**Louis Knore**, in Savannah, Ga., May 12, aged 78. He was graduated from the Oglethorpe Medical College, Savannah, in 1860. He was formerly professor of chemistry in the Savannah Medical College.

**Evan Hadley**, in Mooresville, Ind., May 13, aged 53. He was a member of American Medical Association and the Marion County Medical Society, of which he was at one time president.

**Stuart Bates**, in Virginia, Minn., May 6, aged 33. He was graduated from the Toronto (Ont.) University Medical Faculty in 1888, and was a member of the American Medical Association.

**John W. Kirkpatrick**, at Wyoming, Iowa, May 13, aged 40. He was graduated from the Rush Medical College, Chicago, in 1888. He was president of the Eastern Iowa Medical Society.

**James M. Sims**, in Marion, Ill., May 16, aged 33. He was graduated from the Marion Sims Medical College, St. Louis, in 1899. He was a member of the American Medical Association.

**Joshua Chitwood**, in Connersville, Ind., May 13, aged 65. He was graduated from the Miami Medical College, Cincinnati, in 1858. He served as surgeon during the Civil war.

**Hans J. Englund**, in Cambridge, Minn., May 5, aged 46. He was graduated from the Bennett Medical College, Chicago, in 1888, and from the Rush Medical College in 1895.

**Andrew Jay**, in Evergreen, Ala., May 8, aged 52. He was graduated from the Medical College of Alabama, Mobile, in 1872. He was a member of the State Legislature.

**John H. Shelton**, in Tower Hill, Iowa, May 13, aged 68. He was graduated from the College of Physicians and Surgeons, Keokuk, Iowa, in 1882.

**James S. Hall**, of Worcester, Mass., June 3, aged 46. He was graduated from the College of Physicians and Surgeons, Boston, Mass., in 1897.

**Warner F. H. O'Keefe**, in Pittsburg, Pa., May 20. He was graduated from the New York Homeopathic Medical College and Hospital in 1875.

**Alfred Hasbrouck**, in Poughkeepsie, N. Y., May 9, aged 82. He was graduated from the New York College of Physicians and Surgeons in 1848.

**Clinton H. Lubbock**, in Alameda, Cal., May 20, aged 42. He was graduated from the University of the State of Missouri, Columbia, in 1880.

**A. S. Wilson**, at Wilkes-Barre, Pa., May 27, aged 39. He was graduated from the medical department of the University of Pennsylvania in 1892.

**Charles W. Doyle**, in Santa Cruz, Cal., May 1, aged 53. He was graduated from the University of Aberdeen, Scotland, in 1875.

**Frank Daniel**, in Moultrie, Ga., May 6. He was graduated from the Atlanta (Ga.) College of Physicians and Surgeons in 1902.

**E. L. Acker**, in Allentown, Pa., May 12, aged 76. He was graduated from the University of Pennsylvania, Philadelphia, in 1852.

**Charles C. Sparklin**, at Goshen, Ind., May 5, aged 62. He was graduated from the Rush Medical College, Chicago, in 1861.

**Oliver C. Evans**, in Joplin, Mo., May 5, aged 58. He was graduated from the Pulte Medical College, Cincinnati, Ohio, in 1878.

**Walter B. Sherman**, in Eagle Cliff, Ohio, May 19, aged 72. He was graduated from the Cleveland Medical College in 1870.

**George C. Synon**, in Chicago, Ill., May 21, aged 45. He was graduated from the Rush Medical College, Chicago, in 1880.

**Captain William O. Davies**, an assistant surgeon in the United States Army, died in Philadelphia, May 26, aged 37.

**Alice M. Potter**, in Ithaca, N. Y., May 2, aged 33. She was graduated from the University of Buffalo in 1897.

**Hiram J. Hartley**, at Spring Hill, Ind., May 1, aged 79.

**P. H. Keyser, Jr.**, at Boulder, Colo., May 24, aged 31.

**John Gosman**, at Doylestown, Pa., May 24, aged 70.

**J. B. Forbes**, at Chicago, Ill., June 1.

## SOCIETY REPORTS

### SIXTH TRIENNIAL CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

Held in Washington, May 12, 13 and 14, 1903.

[Specially reported for *American Medicine*.]

Sessions of the Congress.

SECOND SESSION (CONCLUDED).

**On the Surgical Treatment of Obstruction of the Common Bile Duct by Stone or Tumor.**—HANS KEHR (Halberstadt, Germany) looked upon the pressure of bile as the chief factor in forcing stones through the duct. He did not think one could determine at the time of the colic whether the stones were large or small, nor whether they passed through the ductus choledochus or not. Acute obstructions of the duct are rare, and sometimes a spontaneous cure may result, but he attached but little importance to the passage of a stone, because there were probably others. If pancreatic trouble be associated with stone in the gallbladder he advised treating this at the same time, but was not in favor of breaking up the stone, as all the broken parts might not pass through. He believed that drainage was more quickly performed than suturing, and felt that in colotomy, with sutures, many stones were left behind. In his opinion the success of the operation depended upon the pathologic conditions present. He urged the use of a free abdominal incision, and a generous quantity of gauze packing, believing they played a most important part in the results obtained. While he believed that the treatment of obstruction of the ductus choledochus properly belonged to internal medicine, he advised against waiting more than three months before operating. He did not think an incision into the hepatic duct was very often necessary, but attached great importance to the treatment following operation.

**Discussion.**—FRANK BILLINGS (Chicago) commented on the fact that surgeons had, in the greater part of the operations done in the last few years, so enlightened us in the diagnosis of these conditions that it can be much more readily made than formerly, but in spite of this, considered it was absolutely impossible to make a rational diagnosis in many cases. The fact that the most prominent symptom referred to by writers of the present day was pain, usually in the region of the gallbladder apparatus, not always severe, nor always colicky in character, was dwelt upon, as well as the fact that points of tenderness may be present without any pain, especially in patients whose abdominal walls are not too thick. Within one year two patients have called upon Dr. Billings, both of whom had been operated upon for cystic gallstones without the stones having been found, the condition in each case being that of gastric crises, due to locomotor ataxia. The fact that cases of appendicitis were often operated upon for gallstone, and that floating kidney and inflamed appendix may refer pain to the gallbladder region, was briefly noted, and the statement made that in one sense gallstones are harmless, and do not present symptoms sufficient to make a diagnosis until there is infection of the gallbladder region. In the doctor's opinion, by the time we are able to make a diagnosis of gallstone the case is no longer a medical disease, but a surgical one. He emphasized very strongly the fact that if once a diagnosis is made, and one can elicit the information that gallstones have repeatedly occurred in the past, an operation is indicated and should be performed at once. However, he was in favor beforehand of trying to get rid of the infection by proper food, drink, respiratory exercise, and in the case of women, adjustment of the dress, but if these failed he urged operation at once. GEORGE DOCK (Ann Arbor) commented on the fact that nothing but carelessness or ignorance in many cases prevented patients from being sent to the surgeon, and he believed this was largely due to their not knowing the beneficial results to be obtained by surgical treatment. The resemblance of cases of gallstone disease to appendicitis and renal colic was alluded to, but it was claimed that a careful examination will in most cases clear up the diagnosis satisfactorily. In his opinion more has been learned from the surgeon than from the pathologist in these cases, largely owing to the fact that many of them do not come to autopsy at all, so that the pathologist does not have an opportunity of studying them. He referred to a case which recently came under his observation in which there was very marked dilation of the stomach, without any history pointing to the cause. It was probably an example of latent ulcer of the stomach, followed by cicatricial contraction, and the patient's condition was desperate. He was referred to the surgical clinic for treatment, and a few days before the day set for the operation, while the stomach was being washed out, a gallstone came up with the stomach washing. Although confronted with this evidence of what his disease was, the patient could recall no symptoms of tenderness in the region of the gallbladder, but examination before this had shown a resistance in this region. The patient finally came to operation, which, unfortunately, was fatal. It was found that he had old and very extensive disease of the gallbladder and cystic duct, so that they were almost unrecognizable. In a similar case the speaker hesitated to make a diag-

nosis, but finally did so in view of the fact that a cross examination of the patient elicited a history of mild attacks of jaundice. HENRY SEWALL (Denver) discussed the papers under 17 different headings, which were confined to a synoptical statement of the physiologic conditions, whose modifications lead to gallstone formation. After stating that the bile is a continuous secretion, with rhythmic accelerations due to contraction of the larger bile ducts, he said it would be interesting to consider how the bile got into the gallbladder during the intervals between its outpourings into the intestine, which he proceeded briefly to explain. He said it was granted on all sides that the dangers of gallstone disease depend upon bacterial invasion of the gallbladder and gall ducts, and that the formation of gallstones may presuppose such invasion. Commenting upon the entrance of germs from the intestine, the sphincter muscle of the duct must form a useful barrier, but germs must be constantly penetrating the common duct, and once in the duct they must find ready access to the gallbladder, except for the possible filtering power of the Heisterian valve in the cystic duct. He supposed it was well known that all factors restricting the free outflowing of bile (dress, habits of eating, etc.) predisposed to gallstones, and also if the bile, when secreted by the liver, is already infected, it cannot serve as a cleansing fluid. In his opinion a prominent or principal use of the gallbladder is to serve as a flush tank for the common and cystic duct, and it may be suspected that atrophy or extirpation of the gallbladder might predispose to cholangitis. E. G. JANEWAY (New York) called attention to the importance of the character of the food taken by patients suffering with this disease, and urged that this matter should be under the control of the physician. He briefly detailed a case of complete obstruction, which recently came under his notice, and which case was in charge of a physician who had made somewhat of a special study of these conditions. The physician told the speaker that the diagnosis could not be that of complete obstruction because the bile flowed into the intestine, which opinion was based upon a study of the appearance of the stools. Careful cross-questioning of the patient, however, elicited the fact that he had been eating very largely of spinach, and this had stained the passages green. He also mentioned the fact that he had seen two cases operated upon for gallstone obstruction, in each of which the disease was ulcer of the duodenum. Prof. B. G. A. MOYNIHAN (Leeds, England) stated that he had had considerable experience in England with gallstone disease, and that this was the trend of the recent surgical experience in that country. He referred to the paper of Dr. Mayo, and especially to the incision he uses in operations upon the common duct, which is the same as that now being employed by the speaker. Referring to the mortality in these cases, the doctor stated that although operations upon the common duct used to be considered extremely serious, they were not losing at the present time more than 3% or 4%, and he attributed this improvement to the kind of incision which is being used, through which one is able to see the gallbladder and pull out through the wound about one-third of the liver. He expressed considerable satisfaction from this little detail in the operation, and claimed to be able to operate upon the common duct in 20 or 30 minutes. He commented upon the fact that one is being driven oftener and oftener to an inspection of the gallbladder, making it necessary to employ an incision which would permit of this. He referred to some experience he had had when cholecystotomy had been performed, and when there had not been a complete abolition of all the trouble as the patient had complained of an uneasiness in the old scar. After stating that for many reasons surgeons have been driven to the performance of the operation of cholecystectomy, he referred to the fact that they have had more facilities for operating upon the common duct and have been better satisfied with the result.

## ASSOCIATION OF AMERICAN PHYSICIANS.

[Specially reported for *American Medicine*.]

SECOND SESSION.

**Acute Lymphatic Leukemia.**—A. O. J. KELLY (Philadelphia) reported four cases of the disease, with necropsies and a description of the blood findings and anatomic changes, and discussed the alterations in the bone marrow, with particular reference to the nature of acute lymphatic leukemia in its relationship to myelogenous leukemia.

**Report of an Autopsy and the Microscopic Findings in a Case of Acute Lymphatic Leukemia.**—F. P. KINNICUTT (New York) made this report, giving many technical details.

**A Clinical and Pathologic Study of Two Cases of Splenic Leukemia, Presenting Early and Late Stages of Cirrhosis (Early and Late Stages of Banti's Disease).**—GEORGE DOCK and ALDRED S. WARTHIN (Ann Arbor) reported these two cases, both of which presented a typical picture of splenic anemia, splenic fibrosis, etc., stenosis of the portal vein, with calcification of the vein-wall. There was an extensive new formation of lymphoid tissue throughout the mesentery and prevertebral adipose tissue. In one case the new lymphoid tissue was like splenic pulp in structure. In the second case (advanced cirrhosis) the lymphoid tissue presented the charac-

teristics of hyperplastic hemolymph-nodes. Great numbers of phagocytes containing disintegrating red blood cells and blood pigment were found in the blood sinuses. No hemosiderin was found in the liver, spleen or kidneys. No evidence of red blood cell destruction was observed in the spleen. The bone marrow showed numbers of red cell and pigment phagocytes. Similar changes were noted in the hemolymph-nodes in the case showing early cirrhosis. There was a tendency to the deposit of lime salts throughout the portal system, fibrosis of the portal branches, interstitial changes in the pancreas, and presence in the bloodvessels of numerous bone marrow giant cells. Early loss of the splenic function and partial compensation by new formation and hyperplasia of lymphoid and hemolymphoid structures. It seemed probable that hemolysis was only compensatory for the lost splenic function and not the direct result of an intoxication.

**Discussion.**—CABOT (Boston) said that out of 76 cases he had no reason to believe that the two types were ever fused or mixed; they were clearly myelogenous or lymphatic. When a mixed condition had been reported he was inclined to think the examination unsatisfactory. PEABODY (Boston) reported a case without enlargement of the lymphatic glands, in which blood examination showed 150,000 white cells; 91% mononuclears. HERRICK had seen nine typical cases, in two of which there were numbers of nucleated red blood cells. He thought that clinically the cases resembled acute infection; four had angina with exudate upon the tonsils, and the anemia was rapid and progressive. FUSSELL (Philadelphia) had reported a case some three years ago that began with the ordinary symptoms of typhoid fever; moderate enlargement of the spleen; no enlargement of the lymphatic glands. WELCH (Baltimore) called attention to the theory of the origin of lymphocytes and thought this study constituted the principal attack upon Ehrlich's theory. He referred also to the question of the ameboid movements of lymphocytes. He had always believed that the evidence in support of this movement was conclusive. In the majority of instances there was terminal infection. He referred to a case of calcareous degeneration of the portal vein with marked sclerosis of the walls and changes in the spleen and liver. OSLER divided the cases into two groups—one running its course in 10 or 12 weeks; the other lasting for as many years. The acute cases resembled the cases of acute septicemia, with hemorrhages, fever, swollen tonsils, angina, etc.

**The Relation of Chronic Enlargement of the Spleen to Anemia in Infancy.**—JOHN LOVETT MORSE (Boston) gave the histories and blood examinations in 22 cases of anemia with splenic tumor in infancy. He considered that the enlargements of the spleen, liver, and lymph-nodes develop independently of each other, with no direct connection as to cause or effect. They were due to disturbance of nutrition, the anemia being secondary, not primary. He thought the terms "anaemia infantum pseudoleukiemia" or "splenic anemia of infancy" were not justifiable.

**Discussion.**—OSLER (Baltimore) said that many had been convinced for a long time of the frequency of enlargement of the spleen in cases of malnutrition of children. Cirrhosis of the liver was also quite frequent in these conditions.

[To be continued.]

## AMERICAN SURGICAL ASSOCIATION.

[Specially reported for *American Medicine*.]

**The Surgery of the Simple Diseases of the Stomach.**—B. G. A. MOYNIHAN (Leeds, England) stated that the great majority of such diseases susceptible to successful treatment by surgical measures are due to ulceration or to its complications and results. *Perforation* is subdivided into the three classes of acute, subacute, and chronic. *Hemorrhage* from gastric or duodenal ulcers is recognizable either as hematemesis or melena. Hemorrhage may occur from an acute or a chronic ulcer. The characteristics of hemorrhage from an acute gastric ulcer are spontaneity, abruptness of onset, the rapid loss of a large quantity of blood, the marked tendency to spontaneous cessation, the infrequency of a repetition of the hemorrhage in anything but trivial quantity, and the transience of the resulting anemia. Hemorrhage from a chronic ulcer the author divides into four groups, as follows. 1. The hemorrhage is latent or concealed, is always trivial, and often conspicuous. 2. The hemorrhage is intermittent, but in moderate quantity, occurring spontaneously and with apparent caprice at infrequent intervals. The life of the patient is never in jeopardy from loss of blood, though anemia is a persisting symptom. 3. The hemorrhage occurs generally, but not always, after a warning exacerbation of chronic symptoms. It is rapidly repeated, is always abundant, its persistence and excess cause grave peril, and will, if unchecked, be the determining cause of the patient's death. 4. The hemorrhage is instant, overwhelming, and lethal. In hemorrhage from an acute ulcer, the aid of a surgeon will rarely be needed; medical means alone will generally suffice. In a few cases in which the hemorrhage is both copious and recurring—threatening the life of the patient—the performance of gastroenterostomy will prove more effective than any other procedure, both in checking the hemorrhage and in preventing its recurrence. It is mainly in cases of chronic ulcer that the question of surgical treatment for hemorrhage will arise. In

all cases of hemorrhage from a chronic ulcer, an operation ought to be performed at the earliest possible moment. After describing the great diversity of form under which chronic ulcer presents itself clinically, the author takes up the question of operative treatment. In operating upon chronic ulcer of the stomach, he always performs gastroenterostomy, wherever the ulcer is placed, and finds that this procedure will relieve symptoms completely and permanently, and will permit of the sound healing of the ulcer. Excision is unnecessary, often impossible, always insufficient. In the performance of gastroenterostomy he unites the posterior wall of the stomach with the jejunum through an opening in the transverse mesocolon. *Hourglass stomach* is usually described as being "congenital" and "acquired." The author has been unable to find any proof of the existence of the congenital form. The acquired form may be caused by (1) perigastric adhesions; (2) ulcer, with local perforation and anchoring to the anterior abdominal wall; (3) chronic ulcer, generally at or near the middle of the organ; (4) malignant disease. The treatment may be beset with difficulties, and the author specifies six different operations which may be practised: (1) Gastroplasty; (2) gastrogastrostomy or gastroanastomosis; (3) either of the foregoing, with gastroenterostomy from the pyloric pouch, in cases of dual stenosis; (4) gastroenterostomy from cardiac pouch, when the pyloric pouch is so small that it can be ignored; (5) gastroenterostomy from both pouches; (6) partial gastrectomy. The operations selected will necessarily depend upon the condition which is found.

The number of cases upon which Mr. Moynihan's paper is based is as follows:

Perforating gastric or duodenal ulcer, 12 cases, 6 recoveries.  
Gastroenterostomy for chronic ulcer, etc., 70 cases, 1 death.  
Pyloroplasty, 3 cases, no deaths.  
Hourglass stomach, 15 cases, 3 deaths.  
Gastroplasty, 1 case, recovered.  
Excision of ulcer for hematemesis, 1 case, died.

#### Symposium on the Therapeutic Value of the X-rays in Surgery.

**The Value of the X-ray in Superficial Epitheliomas and Tuberculosis.**—WM. L. RODMAN and G. E. PFAHLER, Philadelphia, mentioned the following advantages of the treatment, as given by Pusey: (1) It is painless; (2) it destroys diseased tissue but leaves healthy tissue in its place; (3) it leaves a minimum scar; (4) it can be used when the surrounding tissue cannot be sacrificed; (5) it relieves pain and induces sleep. The following conclusions were then given: 1. The length of time required for the cure of epitheliomas is longer than by surgical or caustic treatment while the cosmetic results are better. The dangers are proportionate to the urgency of the treatment, as indicated by the degree of malignancy. It should only be recommended in cases that are inoperable either because of the extent of the growth or its location. 2. It is probably the best means at our command for the treatment of superficial tuberculosis and gives better cosmetic results. 3. It should follow all operations for malignant disease or tuberculosis with the twofold object of stimulating the healing process and of preventing a recurrence. In some cases it may be of an advantage to give a short course of treatment before operation, to destroy the outlying portions of the growth and make such operation of a less formidable nature.

[To be continued.]

#### AMERICAN ASSOCIATION OF PATHOLOGISTS AND BACTERIOLOGISTS.

Third Annual Meeting, Held in Washington, May 12, 13 and 14, 1903.

[Specially reported for *American Medicine*.]

##### FOURTH SESSION.

**Pathologic Changes in the Nervous System in a Case of Lead Palsy.**—W. G. SPILLER (Philadelphia) included in his paper a discussion of the findings in the cases recorded in the literature, and the description of the pathologic changes in his own case. These changes were chiefly an extensive proliferation of the endothelial cells of the cerebral plex; changes in the spinal ganglia, and in the peripheral nerves and the muscles, the changes in the periphery resembling those seen in rabies.

**The Reactions of the Blood in Experimental Diabetes Mellitus.**—J. E. SWEET (Philadelphia) states that the main results of his work are those obtained in his study of the experimental diabetes produced in dogs by the complete removal of the pancreas. The work was based upon the fact long known that the diabetic organism is abnormally susceptible to infectious processes. This susceptibility to infection is found to be due to a great loss of the complementary substances, a loss of over 50% of the hemolytic complement, and apparently an entire loss of the bacteriolytic complements. No effect of the diabetes upon the leukocytes of any type can be demonstrated. Sweet, therefore, concludes that the leukocyte has nothing to do with the production of those complementary substances which are destroyed by heating to 56° C.

**A Contribution to the Knowledge of the Development and Pathology of the Islands of Langerhans of the Pancreas.**—R. M. PEARCE (Philadelphia) has made a most thorough study of the development of these groups of cells in an unusually good collection of material, having studied their development in 21 human embryos of different stages. With this he has joined a study of the islands in cases of syphilitic pancreatitis of the newborn, and of the fate of the islands in cases of cancerous degeneration of the pancreas. The conclusions from this admirable study are that the islands of Langerhans develop from the acini of the pancreas. They show a remarkable resistance to degenerative processes.

**Discussion.**—HEKTOEN calls attention to the possible complementary hypertrophy of the islands in cases of disease of the liver.

**A Statistical Study of Endotheliomas, with a Report of 15 Cases, and Lantern Slide and Projection Demonstrations.**—W. M. L. COPLIN (Philadelphia) in his paper embodied a thorough analytic study of the cases reported in the literature, with an extended classification of occurrence, etc. The main results of interest to the clinician are those dealing with the relative frequency of occurrence. Coplin classifies 29.13% as arising from the serosa, with which he groups the tumors of the dura; 18.77% arise from the ovary; 11.48% have their origin in the parotid. Metastases occur by way of the blood, and occur principally in the lung and bronchial glands.

**Multiple Thyroid Tumor of Bone and Glands of Cancerous Origin, but with Typical Thyroid Structure.**—ADOLPH MAYER (New York) discussed at length this tumor, which illustrates the tendency of some growths to retain the structural peculiarity of the tissue in which they originate. He also interpolated the description of a tumor, having no connection with his paper, from a case of akromegaly.

**Studies on the Pathology of Forage Poisoning in Horses, So-called Epizootic Cerebrospinal Meningitis.**—M. P. RAVENEL and D. J. MCCARTHY (Philadelphia) gave a preliminary report on this subject. The name "cerebrospinal meningitis" is not justified by either clinical observations or by postmortem findings. The name "forage poisoning" has therefore been suggested. The principal pathologic changes are found in the intravertebral ganglia, and resemble in many particulars those changes seen in the intravertebral ganglia of rabbits dead of rabies. The disease is probably due to the growth of some fungus upon the ensilage.

**Studies of the Bacteriolytic Complements Found in the Serum of the Rabbit.**—Reported by A. C. ABBOTT for E. B. VEDDER (Philadelphia). These studies have thrown light upon many of the important questions occurring in the course of modern work upon immunity. Proof has been brought of the existence of many complements, and interesting facts in regard to their behavior toward filters, etc., demonstrated. Vedder has not been able to support the teaching of the French school, that the complements are elaborated by the polynuclear leukocytes.

**Enzymes and Antienzymes, with Special Reference to the Antibody of Rennet.**—JOSEPH MCFARLAND (Philadelphia) has been able to confirm earlier experiments on the possibility of producing an antibody which has the property of inhibiting the coagulating property of rennet. He has further made an interesting addition to our knowledge, by the demonstration that the antibody combines with the rennet, and not with the casinogen. This fact is proved by the observation that the rennet is prevented from acting upon milk by a much smaller amount of the specific serum when the serum is added to the rennet before the addition of the milk, than when rennet and serum are added separately to the milk.

#### AMERICAN ORTHOPEDIC ASSOCIATION.

[Specially reported for *American Medicine*.]

##### SECOND SESSION (CONTINUED).

**Breaking Down of the Foot in Trained Nurses: A Series of 500 Observations on Normal and Disabled Feet.**—R. W. LOVETT (Boston). This paper will appear in a future issue of *American Medicine*.

**Spastic Paralysis.**—BERNARD BARTOW (Buffalo) reported the following: Case I.—Boy, aged 11 years, born at 7 months. Spasticity was not observed till third month. His development was slow, with marked mental enfeeblement. The condition is spastic double hemiplegia, involving especially the lower extremities. Spasticity largely abated in the higher muscles. There was associated structural shortening with spasticity in the hamstrings. The thigh flexors, adductors, and leg groups were strongly spastic during movement. Reflexes were exaggerated in contracted muscles; electrical reaction very slight in the quadriceps. Malpostures were very characteristic, while erect, standing, and sitting positions were assumed and maintained with difficulty. Locomotion: Sliding and dragging body by grasping fixed objects, never walked. Operations were done June 9 and 20, 1902, with transposition of hamstring tendons to quadriceps, and correction of knee malposition. Relief of spasticity in associated groups followed, and rapid and marked mental improvement. Extension power in quadriceps evident in three months. Standing position was

maintained with support from hands at sixteenth week. The patient was able to walk with crutches in three months, and able to walk three-fourths of a mile in nine months. Case II.—Boy of 15, born at term, weighing four pounds, had double spasticity, especially of lower extremities; flexion and extension good. There was 30° flexion in standing; therefore muscles became spastic when fatigued. Treatment was similar to that of Case I, plus division of the iliotibial band, and result was equally good.

**A Consideration of the Proper Arrangement of the Clothing in Growing Children with Reference to the Prevention of Faulty Attitudes.**—J. E. GOLDTHWAIT (Boston) says that a normal position with the shoulders square can not be long maintained with the clothing supported upon the tips of the shoulders, as is commonly the case. This leads to stoop shoulder, flattening of the chest, protrusion of the abdomen and head, all of which produce muscle-strain, particularly on the spinal muscles, weakness, and frequently lateral curvature. Exercise nor any other form of treatment which does not seek to remove the cause will not overcome the condition. Treatment: Use of a correct waist, which puts the weight on the base of the neck rather than the tip of the shoulders. It can be of the suspender plan leaving the question of high or low neck waist to the tastes of patient. The boys' pattern of the popularly known "easy waist" should be adopted for clinical work, as it almost meets the condition and costs no more than other cheap waists. Stocking straps should be fastened to the suspenders, thus aiding lateral motion, or on a pelvic band (like men's belts) which is too low to interfere with abdominal organs. Stoop shoulder is most frequently seen in girls, and often disappears at puberty.

[To be continued.]

## AMERICAN DERMATOLOGICAL ASSOCIATION.

[Specially reported for *American Medicine*.]

SECOND SESSION (CONCLUDED).

### Report of a Case of Dermatitis Gangræna Infantum.

—J. NEVINS HYDE (Chicago) related this case, occurring in a child 17 months of age, previously healthy, who from unknown cause had marked red blotches on the wrist, which was erythematous. They were symptoms of general eruption and two days later the wrist became swollen. On the fourth day an incision was made and copious watery fluid was evacuated. On the fifth day a similar eruption appeared on the body; there was great edema of extremities and the child lost appetite. On the tenth day there was a temperature ranging from 103° to 105°; the child lay listless and was much emaciated. The general surface was cool, except the hands, which were warm to the touch. On the eleventh day there were superficial pustules, some of which were as large as a twenty-five cent piece. On the twelfth day gangrenous changes on both wrist and foot were noticed. On the thirteenth day the gangrenous process had increased. There were bullous areas over wrist and knuckles. Several of the digits were spontaneously disarticulated, the ulcers extending to the bone, and the fingers held on by shreds. On the fourteenth day the child died. Cultures were made and *Staphylococcus pyogenes aureus* was found. Upon necropsy the internal organs were found free from lesions, except a few thrombi.

**A New Drug Eruption of the Iodoform Type.**—S. POLLITZER (New York) began with the statement that iodoform has been used for 25 years and is now used more carefully, with the result that there are fewer cases of poisoning reported. Mezotan is used for treatment of rheumatism, used externally, causing the skin to become warm, tingling, and markedly red. Salicylic acid is found in the urine one hour after it is used. Erythema and urticaria are both noticed, and if the use of the drug is continued the urticaria becomes worse. In cases where the drug is withdrawn upon the appearance of the dermatitis the dermatitis disappears. The areas involved are irregular in outline; erythema is marked, itching, and burning. He cited a case in which equal parts of mezotan and olive oil was used on an elbow-joint; it was followed by a marked dermatitis of the forearm, with irregular areas across the trunk, some areas on the other arm and also found on the thighs. With the withdrawal of the drug and the use of ichthyol the dermatitis disappeared readily after the first application, except on arm first involved. With continuous use of ichthyol it finally passed away with fine scaling.

THIRD SESSION.

**A Case of Multiple Angioma.**—A. POST (Boston) detailed the case of a girl of 10, who presented a series of tumors on the right arm, which extended to the sternum. They were first noticed at the end of her first year. They were lumpy in outline and her hands were puffy. During the last six years some spots were noticed on her chest, which increased in size, the masses on her hand and arms also increased in size. In the axilla and inner side of the arm they were marked, were irregular masses having a soft, velvety feel, and were elevated about the surrounding skin. On the hypothenar eminence was a very marked group of masses and along the mid arm on the ulnar side were also several groups; they were painful upon pressure. She was subjected to an operation and the masses

cut away; they appeared to be simple, superficial veins. The main artery was ligated, and the masses on the fingers were dissected off. The remaining veins seemed very much increased in size. A month after the operation the veins where the nodules had been showed a marked increase in size. The arm and hand were double the size of the nonaffected arm. The palm was filled with nodular masses projecting one-half inch above the surface; there were also nodules in the axilla. They appeared to be enlarged veins. Pressure had no effect upon them. They appeared more like fibromas than angiomas. Several were incised and they bled freely; the whole arm was enlarged and seemed an enlarged network of veins. Upon microscopic examination they showed to be angiomas of the capillary type. The lining endothelium was more prominent than that of normal vessels. The heart and lungs were normal and no other disease could be detected.

[To be continued.]

## THE AMERICAN CLIMATOLOGICAL ASSOCIATION.

Twentieth Annual Meeting, Held in Washington, D. C.,  
May 12, 13 and 14, 1903.

[Specially reported for *American Medicine*.]

The president, NORMAN BRIDGE (Los Angeles, Cal.) made the opening address. After noting the special field of the Association, which includes climate, mineral waters, and diseases of the respiratory and circulatory systems, Dr. Bridge said that this Association, by its study and publications, has done incalculable good to a vast number of consumptives who have gone to better climates and recovered. And it is not surprising that a few who cannot possibly be helped by the influences that have done such good to the many may have been led by their hope, untempered by wisdom, to rush off to quicker deaths than awaited them at home. Dr. Bridge related several cases of this kind, and called on the profession at large to be more discriminating in their choice of subjects for climatic treatment.

S. A. FRISK read a paper entitled the climate of Nassau. This will appear in a future issue of *American Medicine*.

**Impressions of California Resorts.**—GUY HINSDALE (Philadelphia). This was a characterization of California health stations, and was founded on the experiences of a recent tour of the Pacific Coast. The surroundings of Mount Shasta, San Francisco, Palo Alto, Monterey, Santa Cruz, and Santa Barbara were depicted, and notes regarding the favorable and unfavorable influences of the various climates were given. The visit was made in June, and contrary to expectation the weather was not uncomfortably warm even in Southern California. During the winter and spring eastern visitors are accustomed to spend several months in the more famous resorts, but midsummer is perfectly agreeable at all points on the coast and is not too hot for comfort inland.

**Influence of Altitude on Heart Disease.**—R. H. BABCOCK (Chicago) has observed two cases of pure and uncomplicated obstruction of the mitral orifice in females who declare they feel better in the mountains of Colorado than at Chicago. One of them is relieved of asthma at an altitude of 10,000 feet, but, as she takes very little exercise at the high elevation and does a great deal of walking in Chicago, there are other factors to be taken into account in discussing the merits of a given case. Dr. Babcock described another case, in a woman who has a mitral narrowing with a patent foramen ovale of congenital origin, whose history is interesting. She could ride horseback in the mountains of California and at Asheville, but at San Francisco she had an acute pulmonary edema, with asthmatic symptoms. Babcock was inclined to think that it required a condition of cardiac overstrain to develop her asthmatic tendency which recurred at the lower levels. All these perplexing conditions were discussed but no satisfactory explanation was afforded. Babcock believes that if a cardiopath will remain inactive until accustomed to the altitude he can visit the mountains and journey to California with immunity from symptoms. Persons with healthy hearts are more likely to overdo and overstrain themselves, and the altitude is frequently blamed when the imprudence of the individual is the real cause of trouble.

**Role of Local Sanatoriums in Preventing the Spread of Tuberculosis.**—DELANCEY ROCHESTER (Buffalo, N. Y.) believes that all cases should be reported and registered; that the health department should send an inspector to determine whether the case is one for home or sanatorium treatment. The patient should be taken care of at the State's expense, if necessary, in a sanatorium, and provision made for disinfection of premises, cremation after death, and other measures as required. Dr. Rochester takes radical ground and feels justified in this in view of the serious nature of the problem.

VINCENT Y. BOWDITCH (Boston) reported on the subsequent histories of 164 cases of tuberculosis treated at the Sharon Sanatorium during the past 11 years. Elaborate tables were shown giving all the details. These showed arrest in 79 and death in 12. The present condition of the remaining 67 cases was given and the present occupation. The results were highly creditable, considering the harsh, changeable climate and proximity to the seacoast.

*Discussion.*—E. O. OTIS said that it is one of the most difficult things to obtain the subsequent histories of these patients. Trudeau, Fisk and Solly have published similar records from their private practice, but by no means as extensive as those presented by Bowditch. Otis expressed the thanks of the society to Dr. Bowditch for the immense amount of labor represented.

**Dispensaries for Tuberculosis, with a Description of the Tuberculosis Department of the Boston Dispensary.**—EDWARD O. OTIS (Boston). The Boston Dispensary has been in existence for over 100 years, but the department for tuberculosis was organized only in 1899. Two hundred and seventy-five cases of tuberculosis were treated last year. Incipient cases are referred to the examiners for the State Consumptive Hospital at Rutland, Mass. More advanced cases, not admissible to the State Hospital, are provided for at home or in the vicinity of Rutland, if possible to send the patients away from home. The district physicians, accompanied by visiting nurses, attend patients too ill to come to the dispensary. If proper food cannot be obtained by the patient arrangements are made with a diet kitchen to supply it. Circulars giving instruction as to the means of prevention are issued. The x-ray is used in the diagnosis of tuberculosis and Dr. Otis stated that it frequently shows a greater extent of disease than is indicated by the physical examination.

*Discussion.*—DELANCEY ROCHESTER (Buffalo) referred to the need of two classes of sanatoriums, one for the advanced and one for the incipient cases, and said that every case of tuberculosis should be committed to such an establishment, both for his own good and that of the public in general. JUDSON DALAND (Philadelphia) said that the practical difficulty is that these cases require a great deal of time and study. He believes that large institutions should establish a separate clinic for tuberculous patients. LEONARD WEBER (New York City) advocated the establishment of hospitals for tuberculosis in large cities, especially for the advanced cases, believing that in that way the dangers of infection will be diminished. ARNOLD C. KLEBS (Chicago) spoke of the limitations of sanatoriums and the wider field of the dispensary. The Visiting Nurses' Association of Chicago has appointed a committee of 40, 16 of whom are physicians, to organize an information bureau, so that medical aid, food, and money and employment may be judiciously provided. When information reaches the bureau of a case of tuberculosis in a private family a visiting nurse will be sent to the home of the patient, or if the case warrants it, the association will endeavor to place the patient at some outdoor work on a farm or elsewhere. F. I. KNIGHT highly commended the work of the Boston Dispensary.

[To be continued.]

## AMERICAN MEDICAL ASSOCIATION.

Fifty-fourth Annual Meeting, Held at New Orleans, La., May 5 to 8, 1903.

[Specially reported for *American Medicine*.]

### Section on Practice of Medicine.

#### FIFTH SESSION (CONCLUDED).

**Hemoglobinuric Fever.**—WALTER SHROPSHIRE'S paper abounded in statistics which appeared to prove that hemoglobinuric fever is due to the malarial parasite. He strongly combated the somewhat prevalent opinion among general practitioners that quinin in large doses or in any dose is an etiologic factor. That the malarial parasite is the cause is impliedly proved by the fact that the disease occurs only in violently malarial localities and among chronic malarial victims. The disease yields to quinin treatment when the drug is given hypodermically or intravenously, and in large doses. Forty grains daily at first and gradually reduced. A chologog, preferably calomel, should precede the quinin. The latter may be accompanied by methylene-blue with advantage. Quinin, even in poisonous doses, never produces this disease in the nonmalarious or mildly malarious cases; therefore it is illogical to claim that this drug causes the disease. A tabulated report of many cases was shown.

*Discussion.*—WM. KRAUSS said blood examination of those suffering from hemoglobinuric fever most frequently shows absence of the malarial parasite, therefore why cinchonize? He does not believe the disease is caused by the malarial parasite, though in many cases this germ may be a predisposing factor. The true condition is one of blood hemolysis. He refuses to give quinin. BARRIER said he formerly gave quinin in these cases, but has ceased to do so. J. B. McELROY said the disease depends on a condition induced by the malarial parasite, though it is not purely malarial. Early in the process the malarial germ is found in the blood, but it later appears to leave the peripheral circulation and remain in the deeper vessels. In some instances the germs appear to perish once the disease is established. Quinin is probably a causative agent from its hemolytic action. It may be given with advantage in the intermittent cases, but not in the continuous. It often appears to aggravate the condition. W. S. THAYER thought the symptoms are not malarial, but the malarial parasite has probably prepared the patient for the disease, and yet appar-

ently about the same condition may arise in other diseases, as in typhoid. It occurs most at a time of year when malaria is dying out and people are cachectic. Theoretically, quinin should do no good, yet it should be given if the malarial germ is found in the blood. WILLIAMS, of Scotland, said he had seen a good deal of hemoglobinuria in South Africa. It appears to have no relation to infection, yet it may be a latent condition resulting from malarial infection. SOUTHERLAND said all formerly treated the disease with quinin, but he ceased this as a routine measure 10 years ago. Cases differ so greatly that we cannot treat all alike. To get all the emunctories at work should be the early aim in treatment. Copious draughts of hot water and purgation should be instituted early. L. A. YARBOROUGH agreed in the main with Southerland. The stomach should be washed out early, and purgation started at once. If there is suppression of urine, get the kidneys to acting at once or the issue will be rapidly fatal.

**Clinical Aspects of Tuberculous Peritonitis.**—JOSEPH EICHBERG said necropsy shows that from 2% to 3% of all cases have had at some time in life a tuberculous peritonitis. Effusion as a symptom depends on the time observation is made. It is often absorbed. Fever is inconstant and may disappear for months. The symptoms of the disease are very variable and no two cases present the same. Fever may be high if ulcers are present. Pain may be present and very erratic. Diarrhea is present only when the intestines are the seat of disease. Constipation may be very marked from adherent intestines. The disease is rare in children under 1 year, but common from 6 to 10 years. It is often overlooked because of the great tendency to spontaneous cure. Most patients recover under medical treatment. He is distinctly opposed to surgical treatment in these cases. E. J. BROWN and WILLIAMS agreed with the essayist that surgical treatment should not be permitted. JAMES TYSON said his experience had been that to treat medically is to temporize. Surgical treatment promises most.

**Tuberculosis in the Negro.**—SEALE HARRIS said tuberculosis was unknown among the native Africans until carried to them by the slave traders. It was a rare disease among the slaves of the South. At the present time it is proportionately three times as common among the southern negroes as among the whites. The habits, environments, and his fondness for unhygienic urban life have markedly contributed to this condition. Formerly the average chest capacity in the negro equaled that of the white. At present it is considerably less. The almost universal prevalence of venereal diseases among the negroes makes their tissues less resistant to tubercle invasion. All forms of tuberculosis except lupus are very prevalent among the negroes. Tuberculosis combined with syphilis seriously threatens the race. Eminent authorities are quoted. The remedy lies in education, particularly physical and hygienic; isolation and sanatoriums.

*Discussion.*—A. D. SMYTHE said in his country there were 5,000 whites and 50,000 blacks. The free open country life, with regular hours and good food, saved the negro in slavery days. Today the whole condition is reversed. Tuberculosis and syphilis, natural results of idleness, urban life in the slums, drunkenness, are decimating the race.

**Should the Tuberculous Patient Know the Truth Regarding His Condition.**—C. P. AMBLER held that the patient should be told, not only that he may cooperate intelligently with the physician, but also for the safety of others. Physicians have wrongly educated the public to believe tuberculosis is always fatal. Many patients go to the health resorts not knowing they are tuberculous. This should never be permitted, much less connived at by their physicians. Patients sooner or later learn their true condition, and it is far better to be frank and honest with them at the beginning and tell them the truth.

*Discussion.*—WM. KRAUSS thought it not always necessary to tell him the whole truth, but that his lungs are in a dangerous condition, and thus prepare him for the truth. THEO. POTTER said there is nothing to discuss—patients should be told. Improved methods of early diagnosis, and the present plan of treatment are taking away many of the terrors of tuberculosis if seen in time.

### Section on Surgery and Anatomy.

#### FIFTH SESSION.

At the opening of the session the Nominating Committee was called upon to report, and suggested the names of Charles A. Powers, of Denver, for chairman; E. Wyllis Andrews, of Chicago, for secretary; and William J. Mayo, of Rochester, Minn., as representative of the Surgical Section in the House of Delegates. The report of the committee was unanimously adopted.

**Necessity for More Care in the Treatment of Skull Fractures.**—W. H. EARLES (Milwaukee). Fractures of the skull are not always recognized as such until too late. When not properly treated at or about the time of fracture, they frequently result in death, and, if not in death, in serious remote consequences. When properly treated they usually terminate satisfactorily. With ordinary care and cleanliness, fractures of the skull may be successfully treated by the average surgeon, and under ordinary conditions. The duty of every surgeon

treating such fractures is to know that he has done all possible for his patient.

**Discussion.**—SHERRILL (Louisville) believes that almost all cases of fracture of the skull should be operated upon. In all doubtful scalp injuries we should incise and investigate to see whether there is a compressed fracture. WAGNER (Chicago) reported the case of a boy who fell three stories from a window sustaining severe injury to the skull. For three hours after the injury the boy was practically pulseless. A depressed fracture was elevated, a good recovery resulting. DAVIS (Omaha) said no matter how much or how little is the injury to the bone, the injury to the brain is the all-important factor, and symptoms should guide us when to operate in such cases. Davis cautioned against indiscriminate operation and attempting to do too much in such cases. BROWN (Alabama) reported a case of rupture of the middle meningeal artery from whooping-cough. A clot formed, which caused paralysis of the entire left side of the body. Operation was followed by a good result.

**Epispadias: Report of a Case Treated by a Modification of Cantwell's Operation.**—JAMES B. BULLITT (Louisville). This operation is not as well known as it deserves to be. It consists in separation of the two cavernous bodies back to the symphysis pubis and transplantation of the urethra to the underside of the penis. The urethra can usually be separated out as a tube and drawn forward far enough to suture to the glands. In Bullitt's case, a boy, 7 years old, was operated upon. It was impossible to get sufficient length of the urethra to suture to the glands, and Bullitt resorted to a modification suggested by Van Hook of turning in a flap from the preputial hood to make a tube to which the urethral tube is sutured. The boy has occasional dribbling of urine by day, but no incontinence except by night. There is still a small fistulous opening from which a few drops of urine escape.

**Discussion.**—PARHAM (New Orleans). The older methods of treating epispadias are very frequently unsuccessful, and Parham believes this method is much the simplest and the best method thus far devised. It may be unnecessary to separate the corpora cavernosa, and it is never difficult. The modification which Bullitt credited to him he has never found opportunity to use personally, and he was much pleased to know of its successful use by others. MARTIN (New Orleans) suggested the control of dribbling in Bullitt's case by the injection of paraffin. FENNER (New Orleans) finds the chief difficulty of the operation in dissecting out sufficient of the urethral tube, though it has great distensibility. It is important to use absorbable sutures in these cases. In his case a stitch abscess resulted about a silk suture which he used. He believes it is better to postpone operation in these cases until the patient is 10 years old, for then he can give great assistance by voluntary control of the bladder. A perineal opening is advisable to drain the bladder until healing has taken place. BULLITT, in closing, expressed the belief that had he used perineal drainage, as suggested by Fenner, the fistulous opening would have been avoided in his case. He finds it difficult to dissect the mucous membrane of the urethra away from the glands, and Van Hook's method is of aid when this is difficult. He emphasized the importance of separating the corpora cavernosa far back.

[To be continued.]

## Section on Obstetrics and Diseases of Women

THIRD SESSION.

**Fixation of the Prolapsed Kidney.**—A. H. GOELET (New York) said there are many methods of fixation, many inefficient. The technic submitted has been uniformly successful. External support is ineffectual. It is a substitute for relaxed abdominal walls. In but a small proportion of the cases are the abdominal walls relaxed. An attachment of the organ, with the colon, may pull it down. Belts and corsets may be of use before the descent of the viscus. The indications are always for operation when the organ has descended below the last rib in front. Also, when there is lack of health or of comfort; the draining of the urine is prevented by such descent. The circulation and function of the kidney are impaired. The ovarian vein is pressed upon—a cause of pelvic disease. Nephropexy is justifiable oftentimes in neurasthenic or hysterical patients. The usual preparation should be made for operation. In addition, the correction of digestive disturbance, the securing of the normal function of the liver, careful dieting previous to operation, prevent complications. Important points in the operation are: permanent fixation, separation from the colon, avoidance of mutilation of kidney or patient, the securing of relief of symptoms. The patient in operation should lie upon a pillow, incision should be vertical at the outer side of the rectus muscle down to the aponeurosis; the quadratus should be retracted, the transversalis separated; the fatty capsule is removed, exposing the kidney. Split mostly with scissors. It is generally necessary to deliver the kidney, not always so. Care should be taken to free it entirely from its fatty capsule, the latter being tucked under its lower extremity as a pillow. In inserting the sutures, it is not necessary to deprive the organ of its fibrous capsules. The sutures do not penetrate the parenchyma. The fixation is firmer when the capsule is not stripped back. The suture material used is silk-

wormgut. The sutures are brought through the abdominal wall at the upper angle of the wound and tied over a roll of gauze. In closing the wound, the fascia is united by continuous catgut, the skin by subcuticular suture. A strip of gauze is introduced at the lower angle of the wound to provide drainage and to help support the kidney. The drainage is removed in 48 hours. Eighteen causes of failure were recited, some of them being delay in operating; impaired digestion; ptosis of other organs; failure to prepare the patient; failure to remove fatty capsule; improper insertion of sutures; failure to immobilize; too early removal of sutures; delay in removal of gauze; excessive vomiting or coughing; too early activity of the patient; corset worn too early; attachment of organ too low down. The author has done 159 operations on 126 patients without death or failure. This indicates that the risk of operation is entirely warranted.

**Discussion.**—WAGNER (Chicago) stated that he had used upon the kidney when he could not rely upon adhesions the guy rope suture. The idea of drainage presented corresponds to the plan of Senn, that of causing adhesions. It may be advisable to leave the gauze for five or six days in order to invite adhesions. DUNNING (Indianapolis) stated that he was one of the early ones to begin experiments in this operation. He has given up getting fixation without opening the fibrous capsule. He believes that if Dr. Goelet should leave out the gauze he would have some failures. The advantage of failing to open the fibrous capsule is not seen. By the incision described the kidney still remains below its normal position. This is thought unimportant. It is believed that opening the capsule relieves pain and aids adhesion. Failure is often due to bad after-treatment. RICKETTS (Cincinnati) commended the use of silk-wormgut. He believes in lifting the kidney higher up. It may be a mistake not to split the capsule; it may be a prophylactic for Bright's disease. He does not think it wise to split the capsule of a healthy kidney. CLARK (Philadelphia) raised the two questions: What is a movable kidney, and what is the best method of attaching it? In celiotomies he makes it a habit to measure the range of kidney mobility. He has found that of the right kidney to be 2.5 cm. to 3 cm., that of the left 0.75 cm. Of the methods of fixing the kidney he has drifted to that of splitting the capsule, suturing much as Dr. Goelet. BONIFIELD (Cincinnati) remarked that all movable kidneys do not require operation, just as many hernias do not demand operative interference. The mobility of the kidney is largely dependent upon the general condition of the patient, the amount of fat, etc. He urged the general treatment of the health. CRAIG (Boston) asserted that he had seen cases associated with ptosis of other viscera in which the abdominal belt had aggravated the condition. The belt acts as any splint and by long use weakens the muscles. GOELET, in closing, stated that if the gauze were allowed to remain more than 48 hours wound discharge would collect and interfere with union. Stress was laid upon the necessity of freeing the kidney from all attachments. He has left the gauze drain out with good success. He does not consider the operation a serious one. He now never recommends abdominal belts; the condition is finally made worse by their use. He cited a case in which by the use of a belt the kidney had become fixed in a malposition, complicated with pyelonephritis.

[To be continued.]

## Section on Sanitary Science and Hygiene.

THIRD SESSION.

The committee on nominations reported officers elected: President, G. T. Swarts, of Providence, R. I.; secretary, J. S. Fulton, of Baltimore; executive committee, S. G. Egbert, of Philadelphia; delegate to the House of Delegates, H. M. Bracken, of Minneapolis.

**Tent Life in the Treatment of Pulmonary Tuberculosis.**—R. W. CRAIG (Phoenix, Ariz.) stated that in 1900 14% of the deaths in the United States were due to tuberculosis in one form or another; 65% get well after infection by the tubercle bacillus, as evidenced in the signs of former lesions found at autopsies. The out-door treatment of the disease is based upon this idea and the cure of the disease depends primarily upon the resistance of the patient to the disease. There are two forms in which the disease may terminate in cure; either in caseation followed by calcification or by calcification. The rational treatment of tuberculosis should be based upon the idea of increasing the resistance of the tissues to the invasion. The value of tuberculin is doubtful and creosote, guaiacol and such drugs as interfere with digestion do more harm than good. Most cases recover with good food, air and personal hygiene. Early diagnosis of the disease is important and often difficult before the appearance of the bacillus in the sputum. General malaise, loss of appetite, afternoon rise in the rate of the pulse and slight afternoon rise in temperature are pathognomonic symptoms. Cure depends upon early diagnosis before the secondary infection by pyogenic bacteria. The altitude of a region is not as important as the relative humidity of the atmosphere, the presence of sunshine, moderate exercise and good food with the absence of dust. In Arizona there are less than fifteen rainy days during the entire year. A dry climate is the best for the tuberculous patient. The temperature is not as important as the relative humidity of the atmosphere.

