**GROUND WATER IN ONTARIO,
1955 and 1956**

Prepared under the direction of

A. K. WATT
Director
Water Resources Division

D. N. JEFFS
Supervisor
Ground Water Branch

A. M. SNIDER
Chairman

D. S. CAVERLY
General Manager

801 BAY STREET, TORONTO, ONTARIO.

1968

A. M. Snider, Esq.,
Chairman,
Ontario Water Resources Commission,
801 Bay Street,
Toronto 5, Ontario.

Dear Mr. Snider:

This is Ground-Water Bulletin No. 2
of the Commission, which I am pleased to present to
you and the other members of the Ontario Water
Resources Commission.

Yours sincerely,

D. L. Caverly

General Manager.

Ontario Water Resources Commission
Toronto, 1963.

GROUND WATER IN ONTARIO, 1955 AND 1956

INTRODUCTION

This is the fifth in a series of reports in which basic hydrologic data are assembled on ground-water conditions in Ontario. The four previous reports¹ dealt with data collected in the period 1947-1954. This report is a compilation of data assembled in the two-year period, 1955 and 1956, by the Ontario Department of Mines.

The well data are being referred to constantly by individuals interested in ground-water conditions in areas where wells are to be drilled; by drillers who are interested in hydrologic conditions in other areas than where they normally operate; by town planners, engineers, and geologists who are searching for major aquifers to supply municipalities with groundwater; and by engineers and geologists who are seeking favourable sites for gravel pits, quarries, and other deposits of economic value. To all of these the nature, thickness, and hydrologic properties of overburden and bedrock formations must be known. Although well data are now published for the period 1947 to 1956, information on wells drilled in the interval from 1957 to 1962 is available for reference only in the offices of the Ontario Water Resources Commission, Ground Water Branch.

In April, 1957, the ground-water personnel of the Ontario Department of Mines were transferred to the Ontario Water Resources Commission to form the Ground Water Branch of the Commission. In order to accelerate the compilation and publishing of well data the present format was adopted by the Commission for the bulletin. The bulletin repeats some of the information contained in previous reports. This has been done where it was felt the information was needed as important reference material for the new assembled data.

Acknowledgments

The assistance of many private individuals and municipal officials and employees in the observation-well programme is gratefully acknowledged. The regular taking of water levels and the supervision of water-level recording instruments by these persons without remuneration is a tribute to their public spiritedness.

The water well drillers filed records of well logs and water data with the Department of Mines and in so doing played an important part in the assembly of valuable hydrologic data.

GEOGRAPHY

Topography

Ontario has three main physiographic regions. Most of the area lying north of lines drawn rather irregularly from Midland to Kingston and from Brockville to Pembroke is part of the large physiographic region known as the Precambrian, or Canadian, Shield. The elevation is seldom high, but in places, has an extremely rugged profile.

From the low, swampy areas bordering the south and west shores of James Bay and Hudson Bay, the land surface rises gently to a height-of-land north of Lake Superior, which extends in a general east-west direction. The elevation of this height-of-land ranges from 1,000 to 2,100 feet above sea level. The maximum elevation is reached just northeast of Lake Superior.

South of the Precambrian Shield is the St. Lawrence Lowlands, which may be further subdivided into the Ontario Lowland and the Ontario Upland. The Ontario Lowland extends from the eastern counties of Prescott and Glengarry westward to the Niagara escarpment. There is a maximum relief of about 1,000 feet, which is reached in the hilly interlobate moraine area where it adjoins the escarpment.

The Niagara escarpment marks the boundary between the Ontario Lowland and the Ontario Upland. It is a striking topographic feature, owing its form to the bedrock of dense, white-weathering dolomite underlain by softer shales and dolomites. Differential erosion of these rocks through the ages has resulted in precipitous cliffs rising from the lowlands to heights of more than 200 feet. The land surface dips regionally to the west and south, away from the escarpment, towards lakes Huron and Erie. The highest elevation of the Uplands is in Dufferin and Grey counties where heights of between 1,700 and 1,800 feet above sea level are reached in several places.

Over all Ontario a variety of glacial forms such as recessional moraines, kames, deltas, eskers, and drumlins contribute to the variations in relief within the main physiographic regions.

Drainage

The total area of Ontario is 412,582 square miles of which 17 percent is fresh-water lakes and rivers. Most of these are located in the Precambrian Shield area. Of great importance to the province, is the Great Lakes-St. Lawrence River System which has a drainage basin of over 350,000 square miles. The lake levels vary from one to three feet during the year. The lowest levels are recorded in the winter; the highest, in most cases, in the summer and fall.

Climate

The climatic conditions and geological structure of an area largely determine its hydrologic characteristics. If the climatic factors, precipitation, temperature, wind, and sunshine, and their hydrologic results are observed over a sufficiently long period, a fairly accurate assumption of future climatic and hydrologic conditions can be made.

Table I has been prepared from data published by the Meteorological Service of the Canadian Department of Transport and shows precipitation data for a number of selected meteorological stations in the province.

Agriculture

Many farmers and settlers continued to take advantage of the financial assistance provided by the Department of Agriculture in locating water supplies in Northern Ontario. Subsidies were equal to 50 percent of the cost over \$200.00 involved in locating a water supply with a maximum payment of \$300.00. Subsidy payments to March 31, 1955, totalled \$31,635.69 to 156 farmers.¹ Details of the assistance for the year ending March 31, 1955, are shown in Table II. Details of the assistance from March 31, 1955, to March 31, 1956, are not available but it was reported that 166 wells were drilled under the programme in that year.

TABLE II - ASSISTANCE GIVEN TO FARMERS AND SETTLERS IN PROCURING WATER SUPPLIES

Population

The assessed population of Ontario in 1956 was 5,130,947² an increase of almost 6 percent over the 1954 figures.

GROUND WATER

Source

Ground water occurs everywhere at varying depths below the surface of the ground. Its main source is precipitation--rain and snow. Approximately one third of the precipitation in any area becomes available as surface run off and ground water. The rest is returned to the atmosphere by evaporation from the soil and vegetation and by transpiration. Precipitation averages over thirty inches annually in most parts of Ontario. One third of this amounts to 145 million gallons on each square mile of land surface. Perhaps one half of this is available as ground water before it discharges to a stream or lake. In sandy areas the rate of infiltration will be high in comparison with clay areas where there is a higher proportion of direct run off.

Numerous factors, such as the amount and intensity of rainfall, nature of soil and vegetation, slope of land surface, and wind and temperature conditions are important to an understanding of the amount of precipitation that may become ground water. Before large withdrawals of ground water are planned in an area an attempt should be made to estimate the average perennial recharge to the aquifer. If this is done, aquifers will not be dried up nor costly pumping installations wasted.

