Condé* (1798).

See *L'Histoire de l'Armée de Condé*, by Muret; *Vie de Louis Joseph, prince de Condé*, by Chamballand; *Histoire des trois derniers princes de la maison de Condé*, by Crétineau-Joly; and *Histoire de la maison de Condé*, by the Duc d'Aumale (translated by R. B. Borthwick, 1872).

CONDÉ, Louis de Bourbon, Prince of (1530–1569), fifth son of Charles de Bourbon, duke of Vendôme, younger brother of Anthony, king of Navarre, was the first of the famous House of Condé. Brave though deformed, gay but extremely poor for his rank, Condé was led by his ambition to a military career. He fought with distinction in Piedmont under Marshal de Brissac; in 1552 he forced his way with reinforcements into Metz, then besieged by Charles V.; he led several brilliant sorties from that town; and in 1554 he commanded the light cavalry on the Meuse against Charles. He then joined the Huguenots, and he was concerned in the conspiracy of Amboise, which aimed at forcing from the king by aid of arms the recognition of the Reformed religion. He was consequently condemned to death, and was only saved by the decease of Francis II. At the accession of the boy-king, Charles IX., the policy of the court was changed, and Condé received from Catherine de' Medici the government of Picardy But the struggle between the Catholics and the Huguenots soon recommenced; in 1562, 200 of the latter were massacred at Vassy by Duke Francis of Guise. Upon this Condé retired from Paris, put himself at the head of 1500 horsemen, and took possession of Orleans. Having raised troops in Germany, and entered into negotiations with Elizabeth of England, he marched on Paris, with 8000 foot and 500 horse. A battle took place at Dreux, in which the leaders on both sides, Condé and Montmorency, were taken prisoners. Condé was liberated by the pacification of Amboise in the next year (1563). In 1567 the war broke out again. It was strongly suspected by the Huguenots that Catherine was meditating a great and final blow—the revocation of the Edict of Amboise, the perpetual imprisonment of Condé, and the death of Coligni; and their suspicions were confirmed by the levy of soldiers, including 6000 Swiss, which she was engaged in making. Coligni determined to oppose her with a still bolder plan. The Huguenots were to rise *en masse*, crush the Swiss before they could join the main army, and take possession of the young king, his brothers, and Catherine herself. But both the Swiss and the royal family escaped safely to Paris. Paris was blockaded, and an indecisive battle fought at St Denis. During the next year peace was again made, but soon after Catherine attempted to seize both Condé and Coligni They fled to La Rochelle, and troops were collected. At the battle of Jarnac, with only 400 horsemen, and without having made himself sufficiently certain of the support of the infantry, Condé rashly charged the whole Catholic army. Worn out with fighting, he at last gave up his sword, and a Catholic officer named Montesquieu treacherously shot him through the head (15th December 1569).

CONDÉ, Louis de Bourbon, Prince of (1621–1681), called during the lifetime of his father Duc d'Enghien, but usually known as Condé the Great, was a distinguished French general, and one of the leaders of the Fronde. He was the son of Henry, prince of Condé, and Charlotte de Montmorency, and was born at Paris on the 7th September 1621. As a boy, under the careful supervision of his father, he studied diligently and displayed much talent at the Jesuits' College at Bourges; at seventeen he was sent to govern Burgundy; and while yet in his teens he had displayed his extraordinary courage in more than one campaign.

During the youth of Enghien all power in France was in the hands of Richelieu; to him even the princes of the blood had to yield precedence; and among the obsequious courtiers none more eagerly sought his favour than Henry, prince of Condé. Enghien, therefore, with all his exaggerated pride, was forced to bow and render homage. Once, having ventured to pass through Lyons without visiting the great minister's brother, he was forced to retrace his steps 200 leagues, in order to atone for the slight. But a far more momentous sacrifice was required of him. He was already deeply in love with Mlle. de Vigean, who in turn was passionately devoted to him, yet, to flatter the cardinal, he was compelled by his father, at the age of twenty, to give his hand to Richelieu's niece, Claire Clémence de Maillé Brézé, a child of thirteen years of age.

In 1643 Enghien was appointed to command against the Spaniards. He was opposed by experienced generals, De Mello and Fuentes, and the forces of the enemy were composed of veterans; on the other hand, the strength of the French army was placed at his command, and with him served Gassion and other skilful leaders who had fought under Gustavus Adolphus. At Rocroy a great battle took place. At first defeat threatened the French, but, by the rapidity and boldness of his tactics, Enghien changed the event into a decided victory, and at the age of twenty-two made himself the most famous French general of his day. The achievement was well followed up, and, after several other successes, Thionville was forced to capitulate. Returning to Paris in triumph, Enghien gave himself up to pleasure, and in gallantry and intrigues strove to forget his enforced and hateful marriage. In 1644 he was sent into Germany to the assistance of Turenne, who was hard pressed by the able Comte de Mercy. At Fribourg for several days there was continuous fighting, which cost dear to both sides, but especially to the French, whose lives were ruthlessly squandered by their general. The result, however, was equal to a great French victory; for, alarmed at the stern discipline displayed by his army, the towns of the Rhine, including Mayence, opened their gates to the duke. The next winter Enghien spent, like every other winter during the war, amid the gaieties of Paris. The summer campaign of 1645 opened with the defeat of Turenne by Mercy, but there followed a series of brilliant victories won by Enghien, who fought in person with untiring energy and careless courage. In the battle of Nordlingen, in which Mercy was killed, his horse was twice shot under him, and he received several serious wounds. The capture of Philipsburg was the most important of his other achievements during this campaign. In 1646 the duke of Orleans took the command, and Enghien volunteered to serve under him; but after the capture of Mardyke Orleans returned to Paris, leaving Enghien to take Dunkirk.

It was in this year that the old prince of Condé died. The enormous power that fell into the hands of his successor was naturally looked upon with serious alarm by the regent and her minister. Condé's birth and military renown placed him at the head of the French nobility; but, added to that, the family of which he was chief was both enormously rich and master of no small portion of France. Condé himself held Burgundy, Berry, and the marches of Lorraine, as well as other less important territory; his brother Conti held Champagne, his brother-in-law Longueville Normandy. When, therefore, he sought the office of admiral of France, the Government, determined to permit no increase of his already overgrown authority, refused on various pretexts to comply. But Mazarin did not dare to use it, as he had intended, as a dowry for his niece; and compensation was made to the prince by the gift of the post of captain-general, with power to appoint every officer in the army. Still dissatisfied, Condé now sought permission to raise an army at his own expense, and conquer Franche-Comté for himself. This could not be allowed; and Mazarin made an attempt, which for the moment proved successful, at once to find him employment and to tarnish his fame as a general. He was sent to lead the revolted Catalans. Supported in the meanest way, he was unable to achieve anything, and, being forced to raise the siege of Lerida, he returned home in bitter indignation. In 1648, however, he received the command in the important field of the Low Countries; and at Lens a battle took place, which, commencing with a panic in his own regiment, was retrieved by Condé's coolness and bravery, and ended in a victory that fully restored his prestige.