The sensibility to heat in Arizona is much less in Arizona than in Chicago. The mean temperature is 77° F. Altitude has no influence of itself and he considers that a high altitude is contraindicated for those patients in the advanced stages of the disease. Effusion into the pleuras in these cases is nature's method of immobilizing the lung. The ribs should be immobilized. It is the duty of the physician to instruct patients in personal hygiene previous to sending them West, and he should inform the patient of the fact that he or she has the disease and the dangers of spreading the disease. Physicians make a mistake in telling patients to take violent exercise. Any overexertion causes a rise in the temperature of the patient with a return of the cough. Tachycardia is a contraindication to exercise. It is impossible to obtain perfect ventilation in a room and the ideal sleeping apartments for the tuberculous patient is the tent house. It should be free from drafts. At Phoenix, Arizona, they are built on the pavilion plan with sides of wood for the lower half and canvas curtains for the upper half. The wooden floor is raised at least two feet from the ground. The canvas sides can be rolled up and the house converted into an open pavilion. There are two or three rooms in each house. In addition to the tent house they have tent yards which are enclosed in canvas but open to the sun. Patients can thus get the benefit of the sun by reclining in these yards, with no danger from drafts. The results from the treatment have been excellent. The results are increased appetite with an increase in metabolism, and subsidence of all cough, anorexia and malaise.

*Discussion.*—J. L. McCONNELL (New Mexico) said the value of tent life cannot be overestimated. Immobilization of the ribs is very important. The octagonal tent is the best as it lessens the danger of the wind entering at the corners. The boarding on the sides should not be flush with the flooring, but an intervening space of about one foot should exist, and this space closed by canvas which can be raised after the patient is in bed. An umbrella-like opening in the roof of the tent which can be opened after the patient retires gives good ventilation with no drafts. No medication is necessary. J. N. HURTY (Indianapolis) considers, as a sanitarian, that the inhabitants of tent houses should be compelled to observe certain sanitary regulations. The majority of the tuberculosis of mankind is caused by bad ventilation, and the masses should be educated as to the importance of good ventilation. The custom of closing the sleeping-room airtight is an abominable custom, and because a child has temperature is no reason for keeping it in a closely confined room. On balmy days the place for every one, whether ill or not, is in the sunshine. The masses can be reached through the public schools. Indianapolis has sent out lecturers to the various schools to lecture upon the value of good ventilation. Economy in building a schoolhouse is an evil when it is accomplished at the expense of good ventilation. If there were proper ventilation in all of the schools and workshops tuberculosis would not be so common. JAMES L. WATT (New York City) says that in the arctic regions the Indian has no sunlight during winter and accordingly at the end of winter he is run down, emaciated, and anemic. There is a large number of tuberculous patients among these people. Physicians, in sending patients to antituberculous regions, should tell them what to do and how to live. SWARTS (Providence) said that a great number of tent-house patients take up farming as an industry and they are well able to perform the necessary manual labor. CRAIG, in closing, stated that a patient with a temperature above normal should not exercise at all. If kept in bed in the recumbent position the temperature will decline to normal in one week. They can eat as much as they choose, however. The water around Phoenix contains a large amount of lime salts and patients drink considerable of it. In nearly all of his autopsies there were calcareous nodules and he makes the hypothesis that the water has some influence on the formation of the calcareous nodules.

[To be continued.]

### Section on Nervous and Mental Diseases.

#### THIRD SESSION.

**Atrophy of Hand Muscles with Localized Sensory Disturbances: Possible Early Syringomyelia.**—D. I. WOLFSTEIN (Cincinnati). The patient was an unmarried woman, aged 27, who came under his observation on February 27, 1903, complaining of a localized wasting of the muscles of the right thumb. Her occupation was that of a laundress and general house-servant. There was no history of traumatism, and her family history was negative. She stated that she had suffered from pain in her right arm since her twelfth year; this pain was never severe in character, and was always more noticeable after heavy muscular effort. The arm had seemed weaker at times than its fellow, but it had not interfered with her work. There was no muscular twitching, and subjective sensory disturbances were never observed. At no time did she complain of any numbness, tingling, or coldness. There were occasional cramps in the fingers of the affected hand. There was a narrow area of sensory change beginning at the internal condyle and extending in a straight line not over one half inch at any point to the pisiform bone. In the upper third of this area there was thermoanesthesia, and other objective sensory disturbances.

These did not exactly correspond to the dissociation type of syringomyelia. Wolfstein said he was inclined to believe that the case belonged to the type of uniradicular palsies described by Buzzard. The symptoms pointed to involvement of the root of the first dorsal nerve, evidently in such a way as to exclude the sympathetic fibers for the pupil.

*Discussion.*—H. T. PATRICK (Chicago) said he did not think any positive conclusions could be drawn from the symptoms in the case reported by Wolfstein. They suggested, however, the not uncommon type of atrophy of the hand muscles resulting from overwork and over-muscular strain. It was seen most frequently in slender, poorly-nourished seamstresses, and in girls working in book-binderies, as well as in other lines where a certain group of muscles were overtaxed. WHARTON SINKLER (Philadelphia) said he was inclined to accept Patrick's explanation of the symptoms. A. E. STERNE (Indianapolis) expressed a similar view. F. W. LANGDON (Cincinnati), who had seen the patient with Wolfstein, said that while at first glance he had thought the case was one of early syringomyelia, the subsequent symptoms had practically excluded that affection. He did not agree with those who had attributed the symptoms to the patient's occupation. It was hardly possible to conceive of an occupation atrophy that would merely affect one or two muscles. The sensory disturbances were also peculiar. WOLFSTEIN, in closing, said he thought an occupation-neurosis could be absolutely excluded.

**Ten Cases of Chronic Morphinin and Results of Treatment.**—These were reported by A. J. PRESSEY (Cleveland), and were all very aggravated cases. Each of the cases had been cured more than three years. The writer stated that neither the length of time the drug had been used, the quantity used daily, nor the method of administration seemed to be a bar to permanent recovery.

**The Nervous Phenomena Associated with Movable Kidney.**—WHARTON SINKLER (Philadelphia) stated that the frequency of movable kidney was a point on which there had been wide divergence of opinion. All authorities agreed, however, that it was much more common in women than in men, and they also agreed that it most frequently occurred between the ages of 25 and 40 years, and was rarely met in girls before the time of puberty. They also agreed that it was most common in women who had been pregnant. Some writers stated that this condition of the kidney was met in 25% of women who were examined for pelvic trouble, while others regarded the condition as comparatively rare. The symptoms of multiple kidney were for the most part reflex in character, but there were also those which were local, or due to mechanic action. The principal symptoms connected with displaced kidney were pain and those associated with dyspeptic and neurosthenic disorders. Intestinal disorders were also common. Neurasthenia was probably the most constant nervous affection in a patient with displaced kidney. The treatment of movable kidney was palliative and radical. In a certain proportion of cases the application of abdominal bands with properly adjusted pads sometimes afforded relief, but in the majority of instances the use of any apparatus was entirely unsatisfactory. Many cases in which the amount of displacement was moderate in degree were benefited by such a plan of treatment. As long as the patient was on her back, the kidney remained in a normal position. When the rest treatment had been faithfully tried without benefit an operation should be resorted to.

**A Consideration of the Neuroses of Status Lymphaticus.**—A. P. OELMACHER (Gallipolis, Ohio) described the morbid anatomic features of the condition and stated that a persistent and hypertrophied thymus gland was its most prominent anomaly. He emphasized the relationship between the status lymphaticus and rickets and described certain neuroses with which the lymphatic state had been associated.

[To be continued.]

### Section on Ophthalmology.

#### FOURTH SESSION (CONTINUED).

*Discussion.*—FULTON (St. Paul) referred to the epidemic in St. Paul in which the eye-complications were of a similar character to those reported by Dr. Baker, though perhaps not so acute. He thought it quite possible that it was the same eruption as that occurring on the skin. CONNOR (Detroit) referred to the evil results that had followed the attempts to stamp out the disease by methods of disinfecting and ordinary cleanliness without vaccination; a great trouble was that so many people of more than ordinary intelligence could not be made to see that they were not capable of judging concerning matters about which they had never studied. He thought that facts such as those brought out by the paper of Dr. Baker were great aids in making the people understand the necessity for vaccination. MANN (Texarkana) had had six cases of corneal ulcer resulting from smallpox, in two of the cases the eyes being lost; treatment had no effect. DONOVAN (Butte) said that in an epidemic a few years ago the subject of whether or not the eye complications were the initial lesion was considered, and in some cases it was decided that the eruption appeared on the eye at the same time as on the skin. MILLER (Los Angeles) thought the paper of Dr. Baker presenting such interesting statistics would greatly aid in enabling physicians to bring the laity to a realization of the horrors of smallpox and the value of

vaccination. MORROW (Canton) referred to a case occurring in his practice where the corneal complication was undoubtedly the inoculation lesion; the patient had slept two weeks before with a cousin supposed to have chickenpox but who had smallpox; seven days before the eruption he had the corneal lesion, showing itself first as a small distinct white spot. THOMPSON (Indianapolis) had seen a number of eye complications in their recent epidemic; in the confluent form he had 10 cases of corneal ulcer and lost 4. GREENWOOD (Los Angeles) thought it reasonable to expect that Councilman's discovery would lead to its treatment by a serum and that it would be controlled as diphtheric conjunctivitis had been. HILSHER (Spokane) had had cases in which there appeared a conjunctivitis before the eruption came on resembling a phlyctenular conjunctivitis. WEEKS (New York) thought the determination of the percentage of eye affections occurring in smallpox was of great interest. It was also of interest to know that sometimes the eye was affected primarily, as he had supposed that in all cases the eye affection was a secondary one, due to the entrance of substances from the lids and brows, together with an abrasion of the corneal epithelium. He thought the use of oily substances would help prevent the introduction of infection into the eyes.

**Skin Grafting on the Eyelids.**—OSCAR DODD (Chicago) referred to the surgical principles involved and the conditions requiring the operation—as cicatrices, tumors, etc. He considered the objects to be obtained and the kind of grafts best suited to obtain good results. The advantages of the pedicle graft were the source of nourishment afforded and the firmness, but they were too heavy for the upper lid. The Wolfe grafts were uncertain in results, due to shrinking. He concluded that for the upper lid Thiersch grafts should always be used. That where there is dense cicatricial tissue the pedicle graft is most satisfactory. Should pedicle grafts not be available in such instances then the Thiersch graft could be used.

**Entropion and the Operations Employed for Its Relief.**—JOHN O. McREYNOLDS (Dallas, Texas) discussed the nature of entropion, its causation and pathology, and gave a brief review of the various operations employed, with a modification of the principal ones.

**Discussion.**—WILDER (Chicago) concurred with Dodd as to his conclusions—that when one could get a pedicle graft there was better nourishment—and when there was a contracting scar the Thiersch grafts would shrink. As in the operation for entropion, there was no one operation that would meet all cases, a combination must be made. HAWLEY (Chicago) preferred the use of the Thiersch graft whenever possible. TODD (Minneapolis) referred to the importance of removing the muscular tissue from the under as well as the upper surface of the tarsal cartilage. He referred to the instrument introduced some time ago by Wilder for removing grafts from behind the ear or the palm of the hand. For controlling the hemorrhage he now used adrenalin with gratifying results. MILLER (Los Angeles) had also used adrenalin, but thought there was danger of secondary hemorrhage following its use. He sometimes had an assistant compress the temporal artery for this purpose.

**Traumatic Lesions of the Ocular Adnexa, with Report of a Case of Contused Wound of the Eyebrow Resulting in Complete Monocular Blindness Unaccompanied by Ophthalmic Changes.**—ELLET O. SISSON (Keokuk, Iowa) illustrated a number of cases of traumatic lesions of the eyebrows, orbital walls and soft parts. Wounds of the ciliary region were frequent. He considered the results of injury to the supraorbital nerves. Direct fracture of the superior wall of the orbit was liable to involve the optic nerve. One case was a severe cut over the eyebrow followed by total loss of vision, but within one month vision returned until the patient could see large objects about the room. There had been indirect fracture of the optical canal, resulting in injury to the optic nerve, followed by retrobulbar neuritis. Another case illustrated the result of injury to the soft parts, and was rare in that there was either rupture of an ocular muscle, detachment of its tendon from its insertion into the sclera or an injury to a motor nerve, complicated with an injury to the terminal branches of the superior maxillary nerve with loss of sensation of the parts supplied. The writer referred to the necessity for a guarded prognosis in all cases; the value of asepsis and antisepsis in the treatment of all wounds located in this region.

**Report of a Case of Complete Absence of Both Eyeballs at Birth.**—LAWRENCE R. RYAN (Galesburg, Ill.) made report of a very unusual and remarkable case. The parents were apparently healthy, the father aged 50 and mother 35, and first cousins. He considered that consanguinity might be an important factor in the causation. Aside from deformities the child was normal. The brain was unusually well developed, and up to the time of death, which occurred at 3 years, showed the ordinary progression of childhood.

**Discussion.**—WOOD (Chicago) thought that there was really no such thing as true anophthalmos; the term was not a proper one, because if the case is thoroughly worked out some trace of the eyeball is found. BALL (St. Louis) had reported a case occurring in a child that lived 6 months; lacrimal glands were large and secretion existed. The whole subject had been worked out by Von Hippel, who had collected data in something like 80 or 90 cases. CLAIBORNE (New York) had reported a case in New London two years ago of total anophthalmos. He thought Dr. Wood correct about the wrong use of the word

"anophthalmos," but considered that we must have some term to express the condition. AYERS (Cincinnati) had seen a few years ago a case of so-called total anophthalmos, in the line between the lids there being nothing visible but smooth mucous membrane, as though an enucleation had been done.

**Exhibition of New Instruments.**—W. C. POSEY exhibited an apparatus devised for convenience in carrying bottles of collyria and for preparing compresses of heat and cold. W. F. SUKER exhibited an instrument to facilitate the demonstration of the fundus of the eye to students, so that three students at one time could observe the fundus. TODD (Minneapolis) exhibited a tendon tucker, an improvement over the one presented by him last year.

[To be continued.]

## CONFERENCE OF STATE BOARDS OF HEALTH AND THE SURGEON-GENERAL OF PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE.

First Annual Meeting, Held in Washington, June 3, 1903.

The first annual conference of the State and national public health officers, for which a call was recently issued by Surgeon-General Wyman, in accordance with the provisions of an act of Congress approved July 1, 1902, met June 3. The boards of health of 21 States were represented.

The conference was presided over by General Wyman, and after the meeting was called to order Assistant Secretary of the Treasury Armstrong, on behalf of the government, welcomed the delegates, and assured them that everything would be done to make their stay as pleasant and profitable as possible. He said that in the great work of improving the health conditions of the country cooperation between the States and between the States and nation was the secret of success, and he promised in the name of the national government to do everything to further this end.

Surgeon-General Wyman, in his opening address, outlined the purposes of the conference and what it is hoped it will accomplish. He said the great end in view was closer association and union of effort between State and national health authorities. He then briefly described the system and workings of the United States Public Health and Marine-Hospital Service and suggested a plan of organization by which the work of the national and State health administrations might be coordinated and made more effective.

Dr. Foster, of California, gave a description of quarantine operations in that State, particularly in relation to the plague danger in San Francisco. He said that with the vigorous cleaning out of Chinatown the fear of another attack of this disease was rapidly disappearing. He attributed the success achieved to the hearty cooperation existing between the city, State, and national health officers in endeavoring to stamp out the infection. Dr. Foster was followed in interesting talks by Drs. Townsend, Porter, Egan, Conniff, Bailey, Souchon, Young, Fulton, Baker, and Woodward.

At the suggestion of Dr. J. Y. Porter, of Florida, a telegram was addressed to the Florida Legislature expressing the hope of the conference that the act now pending before that body providing for the collection of vital statistics would receive favorable action.

At the afternoon session the discussion of local health and quarantine conditions was continued, each representative explaining the sanitary laws and the method of carrying them out in his particular State, addresses being made by Drs. Westbrook, Hunter, McAlester, Probst, Lee, Smith, Swarts, Simons, Tabor, and Cooper.

The conference adopted the following resolutions:

WHEREAS, The Conference of the State Boards of Health of the United States with the Public Health and Marine-Hospital Service, having confidence in the earnest efforts and ability of the Governor and State Board of Health of the State of California, acting in harmony with the Bureau of Public Health and Marine-Hospital Service, to thoroughly eradicate bubonic plague heretofore existing in the city of San Francisco, do

*Resolve*, That in the judgment of this Conference, so long as the present effective work is continued, there is no need for quarantine restrictions of travel or traffic to or from that State.

*Resolved*, That the methods of cooperation between national and State health authorities suggested by the presiding officer meets the approval of the Conference.

A committee was also appointed to draft a resolution expressing regret at the death of Dr. Mathew Gardner, late president of the State Board of Health.

The various States were represented by the following delegates: California, Dr. N. K. Foster; Connecticut, Dr. J. H. Townsend; Delaware, Dr. E. W. Cooper and Dr. Alexander Lowber; Florida, Dr. J. Y. Porter; Illinois, Dr. J. A. Egan; Iowa, Dr. R. E. Conniff; Kentucky, Dr. William Bailey; Louisiana, Dr. Edmond Souchon; Maine, Dr. A. G. Young; Maryland, Dr. J. S. Fulton; Michigan, Dr. H. B. Baker; Minnesota, Dr. F. F. Westbrook; Mississippi, Dr. J. F. Hunter; Missouri, Dr. A. W. McAlester; Ohio, Dr. C. O. Probst; Oregon, Dr. Andrew C. Smith; Pennsylvania, Dr. Benjamin Lee; Rhode Island, Dr. G. T. Swarts; South Carolina, Dr. T. Grange Simons; Texas, Dr. George R. Tabor; Utah, Dr. T. B. Beatty; West Virginia, Dr. Samuel F. Myers; District of Columbia, Dr. William C. Woodward.

CLINICAL NOTES AND CORRESPONDENCE

[Communications are invited for this Department. The Editor is not responsible for the views advanced by any contributor.]

NEW INSTRUMENT FOR PERINEAL PROSTATECTOMY.

BY  
HUGH H. YOUNG, M.D.,  
of Baltimore, Md.

Head of Department of Genitourinary Surgery, Johns Hopkins Hospital Dispensary.

In a more extensive article which will appear in the *Journal of the American Medical Association*, I have described at length methods for "conservative perineal prostatectomy." I wish here to make a preliminary publication of the instruments which I have devised for this purpose. The first is a "double prostatic tractor," and is shown in Figs. 1, 2, and 3. This instrument was devised to replace Syms' rubber intravesical balloon which is introduced through a perineal urethrotomy wound, inflated and then used to draw the prostate toward the perineum, where it can be reached by the enucleating finger.

The instrument here pictured is introduced closed (Fig. 1) into the bladder through an opening in the membranous urethra; it is then opened by rotating the external handles, as shown in Fig. 2. It is then ready for whatever traction upon its shaft may be necessary to draw the prostate into the perineal wound. The instrument is very strong, and if sufficient traction is used the prostate may be drawn by means of it almost to the cutaneous surface of the wound, thus furnish-

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

ing opportunity to operate so as to avoid injuring the ejaculatory ducts and the prostatic urethra.

After removal of two lateral lobes, a middle lobe may be

caught and drawn down into one of the lateral cavities by turning one of the blades downward, so as to engage it, making traction and at the same time rotating toward the lateral cavity, through which it is desired to enucleate the median lobe. This can be accomplished without injuring the ejaculatory ducts. An anterior lobe can be removed by a reverse procedure.

The forceps which are shown in Figs. 4 and 5 are used to grasp a lobe which has been partly enucleated. They are made something on the order of obstetric forceps, so as to avoid tearing the lobe, thus greatly facilitating the enucleation of the deeper portion. I have used these instruments in 15 cases and have found them of great assistance. There is no need of a suprapubic incision even when the prostate presents great outgrowth into the bladder.

Fig. 5.

The facility which the tractor furnishes for operating on the prostate in a shallow wound, and the preservation of the ejaculatory ducts and the urethra intact, has transformed the operation of prostatectomy in the hands of the author.

THE EFFECT OF ALTITUDE UPON PNEUMONIA.

BY  
F. GREGORY CONNELL, M.D.,  
of Leadville, Col.

Surgeon to St. Vincent's Hospital, Leadville, Col.; formerly Adjunct Professor of Surgery, College of Physicians and Surgeons, Chicago. (Medical Department, University of Illinois.)

The article in *American Medicine* of April 4, 1903, entitled, "The Influence of Altitude on the Mortality of Pneumonia," by H. W. Hoagland, of Colorado Springs, has led to the following remarks:

Whether altitude *per se* has any influence, either favorable or unfavorable, upon the mortality, or any other phase of that great unsolved problem, pneumonia, is still an open question. Therefore such contributions to the subject as the one referred to are of great interest and of real value. From the article in question we learn that in 709 cases of pneumonia, at an average elevation of 6,580 feet above sea-level, the deathrate was 22.1%. And in 6,116 cases at the level of the sea the percentage of deaths was 26.8. To this I should like to add a small contribution to the statistics of pneumonia at high altitudes, and so aid in an effort at a more rational, or at least a more uniform and comprehensive understanding of the subject.

During the year 1902, in Leadville, Colorado, at an altitude of 10,200 feet, there were treated in St. Vincent's Hospital 12 patients with pneumonia; of these 8 recovered and 4 died. Outside of the hospital 36 cases came under my personal observation, many of them in conjunction with Dr. J. A. Jeannotte, of this city. Of this number 30

patients recovered and 6 did not. From the records of the St. Vincent's Hospital for the 10 years previous 213 cases were collected, with 59 deaths.

## ORIGINAL ARTICLES

ON CYSTS AND OTHER NEOPLASMS OF THE PANCREAS.<sup>1</sup>

BY

ROSWELL PARK, M.D., LL.D.,

of Buffalo, N. Y.

Professor of Surgery, Medical Department, University of Buffalo.

For many centuries, and until comparatively recently, the profession were in absolute ignorance of the nature and function of the pancreas. To be sure Wirsung had described its principal duct in 1642, after which discovery it came to be regarded as an unimportant internal gland with some sort of a secretion. The first epoch in its modern history was marked by the experimental researches of Claude Bernard during the earlier decades of the last century. Another occurred many years later when Langerhans described the peculiar structures or portions of the gland which now bear his name. When Fitz described for us, in this country at least, the acute lesions of this "internal spittle gland," as the Germans call it, he created the third epoch, and the fourth began when Gussenbauer first, in 1882, showed how it might be surgically attacked.

The amount of study of the pancreas and the worth of recent literature concerning it may, perhaps, best be gathered by comparing the brief article in Ziemssen with the long monographs of Oser, Robson and Moynihan, Körte and Truhart. The 1,400 different titles given in Oser's bibliography, in the recent American edition of Nothnagel's System, will serve to show the richness of our present library facilities, while the difficulties with which we still make diagnoses of pancreatic lesions will indicate the fact that many of them have been written to, as yet, little purpose.

The materials for an essay on cysts and other neoplasms of the pancreas have been nearly exhausted, and until more experience has accumulated we will have simply to thresh over what has already been placed before us. Our knowledge is much less complete than it would be were not these lesions rare in animals and seldom met at autopsy. At present the existence of a suspicious tumor in the upper abdomen would lead to an operation in almost every case, when, if it were not operated, an autopsy would be later permitted. And so, while the patient is benefited by the operation, the surgeon has only the somewhat meager opportunities of seeing the tumor, in its fresh state to be sure, but through a very limited opening. The surgeon who finds a cyst which he considers has its origin in a pancreatic lesion will deem it for his patient's interest to so deal with it as to cure it, but not to make an autopsy *in vivo*; and so therapeutic considerations become paramount and pathological inquisitiveness must be suppressed.

I gather from a recent paper by Ricketts that in 1730 Behn tried to cure a pancreatic cyst by injecting into it a solution of silver nitrate, and that in 1857 Parsons reported a case of pancreatic cyst due to obstruction of the duct. A number of years before this, *i. e.*, in 1789, von Doeveren reported a case of cancer of the pancreas, while sarcoma as such was first recorded by Paulicki.

*Anatomic Considerations.*—Aside from the gross anatomy of the pancreas, it is worth while for the surgeon to remember the anomalies that may possibly be met in this region which he may at any time have to encounter, and which might confuse or confound him. These may include:

1. Complete absence of the pancreas, which has been reported as totally lacking in at least one case.

2. Abnormalities of the ducts, of which either one may be absent, or which may empty independently into the duodenum. The duct of Wirsung may be double, or

there may be even three excretory ducts, as in the chicken and pigeon. In 53 of 105 specimens examined by Schirmer, the duct of Santorini passed from the main duct into the duodenum, opening on a papilla an inch above the common duct. In 19 it did not open into the duodenum at all, while in four cases it formed the only pancreatic duct. (Huntington, "Anatomy of the Human Peritoneum and Abdominal Cavity," page 114.) When the duct of Santorini does open into the duodenum it may take the place of the regular duct as when the latter is obstructed by gallstones.

3. One might possibly meet that form of annular pancreas first described by Ecker, in which the descending portion of the duodenum is surrounded or encircled by a band of pancreatic tissue continuous with the body of the pancreas. This portion may have its own duct. Constriction of the gut may be thus produced at this point with dilation of the part above. At least six cases of this character have been recorded. They remind us of the earlier form of the pancreas, when it was largely concealed within and scattered along the intestinal walls and folds of the mesentery. The pancreas may also be divided into two almost separate parts connected by the duct, or it may have an accessory lobule springing from its head and extending anteriorly along the duodenum.

4. An accessory pancreas may also be met. Ruediger has recently collected 20 such cases, of which five were located in the stomach, two in the duodenum, nine in the jejunum and four in the ileum. Three of these were associated with diverticula. (*Journal of the American Medical Association*, April 18, 1903, page 1059.) These may possibly give rise to intussusception or even to carcinoma. (Nicholls, *Montreal Medical Journal*, 1900, Vol. 29, page 903.) They remind us of the pyloric cecums or appendices met in many of the fishes and so well described by Huntington. Each accessory lobe, if large, may have its own duct.

CYSTS.—Oser has been able to collect 134 cases of cysts of all kinds. It seems wise to adopt Robson and Moynihan's classification of these lesions, because it is "as precise as our present knowledge permits:"

1. Retention.
2. Proliferation.
3. Hemorrhagic.
4. Hydatid.
5. Congenital.
6. Pseudocysts—peripancreatic.

1. *Retention cysts* were described by Virchow, in 1863, as consisting of two varieties—one form including a botryoidal dilation of the duct of Wirsung, the other being due to obstruction of the outlet with expansion of the entire canal into cystic outlines, which may attain the size of an orange, and contain mucoid, bloody or calcareous material. This latter form rarely attains a size great enough to require operation. To these types Klebs added a third, originating in the smaller ducts, possibly even in the alveoli, to which he gave the name "acne pancreatica." These are found usually in groups, the larger being formed by coalescence of smaller cysts. The causes of these retention cysts are:

- |            |  |
|------------|--|
| Intrinsic, | { Impaction of calculi.                |
|            | { Stricture.                           |
| Extrinsic, | { Pressure from without.               |
|            | { Abnormalities of shape or position.  |
|            | { Closure or obstruction by parasites. |

Impaction of calculi includes gallstones occluding the opening of the common duct in the ampulla of Vater (which may cause chronic pancreatitis, as well as cystic expansion) and pancreatic calculi which may be found at the termination of Wirsung's duct or along its course.

So far as stricture is concerned, it may be found anywhere along the duct. It may be due to healing of a duodenal ulcer, since Perry and Shaw have collected four instances of this kind; or it may be produced by a chronic lesion, or by the friction and abrasion of a calculus, or by the repair following a traumatism. In rare

<sup>1</sup> Read before the Congress of American Physicians and Surgeons, Washington, May 12, 1903.

cases both the biliary and pancreatic passages may be distended from a terminal stenosis or pressure. By Tilger and by others the most common causative factor is thought to be some sclerosing process, with or without such retrogressive metamorphosis of epithelium as permits autodigestion of the gland by its own juice with the resulting formation of a cavity. There are certainly enough cases on record to justify this view, and henceforth chronic pancreatitis must be recognized as the commonest cause of retention cysts by occlusion of the duct.

That the mere closure of the duct is insufficient, occasionally if not invariably, was proved by those earlier experimenters who showed that ligation of the duct is quite insufficient to produce more than a trifling distention of its lumen, the pancreatic secretions being absorbed after the intracanalicular pressure attained a certain degree. Mere mechanical occlusion, therefore, is only a minor factor in this cyst production, something beyond this being at fault. Heinricius finds this fault in a diminishing or disturbed absorption of pancreatic juice, due either to some admixture with nonabsorbable and abnormal substances, or to a lack of function on the part of the absorbent vascular system.

Of the extrinsic causes pressure from without may be produced in ways rather too numerous to recount, including tumors variously placed or originating, calculi, etc.

Abnormalities include relaxation of the pancreatic supports, permitting ptosis or dislocation of a part or the whole of the gland, displacement by adhesions or growth of tumors, cicatricial retractions, and those congenital anomalies to which attention has already been drawn. Occasional instances of these retention cysts are seen during autopsies. To certain of them Virchow gave the name of "pancreatic ranulae." They have also been met unexpectedly during intraabdominal operations not meant for their particular removal. I fear that hereafter few operators will be able to resist the temptation to attack such cysts should they be thus revealed to sight and prove operable; nor, in the light of our present knowledge, is there any good reason why, when thus recognized, their removal or marsupialization should not be undertaken, the patient's condition otherwise justifying it.

So far as the obstruction of the duct by parasites is concerned, it must be remembered that lumbricoid worms have been known to pass from the duodenum into the duct of Wirsung and there cause obstruction, or by their death cause infection. At least two such cases are on record, Durante reporting one of them.

2. *Proliferation Cysts.*—These may sometimes evince malignancy, many of them being so close to the border line between proliferating cystoma and cystic carcinoma that only the subsequent course of events would indicate on which side of this line they belong. They are really neoplasms comparable to certain cysts in other places. They comprise cystadenoma, of which Cumston (*Annals of Surgery*, February, 1903, page 230) has not been able to find reports of more than 15 cases. These are cystic, glandular tumors, multilocular, lined with cylindric epithelium, sometimes forming crypts and sometimes polypoid proliferations. Some of them seem to be independent of the excretory ducts. They occur near the tail rather than near the head of the pancreas, and their contained liquid is often bloodstained. Some writers, believing that these cysts are really of hemorrhagic origin, have called them *apoplectic cysts*, reasoning that hemorrhage is the result of a passive hyperemia which itself is the consequence of a chronic interstitial sclerosing process; nevertheless these are not blood-cysts in the sense that they result from bleeding into a preexisting cavity. Other writers, Tilger especially, believe that the interstitial contraction of the smaller vessels obstructs secretion and that this leads to formation of minute cysts, which slowly enlarge because of the peculiar

character of their contained secretion, their septa being digested away and larger cysts being thus formed, the argument being that the absence of the fibrin digesting ferment shows that it has been used up in this process. But this ferment is not always absent; sometimes it is the fat or the starch digesting ferment which is missing. The truth is that the pancreas is so protected from hemorrhage that most of the conditions which affect it proceed toward it from the stomach or biliary passages, while the conditions which may lead later to a chronic interstitial pancreatitis are numerous; nevertheless traumatism is not without their influence and observations such as are needed to clear up this question have as yet been few in number.

Under the head of *cystic epithelioma* have been described cases of what were probably better called cystic carcinoma as distinguished from primary carcinoma. It should be said that these are essentially cystic formations with cancerous deposits in their walls, perhaps multilocular, usually accompanied by secondary growths in the liver or adjoining tissues. The latter probability would make most of them inoperable.

3. *Hemorrhagic Cysts.*—Here we must distinguish between a hemorrhage into a cyst and a true apoplexy of the gland with resulting cystic degeneration of the clot. Most cysts containing blood belong to the former, *i. e.*, are retention cysts into which blood has escaped in varying quantity. Those to which the term apoplectic can be best applied attain often considerable size, like Gussenbauer's historic first case, are usually solitary and occupy the left end of the pancreas.

4. *Hydatid Cysts.*—These are exceedingly rare. Oser does not mention them. Tricomi says seven cases are on record. Moynihan mentions a case each of Graham, White, and Peters. We may therefore dismiss these with but curt mention. The Briggs case of sarcoma successfully removed proved to be an echinococcus cyst which had undergone sarcomatous degeneration.

5. *Congenital cystic degeneration* resembles more or less that of the other solid viscera. Moynihan mentions but three of these instances. The condition is probably not one which permits of surgical relief, although it might seriously perplex an operator should he come upon it.

6. *Pseudocysts*, as Körte has proposed to call them, constitute a large proportion of cases reported as pancreatic cysts. These are collections of fluid in the lesser omental cavity or bursa, which sustain such intimate relations with the pancreas as well as other viscera—even containing pancreatic elements—that it is impracticable or even impossible to distinguish between them and the true forms above alluded to. They can also be spoken of as peripancreatic cysts; doubtless cysts of the adrenals or even of the kidneys have been thus mistaken.

Of these as a class it must be said that they have very much to do with the pancreas, being the result usually of injury to that viscus. The escape of blood into the lesser cavity of the peritoneum followed by that of pancreatic juice may very easily produce a tumor which, in the living subject, it may be impossible to distinguish from a true cyst. Lloyd has insisted that the fact that a cavity within the abdomen contains pancreatic secretion is no proof that we are dealing with a pancreatic cyst, but merely that it is connected with the pancreas; nor is it enough to feel the pancreas when the examining finger is introduced through an incision, for if the lesser peritoneal cavity is opened through the transverse mesocolon, the finger will enter a large cavity at the back of which the pancreas should normally be found. This cavity varies in capacity in different individuals, as Moynihan has shown. It lies in front of the pancreas, is closely adherent to it with no intervening fat, even in the most obese. If opened through the great omentum, close to the lower border of the stomach, it appears to be arranged in three compartments. Effusion into it must

produce a tumor strikingly resembling a true pancreatic cyst. Lloyd is doubtless right in holding that contusions of the upper abdomen may be followed by development of a tumor in this region due to fluid accumulations in this lesser peritoneal cavity, whose fluid contents may be able rapidly to convert starch into sugar, and that these have too often been regarded as true retention cysts of the pancreas. He holds, furthermore, that a diagnosis of this condition can usually be made by the characteristic shape of the swelling—it occupying rather the umbilical, epigastric or left hypochondriac regions—as well as by the absence of trypsin.

Moynihan has quoted the case of MacPhedran, who found a pseudocyst in a man of 53, at the bottom of which lay the pancreas, enlarged but firm, covered by healthy peritoneum. Five months later it became necessary to open the abdomen again because of another tumor, which this time was found to be a true pancreatic cyst, whose fluid possessed digestive properties. Mistakes have also arisen by dealing with such cases as effusions in the greater or lesser omentum, or in the walls of the stomach or colon, as well as in the case of retroperitoneal collections of fluid, many of these lesions being due to traumatism. Some of these pseudocysts form very rapidly and thus, as it were, "tell on themselves." Others come on very slowly and produce distress in the epigastrium. The more rapid the growth the less likely that the pancreas is primarily at fault. The injury which causes the hemorrhage may also be followed by an adhesive peritonitis, which may limit the accumulation and even close the foramen of Winslow, and so a cyst may form between the stomach and colon. It appears likely that injury has more to do with pseudocysts and morbid processes than with the true pancreatic cysts. It appears that the greater proportion of the former are met in males, who are more exposed to injury, whereas of the latter the majority seem to occur in women.

For reasons already given pancreatic cysts are then met oftenest in men. The youngest case is recorded by Shattuck, the patient being only 13 months old. Richardson operated upon a patient 14 months old, and Sliéda on one of 76 years. The body of the pancreas is most commonly affected. The cysts may be single or multiple, ranging from the smallest up to 20 liters or more. The contained fluid may be of almost any color, but is usually brown, tinted according to the amount of blood admixture. It is alkaline in reaction and of low specific gravity. It always contains albumin, usually cholesterin, and sometimes various epithelial or fatty debris. It may contain either of the pancreatic ferments, proteolytic, fat splitting or starch converting. The latter seems unimportant, the two former of interest, even of importance. Their presence is of real import, their absence of negative value. When enzymes are present in considerable and active amounts the presumption is strong that this fluid comes from the pancreas.

In rare cases the tumor is movable. When the growth is large, reaching into the pelvis, an ovarian tumor may be suspected. In one case of my own in which I wavered as between hydronephrosis and pancreatic cyst the tumor proved to be an ovarian cyst of one side, pushed up from below by another on the opposite side. The cyst wall is commonly quite vascular and there even have occurred changes enough in the surroundings to alter considerably the nature of the original fluid. When lined with original epithelium the granulation process is interfered with and final closure may be exceedingly slow since a secreting membrane does not readily granulate. In a case of my own, final closure did not occur for seven or eight months.

Fistulas resulting from these operations have thus been exceedingly difficult to deal with in many instances. Körte's case discharged for 2½ years, and then suddenly closed spontaneously. Murray has reported a case of

pancreatic fistula which showed a most interesting phenomenon, *i. e.*, the dependence of transudation upon intravascular pressure and its vasomotor regulation through the splanchnics, since the secretion was wonderfully influenced by the patient's emotions. (Vide also von Brackel, *Zeit. f. Chir.*, 49, p. 293.)

The growth of these cysts is most commonly beneath the stomach and above the colon, carrying before them the gastrocolic omentum, which, therefore, must be divided in exposing their anterior surfaces. The cases of this character are best suited for operative attack whether by drainage or enucleation. These occur, therefore, on a lower level, tend to press the pancreas downward and, by dragging, to produce a ptosis of the surrounding organs. The next most common direction of growth is above the stomach, between this and the liver, where adhesions would make any attempt at enucleation most grave. These cysts present on a higher level than the others.

These cysts are usually adherent, even firmly or densely so, to the adjoining structures. When thus fixed it will be best not to attempt to enucleate, but to drain front and rear. The portal vein has often been found deeply buried in the cyst wall; however, adhesions are not always met and enucleation is sometimes easy. (Cartledge has recently reported complete enucleation of a cyst of the former description, whose firmest attachment seems to have been to the tail of the pancreas, *Jour. Am. Gynecology*, January, 1903, p. 16.) The genuine pancreatic cysts are least likely to be adherent and the pseudocysts most so; still, no *a priori* conclusions can be drawn in this regard.

The symptoms are mainly those caused by pressure and are usually absent until this pressure begins to make them prominent, especially pain toward the end of and after a meal, perhaps with vomiting, usually confined to the upper abdomen, radiating to the left side of the back and left costal arch, varying in intensity from indigestion to violent colic. Vomiting is usually proportionate to the pain. The vomitus is often clear and colorless—the so-called pancreatic salivation of some writers. The other symptoms are vague; emaciation is usually rapid and patients "age" quickly. Fat in the stools and glycosuria when noted are most suggestive, though less frequent in cystic than in other pancreatic diseases, because the whole organ is rarely involved. This is true also of the presence of undigested muscle fibers. Sahli's test may be of some service in these cases. This is based on the fact that the presence of the pancreatic secretion in the intestine causes the decomposition of salol in the duodenum into carbolic and salicylic acids, which may be recognized in the urine. When not found there the assumption is that the pancreatic juice is not being discharged as it should be.

These tumors may present above the stomach, below it and between it and the colon, below the colon, or behind them both, as the diagrams given by Oser and Robson and Moynihan graphically indicate. Usually the stomach is pushed up and to the right, the colon downward. To reach it the parietal peritoneum, the two layers forming the great omentum and the layer of the lesser sac have to be perforated. The colon may be pushed downward several inches. When the tumor presents above the stomach, the gastrohepatic omentum must be traversed. The protrusion of a cyst through the foramen of Winslow and into the greater peritoneal cavity has been noted. The splenic vessels have been found both in front of and behind the tumor and the superior mesenteric vessels have been known to cross the tumor surface. These tumors lie usually between the umbilicus and the left costal border, though often they are medianly placed. Finally, they may almost fill the abdomen. The larger they are the more evident their cystic character; the smaller they are the more easily may they be mistaken for solid tumors. Aortic pulsation is often transmitted; the percussion note will

depend, in the location, upon the position of the stomach and colon.

In general, the symptoms and signs depend upon the size of the growth. These may be modified by bursting of a cyst with its sudden collapse, and perhaps refilling, or by hemorrhage into the cyst with a sudden enlargement. It may burst into the peritoneal cavity or into the bowel. In either event this accident may or may not kill. Sudden collapse and pain mean probably a hemorrhage into the cystic cavity.

To puncture such a tumor for diagnostic purposes is to introduce elements of danger which would best be avoided, nor does it give certain knowledge. A tumor of this character which would suggest exploratory puncture is one in which the abdomen should be opened at all events.

Diagnosis has to be made generally from :

1. Local peritonitis with fluid accumulation.
2. Cholecystitis and distended gallbladder.
3. Hydronephrosis and other fluid tumors of the kidney.
4. Ovarian cysts.
5. Hydatid and other cysts of the liver.
6. Adrenal cysts.
7. Mesenteric cysts, including cysts of Müllerian and Wolffian remains in the mesocolon.
8. Omental cysts.
9. Splenic cysts, hydatids, etc.
10. Cysts of the stomach wall, which have, in at least two cases, closely simulated pancreatic cysts.
11. Retroperitoneal lymph and other cysts.
12. The pseudocysts above alluded to.

It does not seem necessary in this place to go into the differential diagnosis of these various lesions.

*Operative Treatment.*—There is no treatment for these patients save that by operation. This must consist of (1) aspiration; (2) drainage or marsupialization; or (3) enucleation or extirpation.

1. Aspiration has nothing now to commend it scarcely even for diagnostic purposes. As Moynihan says, it is "redolent of mediævalism." It has never been successful, since the cysts always refill if simply emptied. There is a theoretic value attaching to the method, which, so far as I know, has not proved real; that is, the possibility of carrying the patient over a crisis of pressure or glycosuria and thus preparing him for radical operation.

2. Choice of location of incision must depend on the point at which the tumor most prominently presents. The old method of Volkmann is essentially that applied to these cases today. The coverings of the cyst must be gently perforated, preferably after some portion of the cyst wall has been sewed to the edges of the incision, but before thus attaching it, manual exploration should be practised in order to determine immediately the matter of its possible enucleation, as well as its anatomic identity and relations. For thick-walled cysts the instruments used in seizing and tapping ovarian cysts may be advantageously used. Stitching should be secure, and is best done perhaps with silk. After thus anchoring a cyst, but not before, it may be freely opened, but the site of the opening should be free from vessels. It is rarely necessary to do this *a deux temps*, the contained fluid being easily kept out of the general peritoneal cavity, unless the cyst wall be extraordinarily thin so that it is inadvertently ruptured.

Posterior drainage will prove a time-saving measure in many of these cases, so far as final recovery is concerned. This is usually made at the left costospinal angle. Among the precautions and preparations for all of these operations *careful cleansing and scrubbing of the patient's back should be included*, so that this posterior opening may be made without delay when it is indicated. I have already reported a case of gunshot wound of the stomach in which posterior drainage was successfully made and in which this precaution was taken

before the operation. (See *Annals of Surgery*, 1902, xxxvi, p. 228.) A stab wound which may be dilated with forceps is sometimes enough for this purpose, but must be enlarged so that the drain, of tube or gauze, may not be too tightly constricted. It can be made most easily with the left hand in the abdomen as a guide, which should also identify the kidney or the pancreas as well as push them aside. While anterior drainage should be made with a glass or rubber tube, or with a gauze wick, the posterior drain must be of flexible material.

When the cyst is small it may be difficult to attach it to the anterior incision. In this case there must be plenty of packing around the principal drain or a purse-string suture may be used to hold the opening firmly around the tube. This would be preferable if it may be employed. Should this be impracticable, the cavity may be simply packed with gauze which is led out of the abdominal wound, in which latter secondary sutures should be introduced.

Some anomalous cases have arisen requiring especial and ingenious treatment which deserve mention. Thus Hogen (*Archiv. f. klin. Chir.*, Vol. lxii) has reported the case of a boy of 13 with a cystic tumor the size of his head, located posteriorly to the stomach, and so firmly surrounded by adhesions that it was impracticable to reach it directly and impossible to bring it near the surface. In this case he opened through both walls of the stomach and emptied the cyst. Then he found it possible to bring its anterior wall into contact with the parietal peritoneum by displacing the stomach. After this he closed both wounds of the stomach. Even then it was necessary to esect a part of the ninth and tenth costal cartilages in order to let the abdominal wall drop down to a lower level. This patient recovered.

Peters (Moynihan) opened a hydatid cyst of the tail of the pancreas by cutting down directly from the loin, incision being parallel to the last rib, as for nephrectomy. The lumbar fascia was opened, the colon pushed forward with its peritoneum, and the cyst thus reached retroperitoneally.

Robson collected 84 cases of pancreatic cyst. Ransohoff in 1901 (*American Medicine*, July 27, 1901) had gathered a total of 159 cases of pancreatic cyst subjected to operation. Of these 17 were of the type of cystadenoma. This relation may be even more frequent than 1-9 as above. These cystadenomas are the most slow-growing of all and the least painful. Of these 159 cases all but 34 were sewed to the abdominal wall and drained, with but five deaths. In 12 cases the operation could not be completed; four of these patients died. In 23 cases total enucleation was made with two deaths. At least 20 other cases have been reported since Ransohoff collected these statistics. Two of Robson's and Moynihan's 84 patients died subsequently of glycosuria and two others had extension of malignant disease.

The matter of fistula following marsupialization is so important that I think it well to allude to it again, as showing what may happen. Murray has reported a pancreatic cyst in a young woman of 19, in whom a fistula at that time had persisted for three years or more, who wore a rubber tube for one year and after that a small silver tube. During the latter part of this time the secretion or discharge was but very slight save when she became excited or nervous, when it greatly increased. Chemical examination showed this to be a simple transudate with specific gravity often as low as 1,003, devoid of elements indicating tryptic proteolysis. (*American Medicine*, July 26, 1902, page 133.) In this connection it may be remarked that Körte had a fistula stay open for 2½ years, and that Gussenbauer has found a specific gravity of pancreatic fluids as high as 1,610.

In general, experience has shown that after operation on pancreatic cysts recovery may be prompt and satisfactory, and pancreatic function be apparently undisturbed. It is also shown that pancreatic fistulas may persist for a long time without apparent detriment, and may be

expected to close with or without treatment after a somewhat indefinite period.

**SOLID TUMORS.**—From the statistics of Remo-Segrè, Biach, Oser, Rohde, Soyka, Hale White, and others, one may study the records of some 53,000 autopsies, in which only 226 cases of apparently primary malignant disease of the pancreas were found. I say apparently primary, because doubt has been expressed about the primary character of even some of these. The proportion of cases would certainly not be over 1–265 autopsies, perhaps not more than 1 in 400 or even 500.

Cancer is by far more common in the head of the organ, which, like the biliary passages, is most open to infection, more than half of the cases appearing here. It may begin in the glandular epithelium or in the cells of the excretory ducts. Sometimes it attains great size. Terrier has extirpated one as large as the patient's head, which weighed 5½ pounds. Several times these tumors have been found the size of a fetal head. The duct of Wirsung is compressed in nearly all instances. Courvoisier found it obliterated in 55 out of 66 cases. The duct may be dilated beyond the cancer. The intimate relations and the size of some of these growths will explain compression and disturbance of the duodenum, or even of the pylorus. By different observers compression has been noted of the entire stomach as well as of the colon, or of the ureters, portal vein, aorta, vena cava, splenic vessels, superior mesenteric vessels, or thoracic duct. By breaking down of these growths perforations in all possible directions may result, including the portal vein, splenic artery, and celiac axis. They are most frequent after the fortieth year.

Secondary deposits occur, perhaps, most often in the liver, but may be found anywhere or even everywhere, since general carcinomatosis has been reported by Oser. Many of the carcinomas are of the scirrhous type; the softer forms are rare. They include the so-called adenocarcinomas; sarcomas are exceedingly rare.

*Symptoms.*—These may be divided under (1) those pertaining to the pancreas itself and its functions; (2) those pertaining to adjoining and related organs; (3) those indicating dissemination of cancer; (4) the tumor itself.

Of course it is impossible to dissociate these in the study of a given case; nevertheless, they may be considered separately as above.

1. Among the earliest, though vague symptoms, are digestive disturbances, failure of appetite, discomfort after eating, perhaps eructation, heartburn, nausea or actual vomiting. Not one of these is particularly significant, nor are all of them together. Anorexia, even to loathing of food, is sometimes present; at other times patients eat voraciously without satisfaction. Loss of appetite is evidence of obstruction rather than of cancer, since in a number of cases in which cholecyst-enterostomy was done for obstruction of the duct by pancreatic cancer the appetite returned. When the pylorus is obstructed by tumors and the stomach becomes dilated, vomiting and other severe digestive disturbances may follow. When the growth has involved the stomach wall blood may be vomited. Curiously, though the stomach is quite free from disease, there is no free hydrochloric acid in the gastric contents. Fatty stools are noticed occasionally, not usually. Voluminous stools, due to fatty and incomplete digestion, are occasionally noted. This is important and common enough to attract attention as well as to call for it. Should this be followed by jaundice and then by glycosuria with epigastric pain and emaciation, a very probable pancreatic cancer may be assumed. Light colored or bloody stools are not infrequent. Pain is a very uncertain feature. When characteristic it radiates around the sides to the back and may be severe. It may simulate the crisis of tabes, but it lasts longer and is often worse at night. It has been spoken of as "celiac neuralgia." It is sometimes paroxysmal, colicky or anginal. When pain is severe there is accompanying tenderness.

2. Jaundice is an earlier or later feature of these cases, usually later. It is, of course, first a pressure-symptom, but later may be due to disease extending outside the pancreatic limits. The usual concomitants are not lacking—clay-colored stools and high-colored urine. Often a distended gallbladder may be felt. Next comes enlargement of the liver, sometimes regular, sometimes by nodes, which can be felt. In some cases a late shrinking, due to atrophy of the true liver tissues, has been noted. Ascites may result from pressure on the portal vein or involvement of the peritoneum. Meteorism, from pressure on the intestine, may go on even to the point of producing fatal acute obstruction. Pressure on the vena cava may cause dropsy of the limbs, or on the ureter a hydronephrosis. Sahli's test may be also resorted to by giving salol and testing the urine for salicylic and carbolic acids. Their presence would be suggestive, but their absence not positively indicative.

3. When the adrenals are secondarily involved there may be bronzing of the skin. Cachexia is more early and pronounced than in cancer of any of the other viscera. Such symptoms as ascites may indicate general peritoneal carcinoma. Chylous ascites has been noted.