Aquifer Conditions

A water-bearing formation that will yield the water to a well in desirable quantities is called an aquifer. However, if the water-saturated materials are clay, silt, and fine sand, it is difficult to extract sufficient water by means of a well. Such fine soil particles may hold great quantities of water but have such a low permeability that ground water will not move through them into a well quickly enough to meet normal household requirements.

Coarse, well sorted, sand and gravel make excellent aquifers. Rock formations that are well fractured or contain numerous solution channels are also good water-yielding formations. Frequently, saturated lenses of sand or gravel occur close to the surface of the ground, being sustained above the water table by a clay or silt layer. More than one of these may be present in an area above the main saturated zone. Dug wells frequently reach only this upper, perched water table which is subject to considerable fluctuation in water level and may even dry up completely in the late summer and fall of each year.

Drilled and Dug Wells

As a rule a more dependable water supply can be obtained by means of the drilled well which reaches lower aquifers less likely to be affected by seasonal variations in precipitation. The dug well is important, however, in areas where drilled wells are deep and costly to construct, or where only poor quality water is obtained at depth. The larger reservoir of the dugwell can store water percolating slowly into the well from slightly permeable lenses and thus provide sufficient water periodically.

Generally, the dug well is not constructed in a sanitary manner. Contaminated waters occur in a high proportion of them. This is the result of rain water entering the well through cracks or openings at the top where all kinds of contaminated materials exist. Dugwells should be constructed to prevent surface water getting into the well from the top. In addition to using watertight materials, the well top should be raised above the ground surface and the ground should be sloped away from the well top.

Observation Wells

The measurement of water levels in wells at regular intervals is an important part of the inventory of our ground-water resources. Along with other data on pumpages and aquifer conditions this information is needed in order to know the amount of ground water available in the aquifer at any time.

Information on ground-water levels is especially important to municipalities where the water supply is obtained from wells. Water-level measurements should be taken by anyone who is concerned about the amount of ground water available for use in order that a better understanding of the well supply can be obtained.

A slowly dropping static water level may indicate over pumping of the aquifer, less than average precipitation conditions, additional ground-water withdrawals, or reduced recharge because of changing soil or vegetation conditions in the area. A lower pumping level with normal static level indicates a plugging of the openings leading into well. The plugging could occur in the screen where a well is developed in sand or gravel or it could occur in the crevices of a rock formation, because of the gradual sealing of the openings with particles, bacterial growths, or lime or ferruginous scales which have precipitated from the water. In most cases, the well may be rehabilitated in a variety of ways to remove the materials plugging the openings.

In overburden wells where no screen was used at the time the well was constructed, sand may move up the casing over a period of time and gradually reduce the yield of the well. In this case, also, the static level remains normal but the pumping level is lowered.

At the end of 1954, 33 wells were being used as observation wells. Three of these were abandoned in 1955 and one additional well was included in the program in 1958, making a total of 31 observation wells at the end of that year. No measurements were taken in one of these wells during the two-year period and the measurements from two were not regular and are not published. Measurements of water-level variations were taken in 9 of the wells by means of automatic recorders, in 19 by hand, and in 2 by airline.

Table III lists the observation wells under the counties in which they are located. Other observation-well data and individual water-level measurements are given in Appendix A. All measurements have been corrected to give the distance between the land surface at the well head and the top of the water in the well.

Water Level Fluctuations

Hydrographs have been prepared showing water-level variations in a number of the wells that have been under observation for several years. Wherever possible, data on such factors as precipitation, pumpage, and stream flow, which influence to a greater or lesser degree adjacent observation wells, are included in the hydrographs.