In September of the same year Condé was recalled to court, for the regent required his support. She was then engaged in a determined struggle against the Parliament of Paris, which, led by the noble Matthieu Molé, the Pym of France, was, like the contemporary Long Parliament in England, fighting for popular freedom, but hampered, unlike the Long Parliament, both by its too tender reverence for the royal prerogative and by its alliance with De Retz and a section of the nobility, whose sole wish was to make of it a tool to gain the ends of their personal ambition. Influenced by the fact of his royal birth and by his arrogant scorn for the bourgeois, Condé lent himself to the court party. With his usual insolence he bullied and swore in the Parliament; and finally, after much hesitation, he consented to lead the army which was to reduce Paris.

On his side, insufficient as were his forces, the war was carried on with vigour. When an opportunity offered at Charenton, he struck terror into the Parisians by putting 3000 of their picked forces to the sword. But such opportunities were seldom afforded him. The burgher soldiers had too tender a regard for their own safety to expose themselves outside the walls when his troops were in sight; their most warlike achievement was the sham-fight with the garrison of the Bastille, when both sides used blank cartridge, and the duchess de Longueville with her ladies, seated in the thickest of the fire, ate sweatmeats and smiled on their valour. The prince of Conti, who had been won over by De Retz to accept the office of commander-in-chief of the army of the Parliament, considered that he sufficiently fulfilled the duties of his exalted position by riding at the head of his troops through the streets of Paris, and regularly quitting them as they passed out of the gates. Enthusiasm was kept up by the duchess de Longueville's brilliant and crowded receptions. But at length their substantial losses, and a threatening of scarcity of food, made the citizens weary of the war. The Parliament became timid as it watched the events of the contemporary revolution in England. The regent and Mazarin were still more alarmed by the same terrible warning, as well as by their fears of a Spanish invasion and a declaration in favour of Paris from Turenne, who was advancing thither with his army. A conference was accordingly held at Ruel, and with great difficulty Mazarin and Molé brought about peace.

Once more the court met at Paris, again given up to selfish ambition, vanity, and intrigues. Condé, most ambitious and vain of all, too vain to stoop even to civility, quickly earned for himself universal dislike. With no other apparent reason than an arbitrary whim, he forced the queen to reinstate as captain of the guard a certain conceited marquis named Jarsay, who had tormented her with his presumptuous love addresses. He prevented the marriage of one of Mazarin's nieces with the duke of Mercœur, refused to meet the cardinal in the council, and treated him with vulgar rudeness. The other nobles he offended by his airs of unapproachable superiority; he thwarted their attempts to attain the paltry ceremonial dignities—such as the high privilege of sitting at the royal receptions or assisting in the royal toilette—which were the dearest objects of their ambition; he kept them waiting hours in his antechamber, and yawned in their faces when they were admitted into his presence. With the Fronde he was tricked into an open quarrel. By the contrivance of Mazarin shots were fired into his empty carriage, and he was persuaded that they had been aimed at his life, and that De Retz and Beaufort, the noble patrons of the Fronde, were responsible for the deed. The prince at once accused them openly before the Parliament, nor would his pride allow him to own his mistake when the utter worthlessness of Mazarin's witnesses was conclusively proved. De Retz, an intriguer superior to Mazarin in boldness and scarcely inferior in duplicity, now secretly joined with the court. Yet, knowing as he did that he was surrounded by powerful enemies, Condé, secure in his own strength, ventured, by a fresh insult, to goad the resentment of the regent into an uncontrollable desire for vengeance. The young duke of Richelieu was engaged, with the sanction of the queen and of his aunt and guardian, the duchess of Aiguillon, to the profligate Mlle de Chevreuse, but was in love with a widow named Mme. de Pons. His alliance was of the highest value, for his uncle, the great minister, had left him several offices of importance, including the governorship of Havre de Grace. Wishing therefore to gain his friendship, Condé contrived his marriage with the lady he loved, and haughtily informed the queen that his presence rendered it valid without her consent. Urged by her own passionate indignation at the prince's defiance, and by the bitter complaints of the duchess of Aiguillon and Mlle. de Chevreuse, Anne no longer hesitated to resort to force.

Condé, Conti, and Longueville were accordingly arrested. But Bouillon and Turenne, who were also to be seized, made their escape; and Prince Marsillac (the Rochefoucauld of the *Maximes*) carried off his mistress, Condé's sister, the duchess of Longueville. By stratagem the young princess of Condé also obtained refuge in her husband's strong castle of Montrond. Vigorous attempts for the release of the princes began to be made. The women of the family were now its heroes. The dowager princess, though too miserly to part with her money to help her children, claimed from the Parliament the fulfilment of the reformed law of arrest, which forbad imprisonment without trial. The duchess of Longueville entered into negotiations with Spain. And the slighted young wife, with Lenet as adviser, having gathered an army around her, obtained entrance into Bordeaux and the support of the Parliament of that town. She alone, among the nobles who took part in the folly of the Fronde, gains our respect and sympathy. Faithful to a faithless husband, she came forth from the retirement to which he had condemned her, to fight for him with tact and bravery amid the rough bustle of war and politics, and to display an unselfishness and a sense of justice of which there is no other example among those who surrounded her, with their paltry aims and worthless lives. When the Parliament of Bordeaux patriotically refused to accept the assistance from Spain which the Frondeurs wished to force upon it, and the mob was stirred up by the duke of Bouillon to constrain it by violence, she risked her life to quiet the tumult.

The delivery of the princes was not, however, due to her efforts. Bordeaux was fortified, it is true, and resisted Mazarin for a time, but, after the defeat of Turenne by Du Plessis at Rethel, peace was made on account of the vintage. The discomfiture of Mazarin was caused by the junction of the old Fronde (the party of the Parliament and of De Retz) and the new Fronde (the party of the Condés). An angry comparison, that had been drawn by the cardinal between the popular leaders and those who in England had two years before overthrown the monarchy and brought their king to the scaffold, was made by the skill of De Retz to arouse in the Parliament a characteristic storm of indignation, from which Mazarin was glad to escape by flight. The regent prepared to follow him; but her intention became known. The night air resounded with the peals of bells from Notre Dame and all the lesser churches of Paris. The refuse of the city, mingled with respectable burghers and haughty nobles, poured into the streets. The news that the king was about to be carried away was spread everywhere by the emissaries of the coadjutor. The court of the palace was soon filled by the motley crowd. They passed up the staircase, and into the very room where the child-king lay, with precocious cunning feigning to be asleep. At the awful sight, and abashed by the queen's cool derision, the mob reverentially withdrew. But Anne was forced to order the release of the princes from their prison at Havre; and Mazarin, humbling himself, rode down thither, and, falling at Condé's feet, piteously begged his protection and friendship.

The regent at once employed every means to draw Condé from his alliance with the Fronde. She made him offers which, from their very extravagance, might have aroused his suspicion,—he and his family were to hold something like the half of the kingdom; and Condé, relying on these faithless promises, carried out his part of the bargain by breaking with De Retz, the intended marriage of whose mistress, Mlle. de Chevreuse, with the duke of Conti he refused in haughty terms to permit. Meanwhile the queen had secretly gained over the coadjutor. A rumour reached Condé that he was to be assassinated or arrested; he fortified the Hôtel de Condé, and then retired from Paris, collected soldiers, and entered into negotiations with the archduke. He was consequently accused of high treason before the Parliament by order of the regent, and De Retz brought forward the charge. Condé appeared in person to meet it; and the building was filled with two bands of armed soldiers in the pay of the two parties. It seemed that the very Parliament House was to be the scene of civil war. The prince and the coadjutor spoke with vehemence and passion. Condé's hand was on the hilt of his sword, and the soldiers were only waiting for the signal to commence a deadly conflict, when a solemn appeal from President Molé calmed the frenzied assembly, and prevailed upon the rival nobles to dismiss their troops. Condé at once retired to his fortress of Montrond, where, after conference with his brother and sister, as well as Nemours and La Rochefoucauld, he resolved on renewing the civil war.