4. The tumor can usually be detected after a time, the date depending somewhat on the thickness of the abdominal wall. It often resembles a pyloric tumor but is deeper and more fixed, often conveying a transmitted pulsation from the aorta. A double tumor has been noted more than once, the second being the distended gallbladder.

All observers agree that when pain, jaundice, and tumor are present the disease runs a rapidly active course. When jaundice is absent diagnosis is more difficult. It will be more easy when the characteristic fecal changes mentioned are recognized. It will never, however, be really easy, and may be so difficult that primary cancer of the pancreas can only be surmised, not proved.

The disease rarely runs a course of over a few months, and may terminate within ten weeks. Death may result from marasmus, from hemorrhage or from obstruction.

*Treatment.*—Medicinal treatment must be purely symptomatic, and I shall not consider it here. Surgical treatment, because of the obvious difficulties, can rarely be applied. Billroth twice partially resected some part of the pancreas, removing once a portion of the head with a cancerous pylorus and once the tail with a sarcomatous spleen.

Ruggi, of Bologna, is to be credited with the first successful operation on a primary cancer of the pancreas, in 1890. The tumor was considered to be a retroperitoneal adenosarcoma of either the kidney or pancreas. He operated from the loin by an oblique incision, and exposed a soft, diffuse tumor (later proved to be carcinoma), with adherent small intestine and omentum. These were detached and the tumor, which weighed 23 ounces, removed. Complete recovery ensued. Gade's was the second successful case, in 1895. He extirpated a tumor the size of a child's head from the tail of the pancreas. There were no metastases. Terrier, in 1892, removed a 5½ pound tumor as large as a man's head, but lost his patient. Robson tabulates altogether 13 cases of removal of solid tumors of the pancreas and adds a fourteenth of Malcolm's. To these there should be added Briggs' successful case of sarcoma. Of these 16 patients 8 recovered from the operation, while the other 8 died within a few hours or days afterward. Thus, after all, the outlook for radical surgery in solid tumors of the pancreas is not wholly unpromising.

Unfortunately it is but rarely we shall have to deal with cases of this kind. The prejudices of the internists against early surgical procedures, and the fear of operation which deters so many patients, will long combine to keep these cases out of the surgeon's hands until too late for radical measures and until a time when only pal-

liative procedures are possible. Among these, cholecyst-enterostomy is the only one which appeals to a trained surgical instinct, and then only in selected cases. A study of the few reported instances, some 10 in number, shows that there was temporary improvement in most of them, as in 17 cases of cholecystotomy, still death was not long postponed, although much comfort was reported. Cholecystotomy has so little to commend it as compared with cholecystenterostomy that it should be abandoned save in exceptional instances.

I have grouped all the malignant tumors of the pancreas under the general head of cancer. There is the same unfortunate confusion of terms here as in other respects, owing to international differences of meaning. For example, one author describes a giant-celled carcinoma, another a cystic epithelioma, yet others adenocarcinoma and adenosarcoma. It is most difficult to reduce all of these to a systematic nomenclature, but viewed from a clinical standpoint we may regard these histologic differences as of minor importance.

**Adenoma.**—Nicholls, of Montreal (*Journal of Medical Research*, November, 1902, p. 385), has recently gone carefully over the literature of adenoma of the pancreas, of which he describes a typical case met postmortem. He has been able to find but four other recorded cases which would stand the test, though one of these was doubtful, while several cases described as adenoma were in all probability malignant. There is, of course, a likelihood that certain cysts spoken of as cystadenoma had their beginnings in real adenomas, but the subject is and must long remain much confused. There is no probability that any such growth can be accurately recognized without exploration. Should it be met during an operation the effort may be legitimately made to enucleate or extirpate it.

**TUBERCULOSIS.**—Tuberculosis of the pancreas is generally regarded as exceedingly rare. Kudrewetzky, in 1892, however, challenged this statement. He found 44% of tuberculous children showing pancreatic tuberculosis and 9% of adults. In 18 cases of miliary tuberculosis he found it in six; nevertheless, as a primary lesion it is certainly rare. Cases reported by Mayo and Sandler illustrate how tumors in the region of the pancreas may be due to tuberculous disease. Sandler, for example, opened the abdomen of a thin woman who had a movable tumor above the umbilicus. He found behind the stomach a hard tumor the size of a walnut, which he extirpated. This proved to be a tuberculous lymph-node of the pancreas. The patient recovered. [This case is included among those referred to above of removal of solid tumors of the pancreas.] (*La Tuberculose du Pancréas*, Thèse de Paris, 1899.) Lohéac has shown that pancreatic tuberculosis may assume either the form of gummatous nodules or diffuse interstitial proliferation. He would explain the relative infrequency of tuberculous disease in this location by virtue of the peculiar pancreatic secretion which he thinks to be protective as against this kind of infection.

**SYPHILIS.**—Like tuberculosis, syphilis produces in the pancreas lesions of two kinds, the indurative and the gummatous, which can coexist, the former being much more frequent. The latter has been observed in a six months' fetus. It does not appear that these lesions have ever been diagnosed *intra vitam*. Doubtless they occur with many cases of visceral syphilis, which, being recognized, are subjected to suitable and prolonged treatment. There is no known reason why a gumma of the pancreas should not respond to such treatment as readily as does gumma of the liver. As yet these cases have escaped the recognition and the attack of the surgeon.

**PANCREATIC LITHIASIS.**—Kinnicutt (*American Journal of the Medical Sciences*, December, 1902, page 948) has been able to collect but seven cases, including one of his own, in which a diagnosis of pancreatic lithiasis was made. In Caparelli's case over 100 small calculi were discharged through a pancreatic abscess and fistula,

which finally closed, closure being followed by diabetes. Three of the six died, and in one of them the pancreas was found riddled with abscesses. In Kinnicutt's own case biliary and pancreatic calculi coexisted. He suggests that just as the former result from infection of the biliary passages so do the latter from an infection traveling up the pancreatic duct.

In the absence of pancreatic calculi in the stools there are absolutely no diagnostic symptoms. Subjective symptoms are common to too many lesions of various organs. Pain along the left costal arch is suggestive but not pathognomonic; neither is the occurrence of undigested muscle fiber in the stools, since this may occur in diarrhea. Fatty stools are not often a frequent evidence of pancreatic disease, since in 330 cases collected by Ancelet (*Études sur les Mal. du Pancréas*, Paris, 1864) it was noted only 28 times. When present they may be due to coexistence of jaundice with greatly diminished absorption of fat. The most reliable evidence in this regard pertains to failure in the fat-splitting function. Normally at least three-quarters of the fat contained in the feces should appear in the form of fatty acids and soap, even when jaundice is present, but when pancreatic juice is prevented from entering the intestine this decomposition is greatly interfered with. The presence or absence of jaundice is of small import so far as pancreatic lesions are concerned. Glycosuria is quite suggestive, though met usually only after the disease has well advanced. The discovery of pancreatic calculi in the stools being so rare it will be seen that the evidences of pancreatic lithiasis are always very scanty; nevertheless attacks of colic in the upper abdomen with or without jaundice, with undigested muscle fibers in the stools and evidences of diminished fat-splitting and glycosuria, may properly lead to a tentative diagnosis of this condition, which may be confirmed if fragile concretions destitute of biliary pigment and cholesterin are found in the evacuations.

#### CONCLUSIONS.

I am well aware that this is but a hurried survey of what most interests the surgeon and what he can accomplish by operation upon the pancreas. The result of most careful study and deliberation is to formulate advice in this brief sentence that a well-founded suspicion of a palpable pancreatic lesion, of acute or neoplastic character, justifies an early exploration for its discovery and prospective relief, and that when a careful study of the case still leaves one in honest doubt regarding its nature then the best rule to follow will be to operate.<sup>1</sup>

#### FOURTH OF JULY TETANUS.

BY

H. GIDEON WELLS, M.D.,  
of Chicago.

If history repeats itself we shall soon experience the annual epidemic of tetanus, by which we pay the penalty of a barbarous method of celebrating Independence day. Every year in Chicago from 5 to 30 boys are sacrificed in this way. As tetanus is by no means common in this city it is fair to assume that there is a corresponding deathrate in the country at large, which, if true, means that some hundreds of victims suffer death every year from their ill directed efforts at creating a disturbance. Having been interested in this subject for some time I have endeavored to collect statistics concerning it, both as regards distribution and prophylaxis, by sending circular letters to the boards of health and hospitals of the large cities.

Both in New York and Chicago there is produced

<sup>1</sup>I have not attached hereto a bibliography. Those articles to which I have referred which are not included in Oser's bibliography I have quoted in the text. To this I might perhaps add a reference to a paper of my own on the "Surgery of the Pancreas," published in the *Medical News* of February 15, 1902.

each July an enormous augmentation in the number of deaths from tetanus, sometimes amounting to more than occur in all the rest of the year taken together, and nearly all of these July cases are the result of wounds

1899 there were 17 deaths from this cause. The low mortality in July, 1901, is without explanation, except that during the whole of that year tetanus was much less abundant than in every

TABLE 1.—Mortality from traumatic tetanus in Chicago for 1900-1902. Wherever any of the deaths in any month were due to blank cartridge wounds, the tetanus from causes other than this is shown by dotted lines, the space between the two lines showing the mortality from blank cartridge wounds.

produced by blank cartridges. As can be seen by the following chart, blank cartridge wounds produced during other times of the year are also often followed by tetanus, but because of their infrequency they play no

mortality: "In addition to the usual restrictions upon the carrying of concealed weapons, persons less than 16 years of age cannot carry or have in their possession, even openly, upon any street, avenue, road, alley, park,

for some unknown reason the tetanus bacilli were either less abundant or less virulent this year than usual, and the Fourth of July mortality was therefore reduced along with the general mortality. In New York, also, 1901 was singularly free from tetanus, although the distribution through the year was normal, and Dr. Wm. H. Guilfooy, the Registrar of Records, to whom I am indebted for the accompanying table, says that there is no apparent reason for the low mortality of this year.

In the city of Greater New York the curve is quite similar to that of Chicago, although in proportion to population the number of cases is much smaller. In this record the cases due to blank cartridge wounds have not been separated. Washington, however, does not present a corresponding rise in its figures for July, the total for the ten years being surpassed by September and October. This seems to be explained by the stringent regulations regarding the use of explosives, which I quote from a letter from the health officer, Dr. W. C. Woodward, who kindly furnished the table of tetanus

The relative relation between white and colored populations in the District of Columbia is approximately as two to one. The ratio between the deaths from tetanus in the two races, however, as shown by the table, is nearly as one to two.

school house, building or buildings, playground, enclosure for stock, or railroad tract outside of such fire limits for the District of Columbia without the written consent of the owner or occupant thereof and a special permit from the Major and Superintendent of Police. Dealers in explosives are not allowed to sell any firecrackers more than 3½ inches in length, nor any toy pistols less than 5 inches in length."

Putting together the figures of these three cities it is seen that there is a distinct seasonal curve, so that, disregarding the figures for July, the maximum number of deaths is found occurring during the summer months, the minimum during the winter, so that June alone furnishes nearly as many deaths as December, January, February, and March together.

Excluding Washington, where Fourth of July tetanus does not seem to exist, it is seen that July furnishes 38.7% of the year's mortality from traumatic tetanus. Assuming that in July there are as many deaths from causes other than Fourth of July tetanus as in June, and deducting these, it is found that in New York and Chicago 29.5% of all deaths from traumatic tetanus owe their origin to accidents of celebration. Reports from other cities indicate that conditions are much the same in each, in proportion to the population, although there are a few cities in which it is denied that Fourth of July tetanus occurs at all. In Southern cities occasional cases are seen following the Christmas celebration that to some

July injury that causes tetanus—almost without exception the wound made by a blank cartridge is the starting point. For example, of 27 cases occurring from June 25 to July 14, 1900, all but one were from blank cartridge wounds; the single exception being the similar wound received from a toy cannon. Of the 27 the wound was in the hand (most commonly the left) in 24, there being one each of the foot, eye, and thigh. It is interesting to observe that even at other times of the year deaths are reported from blank cartridge wounds, although such wounds are not common during the remainder of the year. On the other hand, wounds from bullets, occurring frequently in this city at all times of the year, and undoubtedly much more frequent than the blank cartridge wounds, have practically never produced tetanus, at least none were reported during the last three years. Other Fourth of July injuries, such as lacerations and burns from firecrackers, which are very common, seldom produce tetanus, there being but two instances during three years. It is unfortunate that it is impossible to learn the total number of blank cartridge wounds that are produced each year to determine in how large a part tetanus develops, but the 20 or so cases in Chicago must certainly represent a very high percentage, especially when compared with the scarcity of cases from other wounds. Even the dreaded nail wound of the foot must fall far behind.

At first sight it would seem that the frequency with which tetanus follows blank cartridge wounds indicates a contamination of the cartridges with the tetanus bacilli. A large number of wads have been examined by different investigators, always with negative results. In the laboratory of the Health Department of Boston, in 1900, 350 cartridges were examined both by animal and cultural experiments, but tetanus bacilli were never found. LaGarde<sup>1</sup> records an examination of 41 samples of powder from cartridges of varying calibers; 30 samples of powder from 6 different kinds of firecrackers; 24 wads from toy pistol ammunition; 30 samples of cardboard from the different kinds of firecrackers above cited. Tetanus bacilli were not found in any. In 1899<sup>2</sup> I examined bacteriologically about 200 cartridges, representing all the makes on the market. In spite of the employment of various methods the presence of tetanus bacilli could never be demonstrated. In 1903<sup>3</sup> ten wads from each of five makes were again examined, also with negative results. These numerous experi-

ments seem to exclude finally the cartridges themselves as the source of the infecting organisms. There seems, on the other hand, little room to doubt that the reason for the great danger in these wounds lies in the nature of the wound itself, and the circumstances under which it is received. In the first place, it will be observed from the tables that tetanus occurs most frequently at that particular time of the year when tetanus from ordinary causes is most frequent. This prevalence of tetanus in summer, as compared with winter, is to be ascribed to the fact that the street dust is frozen fast in winter, and with it the tetanus bacilli, with which it seems amply provided. By examining six specimens of dirt taken from the streets in different parts of Chicago by inoculation, virulent tetanus bacilli were demonstrated in one. Many observers have found street dirt a prolific source of tetanus bacilli. Now, the small boy who shoots a blank cartridge wad into his hand has generally provided the hand with a liberal coating of dirt before the accident, and this dirt is carried well into the wound. The blank cartridge wad, usually striking the hand with its flat surface, has a remarkable tendency to carry before it a disc of the tough palmar skin, and particularly when this happens we have absolutely ideal conditions for the production of tetanus. There is a wound of some depth, often passing through the palmar fascia which seals it perfectly. At the bottom of the wound is a wad of skin and a wad of cardboard, sandwiched between which is a layer of street dirt. On all sides are bruised and injured tissues, with blood clots, and Strick<sup>4</sup> has shown that  $\frac{1}{10000}$  of the ordinary fatal dose of tetanus bacilli will kill a rabbit when injected into a hematoma. If there are any tetanus bacilli on the surface where the wound was received they would seem to be almost certain to produce tetanus, for they are transferred to the bottom of a wound where there is an anaerobic environment, and every opportunity for growth in tissues so injured that there is little possibility of a successful reaction. Such a wound will not drain itself naturally at all. It is in marked contrast with a bullet wound, which less often carries in the surface epithelium, bleeds more because bruising less, and more often passes through the hand entirely and affords much better drainage. Probably these differences explain the greater danger of the blank cartridge wound.

In view of these facts it is perfectly evident what the treatment should be. The first thing for the doctor to appreciate, and most of these wounds are first seen by the family physician, is that *a blank cartridge wound is a most dangerous injury*. It is no trifling accident that is to be treated in a haphazard way, trusting in nature to accomplish everything. Secondly, it is a wound that *properly treated at the beginning is almost without danger*, and therefore the responsibility for bad results lies with the man who first cares for the wound. It might be supposed that tetanus arising from blank cartridge wounds occurs chiefly when the wound has been treated by the patient himself, who is first seen by the doctor when the symptoms of tetanus have begun. Unfortunately this is not the case. I have obtained the histories of about 35 cases of fatal Fourth of July tetanus, and by far the majority of the victims saw a doctor soon after the wound was received. The treatment given them varied from a simple dry dressing to an inefficient attempt to pick the wads out of the wound. In not a single case was a reasonable attempt made to secure proper surgical conditions. Even if there were no such thing as tetanus, is a physician justified in leaving a cardboard wad at the bottom of a contused, deep wound received in a grimy hand? And yet that is just what has been done in nearly all the cases with which I am familiar. Nor is this an unusual experience. For example, Moschocowitz<sup>5</sup> reports a case with the following history:

"On July 4 the patient shot himself in the palm of the hand with a blank cartridge. He immediately

applied for treatment at a hospital, at which the wound was disinfected and bandaged; some of the wad was supposed to have been removed at this time. Subsequently the wound was treated by the family physician." At the operation, performed after tetanus had developed, "the wad of the cartridge, or at least the greatest part of it, was found still at the bottom of the cavity and was removed." He also notes that a large experience in dispensary practice has indicated the frequency with which proper surgical treatment is neglected, "as I have had opportunity to remove on many occasions the bits of cartridge wad from patients who had been under a physician's treatment before coming to the dispensary." Similar reports are given by many other hospital and dispensary physicians.

Every case of blank cartridge wound should be considered from the start as a dangerous emergency, and should be treated with the same thoroughness that would be indicated if it were known positively that tetanus bacilli were in the bottom of the wound. If possible, the patient should be anesthetized, and this is almost necessary in injuries of the palm. The wound should first be thoroughly cleansed on general surgical principles, especial care being taken to remove all contused tissue, not to mention foreign bodies. The entire surface of the wound should then be cauterized, best with the actual cautery, and then packed in such a manner as to ensure that no dead pockets can possibly exist, and that healing will take place from the bottom. The importance of such thoroughness is well emphasized by a report published by Bain<sup>6</sup> from the Massachusetts General Hospital, of a blank cartridge wound treated in such a thorough manner which did not develop tetanus in spite of the fact that the presence of living tetanus bacilli was demonstrated on the wad removed at the operation. It may be regarded as certain that had this wound not been thoroughly treated the patient would have developed tetanus.

Unfortunately, however, tetanus may develop even from wounds that have received good care, sometimes appearing when the complete healing has occurred, and all danger seems over. There is particular danger that the most thorough cleansing may not be effective in those wounds that are brought to the physician a few days after they are received. Then it is possible that bacteria have been carried by phagocytes or by other means outside of the range of cauterization, and in such cases the only safe procedure is the prophylactic use of antitoxin. Unsuccessful as antitoxin has generally been in the treatment of tetanus that has already developed, there can be no question of its value as a prophylactic. A patient who has just developed symptoms of tetanus is not just developing the disease, but is dying of it. According to Ehrlich's theory at that stage the tetanus toxin has united with the motor cells of the anterior horns and basal ganglia, and the damage is done. Antitoxin administered at this time can, at the most, merely prevent further combination of the toxin with these cells or with other cells that are still not involved. But if we inject antitoxin before the toxin has combined with the nerve cells we cause the toxin to unite with the antitoxin, and so protect the cells. Practical experience has been emphatically favorable to this latter use of antitoxin. While little has been done with human tetanus, because the chance that any ordinary wound will cause tetanus is too slight to render its prophylactic use common, still there are many epidemics among horses that have been promptly stopped by the use of antitoxin. Pitha<sup>7</sup> has applied it in the Prague maternity hospital where there was an epidemic of puerperal tetanus, and accomplished the termination of the epidemic at once. So far as reports can be obtained wherever prophylactic use of tetanus antitoxin has been made it has not been followed by tetanus in a single case, nor has it caused any trouble. Therefore, in view of the great danger that certainly exists in blank cartridge wounds, a pro-

phylactic injection of tetanus antitoxin is advisable. In a dose of 5 cc., which should be ample, it is perfectly safe. While in blank cartridge wounds that are treated immediately by thorough methods antitoxin may seem superfluous, still there is no harm in its use, it "makes assurance doubly sure," and the responsibility of the surgeon is terminated. In cases that reach the physician a few days after the injury has been received it is certainly indicated, however well the wound is then treated, and it should always be used. Certain it is that such combined treatment as this would practically exterminate Fourth of July tetanus, and the lives of scores of boys must be worth more than the trouble involved in thorough treatment. Inquiry among most of the large hospitals of the country has shown generally that in their dispensary service the wounds are thoroughly treated from the outset, and they generally report that all the cases of Fourth of July tetanus occurs in boys treated first by some outside physician or dispensary. Only in Bellevue Hospital, so far as information was received, has antitoxin been used as a prophylactic for blank cartridge tetanus, and in no cases so treated has tetanus developed. In Johns Hopkins Hospital antitoxin has been used to some extent as a prophylactic after nail wound of the foot.

After the tetanus has once developed its treatment is much the same whatever the original cause. Radical cleansing of the wound, with removal of the adjacent tissues, best supplemented by the actual cautery, is essential. Although antitoxin has been spoken of somewhat deprecatingly as a means of treatment in preceding paragraphs, yet its use is to be urged in every case of tetanus. Up to the present time tetanus antitoxin has given nothing very positive, so far as is indicated either by statistics or by the general impressions of those who have seen much of its use. By the time tetanic symptoms appear the union of the toxin and the combining groups of the ganglion cells has occurred, and so far as experimental and clinical evidence tell us this union is a stable one that cannot be broken by antitoxin or other therapeutic agents. What we may hope for is that the antitoxin will combine with any toxin still free in the blood, and so prevent further injury. The intracerebral and subdural injections through trephine openings have not seemed on the whole to offer any great improvement over subcutaneous injection. As the toxin has combined chiefly with the cells of the anterior horns of the spinal cord the method of intraspinal injection seems much more rational than intracranial injection, besides being much simpler. Reports of success by this method have been published, and it is well worth trial. The antitoxin treatment is in about this position: It is logical, harmless, and probably of benefit; especially in those cases in which the line between recovery and death is a narrow one; therefore the patient should be given the benefit of the doubt, and receive antitoxin.

A modification of the antitoxin treatment that has been used abroad in a few cases, but apparently not in this country, is the injection of brain tissue from the lower animals. This is based on the famous demonstration by Wasserman that tetanus toxin is firmly combined by nerve tissue equally, whether in its normal condition in the body or as an emulsion in a test-tube. Therefore, injection of emulsion of brain substance may be expected to accomplish much the same things as antitoxin by combining with the free toxin. Russian physicians, especially, have employed this means. The usual method is to obtain the head of a freshly slaughtered rabbit or sheep, remove the brain aseptically through a small opening in the skull, grind it up in a sterilized mortar with sterile physiologic salt solution, and filter through sterile gauze. About 20 cc. to 30 cc. are used to each 10 grams of brain for each dose, which is injected subcutaneously. In cases of tetanus occurring in localities where antitoxin is not obtainable this substitute is to be strongly recommended.

While the virulence of infection is the important matter in determining the outcome of the case, still there can be no doubt that general means of treatment judiciously used will improve the prospects of many doubtful cases. Chief among these is the protection of the patient from the numerous stimuli that bring on the convulsions. He should be in a dark room, with heavily padded floors; the door should be so fixed that slamming is impossible. Morphine should be used, together with chloral and bromids, sufficient to keep the patient in a stupor if possible; these failing, chloroform should be used, and it is always indicated when exhaustion by the spasms is threatened. To increase the elimination of the toxins, as much water should be given as is possible without too much disturbance of the patient. Like the antitoxin, the carbolic acid treatment is also of uncertain value, yet it, too, may well be used, since it offers a possible aid. Ten cc. of a 4% solution may be safely injected three times a day, and in some cases even larger amounts have been used.

Of course the root of the treatment of Fourth of July tetanus lies in preventing the wounds that usually cause it, and this is to be accomplished chiefly by thorough supervision of the sale of firearms and ammunition to minors, and the rigid enforcement of statutes that exist in nearly all cities. The American boy is not to be deterred by advice or instruction as to the dangers of the blank cartridge form of celebration, and it seems improbable that any sort of police regulation can defeat his suicidal tendencies, but much can be done to lessen the number of accidents. In the returns from cities all over the country there seems to be to some extent a relation between the vigor of the measures taken against celebration with firearms and the number of cases of tetanus. We have already mentioned the freedom of Washington from this fatality, and its relation to the rigid laws against the use of firearms. In Chicago, on the other hand, although the Mayor and the Board of Health call attention to this danger, still the topography of the city is such as to prevent any efficient action by the police, so that the celebrator has unimpeded facilities for shooting himself. In New York, according to information from the secretary of the Board of Health, "the ordinances against the use of firearms are usually suspended in this city on the Fourth of July." There is undoubtedly room for much improvement in this respect. For one who has no interest in the sale of explosives the method in vogue of celebrating Independence day shows little evidence of educational or patriotic value, and of its evils tetanus is but one among many. Prohibition of the sale and use of explosives, at least those that produce solely the effect of noise, is the proper solution of the troubles of the Fourth, and making their sale illegal would have a decided effect on the day's events, even if complete prohibition could not be accomplished.

## NEPHROLITHIASIS, WITH REPORT OF CASE.

BY

CHARLES D. LOCKWOOD, M.D.,

of Los Angeles, Cal.

Kidney surgery has of late years been placed upon such a thoroughly scientific basis that we now undertake operations upon these organs with confidence, where formerly the greatest trepidation was felt.

Two factors have contributed chiefly to this changed attitude on the part of surgeons toward this important field of surgery: (1) The possibility of determining

accurately the functional activity of either kidney; and (2) greater precision in diagnosis made possible by the perfection of Röntgen ray photography and ureteral instrumentation.

To illustrate these two points and for the sake of record I wish to report the following case of nephrolithiasis:

Mr. B. W. P., aged 44, consulted me April 25, 1902, for kidney trouble. At the age of 20 he had several severe attacks of pain in the region of the left kidney and along the course of the ureter, associated with blood in the urine. Since that time there had been no acute paroxysmal pain, but a continued soreness in the left lumbar region with occasional hematuria, especially after unusual effort or fatigue. This condition had been much aggravated for the two months preceding his visit to me, with the addition of slight chills and lassitude accompanying the hematuria. He had been passing more blood in his urine, which at times was bright red. There had also been a loss in strength and weight.

*Personal History.*—Occupation, draughtsman; married; temperate in all his habits; no specific history. His father suffered also from what was probably renal calculus.

*Examination.*—Patient nervous, mentally alert, nourishment fair, heart and lungs negative, liver and spleen not palpable, deep palpation under the margin of the ribs on the left elicited pain, but the kidney could not be felt. There was no tenderness on the right, and the patient said the two sides felt differently. After examination the left side was very tender for a day or two, and there was more blood in the urine.

*First 24-hour Specimen of Urine.*—Quantity, 600 cc.; urea, 1.2%; albumin present in considerable amount. *Microscopic examination* showed a large amount of blood and a few pus cells.

Another 24-hour specimen a few days later showed the following: Quantity, 960 cc.; urea, 1.8%; less albumin and blood; thorough examination for tubercle bacilli was negative.

May 10 the patient was feeling better, and I segregated the urine with the Harris instrument, having previously administered phloridzin 2 mg. hypodermically.

The instrument was left in half an hour, and during this time the right kidney discharged 20 cc. of urine, the left only a few drops.

The drops from the left kidney contained a large amount of albumin and blood. Urine from the right side contained a small amount of albumin and a few red blood-corpuscles; reaction, slightly alkaline; about .42% sugar; urea, 1.2%.

The freezing point of this urine was 1° C. below zero. At this time I also withdrew an ounce of blood from the arm and tested its freezing point, which was .6° C. below zero.

May 13, 24-hour specimen of urine —44 ounces; specific gravity, 1,020; albumin, a trace; no sugar, urea 1.1%, small amount of blood.

A radiographic picture of the kidney region was now taken. The first two plates were not well defined; the third, however, showed a distinct shadow in the region of the left kidney.

May 20, one month after he was first seen, the patient was sent to the hospital for operation.

He had improved somewhat in general health, but there was still some blood in the urine, and a deepseated, dull pain in the left loin. For several days preceding operation patient was given urotropin and lithia with potassium carbonate dissolved in hot water.

During the 24 hours immediately preceding operation he was given large quantities of salt solution per rectum.

After anesthetizing the patient for operation I made a cystoscopic examination. The vesical mucosa was normal in appearance. Apparently normal urine was spurting from the right ureteral opening, none from the left.

Patient was turned upon his right side, resting upon a firm roll. A transverse lumbar incision was made through the muscles and fascia down to the retrorenal fat. The kidney, atrophied and firmly adherent, was found high up between the eleventh and twelfth ribs. It was separated with difficulty from its capsule and drawn into the incision.

A hard mass could now be palpated in the pelvis. An incision was made through the lower pole of the kidney and into the pelvis. The calculus was now turned out.

The stone (Fig. 1) was pyramidal in shape, the sharp end projecting into the ureter, and the larger portion or base lay in the dilated pelvis and on adjacent calyx (Figs. 2 and 3).

When the stone was at rest the pointed extremity was tipped up and projected into the dilated pelvis, leaving the ureter free. The attacks of hematuria were doubtless due to the dipping down of the sharp point of the stone into the first portion of the ureter, thereby injuring and completely blocking

it. After removal of the calculus the ureter was probed to the bladder and found free of obstruction. The incision into the kidney pelvis was closed with catgut sutures. This was difficult, as the tissues were very friable. An iodoform gauze drain was introduced down to the site of incision into the kidney and brought out through the flank. Lumbar incision was closed in

Fig. 2.—Location of calculus with reference to bloodvessels and ureter. a, Calculus; b, ureter; c, vein; d, renal artery.

layers. During the operation 1,000 cc. of normal salt solution was given in the breast.

The first 24 hours after operation patient passed 1,430 cc. of urine. It contained considerable blood. The second 24 hours 980 cc. of urine was passed; specific gravity, 1,020; albumin in considerable quantity; urea, 3%; blood abundant.

Patient left the hospital after a stay of four weeks. The external wound became infected and discharged pus freely for three weeks. This retarded recovery somewhat, but the patient steadily gained strength and left the hospital feeling well.

Improvement continued for three weeks, when he began to

Fig. 1.—Oxalate of calcium stone, actual size; weight, 138 grains. A, sharp projecting spine.

Fig. 3.—a, Stone at rest; b, stone impacted in ureter as found at operation.

complain of severe pain in the left loin. No tumor was demonstrable at this time, but a diagnosis of ureteral obstruction was made. The pain was relieved by large doses of morphia. The second night after the appearance of pain a large amount of urine escaped through the external wound, affording immediate relief.

During this period of obstruction the temperature rose to 101° F. The wound remained firmly healed except at three points, where a few drops of urine could be expressed.

Urine discharged from the fistula was examined and found to contain leukocytes, red blood corpuscles, and epithelial cells. Urine passed per urethrum during the existence of fistula was normal. The fistula closed about one week after its appearance and patient began to feel better.

Two months after operation patient had gained some, but complained of polyuria and dimness of vision.

A twenty-four hour specimen examined at this time showed total quantity 54 ounces; specific gravity, 1.018; albumin present; urea, 1%; large amount of sediment. Five months after operation patient had gained 12 pounds in weight. Wound remained clean and firmly healed. Urinalysis practically the same as at last examination. There was still occasional pain in the left kidney region.

This patient has steadily improved up to the present time. I have been unable to secure his consent to another segregation of the urine to determine the present functional activity of the kidney operated upon.

This case suggests several points which I wish to emphasize further:

1. It is usually possible to make an accurate diagnosis of renal calculus with the means now at hand. It is no longer excusable to pronounce every kidney complaint "Bright's disease," as had been done in this case, simply because there is a trace of albumin in the urine.

2. Proper preparation of the patient is an important adjunct in every kidney operation. This preparation consists in the following:

(1) Increasing the functional activity of the kidneys until the total output for 24 hours equals or exceeds the average for a normal individual. This may be done by the free ingestion of fluids and by the giving of enemas of normal salt solution for several days preceding operation. During and immediately following operation salt solution should be given subcutaneously in large amounts.

(2) The administration of urinary antiseptics, especially urotropin and salol. Before every operation attacking the parenchyma of the kidney the following factors should be carefully estimated:

(a) Quantity of urea excreted by either kidney for a definite period of time.

(b) The amount of sugar excreted by either kidney for a definite period of time after the injection of phloridzin.

(c) Cryoscopy or the freezing point of the urine, as compared with the freezing point of the blood in the individual under observation.

The normal freezing point of urine, as determined by Koranyi, is .9° C. below zero. Diminished solids in the urine raise the freezing point. Increased solids in the blood lower its freezing point.

When the freezing point of the blood approaches .6° C. below zero and that of the urine rises above .8° C. below zero, it is dangerous to operate.

In my case the freezing point of the urine was 1° C. below zero and that of the blood .6° C. below.

Kümmel, a German surgeon, reported 24 cases to the congress of German surgeons in April, 1901, showing the value of this method in estimating the safety of kidney operations. Of these cases 17 were for hydronephrosis and pyonephrosis, 7 for tuberculosis. Of the 24 patients, 22 recovered and 2 died, but the deaths were not due to renal insufficiency.

The relative value of the different methods of estimating the functional activity of one or both kidneys can not be definitely stated at this time, as too few observations have been made to justify definite conclusions.

Casper and Richter lay greatest stress upon careful estimation of the following factors: (1) Quantity of urea excretion; (2) amount of sugar excretion after the injection of phloridzin; (3) cryoscopy.

They express the utmost confidence in conclusions based upon these findings. I have found the phloridzin test a very reliable index to renal activity.

I have employed this agent in 12 cases to determine functional activity. The results have been remarkably uniform, and my confidence has grown with each trial.

One half-hour before ureteral catheterization or segregation is begun, 2 mg. of phloridzin is injected deeply into the lumbar muscles.

I have found in my experiments that the normal kidney, after the injection of the quantity named excretes sugar for from one to two hours at the rate of about .42%. The diseased kidney will vary from this standard in proportion to the pathologic changes in it.

The permeability of the kidneys to methylene-blue is also of some value as pointed out by Le Pine and Patoir, French investigators. It is not to be relied upon as an index to the permeability of the kidneys to normal constituents, although it bears a fairly constant relation to renal elimination.

The mortality of kidney operations will be reduced in proportion to the care with which surgeons estimate the foregoing factors before attempting surgical interference. The mortality from uncomplicated nephrolithotomies is low. E. H. Fenwick reports 33 successive cases with no deaths. Israel records 61 operations for nephrolithiasis with 9 deaths, a mortality of 15%. Of these 29 were uncomplicated, with 1 death; 12 for removal of ureteral stones, with 4 deaths; 5 for calculus anuria, with 2 deaths; and 15 nephrectomies for infected kidney, with 2 deaths. Ureteral calculi are now found much more often than formerly, and a perfected technic for the localization of renal stones will doubtless show about 33% lodged in some portion of the ureter.

Of 6 cases of nephrolithiasis seen by me in the last year, 3 have been located in the pelvis, and 3 in some portion of the ureter. Schenck reports 3 cases of ureteral stone operated upon in Kelly's clinic; and at the time of his report, less than a year ago, but 90 cases of ureteral stone had been reported. Leonard, of Philadelphia, to whom we owe so much for his work in this field of diagnosis, found over half, of 47 calculi photographed by him, to be in the ureter.

A very important part of every operation upon the kidney is the passage of a ureteral bougie from the pelvis of the kidney to the bladder, to establish freedom from obstruction.

## ORBITAL CELLULITIS AS A SEQUEL OF SCARLATINA: THE REPORT OF TWO CASES.<sup>1</sup>

BY

BURTON CHANCE, M.D.,

of Philadelphia.

Assistant Surgeon at Willis' Hospital, Philadelphia.

Serous infiltration of the orbital tissues occurring in the course or at the end of scarlatina is a rare affection. Notwithstanding the common references in the treatises as to the causal relations existing between the two diseases, a careful search through the literature has failed to reveal the details of a single case. I desire, therefore, to record two instances of it that have come under my own observation and care.

In February, 1900, in consultation with Dr. William M. Welch, I saw a youth of about 17, who was in the midst of a protracted convalescence from scarlatina. In early life the patient had suffered from vertebral caries, and although the infectious fever had profoundly depressed his vitality there had been no serious complication until in his right orbit there suddenly developed with increasing severity a diffuse cellulitis. This unusual complication commenced with violent pains in the orbit and neighboring parts. It was accompanied by a chill, succeeded by marked elevation of temperature, and soon followed by an effusion of fluid into the areolar tissue with protrusion of the globe.

The eyelids were red, and excessively edematous. Digital examination showed great tenderness of the orbital tissues, which were hard and tense. For several days the protruding eyeball presented no inflammatory changes except a moderate degree of chemosis. The media remained clear and thus afforded ample opportunity for the study of the interior of the eye. At first there was transitory blanching of the fundus;

<sup>1</sup>Read before the Philadelphia County Medical Society, May 27 1903.

this was followed by intense redness, and scattered throughout the fundus were fine hemorrhages. There was marked swelling of the disc, an overdistention of the veins and contraction of the arteries. The orbital pressure rapidly increased and obstructed the lymphatic and venous circulation. There was excessive edema of the conjunctiva and lids, followed by an intense livid redness, due to the distention of the vessels and hemorrhages from the conjunctival capillaries. A day or two before death the surface of the exposed cornea became dry and insensitive, and as its nutrition was interfered with necrosis speedily followed and the eye was lost. Until this took place no evidence of purulent effusion into the choroid and retina was apparent.

In spite of the use of external applications the intensity of the swelling was not relieved until after repeated incisions had been made deep into the orbit, allowing the escape of a thick sanious fluid. No purulent foci were found. The local and general symptoms failed to abate although every effort was made to support the system by the administration of tonics and forced nourishment. The patient became septicemic although the temperature curve was not hectic in character; a short period of delirium and coma was relieved by death, a week after the onset of the local symptoms. The examination of the orbital structures after death revealed only a diffuse serous infiltration; there was no evidence of intraocular suppuration.

In February of the following year I was called to attend a boy of 10 who, like the case just cited, was convalescing from scarlatina, and in whose right orbit there had developed an acute congestion with infiltration of the tissues, producing proptosis between the intensely edematous lids. The localized symptoms were in general similar to those present in the first case. Throughout the course of the process the cornea remained unaffected; the media continued clear and no evidence of intraocular exudation was at any time apparent, although the disc was swollen and intensely congested, as was the choroid.

The local alternate applications of hot and cold compresses and the administration of antiphlogistic remedies failed to reduce the swelling or relieve the tissues from the effects of the pressure. Accordingly, wide and deep incisions were made into the periocular tissues. These allowed the escape of a quantity of blood-tinged serum. Suppuration had not taken place. The boy was of active disposition and robust physique. It had been thought wise to keep him quiet and in bed, because his heart's action had recently become somewhat irregular and weak, although it had not presented demonstrable evidences of endocarditis. An hour or so after my last visit, on the eighth day after the onset of the local affection, without premonitory symptoms the patient was seized with a general convulsion, probably of cerebral origin, and died. Permission to make a postmortem examination was refused.

The records of the daily routine have been mislaid. The onset of the localized symptoms was sudden and there was a decided depression of the general constitutional vigor. The course in each case was rapid, death taking place within ten days after the appearance of the special symptoms. In neither case after repeated careful examinations was there disclosed evidence of any affection of the surrounding cavities or contiguous sinuses. The orbital borders were not diseased. The vision, however, was impaired and later altogether lost by the changes produced by the pressure on the optic nerve. The muscles were no longer capable of contracting, so that the globes could not be rotated, but remained displaced outwardly. The pressure upon the ciliary nerves blocked off the channels of reflex communication between the retina and the iris, so that the pupils remained dilated; and the iris failed to act in unison with its fellow when the eyes were exposed to bright light. The left eye and orbit in each case remained unaffected.

In the first case the short time allowed in which to examine the body and the limitations of the privileges granted made it quite impossible to study the subject with any degree of satisfaction. The refusal of the privilege to make a postmortem examination in the second case was indeed most disappointing, for this child had only suffered from scarlatina, and therefore the condition of his body was apparently dependent upon the pathologic changes occasioned by specific toxins.

In spite of my interest in the study of these cases I can only theorize as to the possible causes for this additional malady. The individuals were apparently progressing favorably toward recovery, yet death occurred soon after the onset of the local disease. To what was death due? Was the orbital affection a part of a general process in a profoundly toxemic subject or

had there become concentrated in the orbital tissues poisonous matters of sufficient virulence as to affect the economy with a fatal result?

In each instance there was satisfactory evidence that the orbital affection was not due to an extension of inflammation already existing in adjoining or communicating sinuses. My first supposition was that I should find suppuration in the orbit and thus assign the cause to the inflammation of these surrounding regions. No bacteriologic examination of the discharge was made, yet the matter was not apparently purulent.

It is not unreasonable to suppose that the morbid elements circulating in the blood of scarlatinal patients have properties which excite changes in that medium and tend to its decomposition; and moreover, the coats of the vessels may become so altered as to favor the formation of a thrombus. These changes doubtless take place more readily when the enfeebled heart is incapable of driving the blood current onward at the accustomed speed.

Thrombotic processes in other infectious diseases frequently present serous or suppurative infiltrations specifically localized in other portions of the body. When the present cases are compared with these others the analogy is quite apparent, for here the effects of such a process were most manifest in the orbital region.

In conclusion, therefore, it is not unreasonable to advance the hypothesis that there had been so great a massing together of the morbid hemic elements as to produce a phlegmon of the orbit which need not necessarily have undergone degeneration or have given rise to suppuration. Consistent with this is the fact that the materies morbi of scarlatina is not essentially saprophytic in its action. In the case of the older boy, it is probable that the local affection had produced a fatal septicemia; while in that of the younger, death may have been due to the sudden passage of an embolus, detached from a heart-clot or from fragments of an unsuspected lymph deposit on one of the cardiac valves, which had become lodged in a vital area in the brain. Again, death may have followed the formation of a thrombus passing either from the ophthalmic vein to one of the communicating vascular sinuses or in the connections between the cervical veins.

When we consider the histories of these cases and note that in each individual the general strength became markedly affected upon the development of the special symptoms, and that in each instance death speedily ensued, there comes to us the thought of the possible good that might have been gained had the eyeball been enucleated. The orbit could thus have been persistently drained of the materials which were rapidly being absorbed by the lymphatics, and which were apparently of such virulence as to cause the death of the individuals. Assuredly it is our duty to establish the drainage of the orbit as early and as completely as possible by elaborate incisions into the periocular tissues, because in these cases whatever relief there was we gained by that means; and it is at least fair to suppose that a more complete drainage might have evacuated the poison which apparently caused death.

#### Pure Milk and Increased Deathrate Among Children.

—The greatly increased deathrate in Chicago among children last week is attributed to impure milk. During the week there were 184 deaths of children under 5 years of age as against 138 deaths during the previous week, or an increase of 33%; compared with the corresponding week of last year the increase was 43.7%. The complaint comes especially from the Jewish quarter where the inferior milk supply has aroused great indignation. This supply is furnished by small dealers in the quarter, and much of it is skimmed and sour before it is delivered. Another serious trouble has arisen from the fact that milk drivers have resolved that only one delivery a day should be made instead of two deliveries as formerly. The health officials of the city are taking active steps to correct the present evil and to punish those guilty of furnishing impure, skimmed, and putrid milk.

## ARTERIOVENOUS ANEURYSM OF THE FEMORAL VESSELS: LIGATION OF THE EXTERNAL ILIAC ARTERY; FAILURE OF COLLATERAL CIRCULATION; AMPUTATION; DEATH.<sup>1</sup>

BY

SCHUYLER COLFAX GRAVES, M.D.,

of Grand Rapids, Mich.

The question of issue in our surgical cases should have no bearing whatever upon the matter of reporting the same or not in the columns of the medical press. The real question is the establishment or accentuation of surgical principles which in their practical application save or prolong the lives of our fellows.

Our obligation to the State as well as the desire to serve our fellows in time of distress should urge us to contribute anything which will add an item of value in the treatment of subsequent patients. Hence the following report:

U. D., aged 21, a young man of Holland Dutch extraction, about six years ago (then a lad of 15) was investigating a gaspipe dynamite bomb held between his thighs when, for some reason or other, it exploded, tearing several irregular openings in the center of the internal aspect of the right thigh. The physician sent for (since deceased) put a simple dressing upon the wound and gave no other treatment. When seen by me the patient stated that a thrill was noticeable almost immediately after the receipt of the injury. Of course a traumatic aneurysm speedily developed and from that time until I saw him it underwent gradual and progressive development.

About the middle of December, 1902, an abscess formed in the tissues overlying the aneurysm, and on December 28 spontaneous evacuation of pus took place. The next morning Dr. George H. Baert, of this city, was called to attend the patient. He found a ragged opening over the aneurysmal sac from which pus and a little blood was oozing. Realizing the extreme gravity of the situation he applied an aseptic dressing snugly about the parts and returned in an hour. Upon the cautious removal of the dressing a stream of blood seemingly as large as his little finger shot out of the abscess opening. Dr. Baert thereupon placed a firm compress over the aneurysm and telephoned for me. I found the young man pale and weak, not from loss of blood, but from general debility and recent illness and pain incident to the development of the abscess. Under the bloodstained compress applied by Dr. Baert and occupying the center of the internal aspect of the right thigh lay an aneurysm as large apparently as two adult fists. Expansile impulse and bruit were very noticeable from the region of Hunter's canal to a point two inches above Poupart's ligament.

The boy was moved to the U. B. A. Hospital where, under anesthesia, the blood current was controlled by a rubber constrictor at the upper limit of thigh, held *in situ* by the Wyeth mattress needless passed through the inner and outer edges of the limb, and the diseased condition carefully investigated.

It was then ascertained that the entire middle third of the thigh surrounding the aneurysm was indurated and brawny from inveterate exudation, thus rendering any thought of attacking the disease at its site simply out of the question. The old surgical rule of treating a traumatic aneurysm by the method of Antyllus, or local proximal and distal ligation plus excision of the sac or not, could not be entertained. When it became evident that distant, proximal ligation was the thing to do the question arose as to the prospective site of that ligation. Right here the principle of John Hunter came in for application, viz., ligation of the vessel where its walls are sound. The artery in the upper confines of Scarpa's triangle and for two inches above Poupart's ligament, as noted before, was thinned, dilated, sacculated and evidently diseased. It was pulsating violently and manifested the expansile dilation and bruit characteristic of aneurysms. It was determined to seek the iliac artery for a safe ligation site.

This vessel was accordingly exposed through a curved incision mainly parallel to Poupart's ligament. After splitting the aponeurosis, severing the anterior (Poupart) attachment of the internal oblique muscle, and, following this, the transversalis fascia, the pouch of peritoneum was exposed. This was gently lifted from the pelvic floor and successfully held out of the way by a broad metallic retractor. The iliacus muscle, the psoas magnus, psoas parvus, and iliac vessels were readily exposed. The vessels, both artery and vein, were dilated to a size larger than an adult thumb and were thin and evidently diseased. At a point about 2½ inches above Poupart's ligament the vessels rather abruptly regained their normal size. At this point the vein, which had lain on the inner side of the artery, passed beneath it and here, by means of a Cleveland ligature carrier cautiously passed, a loop of stout kangaroo tendon ligature was

drawn between the vessels. Two ligatures were tied about the artery, the proximal one first, shutting off the stream, and the distal one about ½ inch from its fellow in order to bring about kindly and definitive healing by serous approximation.

All tumult ceased in the limb and the tissues, especially the toes, became waxy. The limb, except the toes, was buried in thick, warm cotton and the body of the patient as soon as possible after the anesthesia propped in bed for the purpose of stimulating the collateral flow.

Considering the anastomoses between the deep and the superior epigastric arteries, the deep circumflex iliac and the lumbar, the internal and the external pudics, the obturator and the profunda, hope of successful collateral supply had a good basis. In 24 hours this hope seemed about to be realized, for the toes, which after an hour or two of the waxy look grew mottled and suspicious looking and in which sensibility was abolished, took on a pinkish cast and sensation returned to such a degree as to enable patient to detect pin-pricks and to determine which toe was pricked. At least 6 or 8 medical men beside myself who saw the patient that morning thought the collateral supply quite well established, but after 24 hours more gangrene developed rapidly to the aneurysmal site. Amputation, with but slight hope of saving the boy, was done just below the trochanter major. Death, in spite of stimulants and subcutaneous salt infusions, ensued six hours later.

I have been asked why I did not recommend amputation primarily and have replied that high amputation in this case primarily would have been immediately more dangerous to life, as the sequel shows, while the operation chosen offered the boy the best chances all

Distal.

Proximal.

around—the saving of life, the preservation of the limb, and the probable cure of the aneurysm. Amputation naturally would have meant sacrifice of the limb and in the case of this boy would have been more quickly fatal than was the operation done. The deligation plan was the conservative one and the one in my opinion to be elected in such cases.

As to the issue, had death been caused by the hemorrhage the operator might be considered culpable; but for lack of sufficient collateral nourishment no surgeon can be held responsible. This failure I deem due to the infiltrated and solidified condition of the middle area of the thigh.

After amputation I examined the limb and found present two pieces of rough and irregular gaspiping about an inch square. One of the pieces evidently wounded both artery and vein, as an opening one-third inch by one-fourth inch existed directly between the vessels with no intervening sac, thus giving rise to an aneurysmal varix and not a varicose aneurysm.

Fig. 1 shows this opening from the venous side and also shows the opening from the vein into the sac (as indicated by the match). Over the venous side of the arteriovenous fenestra lay a curious, shelf-like fold of

<sup>1</sup> Reported at the annual meeting of the Kent County Medical Society (official branch of the Michigan State Medical Society), Grand Rapids, Mich., January 13, 1903.

tunica intima (indicated by cross) by means of which a large proportion of the return venous flow passed above the stream of arterial blood, a large share of the latter proceeding below the shelf mostly into the sac, although some must have mingled directly with the venous blood.

Fig. 2 exhibits the arterial side of the abnormal opening and also a section of the arterial system, showing point of ligation. This section is composed, as can be understood, of abdominal aorta, stump of left common iliac, whole of right common iliac, stump of right internal iliac, and whole of external iliac (to plane of Poupart's ligament). The ligatures can still be seen about two and one-half inches above the ligament site.

The size of the dilated portions of the arteries and veins is not evident because of the contracting quality of the preservative fluid.

The aneurysm itself, as is the case with all aneurysms of traumatic origin, had no intrinsic sac-wall, its periphery being the condensed surrounding tissue.

In conclusion, the lesson to be learned from this case is that such injuries should always be subjected to radical treatment at the time they are received, or shortly thereafter, and that the procedure to be adopted at such time is the operation of Antyllus.

## A CASE OF POSTOPERATIVE TETANUS, WITH SPECIAL REFERENCE TO THE FOCUS OF INFECTION.<sup>1</sup>

BY

LEVI JAY HAMMOND, M.D.,

of Philadelphia.