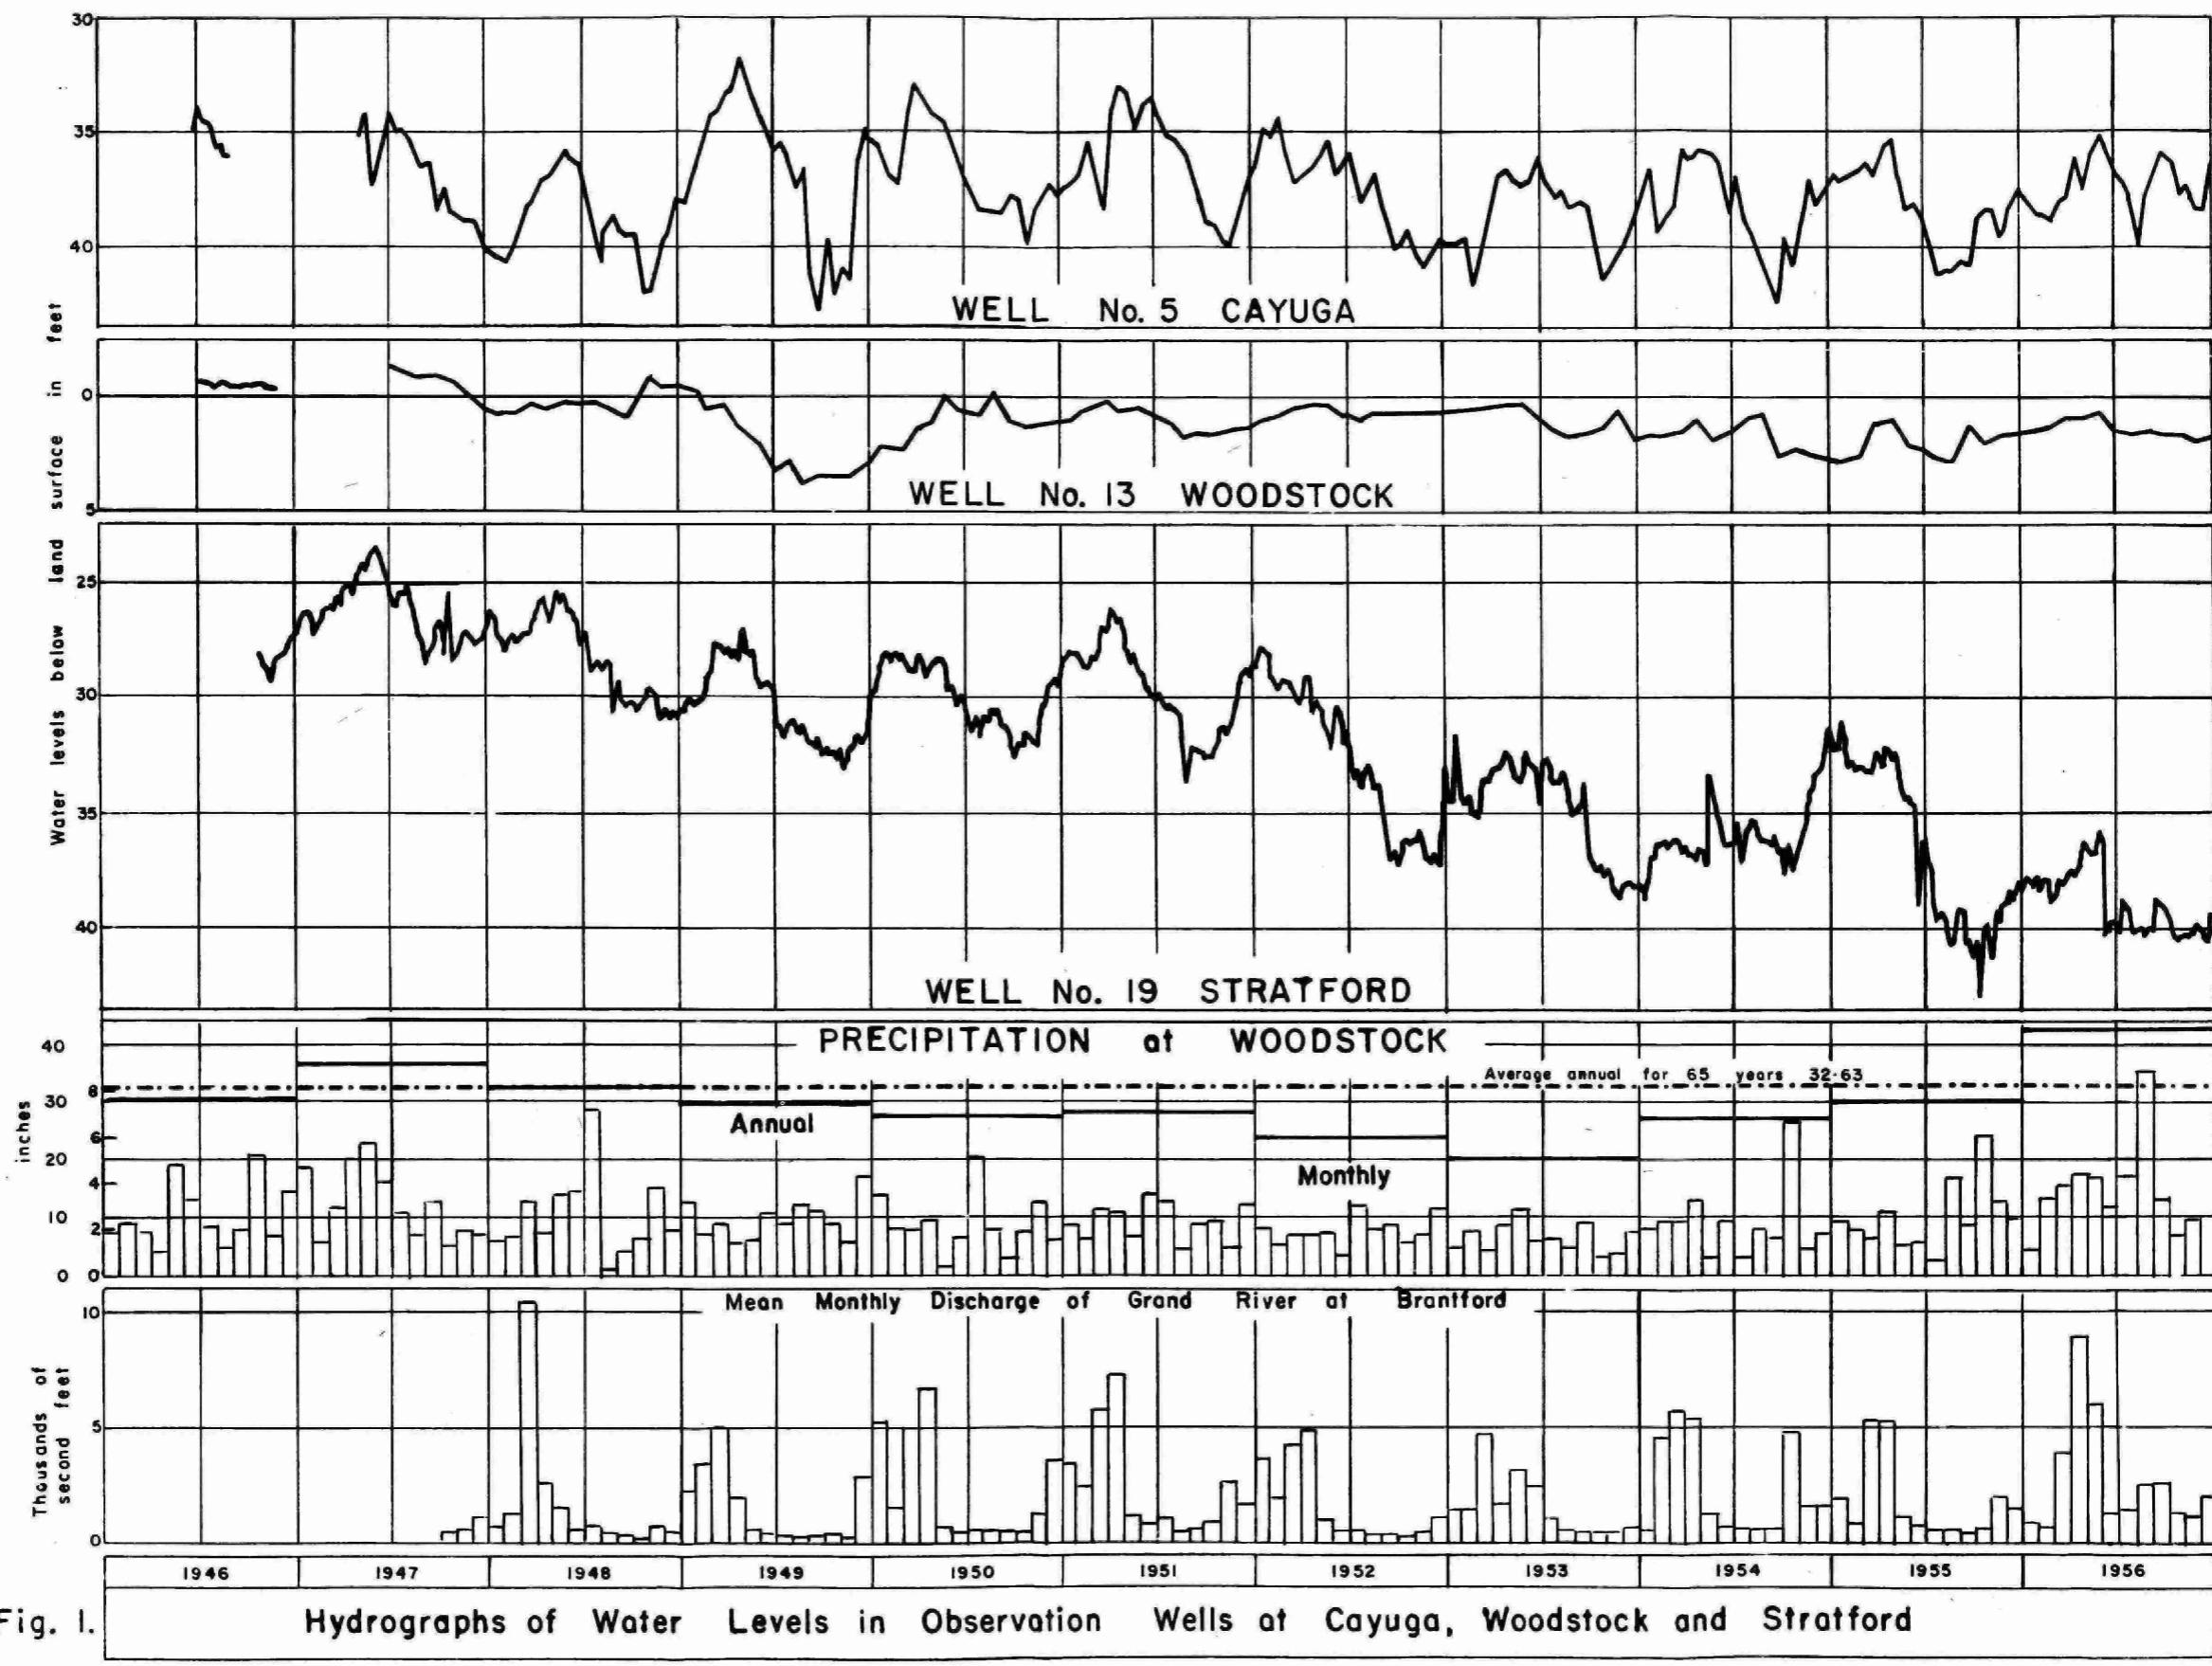

The ground-water balance is in favour of recharge during most fall, winter, and spring periods. The ground-water levels, therefore, normally rise during these seasons. In the summer and early fall, the amount of precipitation intercepted by the plants and soils is usually so great that little, if any, is left to reach the saturated zones below the ground surface which supply the wells and springs. As a result, although the amount of precipitation may be equal to, or greater than, that at other seasons of the year, the ground-water levels usually drop during this period.

Water level variations in observation wells at Cayuga, Woodstock, and Stratford are shown graphically in Figure 1. Little variation is noticed in the Woodstock and Cayuga wells, but a trend to a lower level is apparent in the Stratford well. The trend to a lower level persisted through 1955 and 1956 although the precipitation at Stratford was above normal, suggesting that the aquifer may have been overpumped.

In Figure 2, hydrographs of water levels in wells in London, Westminster Township, and Forest are shown. The correlation between the flow in the Thames River and recharge to wells near the river and its tributary is apparent. Since 1950 a definite downward trend in the water level in the Forest observation well is noticeable.

In Figure 3, hydrographs of water levels in overburden wells at Elmira and Milton are shown. The Elmira observation wells are in the well field but show no trend towards lowered static levels. The variations in water level in the Milton well are typical of dug wells having limited recharge conditions. Frequently wells of this type are out of water during periods in the summer or fall months.

Hydrographs of water levels in observation wells at Kitchener are shown in Figure 4. The extremely sharp drop in water levels during 1955 can be attributed to the large amounts of water pumped during the dry summer months of that year. The considerable variation in water level which occurs each year in the vicinity of the two pumping stations suggests fairly rapid recharge and discharge conditions. Above-normal precipitation affects water levels usually within the year, while ground-water discharge to wells and streams during the summer months when recharge is negligible is reflected by the rapidly lowering water levels.