But his party was far from being as strong as it had been in the previous rising. Two causes alienated many of his most important allies: the rebellion was no longer against a regent, for the king had just attained his majority; and the rebel had sought and obtained aid from the foreign power of Spain. The Parliament of Paris declared him a traitor; Longueville, Orleans, Turenne, and Bouillon went over to the court. Even the faithful city of Bordeaux became estranged, for the duchess of Longueville encouraged the mob in acts of outrage. Mazarin now ventured to cross the frontier with an army. But at once the Parliament proscribed him; and the lieutenant-general, followed by Nemours and Beaufort, took up arms against the court. Mademoiselle forced her way through a hole in the walls of Orleans, with one or two of her ladies, and frightened the magistrates into espousing the revolt. But Beaufort and Nemours did not agree, and their army was in danger of being destroyed by Turenne. Condé came to its help, having in disguise crossed the enemy's country and passed close by the royal troops. The very next night Hocquincourt's camp was burnt, and Condé, hurrying to Paris, formed an alliance with Turenne, and sought to win over the Parliament. But Molé stripped off the veil of patriotism with which he sought to conceal his selfishness, and pointed out that he was allied with a foreign power, and that he was actually treating with the detested cardinal. The prince retaliated by stirring up the mob, and leaving the city to its savage caprice. At length he quitted Paris to save the rebel army which was hotly pressed by Turenne, and the magistrates persuaded the facile lieutenant-general to close the gates. At the gate St Antoine, on the 2d July 1652, Turenne and Condé met. Condé fought in person with marvellous energy; he seemed, said Turenne, to be twelve men at once; but, pressed by numbers as he was, it was apparent that he could hope for safety only by being admitted within the walls of Paris. Fortunately he had in the city as champion one of the most remarkable women of that strange time, Mademoiselle, the daughter of Gaston, duke of Orleans, and the author of the *Mémoires*, who hoped to succeed his sickly wife, or, better still, by his means to obtain the hand of the young king. She frightened and persuaded the provost of the merchants and L'Hôpital, the governor of Paris, into opening the gates, and turned the cannon of the Bastille on the army of Turenne. Keeping his ground so long as daylight lasted, at nightfall Condé entered the city. It was given up to pillage and murder. Fire was set to the building where the magistrates had met, and the magistrates themselves narrowly escaped with their lives. Famine began to be felt, and pestilence appeared. Deserted by crowds of his followers, bitterly disappointed, and worn out, as was whispered at the time, by his excesses, Condé was seized with fever. Mazarin, going into exile, freed the court from the odium of his name; and the Fronde melted away.

On his recovery (October 1652) Condé fled from Paris and joined the Spanish army. The swift, bold tactics which had gained him glory were now impossible; he was constantly hampered by the ancient and ponderous methods of the Spaniards, by their inflexible etiquette, and their lordly laziness. He gained some successes, as the entry into Cambray, which was invested by Turenne, and the raising of the siege of Valenciennes; but fortune was in general on the side of France. At length in 1659, after the disastrous battle of the Dunes, Spain, tired of the war, consented to the disadvantageous peace of the Pyrenees, and at the same time Condé obtained his pardon from Louis, who thought him less dangerous as a subject than as possessor of the independent sovereignty of Luxembourg, which had been offered him by Spain as a reward for his services.

Thenceforth he was excluded from court intrigues, and for several years he resided on his estate at Chantilly, where he gathered round him a brilliant company, which included many of the greatest men of genius that France has seen—Molière, Racine, Boileau, La Bruyère, La Fontaine, Nicole, Bourdaloue, and Bossuet. But the quarrel between Luvois the minister of war and Turenne again opened a field for his ambition. In 1668 he laid before the former a scheme for seizing Franche-Comté, the execution of which was intrusted to him, and successfully carried out. In the next year Condé was offered the crown of Poland, which, however, Louis would not allow him to accept. In 1672, he took part in the war with Holland, and forced the passage of the Rhine, at which engagement he was severely wounded in the wrist. In 1673, he met the Prince of Orange in the great but undecided battle of Seneffe. He served for the last time in 1675, as general of the army of the Rhine, which had been left without commander by the death of Turenne. After this campaign, prematurely worn out by the toils and excesses of his life, and tortured by the gout, he returned to Chantilly, where he spent the eleven years that remained to him in quiet retirement. In the end of his life he specially sought the companionship of Bourdaloue, Nicole, and Bossuet, declared himself a convert, and devoted himself to the ordinances of religion. He died on the 11th December 1686, at the age of sixty-five. Bourdaloue attended him on his death-bed, and Bossuet pronounced a glowing funeral panegyric upon him.

Condé's character is a type of that of the French noble of his day. To be regarded as a brilliant conqueror in love and war, to hold the first place at court, swaying the councils of his sovereign at his will, and receiving universal homage—these were the selfish and only objects of his ambition. His vanity was such that he looked on no man as his equal; Louis XIV. himself could not have shown an arrogance more insolent. He was said by one who knew him well to be the hardest-hearted man in France. Ruthless and savage, he was also an intriguer not less unscrupulous, though incomparably less adroit, than his victorious enemy, the subtile Italian cardinal. Thus he had all the faults of the French noble on a colossal scale; he had also his virtues in a more extraordinary degree. Where all were brave, he was conspicuous above all for a thoughtless courage which nothing could dismay, and to which, combined with the intense enthusiasm and rapidity of thought that inspired him on the field of battle, he owed the most brilliant of his victories. And the evening of his life, when, done with ambition, he gave himself to the delights of literature, reveals a new and finer side of a character that would otherwise appear all harsh and without beauty.

Condé's unhappy wife, Clémence de Maillé, some years before had been banished to Châteauroux. An accident, seized upon by her husband with unseemly eagerness, brought about her ruin. A servant had entered her private room, and after threatening her loudly, stabbed her, and made his escape. Her contemporaries, greedy as they were of scandal, refused to believe any evil of one so pure and noble; but the prince declared himself convinced of her unfaithfulness, placed her in confinement, and carried his resentment so far that his last letter to the king was to request him never to allow her to be released.

M. W.)

CONDÉ, Louis Henry Joseph (1756–1830), duke of Bourbon, and last prince of Condé, was the son of Louis Joseph, prince of Condé. Several of the earlier events of his life, especially his marriage with the Princess Louise of Orleans, and the duel that the prince of Artois provoked by raising the veil of the princess at a masked ball, caused much scandal. At the Revolution he fought with the army of the emigrés in Liége. Between the return of Napoleon at Elba and the battle of Waterloo, he headed with no success a royalist rising in La Vendée. In 1829 he appointed the Duc d'Aumale his heir; and exactly a year after he was found strangled with a handkerchief round his neck. A famous trial was the consequence, in which no verdict was given.