To me it has always been a source of great satisfaction when able to satisfy my own mind that nothing I have done, nor left undone, can be held responsible for post-operative fatalities. Unfortunately we are not, or at least I am not always able to place myself beyond this pale of uncertainty. In the following case, however, I do feel that at least the source of infection can be satisfactorily accounted for, and its particular focus of concealment.

The patient was a young woman of 22, the daughter of a farmer, whose duties, in addition to household work, included milking cows, feeding pigs, and attending to chickens. With the exception of measles and chickenpox, both of which she had in very early childhood, she had never been confined to bed from illness. A contusion of the back caused by a fall from a horse about three years previous was the only ailment from which she remembered suffering. She was sent to me from a distant State by her physician, Dr. Enoch George, with the history of having been confined to bed five weeks with peritonitis, said to be of gonorrhoeal origin. During the early weeks of this attack the suffering had been most intense, but had become less acute by the time I first saw her. There had been through the entire period of her confinement to bed a free purulent discharge from the vagina, which during the early weeks was blood-mixed. She still complained greatly of pain on urination.

She was admitted to my hospital September 30, 1902. The journey to the city, which necessitated a number of hours, was the cause of a renewal, to a great extent, of the intense abdominal pain, and on admission the abdomen was so tender that satisfactory examination could not be made without an anesthetic. Twenty-four hours after admission she was anesthetized, and examination disclosed the presence of a mass in the culdesac, and firm fixation of the uterus posteriorly; there was also very marked thickening of the entire vault of the vagina; the lips of the urinary meatus were everted and eroded; there was a free purulent discharge from the body of the uterus. The pulse, which ranged from 110 to 120, clearly indicated undoubted presence of pus in the pelvic cavity.

As pus was noticed flowing freely from the cervix, an intra-uterine douche of saturated boracic acid solution was given, in conjunction with free irrigation of the vagina, every third hour, with the idea of cleansing, so far as possible, a very likely source of infection at the time of operation, as well as during the period of convalescence.

On the morning of the third day, being the morning following examination under ether, the patient complained of toothache and swelling in the left cheek. Examination of the mouth at this time showed the presence of eleven extensively carious teeth; indeed, most of them were hollow roots. The

inflammation in the alveolar process went on to the stage of suppuration, and on the third day was freely excised and cleansed of a considerable quantity of pus.

On account of the development of this alveolar abscess the abdominal operation was of course postponed; treatment by irrigation of the uterus and vagina being continued, the former once daily, the latter every third hour. By the eighth day after admission, which was two days after all traces of suppuration had disappeared from the alveolar abscess, the uterovaginal discharge had greatly lessened, dysuria also had entirely disappeared, and the patient's general condition had decidedly improved, except the pulse, which continued 100 to 105. It was therefore decided to remove the intraabdominal lesions.

The pathologic condition found consisted of large bilateral pus-tubes with an ovarian abscess on the left side, while the right ovary was the seat of multiple cysts. The difficulties in the operation were no greater than those always encountered when extensive adhesions are present, not only in the structures that are to be removed, but when the body of the uterus is anchored by adhesions. Operation was completed within 40 minutes with no loss of blood, excepting that caused by separation of adhesions, which in this case was extremely slight. Only two pedicle ligatures, one on either side, were left within the abdomen, and these, together with the silk used for closing the abdominal incision were taken from a skein from which I had been using for more than a year, and have since used. Care was taken in this case, as in all of my operations, to pack off thoroughly the viscera from the field of operation before beginning the work of separating adhesions, to avoid the well-known dangers of escape of infective material. In this case the abscesses were removed without breaking the walls, and the uterine end of the tube was thoroughly curetted on both sides, touched with carbolic acid and a cuff of the serous membrane was whipped over the stump, this being the precaution I invariably take against possible infection when there is undoubtedly an infective endometritis. The abdominal wound was closed with five through-and-through sutures without drainage.

The patient reacted in a perfectly natural way, neither pulse nor temperature indicating anything unusual, pulse never going beyond 100; urine was voided five hours after operation, and she complained in no way of pain or suffering from the operation more than the usual amount of distress that is complained of, especially during the first 12 or 14 hours, this being principally a stinging, referred to the abdominal wound. On the morning of the third day after operation the bowels were open twice after administration of a saline (sulfate of magnesia).

From this time on, as is my custom, she was given a semi-solid diet, and progressed as satisfactorily as I have ever known a patient to progress after laparotomy, with the single exception of the pulse, which ranged between 100 and 105 until 1 o'clock on the morning of the sixth day after operation, when she reported to the nurse a strange feeling about her eyes, describing it as a pulling in all directions. As it seemed a trifling complaint the nurse paid little attention to it other than to try to pacify the patient, and within a half hour had succeeded in getting her to sleep again. At 5 o'clock she again awoke with these primary symptoms decidedly increased, and in addition complained that her jaws were stiff. The matter was then immediately reported to me, and I saw the patient within an hour, or between 6 and 7 o'clock. I noticed at once a peculiar expression, also a noticeable standing out of the muscles of mastication; there was not, however, at this time any rigidity of the muscles of the neck. The peculiar smiling expression (risus sardonius) was decidedly noticeable. Though I had never before seen a case of postoperative tetanus my suspicions were aroused. Without delay I undressed and inspected the abdominal incision and found it perfectly dry, without the least erythema about it, and entirely united, with the exception of possibly one-eighth of an inch where there had not been perfect approximation of the skin. There was not a particle of secretion about the wound nor soiling of the dressing. However, the stitches were removed; the abdomen was perfectly flaccid; there was no pain nor tenderness on palpation or percussion, and everything within and without the abdomen seemed perfectly normal. She was given at once sulfate of magnesia, and within a half hour 1.3 grams (20 grains) of chloral and 2.6 grams (40 grains) of potassium bromid. Trismus from this time grew rapidly worse, and by 10 o'clock it was impossible to separate the teeth. The sternocleido mastoid was the next muscle that became the seat of spasm; by 12 o'clock the muscles of the neck were all completely spastic with paroxysms of increased spasm at intervals of three or four minutes. At no time was there any spasm of the muscles of the arms, abdomen, or lower extremities until about four hours before death, when there was noticeable contraction of the muscles of the back and abdomen during the paroxysms only.

At 12 o'clock the patient was given subcutaneously a million units (20 cc.) of tetanus antitoxin, and by enema 4 grams (1 dram) of chloral and 31 drams (1 ounce) of potassium bromid; morphia was given hypodermically in 16 mg. ( $\frac{1}{4}$  grain) doses; eserine was injected directly into the spasmodic muscles. A second injection of antitoxin was given at 2 o'clock; at 9 o'clock 500,000 units (10 cc.) were again injected into the spinal canal, and at 11 o'clock another million units were used subcutaneously. The patient died at 4 o'clock the following morning, or 27 hours after the first symptoms developed.

<sup>1</sup>Read before the Philadelphia Obstetrical Society, February 5, 1903.

The absence of the germ in the one stitch that was examined, the others having been burned with the dressings through mistake of the nurse, and my inability, owing to the tightly closed mouth, to secure a satisfactory culture from the teeth cavities, robs us of the positive proof that it was concealed therein, and compels me to rely for my decision as to the seat of infection on the knowledge possessed of the specific germ of tetanus, whose habitat is known to be in the earth, especially in manure; also that it is not transmitted by the air. It seems reasonable, in view of these facts and with the environment of this particular patient, to consider her specially liable to have become infected with the tetanus germ at her home, and that the extensive caries of the teeth should furnish a most vulnerable storehouse for its concealment. Coupled with this, her long illness so reduced her resisting powers as to require only a further step in the way of operative intervention to enable the germ to develop rapidly. Certain it is that the germ could not have been admitted at the time of operation, for all modern observers (these being mostly among the French, German, and Italian) show that the period of invasion is between 9 and 21 days, and as the patient developed the symptoms on the morning of the sixth day after operation, the evidence is in favor of its having been already within the system. We are further supported in the belief that the germ was hidden within the mouth by the onset of the disease; that is, that the muscular contraction begins in the muscles nearest the point of infection. This view is accepted by such modern observers as W. Fleimer, Leyden and Blumenthal, and Ver Haagen; also by several cases more or less recently reported in support of it, notably one by N. J. Conklin,<sup>1</sup> who cited a case in which an injury to the thumb developed tetanus, the twitching in the hand and rigidity of the muscles of the hand and arm occurring 16 days after the injury was received. Next followed the body and legs, trismus coming on 7 days after contraction of the hand and fingers, or 30 days after receiving the injury.

Morgan, in "Home System of Surgery," states that it is a remarkable fact that the spasm attacks primarily the muscles of the part injured instead of the muscles of the jaw, and relates two cases, one that of a sailor admitted to Guy's Hospital with an injury of the thumb. The first symptom developed two months after injury was received, and consisted of a painful neuralgic affection of the muscles of the ball of the thumb without any appearance of inflammation of the part. The second case was that of a child who had received a blow from a schoolmaster. Both pain and spasm in this instance commenced in the injured part, and the first true symptom of tetanus was gradual spasmodic contraction of the flexor muscles of the hand, drawing all the fingers into the palm. The cramps subsequently extended to the arm and eventually to the muscles of the back.

It is also a fact that the degree of local injury bears no relation to the severity of the symptoms, indeed it is much less frequently met in the severer forms of injury than in less severe forms. Statistics show that in 1,364 operations, both major and minor, only one case of tetanus was observed. In this case, as noted by description given by Dr. Morgan, there was a feeling of stiffness in the tongue as well as marked rigidity of the muscles of mastication.

Alfred Poland says that the first evidence of tetanus but too truly portrays the unmistakable nature of the disease. All observers seem to agree that however great and severe muscular spasms may be, the muscles of the hand and fingers are rarely affected unless the infection is admitted through injury of them.

*Prognosis.*—As to prognosis the same observers also state that it is the gravest when trismus is the earliest symptom noted.

## SPECIAL ARTICLES

### ECHOES FROM THE MADRID INTERNATIONAL MEDICAL CONGRESS.

BY

NICHOLAS SENN, M.D.,  
of Chicago.

The Madrid International Medical Congress has passed into history. The members who attended will relate their experiences and observations in their respective medical circles in near and remote parts of the world, and the profession at large will pass final judgment upon its scientific merits after perusal and study of its published transactions. Like in all similar events praise will not be unmingled with criticism. The attendance was larger than was expected. The register contained the names of 6,961 members, of which number 3,530 were credited to Spain, and 3,431 to foreign countries. The foreigners were represented by the following countries: Germany, 776; Australia, 7; Argentine Republic, 45; Austria, 258; United States of Colombia, 2; Cuba, 13; Denmark, 35; Belgium, 98; Bosnia, 3; Brazil, 252; Bulgaria, 4; Egypt, 12; United States, 195; France, 826; England, 238; Greece, 9; Hayti, 1; Italy, 238; Japan, 4; Luxemburg, 4; Mexico, 25; Norway, 51; Holland, 16; Peru, 4; Portugal, 33; Roumania, 21; Russia, 297; San Domingo, 2; Servia, 9; Sweden, 21; Switzerland, 35; Turkey, 11; Uruguay, 3; Venezuela, 18. The government, or as they were designated here, official delegates, numbered 474. Many of the members who registered by mail did not attend. The tedious railway travel in Spain and the limited hotel accommodations of Madrid did their share in limiting the attendance; the many places of great historic events and the boundless treasures of art in which the country abounds attracted others who were not prompted by a sense of hunger or thirst for additional medical knowledge. The figures quoted above indicate plainly that the Congress was overwhelmingly Latin in its make-up. The euphonious Latin languages—Spanish, Portuguese, and Italian—were most in use in conversation, reading of papers and discussions. The French occupied the second place in the scale of frequency. The average Spaniard has but little desire to acquire foreign languages. Nearly all of the educated classes speak French, very few English or German. Among the medical men German is a rare accomplishment and only a limited number of naval surgeons have acquired a speaking knowledge of English. In the section meetings English was seldom heard and German even less frequently. A fair estimate of the number of delegates in actual attendance would be about 5,000. The delegates were divided into three classes: (1) Official or government delegates, who received a gold badge with a ribbon of the national colors; (2) delegates from medical societies or scientific institutions, who wore a silver badge with ribbon; and (3) members of the Congress by subscription, who were labeled with a plain gold badge. These badges played an important role in the selection for a number of the most important social features, the official delegates being shown a decided preference.

*Opening Exercises.*—Long before the time set for the opening of the Congress, at 3 p.m. Thursday, April 23, the Royal Opera House was packed with a brilliant audience. On the floor every inch of available standing room was occupied by a seething mass of humanity. The boxes were filled by distinguished government officials, prominent citizens, military and naval officers in full-dress uniforms, and invited guests. When the young King entered the royal box accompanied by his mother, Infanta Maria Theresa, and Infanta Isabel, the immense audience rose as a body and the band played the royal march. The royal party was not cheered so vociferously as is the case when one of our Presidents makes his appearance on a similar occasion, but the greeting was a well-meant one, and was participated in heartily by the foreign delegates from all parts of the world. The youthful potentate and his august mother made a very favorable impression upon every one present. The King listened attentively for two hours to the addresses of welcome and the numerous long and short

<sup>1</sup> Ohio Medical Journal, October, 1881.

responses. An incident occurred here which excited some newspaper and public comment. When our country was called upon to respond a profound and at the time a painful silence was the only reply. The call was repeated with the same result. What was interpreted by some as an intentional slight to Spain on part of our delegation was simply due to a lack of organization of our delegates at this as well as subsequent occasions, for which no individual delegate was to blame, but something which should be studiously avoided in the future. As it was no one felt authorized to respond, when our country was called upon, through its scattered delegates. The matter was subsequently explained to the proper authorities, and on leaving Madrid I was informed by a Spanish naval officer of high rank that this incident created rather a favorable impression than otherwise among his countrymen. The King wore the uniform of a field marshal. He did not speak. I was informed that "in public the King never speaks." The Royal Theater is a large and magnificent structure, but its interior proved entirely inadequate to afford even standing room for the immense throng desirous of witnessing the opening ceremonies, the most attractive feature of every International Medical Congress.

*General Sessions.*—The last session of the Congress was held in the large amphitheater of the Central University. At this meeting it was announced that the Moscow and Paris prizes for the best scientific work had been awarded to Grassi, of Rome, and Metschnikoff, of Paris, and that Lisbon, Portugal, had been selected for the next place of meeting.

By what motives and manner of reasoning the committee on nominations decided upon Lisbon as the next place for the Congress is difficult to comprehend. This action necessarily means two consecutive Latin congresses and will inevitably cut down the attendance to a minimum. Lisbon is a much smaller city than Madrid, its hotel accommodations more limited, and it is also less accessible. All serious objections against this selection, to say nothing of the fact that the Latin languages will again rule the deliberations of the Congress. Portugal is an interesting country to visit. Lisbon is a charming little city, but the next Congress should have met in a more central place and in a large city with ample hotel accommodations and in a country where the English and German languages carry more weight. If a general criticism of the Congress just ended is permissible it is the fact that the hotel facilities of Madrid were inadequate to the requirements of so large an attendance, and this difficulty will be greatly increased at the next place of meeting. I am confident the United States will send the usual large contingent of delegates, who will represent in a creditable manner the scientific work of our profession notwithstanding the inconveniences they will meet in finding accommodations, and the difficulties they will have to encounter in making themselves understood.

During the intervening days the general sessions were held in the aula of the San Carlos College of Medicine. Sixteen speakers were on the program, among them Dr. Howard A. Kelly. The title of the address of this speaker was a significant one: "The Passing of a Specialty." The time of the general sessions, called here conferences, interfered seriously with the work of the sections, and it was probably for this reason that the attendance was small. Among the more distinguished speakers may be mentioned Waldeyer, of Germany; Politzer, of Austria; Arthur Thomson, of Oxford; Brouardel and Robin, of Paris; Maragliano, of Italy, and Pawloff, of Russia.

*Section Work.*—There was at this as well as all previous meetings of the International Medical Congress no lack of papers for all of the sections. The furore of the pen of the present generation of medical men is made obvious at all gatherings from the smallest county and city medical societies up to the International Medical Congress. The average attendant is no longer content to listen and learn; he is imbued with a sense of duty that compels him to produce, to write, to teach. The result of such a crowded program was here the same as elsewhere on similar occasions. The limited time allotted to each paper made the reader anxious to go over as much ground as possible, hence he felt it his duty to read rapidly, which only too often meant unintelligibly, followed, if by any, a short and imperfect discussion of the subject presented. The scientific

work of such a large assemblage of medical men must of necessity be done in the different sections. The section program of the Madrid Congress was an unusually prolific one, comprising the titles of nearly 2,000 papers on every possible subject pertaining to medicine and surgery and allied sciences. These papers were distributed among 16 sections and several subsections. Many of the authors of papers announced on the program were conspicuous for their absence, an evil by no means limited to the International Congress and one which should receive the earnest attention of the committee on program. It is not at all unusual for authors to send in the titles of papers they never intended to prepare, much less to present them in person. Such deception deserves censure and should be made impossible by more stringent regulations. Another quite noticeable irregularity is the presentation of papers after they have done service at some previous medical society meeting and after they have found space in some medical journal months and years before their resurrection on such an important occasion. In looking over the general program I had no difficulty in detecting a number of very familiar titles. The friendly spirit of the Spaniards toward the Americans became manifest when it came to the distribution of section honors. The following delegates were made honorary presidents of sections: Dr. Howard A. Kelly, Gynecology; Professor Stuart, Chicago, Physiology; Dr. Reginald Sayre, Diseases of Children; Dr. C. H. Hughes, Neurology; Dr. R. H. Reed, General Surgery; Dr. Harlan, Dentistry; Surgeon-General O'Reilly and Dr. N. Senn, Military Surgery. All of the sections held their meetings in the National Art Gallery and Museum, a spacious and imposing structure, a lasting monument to Spain's perpetual interest in the preservation and promulgation of art. This centralization of section work had many advantages, but was not without objection. This magnificent building is centrally located and easily accessible, but the proximity of the sections and the many priceless art treasures afforded too many diversions from continuous hard section work. The "congressiste" could not resist the temptation in passing through the building to note what was going on in the different sections and to study and admire the wonderful paintings, illustrating modern Spanish art. Then, too, the picture galleries were open to the public, a circumstance which contributed its share in aggravating the confusion. The section meetings were held from 9 o'clock a.m. until noon and often the time was extended for another hour or two. As a rule, the man who spoke loudest and was most liberal in making gesticulations enjoyed the largest attendance. As indicated by the titles of the papers presented most of the modern subjects which are at this time agitating the progressive professional minds were ably presented and thoroughly discussed. Some of the most valuable papers were presented by Spanish authors. The Spaniards are fluent speakers and delight in debate. Spain is keeping pace with her European neighbors in the advancement of the science and art of medicine. The forthcoming transactions of the Congress will bear ample testimony to the correctness and force of this statement. We must come in closer touch with Spanish medical literature if we wish to keep pace with the newest and some of the best work that is being done in unraveling the mysteries of disease and in search of new and more effective therapeutic resources.

Spain can no longer afford to hide what she has done toward the advancement of modern medicine within her own boundaries; her excellent work in this direction must become common property wherever scientific medicine is taught and practised. One of the striking defects of the section work in most, if not all, of the sections was the limited number of demonstrations—the teaching by the kindergarten method. This lack of practical demonstration was keenly felt by those who were not familiar with the languages in most common use. The too numerous and often quite lengthy papers undoubtedly constituted a bar to more satisfactory and extended demonstrative teaching and if so this obstruction should be eliminated at the next meeting of the Congress. What the seeker for knowledge on an occasion like this desires most and looks for are ocular demonstrations illustrative of the ideas the speaker desires to convey to his audience. The section meetings were not so well attended as one would expect after looking over the subjects scheduled in the general program. Too

many of the delegates had come with the intention of doing sightseeing instead of attending to the legitimate duties of the mission on which they had been sent. This kind of dereliction of a voluntarily assumed duty is only too common, and merits, to say the least, a sharp criticism. The confusion of languages that prevailed throughout the entire Congress found its way into the general program. I will give only a few instances of title mutilation as it appeared in the general program for the authors who presented papers in English and German.

My friend, Dr. C. H. Hughes, of St. Louis, was announced to read a paper in the Neurological Section on "Eew Vievos of the Virile Reffiese." I wonder what Lindsay Steven, of Glasgow, thought when he saw printed under his name "A Case of Ocute Lymphatic Leukalmnia urt Minde vous Lymphatic Medules in the Skin." Dr. R. H. Harvey Reed, of de Rock Springo Hugo, was expected to discuss "Metral d'implantation duto the Rectum." I was registered in the Military Section, and drew a long breath when called upon to present my paper on "The First Dirping en the Battlefired."

The German language fared no better than the English in the program.

I am sure the patriotic feelings of Korbitz, of Berlin, received a shock when he saw his name coupled with the title of his paper on "Das Schmelzen des leichtflussigen Forzellans una cin hener electrisher ofen." I do not know the fate of the paper by Grunmach, of Berlin, in the Section of Internal Medicine, but the title as printed was certainly a strange one—"Uibu dis Fortschritte in des Diagnostik dirrili dis X Strahlen."

It would certainly not be in good taste to criticise too severely the orthography of the English and German language in a product of the Spanish press, and I have quoted these illustrations only as a hint to the committee on program for the next meeting of the Congress, to which I desire to add the well-meant suggestion to consult some one who has a fair knowledge of the two languages, which are too widespread and important to be ignored, before they deliver the program to the printer, and then engage the services of a competent proof-reader.

*Exhibits.*—One of the great attractions at the meetings of the American Medical Association is the exhibition hall. It is here where the country and village practitioners replenish their stock of proprietary medicines without depleting their bank accounts and collect current medical literature for their libraries without diminishing the contents of their pocket-books. It is here where he can quench his thirst with sparkling waters of all kinds and satisfy his sense of hunger with predigested bread, milk and meat without augmenting the size of his boarding-house bill. If he is so inclined he can satisfy his desire for alcoholic stimulants without invading the precincts of saloons on his way to and from the meetings, and all that is asked by the exhibitors for his indulgences is the goodwill of the patrons after their return to their respective fields of activity. It is here where he can learn the names and uses of new instruments, apparatuses and splints minutely described and illustrated in catalogs which are distributed with a liberality bordering on actual extravagance. If any of the delegates came to Madrid with any such expectations and intentions they were certainly disappointed. The Madrid merchants and manufacturers either failed to grasp the opportunity or persisted in conducting their business in the usual everyday routine manner notwithstanding the streets of the city were thronged with 5,000 strange doctors from all parts of the world. The only exhibits and efforts at advertisement that I saw were by a Paris firm which dispensed Vichy water and distributed literature pertaining to its health-preserving and health-restoring qualities with laudable liberality, and a small stand where a sorrowful looking individual distributed circulars of a de luxe edition of Don Quixote. No books, no instruments, no proprietary medicines in sight. In speaking of the section work I emphasized the fact that demonstration teaching was not done to the extent it deserves. I must refer here to an exhibit in the surgical section of plaster models by Doctors Bockenheimer and Frohse, of Berlin, which represented the different steps of Bassini's operation for inguinal hernia as performed in Professor von Bergmann's clinic. A study of

these models imparted a full and detailed knowledge of the technic of the operation and demonstrated clearly the value of such object lessons in the teaching of operative surgery. Let me express the hope that this kind of section work will attain greater popularity at future meetings of medical societies, large and small, and more especially of the International Medical Congress.

*Social Entertainments.*—Spanish hospitality has become almost proverbial throughout the entire world. This national virtue is characteristic of all classes of society—high and low, rich and poor, educated and ignorant. The hospitality practised is of a charming kind, it is not a hospitality of the head but of the heart. The Spaniard makes you feel that the house you visit is your own, that the things you enjoy are furnished by you, in fact that you are the host and he the guest. The Spaniard is an ideal entertainer, a polished gentleman, refined in manners, whose pleasure it is to serve his friends. The spirit of the knighthood days lives in spite of time and great national and family reverses. It makes itself felt on the streets, in the mansions of the rich and the hovels of the poor, in places of public amusement, the market, shops, and especially in educational and charitable institutions. The members of the Congress regardless of nationality were made to feel that they were the guests of the nation. The royal family made its appearance on three different occasions for the benefit of the visitors. Few, if any, crowned heads would condescend to receive in his own palace several thousand people in one afternoon as was done by King Alfonso. The reception at the palace at three o'clock in the afternoon on the second day was a brilliant affair. The military men appeared in gala uniform, the ambassadors in court and citizens in full dress. At the entrance to the palace the visitors had to show the card of invitation. The delegates were grouped in different rooms according to nationality. The Americans were assigned to the dining-room, where they were met by Minister Hardy, who introduced the King to a number of delegates who occupied the front row, at the head of which stood Surgeon-General O'Reilly. The King was followed by his mother and Infanta Maria Theresa, both of them dressed in black, while the King wore a handsome uniform. He as well as his mother speak English and German fluently, and conversed in these languages with the members of the American delegation. We were all deeply impressed with the modest and genial manners of the young ruler of the old nation that has played such an important role in the drama of the Old World and made it possible for Columbus to find the new one. We Americans must never forget what Spain has done for us, we must ever keep in mind the jewels of Isabella, the Catholic. After the reception we were invited to visit different apartments and look at the wonderful collection of tapestry. In the afternoon at 4 o'clock, Wednesday, April 29, all of the delegates and ladies in attendance were given a garden party by the royal family. The spacious garden behind the palace was at its best. The soft green of the well-kept lawns, the new headdress of the giants of the forest, the flowers in all colors, the many fountains in action and the throng of at least 5,000 people in their best attire, made a picture that time will never efface from the memories of those who were privileged to witness it. Six bands stationed in different parts of the park-like garden played alternately while the people strolled about leisurely in the full enjoyment of a lovely spring day, made memorable by the environments and the hospitality of the King that prompted the occasion. The King entered the garden in a carriage accompanied by his mother and the two infantas. After leaving the carriage the royal party made its way through the dense crowd, addressing a few words to those standing near by as they passed along the principal avenues of the garden.

A splendid buffet lunch, including champagne, was served at a long table, around which several hundred people could be seated and help themselves at the same time. This garden party was one of the most pleasing features of the Congress and I am sure that every one who was present will remember with gratitude the royal host who, by his dignified manner and charming hospitality, added so much to the success and pleasures of the Congress. Of the section entertainments I can only speak of the military section. The afternoon was devoted to the

visiting of government institutions, notably the Military Hospital and the Laboratory of the Army and Navy. These visits always ended with a most excellent lunch, including the native wines and champagne. The section dinner was given in one of the dining-rooms of the Inglaterra Hotel. The Minister of War and a number of military and naval officers of the highest rank were present. The dinner was one which it would be difficult to duplicate in America. The parting speeches were numerous, in many languages, and most of them eloquent. Contrary to what we were made to believe before we entered Spain, after ample experience we had to come to the conclusion that the Spanish kitchen is a most excellent one. The rooms in the hotels are large and the beds not only comfortable but luxurious. Receptions by the mayor of the city and the Minister of the Interior and an opera party completed the list of entertainments.

The Committee on Entertainments very wisely excluded from the program the national sport—bullfighting. It is needless to say, however, that most of the delegates, including their wives, secured admission tickets in time and were in their seats at 4 o'clock Sunday afternoon when the first bull made his attack on the poor blindfolded horses, who looked in vain for protection from their stupid riders. The bull in turn was teased, worried and tired out when the gaudily dressed bullfighter (butcher) entered the ring to put an end to the misery of the half dead brute. This brutal sport was repeated six times before the program was finished. The Madrid bullfight is a tame affair compared with that of the City of Mexico, and it is safe to say that no foreign "congressiste" will ever care to witness another one. The royal family neither attends nor encourages this sport. For years repeated efforts have been made to suppress it and its days are evidently numbered. It is a relic of former days and so far as brutality is concerned it is no worse than the cockfights and football games so well patronized in our own country.

*Reflections.*—It is much easier to criticize mistakes than to avoid them. The local committees of the Congress did much creditable, hard work. The medical profession of Madrid and Spain at large was anxious to make the Congress a great success. In many things the efforts succeeded, in others they fell short of expectations. The government officials from the King down to the employes of the lowest grade did their duty. The railroads and steamship companies offered sufficient inducements by reduction of rates to secure a large attendance. Looking backward, it is not difficult to ascertain where better arrangements could have been made. The system of registration was very defective. No reliable bureau of information. Only two persons were in charge of the mail; it required both patience and perseverance to call for letters. The "Bureau de logement" assumed a difficult task when it undertook to secure desirable accommodations for the visitors. Many bitter complaints were made by members who were assigned to quarters outside of the hotels. The hotel guests had no reason for well-grounded dissatisfaction. The general program did not give the desired information. The titles of the papers for the sections were thrown together without any reference to the time when the papers were to be presented in the respective sections. The *Diario Oficial*, under the editorship of Dr. Enrique Salcedo, contributed something toward the remedying of this defect, but failed in doing away entirely with the existing confusion. The *Suplemento Diario Oficial*, containing the names and local addresses of the members, made its appearance on the day the Congress adjourned. Hence there was no way by which we could ascertain the addresses of friends we were anxious to meet and visit. Nine numbers of the *Diario* were issued, the last number the day after the Congress adjourned. The foregoing are some of the shortcomings of the Arrangement and Program Committees which should be remembered, and, if possible, avoided by those who will be placed in charge of the management of the next Congress. On the whole, however, we fared much better than we had reason to anticipate. The merits of the Congress overshadow the demerits, the pleasures, the disappointments. We can say with the editor of the *Diario Oficial* (Numero 8): "Le lien n'est pas opportun pour parler des fruits du Congrès, ils sont consignés dans les *Actes* qui seront comme un livre d'or, dans le

vaste champ des sciences médicales, mais nous pouvons bien dire que le XIV<sup>ème</sup> Congrès de Médecine, continue la glorieuse tradition des antérieurs et qu' il est l'honneur de notre Faculté."

Two evils threaten the future successes of the International Medical Congress. They are: 1. Too great laxity in the admission to membership. 2. Too large attendance. The elimination of the first evil will correct the second. The Congress should be strictly a delegated body. The appointment or selection of delegates should be restricted so that at no time the attendance would exceed 2,000. The selection of the delegates should be made by a committee of the National Medical Association of the countries seeking for representation, or in the absence of such by the governments. The doors of the Congress should be closed to laymen so far as membership is concerned. So far each Congress has had its full share of camp followers, who take advantage of reduced transportation rates, crowd the hotels, and never fail in taking in all the entertainments which are always given as a compliment to the doctors in attendance, as the present requirements for membership in the Congress are such that any one, professional and layman, who pays the stated subscription fee is admitted and is entitled to all the privileges accorded the delegates. There are few cities large enough to secure desirable accommodations for more than 2,000 to 3,000, hence the desirability of restricting the attendance. A change in this direction cannot be made too soon, and it is to be hoped that the authorities of the next Congress will consider this matter and formulate the regulations accordingly, inasmuch as the hotel accommodations of Lisbon are greatly inferior to those of Madrid and the other cities in which the Congress has met in the past.

The delegates returning from Madrid have much to be grateful for. We have seen Spain, her antiquities and works of art. We have seen her rugged mountains and fertile plains. We have seen the royal family, and have come in touch with her chivalrous, hospitable people. We have become familiar with her excellent charitable institutions, her schools and universities, and more than all this, we have established, I trust, a bond of permanent friendship between the Spanish and American medical profession.

In conclusion, I desire to extend my sincere thanks to Captain Juan Redondo, of the Spanish Navy, who was my constant companion from the time I arrived at Madrid until my departure, and through whose influence I received many courtesies and much valuable information, which, without his friendly intervention, would not have been obtainable.

MADRID, April 30, 1903.

**Roof Garden for Consumptives.**—Director Martin has recommended that a portion of the roof of the Philadelphia Hospital be converted into a roof garden where consumptives may sleep during the summer months in the open air. Not only will the roof serve as a sleeping place, but a portion will be set aside where work may be planned and done by the inmates. Flowers and shrubbery will be scattered on the roof and everything will be made as attractive for the afflicted patients as may be. It is believed that this is the first attempt to inaugurate this plan of open-air treatment on a large scale in the United States. Dr. Martin's plan will be watched with interest.

**Preparatory Course for Nurses' Training School.**—Beginning September 17, the Drexel Institute of Philadelphia will inaugurate a course of study and training for young women, which is designed to serve as a preparatory course for hospital training schools for nurses. The announcement says that the conviction among those who have given the matter special attention appears to be that this scientific knowledge could be more advantageously acquired if given independently of the professional work, and the general conclusion has been reached that if a preparatory course of training in the scientific branches, a knowledge of which is essential to a fully equipped nurse, should be provided, relief from the pressure upon the women in the first year of the training school can be obtained, while the standard for the education of nurses would be raised along the whole line. Instruction will be given in the following branches: Anatomy and physiology, medical chemistry, materia medica, domestic science and economics, English language, vocal expression, physical training. Among candidates for places in the various training schools of the city, preference will be given to those holding certificates of this institute. James McAlister, president of the Institute, and Dr. S. Weir Mitchell have been active in promulgating this course.

6.—**Ideals in Dental Education.**—C. C. Chittenden calls attention to the freedom of the schools in this country from domination by the medical profession. In Europe dentistry is treated as a mechanical art and tacked onto a background of medical didactics. Dental literature now demands high school graduation and four years of special training as the minimum standard. The fourth year is to be added to the curriculum during the present year. The schools should be relieved of the commercial handicap by union with properly endowed universities. Notwithstanding the raising of requirements there has been unprecedented prosperity. The writer deplors flagrant attempts on the part of schools in the N. A. D. F. to evade the rules. [H.M.]

7.—**Venesection.**—R. Reyburn points out that the class of cases benefited are chiefly those in which there is abnormal blood-pressure in the body which threatens the rupture of a cerebral bloodvessel or causes a stasis of blood in some vital organ. He specially considers its applicability in threatened apoplexy, in pneumonia and in uremia. [H.M.]

8.—**Leprosy.**—J. T. McDonald believes as the result of his experience that the microscope is the supreme agent in the final diagnosis of leprosy. No patient should be committed to a colony without this. Maculas, chiefly leukodermic spots, are found in 89% of all cases. The lepra nodule is found in 74% and is the chief distinguishing lesion of skin leprosy. Thinning or complete loss of eyebrows and lashes is present in 63%. Atrophic changes in hands and forearms with retraction and contraction of the fingers and enlarged ulnar nerve in 32% are leading features in nerve epilepsy. The plantar ulcer found in 26% is usually on the ball of the foot. Absorption of phalanges occurs in 16%, with occasional spontaneous amputation. Elephantiasis of hands and feet occurs in 16% and facial paralysis in 11%. The entire body should be tested for anesthetic areas. Several of the above symptoms can be found in some slight degree at least in every leprosy subject. [H.M.]

9.—**Chemistry of Cerebrospinal Fluids.**—T. Sollmann gives a table of his own findings and those of other investigators. The molecular concentration in three of his specimens was that of normal serum. There seems to be something in the fluid that protects the corpuscles against laking. The specific gravity is in all animals lower than that of serum on account of the small proteid content. The reaction is always slightly alkaline. Inorganic salts are in about the same amount as in serum and consist mainly of chlorid. Foreign salts can pass from the circulation into the cerebrospinal fluid, but the passage is slower than into other fluids. The reducing substance in the fluid gives all the tests of dextrose. The sugar disappears on standing. The proteid which it contains is globulin. The normal absence of albumin in a fluid containing globulin is apparently a unique phenomenon. The presence of albumin might be due to admixture of inflammatory exudate and have a diagnostic value. The proteid varies between wide limits, but  $\frac{1}{3}$  of the analyses show less than 2%. Diastatic ferment may be

present, although in less amount than in lymph or serum. [H.M.]

## Medical Record.

June 6, 1903. [Vol. 63, No. 23.]

1. Perforating Gastric and Duodenal Ulcers: Unilateral Exclusion of Duodenum for Perforating Ulcers of Its Posterior Wall. ALBERT A. BERG.
2. Results of Preventive Medicine in Providence, R. I., 1885-1902. FREDERICK S. CRUM.
3. Fatal Gastric Hemorrhage, with Autopsy. MARSHALL LANGTON PRICE.
4. The Local Treatment of Acute and Chronic Gonorrhoea. R. O. KEVIN.
5. Preliminary Report of a Successful Operation for the Radical Cure of Complete Prolapse of the Rectum of Sixteen Years' Duration in a Case of Primary Dementia. JOHN RUDOLPH KNAPP.
6. A Hint in Urinary Analysis for General Practitioners. LOUIS FAUGERES BISHOP.

1.—**Perforating Gastric and Duodenal Ulcers.**—A. A. Berg says the results of perforation depend on two factors: (a) rapidity with which the ulcerative process extends through the visceral wall; and (b) the site of the ulcer. A slow ulcerative process permits adhesions to form in advance. If ulceration is through the anterior wall of the stomach, extravasation takes place into the general peritoneal cavity with a resulting general peritonitis; if on the lesser curvature, or on the posterior gastric wall, there follows extravasation into the lesser peritoneal cavity, and no obliteration of liver-dulness, unless gas escape through foramen of Winslow, which is unusual; if on the posterior duodenal wall the extravasation will be most likely into the cellular tissue posterior to the viscus, the ascending colon, and the perinephritic space. In reference to symptomatology, the writer says perforation may be preceded by no symptoms, and it may not be attended by collapse, for the latter is dependent entirely upon extravasation, and not upon ulceration *per se*. The upper half of the abdominal wall is rigid and does not enter into the respiratory movement; at the time of perforation there is tearing pain in the gastric region; obliteration of liver-dulness depends on the site of perforation. Several hours after perforation the symptoms of septic peritonitis mask all the other symptoms. Abscess formation will result if extravasation takes place into the lesser peritoneal cavity or into retrovesical cellular tissue. The writer reports a series of four cases operated upon, two of the patients recovering. He says surgery has accomplished much in perforating ulcers, and promises more with earlier diagnoses and improved methods. Bolton Carter collected 59 published cases of perforating duodenal ulcers. Of these 27 died without operation, the lesion being found postmortem; of 32 subjected to operation, 11 recovered (34%); Lenander states that the statistics so far published (1898) show that one-fourth to one-third of the perforating ulcers of the stomach and duodenum are saved by operation, and that prognosis depends on the length of time that elapses before operation is undertaken, and on the extent and character of the peritonitis. [A.B.C.]

2.—**Preventive Medicine in Providence.**—The statistics from 1885 to 1902, presented by F. S. Crum, appear as evidence that improved methods of diagnosis and medical treatment have had more to do with improved mortality than sanitary science. In typhoid fever the ratio of deaths to cases has declined from 35.4% to 23.8%, while in the middle period of this

decline the number of cases per 10,000 of population increased. In diphtheria the average of deaths has decreased from 32.9% to 12%, while the number of cases has increased absolutely and relatively. The increase, however, may be partly accounted for by greater certainty of diagnosis and the greater vigilance of the health officials. In scarlet fever the decrease has been from 15.7% to 2.9%, while the number of cases during the middle period of the decline was double that in the first period. The ratio of deaths to cases has been uniformly highest for typhoid fever and lowest for scarlet fever. [H.M.]

**3.—Fatal Gastric Hemorrhage.**—M. L. Price reports the case. A man of 50 entered the hospital, and within a few minutes, in spite of stimulants and saline infusion, died, having had the cardinal symptoms of internal hemorrhage. Necropsy showed abundant blood in the stomach and intestines. The report, with reference to the stomach, is as follows: It is markedly distended, and on section fluid and partly clotted blood exudes to the amount of about two gallons. Near the cardiac end on the posterior surface is a large sloughing mass about 8 cm. long, 5 cm. wide. The entire mucosa in the neighborhood has sloughed away. Numerous foul-smelling granulations arise. The ulcer has perforated the stomach and is firmly adherent to the left lobe of the liver. This adhesion is firm and can be separated only by considerable force. On the outer surface of the stomach where adherent to the liver there is present an ulcerated area about 4 cm. by 3 cm. The base of the ulcer contains a mass of cauliflower granulations. The ulcer begins about 1 cm. from the esophageal opening, but does not involve the esophagus. Microscopic examination of the ulcerated tissue showed it to be due to colloid cancer. [A.B.C.]

**4.—Treatment of Acute and Chronic Gonorrhea with Argyrol.**—R. O. Kevin has during the past year had experience with some 2,500 cases of acute and chronic gonorrhea in the dispensary service of the Jefferson Hospital of Philadelphia. In the treatment of these he has used argyrol to the exclusion of the other silver salts. His several methods of using the drug, depending on the time, condition, complications, etc., are given in full. He closes with the conclusion that argyrol for both acute and chronic gonorrheal infection is the best and safest of the silver preparations. [A.B.C.]

**5.—Radical Cure of Complete Prolapse of the Rectum.**—J. R. Knapp reports the case. A man of 35, suffering from primary dementia and confined in the asylum for 16 years, had most of this time been confined to bed from a complete prolapse of the rectum. The prolapse could until recently be reduced by manipulation, but it recurred when the patient was in the erect posture, or had diarrhea, which was frequent. Since the bowel could of late not be reduced operation was deemed justified. Laparotomy was performed by an incision through the left rectus. The sigmoid was grasped, traction made, and the prolapse reduced without serious difficulty. The bowel was drawn fairly tense and anchored by several sutures to the abdominal wall near the lower angle of the wound. After-treatment consisted in liquid diet, elevation of the foot of the bed, binding up the bowels for several days, then evacuation by oft repeated small doses of salines, and rectal injections of oil. Within 24 days after the operation the patient was partaking of usual house diet, and somewhat later was going freely about the wards, having natural movements of the bowel without any sign of prolapse. Recovery seems complete and the general condition of the patient is much improved. [A.B.C.]

**6.—Urinary Analysis for General Practitioners.**—L. F. Bishop says in the physician's office laboratory two of the petty annoyances in testing for albumin are dirty test-tubes and specimens that need filtration. He says: Obtain a clean test-tube and a clear specimen; take an ordinary cotton tampon on a string, such as is used in gynecologic work, push it to the bottom of a test-tube with a stick or glass rod and pack it in firmly. Then pour the urine into the test-tube and pull the tampon out very slowly. This, on account of the atmospheric pressure, causes the urine to pass through the tampon and remain in the tube. The tampon carries out with it any particles that can be removed by filtration and at the same time cleans the inside of the test-tube. If there are several specimens to be filtered, the tampon can be rinsed under the faucet and used over again. The process can be repeated quickly two

or three times if the first filtration is not satisfactory. In detecting very small traces of albumin, a perfectly clean test-tube is of great importance. [A.B.C.]

8. Chronic Pneumonia. E. PALIER.

**1.—Backache.**—R. W. Lovett considers this condition from the standpoint of an orthopedic surgeon and divides the cases into two groups: (1) Those due to causes existing in the spine itself, and (2) those due to causes existing outside of the spine, as in the feet. The causes existing in the spine itself are either mechanical, or static, to be classed as faulty attitude; or occurring as the result of injury or inflammation. The pain which is the result of faulty spinal attitude is generally localized at one or more points in the spine; it is apt to be very severe and to be aggravated by exertion. In cases of long standing the diagnosis from such conditions as Pott's disease and arthritis deformans of the spine may be very difficult; an injury may be, and often is, the starting point of the affection. Treatment consists in improvement of the general condition, and in the severer cases, at first rest on the back most of the day is imperative; and when the patients are erect, some form of light elastic brace, to hold the spine extended, is advisable for a time. In cases of slight lateral deviation of the whole spine, due oftenest to a short leg, pain in the back or to one side of it is not uncommon. The correction of the short leg, by increasing the thickness of the sole, will, in many cases, do away with the backache. Sprains of the back are best treated by recumbency or at least by restricted use, the spinal movements being limited by a light brace. Gymnastics, massage and douching tend to restore the circulation. A plaster jacket should be used for a "chronic sprain" of the spine. The cases in which some mechanical difficulty in the foot is the cause of persistent and obscure backache are those of real flatfoot, pronated foot and contracted foot. The first two conditions should be treated by flatfoot plates. The third condition is characterized by a shortness of the muscles at the back of the calf. The pain is generally in the small of the back, and is aggravated by standing or stooping forward, although it also results from walking. It shoots down into the pelvis and thighs in some cases. It is essential in these cases to support the arch of the foot and to stretch the calf muscles. The contraction usually yields readily and a few stretchings give relief to the symptoms in most cases. [C.A.O.]

**2.—Cocain Herniotomy.**—Alexander Syer considers the various steps in the radical cure of inguinal hernia by substituting cocain anesthesia for general narcosis. Fifteen such operations have been performed by the author with good results. Twelve of these cases were simple inguinal hernia, one was congenital, and two were irreducible epiploceles, in which it became necessary, after freeing the attachment between the omentum and the sac, to tie off and remove, in one case 6 ounces, and in the other 8 ounces of omentum. One-half of 1% solution of cocain was used for the skin. The nerve-trunks were picked up in most cases and a few minims of one-quarter of 1% cocain solution injected into the sheath. In no case had  $\frac{1}{2}$  grain of cocain been exceeded in the whole operation. The author uses the Bassini method in all respects excepting the treatment of the sac, in this he uses the Macewen method. [C.A.O.]

**3.—The Essentials for Aseptic Labor.**—A. E. Gallant says the absolute essentials for aseptic labor are: (a) A good-sized handbag, to be used for this purpose and no other; (b) stocked with the necessary drugs; (c) steam-sterilized gauze, gown, and cotton ball sponges; (d) hand brushes, silk-wormgut, rubber gloves, and catheter, ready to be boiled in plain water; and (e) a set of metallic instruments to be boiled

in soda solution when needed. The hand cleaning can best be accomplished (without antiseptics) by the liberal application of the tincture of green soap, rubbed thoroughly into the dry hands and arms (two or three coats); then, when they are thoroughly coated and dry, scrubbing with a stiff brush, in running water, until all traces of soap have been scrubbed away. Before applying forceps or making a vaginal examination the parts must be cleansed as thoroughly as the hands. [C.A.O.]

**4.—The Eye and General Disease.**—N. D. McDowell discusses briefly the diseases of the eye which occur during the progress of the general diseases. Paralysis of the ocular muscles and those of the lids are not uncommon in diabetes mellitus. Keratitis and iritis are also met with. Cataract occurs in about 15% of all cases of diabetes. The anemias are a fruitful source of asthenopia, and hemorrhages in the retina as a result of the anemia present in many general diseases are not uncommonly met with. One of the most frequent eye complications of the disorders of the digestive tract in children is phlyctenular inflammation of the conjunctiva and cornea. Constipation and consequent straining at stool has led to hemorrhages in the conjunctiva and retina, and, according to Berger, has brought on an attack of acute glaucoma. Gonorrhoeal ophthalmia with a destructive keratitis resulting is a frequent complication of gonorrhoea, and iritis often accompanies gonorrhoeal rheumatism and gonorrhoeal inflammations of the joints. Magnus alleges that about 2% of blindness is due to syphilis. In both the congenital and acquired forms of syphilis the uveal tract is usually the part attacked. About 50% of our cases of iritis are due to this disease, and usually the attack occurs during the secondary stage. Interstitial keratitis is the most common eye complication of congenital syphilis. Edema of the lids, conjunctivitis, keratitis, and paralysis of the ocular muscles occur in parotiditis, and like the testicle, the lacrimal gland may be the seat of inflammation. Before the introduction of vaccination it was asserted in Germany that 35% of all cases of blindness was due to variola; now, according to Fuchs, only about 2% may be assigned to this cause. The ocular lesion most frequently met with in diphtheria is the partial or rarely complete paralysis of accommodation. After typhoid and other exhausting fevers there is sometimes marked weakness of accommodation. [C.A.O.]

**5.—Röntgen Ray Treatment of Sarcoma of the Kidney.**—C. H. Richmond reports a case of supposed sarcoma of the left kidney in a woman of 40 apparently cured by Röntgen ray treatment. She received daily treatments of 15 minutes each for 19 consecutive days. At the end of this time the temperature was nearly normal, night sweats had lessened, the tumor had apparently ceased to grow and seemed softer, her appetite was good, she slept well, and the pulse had improved. She was then removed to a hospital and treatment continued for nine weeks, when the growth had entirely disappeared, so far as could be determined, and the patient had apparently recovered perfectly. [C.A.O.]

**6.—Urogenital Tuberculosis.**—Two cases are reported by C. G. Cumston to demonstrate the pathogenesis of ascending and descending urogenital tuberculosis. The first case is that of a man of 30, who had been a sufferer from pulmonary tuberculosis for years. The seminal gland became involved, but the process appeared to remain stationary there for some time and then it extended slowly up the spermatic cord. The seminal vesicle then became involved. The next organ attacked seemed to be the prostate, and from this point it would appear that the infection traveled toward the ureter directly by the lymphatic system, and more especially concentrated its attack upon the right kidney by direct extension of the process. At the autopsy the right kidney was found enlarged, with an adherent capsule and important destructive ulcerative changes. The ulceration found in the bladder appeared to have occurred after the kidney became involved. The second case is that of a woman of 27, who gave the history and presented the signs of a cured tuberculous process in both pulmonary apices. A large bunch of tuberculous glands in the axilla were removed by extensive dissection, and an uninterrupted recovery followed. Two years and a half later the urinary apparatus became involved. She lost considerable blood from the bladder, and complained of

pain both before and after passing urine, and a constant desire to urinate. Palpation of the left kidney showed that it was involved. At this time a gland in the axilla that had not been removed was found to be involved. Nephrectomy was done and the typical macroscopic lesions of advanced chronic tuberculous nephritis found. Twelve days later the patient died. [C.A.O.]

**7.—Hereditry and Tuberculosis.**—Maurice Packard and L. L. Roos have reviewed the literature of this subject thoroughly and from the cases reported by different authors and experimental researches they conclude that tuberculosis can be hereditarily transmitted both by way of the placenta and the spermatic fluid. [C.A.O.]

**8.—Chronic Pneumonia.**—E. Palier reports such a case in a girl of 19. When first seen she had a temperature of 103° F., pulse 130, headache and lassitude with some sore throat. Scattered rales were heard in the lungs. The case was then considered one of grip. One month later the temperature was about normal, but the pulse was 130. On examining the lungs there was found dulness and bronchial breathing on the left side, from under the scapula to the base of the lung and as far anteriorly under the axilla and under the nipple as the lung tissue extends. Two months later there was scarcely any change in her condition. Sodium benzoate with guaiacol carbonate was prescribed for the lung trouble, and nux vomica and iron was given as a tonic. Fresh air but not much exercise was advised. Recovery gradually followed. Her sickness lasted about five months. Palier believes that this affection is frequently mistaken by physicians for tuberculosis. [C.A.O.]

2.—See *American Medicine*, Vol. V, No. 23, p. 898.