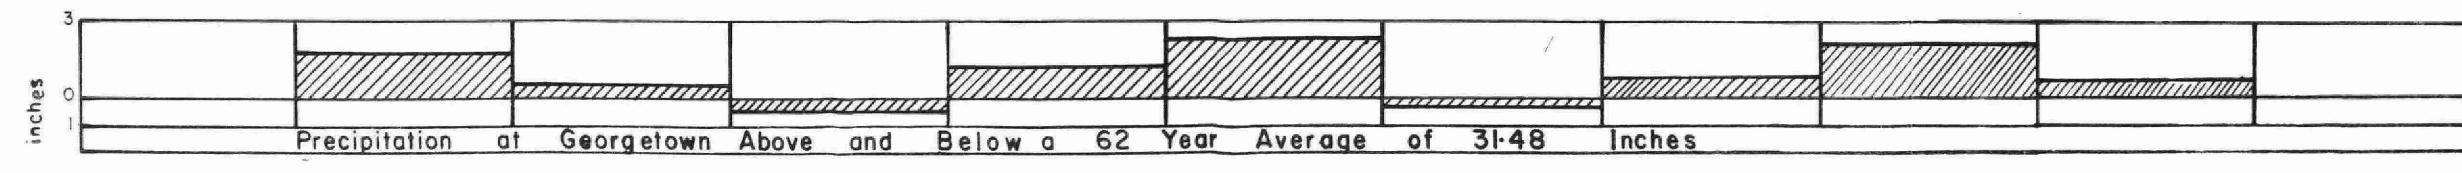

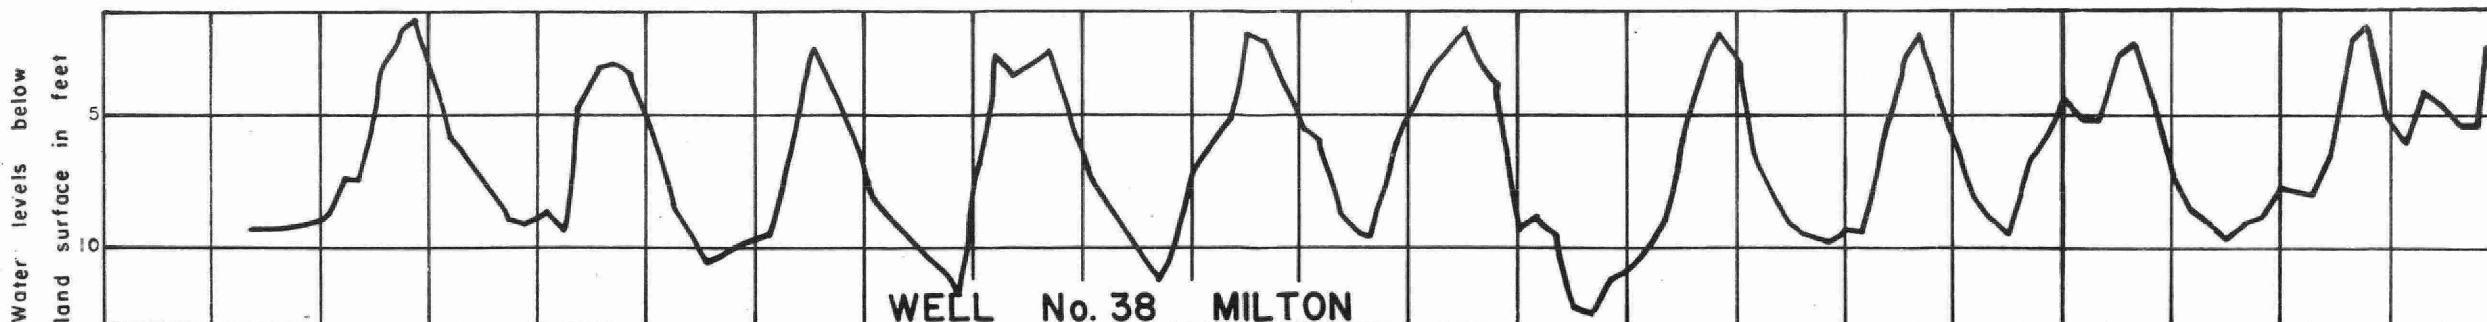

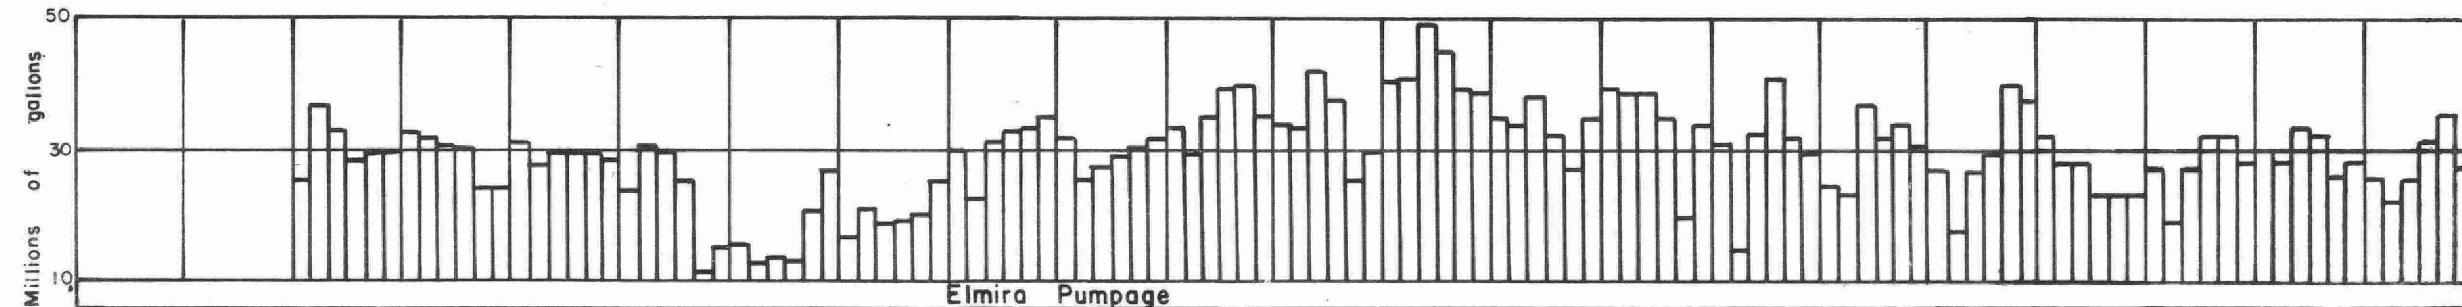

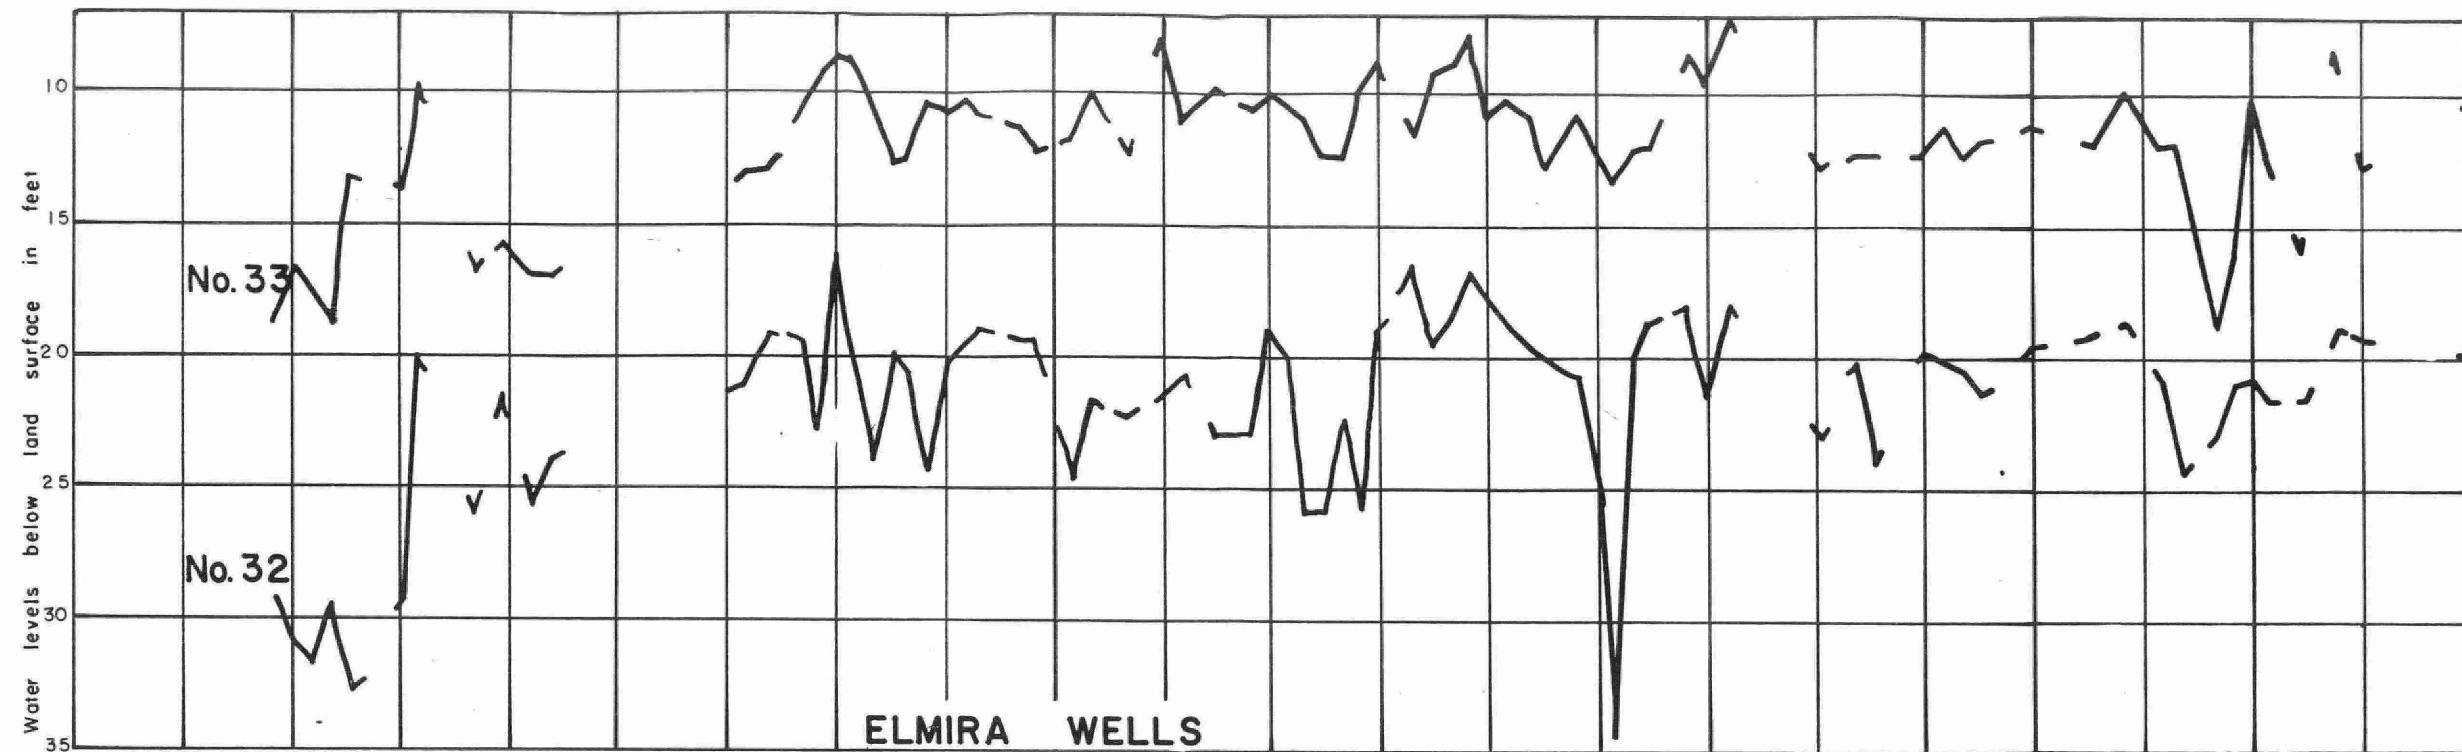