CONDE, José Antonio (1765–1820), a distinguished Spanish Orientalist, was born at Paraleja, in the province of Cuenca, and was educated at the university of Alcala. Intended by his father for the law, he found means to learn not only Greek, but even Hebrew and Arabic. A subordinate post in the royal library enabled him at an early age to abandon his legal studies, and to devote himself entirely to literature; and in 1796 he published a volume of paraphrases from the Greek idyllists. This was followed, in 1799, by an edition of the Arabic text of Edrisi's *Description of Spain,* accompanied with notes and a translation. Though by no means free from inaccuracies, this publication greatly advanced the editor's reputation. He was made a member of several learned societies, and was one of the commission of three appointed to continue the bibliographical labours of Sanchez; and he received royal aid in the studies requisite for the composition of his next work, the famous *History of Moorish Rule in Spain.* On Napoleon's appearance in Madrid (1808), Conde identified himself with the party of France. Joseph Bonaparte made him librarian in chief at the royal library; and he had to leave his native land with the retreating invaders. After a residence of some years in Paris, spent in arranging materials for his history, Conde was at last permitted to return to Spain in 1818 or 1819. His countrymen, however, would not forgive him for his apostasy; he sunk into poverty, and died soon after his return. His history (*Historia de la Dominacion de los Arabos en España*) was published by subscription. Only the first volume received the author's final corrections, the other two being compilations from his MSS. This work, although confused and inexact, a chronicle rather than a history, may yet be read with advantage; an English translation (1854) occupies three volumes of Bohn's *Standard Library.* Notwithstanding its imperfections, the book opened an era in Spanish literature; and Conde himself must be regarded as the earliest labourer in a field which has since yielded a rich and abundant harvest.

CONDER, Josiah, an English littérateur, was born in Falcon Street, Aldersgate, London, on 17th September 1789, and belonged to an old nonconformist family, proud of its hereditary piety and nonconformity. Leaving school at the age of thirteen, he began to assist his father in his business as a bookseller at Bucklersbury; and in this situation he found abundant pabulum for the literary tastes which he had already begun to develop. The first time he appeared in print was in the poet's corner of the *Athenæum*, No. 11; and in 1810 he joined the well-known Taylor family in the little volume called the *Associate Minstrels*. From 1811, when his father retired, till 1819, he carried on the business on his own account; but in the latter year he determined to adopt literature as a profession, and thenceforward till his death his pen was never idle. As editor of the *Eclectic Review*, which had been published under his name since 1814, he was regarded as the literary representative of evangelical nonconformity; and in 1832 he became still more publicly and completely associated with the interests of the party as the editor of the newly established organ called the *Patriot*. Besides contributing voluminously to both these periodicals, he published work after work on religious, political, and miscellaneous subjects; but in too many cases these owed their origin merely to the necessity of producing something that had a market value. That he frequently put forth mere paste and scissors work he makes no shame to confess,—conscious that if his labour was somewhat ignoble it was at least performed with scrupulous honesty. His whole literary activity was influenced by his religious convictions, and it was not only as editor of the *Eclectic* that he endeavoured to "reconcile those long divorced parties—religion and literature." His most popular work was his *Modern Traveller*, a series of thirty volumes descriptive of the various countries of the globe; but he will probably be longest remembered as the author of a few hymns not unworthy to rank with the best examples of nonconformist psalmody. He died on December 27, 1855. His life has been written by his son, Eustace R. Conder.

His principal publications are—*On Protestant Nonconformity*, 2 vols., 1818; *The Star in the East, with other Poems*, 1823; *Analytical View of all Religions*, 1838; *The Literary History of the New Testament*, 1845; *The Harmony of History with Prophecy*, 1849.

CONDILLAC, Étienne Bonnot de (1715–1780), Abbé de Mureaux, a distinguished writer in logic, psychology, and economic science, was born at Grenoble. Very little is known about the particulars of his life. He was the younger brother of the Abbé de Mably, and associated in his youth with Rousseau, Diderot, Duclos, and other philosophers, but afterwards allowed the intimacy to die out. He was of a serious and dignified character, and devoted himself to a life of laborious study. Like Comte and Mill, he acknowledges himself to have been largely indebted to a lady for his philosophical inspiration. While still young he was appointed preceptor to the duke of Parma, grandson of Louis XV., for whose instruction a large number of his works were composed. He was chosen by the French Academy of Sciences to succeed the Abbé d'Olivet in 1768, but after delivering a discourse on that occasion he never again appeared at the meetings. He lived in retirement on his estate of Flux, near Beaugency, till his death on 3d August 1780.

Condillac's philosophical opinions are contained mainly in *L'Origine des Connaissances Humaines*, *Traité des Systèmes*, *Traité des Sensations*, *Grammaire*, *L'Art d'Écrire*, *L'Art de Raisonner*, *L'Art de Penser*, *La Logique*, and his posthumous work, *La Langue des Calculs*. The first of these was his earliest production, and may be regarded as the preliminary sketch of his entire system. It touches more or less distinctly on all the topics which are discussed in the others. But the doctrines it contains receive a fuller and more mature statement elsewhere, and there are many important departures from them in the later works.

Condillac's philosophical writings may be studied from three points of view. Like Locke, he begins with a polemic against innate ideas and abstract systems. This takes up a large part of the *Essai sur l'Origine* and almost the whole of the *Traité des Systèmes*. In the *Logique* and the *Art de Raisonner* he expounds and illustrates the analytic method, which he regards as the only true method of science, and which is further illustrated in *La Langue des Calculs*. *L'Art de Penser* consists largely of quotations from the *Essai sur l'Origine*. In the *Traité des Sensations*, Condillac applies his analytic method to the solution of the psychological problem of the origin of our ideas and the formation of the mental faculties. It cannot be said that he strictly confines himself to the questions here assigned to his different works. His inveterate antipathy to innate ideas and abstract systems, his favour for analysis, and his peculiar psychological doctrines appear more or less in them all.

Condillac's main attacks are directed against the innate ideas of Descartes, Malebranche's theory of the mental faculties, the monadology of Leibnitz, and the first part of Spinoza's *Ethik*. He thinks that innate ideas were assumed because men had not sagacity and penetration enough to go back to the origin of ideas and trace their genesis, and he finds the consequences of the system to be the multiplication of abstract principles, and a pretence of accounting for everything by the use of abstract terms. Malebranche is justly censured for giving comparisons instead of reasons in his explanation of understanding and will. In criticizing the monadology of Leibnitz, Condillac exaggerates the vagueness and inadequacy of the ideas furnished by the reason, and the clearness of those of the senses. He cannot comprehend how each monad represents the universe in virtue of its relations to it. But may there not be a sense in which the ultimate particular in the infinitude of its relations is a mirror of the universe? Condillac regarded Spinozism as the best example of an abstract system, and criticized in detail the first part of the *Ethik*, in order to show that Spinoza failed both as to clearness of ideas and precision in the use of signs—two essential conditions of the geometrical method which he adopted. Condillac divides the various philosophical systems into three classes:—(1) abstract systems which rest only on abstract principles; (2) hypotheses, or systems grounded on mere suppositions; (3) one true system, that of Locke, which is evolved from the facts of experience. The first he treats with unmitigated scorn; the second he admits under limitations; the third alone he regards as the true method of philosophy.