3.—**Bacteriuria Resembling Weil's Disease.**—G. R. Satterlee presents a case in which the original picture was that of acute febrile jaundice. There was a severe general infection which must have caused degenerative changes in the liver as well as the kidney cells and which showed itself in prolonged weakness and general muscular pains during convalescence. Experiments with a bacillus isolated from the urine showed it to be toxic to guineapigs and in a lesser degree to rabbits. Acute hepatitis was marked in all cases that came to autopsy. Acute nephritis was also found. In the animal which survived the inoculation the urine showed bacteriuria with albumin and casts. [H.M.]

4.—**Pelvic Suppuration in the Female.**—A. Brothers divides pelvic suppuration into adnexal and connective tissue. Pelvic inflammation precedes suppuration, and only in a small proportion of cases produces pus. In the course of 18 years, experience he has seen hundreds of cases of pelvic exudates disappear without operation. He has seen only 5 cases of pelvic suppuration under 20 years of age, and 5 beyond 40 years. Of 91 cases studied on the operating table, there were of gonorrhoeal origin alone 33; the same associated with abortion, 4; puerperal origin, 25; traumatic, 25; appendicular, 3; tuberculous, 1. Twelve cases of pyosalpinx were due to manipulation in office practice, such as violent examination of diseased women, use of sound for diagnostic purposes, and use of cervical dilators to cure sterility. Although small pus collections may undergo spontaneous absorption, lose their virulence and remain innocuous, or may occasionally discharge themselves into the uterine cavity, still there is only one legitimate method of treatment for pelvic suppuration, and that is surgical. As a rule Brothers prefers the abdominal route for pelvic suppuration, though a pelvic abscess bulging through the vaginal vault, no matter what its origin, is clearly a case for vaginal section and drainage. As the result of his experience he lays down these rules: 1. To prevent suppuration, examina-

tions in patients suffering from any variety of pelvic inflammation should be made gently and infrequently. 2. The use of sounds and cervical dilators, under ordinary circumstances, should be restricted to the operating-room where the parts can be thoroughly prepared and the operator, nurse, and instruments thoroughly asepticized. 3. After a gonorrhoeal pus-tube has been removed, the woman must be warned of the possibility of the invasion of the opposite side, if she takes the chance of reinfection from the diseased male. 4. Abscesses, irrespective of their origin, when pointing above or below, should be treated by simple incision and drainage. 5. Sacculated abscesses presenting the characteristics of intraperitoneal tumors should be treated by laparotomy, without unnecessary delay. [w.k.]

#### EDITORIAL COMMENT

**The Etiology and Pathology of Beriberi.**—The literature of this obscure affection is so voluminous and the multiplicity of supposed etiologic factors so great that new communications anent the subject are apt to be regarded with suspicion. Very suggestive, however, is the recent report of the Institute for Medical Research of the Federated Malay States. The report is an exceedingly lucid summary, arranged in terse numbered paragraphs, of a geographic study of beriberi extending over nearly a year, and includes an enormous number of tabulated statistics. An exceptional opportunity for studying the disease was afforded by the gaol at Kwala Lumpur, which contains from 400 to 500 prisoners, and furnishes 100 cases of beriberi yearly. Certain blocks in the gaol were isolated in order to determine if the disease was brought by recently entered convicts or arose within the gaol. The result of eleven months' observation has convinced Director Wright that beriberi is independent of diet considered as diet; that the gaol itself is a focus in which the virus of beriberi is generated; and that beriberi is an infectious disease. A concise statement of Wright's views is best given in his own words: "The theory of the causation of beriberi that fits the above facts and all others observed in British Malaya is that beriberi is due to a specific organism which gains entrance to the body via the mouth; that it develops and produces a toxin chiefly in the pyloric end of the stomach and duodenum, and that the toxin being absorbed acts atrophically on the peripheral terminations of the afferent and efferent neurons. Further, that the specific organism escapes in the feces and lodges in confined places through accident or careless personal habits of those affected by this disorder, and that in the presence of congenial meteorologic, climatic and artificial conditions of close association from overcrowding, the organism becomes virulent and gaining entrance to the healthy body in food, etc., contaminated by it, gives rise to an attack of the disease." Wright classifies the disease as acute pernicious beriberi, which is always fatal; acute beriberi, which lasts from three to six weeks and leaves the patient paralyzed, and beriberic residual paralysis, which persists after the specific virus has ceased to act. The entire report, which is preliminary in nature, bears evidence of being a genuine research instead of an attempt to prove a preconceived theory. As such it is a valuable contribution to the recent literature of a subject about which much is written and comparatively little known.

#### REVIEW OF LITERATURE

**Cancer and Heredity.**—The interesting problem of hereditary transmission of cancer has been studied by W. N. Geinatz.<sup>1</sup> This question has more than a merely theoretical importance in view of the prevailing tendency among laity and certain physicians to admit hereditary cancer. As a result we not infrequently see persons who have had the misfortune to lose a near relative from carcinoma become mentally unbalanced by the fear of imminent danger to themselves. The number of such cancerous neurasthenics appears to be quite large, and while some of them really succumb to the dreaded disease the majority make themselves and their friends miserable and spend their time in waiting for the sword of Damocles to fall. This state of affairs makes a study of the question very desirable and our author from his own investigations into literature asserts that there is no evidence in support of the hereditary theory, at least in a great majority of cases. Exceptions may be disregarded in formulating a general rule. The percentage of cancer among individuals having no cancerous antecedents is even greater than among descendants of cancerous individuals. Hence the fears of such descendants are entirely unreasonable. Cancer may be acquired by intercourse with its victim, that is, a contagiousness cannot altogether be denied, but no disposition to the disease is inherited. The sooner we annihilate the hereditary belief the better, since new lines and fresh encouragement will then be offered to prophylaxis. Whatever the cause of cancer, whether microorganisms or chronic irritation or unsuitable food, an intelligent struggle with the disease must gain additional zest from the conviction that it is not a hereditary affection. [L.J.]

**Diverticulum of the Esophagus.**—J. McFarland and J. M. Swan<sup>2</sup> report a case of diverticulum of the esophagus, of the pulsion variety. The patient had been under observation for about six years, but the diverticulum was not diagnosed until at the postmortem. It was situated on a level with the cricoid cartilage, and when in the relaxed condition measured 5 cm. by 3 cm. (2 in. by 1 in.). The points of greatest interest in the case are (1) the existence of a diverticulum of the esophagus, which gave rise to recurrent attacks characterized by the symptoms of an acute infection, in the intervals of which, except for regurgitation of food, the patient was fairly comfortable; (2) the existence of all the evidences of dilation of the stomach during life, with the finding at autopsy of a small and contracted organ. [A.G.E.]

**Prurigo Lymphatica.**—Buschke<sup>3</sup> reports the case histories of three patients, all of whom complained with violent itching of the skin; had enlarged lymph-glands, pruriginous and urticarial eruption over the extensor surfaces of the skin, many pigmented scars, enlarged spleen, slight albuminuria, small petechial hemorrhages in different parts of the body, no anemia, leukocytosis or lymphocytosis. The author is inclined to consider these cases related to Hebra's prurigo, from which it differs by the greater diffuseness of the eruptions, although it limits itself to the extensor surface, and the onset occurring late in life; but neither he nor other observers have been able with positiveness to exclude pseudoleukemia and tuberculosis of lymph-glands. The prognosis of the condition is unfavorable as regards recovery, the best which has been attained thus far being temporary improvement. [E.L.]

**Action of Morphin on Gastric Secretion.**—H. Holsti's<sup>4</sup> method of investigating this question was to administer  $\frac{1}{2}$  to  $\frac{1}{4}$  grain of morphin with a test-meal, then obtain the gastric contents at various intervals of time, and determine the amount of free HCl. The results were compared with the normal amount, of HCl previously determined for each person experimented upon. The first effect of the morphin was to diminish the gastric secretion, the degree of diminution varying greatly. In most cases this primary decrease was quickly followed by a variable increase in secretion. In some cases morphin was administered without food and on an empty stomach, the results showing a stimulation of gastric secretion. Continuous

<sup>4</sup> Zeitsch. für klin. Med., Bd. xlix, p. 1.

use of morphin was found to diminish the acidity of the gastric contents, and also to disturb gastric motility. [B.K.]

**Seventy-one Attacks of Acute Psychic Disturbance in Alcoholics (50 Individuals).**—Feldman's<sup>1</sup> paper is a statistical report of 71 attacks of delirium tremens during acute alcoholism, observed in the insane department of the municipal hospital at Stuttgart. He has found but few complications, and notes only one death. He states that delirium tremens patients should be treated in hospitals instead of insane asylums, inasmuch as the disease is usually of short duration, and the treatment in hospitals promises to be more appropriate. [E.L.]

### EDITORIAL COMMENT

**Popular Confidence in Surgery Increasing.**—As before announced in the columns of this journal we have no sympathy with the faddists who claim that intractable neurasthenia, hysteria, confirmed gastric irritability and dyspepsia will soon be recognized as affections for surgical treatment. Popular confidence in the efficacy of surgery within its proper limits is, however, quite another matter. It is not many years since every patient was wont to approach the operating table only as a last means of saving life, and only then when death was imminent. The modern introduction of comparatively safe anesthesia; the more recent introduction of methods having to do with asepsis and antisepsis; a vast array of lives saved, and much suffering relieved, almost without pain, by surgical means, have had a wonderfully transforming effect upon the popular mind. That Sir Frederick Treves alone can report many more than 1,000 *interval* operations for chronic appendicitis; that Kocher can report *thousands* of operations for the extirpation of goiter, many of which would doubtless never have proved fatal; that many other surgeons can report operations by hundreds for gallstones, in many instances of which the patients had not suffered from nerve-racking gallstone colic—all serve as a sufficient commentary upon the change in the popular mind with reference to the dangers of surgical procedure. When the late President McKinley died in spite of able surgical treatment those were not wanting, even in the profession, who gloomily predicted that in the eyes of the public surgery would suffer as a consequence. If the popular mind was at all influenced by this unfortunate termination, confidence was more than restored by the more brilliant results in a comparatively simple operation upon King Edward. Recently a prominent New York financier suspended all business operations, called a surgeon and with perfect confidence in the result asked to have his appendix removed. The case was notable not because of the request but because of the prominence of the individual. Such requests are by no means curiosities to those connected with hospital practice. The equanimity and almost absolute trust with which patients often submit to the advice of the surgeon is remarkable. In fact, among women there is what might almost be called a condition of "over confidence," in that they frequently seek operative treatment for conditions, fancied or real, which surgery cannot remedy. Summing the matter up, it is plainly evident that popular confidence in the efficacy of surgery and in the surgeon has greatly increased within the past few years; that persons afflicted with probable surgical maladies are coming more and more to be guided entirely by the judgment of the surgeon; that these facts have among others this advantage, that malignant and other diseases in which time is an important factor will meet with more prompt and efficacious treatment. Let the conduct of surgeons, however, be such that this increasing confidence shall be warranted—shall increase, not diminish.

## REVIEW OF LITERATURE

**Traumatic Cyst of the Pancreas, with Recovery; Traumatic Diabetes.**—K. Pichler<sup>1</sup> reports the case of a cyst of the pancreas in a man of 37. He based his diagnosis upon the history of a violent blunt injury to the upper part of abdomen, followed by collapse; the development within a few weeks of a large resistant dull mass between stomach and transverse colon; and the physical appearance of fluid withdrawn from the mass by puncture. At the operation the cyst wall was sutured to abdominal wall and punctured. It contained 10 pints of a dark-red fluid. The cyst cavity was packed with iodoform gauze. During his convalescence the patient developed glycosuria, which lasted fully a month, and was most likely due to inflammatory irritations of other parts of the pancreas. Convalescence was protracted, but recovery was ultimately complete. [E.L.]

**Angioneurotic Erythema and Its Surgical Treatment by Neurectomy.**—Three cases of this somewhat rare disease are detailed by J. C. Bloodgood.<sup>2</sup> Case I is summarized as follows: Angioneurotic edema of both cheeks, secondary to drainage of the antrum cavities, relieved by neurectomy of the infra-orbital nerves. A second area, on the left side of the abdomen, relieved by the division of the intercostal nerves. A third area, in the lower abdominal zone, still under observation. Case II, angioneurotic edema of the mastoid. Case III, angioneurotic edema of the elbow-joint has been reported previously. In the first case the areas of erythema differed from the usual cases of angioneurotic edema, first described by Quincke, in the persistence of the vasomotor dilation. The case is considered remarkable in its multiple areas and in the persistency of the erythema. It is of interest surgically because of the thus far permanent relief after neurectomy. [A.G.E.]

**A Case of Tumor of the Prostate.**—G. Kapsammer<sup>3</sup> reports the case of a man of 40 suffering from sarcoma of the prostate, whose first symptom was complete urinary retention four weeks before digital and systoscopic examination revealed any change in the size of the gland; as first symptom of the tumor this retention is, therefore, very curious. During the life of the patient many pieces of the tumor were discharged by urethra. The tumor was found to be a round-cell sarcoma, with islands of hyalin cartilage. [E.L.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### EDITORIAL COMMENT

**The Dangers of the Curet.**—The apparent simplicity of the operation of curetage makes it often dangerously attractive to the tyro in gynecologic surgery. It is hard for him to realize that this procedure is one of the most important in the treatment of pelvic disease, that there are certain indications and also positive contraindications as to its performance. To be able to say whether curetage is indicated is to be able to run the entire gamut of pelvic diagnosis, to estimate uterine mobility, to ascertain the presence or absence of tubal disease, and to handle instruments with precision and delicacy. The number of reported accidents and the far greater number of unreported ones from the curet, plainly indicate that its use is fraught with danger to the patient. In the presence of pelvic inflammation or puerperal infection without the retention of secundines, its use may render acute a chronic inflammatory process, or open avenues for reinfection in a quiescent or subsiding infection. Opie mixed his paint "with brains" and brains are required in using the curet. The use of the instrument is therapeutic, to remove diseased endometrium; and diagnostic, to determine after thorough dilation of the uterus the presence of intrauterine growths, or in cases of supposed suspected malignancy of the body of the uterus to remove scrapings of tissue for

<sup>1</sup> Wiener klinische Wochenschrift, December 25, 1902.

<sup>2</sup> Johns Hopkins Hospital Bulletin, May, 1903.

<sup>3</sup> Wiener klinische Wochenschrift, January 29, 1903.

examination. In cases of puerperal infection following labor, it is better to use the finger to explore the interior of the uterus and remove fragments of retained tissue; and after the organ has once been thoroughly emptied, the physician should refrain from meddlesome intra-uterine manipulation. We firmly believe that the unwise use of the curet increases the morbidity and the mortality in puerperal sepsis.

#### REVIEW OF LITERATURE

**Heredity in Syphilis.**—R. Matzenauer<sup>1</sup> treats in the first part of his article of hereditary syphilis as acquired from the mother. The portals of infection may be a syphilitic ovum, or through the placental circulation. The fetus may be infected at any stage of gestation as late as the eighth month, but the earlier this occurs the graver the result for the child. Infection before the fifth month usually terminates in abortion, premature labor, death of child, etc., while those infected late may even be apparently healthy at birth. He denies that infection directly through the father has ever been demonstrated, and after opposing the arguments for and against such a possibility, comes to the conclusion that no exception to Colles' law has ever been reported. All the cases for which such an exception is claimed rest upon easily demonstrated errors. Therefore, every mother of a congenitally syphilitic child is without exception immune, because she already has syphilis, if not in a demonstrable, at least in a latent form. There being, therefore, no congenital syphilis from nonluetic mothers, it follows that every such mother, although she may present no symptoms at all, must be given antisymphilitic treatment; she may nurse her child without fear of infection. Syphilitic parents may bring about infection of a previously healthy child. A syphilitic man should, to prevent his wife's infection, undergo repeated courses of treatment during several years. [E.L.]

**Vulvovaginitis in Children.**—W. J. Dukelsky<sup>2</sup> distinguishes two kinds of vulvovaginitis in childhood—the infectious and the noninfectious. The infectious variety is in 80% of all cases produced by gonococci, while diplococci and other as yet unknown bacteria are responsible for the remaining 20%. There are certain characteristic features in the symptoms and course of these types. Thus the gonorrheal variety is invariably chronic though beginning acutely; it is furthermore apt to be complicated with Bartholinitis, which does not occur in the other varieties. The form of vulvovaginitis due to diplococci and the unspecified bacteria is characterized by an acute course and rapid recovery. Finally, the noninfectious form is always catarrhal and chronic. The disease is, according to the author, most frequently given to the children by their mothers, and it seems that the little ones are susceptible irrespectively of their general health. Infection may even take place during labor. Whenever the transmission is direct, as in sexual abuse, the resulting disease is usually very severe and apt to present serious complications. [L.J.]

**Certain Forms of Menstrual Suffering and the Action of Potassium Permanganate Therein.**—W. Stephenson<sup>3</sup> describes conditions in which there is a disturbance of the balance normally maintained between the venous and arterial systems. In some venous distention may show itself in the legs which before a period become full and heavy, the veins standing out, occasionally becoming varicose. In others there is entire suppression of the flow, or the latter is doubled or it may come in black stringy clots. Headaches occurring once a week or oftener sometimes have been due in the beginning to vascular changes associated with the mensal cycle. The writer uses potassium permanganate in 2-grain doses three times daily in such conditions for both diagnosis and treatment. This restores function, regulates the periodicity, checks the flow when excessive, and affords relief to pain. It is necessary in some cases to administer the drug continuously for six months. [H.M.]

#### TREATMENT

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPLEMAN

#### REVIEW OF LITERATURE

**Serotherapeutic Treatment of Basedow's Disease.**—O. Lanz<sup>1</sup> reports four other cases of exophthalmic goiter in which the milk of goats from which the thyroid gland had been removed was used with considerable advantage and improvement. He acts upon the theory that exophthalmic goiter being due to a hypersecretion and absorption of thyroid juice the disease should be materially improved if an excess of poison neutralized by this secretion is given the Basedow patient. He therefore produces cachexia strumipriva in goats and feeds their milk to patients with exophthalmic goiter. [E.L.]

**Voluntary Respiratory Ventilation in Convalescents from Pulmonary Disease.**—Tissier (Pneumotherapy: Cohen's System of Physiologic Therapeutics, Vol. x) contends that there is always an indication to ventilate the lungs, to stimulate their circulation, and to strengthen their resistance, whenever the latter has been impaired by any cause, such as a sedentary mode of life, or certain diseases of the lungs. During convalescence from bronchopulmonary affections, the need of increasing the amplitude of the respiration by inducing a more vigorous action of the respiratory muscles is imperative. For when these muscles have been maintained in a state of relative inactivity by an affection that causes shortened respiration, they tend to fall into a state of atrophy, in the same way as do the muscles in the vicinity of a diseased joint. The patient, at first compelled by his disease to restrain the respiratory movements, sometimes keeps up this habit of lessened functional activity after every physical obstruction to the expansion of the lungs has disappeared. Convalescence from pneumonia might often be materially shortened if the patient could be made to practise deep respiration from the beginning, thus inducing in the pulmonary vesicles the activity necessary for their nutrition. At first every organ the seat of an inflammatory disease is functionally at rest; in fact, it is to a certain degree in a condition of paresis, of inactivity, which diminishes its functional capacity, apart from any structural condition capable of inhibiting its activity. This functional inactivity is always observed in the respiratory organs; but, in addition, the disease, whatever its nature, almost always leaves behind some anatomic traces that can be made to disappear only by exercise. The lung invaded by pneumonia must resume the full measure of its normal function as early as possible, in order that the nutrition of the vesicles may recover its previous activity, which is the best preventive of chronic pneumonia and the best protection against the tubercle bacillus. In pleurisy, prompt return to deep and vigorous respiratory movements is the only means of preventing the formation of adhesions that threaten to bind down the lung. It also effectively prevents the thoracic walls from falling in as the effusion is absorbed. Finally, after all inflammatory diseases, there persist disorders in the pulmonary circulation, a tendency to stasis, to passive congestion, against which no means is known to be more efficacious than extensive and profound respiratory movements. These movements act upon the contents of the capillary vessels of the lungs like the piston of a suction-pump in accelerating the flow of blood. But exercise in disorders of the respiratory apparatus influences not only the contents of the chest; it often has the effect of modifying the shape of the thoracic cage by mobilizing the osseous parts that compose it. The indication to restore the normal shape of the thorax is often present when a chronic pulmonary affection has habituated the lung to greatly restricted movement. These habits of restricted respiration have permitted the costovertebral and costosternal articulations to fall into a certain degree of ankylosis, which, at the end of a number of years, renders extensive respiratory movements impossible. The functional insufficiency of the thoracic bellows is also frequently observed in the old, as age is accompanied by stiffening of the ligaments, disappearance of the synovial fluid, and ossification of the articular cartilages.

<sup>1</sup> Münchener medicinische Wochenschrift, January 27, 1903.

There is an indication in all these cases to induce movements in the costal articulations, just as one does in the case of an ankylosed joint.

**FORMULAS, ORIGINAL AND SELECTED.**

**Two Prescriptions for Enuresis.**—Sheffield<sup>1</sup> has found the following combination useful in incontinence of urine due to atony:

- Fluid extract of ergot . . . . . 12 cc. (3 drams)
- Fluid extract of rhus toxicodendron. 4 cc. (1 dram)
- Five to ten drops every four to six hours for a child of 6.

In incontinence due to hyperesthesia of the neck of the bladder he recommends the avoidance of irritating foods, the use of the sitzbath, and antispasmodic treatment, as:

- Fluid extract of hyoscyamus . . . . . 2 cc. (30 minims)
- Sodium bromid . . . . . 4 grams (1 dram)
- Anise water . . . . . 30 cc. ( 1 ounce)
- Syrup enough to make . . . . . 60 cc. ( 2 ounces)
- Teaspoonful every four to six hours for a child of 6.

Counterirritation (mustard plasters) over the lumbosacral region is also useful. [H.C.W.]

**THE PUBLIC SERVICE**

**Health Reports.**—The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended June 6, 1903:

**SMALLPOX—UNITED STATES.**

		Cases	Deaths
Alabama:	Mobile . . . . . May 23-30 . . . . .	6	
California:	Los Angeles . . . . . May 16-23 . . . . .	1	
	San Francisco . . . . . May 17-24 . . . . .	1	
	Jacksonville . . . . . May 24-31 . . . . .	3	
Florida:	Pensacola . . . . . May 16-23 . . . . .	2	
	Baker County . . . . . May 16-23 . . . . .	1	
	Columbia County . . . . . May 16-23 . . . . .	3	
	Levy County . . . . . May 16-23 . . . . .	5	
	Washington Co. . . . . May 16-23 . . . . .	1	
Illinois:	Belleville . . . . . May 23-30 . . . . .	4	
Indiana:	Evansville . . . . . May 23-30 . . . . .	1	
	Indianapolis . . . . . May 23-30 . . . . .	4	1
	Des Moines . . . . . May 21-30 . . . . .	1	
Iowa:	New Orleans . . . . . May 23-30 . . . . .	8	
Louisiana:	Paiten . . . . . May 27 . . . . .	1	
Maine:	Baltimore . . . . . May 23-30 . . . . .	1	
Maryland:	Fall River . . . . . May 23-30 . . . . .	16	
Massachusetts:	Holyoke . . . . . May 23-30 . . . . .	1	
	Detroit . . . . . May 23-30 . . . . .	9	
Michigan:	Grand Rapids . . . . . May 23-30 . . . . .	3	
	Winona . . . . . May 23-30 . . . . .	2	2
Minnesota:	St. Louis . . . . . May 24-31 . . . . .	3	
Missouri:	Helena . . . . . May 1-31 . . . . .	3	
Montana:	Omaha . . . . . May 23-30 . . . . .	1	
Nebraska:	Nashua . . . . . May 23-30 . . . . .	8	
New Hampshire:	New York . . . . . May 23-30 . . . . .	3	
New York:	Cleveland . . . . . May 23-30 . . . . .	1	
Ohio:	Hamilton . . . . . May 23-30 . . . . .	3	
	McKeesport . . . . . May 23-30 . . . . .	3	1
Pennsylvania:	Philadelphia . . . . . May 23-30 . . . . .	41	7
	Pittsburg . . . . . May 23-30 . . . . .	19	3
		Four cases imported.	
South Carolina:	Charleston . . . . . May 23-30 . . . . .	1	
Tennessee:	Memphis . . . . . May 16-30 . . . . .	4	
Utah:	Salt Lake City . . . . . May 23-30 . . . . .	6	
Washington:	Tacoma . . . . . May 25-June 1 . . . . .	2	
		One case imported.	

**SMALLPOX—FOREIGN.**

Austria:	Prague . . . . . May 2-16 . . . . .	14	
Belgium:	Antwerp . . . . . May 9-16 . . . . .	7	
	Brussels . . . . . May 2-16 . . . . .		4
	Ghent . . . . . May 2-16 . . . . .		*2

	Karachi . . . . . Apr. 26-May 3 . . . . .	187

**Changes in the Medical Corps of the U. S. Army for the week ended June 6, 1903:**

**BROWN, IRA C.**, contract surgeon, is granted leave for twenty-five days, from about May 25.

**APPEL, Major DANIEL M.**, surgeon, now at San Francisco, Cal., will proceed to Denver, Colo., and report to the commanding general, department of the Colorado, for further orders.

**DUVAL, First Lieutenant DOUGLAS F.**, assistant surgeon, is granted leave for two months on surgeon's certificate.

**HART, JAS. W.**, contract surgeon, will proceed from Fort Washington to the artillery district of Portland and report to the district commander for assignment to a station where his services may be needed. At the close of the maneuvers he will return to Fort Washington with the 37th company.

**DAYWALT, GEO. W.**, contract surgeon, will, upon the arrival at Fort Schuyler of Assistant Surgeon Chas. N. Barney, proceed to the artillery district of Portland and report to the district commander at Fort Preble for temporary duty at Fort Levett. When his services are no longer required in connection with the army and navy maneuvers, he will, when relieved by the district commander, return to his station.

**MAUS, Lieutenant-Colonel LOUIS M.**, deputy surgeon-general, extension of leave granted April 24, is further extended twenty days.

**STRAUB, Captain PAUL F.**, assistant surgeon, leave granted January 29 is extended fifteen days.

**GREENLEAF, First Lieutenant HENRY S.**, assistant surgeon, leave granted May 12 is extended one month.

**JUENEMANN, GEO. F.**, contract surgeon, now in Washington, D. C., will proceed to Fort Columbus for duty.

**CHAFFEE, First Lieutenant JEROME S.**, assistant surgeon, resignation accepted to take effect July 1, 1903. Leave to include July 1, 1903, is granted, to take effect upon his relief from duty at Fort Porter.

**DE WITT, First Lieutenant WALLACE**, assistant surgeon, now under treatment and observation at Fort McPherson, will proceed to Fort Porter for duty, to relieve First Lieutenant Jerome S. Chaffee, assistant surgeon.

**COLLINS, First Lieutenant G. L.**, assistant surgeon, is granted leave for ten days, from about June 14, 1903.

**Changes in the Medical Corps of the U. S. Navy for the week ended June 6, 1903:**

**BAKER, M. W.**, assistant surgeon, detached from the Naval Academy and ordered to the Brooklyn—May 29.

**GROVE, W. B.**, passed assistant surgeon, detached from the Naval Dispensary and ordered to the Naval Hospital, Philadelphia, Pa.—May 29.

**FARENHOLT, A.**, passed assistant surgeon, detached from the Independence and ordered to the Boston—May 29.

**PICKRELL, G.**, surgeon, detached from the Naval Academy and ordered to the Texas—June 2.

**AMES, H. E.**, surgeon, detached from the Texas and ordered to the Naval Academy—June 2.

**LUNG, G. A.**, surgeon, detached from the Naval Hospital, Philadelphia, Pa., and granted sick leave for three months—June 3.

**DUNCAN, G. F.**, acting assistant surgeon, ordered to duty with Recruiting Party No. 3—June 3.

**KEENE, W. P.**, acting assistant surgeon, ordered home to wait orders—June 3.

**Changes in the Public Health and Marine-Hospital Service for the week ended June 4, 1903:**

**BROWN, B. W.**, passed assistant surgeon, to proceed to Memphis, Tenn., for special temporary duty—June 1, 1903.

**WICKES, H. W.**, passed assistant surgeon, granted leave of absence for one day June 10—June 4, 1903.

**GREENE, J. B.**, passed assistant surgeon, granted leave of absence for eight days from June 10—June 2, 1903.

**LUMSDEN, L. L.**, passed assistant surgeon, bureau order of May 26, 1903, directing him to proceed to San Juan, P. R., for temporary duty, amended so that he shall be relieved from duty at New Orleans, La.—May 29, 1903.

**KING, W. W.**, assistant surgeon, granted leave of absence for two months from June 10—June 2, 1903.

**ROBERTSON, H. MCG.**, assistant surgeon, granted leave of absence for seven days from May 29, 1903, under paragraph 191 of the regulations.

**GOLDSBOROUGH, B. W.**, acting assistant surgeon, granted leave of absence for seven days from June 3—May 29, 1903.

**SINCLAIR, A. N.**, acting assistant surgeon, granted leave of absence for twenty-five days from June 24—June 3, 1903.

**TAPPAN, J. W.**, acting assistant surgeon, granted leave of absence for one month from May 25—June 3, 1903.

**ALLEN, G. C.**, pharmacist, granted leave of absence for seven days from May 29, 1903 under paragraph 210 of the regulations.

**MASON, M. R.**, pharmacist, relieved from duty at San Francisco, Cal., and directed to proceed to Dutch Harbor, Alaska, for special temporary duty; thence to Nome, Alaska, and report to acting assistant surgeon in charge for temporary duty—May 29, 1903.

VOL. V, No. 25.

JUNE 20, 1903.

\$5.00 YEARLY.

**Waterborne Infection and the Chicago Drainage Canal.**—It is said that even angels have pleasure in saying "I told you so," and Dr. Reynolds may certainly be pardoned a just degree of self-satisfaction in sending out to friends and critics the "Report of Streams Examination" of the sanitary district of Chicago. It is a pity he could not have secured the cooperation of the St. Louis governmental and health authorities. The regret is tempered by the thought that if the results had been as convincing and as fully stated as those of the published reports of the laboratory of the city of Chicago and of the University of Chicago, the printer's bill would have been higher and the reviewer's duties harder to bear. In a word, the present reports may be summarized in Professor Burrill's words, that "the studies in detail and as a whole tend strongly to show that neither before nor after the opening of the Sanitary Canal had the drainage waters from the city of Chicago for the period covered by this report any appreciable effect bacteriologically upon the waters of the Mississippi river. Even if the waters of the Illinois river at its mouth were proved to be a source of contamination to those of the Mississippi, the above statement would still seem to hold good, because of the conditions shown to exist at Averyville and Pekin. It is still more clearly apparent that Chicago sewage cannot be held responsible for the contaminations existing in the commingled waters of the Mississippi and Missouri rivers."

**Pathogenic Bacilli and the Chicago Drainage Canal.**—We are not of those who think the drainage of city sewers should be into the streams. There are better methods, and far more economical, of disposing of the most valuable and most wasted nitrogen, as has been fully demonstrated. And even if the present problem of contamination and spread of disease is temporarily disposed of, it is only postponed by using the rivers as sewers. The growth of the population of the country will surely bring the question up again. In the meantime Dr. Reynolds' thorough-going report certainly seems to answer the contention of the Mississippi river cities in a convincing manner. Professor Jordan concludes as follows:

Considering the problem as a whole, it must be remembered that it is not so much the history of the nitrogen compounds that is significant, especially where conditions are so

intricate as in the present instance, as the story of bacterial life. If the question be plainly put as to whether typhoid bacteria or similar pathogenic microbes are likely to pass from Chicago to Grafton in the water of the Illinois river under any of the conditions prevailing during our investigation, it must be plainly answered that all the evidence that we have been able to secure is against such an occurrence. A study of the deathrate among the colon bacteria added to the river water in sewage lends no countenance to the view that typhoid bacteria will survive passage down river. The facts indicate that the colon bacteria, which are present in such large numbers in Chicago sewage—undoubtedly in much larger numbers than typhoid bacilli—disappear almost completely in less than 150 miles' flow. Since all investigators are agreed that the colon bacillus is more hardy than its relative, the typhoid bacillus, and can live in water for a longer time, there is every reason for supposing that the latter microbe dies out with at least the same rapidity. Even were typhoid bacteria found in the water at the mouth of the Illinois, there are scores of communities to which they might certainly be more plausibly traced than to Chicago.

**Deaths from Plague of Laboratory Workers.**—As a result of accidental infection the death of Dr. Sachs, of Berlin, a worker in the Koch laboratory, is reported. In 1898 Professor Nothnagel and his assistant, Dr. Barisch, contracted the disease in Vienna in the same way. The latter died, as did also his attending physician, Dr. Müller. In studying the disease in 1899 Professor Pestana, of the Bacteriologic Institute of Lisbon, was infected during an autopsy conducted at Oporto. Two days after returning to Lisbon he experienced symptoms of the dreaded disease. He ordered his own isolation in a special ward of the hospital, and made a record of every detail of his illness that could be useful to his assistants. Foreseeing the end, he left instructions for a postmortem examination, the disinfection and burial of his body, and for the transmission of various data to the Pasteur Institute in Paris. He died giving an imperfect lecture on his own case. Other cases, though not ending fatally, have occurred. It is said that the German government has stopped further laboratory investigation of plague, but the report may be doubted. The deadliness of the disease makes it all the more a duty to carry on experimental study, and men with the scientific instinct and moral courage to do so should at least not be prevented from risking their lives, of course under rigid rules as to dissemination of the germs, in a work of such great importance to civilization.

**The annual Fourth of July noise and slaughter** is beginning earlier, continuing longer, and growing more frightful each year. Officers, and especially the health officers of cities, should ponder well the article published on "Fourth of July Tetanus" by Dr. Wells in *American Medicine*, June 13, 1903. In Chicago the health commissioner a month before the craze should begin, already reports during the five preceding weeks 7 deaths from tetanus due to firearms, toy pistols, etc. In last year's entire season there were only 12, and in 1901 when the Mayor's proclamation was enforced the number was reduced to 4. It had been 24 in 1900. Health officers should issue popular directions how to treat such wounds, as Dr. Reynolds has done. The *Journal of the American Medical Association* says that the greater number of cases follow bad treatment of physicians, who do not act with scientific thoroughness. "The responsibility lies with the physician who first sees the wound." The selling or use of the deadly and misnamed toy pistol should be punished. And one day is enough! If mayors cannot be made to do their duty as to this single day let them rigorously prevent criminal folly from beginning a month or two before and dragging on for a month after the fatal day of "celebration."

**The Suppression of the Truth as to Plague in California.**—The report on this subject of the Oregon State Board of Health, by its secretary, Dr. Woods Hutchinson, has reached us too late for publication synchronously with that of the society. The history of the shameless suppression of the truth by the previous State officers of California is retold without fear or favor, and confirms a useful lesson that should prevent any repetition of the experience. Dr. Hutchinson describes the beginning of the suppression of the truth as follows:

As soon as the first plague case was clearly identified by autopsy and cultures, the United States Marine-Hospital inspector at San Francisco sent a telegram to the then secretary of the State Board of Health of California, Dr. Matthews; he promptly came down in person, saw the specimens, slides, and cultures, accepted the diagnosis, and said that it was just what he had been expecting. A joint meeting of the Marine-Hospital inspector, the City Board of Health of San Francisco, and the State Board of Health, as represented by the secretary, was held that same evening. The existence of plague was unanimously conceded, and a set of resolutions drawn up for publication announcing the fact, and the usual notification ordered to be sent to the other State Boards and inspectors. To the astonishment of the mover and seconder of the resolutions these appeared in the San Francisco papers the next morning just as passed, with the trifling exception that in every affirming clause a negative was inserted, making them state that the plague did *not* exist in San Francisco, and that it was *not* necessary to notify the other boards of health of any danger from infection.

How similar methods were used until the present administration came into power are described in the body of the report, and these, in a general way, are familiar to our readers. In another column we give Dr. Hutchinson's recommendation as to the sterilization of Chinatown.

**Of Poisons and Poisoning.**—The repeated occurrence of murder in some of its most revolting forms has within the present year but too prominently engaged

the attention of the public of Great Britain, both lay and medical. And the number as well as the variety tends, unhappily, to show that the extension of liberty and the widespread distribution of education and general intelligence leave still a full share of employment for the criminal lawyer as well as for the moral and the religious teacher. The fact that the struggle for life is increasing in intensity, while the limitations of individual action have been lessened and the facilities for mischief and the knowledge of the methods by which it can be effected have been made more easily attainable, tend to maintain the uniformity of the statistical record of some of the most atrocious forms of crime, even in presence of all the philanthropy and altruism of our advanced civilization. Throughout the cosmopolitan arena of human emulation there has, at all times, necessarily existed the universal endeavor of each individual to disable or disarm his antagonist. At every period of history force has been the usual weapon of the strong and fraud of the weak. Before the development of civilization bloodshed was always and everywhere freely resorted to. As communities increased in numbers and life became more settled, mutual concession and adaptation became absolutely necessary. Accordingly, more subtle methods of mutual injury and destruction were discovered and adopted. Poisoning was, therefore, of later practice than the destruction of life by the shedding of blood. It was also a weapon of the weak rather than of the strong; of the subtle and intellectual rather than of the violent and the coarsely energetic. For these reasons it became a method of the Oriental and subtropical resident rather than of the inhabitants of the northern and western countries; and of the female rather than of the male; of the oppressed rather than of the conqueror. Instances of the utilization of the destructive powers of certain preparations of antimony against human life have of recent years been brought very prominently under the notice of the English-speaking world, notably in the medicolegal investigations of the celebrated "Bravo case," and of the still more gruesome Chapman atrocities, which were revealed in London a short time ago. The very existence of poisons forms, indeed, one of the specially mysterious items in the methods and purposes of an inscrutable Providence. We know that every powerful medicinal agent is a "poison." Even common table salt has proved a fatal poison when taken in large quantities on an empty stomach. And the properties of every one of the more deadly poisons present, in each individual instance, something weirdly interesting in their characteristic peculiarities. If we turn to the products of the vegetable kingdom we there find the active crystalline principles of the aconite ("monkshood") digitalis ("fox-glove") and belladonna ("deadly nightshade") occupying the foremost rank by right of their deadly destructiveness. The "alkaloids" which modern chemistry has extracted from those plants are the most fatal to animal life of any (merely chemic) agents known to modern science. Those of the two former are, even in the present state of experimental knowledge, decidedly difficult to trace in the body after death when present in but small quantities and not sought for till after complete absorption.

from the gastrointestinal surface has taken place. In the latter years of his life Sir Robert Christison, professor of medical jurisprudence in the University of Edinburgh, used to relate to his class at lecture certain of his medicolegal experiences as an "expert witness" in this connection. He was *the* great toxicologic authority of his generation. Accordingly his skilled evidence was frequently in requisition. On one of those occasions, when undergoing cross-examination regarding the possibility of satisfactorily recognizing poisonous substances sought for in the dead body, he turned to the judge and said: "My Lord, there is but one deadly agent of this kind which we cannot satisfactorily trace in the human body after death; and that is—," when the judge at once interrupted him with: "Stop! stop! Mr. Christison, please; it is much better that the public should not know it." It was afterward remarked by more than one of his then student class that Lamson, who was afterward executed for the poisoning of his nephew by aconitin, was a member of his audience, and was exceptionally careful in taking notes on one of those occasions when Professor Christison was explaining to his class that aconitin was the poison which he had been prevented by the court from naming.

**Indecent and fraudulent advertisements in newspapers** are expressly disapproved of by the grand jury of Buffalo, which says that "by lending their influence to fleecing the credulous and unwary instead of protecting the interests of the public by exposing such frauds or refusing such advertisements" the newspapers are abettors of the crimes of their advertisers. In all large cities and many small ones there are daily appearing invitations to the most degraded rottenness and immorality. In a majority of country newspapers throughout the United States, and in a multitude of crank journals, these vile notices of abortifacients, obscene literature, self-confessed frauds, etc., make up a large part of the disgusting advertising columns, freely placed in the hands of every woman and child. The alcoholic nostrums constitute another portion. Without the money derived from these criminal practices these good-for-nothing periodicals could not live. But just as plainly they are mostly illegal. The difficulty is to get the law enforced by prosecution of the offenders. Remonstrance will usually prove unavailing, but not always, and self-respecting editors and publishers should be persistently appealed to by physicians and their friends. The more thorough-going reform will come from the action, if it can be aroused, of medical societies, and by appeals to the Postmaster-General. One-half the periodicals now issued have no right to the use of the United States mails.

**The Doctor's Vacation.**—By common consent this season of the year has become the vacation period for nearly all classes of society and the number who take vacations is yearly becoming greater. For one reason or another the practitioner of medicine and surgery often feels that he cannot take advantage of this important means of storing up strength for a year's work. Some members of the profession would make the excuse that they can not afford it, more would say that they find it

impossible to get away from their practice. In most cases neither of these excuses is really adequate. While few of us ever accumulate very much money, physicians as a class are in comfortable circumstances and could, without great sacrifice, spare a few extra dollars for a short season of rest and recuperation. And as to getting away from practice, few men are so situated that they could not turn over their practice to a friendly neighboring practitioner, to some recent graduate, or even to an advanced student of medicine. Fortunately the early summer season is usually a healthy one and the average doctor would find less occasion for conscientious scruples about turning his practice over into the hands of another for this reason. Thirty or forty years ago vacations were not considered essential by any considerable portion of the people of this country, but this period has long gone by. Life is becoming more strenuous, competition greater in all lines of work, and men generally are coming to realize the necessity for shorter hours of labor, for occasional periods in which to build up a supply of energy for a hard year's work. The medical profession is no exception to the general rule, in fact, men in few occupations are probably so generally overworked or in as great need of a change. The vacation is a good investment of time and money, and every member of the profession should take advantage of the first opportunity when practice is a little slack to get away for a few weeks' holiday.

**"Expectorate" and "Spit."**—Commissioner Lederle has received letters objecting to the use of the word "spit," in the ordinances and advising the word, "expectorate." When President Roosevelt was police commissioner he strenuously urged the use of "spit," and called "expectorate" "a vile word." One must side with the President in this matter, in a general way, although it might be permissible to add that etymologically speaking "sputum" and "expectoration" may designate two different excreta. The sputum (allied to *splatter*) may be from the chest or may not be, although this is not the question in mind when framing the ordinances. The sanitarian does not aim at a differentiation. People who "expectorate" will probably "perspire" instead of "sweat." That some officials do find a distinction where others do not is shown by the fact that in an eastern city the following notice is displayed in the street cars: "Passengers must not expectorate nor spit on the floor of this car." "Expectorate" is morbid alike in a medical, a philologic, and a social sense, but no charge can be made by philology against "spit." According to the editor of "Literary Notes" of the *British Medical Journal* the only advantage "expectorate" can claim is that it once incited a good pun: "Some one speaking to a lady of a friend of whom it might have been said that he had no manners and his customs were beastly, gave an example that he would not hesitate to expectorate in her presence. She at once replied, 'Then he cannot expect to rate as a gentleman.'" Nowadays, even the spitter must expect berating.

**The relation of sunshine and the deathrate** is more than suggested by the last report of the bulletin of

the Chicago Department of Health, which says that there has been a drop of more than 21% in one week, and of 9.8% under the average June deathrate of the previous ten years. In Chicago since the first of the year there has been but a little more than one-half (55.8%) of "possible" sunshine. In January there was only 45%; in February, 55%; in March, 52%; in April, 60%; and in May, 67%. The increasing amount in the last two months, with the certainty of a continuing increase during the next two months, strengthens the hope and belief that there will be a diminishing deathrate and an improving condition of the public health for some time.

"An honest pensioner" is thus described by the *Baltimore Sun* and the *Chicago Tribune*: When requested by the Pension Bureau to explain how he incurred physical disabilities, he sent in the following minutely graphic statement:

The way I got my war ingyry was a ketchin of a hog. The Hog war a sow hog and ur captain wanted her for forege. We was chasin the sow, and she crawled threw a hoal in a rale fence. It war a big hoal, and I thot I war about the sis of the hog, and tried to crawl threw, but I stuk and trin' to wigle out I throve the rales off and one hit me on my hed and nocked me senseless. I do not think the sow pig had nothing to do with my line of duty, for I did not kech the hog. Wich she never war caut.

Napoleon is reported to have said that "an army travels upon its belly," and if the commissary department is a prime necessity in war then one may hope this frank and honest old soldier may get his pension. In spite of himself he was "acting in the line of his duty," "he done the State some service," or would have done it. It is a pity "she never war caut."

## EDITORIAL ECHOES

Combined effort appears to be a distinguishing feature of this new twentieth century. This is seen in nearly all forms of civic and commercial life, and even scientific and professional effort. It would seem that when the history of the twentieth century is written there will be lacking those great and single characters looming way above the average, leading, directing, or dictating; instead there will be an elevation of the average, the best individual effort will neither in purpose nor effect aggrandize the individual, but will be exerted in connection with other effort of like nature for the establishment of a parity of well being among all. This, I take it, will be the keynote of our action, bearing constantly in mind the actual results to be attained and being determined to attain them.—[Dr. Walter Wyman.]

**Limits the Spread of Diphtheria.**—What the Pasteur Institute considers the most effective blow yet dealt diphtheria consists in a discovery just formally announced to the Academy of Medicine by Dr. L. Martin, with the collaboration of Dr. Roux. Martin has found that Roux's famous antidiphtheric serum can be administered to patients in the form of pastilles or bonbons as well as by means of subcutaneous injection. Dr. Martin explained to the Academy that the serum is useless for the destruction of the bacilli during the convalescent stage of the disease. Throughout that period the throats of patients are still full of contagion—a condition which is responsible for the fearful spread of the disease. By direct contact of the pastilles with the throat the bacilli are destroyed—an effect obtainable in no other way. The Academy passed a vote of honor to the discoverer, whose experiments have left no doubt of the validity of his theory.

## AMERICAN NEWS AND NOTES.

### GENERAL.

**Tired of the Experiment.**—The experiments which Dr. Wiley, chief of the Chemical Division of the Agricultural Department, has been conducting on a number of volunteers for the purpose of testing the effects of borax and other preservatives in food will be suspended on June 30. The list of volunteers has fallen from 12 to 7, and there have been many complaints since warm weather began from the government boarders, who want a change of diet.

**Married Woman's Liability.**—The *New York Times* says: "A judgment recovered by Herbert Hazard on an assigned claim of Drs. Emory M. Wadsworth and Stuart H. Benton against Mrs. Caroline Potts for medical services has been reversed by the Appellate Term. The court holds that a married woman is not liable for medical attendance rendered to her husband and his family unless in the first instance she pledged her personal credit to the attending physician."

**Plague Increase in Manila.**—From Manila comes the following: Assistant-Surgeon Heiser says the number of cases of plague has been steadily increasing of late. With the view to preventing its spread to other parts of the islands and to the United States, it has been deemed necessary to fumigate with sulfur in order to kill rats and vermin, the entire shipping which enters and leaves this port. This is a very large undertaking, and taxes the station force to its utmost limit. The Board of Health is cooperating on land in this matter. They have employed a number of rat-catchers, and pay a five-cent bonus for every rat delivered to them. In addition they contemplate inoculating every Chinese with Shiga antiseptic serum.

### EASTERN STATES.

**Trenton's Attack on Mosquitos.**—Trenton has begun a crusade against the mosquito along lines laid down by Professor Smith, State Entomologist, who made an inspection of the city at the request of the Board of Health. Professor Smith said he had no doubt that the malaria prevalent in Trenton could be traced to the mosquitos that breed in the swamps around the Florence Mission.

**Massachusetts Medical Society.**—The one hundred and twenty-second anniversary of the Massachusetts Medical Society was celebrated in Boston on June 10, a large number of medical men being in attendance. Since the last meeting, 42 members have died, and 173 members have been admitted. A number of well-known physicians contributed important articles and the meeting was a decided success.

**Mortality in Connecticut.**—From the report of Dr. Charles P. Linsley, secretary of the State Board of Health in Connecticut, it appears that pneumonia is the cause of more deaths in the State of Connecticut than is tuberculosis. His report says that there were 1,264 deaths in Connecticut during May, 1903, being 164 more than in the same month last year, and 156 more than the average number of deaths in May for the five years previous. Dr. Linsley said that pneumonia is now the cause of a larger mortality than tuberculosis in Connecticut. During the past five months there were 570 deaths from tuberculosis to 845 from pneumonia.

### NEW YORK.

**Summer Rest for Sick Girls.**—A New York exchange states that St. Andrew's Convalescent Hospital for Women and Girls has been closed for the summer, but the managers have opened a summer rest at Woodcliff, Bergen county, N. J., where patients will be received for two weeks, or a longer period if necessary.

**The Gudsell-Bedell Bill.**—*Charities* for the week ended May 23 severely criticises Governor Odell, of New York, for approving the Gudsell-Bedell bill. It appears that the Governor's explanation of his signature is weak in some particulars. He is quoted as saying "It (the bill) seeks to prevent the erection of such hospitals without the consent of the Board of Supervisors of the county or the board of the town in which the hospital is to be erected." *Charities* says "By substituting or for and, the Governor has taken away much more than half the iniquity of the measure." Unfortunately, the act as approved requires the consent of both county and town authorities. The law before the enactment of the present measure required the consent of the local Board of Health and the approval of the State Commissioner of Health. According to the Governor's explanation, this bill substitutes for the State Commissioner of Health, the local Board of Supervisors of the county, and for the local Board of Health the town board. The journal just quoted states that the bill makes no such substitution. It does not substitute one set of consents for another, but adds new ones. The act does not repeal earlier provisions of the health law, but clearly adds others. The measure is considered very inimical to the interests of New York City, and it is virtually prohibiting the erection of hospitals for tuberculosis outside of the city limits."

## PHILADELPHIA, PENNSYLVANIA, ETC.

**Discontinuance of the Philadelphia Medical Journal.**

—In its issue for June 13 the *Philadelphia Medical Journal* announces its consolidation with the *New York Medical Journal* and its removal to New York. The statement is made that "the reasons for this change are entirely administrative."

**Pupils Must be Physically Sound.**—It is stated that all children hereafter entering the public schools in Camden will be required to undergo a physical examination; at least a recommendation to this effect has been made to the Board of Education by the instructor in physical training in that city. Those found unfit to enter school will be recommended for treatment.

**The Board of Education Committee on Hygiene has adopted a resolution** that all applicants for admission to the Philadelphia Normal school or the school of pedagogy and applicants for examination for certificates to teach or for positions as teachers in the public schools of Philadelphia shall be required to furnish certificates of physical fitness, each certificate to be signed by a physician appointed by the Committee on Hygiene.

**Vaccination.**—Concerning those in the city who refuse to be vaccinated, Dr. Martin is quoted as saying: "The names and addresses of those whom the physicians find out and who have not been and will not allow themselves to be vaccinated will be sent to the department. Should the disease continue to spread the entire square in which the persons live who refuse to be vaccinated will be placed and kept under quarantine until the disease leaves the ward."