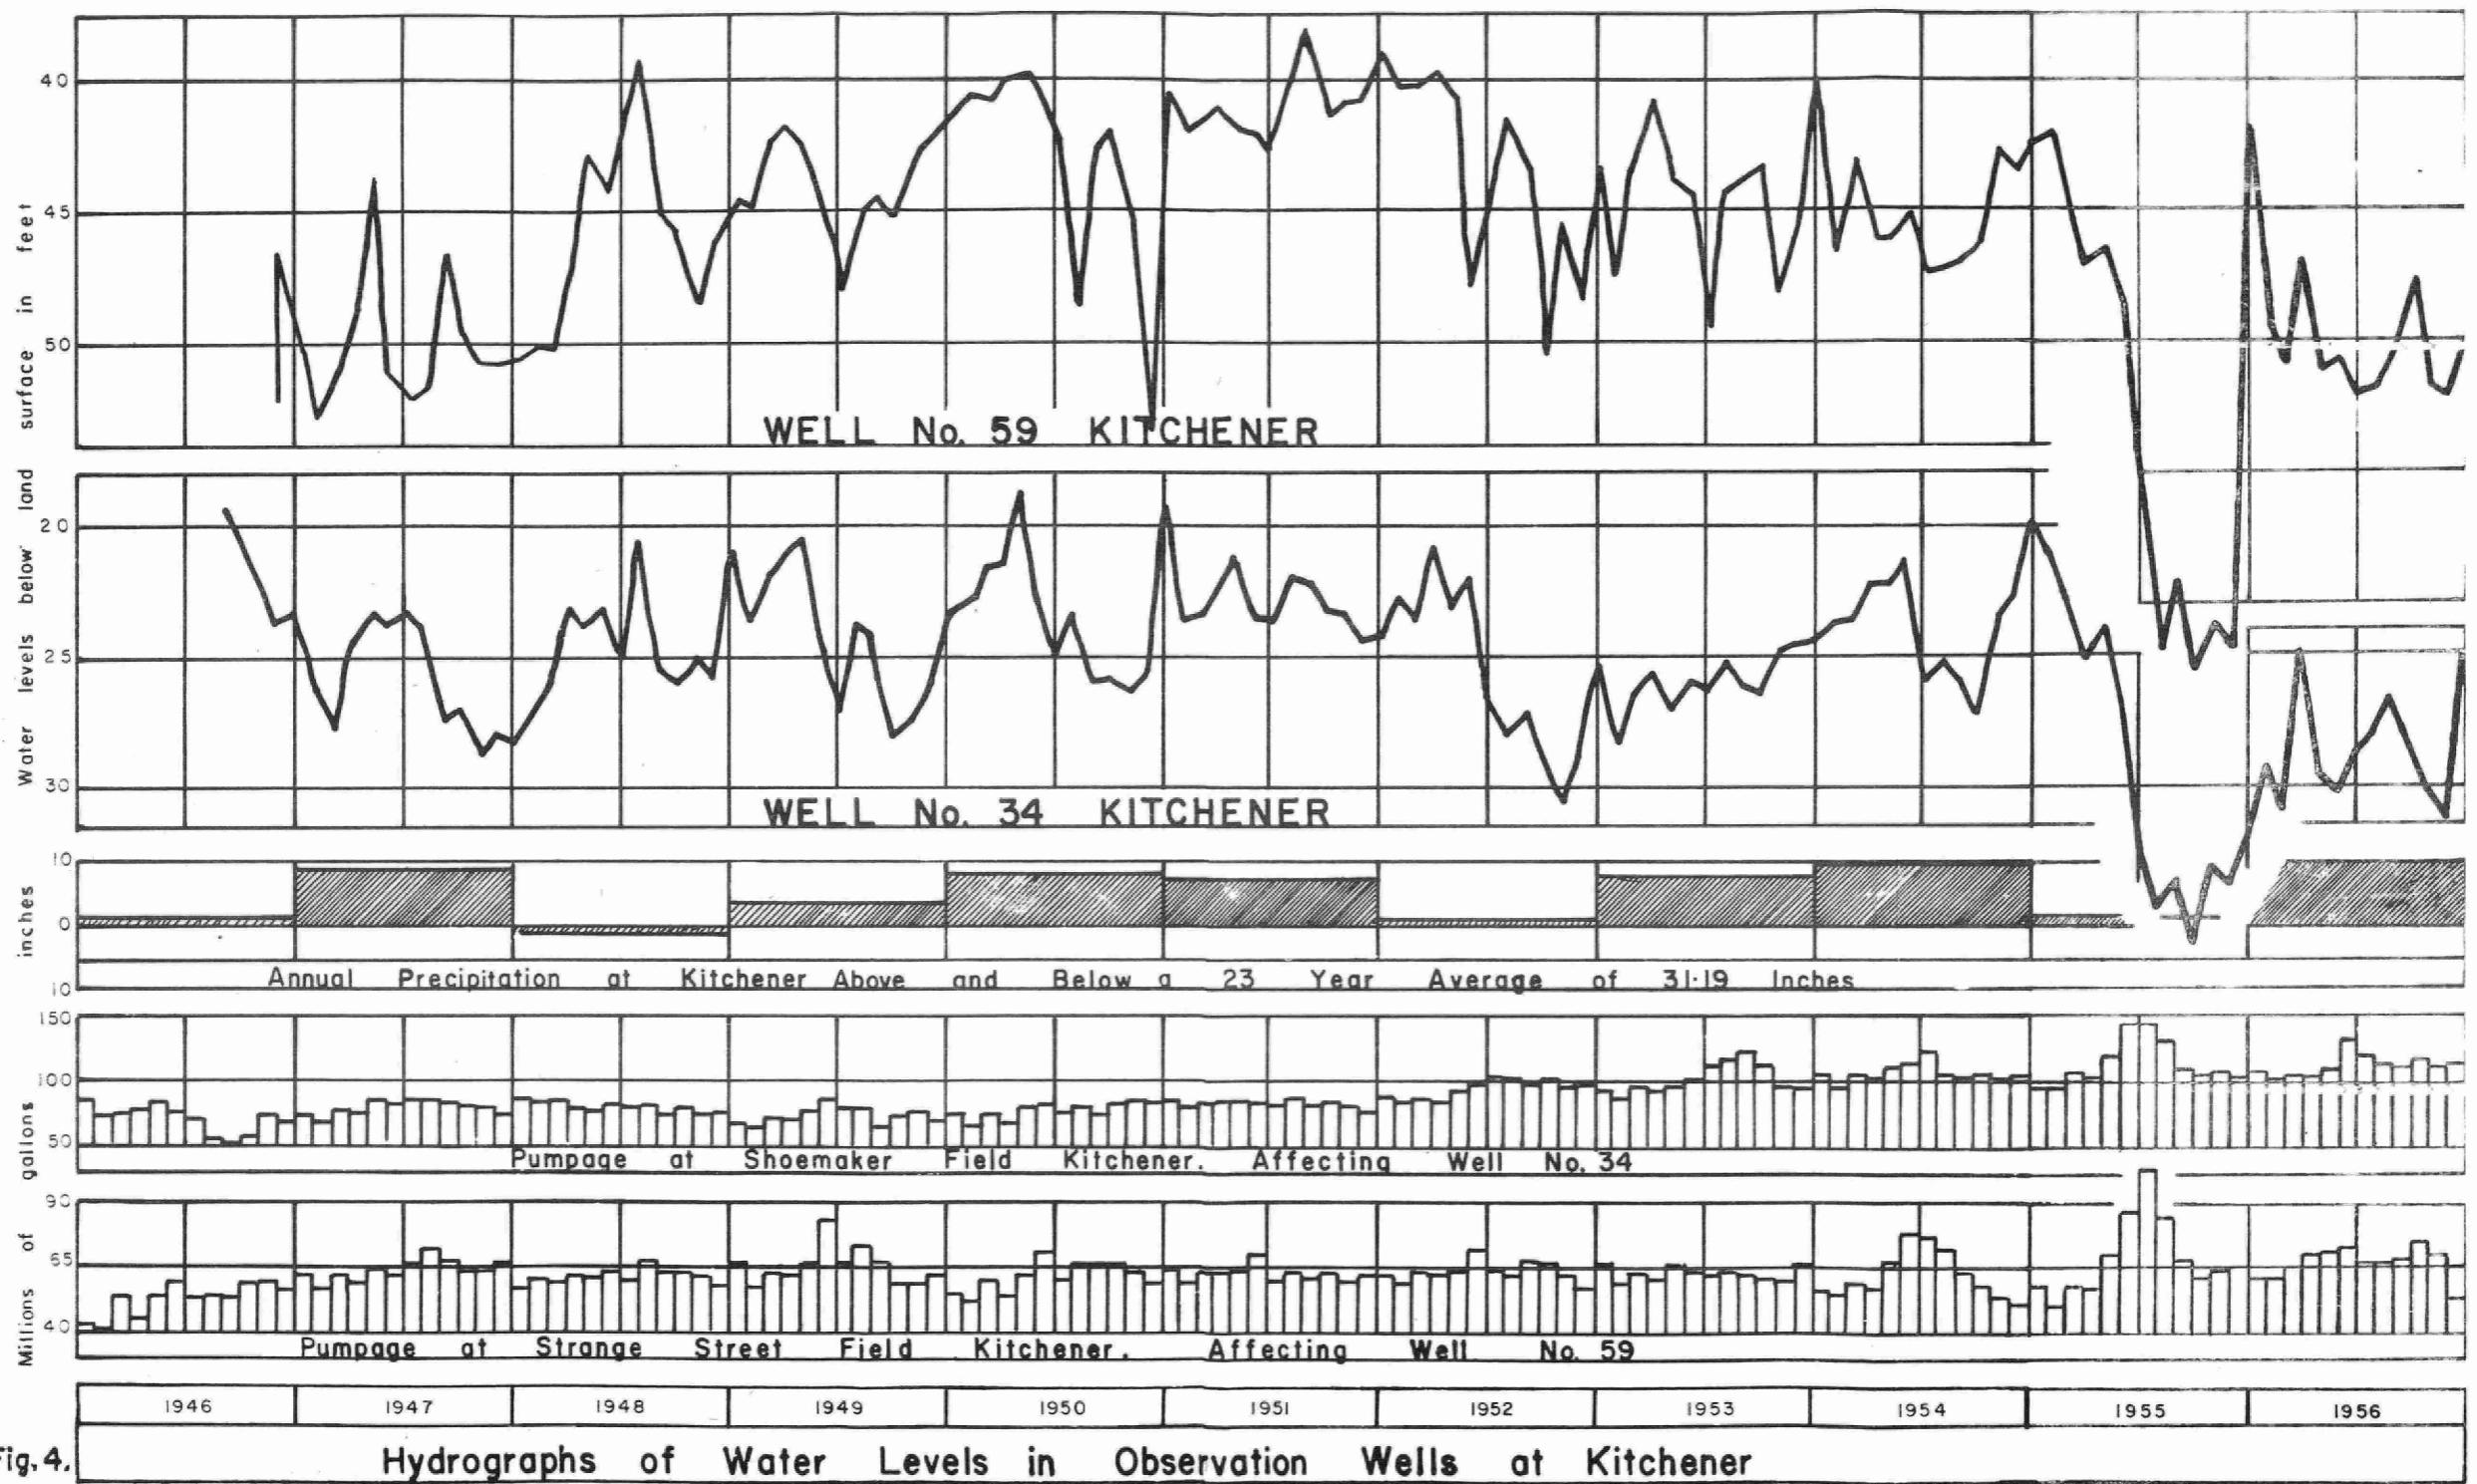

Fig. 3. Hydrographs of Water Levels in Observation Wells at Elmira and Milton

The Hydro-Electric Power Commission of Ontario

The Hydro-Electric Power Commission of Ontario set up a number of observation wells in 1948 and 1949 to study the effect of ground-water levels on the operation of storage basins and generating stations.