An act of reasoning, according to Condillac, consists in detecting a judgment which is implicitly contained in another. Sometimes, to go from the known to the unknown, it is necessary to pass through a series of intermediate judgments, each of which is contained in the one preceding. For example, the judgment that mercury will rise to a certain height in the barometer is contained implicitly in the judgment that air has weight; but we require a series of intermediate judgments to see that the former is a consequence of the latter. The evidential force of a reasoning thus consists in the identity between the judgments of which it consists. They are the same; only the expression changes. Such a principle could not be made to cover all the varieties of reasoning. Accordingly Condillac tries to reduce them all to the mathematical form. To reason is to calculate, and to calculate is to reason; and reasoning, like calculation, comes to be a merely mechanical operation. Condillac rejects the common explanation of reasoning, that it is a comparison of two terms with a common third to find their relation to each other. He sees no need for a middle term. The force of the demonstration, he thinks, lies in the identity of the two extremes, which is made evident by decomposing them. Of the syllogism he says that it makes reasoning consist in the form of expression rather than in the development of the ideas, and that most of its rules have been framed with a view to concluding from the genus to the species, whereas thought sets out from particulars.

Regarding the criterion of truth, he attacks the Cartesian test of truth, and proposes instead of it his own criterion of identity. In the *Essai sur l'Origine des Connaissances* he brings two objections against Descartes:—(1) the methodic doubt is insufficient and even useless, because, while calling our ideas in question, it leaves them in all their indeterminateness; (2) it is impracticable, for we cannot doubt about the relations which exist between familiar and determinate ideas like those of numbers. Of the Cartesian criterion of truth, "all that is contained in the clear and distinct idea of a thing may be affirmed of it with truth," Condillac says that it is both useless and dangerous, and should not have been extended to cases different from the one which gave it birth. For Condillac the sign of truth is identity. The evidence of a proposition is in the identity of the two terms. The evidence of a reasoning is in the identity of the successive propositions. No definition, however, is given of identity. It is said to be recognized when a proposition can be expressed in terms equivalent to these,—"the same is the same." But Condillac draws a distinction between identical propositions that are frivolous and those which are instructive, and explains the latter to be those in which the terms are identical in thought, but different in expression. Condillac held that three kinds of evidence are needed to arrive at certainty—the evidence of fact, the evidence of feeling, and the evidence of reason. The evidence of fact informs us of the relations which bodies have to us; it can have no other object. The evidence of feeling enables us to distinguish what passes in us, the modes or states of the mind. Some good remarks are made in chapter iii., part i., of *L'Art de Penser*, on the attentive observation of consciousness. The evidence of reason is discussed in the first three chapters of the first part of *L' Art de Raisonner*. There Condillac merely formulates the principle of identity, and cites as examples the geometrical theorems which his pupil will require, that he may understand the rest of the work.

Condillac was of opinion that one method of analysis is common to all the sciences. Our cognitions ought to form a system in which all is strictly connected together. Every series of facts should be reduced to an initial fact, of which the others are only transformations. Identity is a rule of method as well as a criterion of certainty; and analogy completes the primary lessons which are given us by nature. Condillac takes as his model the method of mathematics, and reiterates through his logical writings that we must take nature for our guide. On the relation of analysis to language he held that there is an innate language, although there are no innate ideas. This language produces a kind of analysis, since it is necessary for the communication of our ideas to analyze and express in succession what is simultaneous in thought. Analysis then reacts on language and improves it. Finally, perfection of language leads to perfection of analysis, and science is only a *langue bien faite*.

The method of invention is discussed chiefly in the *Essai sur l' Origine des Connaissances* and in the *Langue des Calculs*. In the former, Condillac bids us take the simple ideas furnished by sensation and reflection, form different collections of them, which in their turn will produce others, and give distinct names to these different collections. In the *Langue des Calculs* the idea of analogy is developed. This is not the analogy set forth in the *Art de Raisonner*, which consists only in forming more or less probable conjectures about the unknown from the known. The analogy of the *Logique* and the *Langue des Calculs* is that which creates and regulates languages, which causes us to invent different systems of signs and submit them to uniform rules.

Reasoning cannot have the purely subjective character which Condillac's theory assigns to it. It takes its departure from the idea, which is objective, and therefore establishes a real relation between the mind and its object. On the question of the need for a middle term it is not enough to decompose the two ideas. The two decompositions must meet at a point, and that is the middle term. Laromiguière preserves the intermediate ideas, which he thinks are found by analysis of the extremes. So they are. But it has been urged that there is a twofold analysis—of the species into its genera and of the genus into its species—whereby the middle term is found. Condillac is inconsistent with himself in his criticism of Descartes. His first objection to the methodic doubt is based on the opinion that all our errors proceed from the indeterminate character of language, and that the use of definite signs is the only security against error. But he believes that analysis makes language; and the methodic doubt is a kind of analysis, for it remounts to the primary truths. His second objection, that we cannot doubt about mathematical relations, is invalidated by his own statement that mathematics are only part of metaphysics. Condillac is right in saying that the Cartesian criterion of truth lacks a theory of ideas and of their origin. But it is not to be condemned as useless because it is incomplete. Condillac was led away by the supposed need for a sign whereby to recognize truth. As Hegel would have put it, he refused to go into the water until he could swim. But it would be as difficult to determine the value of the sign as that of the truth itself. Some such criterion as identity is the only resource of empiricism. But if the notion of identity is derived from experience, it cannot give certainty. If, that it may serve as the basis of logic, it is regarded as necessary, then empiricism cannot reconcile it with its psychology. Laromiguière tries to get over the difficulty of accounting for progress in a system based on the notion of identity, by drawing a distinction between partial identity and total identity, and saying that the former alone should be admitted. But what is partial identity? Condillac himself takes refuge in extreme idealism. Truth, he says, considered in itself and in the divine intelligence, is one and identical. But he had himself laid down the rule to limit our consideration to the condition of human knowledge, and of course he had no idea of developing thought as such from its primal unit by a dialectic process after the manner of Hegel. As to the three kinds of evidence, Condillac in reality reduces the evidence of fact to that of feeling and that of reason. His numerous contradictions are largely due to his attempts to defend the authority of the senses, while he accepts the idealistic theory of external perception. The objections to identity as a criterion of truth apply as well to Condillac's statement of the evidence of reason. And if the three kinds of evidence are inadequate taken separately, they cannot suffice when combined. Condillac rightly insisted that there is one fundamental method for all the sciences; but he nowhere reconciles this unity of method with the variety of form which it assumes as applied to different objects. By demanding at the outset the initial fact, of which all the others are to be shown to be transformations, he virtually quits the safe road of experience. He errs, too, in thinking that the method of mathematics is applicable to all the sciences. His oft-repeated advice to follow nature would have been advantageously accompanied by a clearer explanation of what nature is. One thing which he certainly excludes from it is the mind viewed as the seat of intellectual principles. Condillac's analysis combines what are generally regarded as the two distinct processes of analysis and synthesis. Synthesis he conceives to be that method which starts from abstract principles, and accordingly he treats it with supreme disdain. But while banishing the name he retains the thing, and insists that no analysis is complete without a process of recomposition.