**Smallpox in the Twenty-eighth Ward.**—A house to house vaccination in the Twenty-eighth ward has been ordered by Dr. Edward Martin, Director of Public Health, to check the spread of smallpox, which lately has increased to an alarming extent in that ward. Dr. Martin said that he did not consider a wholesale fumigation of residences in the locality necessary, but felt that the application of extraordinary precaution in the houses where diseases of that class are now under treatment would suffice and stop the contagion spreading.

## SOUTHERN STATES.

**The LaGrange Sanatorium** opened March 25. The building is of three stories and there are accommodations for 12 patients. An able corps of consultants are in attendance.

**Rabies.**—The Georgia Pasteur Institute, in Atlanta, now has 17 patients under treatment, which is the largest at any one time since its establishment. Rabies is asserted to be much more prevalent than usual in the South.

**Health Conditions in New Orleans.**—Dr. Kohnke, chairman of the Board of Health of New Orleans, has submitted his report, which in part is as follows: "That the health conditions of New Orleans are progressively and persistently improving is again shown by the mortality statistics for the last month. During May of the present year there occurred 614 deaths as against 656 for May of 1902. The total mortality during the five months of this year shows a decrease as compared with the record of last year of 152. A decreasing mortality in the face of an increasing population means, of course, much more than the mere figures given imply."

## WESTERN STATES.

**Deathrate in Chicago.**—The mortality rate in Chicago during the first week of June took a sudden turn for the better. The decline amounted to a little more than 21% from the previous week, making the rate for the past seven days 9.8% less than the average June deathrate of the previous 10 years, and 5.7% less than that of the corresponding week of 1902.

**Pneumonia in Chicago.**—The Chicago Bulletin of the Health Department for the week ended May 31 says: "Since the first of January there have been 2,891 deaths from pneumonia, as compared with 1,321 from tuberculosis and 1,238 from all other communicable, contagious, or infectious diseases, including diphtheria, erysipelas, influenza, measles, puerperal fever, scarlet fever, smallpox, typhoid fever, and whooping-cough. This is an excess of 382 pneumonia deaths over the deaths from all the other preventable diseases—1,570, or 118.8% more than the deaths from tuberculosis, and 1,653, or 133.5% more than those from the other specified diseases."

**Notice to Milk Dealers.**—The Bulletin of the Chicago Health Department, week ended June 6, gives the following as a notice placarded on milk platforms from Dr. Reynolds, Commissioner of the Health Department, to milk dealers: "Shippers' cans must be returned to farmers clean and dry. All vessels used in handling milk should be scalded or sterilized daily. All milk bottles should be washed with hot soap suds, rinsed in clean water, and then sterilized in boiling water or live steam before milk is put in them. No dealer can expect to hold his bottle trade unless he does this. If possible every dealer should visit the farm where his milk is produced, so he can assure his customers that it is produced under clean and healthy conditions."

## FOREIGN NEWS AND NOTES

## GENERAL.

**Slot Machines for Patent Medicines.**—It is said that in Paris patent medicines are to be dispensed by means of slot machines. The physicians are making a vigorous protest against the innovation, claiming that it will be attended with much danger, since the wrong drug may be easily dispensed.

**Government Prohibition Against Plague Germs.**—From Berlin comes the following news: In consequence of the death from plague at the Berlin hospital of Dr. Milan Sachs, the young Viennese physician, the government has decided to issue a decree forbidding further experiments with plague germs, the risk of spreading infection being considered more dangerous to the public health than the knowledge gained in studying the deadly microbe justifies. Dr. Sachs caught the plague in Dr. Koch's bacteriologic laboratory for infectious diseases. The laboratory is isolated, and the most minute precautions are taken at the doors and windows to prevent the escape of the germs. No one is allowed to approach or enter the building except the investigators.

**Motor Intoxication.**—The *St. James Gazette* says: "The opinion of Dr. Forbes Winslow, the eminent specialist on brain disorders, that the racing motor has outdistanced the powers of the man who drives it, is borne out by the fact that a new disease called 'motor intoxication' has been discovered by the savants of Paris. It is the temporary mental disorder of speeding automobilists. M. Hachet Souplet, at the last meeting of the Société d'Hypnologie et de Psychologie, spoke of the intoxicating effect of rapid motor locomotion. The mental and moral states of the driver become abnormal. He grows vindictive, furiously aggressive, and lets himself be carried away by the angry impulse of the moment. The high rate of speed works him up into the very same state of mind which makes the habitual drinker of alcohol regardless of consequences."

**Plague in Bombay.**—From an exchange we take the following: "Captain Harris, master of the British steamer, 'Queen Alexandra,' which lately arrived from Bombay, said that 2,009 deaths were reported in that city in the week ended April 21, from the bubonic plague and smallpox. On the following week the deaths numbered 1,747. Although deaths as the result of the plague have always occurred in Bombay, the disease first began to rage as an epidemic about January 1. Since then the health authorities have waged a constant battle against it. The number of deaths is gradually becoming less as the season advances, the warm weather aiding the efforts of the physicians in checking its progress. Most of the bodies are burned in accordance with the provisions of the natives' religion, and for this reason little trouble is experienced in disposing of the dead. Captain Harris said that the sanitary regulations in Bombay could not be surpassed. The natives, however, huddle together and are not particular about their personal cleanliness. The disease is confined to them almost exclusively."

## OBITUARIES.

**John N. D. Shinkel**, in Friar Point, Miss., May 26. He was graduated from the Rush Medical College, Chicago, in 1885. He was a member of the American Medical Association, Mississippi State Medical Association, Mississippi State Board of Health, Tri-State Medical Association, and he had also served as vice-president of the International Association of Railway Surgeons.

**John F. Golding**, in Brooklyn, N. Y., June 7, aged 49. He was graduated from the College of Physicians and Surgeons, New York City, in 1875. He was professor of osteology, and also held the chair of theory and practice of pharmacy in the College of Pharmacy. He was a member of the Kings County Medical Society and of the Kings County Pharmaceutical Society.

**Edward P. Luce**, at Bayonne, N. J., June 12, aged 75. He was graduated from the Cincinnati College of Medicine and Surgery in 1862, and afterward served as surgeon in the United States army during the Civil War.

**Charles F. Hamlin**, in Medway, Mass., May 16, aged 34. He was graduated from Medical School of Maine, Bowdoin College, Brunswick, in 1892, and was a member of the American Medical Association.

**Leon H. Armstrong**, formerly an acting assistant surgeon in the United States navy, died at Atlantic City, N. J., June 11. He was graduated from the Jefferson Medical College, Philadelphia, in 1871.

**Samuel S. Scott**, in Erlanger, Ky., May 22, aged 77. He was graduated from the Medical College of Ohio, Cincinnati, in 1854, and served as surgeon in the Confederate service during the Civil War.

**Mark T. Loope**, at Spokane, Wash., May 22, aged 46. He was graduated from the Baltimore Medical College, in 1893, and was a surgeon of the Northern Pacific Railway.

**William Caldwell**, at Rockville, Md., June 6, aged 41. He at one time occupied the chair of anatomy and physiology in the West Virginia University at Morgantown.

**Edward M. Kanouse**, of Wausau, Wis., died at Three Rivers,

Wis., May 25, aged 60. He was graduated from the Hahnemann Medical College, Chicago, in 1880.

**Bernard C. Nunez de Villavicencio**, in New Orleans, La., May 21, aged 64. He was graduated from the University of Pennsylvania, Philadelphia, in 1865.

**Nicholas Pfelfer**, in Lindenhurst, Long Island, N. Y., May 24, aged 83. He was graduated from the Penn Medical University, Philadelphia, in 1883.

**John R. Van Horn**, in Clay City, Ind., May 23, aged 42. He was graduated from the Georgia School of Eclectic Medicine and Surgery, Atlanta, in 1894.

**Augustin Thompson**, of Lowell, Mass., June 8, aged 67. He was graduated from the Hahnemann Homeopathic College, Philadelphia, in 1867.

**Joseph B. Cutts**, in St. Louis, Mo., May 18, aged 83. He was graduated from the Medical School of Maine, Bowdoin College, Brunswick, in 1842.

**Max J. Reingold**, in Williamsport, Pa., May 12, aged 47. He was graduated from the Hahnemann Medical College, Philadelphia, in 1879.

**W. O. Bullock**, in Lexington, Ky., May 18, aged 61. He was graduated from the Bellevue Hospital Medical College, New York City, in 1869.

**Asa E. Hoskinson**, in Columbus, Ohio, May 19, aged 45. He was graduated from the Starling Medical College, Columbus, Ohio, in 1883.

**John A. Bitting**, in Sherman, Texas, May 14, aged 50. He was graduated from the Jefferson Medical College, Philadelphia, in 1874.

**Edgar T. Schmidt**, in St. Paul, Minn., May 17, aged 48. He was graduated from the Jefferson Medical College, Philadelphia, in 1876.

**William R. Irons**, in Allegheny, Pa., May 24, aged 42. He was graduated from the Jefferson Medical College, Philadelphia, in 1890.

**R. B. McCants**, in Demopolis, Ala., May 28, aged 45. He was graduated from the Southern Medical College, Atlanta, Ga., in 1882.

**Gustave Boncher**, of South Brooklyn, N. Y., May 21, aged 57. He was graduated from the Royal University of Naples, Italy, in 1864.

**Henry Klemm**, in St. Louis, Mo., May 24, aged 61. He was graduated from the St. Louis College of Physicians and Surgeons, in 1882.

**James M. Park**, of Little Rock, Ark., May 15, aged 51. He was graduated from the Eclectic Medical Institute, Cincinnati, in 1871.

**Joseph T. Moreland**, of Atlanta, Ga., May 22, aged 56. He was graduated from the Chattanooga (Tenn.) Medical College in 1901.

**James I. Lamar**, in Deatsville, Ala., May 11, aged 73. He was graduated from the Medical College of Georgia, Augusta, in 1851.

**S. E. Farnsworth**, in Minneapolis, Minn., May 21, aged 65. He was graduated from the University of Vermont, Burlington, in 1867.

**Tyson Smith**, at Kalamazoo, Mich., May 11, aged 55. He was graduated from the Homeopathic Hospital College, Cleveland, in 1881.

**Samuel H. Thompson**, of Arlington, Texas, May 20. He was graduated from the University of Tennessee, Nashville, in 1892.

**James F. Rawlings**, in Eldorado, Ill., May 13, aged 34. He was graduated from the Medical College of Ohio, Cincinnati, in 1891.

**Charles Cochran**, in Los Gatos, Cal., May 25, aged 86. He was graduated from the Willoughby (Ohio) University, in 1848.

**Andrew L. Chapman**, in Kansas City, Mo., May 15, aged 77. He was graduated from the St. Louis Medical College, in 1857.

**A. M. Gontner**, of York, Pa., May 17, aged 47. He was graduated from the Jefferson Medical College, Philadelphia, in 1878.

**E. M. Flne**, in Veedersburg, Ind., May 17, aged 59. He was graduated from the Medical College of Ohio, Cincinnati, in 1872.

**H. D. Belden**, in St. Albans, Vt., May 21, aged 57. He was graduated from the University of Vermont, Burlington, in 1877.

**Charles H. Blair**, at Beloit, Wis., May 17, aged 46. He was graduated from the Bennett Medical College, Chicago, in 1895.

**John A. Robinson**, in Due West, S. C., May 25. He was graduated from the Jefferson Medical College, Philadelphia, in 1868.

**Henry M. Beer**, in Valparaiso, Ind., May 26, aged 65. He was graduated from the Cleveland Medical College, in 1868.

**John N. McCune**, in McKeesport, Pa., May 17, aged 52. He was graduated from the Cleveland Medical College, in 1878.

**Thomas H. Rye**, in Turbine, Tenn., May 26, aged 74. He was graduated from the University of Nashville in 1859.

**Charles T. Hudson**, in Yazoo City, Miss., May 21. He was graduated from Tulane University, New Orleans, in 1882.

**John F. Cronin**, at Daytona, Fla., May 23. He was graduated from the Medical College of Georgia, Augusta, in 1890.

**Sterling Loomis**, at Springfield, Mass., June 5, aged 30. He was graduated from the Yale Medical School, in 1898.

**W. M. Willingham**, of Crawford, Ga., May 12. He was graduated from the Atlanta (Ga.) Medical College, in 1874.

**J. K. Ruffin**, in Wilson, N. C., May 23. He was graduated from the University of Pennsylvania, in 1837.

**Joseph Lee Carr**, of Clarksburg, W. Va., June 9, aged 85.

**Edmund B. Myers**, in York, Pa., May 13, aged 73.

**B. F. Klugh**, of Florin, Pa., May 16, aged 61.

## SOCIETY REPORTS

### SIXTH TRIENNIAL CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

Held in Washington, May 12, 13 and 14, 1903.

#### ASSOCIATION OF AMERICAN PHYSICIANS.

[Specially reported for *American Medicine*.]

SECOND SESSION (CONTINUED).

**Chronic Cyanosis with Polycythemia and Enlarged Spleen, a New Clinical Entity.**—**WM. OSLER** (Baltimore) reported a group of cases of obscure etiology, the symptoms being chronic cyanosis, polycythemia, constipation, enlarged spleen, a trace of albumin in the urine, without signs of disease of the heart, lungs, or kidneys, and with no emphysema.

*Discussion.*—**CABOT** (Boston) referred to two cases of polycythemia previously reported by him, one with and one without splenic enlargement, giving details of these cases. **SHATTUCK** (Boston) had seen several cases, in one of which the urine showed the characteristics of interstitial nephritis. There was great cyanosis and congestion of the mucous membranes, with a blood count of 10,000,000 or 12,000,000. **STOCKTON** (Buffalo) reported a similar case, followed for two successive years, in which there was striking cyanosis, a trace of albumin, and a red blood count of 10,000,000. **MCPHEDRAN** (Toronto) had such a patient with extreme cyanosis, and in addition a bronzing or pigmentation of the skin. He referred also to cases of anemia with high color, and considered such more frequent in northern countries and high altitudes. **HARE** (Philadelphia) had had a case corresponding to those described by Osler with polycythemia, enlargement of the spleen, albuminuria and constant cyanosis. As to the polycythemia of high altitudes, he did not consider that view universally accepted. Experiments in that direction had been very contradictory. **BIGGS** (New York) had a patient under his observation, a man deeply cyanotic constantly, with protrusion of the eyes and a blood count of 8,000,000. **STENGEL** (Philadelphia) reported a similar case which had been under observation for some time, with nephritis and protrusion of the eyes. **EDSALL** (Philadelphia) had had a case identical with Osler's description in which there was no emphysema nor cardiac disease; the blood count between 10,000,000 and 12,000,000. **JOSLYN** spoke of a case of cyanosis due to acetanilid, and referred to a second case which he had reason to believe was due to the same cause. **COHEN** (Philadelphia) considered that cyanosis and a large hemoglobin count were rather contradictory, and asked if the count of the blood taken from the vein was the same as that taken from the peripheral circulation. **OSLER**, closing the discussion, said the protrusion of the eyes had suggested ophthalmic goiter, but the condition lasted for many years with no enlargement of the thyroid. **CABOT** said that in one of his cases the spectroscope was used and the ordinary oxyhemoglobin bands found. Hemoglobin was in excess.

**Officers Elected.**—President, **W. T. Councilman**, Boston; vice-president, **Edward L. Trudeau**, Saranac Lake; secretary, **Henry Hun**, Albany; recorder, **S. Solis Cohen**, Philadelphia; treasurer, **J. P. Crozer Griffith**, Philadelphia; councillors, **Victor C. Vaughan**, Ann Arbor, and **George M. Kober**, Washington.

THIRD SESSION.

**Gonococcal Peritonitis in Children Simulating Appendicitis.**—**W. P. NORTHRUP** (New York) reported several cases of gonococcal peritonitis with symptoms like those of appendicitis, with operation upon one case.

*Discussion.*—**KINNICUTT** (New York) thought a decidedly favorable prognosis could be given in these cases without operation. **JACOB** (New York) thought these cases rather frequent. The prognosis was good without operation if one had patience to wait. There was a good opportunity for the development of chronic salpingitis when these cases occurred before the age of puberty.

**A Preliminary Report on the Influence of Alcohol in Infectious Diseases.**—**H. A. HARE** (Philadelphia) had conducted experiments to determine whether it was possible for alcohol to act favorably in infectious disease by increasing the bacteriolytic power of the blood. It seemed to be pretty conclusively shown that alcohol did increase the bacteriolytic power of the blood very materially. The author concluded that the use of alcohol combated infectious disease by increasing the bacteria-destroying power of the blood, and the effect seemed to be due to an increase in the complement.

**Infantile Scorbutus.**—**THOMAS R. ROTHE** (Boston) reported a case of a peculiarly grave type, illustrating the necessity of careful differential examination, with reference to osteosarcoma and osteomyelitis. In one case there had been subperiosteal hemorrhage along the right tibia, causing the case strongly to simulate osteomyelitis. Large sequestrums were removed by surgical procedure, and rapid improvement followed the administration of orange juice. In the other case, that of a child nine months old, swelling and extreme hardness of both femurs rendered diagnosis from osteosarcoma very

difficult. Recovery in this case also followed the use of orange juice.

**Sudden Death and Unexpected Death in Infancy and Childhood, with Special Reference to the So-called Thymus Death.**—J. P. CROZER GRIFFITH (Philadelphia). This paper will appear in a future issue of *American Medicine*.

*Discussion.*—BLUMER (Albany) has seen nine cases of the so-called thymus death in the last four or five years and divided the cases into two classes; those in which the organs were practically sterile at autopsy, and those in which infection existed. Some cases simply predisposed the individual to infection. JACOBI (New York) said a number of sudden deaths in infancy were caused by pressure of the thymus. It might in other cases be due to general disintegration, or atrophic disorder. The deaths sometimes occurred in the first stage of laryngismus stridulus, the child not living long enough to develop the cooing respiration.

[To be continued.]

**AMERICAN SURGICAL ASSOCIATION.**

[Specially reported for *American Medicine*.]

SECOND SESSION (CONTINUED).

**Further Observations on the Influence of the Röntgen Ray Upon Sarcoma.**—WILLIAM B. COLEY (New York) stated that from February 1, 1902, to May 11, 1903, he had treated at the General Memorial Hospital 36 cases of inoperable sarcoma, the pathologic classification of which was as follows:

Round-celled .....	21 cases
Spindle-celled.....	6 "
Mixed-celled.....	2 "
Melanotic sarcoma .....	1 "
Osteosarcoma, round-celled.....	1 "
Type of cell doubtful.....	5 "

He stated that in four cases which he had reported to the society last year the tumors had entirely disappeared, and in every case there has since been a recurrence. He then gave a brief history of the physical condition and treatment of several cases, and expressed the opinion that the x-ray has a much more powerful effect upon sarcoma than carcinoma. In regard to the relative merits of the toxins and x-rays in inoperable sarcoma, he felt that the time had been too short and experience too limited thus far to definitely decide this question. He had noted, however, in several cases of inoperable round-celled sarcomas in which the toxins had been tried and failed the x-ray had caused entire disappearance of the tumors, but there had been a speedy recurrence in every case. On the other hand, in a much larger number of cases of inoperable sarcoma the tumors have entirely disappeared under the toxin treatment and remained well from three to ten years after the treatment. The dangers from this method of treatment are burns, toxemia, and metastases resulting from the cells being broken down and carried to other parts of the body. He did not believe that the x-ray method should be employed in operable cases of sarcoma, with the possible exception of carcinoma of the extremities, in which operation would necessitate amputation. In such cases he recommended a brief course of the combined x-ray and toxin treatment, reporting a case of sarcoma of the fibula which had been treated by this method which had been treated six years ago by the toxin method and has remained perfectly well ever since.

**Experiences in the Treatment of Inoperable Malignant Growths by the X-rays.**—ALEXANDER B. JOHNSON (New York) reported 10 cases, 9 of carcinoma and 1 of sarcoma; 8 died under treatment and 2 are still alive and have apparently improved, one of them being the case of sarcoma. After a considerable time severe dermatitis was produced in each of these cases, and it was advised the treatment be discontinued at intervals for at least six months. The source of the current was 110 volts, direct commercial current; fifteen-inch spark length, Willyoung induction coil. The distance was at first 12 inches, which was gradually diminished to six as tolerance at that distance became evident on the part of the patient. The surrounding parts were protected by sheets of lead foil weighing 10 ounces per square foot.

**Results of 1,000 Operations for the Radical Cure of Inguinal and Femoral Hernia Performed Between 1891 and 1902.**—WILLIAM B. COLEY (New York) stated that out of 1,003 cases which he had operated upon between August, 1891, and December, 1902, there 937 cases of inguinal hernia, 756 of which occurred in males and 181 in females; and 66 cases of femoral hernia, all males. In the 66 cases of femoral hernia there was no mortality, and the primary union was obtained in all but one case, which formed the only recurrence, the balance having remained well from 6 months to 11 years. The Bassini method for femoral hernia was employed in 16 cases, and the pursestring suture (with kangaroo tendon) in 50 cases. Out of 181 operations upon the female for inguinal hernia there was no recurrence and no relapse, the method employed being practically Bassini's method for the male. There were no mortalities in any of the 1,003 cases. In children operation should seldom be advised under 4 years, the reasons being that many of the cases at this age are cured by a truss, but after that age in which a truss has been tried and failed, or cases in which the presence of reducible hydrocele prevents a truss from holding the rup-

ture, operation is advised. In all adult cases under the age of 50 years operation is advised unless there are strong contraindications. Between the ages of 50 and 70 years operation is advised in patients in good health in cases in which the rupture is held with difficulty by a truss. Six hundred and fifty of these cases were found well from 1 to 11 years; 708 cases were found well from 6 months to 11 years, and 467 from 2 to 11 years. A careful review of the literature on the subject and a comparison of the results obtained by other operators was given.

**Report of a Case of Gangrene of Fifteen Inches of Cecum and Ileum After an Operation for Appendicitis: Relief of Artificial Anus After Repeated Operations.**—N. P. DANDRIDGE (Cincinnati, Ohio) stated that on opening the abdominal cavity for the purpose of removing the appendix it was impossible to locate it, but there was discovered a mass on the inner side of the colon above the ileocecal valve, beneath the peritoneum and lying on the psoas muscle and overlapping its inner edge. The tumor was removed after ligating an artery which ran through it and subsequent examination proved it to be enlarged mesenteric glands. This, together with the appendix which was found behind the cecum, was removed, and the wound closed without drainage, after which the patient progressed well until the evening of the eighth day, when the dressings suddenly became saturated with a thin fecal fluid, and were changed, and the same condition was found again the next morning, and on opening the wound gangrenous tissue was exposed, which increased in extent until a day or two later a section of the ileum, nine inches long, was washed out, entirely gangrenous. A complete artificial anus was established, a drainage tube inserted and with this drainage the pus and fever disappeared. At the end of seven weeks a lateral anastomosis between the small intestine and colon was done, in order to partially relieve the artificial anus, but proved to be a complete failure so far as this was concerned. Some months later an end-to-end anastomosis of the ileum and colon was made by the Murphy button, a small fecal fistula remaining in the side. Two attempts were made to close this fistula and a colostomy had added much to the patient's comfort and diminished still more the size of the opening, which was finally closed by means of pressure from an elastic sponge held in place by an elastic bandage around the body.

[Specially reported for *American Medicine*.]

SECOND SESSION (CONCLUDED).

**Bone-wiring for Recent and Ununited Fractures.**—S. L. McCURDY (Pittsburg). The frequency of location for delayed union occurs in the humerus, tibia, fibula, radius, and ulna respectively. The causes are: Lack of rest, meddlesome attendants, etc.; too light or too loose bandages; nonapproximation of ends; want of blood supply; defective innervation; bone disease. Treatment: 1. Bone ends freshened (don't saw off ends unless too long) and wire while the ends remain in their normal position, thus preserving the nutrition, preventing necrosis, and guaranteeing union. 2. The use of iron (broom wire) instead of silver wire, because iron is a normal constituent of the body; is therefore less irritating, does not bleach as does silver by absorbing sulfur, is stronger and cannot be twisted, thus never coming loose as does silver. Do not pass the wires directly through the bone, but pass them obliquely in order to prevent injury to the medullary canal. 3. Anchor bone fragments to external bridge work to hold them in position during the process of repair.

**An Unusual Case of Pott's Abscess.**—S. L. McCURDY (Pittsburg). The case was that of a boy aged 18; abscess of maxillary bone; a secondary infection resulted, destroying the lower cervical vertebrae. A cough developed and soon pus was expectorated. An abdominal abscess pointed and was opened below Poupart's ligament. Repeated irrigations into this cavity with a solution of methylene-blue caused the expectorated pus to be colored upon every occasion.

*Discussion.*—H. AUGUSTUS WILSON (Philadelphia) recommended a hollow bone-needle constructed by J. Torrance Rugh, of Philadelphia, which overcomes the difficulty experienced by all in passing wires.

**A Treatment of Osteitis Deformans and Osteoarthritis.**—FRANK E. PECKHAM (Providence). The literature on this subject seems to be largely on the pathology and physiology of the disease, and this paper was written to offer a plan of treatment. Case I occurred in an overseer in a mill. He had a history of a slightly stiff knee for three years, which always became aggravated on exposure to cold. Had been treated for rheumatism. There was good motion, though some atrophy and shortening of 1½ inches. Treatment: Tuberculin was tried twice with no reaction. Actual cautery was then used once a month for a period of one year and in the middle of the month a small cantharidal blister was applied over the spine corresponding to the nerve center for the particular area involved. Prior to treatment the patient had been in bed, but upon beginning treatment he was sent to work, rapidly improved from the start, and is now well. Case II was that of a male clerk, aged 50, with a history of previous good health,

except spraining his knee 12 years ago. In 1898 an inflammation of the periosteum developed. The first symptoms were noticed by his friends, who called his attention to his limping. A slight pain soon began, the trochanter thickened, and there was some shortening. Diagnosis of osteitis deformans was made with the aid of the x-ray. Treatment: Same as Case I, with equal success. Case III was in a motorman, aged 42. In 1902 pain began in knee; one month later patient suddenly fell on the street and was unable to walk without crutches since the accident. There was  $1\frac{1}{2}$  inches shortening and a squeaking sound was elicited upon motion. Treatment: Same, and in four months patient was at work apparently well. Case IV occurred in a male, aged 37. Symptoms began with pain in knee in 1898. The legs became bowed; night-sweats developed in 1902; patient lost 14 pounds in weight and was compelled to cross his legs in order to sleep. Treatment: Same. After first application patient said the treatment was too severe and did not return. Case V was that of a male, aged 50. The patient was unable to sleep in dorsal position on account of pain in his shoulder. In 1901 the arm was held rigid and any motion caused great pain. Treatment: Similar for one year. The patient is now recovered, motion being free, except when the arm is raised to over a right angle.

*Discussion.*—J. E. GOLDTHWAIT (Boston) said it is well known that any counterirritant relieves these conditions and permits motion, but no such treatment changes the course of the disease. He did not believe the cases were osteitis of the hip or rotation would have been impossible. The symptoms resembled those of iliopectineal bursa. In the shoulder case, a change of position with pillow in axilla relieves the condition.

**Officers Elected.**—President, Reginald H. Sayre, New York; vice-presidents, J. E. Goldthwait, Boston, Gwilym G. Davis, Philadelphia; treasurer, E. G. Brackett; secretary, John Ridlon, Chicago.

## AMERICAN DERMATOLOGICAL ASSOCIATION.

[Specially reported for *American Medicine*.]

THIRD SESSION (CONTINUED).

**The Present Status of Phototherapy.**—F. H. MONTGOMERY (Chicago) said that in the Finsen Institute of 800 cases of lupus vulgaris treated by the Finsen light, marked improvement in 90%, with a cure of 70%, and reappearance in 20%. The recurrence was generally on mucous membrane. Lupus erythematosus and epithelioma have been benefited in nearly all cases with a cure in one-third of them. In alopecia areata, a good result was obtained in 90% of the cases. In acne but a small percent was benefited, as was also true in chronic eczema. One case of lupus erythematosus grew worse under the treatment in the author's own cases. The apparatus has been greatly improved, the light has been increased fourfold, the time and expense has been reduced one-half to what it was in 1900. There are several new lamps now. The lamp most widely used is the London hospital lamp; it is cheaper and requires but 15 minutes' exposure, and an attendant is not necessary, thus reducing the cost. It is most useful for small superficial lesions. In the deeper seated lesions it is not so effective as the regular Finsen lamp. It is ineffective in ringworm, while some good results have been obtained in lupus vulgaris or other tuberculous affections of the face. The crusts should be removed by curet before the light is used. Where old scars exist, thickening or much pigment, the light treatment is not beneficial.

*Discussion.*—G. T. JACKSON (New York) said that the lenses must be made of rock crystal to be beneficial. He said he had treated two cases of lupus erythematosus, using on one side of the face the London hospital lamp and on the other side used tincture of iodine with quinin internally; the latter has given the best result. He had also used the London hospital lamp in three old cases of lupus vulgaris in which other remedies had been used before, in which there was thickening and cicatricial tissue, with no results. He said he had also used it on three cases of superficial epithelioma with good results. In one case there was entire disappearance on three applications. W. A. PUSEY thought that the rays at the middle of the spectrum were most beneficial while most observers thought the ultra violet rays were best. He said he found best results in treating flat nevi by phototherapy; it is undoubtedly the safest. E. B. BRONSON said he did not think that the ultra violet rays alone were effective, as only one-third of ultra violet rays penetrate the skin, while two-thirds of them are absorbed. This is one reason why the Finsen original light is better than the later lamps, as they are built on the ultra violet light plan almost entirely. He thought adrenalin as used by Farre, to produce ischemia before using the light, was beneficial. G. W. WENDE said that he had used the red light in the treatment of both erysipelas and measles without good result.

**Some Precancerous Affections of the Skin.**—M. B. HARTZELL (Philadelphia) says that eczema and psoriasis have been known in several cases to terminate in carcinoma. Workers in tar and paraffin very often suffer from a multiform dermatitis, which begins acutely, afterward becoming dry and fissured with a superficial ulceration, a marked hyperplasia of the epiderm. This condition differs in individuals as

some workers are immune and cleanliness plays an important part. Several cases of carcinoma have been reported as a result of this condition. Lupus vulgaris is sometimes followed by epithelioma either in the scar tissue or in the lupus tissue itself. Other tuberculous skin lesions are sometimes followed by carcinoma. Lupus erythematosus is also followed by epithelioma. Tertiary syphilitic lesions have been known to be followed by carcinoma, also many congenital growths, especially warts and pigmented nevi. It is very often in these difficult to determine if they are not carcinomatous from the beginning. About 10% of chronic leg ulcers become cancerous. Cicatrices, especially from burns, are liable to carcinoma. Circumscribed keratoses predispose very much. Arsenic poisoning cases are the most interesting, most begin as a disturbance of the palms about the mouths of sweat ducts. Mackenzie has seen it occur in an individual 15 days after taking arsenic. In chronic arsenic poisoning, warts are very liable to become carcinomatous. Senile seborrhea is the most common of the keratoses which become epitheliomas, pinhead in size, with crust formation, skin under crust moist and red, no subjective sensations, and is most common in those who do manual labor; more frequent in men than in women. They may become superficial papillomatous epithelioma. In three cases of senile keratoses the greatest thickening was at the mouths of the sweat-glands, a disappearance of the granular layer; except about the sweat-glands increase of the rete mucosa. The corium was but little altered, glandular changes were not noticed. The corigrams and ducts showed pathologic changes, a slight increase in the corium layer. X-ray dermatitis as well as psoriasis will be followed in a certain number of cases of cancer.

*Discussion.*—W. A. PUSEY said that he had seen cases of chronic x-ray dermatitis resembling precancerous keratoses result in epithelioma which developed on the hand and required the amputation of the hand. Xeroderma pigmentosum is also a precancerous affection. In his experience carcinoma was more common after lupus vulgaris than after lupus erythematosus.

## THE AMERICAN CLIMATOLOGICAL ASSOCIATION.

Twentieth Annual Meeting, Held in Washington, D. C., May 12, 13 and 14, 1903.

[Specially reported for *American Medicine*.]

**Tent Life for Consumptives.**—J. EDWARD STUBBERT (New York). After noting the revolution with reference to the out-of-door treatment of consumptives as compared with the former dread of air, and especially cold air and night air, said that this treatment stood alone in therapeutics in that the larger the dose the better for the patient. He advocated sleeping out of doors. This has been very successful in the cure of tuberculosis, as was shown by the history of cases cited. A camp for consumptives is to be established at Liberty, New York, under Dr. Stubbert's direction. In Pennsylvania the Forestry Commission has made experiments on a State reservation at Monte Alto to determine the efficacy of the outdoor treatment, and they have issued a circular letter in which it is stated that any reputable citizen of the State, who is seeking health, may establish himself on any of the State's reservations, so long as he violates no law. Mention was made of the practice of arranging the beds of patients in the Rutland Sanatorium so that they can be extended into the outer air at night. In this practice a curtain is dropped from the lower sash of the window about the neck of the patient, ensuring warmth for the body, while with a cap on the head the patient takes the "cure" during his sleep. In case of rain he can raise the curtain, and without leaving it, roll the bed into the room or the ward.

RICHARD A. CLEMANN presented plans for a cabin for open air treatment. It was shown that tents in ordinary army use are liable to bad ventilation. The air does not pass through the canvas to any great extent. Even a metal gauze is well known to be a complete safeguard, as shown in the miner's lamp invented by Davy. Cleemann's plans showed a cabin erected on four posts. The floor is  $2\frac{1}{2}$  feet above the ground. The walls are 8 feet high and three of these are hinged at the lower edge so that they can open outwardly and rest on posts driven at suitable distances. The fourth wall contains the double folding doors which afford access to the interior. The roof, made of boards covered with felt, extends 18 inches beyond the walls. It is peaked and has at its base a horizontal false roof. It is intended that two sides, except in the most inclement weather, shall remain open. It is intended for one person. The cost is approximately \$225.

*Discussion.*—CHARLES L. MINOR (Asheville) said that he treated a case of tuberculosis at home, in a tent, and found that the results were not good and he accordingly moved the patient to a portico outside of the bedroom and noticed a marked change for the better. F. I. KNIGHT agreed with Minor in preferring barracks or cabins, having found that the air is usually bad in tents, especially when artificial heating is necessary. S. A. FISK (Denver) said that few persons can live in tents in mid-winter, but he affirmed, from having lived in a tent himself, that when one is somewhat accustomed to tent-life and has lived and slept in a tent he does not care to live in anything

else. STUBBERT said that tents when used should be opened sufficiently to provide proper ventilation, the sides being raised during the day and lowered in bad weather only. SOLLY said that it would be an advantage if the walls of Cleemann's cabin were raised instead of allowing them to fall down. It would give more space and better protection. The advantage of a hut over a tent is that the heat and cold can be kept out better. If stoves are used it is liable to be too hot in tents but with the cabins described the heating can be better regulated. MINOR said that in Germany these cabins are made in separate parts and can be shipped anywhere.

THOMAS D. COLEMAN (Augusta, Ga.) read a paper on the susceptibility of the negro to tuberculosis. This will appear in a future number of *American Medicine*.

*Discussion.*—THOMAS DARLINGTON, JR. (New York) said that he found negroes reluctant to take medicine, and added that in his experience they all had syphilis. THOMAS J. MAYS (Philadelphia) said that both insanity and tuberculosis had become much more frequent in negroes since the Civil war. The order is syphilis, insanity, tuberculosis. MINOR said that he does not believe that there is any racial susceptibility on the part of the negro to tuberculosis. The causes of the prevalent diseases are bad ventilation, late hours, excessive sexual indulgence and bad food. SANGER BROWN (Chicago) said that we can snap our fingers at bacteria if we have pure air and good living, and no matter how we protect ourselves from bacteria if we live in unventilated dwellings, and are not out of doors, and do not have fresh air, we will have tuberculosis. E. R. BALDWIN (Saranac Lake) said he firmly believed in the racial susceptibility of the negro to tuberculosis.

BEVERLEY ROBINSON (New York) opened the discussion on the community and tuberculosis. Dr. Robinson stated that in New York City there is accommodation for approximately 1,000 of the consumptive poor, but requirement for 10,000 to 20,000 more. Tent life was advocated, and the New York Board of Health commended for adopting a method of tent treatment for the consumptive poor in the incipient stage. The amount of exercise incident to camp life is a distinct advantage to these sufferers. The mind is occupied, the body freshened and strengthened. Except in the febrile exacerbations or in cases of extreme weakness there are few instances in which tuberculous patients will not obtain distinct advantages from this mode of life. The cottage tent of Dr. A. M. Holmes was referred to. It was also shown that the widespread fear of contact with consumptives was both fallacious and heartless. The disease is not contagious in the ordinary sense of the word.

[To be continued.]

## AMERICAN MEDICAL ASSOCIATION.

Fifty-fourth Annual Meeting, Held at New Orleans, La.,  
May 5 to 8, 1903.

[Specially reported for *American Medicine*.]

Section on Surgery and Anatomy.

FIFTH SESSION (CONTINUED).

**Cicatricial Ankylosis of the Jaws: A Contribution to Its Operative Treatment.**—RUDOLPH MATAS (New Orleans) referred to the difficulty in treating these cases, and reported a case of bilateral cicatricial ankylosis of the jaws in which the mouth was entirely closed, so that a knife blade could scarcely be inserted between the teeth. The condition had existed so long that the teeth had grown inward horizontally and there were bony bands connecting the jaws. A bilateral incision was made from the angle of the mouth and extending outward to the masseter muscles, and the mucous membrane was sutured to the skin. After healing occurred there was considerable cicatricial contraction and it was necessary to reopen the incision and turn up flaps from the neck on either side. The adhesions binding the jaws together were divided with a very good functional result.

*Discussion.*—MURPHY (Chicago) mentioned a case in which after dividing the mucous membrane and opening the jaws the large raw surfaces on the inside of the cheek were covered by a flap taken from the neck. To insert this flap within the cavity of the mouth an incision was made through the cheek along the anterior border of the masseter and the flap turned up from the neck was passed through this incision and sutured in place. The mouth was then packed with iodoform gauze. A very satisfactory movable jaw was obtained, although a second operation proved necessary. MARTIN (New Orleans) finds that in cases of contracture after injury it is frequently possible to pry the jaws open gradually by using a wedge-shaped piece of wood. He mentioned a case in which he found six months necessary to accomplish this before a movable jaw was obtained. In very bad cases Martin would consider the advisability of excising the lower jaw entirely subperiosteally. MATAS, in concluding, expressed the belief that the results of the operation by Murphy and himself showed very positively the value of plastic flap methods in treating these cases. He doubts whether a very satisfactory jaw would ever be reproduced in case excision was carried out as Martin suggested.

Further Contribution to the Surgery of Undescended

**Testicle.**—ARTHUR DEAN BEVAN (Chicago) finds this condition relatively common, occurring in 1 out of about 500 men. It produces a good deal of mental as well as physical distress. In a great proportion of cases it is accompanied with hernia, discomfort from pressing of the organ in the inguinal canal, and there is a possibility of malignant degeneration. The results of experimental work were given, which seemed to show that the spermatic artery or veins or both can be ligated without injury to the testicle as it gets sufficient blood supply from the artery of the vas. Bevan finds that the structures which are tense and interfere with bringing the testicle down are the spermatic vessels, and by dividing these he has always found the vas long enough to permit the testicle being brought down. In over 100 operations of ligation of the vein for varicocele atrophy of the testicle has very seldom followed. In his operation he has never failed to find a vaginal process of peritoneum which precedes the hernia. This is excised at the time of operation. The repair of the wound is carried out in these cases the same as for Bottini's operation, and the neck of the scrotum is entirely closed. The results in the cases in which he has operated have been so successful that he now feels that he can confidently advocate the operation. The age between 6 and 10 years is the most desirable for operation, for then there is no interference with development.

*Discussion.*—ECKLEY (Chicago) drew diagrams illustrating the development of the genital organs in segments. In the process of development the upper segment atrophies while muscular fibers are developed in the lower segment which draw down the testicle. Bevan's paper also brought out the point that the peritoneum descends as a pouch above the testicle, and this seems to be the reason why that undescended testicle and hernia so often coexist. OCHSNER (Chicago): Until Bevan's original paper appeared most surgeons were accustomed to excise undescended testicles. Now it is possible to avoid this in many cases. Ochsner has performed Bevan's operation without success several times, and believes it is a procedure of great value. RODMAN (Philadelphia) believes that this operation is desirable because of its mental effect, because that sarcomatous changes are less likely to result from pinching and irritation, and that the development of the patients will not be interfered with. BEVAN, in closing, stated that in every case of 20, even when the testicle was high up in the abdomen, he had succeeded in bringing it down into the scrotum.

**Surgery of the Urinary Tract in the Female, Experimental and Clinical.**—J. B. MURPHY (Chicago) states that the conditions which are called upon to treat surgically are pyelonephritis, hydronephrosis, and pyonephrosis. The latter condition results from infection of hydronephrotic kidney. The most striking part of Murphy's communication was his advocacy of the treatment of pyonephrosis by conservative operation. He believes that it is not only desirable to save all the secreting substance of the kidney possible, but the mortality would be much lessened by such conservative methods. If the disease of the kidney is local he advises resection of the diseased portion. He also sometimes excises a part of the pelvis of the kidney with immediate suture. In order to resect the dilated pelvis successfully it is necessary to make a large incision and bring the kidney wholly out of the wound. He reported very good results from his operation.

*Discussion.*—MCLAREN (Chicago) suggested decortication of the kidney in cases of pyelonephritis, and mentioned cases in which he had seen good results from this treatment. He considered Murphy's suggestion for plastic operation on the pelvis of the kidney a very important one. GOODHUE (Iowa) advocated segregation of urine instead of catheterization of the ureter in cases in which examination of the urine from both sides was considered desirable. MATAS (New Orleans) considered Murphy's suggestion very important, but believed that provision should be made for free drainage in cases in which infection exists. He suggested drainage of the pelvis of the kidney through the cortex until healing was complete. MURPHY, in conclusion, stated that his main reason for advocating a plastic operation instead of nephrectomy was because of the smaller mortality.

**Tuberculosis of the Mammary Gland.**—A. H. LEVINGS (Milwaukee) considers it strange that tuberculosis of the mammary gland is so seldom seen, since tuberculosis of the other organs of the body is so common. The infection may be either indirectly through the blood current, or he believes that infection is possible by retrograde current from the lymph vessels of the axilla. The condition is confined almost entirely to women, and is not even dependent on any known antecedent tuberculous disease of other parts of the body. Small nodules usually first appear which increase in size, possibly to the size of a hazelnut. Later on they may break down and sinuses be formed. Enlargement of the axillary glands occurs in about two-thirds of the cases. In the diagnosis from scirrhus carcinoma it must be remembered that the patient is usually older in carcinoma, and the breast is much harder. Actinomycosis could be differentiated by the presence of sulfur granules, and by microscopic examination; cysts may be somewhat difficult to differentiate in some cases, but diagnosis may be made by puncture with a hypodermic needle. The condition is chronic, in most cases more so than the other forms of abscesses of the breast. Levings reported seven cases, in three of which both breasts were affected. In the treatment of these cases a single

abscess may be drained or in case the disease is localized to one part of the organ a quadrant of tissue may be excised, or in more extensive diseases it may be necessary to excise the entire organ.

*Discussion.*—DAVIS (Omaha) had seen only two cases in which the diagnosis was confirmed by microscopic examination. There was no enlargement of the axillary glands in either of these cases; in one case it was necessary to excise the entire breast. MCKNIGHT (Hartford, Conn.) did not consider the treatment by opening and curing the abscess which Levings mentioned suitable as it would tend to disseminate the disease. In closing the discussion, LEVINGS stated that in two of his cases the disease was secondary to axillary tuberculosis, and in one to tuberculosis of the lung.

[To be continued.]

### Section on Obstetrics and Diseases of Women

#### THIRD SESSION (CONTINUED).

**A Combined Clinical and Laboratory Study of the Effects of Peritoneal Saline Infusions in Abdominal Operations.**—J. G. CLARK (Philadelphia) based his study first on the established fact that there are definite peritoneal currents which waft all minute bodies from the lower portions of the abdomen toward the diaphragm; peritoneal infusions have been used in all abdominal operations. The results of 250 abdominal cases have been studied, and the fact is established beyond doubt that the use of saline infusions does not increase mortality or postoperative complications. On the contrary, the mortality is decreased and postoperative complications, such as thirst, vesical irritation and renal complications, are greatly lessened. A study of a series of animals in which a virulent culture of *Staphylococcus aureus* was employed demonstrated that 1 cm. of undiluted bouillon culture would invariably kill the animal when introduced into the peritoneal cavity; whereas the same amount of culture introduced into the peritoneal cavity and then diluted with 100 cm. of hot normal salt solution resulted in the saving of 48% of the animals and in prolonging the life in lethal cases. Hot salt solution, when introduced into the peritoneal cavity, acts by increasing leukocytosis and diluting the toxic products, thus hastening their elimination.

*Discussion.*—BOVÉE (Washington, D. C.) referred to a paper which he wrote several years ago in which he took a position similar to the present one of Dr. Clark. There are several reasons for the value of normal salt solution in the peritoneal cavity, some of which are lessened mortality when sepsis is present, a less likelihood of adhesions, stimulation to circulation. The temperature of the solution should not be above 115°. Adhesions have doubtless occurred as a result of too hot a solution. STACEY (Kansas) wished to call attention to the advantage of using normal salt solution by the rectum. The value of employing a temperature above 105° or 106° is not seen. LAWRENCE (Columbus) has noted the sudden appearance of shock when solution at a temperature above 105° or 106° has been used. The lymphatics were likened to scavengers. Sepsis is diluted by the use of salt solution, both in the abdominal cavity and also in the lymphatics. BONIFIELD (Cincinnati) said there was one possible fallacy in the experiments reported. When used, for example, in cases of appendicitis or pyosalpinx, leukocytosis has been under way before operation. In the experiments no such condition preexisted, but the infection was thrown directly into the general peritoneal cavity. The question was raised as to the danger of scattering infection by the use of salt solution, and the necessity emphasized of keeping infection out of the general peritoneal cavity. RICKETTS (Cincinnati) formerly believed all benefits to accrue from the use of salt solution. He now keeps the abdominal cavity as dry as possible. He does not allow a drop of water to enter the cavity, even in ruptured ectopic gestation. He is careful to wall off infected areas. THEINHAUS (Milwaukee) asserted that bacterial infection does not lie on the surface of the peritoneum. If the adhesions are tender he hesitates to wash lest they be broken down. If, however, the infection is general, he washes out freely. SHUMARD (Alabama) cited a case of sepsis from incomplete abortion, in which he had maintained the correlation between the temperature and pulse better by the use of salt solution than by any other method. WAGNER (Chicago) used salt solution freely 8 or 10 years ago. He has abandoned it for the dry treatment. He uses dry sponges. He has had less elevation of temperature; has done five hysterectomies for puerperal fever with good success. Shock is combated by salt solution per rectum. CLARK, in closing, said that the temperature of the solution should not be above 110°, the quantity should not be excessive, one liter preferably. In the case of a walled-off abscess it is culpable to break through adhesions. His dictum as to drainage is, when in doubt do not drain.

**Retroversion of the Uterus: A Clinical Study of the Complications, Symptoms and Treatment.**—L. H. DUNNING (Indianapolis) said his study is based upon 112 recorded cases of retroversion of the uterus examined in the office of the writer. The study was with the hope that the findings might be helpful in furnishing positive indications for treatment. Of the cases 56 were treated. In 85% of the cases retroversion was but one of three or more pathologic conditions present. Pain was the one symptom almost invariably present. The three

symptoms most prone to persist after treatment are painful menstruation, pain in the inguinal region, and nervousness. Thirty-five cases were treated by nonoperative methods, that is, by posture, tampons, pessary, topical applications and internal medicines. In a few cases a curetage was done. As regards treatment the author of the paper considers his cases under six groups, making an exhaustive study of the series: Group 1. Eight cases treated with tampons or pessary, internal medicines and posture; cured. Group 2. Eight cases, retroversion treated by tampons; benefited. Group 3. Twelve cases treated with pessary, supplemented by medicines and topical treatment; markedly benefited. Group 4. Seven cases not benefited by tampons and pessary treatment. Complications present in each case and failure predicted in most of them. Group 5. Thirteen cases treated by major operative measures, 9 cured and 4 markedly benefited. In 12 of the cases abdominal section was done and one or both ovaries were removed. Ventrosuspension was done in 9 of the cases, ventrofixation in 2. Group 6. Three cases major operations done with little or no benefit. In the series there were two cases in which ovarian tumors produced the displacement, the malposition disappearing on removal of the tumor. Hysterectomy was done in 3 of the cases for fibroid tumors. The conclusions reached in the study are: 1. Simple uncomplicated retroversion gives rise to few symptoms, the chief being backache and bearing down pain. Painful menstruation occurred in 37% of the cases. 2. The severity of the symptoms and the prospect of cure depends largely upon the number and character of complications. 3. The most common complications are prolapse of one or both ovaries, 42%; endometritis, 28%; laceration of the cervix, 24%; prolapse of the uterus, 15%; adhesions, 13%; laceration of the perineum, 7%; movable kidney, 7%; ovaritis without displacement, 8%. 4. In the treatment of the simpler and less complicated cases the nonoperative treatment yields satisfactory results. Recent cases, especially those following labor, improve rapidly under this form of treatment. 5. Displacements of long duration accompanied by the more serious complications are not cured by this method, and the benefits resulting are scarcely sufficient to justify the effort. 6. Operative methods in the severest forms of displacement and complication are attended by a large percentage of cures and should be employed in preference to all other means. 7. The danger of attending the operative method of treatment is very small. In the 24 cases reported there was no mortality.

**A Further Report on Operations on the Uterosacral and Round Ligaments for Retrodisplacements of the Uterus.**—J. WESLEY BOVÉE (Washington, D. C.). This report includes 17 cases operated upon by each of the two routes—abdominal and vaginal. There has been no fatality or notable morbidity. In shortening the round ligaments the plan suggested by Webster and Baldy has been practised. In all the cases other reparative operations were done. In 9 cases the round ligaments and in 8 the uterosacral ligaments were shortened. In none of the vaginal operations were both sets of ligaments shortened, but in 6 by the abdominal route both were shortened. In the author's paper of last year an effort was made to show the very important part played by the uterosacral ligaments and the anterior vaginal wall or uterovesical ligaments, and of the round ligaments in maintaining the position of the uterus. He has found nothing to modify his views. He has done no other operation for retrodisplacement for more than a year. Ventrosuspension, ventrofixation, and Alexander's operation, all practised without accident, have been abandoned. The reason for abandoning the latter are the reports of a large number of hernias, suppuration and relapses. Attaching the uterus to the abdominal wall is not an ideal procedure. If the lower supporting structures of the uterus be faulty from maldevelopment or injury one must expect failure, as a rule, to follow the operation, and the ligament traversing the peritoneal cavity would seem to be dangerous. Not a few cases of fatal intestinal obstruction have been reported as caused by this ligament, and many cases of cesarean section have been made necessary by this attachment. The results in these 41 cases are nearly perfect. He has determined to examine very critically every patient in which surgical treatment of retrodisplacement is contemplated to decide the exact causes of the real position and to plan the measures to be employed. All pathologic conditions should be recognized and given their proper positions in etiology that treatment may be scientifically applied. Intrapertoneal conditions are best mastered by the abdominal route; adhesions should be severed under sight. The author, therefore, prefers always to open the abdomen when such work is to be done.