Table IV lists certain particulars of these wells. A copy of all the water-level measurements is available for reference at the Ontario Water Resources Commission offices in Toronto.

TABLE IV - OBSERVATION WELLS MEASURED IN 1955 AND 1956
BY THE HYDRO-ELECTRIC POWER COMMISSION OF ONTARIO¹

Drainage Area	Watershed	Location	Measurement of Water Levels Commenced
Lake Huron	Mississagi River	George W. Rayner generating station	Dec. 15, 1952
	Abitibi River	Abitibi Canyon generating station	Oct. 14, 1951
Moose River	Frederick House River	Frederick House dam	July 12, 1948
		Night Hawk Center	Aug. 9, 1948
		Shillington	Aug. 9, 1948
		South Porcupine	Aug. 9, 1948
		Algonquin Park headquarters	Oct. 21, 1949
		Bancroft	Nov. 12, 1949
Ottawa River	Madawaska River	Bark Lake dam	Nov. 7, 1949
		Carlow	Nov. 18, 1949
		Princes Lake	Oct. 29, 1949
		Sproule Bay	Nov. 26, 1949
		Whitney	Oct. 28, 1949
Winnipeg River	English River	Ear Falls No. 2	Mar. 22, 1954
		Ear Falls No. 4	Mar. 22, 1954

1. Data supplied by the Hydro-Electric Power Commission of Ontario.

Drillers Licensed to Drill in 1955 and 1956

In Appendix B is a list of water-well drillers licensed during the period 1955-56. The drillers are listed separately or under a drilling firm name, if such a relationship existed. In some instances a driller's name appears under two drilling firms due to a change in employment during the two-year period. A driller's name will also be listed separately as well as with a firm, if he has made a move from employment by another into business for himself. The number of drillers licensed in 1956 was 589 compared to 549 in 1954.

Due to the numerous changes of employment the wells reported by the drillers may not all be listed under the proper contractor or drilling firm. The number of wells or test-holes drilled each year is indicated opposite the partnership, firm, or employer's name, where such a relationship existed, in preference to the licensed driller who may actually have done the work. This number corresponds to the total number of records filed with the Department each year.

No fee was charged for a water-well driller's license. It was issued and renewed annually to those who observed the Well Drillers Act and the Water Well Regulations.

Water Well Records

Records for 12,271 water wells were forwarded by the drillers during the two-year period, 1955-1958. They are available to the public for reference at the offices of the Ontario Water Resources Commission, in Toronto.

Most of the important information from the records has been compiled in Appendix C and summarized in Table V. Any obvious errors in the records have been corrected by the staff of the Ground Water Branch. The spelling of the names of property owners is given as supplied by the well drillers. The logs have rarely been changed. The very few exceptions dealt mostly with long logs where a repetition of formations could fit under one description.

The locations of some wells may be listed in parts of townships which have been annexed to another municipality since the wells were drilled.

The pumping test, reported in gallons per minute, was not necessarily the rate at which the well could continue to supply water. Some of the wells may soon have been pumped dry at the reported rates. Others may have been capable of being pumped steadily at a much higher rate than that carried out in the pumping test.

The percentage of fresh, mineral, and dry wells remained approximately the same as in the previous two-year period, although there was a moderate increase in the percentage of wells that encountered salt.

Well water intended for use in churches, schools, hotels, and buildings generally occupied by several families or groups of people, was classified as public supply under the "Use" heading. Water used in garages, stores, and restaurants was classed as commercial; in greenhouses, dairies, and market gardens, as industrial.

Many test holes had no water data recorded. In most, if not all, of these holes some water was encountered, but as a large supply was being sought, usually for municipal purposes, no attempt was made to measure any flow where the formation or water conditions appeared unfavourable.

About seven percent of the holes drilled for water were dry or abandoned because of poor quality of water or insufficient supply. This percentage was approximately the same as in the previous two-year period with the three counties of Kent, Lambton, and York still having the greatest number of abandoned wells.

The trend towards more irrigation wells continued at a much slower rate than in 1953-54, so that the percentage of wells drilled for irrigation purposes declined. There was a definite increase from the previous two-year period in both the numbers and percentages of wells drilled for commercial and public supply purposes.

TABLE V - SUMMARY OF WATER-WELL DRILLING DATA FOR 1955 AND 1956

APPENDICES

APPENDIX A - OBSERVATION WELLS AND WATER-LEVEL MEASUREMENTS

1955 and 1956

Carleton County

Observation Well No.73.- Canadian Department of Agriculture, Central Experimental Farm, Ottawa. Rideau River watershed. Abandoned dug well; depth, 13 feet. Automatic weekly recorder installed September 18, 1950. Measuring point, top of wooden plank 2.7 feet above land surface. Measurements made by F. W. Baker.

Daily lowest water level below land surface
(from recorder charts):

Welland County

Observation Well No.2 - Humberstone township, Con I, lot 15, adjacent to Lake Erie. Property of W.R. Davison. Used drilled well; diameter, 6 inches; depth, 32.5 feet; limestone aquifer. Elevation, 582 feet above sea level. Measuring point, top of casing 2 feet above land surface. Measurements made by W.R. Davison; no measurements taken in 1955 and 1956.

Observation Well No.3 - Pelham township, Con VIII, lot 5, Welland River watershed. Property of F. Misener. Used dug well; diameter, 5 feet; depth, 21 feet; sand aquifer. Elevation, 688 feet above sea level. Measuring point, top of wooden covering level with land surface. Measurements made by F. Misener; discontinued March 30, 1955.

Distances of water level below land surface :

	1955	feet
Mar. 30		9.23

Wellington County

Observation Well No.47 - City of Guelph, Emma Street, Grand River watershed. Property of Guelph Public Utilities Commission. Used municipal drilled well; diameter, 12 inches; depth, 152 feet 8 inches; dolomite aquifer. Measurements computed from air-line readings taken by H. Theaker.

Observation Well No.42 - Etobicoke township, Con II, fronting Humber, lot 13, Mimico Creek watershed. Property of Etobicoke township. Abandoned drilled well; diameter, 4 inches; depth, 105 feet; sand and gravel aquifer. Measuring point, top of casing 3 feet above land surface. Weekly automatic recorder installed on April 13, 1950. Measurements made by S. Parker; discontinued March 1, 1955.

Daily lowest water level below land surface
(from recorder charts):