The logic of Condillac finds its most important application in psychology. In the *Essai sur l'Origine des Connaissances* he starts from sensation as the primitive fact, and seeks to show that all the ideas and operations of the mind are only transformations of it. He neglected, however, to make sure of his way back to the primitive fact of sensation, before using it as his starting point. Under the influence of Locke, he simply assumed it, and applied his ingenuity to derive from it all the ideas and operations of the mind. Throughout the *Essai sur l'Origine* he confounds sensation with perception in a way that vitiates his whole argument. At the outset he affirms that sensations are ideas, because representative of objects. It is difficult to understand in what sense he uses such language. For a long time it was supposed that he regarded the pure sensation as the primary element of consciousness; but his more recent followers have adopted a different interpretation. They try to make out that his meaning was that in the simplest state of consciousness the whole mind is to be found, equipped with all its so-called faculties. Condillac found an opinion prevailing that the mind is partitioned off, as it were, into a variety of different faculties, each having its separate function, which it discharges independently of the others. It was against this opinion, they say, that he contended. He maintained that the mind is not a congeries of faculties, but is one and indivisible, and appears in all its forms of activity in the simplest state of consciousness. This opinion is difficult to reconcile with his avowed purpose, to which he adheres throughout all his psychological treatises, of tracing the genesis of the faculties; for sensation would then not be a primitive fact, from which all the later furniture of the mind is derived by a process of transformation. There would, in fact, be no generation of the faculties, for all would be given in the rudimentary consciousness, and any reasoned account of their relations to each other would need to refer to something anterior to the individual consciousness. Probably the more correct view to take of Condillac's psychology is that when he tried to deal with sensation, pure and simple, he found it impossible to do so, and was compelled to invest the mere sensation with all the ideas of reason, that it might do duty in his system. No doubt either interpretation would save Condillac's consistency with his great principle of identity. The sameness of the elementary sensation with the higher faculties and ideas is secured, whether the faculty is degraded to the level of the sensation, or the sensation is raised to the level of the faculty. And there is much in Condillac to countenance either view. But it is probable that if he had been willing to concede that the mind is all in the primary sensation, in the sense in which his later followers understand him, he would have felt the necessity of exhibiting the relations of the different mental operations, which in such case would be moments of the sensation, anterior to the sensation, instead of subsequent to it, in terms of the relations of different sensations to each other. The opening sentences of the *Traité des Sensations* show that Condillac was aware of the difficulties attending the study of our rudimentary consciousness on the presuppositions of sensationalism. If the mind at birth was a *tabula rasa*, there can be no traces left of our primary state. It is in vain therefore to interrogate our consciousness to learn what it was then. To show how all proceeds from sensation, we must consider our senses separately. As Condillac could not do this by examining his own consciousness, he devised the experiment of the statue. It is supposed to be possessed of a mind destitute at first of every sort of ideas, and only to have the use of its senses at the pleasure of the experimenter, who opens them at his choice to their appropriate impressions. A beginning is made with the sense of smell, because it seems to contribute least to our knowledge. The other senses are successively experimented on, singly and in groups, and at last the statue is found to have become an animal able to preserve itself. Condillac claims to have stripped man for the first time of all his habits. Feeling is observed at its birth, and proof is given of how we acquire the use of our faculties. The principle of their development is found in the various degrees of pleasure and pain attaching to our sensations; for none of them are indifferent absolutely. The contrast between pleasure and pain impels us to court some sensations and flee others. A sense of need is produced by the want of an object judged necessary for happiness. Needs beget desires; old needs repeated and new ones formed are the ground of the development of our knowledge and our faculties. The outcome of Condillac's psychology is given in briefest form in chapters vii. and viii. of the *Logique*. Laromiguière corrected Condillac by substituting attention for sensation as the principle of the active half of the mental phenomena. Cousin pointed out that attention is a voluntary act. He showed the essential difference between desire and will, as also between sensation and desire, and remarked that the organic impression must not be confounded with the sensation. If the sensation is the condition of the exercise of the faculties, still it is not the principle of any.

Condillac defines personality to be a collection of sensations plus the ability to say "me." But this plus is of vast importance. How comes it that this particular collection of sensations can say "me?" Because, answers Condillac, it is a collection of present and remembered sensations. But whether does the statue say "me" because it can remember its sensations, or remember its sensations because it can say "me"? Is not all that is involved in saying me already involved in memory, so that his answer merely repeats the fact which it professes to explain? Condillac thought so in his first stage, as he then found the feeling of one's own existence to be an essential element of reminiscence. Then, indeed, reminiscence was distinguished by him from memory, but only in an artificial way. A collection of sensations is a less correct account of personality than the synthetic unity of Kant. What renders the collection possible? For Condillac its essential condition, a unifying principle, is wanting. That cannot be found in sensation. It is a condition of the ordering of sensations, and is the all-important unit out of which a true philosophy of spirit must grow. Sensations cannot give an answer to the question what constitutes experience. Even Mill had to confess that it must at least be sensations which have the strange property of turning back upon themselves. Condillac has the very same phrase, "As long as the statue changes not, it exists without any return upon itself."

Thus, in their own inarticulate way, the sensationalists are compelled to postulate the synthetic unity of Kant. And just as it is present in the first fibre of personality, the first flash of self-consciousness, its various modes of operation are no less essentially present throughout all the subsequent fabric of experience, and in the full sunlight of conscious life. To trace and treat them is the work of philosophy proper, which may be briefly distinguished from the natural sciences as that which deals with the universal aspect of thought, while they deal with the particular. Both are necessary factors of concrete thought. Experience will never spring out of categories alone, nor will it arise out of particulars alone. The method of observation proper to the natural sciences may lead us to the border ground of the two territories, but for exploring the region of the universals there is needed a keener vision and a deeper principle. It is the fault of Condillac, as of all the sensationalists, that he does not apply the analytic method faithfully enough to bring himself consciously face to face with the universal factor of experience. It is interesting to note in him the progress towards a more thorough use of analysis In the *Essai sur l'Origine* he was of opinion that any single sensation was an idea, *i.e.*, representative of external entities, and that a single sense is adequate to produce an experience more limited in degree, but the same in kind as ours. So he maintained against Locke and Berkeley that we can know through sight alone the magnitudes, distances, and situations of objects. His position then much resembled that of the so-called common-sense philosophers. To him an external world was as necessarily present in sense as to them; and his criticism of Spinoza, that the assumption in his definitions of what he meant to prove by means of them made his work easy, may very aptly be applied to the *Essai sur l'Origine*. If a complete experience is given in a single sensation, it will be easy to find it in a succession of them. But the *Traité des Sensations* marks an advance upon these views. Now a sensation is not *per se* an idea. A stricter use of analysis detects other elements in ideas. Condillac saw from the first that a sensation to be an idea must be representative of something out of the present consciousness. Now he sees that, to be so, it must either exist in the memory or be modified by judgments. That is to say, it must be the sensation of a series of sensations, which has the marvellous power of returning upon itself; or, in more intelligible language, it must be held in the grasp of the synthetic unity of thought. In the *Origine* Condillac really develops experience out of perceptions, or sensations regarded as synonymous with ideas. In the *Traité des Sensations* he has come to know that a sensation as such is not an idea. But although he still professes to develop all the mental operations out of sensation, he is as far as ever from bridging over the gap between sensations and ideas, or even from acknowledging in his actual procedure the existence of such a gap at all.