#### THIRD SESSION (CONTINUED).

**Where Under Our Form of Government Do Public Health Powers Reside, and How Should They be Exercised?**—W. H. SAUNDERS (Montgomery, Ala.) stated that in his opinion the exercise of power depends upon the seat of the power. Public health powers should reside in the States. Although the federal government is all powerful in civil matters, it is not essential that such should be the case as regards public health powers. The State has the right of self-preservation, and

the supreme court of the United States has decided that under the tenth amendment to the constitution this power does reside in the State. He cited several opinions in proof of this. However, some public health power should be vested in the national government. In a monarchy the supreme public health power resides in the monarch, but in a democracy it should not be vested in one individual. Our present system is well suited for a monarchical form of government, but not for a domestic form of government, as the people have no voice in regulating the supreme power. This can be overcome by the establishment of a National Bureau of Public Health, composed of medical men exclusively. The county medical society should form the county board of health. The county committee on public health which would have the power of our present boards of health would be elected by the medical society and all the minor offices likewise. Politics should not figure in matters of public health. Over the county board of health there will be the State Board of Health which should be the State medical society. The State Board of Health should elect its State committee on public health, and the president or chairman of this committee should be a member of the Governor's cabinet. Over the State Board of Health there should be a National Bureau of Public Health to act as an advisory board. The members of this national bureau should be elected by the American Medical Association. Every medical officer acting under this proposed system will derive his power from the physicians in the local section. The three essentials for the proper operation of a public health system are skill, executive ability, and money. All three of these would be supplied by the proposed system. The advantages of the system are that the responsibility could always be fixed, there would be cooperation of the several State Boards of Health, and authority would be taken from one man and divided. This system has been working satisfactorily in Alabama for the past six years.

**Discussion.**—H. A. MOODY (Mobile, Ala.) said that every American citizen enjoys feeling that he has a voice in the government and that he can punish any official for an evil. The control of the State public health should not be vested in one man. With the present system there may come a time when the local man appointed by the Marine-Hospital Service will be obnoxious to the local section and yet the community will have no authority to remove. He does not think that the Marine-Hospital Service should have discretionary powers in the matter of State quarantine. The public health system should be arranged upon a democratic basis and not upon a dictatorial basis. R. D. MURRAY (Key West, Fla.) stated that the local officer appointed by the Marine-Hospital Service can always be reached. A local man is not always capable of managing the quarantine station, as he is apt to be prejudiced by local influence, and for this reason it is best to have a foreign man over the local community. H. D. HOLTON (Brattleboro, Vt.) is of opinion that the scheme outlined by Dr. Saunders is admirable upon paper, but its practical feasibility is doubtful. It is doubtful whether the recent graduate in medicine has the proper knowledge for an efficient public health officer. The foreign quarantine officer is best, as he is less likely to be influenced by local prejudices. The national government should undoubtedly have some power in regulating quarantine regulations. J. M. LINDSLEY (Havana, Cuba) stated that the gulf ports are ports of the entire Mississippi valley and the power of regulating quarantine in these ports should not rest with the State. The present quarantine regulations are too strict. SAUNDERS, in conclusion, said that the theory of a foreign man being the best to supervise local conditions cannot be accepted as true. Under the proposed scheme there would be a city health officer, a State health officer, and a national health officer, and all doubtful cases would come up before this triumvirate. The cost of fighting an epidemic in any locality would be divided between the locality, the State, and the National government. This would stimulate all officers to strict prophylactic measures. The ultimate power would be the Advisory Board of the American Medical Association. The nation has the right to delegate this power. The present scheme has been working since 1897 and since then there has never been a case of yellow fever in Alabama, although Mississippi and Louisiana and Florida have each had their share, and the total cost of conducting quarantine in Alabama for the past three years has been only \$20,000.

**The Future of Preventive Medicine.**—H. A. MOODY (Mobile, Ala.) believes that about 20% of the population are infected with tuberculosis, and 150,000 persons die of it every year in the United States. Better hygienic measures should be taken with tuberculous patients. Preventive medicine is just starting in its development. There is no known prevention for pneumonia, typhoid fever, and many other diseases. The prophylactic treatment of yellow fever, bubonic plague and malaria has been a great stride in its development. Hydrophobia, which was at one time a very common disease in Germany, is now almost unknown from the fact that all dogs are kept muzzled. The mosquito-bar and wire screens are the muzzles against the mosquito, and the masses should be educated along these lines. The public should be educated, also, in the principles of asepsis and antisepsis. If there can be obtained international cooperation we can rid the world entirely of typhoid fever and tuberculosis. The work should be taken up in very much the same manner and followed with as much enthusiasm as that of the W. C. T. U. The American Medical

Association should appoint a committee to investigate the best methods of accomplishing the desired end, and this committee should report at the next meeting of the Association. The laymen should be consulted and their cooperation sought for. In fact, for the movement to accomplish any good it must be made an international affair. A textbook dealing with preventive measures against disease should be adopted by the public schools, and this book should contain also the elements of pathology, bacteriology and physiology. If the laymen knew more about these subjects there could be no Christian Science and no quackery. It is the duty especially of the Section on Sanitary Science and Hygiene to start this educational movement, and preventive medicine will not be complete until such a movement is started.

**Discussion.**—SAUNDERS (Montgomery, Ala.) said such a movement is undoubtedly needed and it will surely bear good fruit. There is no doubt but that the public needs education along hygienic lines. G. M. KOBER (Washington) said the American Medical Association already has a committee on public health.

[To be continued.]

## Section on Nervous and Mental Diseases.

THIRD SESSION (CONTINUED).

**Carcinoma of Spine and Meninges Secondary to Cancer of the Breast.**—F. SAVARY PEARCE and A. C. BUCKLEY (Philadelphia). The patient was a woman of 70, a houseworker, who was brought to the Philadelphia Hospital February 8, 1902. At the time of her admission she was practically moribund and a thorough examination was out of the question. The only history obtainable was that for the past three years she had had a lump in one breast, had suffered from vomiting and diarrhea, and had complained of pain over the chest and stomach and in the precordial region. When admitted she had no control over the bowels and bladder. A diagnosis of compression myelitis, possibly due to a metastatic growth, was made. The woman died shortly after her admission to the hospital and the autopsy revealed a neoplasm about 5 mm. in thickness, extending from the tenth to the twelfth dorsal segments of the spine. There was considerable thickening of the dura. The histologic examination proved that the case was one of carcinoma of the spine and meninges, secondary to cancer of the breast.

**Some Toxemias in Relation to the Production of Nervous and Mental Disease.**—SAMUEL BELL (Detroit) stated that as the result of the advancement made by the physiologic chemist, bacteriologist and pathologist, and earnest workers in laboratories in different parts of the scientific world, new avenues have been opened for those who have been accustomed to study mental and nervous disease largely from a clinical standpoint. Those who have had the opportunity of looking daily on hundreds of cases suffering from the different forms of mental aberration cannot but be profoundly impressed with the importance which somatic conditions obtain in relation to the mental. Although by some investigators there has been a tendency to build up plausible theories that almost all forms of mental and nervous diseases result from some form of autotoxemia, these conclusions did not seem warranted when viewed from the experienced clinician's field of observation.

**The Treatment of Emotional Disturbances.**—HOWELL T. PERSHING (Denver) stated that emotion is much more than a state of feeling. Intense fear, grief, anger, or even joy begins as a sort of cortical storm which involves an energetic disturbance of the entire body. Such a disturbance may be a very serious or even fatal complication of a preexisting disease. The ways in which a physician may dissipate or control an undesirable emotion may be arranged under the following heads. It is necessary to keep these methods entirely distinct in mind, for although we usually combine them in practice, the combination to be chosen varies greatly according to the nature of the case, and some one method is always the most important and should predominate over all the others: (1) The idea exciting the undesirable emotion should be so far as possible removed and replaced by ideas of an opposite tendency, as when a patient who is frightened and depressed by the idea that he has heart disease is thoroughly examined and positively assured that the heart is perfect; (2) the motor reaction characteristic of the emotion should so far as possible be voluntarily suppressed, and replaced by the motions and demeanor characteristic of the opposite emotion, as when a patient threatened with an hysterical attack forces himself to breathe deeply and slowly, relaxes the muscles and assumes a calm demeanor; (3) an exhausted and irritable nervous system must be rested, built up and soothed, so as to make it less susceptible to emotional storms; (4) poisons which irritate and depress must be eliminated, as in the so-called uric acid diathesis, uremia, diabetes, alcoholism, etc.; (5) a diseased organ which sends abnormal sensory impulses to the cortex and thus causes the feeling of fear or of grief without such mental cause as would otherwise be necessary must receive appropriate treatment, as in certain cases of disease of the heart, stomach, liver, intestinal canal or pelvic organ; (6) other means proving inadequate, a painful emotion may be controlled by full doses of opium, as in the opium treatment of melancholia.

**Officers Elected.**—Chairman, F. Savary Pearce, Philadelphia; secretary, D. I. Wolfstein, Cincinnati.

## Section on Ophthalmology.

FIFTH SESSION.

**Officers Elected.**—President, R. L. Randolph, Baltimore; secretary, A. E. Bulson, Fort Wayne; delegate, Casey A. Wood, Chicago.

**Extraction of the Crystalline Lens in High Myopia.**—H. V. WURDEMAN and NELSON M. BLACK (Milwaukee, Wis.) gave statistics of measurements of over 12,000 pairs of lenses and 8,021 eyes in which complete examination under cycloplegic was made, including 34 cases of high myopia. They considered the benefits derived from correction of full refraction in moderate and high myopia generally full correction for distance and weaker concaves for near, in combination with full astigmatic correction. When indicated, prisms or operations on ocular muscles were resorted to. Six eyes operated on for high myopia were selected from the few cases in which correction of the refraction could not be tolerated and who were thereby incapacitated for the ordinary duties. All the operations were successful, patients receiving marked benefit and being able to pursue their vocations. The writers concluded that surgical treatment should be limited to cases over  $-12.0D$ , who suffer from inconvenience from correcting lenses. Ideal cases for operating were  $-17.0$  to  $-18.0D$ . The operation was mainly indicated in young adults. Cases having active disease and changes in ocular structures, such as progressive myopia, choroiditis, fluid vitreous, or detachment of the retina, are not applicable. Danger of operative interference was more than counterbalanced by results achieved, that is, increase of visual acuity, extent of visual field, etc.

**The Management of Myopia.**—J. H. CLAIBORNE (New York) says his present views are based upon the paper of Förster. He approved, as a rule, always under the age of presbyopia, total correction. Exceptions were rare, generally occurring in cases complicated by organic changes at the pole. He thought that careful records should be kept so that the weight of voluminous statistics may be brought forward as evidence. He referred to the rarity of myopic errors in this country as compared with hyperopic ones and considered the advisability of carefully examining the eyes of all children at regular periods, particularly at the age when myopia is apt to arise. He advocated the use of the student lamp and considered the Welsbach too white a light. There should be regular inspection of the schools and proper arrangement of the school-room illumination. Desks should be so arranged that the children would not be induced to bend over. All myopia under the age of presbyopia was vicious and should be handled with much care. After presbyopia myopia had a tendency to decline rather than increase. The author favored total correction of myopia and varied from that practice only under exceptional conditions.

**Discussion.**—JACKSON (Denver) thought that no hard and fast rule could be laid down as to whether cases were suitable for operation or not. Cases should be repeatedly seen and studied. He had found lenses of 18 and 20 D. worn with comfort for years. The contraindications for operation could not be stated very definitely either. He emphasized the necessity for making a moderate dissection; while it might entail waiting, it was much safer. If there is necessity for removing the lens as soon as possible it would be better to remove it without any dissection. HALE (Chicago) had had 10 cases upon which he had operated and which had not been reported yet, in which the results had been very good. BRUNS (New Orleans): In 2,500 cases of refraction had operated seven times for the removal of the lens in myopia. He considered the great value to be the prophylactic one. He agreed with what had been said about the moderateness of the dissection and considered that it held true of all dissections. A small dissection should be made and then wait until the result is seen—until it is known how the eye tolerates it. FULTON (St. Paul) had been so pleased with the results of dissection that he did not see why linear extraction should be done. MOULTON referred to the necessity of securing the cooperation of the parents in these cases of myopia, to have them provide the children with suitable conveniences for study. DODD (Chicago) had for the past few years given full correction in his myopic cases and found that they were much more comfortable and that the condition remained stationary, while in those not fully corrected the changes were much greater. DE SCHWEINTZ (Philadelphia) desired to go on record, as he had often done before, as advocating full correction for these cases. He agrees with Jackson fully that full correction is the object to be attained for young persons with normal visual acuity and binocular near vision, no matter how high their myopia.

**Calcereous Degeneration of Corneal Cicatrices.**—H. MOULTON (Ft. Smith, Ark.) considered certain rare types in which lime salts are deposited in old cicatrices in the form of plates or solid masses of considerable size. Two cases were related of adherent leukomata in which deposits were deeply situated and in which the symptoms were neuralgic and asthenopic respectively, and not such as a foreign body would usually excite. Perfecting and lasting relief was obtained by cutting into the cicatrices and removing the deposits.

**The Voluntary and Involuntary Brain Centers Controlling the Ocular Muscles.**—G. C. SAVAGE (Nashville, Tenn.) considered that the nine volitional centers were each connected with two muscles, one muscle belonging to each of

the two eyes. That five of these centers control the recti and four the obliques. A discharge of nerve impulse (neuricity) for a volitional center is equally divided between the two muscles under its control. If the tonicity of the one muscle equaled the tonicity of the other there would be an even, equal response on the part of both; but if unequal in tonicity the basal center of the weaker muscle acts in order to produce harmony in movement. There were 12 basal or reflex centers, each one of which is connected with one muscle only. That all these were under the control of the fusion faculty and were in no sense volitional. They discharged neuricity only under abnormal conditions and only in the interest of binocular, single vision. These centers became exhausted in heterophoria and excite the sympathy of other brain centers. Cure of heterophoria brought rest to these reflex centers and relieved the symptoms caused by their excitation.

## THE WEST VIRGINIA STATE MEDICAL ASSOCIATION.

Thirty-sixth Annual Meeting, Held at Charleston, W. Va.,  
May 26, 27, and 28, 1903.

[Specially reported for *American Medicine*.]

**President's Address.**—H. B. STOUT (Parkersburg) made many suggestions of great importance to the moral and material welfare of the Association. The paper will go down in the history of the Association as one of the most practical and most useful presidential addresses.

The secretary's report showed the Association to be in a prosperous condition and showed clearly that the great strides it has made during the past year were made possible by its partial reorganization at the last meeting. The report closed with the recommendation that the Association undertake to protect its members in suits of malpractice. The Association acted upon this recommendation and adopted the following resolution: That this Association pledges its moral support and will substantially defend any member who shall be sued; and further pledges the services of any and all its members when called upon to attend any trial and testify in behalf of the member sued.

## PAPERS AND DISCUSSIONS.

The following papers were read and discussed:

- "The Organization of the Medical Profession," by J. N. McCormack, Bowling Green, Ky.
- "The Constitution and By-laws, with Some Comments and Suggestions," by Wm. W. Golden, Elkins.
- "Puerperal Eclampsia," by E. T. W. Hall, Weston.
- "The Present Status of Serum and Organotherapy," by J. M. Sites, Martinsburg.
- "The Promising Outlook Along Electrotherapeutic Lines," by T. L. Barber, Charleston.
- Symposium on Quarantine; "The Microbiology of the Common Communicable Diseases," by J. Schwinn, Wheeling.
- "The Etiology of the Common Communicable Diseases, with Especial Reference to the Common Methods of Communication," by A. G. Staunton, Charleston.
- "The Management of the Common Communicable Diseases, with Especial Reference to Public Safety," by S. L. Jepson, Wheeling.
- "The Public and the Physician in Relation to the Common Communicable Diseases," by J. C. Irons, Elkins.
- T. L. Barber to open discussion with an illustrated paper on "Uniform Signals of Contagious Disease for State and Nation."
- "Collapse and Shock," by W. S. Keever, Parkersburg.
- "Mastoiditis," by T. V. Churchman, Charleston.
- "Demonstrations of the Value to the Physician of Modern Methods of Diagnosis," by A. Rose, Hinton.
- "The Country Practitioner and What He Can Do for His Patients as a Specialist," by Jno. R. Cook, Fairmont.
- "Dystocia and Its Treatment," by W. H. Sharp, Parkersburg.

**Reorganization Completed.**—At its last meeting at Parkersburg, W. Va., the Association adopted, with certain modifications, the constitution and by-laws recommended by the American Medical Association for State Societies. One of these modifications was the omission of the House of Delegate feature, on account of the very small number of the county societies then in existence and the lack of self-confidence to be able to organize many such societies before many years. The efforts in this direction during the past year, however, have proved very successful and encouraged the Association to adopt the delegate system for the next meeting, thus making its reorganization complete. To Dr. J. N. McCormack much credit is due for valuable assistance in this matter.

**Officers Elected.**—President, Dr. T. L. Barber, Charleston; first vice-president, Thomas M. Hood, Clarksburg; second vice-president, Dr. E. T. W. Hall, Freemansburg; third vice-president, Dr. Rolla Camden, Parkersburg; secretary, Dr. Wm. W. Golden, Elkins; treasurer, V. T. Churchman, Charleston. Councillors: First district, C. A. Wingert, Wheeling, and J. W. McDonald, Fairmont; second district, C. S. Hoffman, Keyser, and W. H. Proudfoot, Rowlesburg; third district, W. W. Tompkins, Charleston, and O. O. Cooper, Hinton; fourth district, W. S. Keever, Parkersburg, and H. B. Stout, Parkersburg; fifth district, C. R. Enslow, Huntington, and T. W. Moore, Huntington. Delegates to the American Medical Association, S. L. Jepson, Wheeling, and W. H. Sharp, Parkersburg. Fairmont was chosen as the next place of meeting.

## CLINICAL NOTES AND CORRESPONDENCE

[Communications are invited for this Department. The Editor is not responsible for the views advanced by any contributor.]

### FEWER DRUGS AND MORE DISCRIMINATION IN THE USE OF THEM: A PHARMACOLOGIC COMMISSION.

BY

BOARDMAN REED, M.D.,  
of Philadelphia.

What Dr. J. Madison Taylor wrote in *American Medicine* of April 25 on "The Dangers of Drug Using Without Guidance" I most earnestly endorse. Much harm is resulting both to the medical profession and to the people from the extraordinary multiplication of drug compounds of secret or half-revealed composition and patent foods containing alcohol or other injurious ingredients and pushing them into an extensive use through the medium of physicians in so far as the latter can be induced to prescribe them, otherwise directly through advertisements in the lay press, especially the religious journals.

A few manufacturing drug firms doing a legitimate business have advanced the cause of medical science by pharmacologic researches of real value, but the flood of worthless or downright pernicious products of drug factories on both sides the Atlantic now being poured out upon an unresisting profession and people is a serious danger. The evil is too manifest to expatiate upon and it seems high time that the profession should apply itself seriously to the task of finding a remedy.

One thing which obviously ought to be done is to have a committee, or perhaps better, a permanent commission of pharmacologic and therapeutic experts appointed by the American Medical Association to investigate thoroughly and report every year upon the merits of alleged new remedies. This would cost something, but the profession can well afford to pay the cost rather than see itself crushed between rampant quackery on the one hand and the commercialism of drug manufacturers on the other.

It is true that with a better knowledge and larger employment of more natural and hygienic remedies, such as diet, rest, exercise, water, electricity, massage, and allied forms of mechanical treatment, the use of drugs can and should be much more restricted than hitherto, yet there are many emergencies for which medicines are needed and when we prescribe these we should know accurately what they contain and the action which they exert upon every part of the body in their smallest as well as in their largest doses, the fact being now well established, which was proved conclusively by me in a paper published in the *London Practitioner* for April and May, 1888, that these two ranges of doses are usually contrary to each other in their effects.

Quite as bad as prescribing drug preparations of unknown composition for conditions more or less unknown, because often unknowable, is the reckless administration of remedies, such as acids and alkalies well understood to exert powerful effects in certain directions, in gastric conditions wholly unknown through a failure to make or have made tests which would accurately reveal them. I see every day cases in which serious harm has been done by prescribing hydrochloric acid for a patient whose stomach was at the time secreting twice or thrice the normal amount of the same acid, and other cases in which an alkali has been pushed, while every dose was increasing still further a previous deficiency of gastric secretion. These things should not be.

### SOME UNEXPECTED EFFECTS FROM ATROPIN AND BELLADONNA.

BY

S. GLICK, M.D.,  
of Downleville, Cal.

Reading Dr. S. E. Ives's description of a case of "Atropin Poisoning from Ocular Instillation" in *American Medicine* of April 4, current volume, I was reminded of my varied experience

with this group of drugs. As county physician it is my duty to treat from 35 to 50 inmates of our county hospital and almshouse. These patients range in age from 60 to 97. Cases of incipient cataract and chronic constipation are always present. Until the cataract ripens for operation the vision is improved by daily or semiweekly instillation of 1 or 2 drops of a 0.4% solution of atropin. After two or three such ocular instillations, every third or fourth patient complains of suppression and retention of urine. The instillations being discontinued, secretion of urine soon returns, but retention remains from three to four days to as many weeks. Quite a number of times in the past seven years I have had the same experience with patients who are given a "tonic laxative pill or tablet" containing 8 mg. ( $\frac{1}{8}$  grain) belladonna with fractional doses of aloin, strychnin, and cascara. The directions are to take 1 to 3 at bedtime. They are warned not to take more than three in one day. Yet this small dose frequently produces flushed face, mild delirium, bounding pulse, dryness of mouth and pharynx, dilation of pupil, and suppression of urine. I am beginning to be very careful with these treacherous remedies.

### THE ADMINISTRATION OF DRUGS IN TABLET FORM.

BY

LAWRENCE E. HOLMES, M.D.,  
of Biltmore (Asheville), N. C.

Some months ago I reported in *American Medicine* the case of a woman in whose intestinal tract five-grain phenacetin tablets remained undissolved for four days, and were then passed by the bowel practically unchanged. Since then I have prescribed drugs in the tablet form much less frequently, though for the sake of convenience I did so in the case of salol and phenacetin tablets (of each 2½ grains) a short time ago. The directions were to take one tablet every two hours. In all, eight were taken. Twenty-four hours after the last one was taken four of them were passed unchanged by the bowel. The others may have passed unnoticed, or they may have been dissolved. Cases of this kind should, I think, be reported, in order to keep before our minds the fact that in spite of its great convenience, the administration in the form of compressed tablets of those insoluble preparations whose constitutional action we desire, is a method always unreliable and may be unsafe.

### COMPRESSION OF THE AORTA IN POSTPARTUM HEMORRHAGE.

BY

BYRON ROBINSON, M.D.,  
of Chicago, Ill.

To the Editor of *American Medicine*:—Dr. L. D. Sheets,<sup>1</sup> in his report of compression of the aorta in postpartum hemorrhage, appears to conclude that it is the compression or occlusion of the aorta that checks the hemorrhage. The idea of compression of the aorta in postpartum hemorrhage is over a century old, but I think that the result of aortic compression has been erroneously interpreted. It is not the compression or occlusion of the aorta that checks the hemorrhage, but it is the irritation or stimulation of the hypogastric plexus surrounding the aorta which contracts the caliber of the bloodvessels in the uterus that produces the effect. Dr. Sheets noted that "the perspiration dried up." This fact is due to the control of the sudoriparous glands by the sympathetic, stimulating the hypogastric plexus made the system tend to normal as visible perspiration drops is due to disordered innervation. He also noted that the hemorrhage ceased. This was due to stimulation of the hypogastric plexus, which induced the thousands of uterine muscular bundles to contract like elastic living ligatures on the uterine vessels, controlling their uterine lumen.

<sup>1</sup>*American Medicine*, April 11, 1903.

## A NEW PROCTOSCOPE AND SIGMOIDOSCOPE.

BY  
F. B. MARSHALL, M.D.,  
of Muskegon, Mich.

This instrument consists of two tubes. The inner, fitting closely inside the outer and closed at the distal end, is composed of glass and acts as an entering plug. The outer being open at both ends allows direct application to any part of the bowel explored, when the inner tube is withdrawn and light reapplied. When the instrument has passed the sphincters the inner tube should be withdrawn, to allow atmospheric air to inflate the bowel, and reintroduced before attempting to pass the rectosigmoid valve.

The light in the inner glass tube affords the operator a good view of every portion of the bowel explored and enables him to avoid pushing the instrument against ulcerated surfaces. The metal plug instruments have been pushed through deeply

ulcerated portions of the bowel, as it is impossible for the operator to see each portion of the bowel before the instrument reaches it.

These instruments possess every advantage of other proctoscopes and sigmoidoscopes, are inexpensive, and can be safely used by the most inexperienced physician.

The patient should have all constriction removed from the waist and be in the knee-chest position. The operator should constantly bear in mind the normal direction of the bowel; through the distal two inches the instrument should be made to pass as though the umbilicus were the objective point, then turned abruptly backward, or rather upward in the proctoscopic posture, into the hollow of the sacrum, the concavity of which is closely followed for the succeeding four inches. The instrument readily enters the sigmoid after passing the rectosigmoid valve.

## ESTABLISHMENT OF THE PHIPPS HOSPITAL IN THE FIFTH WARD.

BY  
SAMUEL STALBERG, M.D.,  
of Philadelphia.

To the Editor of *American Medicine*.—In an editorial in your issue of February 14, 1903, discussing the opposition to the establishment of the Phipps Hospital in the Fifth ward, my name, from its reported connection with that opposition, is mentioned in a discreditable manner. That report, however, did not place my position in its true light, and I wish to say a few words in explanation.

While admitting that I did not favor the establishment of the hospital in that locality I wish to state that my objections were based, not on any fear of the hospital as a source of contagion, but on the following reasons:

In the first place, it will be remembered that it was the intention of the founders of the institution to place it in the midst of a congested district, one in which the proportion of the

tuberculous is notably large. Neither of these facts is true of the present site.

In the second place, it is recognized that in the modern treatment of tuberculosis by means of special hospitals three kinds of sanatoriums are required.

*First*, mountain sanatoriums for the improved and incipient cases. Such a sanatorium with reference to Philadelphia is that situated at White Haven, Pa., in which, however, patients with more advanced cases are treated also.

*Second*, one or more "city sanatoriums" situated in the outskirts of the city for the treatment of patients with the more advanced cases and for the preparatory treatment of those to be sent to the mountain sanatorium.

*Third*, a hospital located in the center of the city to serve as a dispensary; for the treatment of the ambulant patients and their education regarding hygiene; and for the treatment of those patients who for any reason cannot be sent to one of the other sanatoriums. But such a hospital must be built according to modern principles of hygiene and sanitation, which fact not being true of the building selected rendered it, in my mind, unfit for the purpose.

These were the reasons for my opposition which I gave at the meeting, but I am also glad to be able to say that the major part of my remarks was devoted to an exposition of the great importance of the work being done in the treatment of tuberculosis by means of sanatoriums and special hospitals, and of the duty devolving upon all citizens to aid in that great work.

But the fact that I entertained no fears for the hospital as a source of contagion must not be construed to mean that every precaution should not be taken for the prevention of the dissemination of the contagion. On the contrary, though we know that tuberculosis is often not communicated even by intimate contact with the tuberculous, still from what we know of the nature of the dissemination of the tubercle bacilli, viz., mainly through the sputum, dried or in fine spray, such dissemination should be guarded against by the enforcement of modern methods of prevention, including the restriction of spitting by patients in the streets and in the hospital, the destruction of the sputum or its disinfection, etc. According to Knopf, objections to the establishment of tuberculosis hospitals are still to be overcome in parts of this and other countries. These are unfounded, for from the presence of properly conducted sanatoriums there is not the least danger to the neighborhood.

Permit me to say a word in regard to the remark in the editorial that "Two of these persons are said to have the title 'Dr.' before their names." Not stopping to discuss the validity of that title, or whether or not it was well-earned and well-deserved, I yet wish to say that, under the circumstances, that aspersion was unmerited.

## PRIMARY VACCINATIONS.

BY  
A. L. BENEDICT, M.D.,  
of Buffalo, N. Y.

In a vaccination experience of about 1,800 to 1,900 cases, including some 400 to 500 primary cases, I have had no absolute failures of primary vaccination. Of course, I do not allude to the common failure of a first inoculation, from defective virus, error of technic, etc. A few children required several attempts. One boy, G. H., was supposed to be immune to vaccinia, having already been vaccinated several times without success. He was intelligent beyond his years, and willingly reported for observation and revaccination. He was vaccinated two successive autumns, three or four attempts being made within a month or two. The third autumn he was successfully vaccinated, the lesion having every indication of being primary and thus corroborating the history and the lack of scars of considerable size. As nearly as could be determined, he had been vaccinated in all 12 to 15 times before a successful result was achieved. There was no definite history of hereditary immunity either to variola or to vaccinia, nor of actual exposure to smallpox, although smallpox had prevailed to some slight extent in the city. It may be observed that after an unsuccessful attempt at primary vaccination two points were used in every subsequent attempt.

## SUDDEN DEATH AND UNEXPECTED DEATH IN EARLY LIFE, WITH ESPECIAL REFERENCE TO THE SOCALLED THYMUS DEATH.\*

BY

J. P. CROZER GRIFFITH, M.D.,  
of Philadelphia.

Professor of Diseases of Children, University of Pennsylvania.

The term "sudden" may be used to indicate a death occurring in from a few seconds up to a few hours at the utmost, while "unexpected" may be conveniently applied in this connection to the deaths taking place somewhat more slowly and yet entirely unexpectedly in patients who had previously shown no alarming symptoms or any reason why a fatal issue need be apprehended. Occurring in either of these methods, death is not infrequent at any age, but is especially common in the first two years of life. West reported 627 instances at all ages collected in London in 1854 (Brouardel<sup>1</sup>). Of these 272 occurred in children under 5 years old, and in 126 of these the infant was not yet 1 year old. Richter<sup>2</sup> reported 1,797 cases of sudden death in children up to the age of 15 years occurring during five years. Of these 1,525 were in the first year. The causes are rather different at this early age, however, from those operating in adult life. In later years we find sudden death from such causes as valvular heart disease, angina pectoris and apoplexy predominating. In infants, on the other hand, more prominent among the causes are convulsions, syncope, and especially diseases of the respiratory apparatus.

Doubtless all of us have met with cases in our practice among young children in which death occurred suddenly and very unexpectedly. The reason has often been very obscure or entirely undiscovered. Even an autopsy has revealed nothing in the way of explanation. The child may have appeared to be perfectly well and then died suddenly. In other instances death perhaps has occurred unexpectedly during some disease in which we had no reason to dread a fatal issue, at least at the time. In still other cases it is probable that some condition was operative which, although overlooked by the mother, was of a nature which would have been evident to a physician had one been present. In any event, as the occurrence is most disturbing to the parents, and possibly a cause of reflection by them upon the physician, the matter is worthy of study apart from the natural scientific interest which pertains to it.

We cannot pass in review all the possible causes, but must limit ourselves to some of the more prominent or most interesting of them. The low resisting power of infants and the great excitability of the nervous system are the principal reasons for the occurrence of sudden death at this age. Conditions affecting the *respiratory apparatus* are generally, and with good reason, considered to hold the most prominent etiologic place. *Coryza* occurring in the newborn may rarely be the cause of sudden death by what has been described as aspiration, or swallowing, of the tongue. By the violent efforts at breathing through the mouth the tongue is drawn backward and its inner surface and tip become pressed against the hard palate, cutting off more or less the entrance of air. Death in the same way is said occasionally to occur in young infants with pertussis. Doubtless this accident is not of so frequent occurrence as was formerly supposed, yet apparently death does undoubtedly take place at times in this way, and perhaps oftener than we imagine. Bouchut<sup>3</sup> was the first to call attention to this. He has observed it several times and details an interesting case in a child of three weeks where breathing had been badly obstructed by coryza

and where death occurred. Henoeh<sup>4</sup> describes two cases of the same nature. In one of these instances in order to relieve the condition it was necessary to keep the tongue drawn forward by a catgut thread passed through its tip.

*Asphyxia from overlying* is a cause of sudden death in infancy which has long been recognized. I may call to your mind, for instance, the judgment of Solomon between the two mothers, one of whom had overlain her own child and claimed as hers the living child of the other. In view of the interest possessed by death from suffocation from a medicolegal standpoint, it is important to bear in mind that asphyxia from overlying or from direct smothering with criminal intent is undoubtedly of very much less frequency than has been commonly supposed. Most infants believed to have died in this way probably owed their death to other causes. We must remember that weakly, and especially premature, children, born with a certain degree of asphyxia, are exceedingly prone to suffer from a fatal relapse after the physician in attendance has supposed that all danger was over. The necessity of constant watchfulness for days in these cases is very great.

Undoubtedly *spasm of the glottis* has appeared to be one of the most prominent and startling causes of sudden death, especially in those infants who have been in apparently perfect health. It may be that we have been warned by previous attacks of laryngeal spasm. In other cases there has been nothing to indicate the danger. The spasm depends on the very great irritability of the nervous system, oftenest seen in debilitated or rachitic children, but sometimes occurring quite independently of such conditions. It is probable that many cases of death attributed to other causes in reality depend upon this. Perhaps still oftener, however, death only *seems* to be the result of laryngospasm, but in reality is dependent upon syncope. There is reason to believe that this is true of many, or even of most, of the cases of death attributed to laryngospasm. This will be referred to again later. I may detail the following interesting history of a case of sudden death from what appeared to be spasm of the larynx:

CASE I.—Hymen Goldstein, 7 months old. Admitted to the Children's Hospital, Philadelphia, January 6, 1902. The history was of a very vague character, the child's mother, who could speak little English, saying that the "child died every day." The child had a convulsion in the receiving ward and another the same night in the hospital ward, the latter of very short duration.

The examination showed a well-nourished child, with the heart and lungs exhibiting nothing abnormal; the fontanel too large and too prominent; blue veins over the scalp; no teeth; beaded ribs; abdomen distended and the veins over it prominent; the spleen not felt, probably owing to the distention. There was also a slight tendency to abdominal tache.

No further symptoms, however, were manifested, and the general condition was excellent until January 12, when at 5.45 p.m. the child, without apparent cause, became cyanosed and stiff, and respiration and the action of the heart ceased. It immediately became relaxed, the cyanosis disappeared, and the pupils became dilated, but the heart failed to respond to active stimulation, and artificial respiration and oxygen were of no avail. During the illness the temperature was about 98°, with occasional rises to 100°.

The characteristic features of the clinical history were the presence of well-developed rickets, and the repeated occurrence of laryngospasm before entrance into the hospital.

The autopsy was of particular interest. It showed the subcutaneous fat well preserved, the blood very dark, the lungs almost airless and deeply cyanotic, the thymus gland hypertrophied, red, with the two lobes overlying the heart, hiding it from view, and extending down to the diaphragm. It measured 8½ cm. in length, 4½ cm. in breadth, 1 cm. in thickness, and weighed 21 grams. There was no evidence of compression by the thymus of the surrounding structures. The trachea was patulous; the mediastinal and bronchial glands slightly enlarged; the liver of normal size, slightly fatty; the spleen enlarged, weighing 34 grams. Peyer's patches were very prominent and the mesenteric glands were enlarged and very numerous, but not caseous. Tubercle bacilli were found in the latter on microscopic examination. The kidneys were dark and slightly lobulated.

The characteristic feature of the autopsy was the general lymphatic enlargement, especially of the thymus gland.

\* Read before the Association of American Physicians, May, 1903.

Another very similar case may be detailed:

CASE II.—Steve Lazo, aged 6 months, admitted to the Children's Hospital, February 6, 1903, for convulsions. The child had been having convulsions at irregular intervals since January 1, 1903, and seemed in the intervals to be fretful, and cried a good deal of the time. On February 8 he was noticed to be somewhat rigid, with the thumbs held in the position of tetany. Examination on this morning showed a well-nourished child with the head rather rachitic in shape and with rather large fontanels; some veining of the scalp and at the root of the nose; a moderate degree of beading of the ribs; no enlargement of the wrists; the abdomen somewhat distended with gas; the spleen not felt; a few coarse rales in the chest. No convulsions occurred, but the child did not look well, and on February 11 commenced to vomit its food with considerable force immediately after taking it. On the afternoon of February 13 the child looked better and slept some hours. On waking from sleep at 3 p.m. he exhibited slight twitching of the face, and then immediately developed intense jactitation, as though unable to breathe. A few ineffectual efforts at respiration took place, and the heart beat very feebly and intermittently, and in a few moments death occurred. There was no rigidity or general clonic movements in the attack. Slight fever had been present since the day of entrance.

The autopsy showed the external lymphatic glands of the body slightly enlarged, and the subcutaneous fat well preserved. The tonsils were decidedly enlarged, and the glands at the base of the tongue slightly so. There was slight hypostatic congestion of the lungs; the bronchial and mediastinal lymph nodes were moderately enlarged; the heart appeared normal; there were numerous enlarged glands in the mesentery. The lymphatic tissue of the intestines was hyperplastic. The spleen was moderately enlarged, deep red in color, with the Malpighian bodies increased in number and size. The liver was slightly enlarged; the kidneys normal. The most interesting feature was the condition of the thymus gland. This organ occupied the upper third of the mediastinum and extended downward over the base of the heart, the lower third of it more or less surrounding the great vessels. It measured  $7\frac{1}{2}$  cm. in length and 4 cm. in breadth at its widest portion. There was no evidence that it exerted any pressure upon the trachea or other organs.

The main features of note in both cases were the presence of rickets, the history of convulsions, the sudden death, and, at the autopsy, the decided widespread hypertrophy of the lymphatic tissue of the body, and especially of the thymus gland.

In both these cases the condition during life and at and after death corresponds entirely with the condition found in the much discussed "thymus death." Cases of this nature and under this heading have been reported many times in literature, and much has been written for and against the possibility of the occurrence of death due to enlargement of the thymus gland. The literature on the subject is large, and the controversy has been at times very active. An extended review of the whole subject would be of little value in this connection, as it would but repeat what has been well done by others, notably Friedjung,<sup>5</sup> in an exhaustive and able critical review. Only a very brief review of the subject can be given.

As early as 1614 Plater<sup>6</sup> called attention to the fact that the thymus was often found enlarged in cases of sudden death. After that the connection was repeatedly referred to, and in 1830, after writings by Kopp,<sup>7</sup> the belief in the existence of a thymic asthma due to an enlargement of the thymus became general, and the identity of this with laryngospasm was accepted. The extensive investigations of Friedleben<sup>8</sup> overthrew the earlier views completely. He denied the existence of a thymic asthma, or of any relation between the thymus gland and laryngospasm, and upheld his position so successfully that his views were generally accepted. This state of things continued, and only a few writers held to the earlier views until Grawitz<sup>9</sup> directed renewed attention to the possibility of compression of the trachea by an enlarged thymus, and detailed two cases of sudden death which he attributed to this cause. Many others followed his lead with cases purporting to be instances of death from pressure, until Paltauf<sup>10</sup> advanced his theory of the influence of the lymphatic constitution, or the "status lymphaticus," in the production of sudden death. According to this view, accepted by Escherich<sup>11</sup> and followed by many others, the enlargement of the thymus, as of other lymphatic tissue of the body, is but the ana-

tomical manifestation of a certain disordered constitutional state of a lymphatic-chlorotic nature, which so influences the nervous system that sudden death may occur from the cessation of the heart's action, brought on by very slight and varied causes.

The whole subject is in a state of discussion still, and it seems impossible to reach as yet any final conclusions. At least it seems certain that it is possible for a much enlarged thymus to compress the trachea—or perhaps the heart, large vessels or recurrent laryngeal nerves—and produce death. A case was reported by Siegel<sup>12</sup> from Rehn's clinic, in which there was increasing dyspnea apparently from pressure upon the trachea. Tracheotomy was without avail. The jugulum was then incised, and the thymus found and anchored to the edges of the wound, the symptoms being at once relieved. A very similar case of relief was reported by Koenig,<sup>13</sup> and still another by Perrucker.<sup>14</sup> A certain small number of cases has been published in which there seemed at the autopsy no doubt that the trachea, the large vessels, or the nerves had been compressed during life. Thus in a case of Marfan's<sup>15</sup> a child of  $2\frac{1}{2}$  months exhibited symptoms during 24 hours or more before death; and at the autopsy the trachea was found almost completely flattened by a very large thymus gland. Other cases of death apparently due to compression are those of Clessen,<sup>16</sup> Kruse and Cahen,<sup>17</sup> Kohn,<sup>18</sup> Flügge,<sup>19</sup> Biedert,<sup>20</sup> Abelin,<sup>21</sup> and others. However, in the great majority of cases attributed to pressure there has existed no real evidence either during life or at the autopsy that death was actually produced in this way. This is true, for instance, of the cases reported by Grawitz,<sup>9</sup> Lange,<sup>22</sup> and d'Oelsnitz.<sup>23</sup> It has been assumed merely that because the thymus was found enlarged death must have resulted from its pressure. But if the death is one from pressure on the trachea, the symptoms should have come on more slowly, with increasing difficulty of respiration not relieved by tracheotomy. This is, however, not the usual history. It is characteristic of the truly sudden "thymus death" that the child has previously been in good health or entirely free from alarming symptoms, and has then died quite suddenly as though from laryngospasm or heart failure. To meet this difficulty the view has been advanced repeatedly that the thymus, already hyperplastic, undergoes, for reasons not understood, a sudden congestive swelling, or possibly a sudden increase in size dependent upon its own secretion, and that this gives rise to the pressure symptoms and the immediate fatal ending, which is aided, too, by any bending backward of the head, since this narrows the space occupied by the thymus gland and adjacent structures. Beneke<sup>24</sup> reported three cases of sudden death in which he believes that this bending backward was a prominent factor. It is true that the space between the manubrium sterni and the vertebral column is very small—1 to 3 cm. at 2 years of age, Pott;<sup>25</sup> 2 cm. at 8 months (Jacobi<sup>26</sup>)—and that the sudden swelling of the thymus could readily produce pressure-symptoms. But for the view, convenient as it is, that such swelling does or can occur, there is still lacking either anatomic or physiologic proof. Friedleben has shown that the blood-vessels of the thymus gland are comparatively few in number and small, and that no considerable enlargement of the gland through congestion could be produced by experiments on animals. Again, although he shows that under certain influences enlargement may follow from the secretion of the gland, he states that there is no proof that this is of such a sudden and considerable nature that pressure-symptoms can result.

With reference to the existence of the so-called status lymphaticus as an entity and its relation to sudden death only this much can be admitted without question, viz., that in a large proportion of cases dying supposedly of laryngospasm the thymus gland has been found enlarged. The enlargement is not, as a rule, great. Friedleben states that out of 75 such cases there were only 7 in

which the thymus was above an average size. Nevertheless the statistics also show, as Biedert<sup>20</sup> points out, that large thymus glands are commoner than small ones in cases of laryngospasm, so that after all some connection may exist. Richter,<sup>2</sup> on the other hand, found what he recognized as the status lymphaticus with much enlarged thymus in only one of his 1,797 cases of sudden death. Thus sudden death can occur without enlargement of the thymus; and it is noteworthy, too, that in many cases where the thymus had been found to be abnormally large neither a sudden death nor a slower death with distinct pressure-symptoms had taken place. Thus in a child of six months coming under my care in the Children's Hospital and seen at the same time as the infant, Steve Lazo, the death took place after several days of vague symptoms, the most prominent being failing heart strength, cyanosis, a semicomatose condition, and a difficulty in swallowing, dependent apparently upon the mental state or the great weakness. The autopsy showed a widespread bronchopneumonia of a lobar type of both lungs and an enlarged thymus gland weighing 12.88 grams and almost identical in size and in appearance with that seen in the previous case (Steve Lazo), but with little enlargement of other lymphatic tissue except the spleen. In these cases the symptoms were absolutely different from those of the "thymus death" and death evidently resulted from pneumonia.

As regards the possible hyperthymization of the blood or some other form of autointoxication arising from a hyperplastic gland, a theory suggested by Escherich<sup>11</sup> and emphasized by Svehla,<sup>27</sup> this does not seem to be supported by any clinical evidence. Thiemich,<sup>23</sup> Ganghofner,<sup>29</sup> and others express themselves strongly against it.

One fact does, however, remain clear—that there is a certain constitutional anomaly seen in some children, and even in adults, which predisposes to sudden death from trivial causes. It is true that enlargement of the thymus and of other lymphatic tissue is very often seen in these cases, but whether these are accidental accompaniments or not is uncertain. If they are accidental, as seems very probable, then the lymphatic system has nothing to do with the matter, and the name "status lymphaticus," as applied to the constitutional condition, is a misnomer. In other respects, however, Paltauf's views are supported by much clinical evidence and are shared by many writers. The only question is whether the constitutional anomaly rests upon an anatomical basis, either of the lymphatic organs or of others.

This constitutional disturbance depends on a state of faulty nutrition. Not that there is any wasting of the child, but that the condition of metabolism is in some way at fault. It is attended by pathologic disturbances of the nervous centers, giving this system an extreme irritability. The nerves controlling the action of the heart are, of course, involved, as are also to some extent those controlling respiration. It is on this account that many cases suffering from this anomaly exhibit a tendency to repeated attacks of true laryngospasm. The final sudden exitus appears, however, not to be due to spasm of the larynx, although it may so seem, but to a sudden cardiac paralysis, as pointed out by Escherich,<sup>11</sup> Pott,<sup>25</sup> and others. This appears to be true of the cases I have detailed, the heart having ceased to beat at the beginning of the attack.

The true laryngospasm is probably seldom fatal. In 425 cases of what had been designated as spasm of the larynx, Soltmann<sup>30</sup> found a mortality of but 11%. It is extremely likely that many, or most of these fatal cases owed the fatal issue to cardiac failure. Very slight causes are sufficient to produce this sudden cardiac death. Slight traumas are often sufficient, such as the giving of a hypodermic injection, or the puncture-test for a pleural effusion. The much quoted Langerhan's case of death after the injection of antidiphtheric serum is believed by Escherich<sup>11</sup> with reason to belong to this category.

Many sudden deaths during general anesthesia doubtless belong here also, as do the sudden deaths of persons in bathing, as reported by Nordmann<sup>31</sup> and others, and the interesting cases of death after applications to the skin, such as the use of lead water mentioned by Ranke<sup>32</sup> and the packing in salicylic acid solution reported by Escherich.<sup>11</sup>

The condition is a neurosis, but it is not necessarily the so-called status lymphaticus, as Ganghofner<sup>29</sup> has pointed out, and as I have already mentioned. The lymphatic overgrowth may probably exist without the neurosis and vice versa, although it is probable that they are generally combined. So, too, rickets is very frequently present also, for the reason that the disturbances in the nutritional condition are liable to produce all three conditions.

The symptoms of sudden death in these cases are very characteristic and very uniform. Often the child has appeared entirely well. In many cases, however, there is a puffy or pasty anemic appearance, and not infrequently the patient is rachitic. Enlargement of the lymphatic tissue of the body may or may not be found. In the great majority of the cases the death is entirely unexpected, and not preceded by any indications of danger. Very often the child is found dead in bed. In other cases there has been striking restlessness before the symptoms immediately attending death have commenced. These final symptoms have been well described by Pott.<sup>25</sup> The child suddenly throws back its head, makes noiseless, gasping efforts at respiration, and rolls its eyes upward. The pupils dilate; the face becomes cyanotic and swollen; the tongue is cyanotic, greatly swollen, caught between the jaws and pressed against the hard palate. The veins of the neck stand out as thick cords; the hands are clenched, with the thumbs in the palms and the forearms strongly pronated and adducted; the lower extremities are extended, and the toes adducted and dorsally flexed; the spinal column is arched. There occur slight twitching movements of the face and a few unavailing efforts at inspiration. The convulsions then stop at once, the face becomes ashy, the cyanosis lessens, and in at most one or two minutes death occurs. The action of the heart ceases at the beginning of the attack.

I may report another very interesting case in which death seemed to the attendants to have taken place on two occasions before the fatal issue really occurred. In the absence of an autopsy we do not know with certainty whether the thymus was enlarged or not.

CASE III.—Marie U., born November 16, 1900. When two months old, in January, 1901, while having her nose sprayed with an atomizer she suddenly stopped breathing and became blue in the face. She was carried immediately to the Children's Hospital, which was close by. Sylvester's method of artificial respiration was employed together with oxygen and stimulation. It was only after ten minutes that respiration was again established. From this time on she was troubled with accumulation of mucus in the throat, which appeared at times to interfere with nursing, causing her to choke, although never in a suffocating manner. Any violent attack of crying, however, was liable to bring on a momentary suffocative attack, apparently of the nature of brief laryngospasm. Her general nutrition was only fair, and she cried a great deal, probably the result of hunger. There appeared also to be obstruction to respiration through the nose, which probably accounted for much of the difficulty in nursing. There was also much flatulence.

Under careful management of her diet her weight steadily increased. She weaned entirely at the age of 5 months and continued to gain and to be in very fair health, except for a constant disposition to keep her mouth open as though adenoid growths were present. At the age of 6 or 7 months she passed successfully through a severe attack of pneumonia, apparently croupous in nature. When a little over a year old, January, 1902, having been apparently well previously, she was taken to a neighbor's house by her mother. While returning she developed difficulty in breathing, became blue, and then ceased to breathe entirely. The attack appeared to be the result of exposure to the cold air. She was again taken to the Children's Hospital, which was fortunately nearby. The same methods were employed as before, but apparently without success, and she was considered dead. Finally, however, by the use of Sylvester's method of artificial respiration and by the

administration of oxygen, with hypodermic injections of whisky, she recovered by the end of 15 minutes, respiration starting of its own accord, and the child's color became normal. From this time she continued in very fair health, except for the positive presence of large adenoid growths, which, however, Dr. Walter J. Freeman, who saw her at the time, feared to remove on account of the suffocative attack at the time when the nose was sprayed. Examination in February, 1902, showed a slight dulness over the upper sternum, indicating possibly an enlargement of the thymus gland, but not being at all conclusive. In July, 1902, she suffered from a slight attack of scurvy.