When Condillac, largely owing, as he tells us to the influence of Mlle. Ferrand, abandoned the position of the *Essai sur l'Origine*, that by sight alone we can judge of the magnitudes, distances, &c., of objects he seems to have been in unstable equilibrium between sensationalism and a very different mode of philosophizing. In the *Traité des Sensations* he shows how these judgments are founded not upon the direct intimations of sight, but upon an association that has sprung up between the sensations which we owe to different senses. The mind, he sees clearly, has come to deal with relations among sensations. He even goes the length of saying that the idea of impenetrability cannot be a sensation, but is a judgment founded on sensation. He was then on the verge of intellect proper, and within sight of something deeper than sensation. The intelligible order of things is dimly seen by him to be the reality for us, and he tries hard, in the *Traité des Sensations*, to show how we become aware of it through the interaction of the different senses. But just then he falls back again into sensationalism. He loses hold of judgment as the all-important element, and conceives the senses in some strange way to acquire a habit of immediately informing us of what a moment before he saw it needed an act of judgment to reach. For an instant he had a glimpse of thought as constitutive of experience. But forthwith the vision passes, and its place is taken by a mysterious and totally unintelligible habit or instinct of sense. Accordingly, in the *Art de Penser*, he is back again to the gross statements of the *Origine*, that we may find in sensation the ideas of extension and figure, and perceive as distinctly and clearly that they do not belong to us, or to what in us is the subject of thought, but to something outside of us.

It is not difficult to see how his theory of reason sprang out of his theory of the origin of knowledge, for of course his psychology was thought out before his logic. If all is sensation, and we can never get beyond sensation, then our advancing knowledge must be only a ringing of the changes upon the primary sensation. The latest results will be identical in the fullest sense with the first beginnings, and all science will be reduced to a development of language, a series of identical expressions, to which we are driven by the limitation of our faculties preventing us from seeing the identity between remote terms. Thus, in *L'Art de Raisonner*, he shows at length that the demonstration of the rule for finding the area of a triangle is necessitated by our inability to see the identity between the idea we have of "measure" and that we have of the product of the height of the triangle by half the base. Similarly, the argument in the *Traité des Sensations* is necessitated by our inability to see the essential identity between sensation and thought. Every successive proposition is identical in idea with the preceding one, and differs from it only in expression. There is no advance or development in matter. In his psychology it is the same sensation throughout. In his theory of reasoning it is always the same idea throughout. The difference is merely in form, and it is not difficult to see how, in a philosophy which neglects intelligible relations, and ignores the truth that they are constitutive of experience, form must of necessity be degraded and become mere form of words. This is the complaint which is urged by Hegel against all the natural sciences. He, so to speak, accepts the verdict of Condillac upon them. So far as they attempt to prove anything, he says, they are a mere string of identical propositions. But to Hegel form was everything. The development of the notion is what constitutes the universe; and accordingly he thought that a different formula of reasoning must be found from any hitherto recognized. Syllogistic reasoning is not adequate to any real development of form. It sinks down into a mere change of verbal expression, as Condillac had asserted, while the matter of thought is left precisely where it was. But matter is only the potentiality of form, and form is no mere transformation of verbal expression, but an organic growth of thought. Is there any standing ground between the identity of Condillac and the dialectic of Hegel?

There are many later systems which it would be interesting to compare with the thoughts of Condillac, notably the psychology of Beneke, the later views of Mr Lewes, and the logical doctrines of Professor Jevons. There is a remarkable similarity between the identity of Condillac and the substitution of similars of Professor Jevons. The logical machine is almost like a realized ideal of Condillac; and Professor Jevons's new system of symbols would probably have been hailed by Condillac as the *langue bien faite*, the counterpart of algebra, for which he sighed in vain.

Condillac's important work *Le Commerce et le Gouvernement* was published in 1776, the same year in which the *Wealth of Nations* appeared. The best European economists are said to be now gravitating to the opinion that Condillac's is the true conception of economic science. His work treats economic science as the science of commerce or exchanges. It was originally intended to consist of three parts, but the last never appeared. In the first part he develops the principles of economic science, and treats of the phenomena of commerce or exchanges. The second part considers the relations of commerce and government, and their reciprocal influence. The third part was to have contained a number of examples, to show that his theories had facts to rest upon as well as argument. His great merit was to have fixed upon the wants and desires of the human mind as the source of value. Hence he did not look on labour as a cause of value. In an exchange both parties are gainers, for each gives what is comparatively superfluous to him for what is necessary. Therein, he thinks, lies the spring of all commercial activity. He is a strong free trader, and answers by anticipation Saint Simon, Fourier, and their followers regarding the right of inheritance.

Condillac was a most voluminous writer. A collected edition of his works was published in 23 volumes at Paris in 1798, and was followed by another in 32 volumes in 1803. Several partial editions, containing those of his works which form *the Cours d'Études* for the young duke of Parma,[1] were published at different times. The following is a list of his works:—*Essai sur l'origine des connaissances humaines* (1746); *Traité des systèmes* (1749); *Traité des sensations* (1754); *Cours d'études*, published in 13 volumes in 1755, comprising the "Grammaire," "l'Art d'écrire," "l'Art de raisonner," "l'Art de penser," "l'Histoire ancienne" and "l'Histoire moderne," "l'Étude de l'histoire," and "Traité des animaux;" a sequel to the *Traité des sensations* (1775); *Le commerce et le gouvernement* (1776). *La Logique*, written as an elementary treatise at the request of the Polish council of public instruction, appeared in 1780, a few months before the author's death. *La langue des calculs* was not published till 1798. An English translation of the *Essai sur l'origine* by Thomas Nugent was published in 1756, avowedly as a supplement to Locke's *Essay on the Human Understanding*.

CONDOM, a town of France, at the head of an arrondissement, in the department of Gers, 26 miles from Auch, on the Bayse, a tributary of the Garonne, there crossed by two stone bridges. The church of St Peter, formerly a cathedral, is included among the historic monuments of France, and deserves notice for the height of its vaulted roof. The manufactures of the town include woollen fabrics and porcelain; and its trade is mainly in rural produce and brandy. The nucleus of the place was furnished by an abbey, founded in the 10th century; in 1317 it was made a bishopric by Pope John XXII., and in 1549 the monks were appointed canons of the cathedral. In the 18th century it was the centre of a district called Condomois, which contained the towns of Nerac, Gabaret, and Mont de Marsan; and it possessed three convents and two nunneries. Among its celebrities are Dupleix the historian, and Montluc the leader of the crusade against the Albigensians. Bossuet was bishop of Condom in 1669. Population in 1872, 5205.

CONDOR (*Sarcorhamphus gryphus*), a New World vulture, and the largest of existing birds, although by no means attaining the dimensions attributed to it by early writers. It usually measures about 4 feet from the point of the beak to the extremity of the tail, and 9 feet between the tips of its wings, while it is probable that the expanse of wing never exceeds 12 feet. The head and neck are destitute of feathers, and the former, which is much flattened above, is in the male crowned with a caruncle, or comb, while the skin of the latter in the same sex lies in folds, forming a wattle, dilatable at pleasure. The adult plumage is of a uniform black, with the exception of a frill of white feathers nearly surrounding the base of the neck, and certain wing feathers which, especially in the male, have large patches of white. The middle toe is greatly elongated, and the third but slightly developed, while the talons of all the toes are comparatively straight and blunt, and are thus of little use as organs of prehension. The female, contrary to the usual rule among birds of prey, is smaller than the male.

The condor is a native of South America, where it is confined to the region of the Andes, from the Straits of Magellan to 4 north latitude,—the largest condors, it is said, being found about the volcano of Coquimba, situated on the equator. It is often seen on the shores of the Pacific, especially during the rainy season, but its favourite haunts for roosting and breeding are at elevations of 10,000 to 16,000 feet. There, during the months of February and March, on inaccessible ledges of rock, it deposits two white eggs, from 3 to 4 inches in length, its nest consisting merely of a few sticks placed around the eggs. The period of incubation lasts for seven weeks, and the young are covered with a whitish down until almost as large as their parents. They are unable to fly till nearly two years old, and continue for a considerable time after taking wing to roost and hunt with their parents. The white ruff on the neck, and the similarly coloured feathers of the wing, do not appear until the completion of the first moulting. By preference the condor feeds on carrion, but it does not hesitate to attack sheep, goats, and deer, and for this reason it is hunted down by the shepherds, who, it is said, train their dogs to look up and bark at the condors as they fly overhead. They are exceedingly voracious, a single condor of moderate size having been known, according to Orton, to devour a calf, a sheep, and a dog in a single week. When thus gorged with food, they are exceedingly stupid, and may then be readily caught. For this purpose a horse or mule is killed, and the carcase surrounded with palisades to which the condors are soon attracted by the prospect of food, for the weight of evidence seems to favour the opinion that those vultures owe their knowledge of the presence of carrion more to sight than to scent. Having feasted themselves to excess, they are set upon by the hunters with sticks, and being unable, owing to the want of space within the pen, to take the run without which they are unable to rise on wing, they are

[1] Condillac's opinions about education, which he carried out in the instruction of the young duke of Parma, are interesting and important. He declares his method to be the same as that by which men have created the arts and sciences. He is very severe upon the error of cultivating only the memory until a supposed "age of reason" has been reached. The young child begins to reason, he thinks, in learning to use its senses, and no delay should be made in encouraging him to observe his own mental processes and the facts around him. So long as he is unable to make observations for himself he should be informed about those of others. The teacher's great object should be to train his pupil to think, to find pleasure in mental exercise, and to frame just ideas. Condillac took the hint as to the right order of studies from the experience of nations. First he directed his pupil's attention to those objects and studies which meet the primary wants of man. Then he cultivated his taste. Finally, he directed his thoughts to speculation. He characteristically regarded the arts of speaking, writing, reasoning, and thinking as fundamentally the same, and reduced them all to that of speaking. Condillac had perfect confidence in his method, and boasted of its success, although it does not seem very appropriate for a child of seven years, the age of the prince. His ideas on the importance of early attention to the cultivation of the reasoning powers and the educational uses of observation and experiment are far from being obsolete.

readily killed or captured. They sleep during the greater part of the day, searching for food in the clearer light of morning and evening. They are remarkably heavy sleepers, and are readily captured by the inhabitants ascending the trees on which they roost, and noosing them before they awaken. Great numbers of condors are thus taken alive, and these, in certain districts, are employed in a variety of bull-fighting. They are exceedingly tenacious of life, and can exist, it is said, without food for over forty days. Although the favourite haunts of the condor are at the level of perpetual snow, yet it rises to a much greater height, Humboldt having observed it flying over Chimborazo at a height of over 23,000 feet. "No other living creature," says a recent traveller in the Andes, "can remove at pleasure so great a distance from the earth, and it seems to fly and respire as easily under the low barometric pressure of 13 inches as at the sea-shore. It can dart in an instant from the dome of Chimborazo to the sultry coast of the Pacific." In walking it trails its wings on the ground, and has an exceedingly awkward gait, but on wing the movements of the condor, as it wheels in majestic circles, are remarkably graceful. The birds flap their wings on rising from the ground, but after attaining a moderate elevation they seem to sail on the air, Darwin having watched them for half an hour without once observing a flap of their wings. There is a brown condor, "condor pardo," which naturalists have generally regarded as the young of the "condor negro." Recent investigations have, however, proved it to be a distinct species. It has been named *Sarcorhamphus æquatorialis.*

CONDORCET, Marie Jean Antoine Nicolas Caritat, Marquis de, was born at Ribemont, in Picardy, on the 17th of September 1743. He descended from an ancient family who took their title from the castle of Condorcet, near Nion, in Dauphiny. He was educated at the Jesuit College in Rheims and at the College of Navarre in Paris, and early displayed the most varied mental activity. His first public distinctions were gained in the department of mathematics. At the age of sixteen, his performances in analysis elicited high commendation from D'Alembert and Clairaut, and at the age of twenty-two, he composed a treatise on the integral calculus which obtained warm and general approbation from the most competent judges. With his many-sided intellect and richly-endowed emotional nature, however, it was impossible for him to be a mere specialist, and least of all to be a mere mathematician. Philosophy and literature attracted him no less than geometry or the calculus, and social action, work for the public weal, was dearer to him than any form of intellectual exercise. In the year 1769 he was received as a member of the Academy of Sciences. His contributions to its memoirs are numerous, and many of them are on the most abstruse and difficult mathematical problems. Being of a very genial, susceptible, and enthusiastic disposition, he was the friend of almost all the distinguished men of his time, and a zealous propagator of the religious and political views then current among the literati of France. D'Alembert, Turgot, and Voltaire, for whom he had great affection and veneration, and by whom he was highly respected and esteemed, contributed largely to the formation of his opinions. His *Lettre d'un laboureur de Picardie à M. Necker* was written under the inspiration of Turgot, in defence of free internal trade in corn. His *Lettre d'un théologien, &c.*, was attributed to Voltaire, being impregnated throughout with the Voltairian anti-religious spirit. He was induced by D'Alembert to take an active part in the preparation of the *Encyclopedie.* His *Éloges des Académiciens de l'Académie Royale des Sciences morts depuis* 1666 *jusqu'en* 1699 (1773) gained him the merited reputation of being an eloquent and graceful writer. He was elected to the perpetual secretaryship of the Academy of Sciences in 1777, and was received into the French Academy in 1782. Three years afterwards he published a work on the application of the mathematical theory of probabilities to judicial decisions. This work is admitted to have demonstrated that the calculus had a wider range than had previously been suspected, and to have permanently secured for its author a distinguished place in the history of the doctrine of probability. A second edition of it greatly enlarged and completely recast and revised appeared in 1804, ten years after his death, under the title of *Éléments du calcul des probabilités et son application aux jeux de hazard, à la loterie, et aux jugements des hommes,* &c. He married, in 1786, a sister of Marshal Grouchy and of Madame Cabanis. His wife, said to have been one of the most beautiful women of her time, is known in literature by her excellent translation of Adam Smith's *Theory of Moral Sentiments.* In 1786 Condorcet published his *Vie de Turgot,* and in 1787 his *Vie de Voltaire.* Both works were widely and eagerly read, and are, perhaps, from a merely literary point of view, the best of Condorcet's writings.