At the end of October, 1902, being now nearly 2 years old, she developed a bronchitis. A day or two later she developed considerable fever and a remarkable degree of jactitation, with some increase of the rapidity of respiration, although without any other special evidences of dyspnea in the form of heaving of the chest or moving of the alæ. No physical signs of pneumonia could be found. By the next morning she was greatly worse; pale, slightly cyanotic, with numerous scattered rales in the chest. By afternoon she was taken into the Children's Hospital where, in spite of inhalations of steam, the use of atropin, and other appropriate treatment, she grew rapidly worse, and died within 24 hours from the time of the onset. No autopsy was permitted.

The cause of death in this case may possibly have been a rapidly developing bronchopneumonia. Yet the impression at the time was that the child was smothering, in spite of our inability to find in the lungs a satisfactory explanation for this. Pressure by an enlarged thymus may perhaps have existed, but the case is very similar to that of Kohn,<sup>18</sup> in which there was the same great restlessness, and pneumonia was suspected. The thymus gland in his patient was found enlarged at the autopsy, yet there seemed to be no proof that death occurred from pressure. In this case as well as in my own it is probable that the death was due to a heart failure, depending on the neurosis already described, and that the status lymphaticus may have been combined with it.

Sudden death may occasionally occur in *pertussis* as a result of bronchopneumonia or oftener of a spasm of the larynx. Ducastel<sup>33</sup> and others have reported cases of this nature. Death from aspiratio linguæ in this disease has already been referred to. Death may also occasionally take place in infants from *expiratory apnea*, as Kasowitz denominates it.

What is probably a central involvement of respiration sometimes occurs and ends fatally. Sometimes this is seen in children who have the neurotic tendency which might in some cases lead to laryngeal spasm. In such instances the child dies almost instantly, as though from heart failure, and indeed, in some cases, probably from this. In other cases, respiration becomes more and more rapid without other symptoms, and without discoverable cause, and the infant dies in a few hours. It may take place in the course of some other illness or in children not previously sick. An interesting case of this nature, in which the child recovered from a desperate condition, has been reported by Westcott.<sup>34</sup> The following instance, in a patient seen with Dr. Herbert P. Fisher, illustrates this condition:

CASE IV.—Wellington H., 10 months old. In July, 1899, he suffered from a disturbance of the bowels in which, although there was diarrhea, the evidence of constitutional involvement appeared by far the most prominent symptom. The stools were offensive, green, not very frequent, and contained some mucus. The child appeared to be improving steadily, when he developed an unnatural drowsiness with slight fever and extremely rapid respiration; the most rapid, Dr. Fisher says, that he has ever seen in any child. There was no cyanosis, and the pulse was not rapid in comparison with the respiratory rate. The child refused nourishment, and lay perfectly quiet except for the rapid breathing. This condition developed in the afternoon and continued more or less during the night with little improvement. Toward morning large watery stools were passed, the result of a purgative given, and the rate of respiration rapidly returned to normal, leaving the child pale and weak, but wonderfully improved at the time when I saw him.

In this instance, although death did not occur, yet it was so imminent that the case may well be used to illustrate the danger of a fatal ending from a central respiratory involvement, the nature of which is not clear.

I may report still another instance in which, unfortunately, the issue was not so happy.

CASE V.—Baby D., first seen December 19, 1900, when 6 months old. The child was at that time in an extremely wasted condition, starving upon a food which was insufficient to support life, yet which had appeared to be the only thing it could take without vomiting or diarrhea. On very careful feeding the baby steadily improved, was bright and apparently entirely convalescent except for an occasional tendency to looseness of the bowels. By the end of February it had gained three pounds in weight. After that there was an inconsiderable loss with rather more frequent movements. On March 11 the child was slightly colicky yet looked well, and I told the parents that I had no further anxiety about it. In the late afternoon of the twelfth it still looked well, and the parents had noted nothing amiss. I observed, however, that the respiration was decidedly too fast. No fever, cough, nor labored breathing was present, and nothing abnormal could be found in the chest. In the next few hours the child failed with extraordinary rapidity, the respiration growing more rapid and shallow. The child died suddenly in the early morning hours of the thirteenth before a physician could be summoned. Percussion of the chest after death showed nothing abnormal. There was no autopsy.

The diagnosis in this case was a respiratory failure from intestinal toxemia, no other cause seeming to suggest itself.

The rapid development of *bronchopneumonia* may sometimes kill with apparent suddenness, the attendant having noticed no symptoms, or the gravity of the symptoms being entirely overlooked. This is of very common occurrence in the newborn. Probably the majority of cases of sudden, or at least rapid and unexpected, death at this age are due to this cause.

Sudden death from *heart failure* is not uncommon in early life. This is not infrequently seen in infectious diseases, especially diphtheria, due to changes in the heart muscle, or to the influence of toxins in the blood. It may also occur in debilitated states or in respiratory diseases, especially pleural effusion, as a result of too sudden a movement, improper position or excitement. I recall a case of severe diarrhea in an infant of less than a year, in which collapse, followed by death in little more than half an hour, appeared to have been precipitated by the careful raising of the infant into the sitting position for the purpose of examining the lungs. Sudden cessation of the heart's action may take place also in cases of acute nephritis on account of the strain which increased arterial tension has thrown upon the heart. So, too, stopping of the heart may occur as the result of distant nervous influences. Thus it is possible that the sudden death in healthy children which has occasionally followed sudden movement or excitement, as, for instance, tossing the child into the air, has been caused by inhibition of the heart's action. As we know, however, that excitement of this nature is well capable of producing spasm of the larynx, it is equally possible that the death may have been due to the latter. In fact, many cases of sudden death placed in other classes might with propriety be considered as due to heart failure.

Sudden death in children known to have *organic heart disease* is probably not so common as in adult life. It may, however, occur where we expect it not at all. The following case is an illustration of this fact:

CASE VI.—Bertha Sweeney, 3 years old. Admitted to the Children's Hospital on November 21, 1901, for genu valgum, the result of well-marked rickets. She developed a scarlatinal rash and was sent home five days after admission. The family physician pronounced it a "baby rash," and the child was readmitted to the hospital about December 2, to be operated on for bowlegs. She had become apathetic and drowsy, and in a few days desquamation was discovered on the body and albumin and casts in the urine, and the child was again sent home on account of danger to other patients. Her heart at the time showed nothing abnormal. On January 11, 1902, she was readmitted. Examination showed slightly cyanosed lips, rapid breathing, some dyspnea and cough, and a few rales in the lungs. The urine did not contain albumin. A double murmur was heard at the cardiac apex, with accentuated aortic and pulmonary second sounds. On January 14, at 9 a.m., after seeming very bright and not at all ill, her heart suddenly ceased beating and failed to respond to stimulation. The only other symptom present was the fact that she had vomited five times during the previous night.

The autopsy showed a considerable amount of clear fluid in each pleural cavity, with some hypostatic congestion of the lungs. The pericardial sac was much distended with clear fluid without evidence of recent pericarditis, but the pericardium was firmly adherent to the upper portion of the right auricle. The endocardium of the right auricle was yellow and fibrous; the lining of the other chambers and of the valves was apparently normal. Death appeared to have been due more to hypertrophy and dilation of the heart than to the existence of actual valvular lesions.

Sudden death in infants with *asthenia* is of comparatively frequent occurrence. It happens often that an infant who has been ill in bed in apparently the same weakly condition which has lasted for days or weeks will unexpectedly be found to have died without any change of symptoms to account for this. This is especially common in cases of premature birth. The autopsy often shows no lesions whatever. An instance of this inexplicable sudden death is the following:

CASE VII.—Helen Elizabeth M., 9½ months old in June, 1902. She had suffered severely from whoopingcough, possibly complicated by pneumonia, several months before. She had recovered from this, but was always underfed, and had not been gaining in weight. There was a constant moaning cry, and the child was evidently starving. Under a carefully regulated diet she steadily and rapidly improved. I had felt all uneasiness about her disappearing, when I was told that she had been taken out in her coach one morning, apparently well, and then died suddenly without discoverable cause. The abdomen is said to have been somewhat swollen on the morning of the day of death, but to no greater a degree than she frequently experienced. There is said to have been slight edema present a few days before death. The weight of the baby when completely dressed with clothes for outdoors was only a little over nine pounds.

It is a noteworthy fact that these wasted infants sometimes gain in weight shortly before death occurs. In such cases the gain may be due to a degree of general edema, depending upon the feeble cardiac power.

I have already alluded to many cases of death, which evidently depend upon disordered states of the nervous system, although exerting their influence upon some special region of the body, as for instance, in spasm of the larynx, heart failure, etc. Still another very common cause of sudden death included among nervous affections is *convulsions*. These are, after all, only a symptom and are in many cases rather the attendant than the cause of the fatal issue. *Hyperpyrexia*, due, of course, to the influence of some agency upon the nervous system, is a not infrequent and very unexpected cause of death, very rapid even if not actually sudden, occurring in children who have been perfectly well or only slightly ailing but a few hours before. This may be seen in heat-stroke in infants and in malignant eruptive fevers and very frequently in pneumonia. As a rule, a general convulsive condition attends death in such cases. The following case, one of heat-stroke, seen in consultation with Dr. W. K. Evans, illustrates this point:

CASE VIII.—James A. H., 2 years 11 months old. On July 14, 1900, he suffered from slight diarrhea. By July 15 he had recovered entirely. On the seventeenth he was exposed to prolonged heat while playing in the sun during the afternoon of a very hot day. Slight diarrhea followed with a temperature of 100.4° and symptoms suggesting cerebral involvement. On the morning of the eighteenth the bowels were somewhat better, the abdomen still tender and tympanitic. The child seemed irritable and did not wish to be lifted from the sofa, where he lay persistently on the right side. The temperature was 101°. By afternoon of the same day the condition was much the same. By the next day the symptoms were improved in every particular, and by the twentieth still more so and the child seemed practically well. On the twenty-first there was a relapse with some vomiting and a return of diarrhea. The mental state became heavy. The child felt the intense heat of the weather very much and sponging and stimulants were used repeatedly. There was no vomiting and the action of the heart was good. By 5.30 the temperature had risen to 106°, and unconsciousness with convulsions developed. The temperature was reduced, but rose by 8 o'clock to 108°. An ice-pack reduced the temperature to 100°, but consciousness was not recovered. The temperature again rose rapidly, attained 108° by midnight, and death took place shortly after.

Death in this case was entirely unexpected. There were really no bad symptoms of any kind until the late

afternoon of the last day of life, when the convulsive and comatose condition developed. The extreme elevation of temperature at 8 o'clock was entirely unsuspected. We were about to give a warm bath for the convulsions when the thermometer revealed that cold water and not hot was urgently needed. These cases of heat-stroke in infants are common. I have seen them repeatedly.

Another case may be related, showing the unexpected death depending on hyperpyrexia in pneumonia.

CASE IX.—Baby V., 3½ months old, had been suffering for a short time from whoopingcough which was not particularly severe. Examination of the chest had revealed what had hitherto not been suspected—that the child was also the subject of congenital heart disease. The physical signs were very positive, the murmurs being loud, yet the baby exhibited no cyanosis. In June, 1896, the child suddenly developed slight physical signs of pneumonia, convulsions and a rise of temperature to 108°. Cold baths were employed and the temperature fell to the neighborhood of 100°. The convulsions ceased, but the child remained weak, and died in an hour or two after the onset of the critical symptoms.

Of course neither of these cases is at all uncommon. I have detailed them merely as illustrations of a condition too often seen.

Convulsions are, of course, due to many other causes than hyperpyrexia. Nervous reflex irritability of various parts of the body may be responsible. All of us, unfortunately, are doubtless rich in experience of sudden death from convulsions in the case of children about whom neither we nor the parents had had the slightest anxiety.

To be classified in diseases of the nervous system are probably those cases in which death takes place in marantic states apparently due to the *depressing effect of chilling* or to a fall of bodily temperature without discoverable cause.

*Congenital syphilis* is a not infrequent cause of sudden death even in infants which appeared perfectly healthy. This has been emphasized especially by Fournier.<sup>35</sup>

Rarely asphyxia may result from the *rupture of a caseous bronchial gland* or a *retropharyngeal abscess* into the respiratory tract. This latter has been reported in a good many cases. The symptoms of an abscess of this kind are apt to be overlooked by one who is not familiar with them, and death may take place very suddenly if the abscess ruptures. In other instances death results from *pressure of intrathoracic growths* or enlarged glands upon the pneumogastric nerve. The *aspiration of food* into the windpipe has been assigned as a cause of sudden death. Parrot (quoted by Brouardel<sup>1</sup>) has reported a number of such cases. The occurrence probably takes place much less often than has been supposed, and only in the weakest infants in which the ability to cough has disappeared. It seems very likely in the cases where a curd of milk has been found in the windpipe that it has reached this position only because the child was in the act of dying when the final vomiting took place. The same is true of asphyxia from the *entrance of ascarides into the larynx*. Although death has been repeatedly ascribed to this cause, in most instances it is probable that the worms entered the respiratory tract after death. A very interesting case has, however, recently been reported by Wagner<sup>36</sup> in which there was no doubt that the sudden death was the result of suffocation from a cluster of ascarides obstructing the glottis.

*Gastrointestinal affections* seldom occasion sudden death in early life. A number of cases are reported by Bouchut<sup>3</sup> and others where sudden death appeared to have been induced by large numbers of ascarides in the intestines. It is probable, however, that this is of rare occurrence.

Various *malformations and accidents* not already mentioned may also produce death. Among these are perforation of the intestines, entrance of foreign bodies into the larynx or trachea, injury from forceps, strangulated hernia, external hemorrhage from the stomach or bowels, and internal hemorrhages, especially in the new-

born. Meningeal hemorrhage is the most frequent form of this latter, but other regions may suffer. I may close with an interesting instance of an entirely unexpected death from hemorrhage.

CASE X.—Baby C., female. Born June 7, 1902. Owing to a contracted pelvis on the part of the mother, the child was delivered presumably at the eighth month, although its well-developed state after birth renders it probable that some mistake was made regarding the exact stage of pregnancy. Labor was rendered difficult only by a remarkable degree of uterine inertia, which made podalic version necessary. The aftercoming head was delivered, however, largely by internal effort. There was a moderate amount of asphyxia present immediately after birth, relieved promptly, however, in a few seconds, and never returning. Everything was favorable during the five days of life, excepting considerable colic with a slight difficulty in nursing from the breast, apparently not due in any way to lack of strength. On the night of the fifth day of life the child cried a great deal, apparently as a result of colic, was fed in the early morning, became quiet, and was laid down asleep in good condition. Shortly afterward, when again lifted, it was found to be breathing its last.

An autopsy showed the peritoneal cavity apparently nearly full of fresh blood. Dr. Alfred Hand, Jr., who made the examination, estimated roughly that "nearly a pint must have been lost." The source of the hemorrhage could not be discovered.

The cause of the hemorrhage in this case is difficult to discover. Sepsis not infrequently occasions widespread hemorrhage in the newborn. There was, however, no evidence of this condition here. In other cases the accident is due to strain put upon bloodvessels during difficult delivery. It seems probable that the case was of this nature. The hemorrhage may take place, primarily, directly into some organ, or secondarily, by bursting from some abdominal organ into the peritoneal cavity. The suprarenal bodies are perhaps the most frequent site of primary hemorrhage.

## THE TOILET OF THE PERITONEUM IN APPENDICITIS.<sup>1</sup>

BY

G. R. FOWLER, M.D.,  
of Brooklyn, N. Y.

In selecting the best method for performing the toilet of the peritoneum in operative attacks in cases of appendicitis, the surgeon will be guided largely by the condition of the peritoneum itself. From this point of view the subject under discussion may be divided into the following:

### 1. Cases in which no peritonitis is present.

<sup>1</sup> Read before the American Surgical Association, Washington, D. C., May 13, 1903.

2. Cases in which the infection of the peritoneum is present, but confined to the immediate neighborhood of the appendix.

3. Cases in which the pelvis is the seat of a seropurulent collection.

4. Cases in which the peritoneum and enteronic areas are the seat of infection (more or less generalized septic peritonitis).

5. Cases in which the entire peritoneum, pelvic, enteronic, and diaphragmatic is involved (diffuse septic peritonitis).

1. *Cases in which No Peritonitis is Present.*—Here the whole matter resolves itself into methods of protecting the peritoneum from infection during the operation, the details of which need not be entered into in this connection. It should be borne in mind, however, that whether the operation be undertaken during the period of quiescence or during an attack, yet, while the infection is still confined to the appendix, the mere fact of the removal of the latter involves opening the intestinal canal and the exposure of the peritoneum to infection from this source. It may therefore happen, from some awkwardly executed movement in the manipulation or other cause, that the peritoneum may become infected from the intestinal canal and render necessary a more than mere protective treatment of the peritoneal cavity.

2. *Cases in which Infection of the Peritoneum is Present, but Confined to the Immediate Neighborhood of the Appendix.*—Cases in this class may be subdivided into (a) those in which adhesions are present without suppuration; (b) those in which adhesions and suppuration are both present; (c) those in which neither adhesions nor suppuration are present.

In the first two subdivisions in this class a tumor will usually be felt before entering the abdomen, and the surgeon's first care upon opening the cavity of the peritoneum will be to safeguard the peritoneum by introducing gauze pads in such a manner as to "pack off" the portions still free from infection. I have not the fear of sublimate solutions in the peritoneal cavity held by some surgeons, and do not hesitate to saturate these gauze pads with a 1-2,000 solution of mercuric chlorid. It frequently happens that a sudden gush of horribly foul and infectious material takes place as adhesions are separated in approaching the appendix. This sometimes occurs with such force and in such quantities as to fill rapidly the gauze pads and even pass through and beyond these before it can be wiped away. In view of this it is only rational that an attempt be made to deprive this material of its highly infectious properties to an extent, at least, by contact with the sublimate as it filters through the pads. I have never seen harm result from the presence of the sublimate, and I think I have seen instances in which this precaution has prevented the spread of infection. If no pus is found, a simple sponging of the cavity in the adhesions in which the appendix lay, after the removal of the latter, with hydrogen dioxid, afterward cleansing this away with sterile salt solution, completes the toilet of the peritoneum. If pus is present this should be carefully removed by means of rapid sponging, the septic cavity from which it escaped treated with hydrogen dioxid, and the task of removal of the appendix proceeded with then, and then only. After the removal of the appendix the question of drainage will come up. This should be decided in each case in accordance with the conditions present. If there be no perceptibly septic conditions remaining, such as sloughing adhesions and slate-colored patches of lymph in the neighborhood; if the stump of the appendix or the opening in the cecum from which it has been removed is well secured, the walls of the latter permitting the application of a purse-string suture or other trustworthy means, then thorough cleansing may be followed by immediate closure without drainage. If, however, the surgeon has any doubt upon either of the points mentioned, he should drain. The point selected

for the drain to emerge, however, should not be through the wound in the anterior abdominal wall, on account of the risks of subsequent ventral hernia which this involves, but laterally, just above the crest of the ilium and well in front of the line where the lumbar fascia joins the internal oblique and transversalis muscles. This will bring the point of emergence of the tube about on a plane half-way between the anterior superior spine and the highest point of the ilium. The track for the tube is made by a stab cut from without; the point for the entrance of the knife within is located by a finger in the peritoneal cavity, which also protects the colon from injury. Before withdrawing the knife a narrow forceps is passed along its blade and in the jaws of this a finger-sized rubber tubing is grasped and drawn into position. The inner end of the tube should project slightly beyond the peritoneal surface. A narrow strip of sterile gauze should be passed through the tube, its inner end resting in the septic space. The outer end of the tube and contained gauze drain should be dressed separately from the wound in the anterior abdominal wall.

When pus is present the patients should be treated in the above manner, particularly if the pus is very offensive or large in quantity. Patients in whom localized peritonitis is present, with neither adhesions nor suppuration, usually do well with removal of the focus of infection, cleansing of the region in which the appendix lay, and immediate closure. This is particularly true if neither gangrene nor perforation of the organ is present. The risks attending the occurrence of the first named are considerable and the attending peritonitis may be slight, moderate, or intense. In either case the damage which has already been done cannot be undone, and, with the removal of the appendix and cleansing of the surroundings, the peritoneal cavity may be closed. The more manipulation exercised at this time beyond that which is absolutely necessary, the more harm will be done, and no amount of drainage will control the spread of the peritoneal inflammation. Much harm may have been done by attempting to pass strips of gauze between coils of intestine in the effort to drain localities in which no fluid exists. The most rational course to pursue under these circumstances is to close the peritoneal cavity when cleansing has been effected, and that without drainage.

In cases of perforative appendicitis, the peritoneal cavity being unprotected by adhesions, practically the same course may be followed. Here, as well as in the case of a gangrenous appendix, isolation of the non-infected area during the operation should be practised. The use of the gauze pads is a necessity, and thoroughly wetting these with sublimate solution adds an additional element of safety. When a perforated appendix is found floating free in the peritoneal cavity search should be made for fecal masses or concretions in the neighborhood. With removal of the source of infection and local cleansing the surgeon has reached the limit of his endeavors so far as the toilet of the peritoneum is concerned. Unless doubt exists as to the closure of the cecum or the integrity of the intestinal wall at this point, the indications for drainage are not present, and this step should be omitted.

3. *Cases in which the Pelvis is the Seat of a Seropurulent Collection.*—It occasionally happens that a seropurulent collection is present in the pelvis in addition to a similar collection immediately surrounding the appendix. It is usually manifested by a sudden gush following the giving way of adhesions between coils of intestine, when there was no evidence of its presence previously. After carefully cleansing the original focus following removal of the appendix, a small bunch of gauze in the grasp of a forceps passed over the ileopsoas muscle and into the pelvis will detect such a collection. Once its presence is detected it should not be ignored. It should be removed by repeated yet gentle sponging with gauze, the intestines being carefully held away

from the pelvic brim and the surgeon's finger guiding the forceps grasping the gauze to prevent damage to the intestines. Following its removal a good-sized glass drainage tube is passed into the pelvis close to the ileopsoas muscle and into this equal parts of a 15 volume solution of hydrogen dioxid and a saturated solution of sodium carbonate are poured. A portion of this is forced out of the tube by means of a piece of gauze grasped in a hemostatic forceps acting as a piston, to cleanse the surroundings. In the male this tube is allowed to remain for 24 hours, or as long as more than a dram of fluid is aspirated therefrom each two hours. This tube is dressed separately and not included in the abdominal dressings and binder. I have known such a tube to be forced upon and produce perforation of the rectum from neglect of this precaution. In females drainage may be advantageously made through the cul-de-sac of Douglas and into the vagina with a rubber tube.

4. *Cases of More or Less Generalized Septic Peritonitis.*—By the term "general peritonitis" is to be understood infection of both the pelvic and enteronic areas. The involvement of such a large portion of peritoneal surfaces brings the surgeon face to face with a very serious condition, and operators differ somewhat as to the course to be pursued in making the toilet of the peritoneum under these circumstances. Most patients in this condition do not bear operative shock at all well, and in general terms it may be said that the less done beyond the immediate requirements of the case the better, namely, the removal of the primary focus of infection—*i. e.*, the appendix—particularly in that class of cases in which the peritoneum presents a coppery hue and but little, if any, fluid is present. In this class of cases the surgeon should feel that he has accomplished much when he has rid the patient of the source of the sepsis, and rest content with this. Here and there he will encounter a case in which intestines considerably reddened, or even but slightly so, will be seen floating in a milky fluid. In this class of cases the patients are, as a rule, not in so desperate a state as those last mentioned, and something further may be attempted for them. It has been my practice in recent years to insinuate gently the point of a Chamberlain tube between the coils of intestines in the direction of the liver and spleen successively, and irrigate the abdominal cavity with warm saline solution. Considerable force is given to the stream by employing a very large tube and rubber-hose connection and elevating the reservoir to a height of eight feet or more. Large quantities, sometimes as much as six gallons, are used. So soon as the fluid returns clear from one place the Chamberlain tube is changed to another, until all parts are as clear as they can be made by flushing. It is not claimed that the cavity of the peritoneum can be thoroughly cleansed by this process, but it is made relatively clean, which is some gain. Again, as much of the saline as possible is left in the cavity, which serves the twofold purpose of diluting the infection which remains and inviting a rapid peritoneal leukocytosis, than which no better bactericidal effect can be obtained.

Eventration for the purpose of more thorough cleansing does more harm than good, and the so-called "scouring" method of ridding the intestinal coils of patches of plastic lymph is mentioned only to be condemned.

Finally, as I have heretofore described and practised,<sup>1</sup> there is something to be gained in this class of cases by placing the patient in a position to take advantage of gravity in causing the fluids in the peritoneal cavity to flow to the pelvis, and at the same time to antagonize the action of the diaphragm in attracting fluids to the upper part of the peritoneal cavity. The large stomata of the enteronic and diaphragmatic areas, which open

<sup>1</sup> Medical Record, Vol. lvii, No. 15, p. 617, 1900; Vol. lvii, No. 24, p. 1029, 1900.

out of the enormous lymph sac which constitutes the cavity of the peritoneum, are not readily closed by the coexistent septic lymphangitis, and their permeability to the passage of septic fluids leads to a transference of these to the circulation with resulting distant infection or general intoxication, or both. On the other hand, the gravitation of these septic fluids into the pelvic cavity results in an environment unfavorable to their absorption. The anatomic peculiarities of the pelvic peritoneum with its capillary lymph vessels is such that, as is well known, septic conditions of the most pronounced character may exist for a long time without grave danger to the individual. These anatomic points have been so well brought out by Byron Robinson<sup>1</sup> that it is unnecessary to dilate upon them here.

5. *Cases of Diffuse Septic Peritonitis.*—Cases in which apparently the entire peritoneum, pelvic, enteronic, and diaphragmatic is involved come under the head of diffuse septic peritonitis. It is probably true that the entire peritoneum is not necessarily infected in these cases, but the fact that all three of the areas mentioned are involved suggests the term "diffuse." The toilet of the peritoneum in cases in which this condition is due to appendicitis consists of removal of the septic focus, as thorough local cleansing as the circumstances will permit, the introduction of a glass drain into the pelvis, and rapid closure of the peritoneal cavity; these constitute the measures with which the surgeon must content himself in the majority of cases. Exceptionally, a patient may be presented in whom all three of the areas mentioned are involved in the infection, and who still may have retained sufficient vitality to justify the surgeon in proceeding further and flushing the peritoneal cavity with the Chamberlain tube and forced irrigation. Even the most favorable of the cases in this class do not bear the shock of intraperitoneal manipulation well, and whatever is done for them must be done as quickly as possible. But haste must not be permitted to give rise to rough manipulation or otherwise careless work. A patient with diffuse peritonitis of appendicular origin who survives after eventration is employed to assist in the cleansing of the peritoneal surfaces would have recovered without this aid. On the other hand, the promptness with which patients have died following this manipulation in my experience suggests to me that this has had something to do with the rapid death, and that the patients would have had an equal, if not better, chance for recovery without the additional shock which this measure entails. Whether flushing is resorted to or not the employment of the elevated head and trunk position, provided too much work is not thrown upon the heart by its use, assists in encouraging the passage of fluids in the upper peritoneal cavity to the pelvic area.

To sum up the subject of the toilet of the peritoneum in appendicitis cases the following propositions may be advanced:

1. In cases in which the infection is confined to the appendix the surrounding peritoneum should be carefully guarded against infection from the opening left in the cecum by the excision of the organ.

2. In cases in which suppurative collections are present the cavity of the peritoneum should be carefully guarded by gauze pads, which may be advantageously wet with 1-2,000 sublimate solution before breaking down limiting adhesions in approaching the appendix.

3. As soon as a pus cavity is opened the septic material should be rapidly sponged away and the neighborhood cleansed with hydrogen dioxid. Following this the appendix should be removed, after which the parts are subjected to a second cleansing process.

4. Outlying infection of the peritoneum may, as a rule, be left to take care of itself after the removal of the appendix and local cleansing.

5. In peritonitis more or less generalized in the pelvic and enteronic areas the method of procedure will depend upon the presence or absence of markedly septic seropurulent material. When the latter is present it should be carefully sponged away. If only thin and slightly turbid this will usually suffice. If, however, this is more decidedly purulent, and particularly if flakes of grayish, slate-colored lymph are floating about in it, providing the patient's condition will permit of it, the infected area may be forcibly flushed with saline solution and drained from the direction of the pelvis, the force of gravity being utilized in the after-treatment to encourage the flow of septic fluids from the enteronic to the pelvic area.

6. In diffuse septic peritonitis the conditions are usually such as to prohibit prolonged interference, and the surgeon will, in the majority of cases, be justified in interference only to the extent of removing the appendix and cleansing locally. In selected cases flushing the peritoneal cavity has advantages. The elevated head and trunk position should be employed in the after-treatment whenever possible. Favorable results from eventration can only rarely be claimed legitimately. Socalled "scouring" of the peritoneal surfaces for the removal of plastic lymph is a most unsurgical procedure.

7. Drainage, when instituted, should be by glass or smooth rubber tubes. Massive gauze packing or multiple and radiating gauze strips placed between the intestinal coils is probably never of real service, and may be productive of harm.

## THE ANATOMY OF THE PANCREAS.<sup>1</sup>

BY

EUGENE L. OPIE, M.D.,

of Baltimore, Md.

Associate in Pathology in the Johns Hopkins University.

In the brief time at my disposal I will review a few facts which have an important bearing upon the physiology and the pathology of the pancreas and will emphasize especially those which as yet have attracted little attention. The pancreas performing a variety of diverse functions is more complex in structure than the other glandular organs which it closely resembles. Pathological alterations have given importance to many anatomical details previously regarded as insignificant.

The earlier anatomists, among them Galen and Vesalius, gave, it seems, little thought to the organ, believing that it acted as a cushion to support and protect the adjacent structures, and it was not until the middle of the seventeenth century that the duct of the gland was discovered by Wirsung, who thus made possible a proper interpretation of its physiology. The organ has since been regarded as a type of secreting gland and to its study we owe many of the facts that have served to explain the process of secretion in general. The socalled salivary gland of the abdomen resembles the salivary glands of the mouth, but the peculiarities which characterize it have been known only since Langerhan in 1869 published his dissertation describing its minute anatomy. Yet until the last few years the histological structures which bear his name have attracted so little attention that their significance has remained obscure.

Few organs are subject to greater variation than the pancreas and of these variations particularly I wish to speak. It will be necessary to refer briefly to the normal embryology and anatomy of the gland. Santorini and subsequent anatomists have shown that it is provided with an accessory duct which, in some cases, can act as an outlet for the pancreatic juice, should the larger duct

<sup>1</sup> Read before the Congress of American Physicians and Surgeons, May 12, 1903, at the session devoted to a consideration of "The Pancreas and Pancreatic Disease."

be occluded. In different vertebrate species and even among members of the same species the ducts of the pancreas vary greatly, and until recently it has been believed that the embryonic origin of the organ is subject to equal irregularity, but evidence that is still accumulating has shown that development follows a plan which is common to all species of vertebrates.

The organ, according to most embryologists, makes its appearance as an outgrowth or bud upon the dorsal aspect of the intestinal canal at a point between the hepatic duct which has already appeared and what will subsequently become the stomach. A little later two additional embryonic buds develop at either side of the hepatic duct upon the ventral aspect of what is now the duodenum. The subsequent history of these rudimentary structures varies in different species. In man one of the two ventral outgrowths disappears, fusing, perhaps, with the other, so that the adult gland is formed by the union of a ventral part in contact with the bile duct and a dorsal part which forms the greater mass of the organ.

In accordance with this plan of development the gland is in most cases provided with two ducts of which the larger, the duct of Wirsung, enters the intestine in company with the common bile duct. The smaller accessory duct, the duct of Santorini, terminates in a papilla situated nearer the stomach than that of the larger duct. I hope I will not seem to cite unnecessarily, well-known facts if I recall the usual relation which exists between these two ducts. The duodenal orifice of the accessory duct is very minute; receiving branches from all sides, the duct increases in size and finally joins the duct of Wirsung, into which during life it doubtless pours its contents. Variations from this normal or usual type have been frequently noted. In many instances the two ducts fail to anastomose; at times that which is nearer the stomach, namely, the duct of Santorini, is larger than the duct of Wirsung; often the duodenal orifice of the accessory duct is obliterated, while occasionally one or other duct has not been found. More surprising, in view of the embryologic relations already described, is the claim that the bile duct occasionally enters the duodenum in company with the duct of Santorini, while the duct of Wirsung enters the intestine at a point more distant from the stomach. In such case the dorsal embryonic bud, in which originates the duct of Santorini, could not have arisen from the duodenum at a point between the hepatic duct and what will become the stomach.

Are the variations to which the pancreatic ducts are subject in the adult explicable upon the supposition that the pancreas develops from three original buds which bear a constant relation to the bile duct? Of more practical interest is the functional significance of the two ducts and their relation to lesions of the liver and pancreas. In order to obtain data more accurate than those at present available, I have dissected the ducts after injection in 100 subjects. The results of this examination, differing in some important particulars from those previously obtained, will be, I hope, of some interest.

Though the ducts varied considerably, there was no departure from the embryologic type already described. Two ducts were present in every instance, but occasionally one or the other was so small that it was found with difficulty. The common bile duct always joined the duct of Wirsung, while the duct of Santorini, unaccompanied, entered the intestine at a level nearer the pylorus. In 10 of 100 instances the two ducts failed to anastomose within the gland, and in 4 additional subjects the two ducts were united by such a minute twig that they might be regarded as independent of one another. In 20 instances the duodenal end of the duct of Santorini was not patent. These figures show that in at least a third of all individuals the duct of Santorini cannot act as an accessory outlet when the duct of Wir-

sung is occluded. Moreover, in a considerable number of specimens the orifice of the duct of Santorini, though patent, was so minute that its functional significance was slight, the accessory duct being functionally a branch of the larger channel. In 11 of 100 specimens the duct of Santorini, on the contrary, was equal in size or larger than the duct of Wirsung, so that during life it was doubtless the outlet for a considerable, if not the larger part, of the pancreatic juice.

Since cholelithiasis and other changes in the biliary passages are frequently the cause of lesions of the pancreas, the relationship of the pancreatic duct to the common bile duct has assumed increased importance. The two ducts usually unite to form a short common channel, the diverticulum of Vater, which is subject to almost as much variation as the pancreatic ducts themselves. I have examined the orifice of the two ducts in 100 specimens. In 11 instances no diverticulum was present and the two ducts entered the duodenum separately at the summit of the bile papilla. In the remaining cases the diverticulum varied in length from less than 1 to 11 millimeters, while in only 30 specimens did this measurement equal or exceed 5 millimeters. The duodenal orifice of the diverticulum of Vater had an average diameter of 2.5 millimeters. The figures are cited to show that unless a calculus, which has become impacted within the orifice, be of very small size, it will completely fill the diverticulum and occlude both ducts that enter.

The pancreas consists of a duodenal part, the head, and a narrower body which constitutes the greater part of the organ and is not definable from the splenic extremity designated the tail. This classical description should, I think, be somewhat altered, for the head, I find, consists of two well-defined lobes corresponding to the two ducts of the gland. The anterior and lower part of the head is tributary to the duct of Santorini and consists of lobules grouped about the duct and its branches. A second lobe is formed by a smaller mass of parenchyma disposed about the duct of Wirsung as it passes through the head of the gland, and is situated behind the larger lobe. In the specimens which I have examined a cleft filled by loose areolar tissue separates the two lobes and is demonstrated most readily after the gland has been placed in a hardening fluid. The adjacent lobular surfaces, when exposed, are as smooth and well-defined as the external surface of the gland. This interlobular cleft, in contact with the duodenum, lies midway between the two pancreatic ducts and its depth depends upon the distance from the duodenum at which the ducts anastomose.

Recent observations have disclosed a fact which, seemingly of little importance, serves to explain the occurrence of certain abnormalities of the gland. Within the papilla of the duct of Santorini, Helly has found in many individuals lobules of pancreatic parenchyma situated immediately below the duodenal mucosa. Occasionally provided with an independent duct which enters the duodenum near the orifice of the duct of Santorini, they constitute a true accessory pancreas. Studying the papilla in the embryo, Helly found that this pancreatic tissue originates at a very early period of development from lateral branches which bud from the duct as it passes through the mesoblastic layers of the intestinal wall.

This process, I believe, explains the occurrence of small masses of aberrant pancreatic tissue embedded in the wall of the stomach or of the intestine at a variable distance from the pancreas. Such aberrant glands are by no means so rare as has been supposed. I have collected from the literature only 22 examples, but in 1,800 autopsies performed in the pathological laboratory of the Johns Hopkins Hospital this anomaly has been observed in 10 cases. Nodules of pancreatic tissue 1 or 2 centimeters across have occupied the submucosa or muscularis of the stomach, duodenum or jejunum. In seven cases the accessory gland was situated above the

pancreas in the wall of the stomach or of the duodenum, and in three cases below the pancreas in the duodenum or in the jejunum. Of some importance, as will be shown, is the fact that in two instances two accessory glands occurred in the same individual.

The earlier writers, notably Zenker, assumed that an aberrant gland arose from an accessory embryonic outgrowth or bud from the intestinal canal. The constancy with which the pancreas of all vertebrates develops from three definitely situated duodenal outgrowths has, however, made it improbable that in man such a fundamental process is subject to variation. At the same time, this multiple origin has suggested that one of the embryonic structures which normally disappears may persist as an accessory pancreas.

In one case from the literature and in two of my cases two aberrant masses of pancreatic tissue were situated either above the pancreas, as in my cases, or below the pancreas, as in the case of Zenker. The existence of more than one accessory gland cannot be explained by the persistence of one or more embryonic structures, for in my cases the pancreas itself had undergone normal development and was provided with two ducts. A more probable explanation is the following: At a very early period of embryonic life a lateral branch of the pancreatic duct entangled in the mesoblastic layers of the intestinal wall is, by longitudinal growth of the intestine, carried a variable distance from the pancreas and a new duct is formed in much the same way that the pancreatic duct regenerates after section. In confirmation of this hypothesis I have found pancreatic tissue in the papilla of the duct of Santorini in two cases—the only ones examined—in which aberrant glands were found in the wall of the stomach, and in one case in which an aberrant gland was situated in the jejunum, that is, below the pancreas, lobules of pancreatic tissue were found within the bile papilla about the duct of Wirsung as it entered the intestine. Here pancreatic tissue has been rarely, if ever, found.

*Histology of the Pancreas.*—The larger ducts of the pancreas are lined by high columnar epithelium. The cells which form the smaller ducts become lower and finally flat as the secreting acini are approached. The acini are composed of large cells containing zymogen granules which, as Heidenhain has shown, present characteristic variation during different stages of secretion. Within the lumen of each acinus Langerhans found cells which resemble those of the terminal ducts and represent, as it were, an invagination of the duct into the lumen of the acinus. The nature and the significance of these centroacinar cells is not known. Of greater importance are the structures to which their discoverer's name has been given, the so-called islands of Langerhans.

Scattered among the secreting acini, several times the size of a single acinus, they are round or oval bodies composed of polygonal cells grouped together to form short, tortuous columns, which unite with one another in such a way that space is left for a network of wide capillary bloodvessels. If the bloodvessels of the pancreas are injected, glomeruli of tortuous dilated capillaries represent the capillary vessels of the interacinar islands, and though they have a superficial resemblance to the glomeruli of the kidneys, unlike the latter, they freely communicate by numerous anastomoses with the capillary network of the surrounding tissue.

The interacinar islands have been found in many species of mammals, birds and amphibia. For a time it was claimed that certain species did not possess them, but extended comparative studies have demonstrated the occurrence of analogous structures in all higher vertebrates and in a constantly increasing number of reptiles and fish.

The embryological studies of Laguesse and others have shown that the cells which form the islands of Langerhans have a common origin with those of the

secreting acini, and in the syphilitic pancreas of the fetus I have found that the columns of the island as a result of retarded development are continuous with the small ducts of the gland. When, however, the organ has completed its development the islands are wholly independent of the secreting elements, and it is not possible to trace a communication between the ducts of the gland and the interacinar islands.

The islands of Langerhans consist of columns of cells in intimate relation to a rich vascular supply and, having no communication with the pancreatic ducts, resemble in structure certain ductless glands, the parathyroid bodies and the adrenal glands and somewhat less closely the thyroid glands. Common to all vertebrate species, they doubtless have some important function. Independent of the secreting elements of the gland, they are not concerned in the elaboration of the pancreatic ferments. The relation of their cells to a rich vascular supply suggests that their action is through the medium of the blood. Abundant evidence in accord with these facts has shown, I believe, that the islands of Langerhans exert that influence upon carbohydrate metabolism which was formerly attributed to the pancreas as a whole.

In the human pancreas as in the human liver the lobules of the gland are not sharply defined, but in certain lower animals they are more clearly outlined by septa of connective tissue. In the pancreas as in many other organs the smallest lobule constitutes a unit of structure which repeats itself throughout the parenchyma. In the pancreas of the cat, for example, such a lobule outlined by connective tissue consists of a group of acini drained by a single duct; in some parts of the gland every lobule contains near its center an island of Langerhans. From the small arteries and veins which lie in the periphery of the lobule capillary vessels penetrate between the acini; several wide capillaries supply the rich vascular network of the island of Langerhans.

In man the individual lobules are often so fused together that their outlines are not discernible, but in general the same plan of structure exists. Of some importance is the fact that islands of Langerhans are not equally abundant in all parts of the gland. Actual count demonstrates that they are about three and a half times more numerous in the splenic extremity of the gland than elsewhere. In the pancreas from different individuals, moreover, the number varies considerably, and it is possible that in some instances as the result of a congenital defect the interacinar islands are too few to exert a normal influence on carbohydrate metabolism. In the pancreas of a child who died with diabetes the number of islands of Langerhans was almost a third of that usually present; the disease in this case was hereditary and affected six members of the same family. It suggests the possibility that diabetes may occasionally be the result of a congenital anatomical defect in the gland. The evidence in favor of such an hypothesis is at present inconclusive.

In conclusion, I may say that two anatomical peculiarities of the pancreas, I believe, have not as yet received the attention they deserve from the physiologist, the pathologist, and the clinician. In the first place, the organ consists of two functionally diverse elements—on the one hand cells which supply to the intestine important digestive ferments, and on the other hand cells having no communication with the ducts of the gland but in intimate relation to the bloodvessels. In the second place, the close anatomical relation of the pancreatic duct to the common bile duct favors the transmission of morbid processes from the liver and bile passages to the pancreas.

*To Assist in War Against Tuberculosis.*—Charities states that one of the large manufacturing companies in the Argentine Republic has joined the antituberculosis crusade by sending out 3,500,000 boxes of matches each labeled with special instructions relative to the prevention of tuberculosis.

## MANAGEMENT OF MALIGNANT DISEASE OF THE UTERUS.

BY

GEO. ERETY SHOEMAKER, M.D.,

of Philadelphia.

Gynecologist to the Presbyterian Hospital.

Medical opinion is prone to move in waves, which are either too high or too low. A note of unwarranted pessimism has been recently struck as to operative treatment of uterine cancer, especially cancer of the cervix. A few men have mourned that nearly all their patients operated on more than two years are dead. The inference that malignant cases are practically unbenefited by surgery is totally unjustified. Hysterectomy for cancer of the body of the uterus is well known to give many years of freedom from recurrence if not permanent cure; but even epithelioma of the cervix, if taken reasonably early, will give operation results by no means discouraging. There is much to show that metastases and gland involvement are relatively late in this disease. Dr. Thaddeus A. Reamy at the 1903 meeting of the American Gynecological Society voiced this view and cited cases. To be sure, where one patient applies to the operating gynecologist in an eradicable stage, three patients come with bladder, rectum and broad ligaments involved by extension, but that is not the fault of the disease. It is partly the fault of the reticence of patients and partly the fault of physicians of all schools. The pitiable histories of the consulting-room show that physicians today are treating with ergot and hydrastis by the year patients in middle life who show increased average bleeding; not in honest doubt over an obscure diagnosis made after reasonable effort, but totally without examination, to say nothing of fair study; though the changes in those particular cases may be gross, and need only a touch or a glance to be recognized. Of course, not all bleeding cases are malignant; witness three private cases:

Z., aged 48, sent by Dr. J. B. H. Gittings. Hemorrhage, palpable. Examination, gangrenous intrauterine fibroma. Removal from cavity; cure.

Y., aged 70, sent by Dr. Longnecker. Soft bleeding mass. Examination showed a polypus long enough to chafe and bleed. Removal; cure.

X., aged 30, sent by Dr. John B. Roberts. Soft bleeding growth of cervix. Microscopic examination, benign papilloma. Excised, cauterized, cured.

It may be worth while to review the principles which may guide us in the management of suspected or proved malignant disease in its various stages.

**Diagnosis.**—The time has passed when the diagnosis of malignant disease should be expected to rest upon the fully developed series of classic symptoms formally described in textbooks. After a patient has shown emaciation, cachexia, and suffers severe pain of a lancinating character, after the odor of decomposition becomes prominent, and hemorrhage severe and continuous, the tyro may make the diagnosis; and, unfortunately, so far as the patient is concerned, there may be little difference whether it be made or not. It is too late. The only hope of permanent cure is in the early diagnosis at a time when only one of these symptoms may be present, or when no one of them has become marked. The keynote of the whole subject is investigation with the aid of the microscope.

**Examination.**—If there is cancer of the body of the uterus, absolutely nothing can at first be detected by the eye or hands except possibly slight enlargement of the organ. The cervix will be normal, the uterus entirely movable; there will be no gland involvement. If there is excessive bleeding cureting must be done, and the material obtained examined by a competent pathologist. This treatment is indicated whether the disease proves to be malignant or not. Should there only be hypertrophic glandular endometritis, which is a very common cause of hemorrhage in middle life, there is no treat-

ment so likely to prove quickly and permanently helpful as cureting, and no condition in which office treatment is as useless. It is just at this point that the ideas popularly prevalent among both patients and physicians have been responsible for the long array of patients dying with hopeless cancer when they come to the hands of the gynecologic operator. The old idea that abnormal symptoms, such as excessive bleeding or discharge occurring in a woman after the age of 35, may be due to an approaching menopause, has long since been exploded, but it is still responsible for thousands of deaths. Let the truth be appreciated and acted upon that any average loss of blood continuing for several months, near the menopause or not, which is greater than the normal average of that individual judged by her earlier life, is pathologic and not physiologic, and calls for rigid explanation and immediate correction. If this be done, half the problem of the successful management of cancer will be solved. The physician who waits to add to the symptom of hemorrhage the odor of necrotic material before making an investigation is oftentimes responsible for the patient's early death. She comes to him with the diagnosis ready made by herself and friends that it is the menopause, but the responsibility for better knowledge is his.

**Prevention.**—Much may be done toward the prevention of cancer by the repair of serious injuries to the uterine cervix and by the correction of its gland degenerations. When these injuries are repaired, systematic examination of the removed tissue will occasionally discover an early malignancy, when a more radical operation can be performed. The repair of slight tears of the cervix, when no degeneration of the uterine surfaces exists, may be rightly termed meddlesome surgery, but, on the other hand, the obligation is strong to remove degenerating surfaces and cicatricial tissue when irritated. The cureting of hypertrophied tissue, which is causing hemorrhage, is also in the direct line of prevention of adenocarcinoma of the uterus, as the malignant disease is often engrafted upon a perfectly benign adenoma of the endometrium. I have had several cases in which there had been excessive bleeding for many years, evidently from benign forms of gland degeneration of the endometrium, and in which this subsequently assumed the cancerous form. In the same microscopic slide may be seen benign adenoma and malignant adenoma side by side. Should cureting fail to cure in these apparently benign cases, it should be repeated persistently, as the beginning adenocarcinoma may occupy but a small portion of the endometrium. The first examination may therefore fail to show the more important disease simply through taking up the wrong piece of removed tissue.

**Operable Cases.**—All cases are suitable for hysterectomy and complete removal of broad ligaments, tubes and ovaries, as much cellular tissue as is possible about the uterine attachments, and a portion of the upper vagina, when the disease is apparently confined to the parts mentioned. When the broad ligaments are evidently infiltrated out to the pelvic wall, thereby restricting the movements of the uterus, the prognosis is not so good as to return, but the operation should still be undertaken if the diseased tissue can all be removed. The actual cautery should be deeply and thoroughly applied to all accessible parts of the growth before a tenaculum is introduced or any other instrumental traumatism is produced. The vaginal attachments also should be seared by the cautery, and as much of the other structures as the proximity of bladder, ureters and rectum will admit. If the electrothermostat is used, additional cauterization with a fine point should be given to the vaginal attachments in front and behind, where the action of the thermostat is ordinarily wanting. In cases in which a large amount of new tissue presents in the vagina, this should first be thoroughly removed, using the cautery as a knife, preferably several

days before the hysterectomy. If this is thoroughly done necrotic material is entirely removed, and it is possible to do the major operation through apparently healthy tissue, in this way greatly lessening the risk of dissemination of cancerous infection into fresh surfaces. This risk of infection appears to be real, however little we may know of its actual method of working. The importance of this preliminary use of the cautery is insisted upon because in my experience those cases have shown the longest immunity from recurrence under otherwise unfavorable circumstances in which this was carried out, and because the whole trend of surgical experience in combating cancer shows that the cautery is our most effective weapon against the disease. The best statistics of results of a reliable character, that is, which have covered a sufficiently long period of years to be conclusive, have been those of Dr. John Byrne, of Brooklyn, N. Y., whose method of operating upon cancer of the cervix, which is confessedly the most difficult to cure, consisted wholly of the removal with the cautery, and without a cutting instrument, of the upper vagina and as much of the uterus as possible without opening the peritoneum. These statistics have been unimpeached and far surpass in low immediate mortality and freedom from recurrence those in which the cautery did not figure. That it is the cautery and not the extent of tissue removed which gives the improved results is shown by the fact that in his system less tissue is removed than in several methods of either abdominal or vaginal hysterectomy. Vaginal hysterectomy for cervical cancer has been much practised, and it was the comparatively unsatisfactory results from this method which led to the introduction of hysterectomy from above the pubis, and later to those extensive dissection operations which called for the removal of pelvic lymphatics behind the pelvic peritoneum and in the neighborhood of the iliac vessels. The poor results were due to the difficulty in removing a sufficient amount of tissue at the vaginal junction, and probably not to any less amount removed from inside the pelvis. By a well conducted vaginal operation quite as much of the broad ligament is removed by the necrosis which follows the clamp method as is usually removed from within the abdomen by ligature. Later experience with the extensive intrapelvic dissection operations has not demonstrated their value. The high primary mortality, the liability to postoperative complications, and the failure to get improved results as to recurrence, are rapidly placing them on the retired list, even in the hands of some early enthusiastic workers in that line. In some cases of epithelioma of the cervix, well marked and microscopically identified, cure has resulted from removal of the cervix alone under cautery methods. This in itself shows that gland involvement is not always present, and if present may be late, and it gives encouragement for the use of surgical methods at the earliest possible moment, and later on whenever all of the disease is accessible. As to technic I prefer to begin by the vagina, destroying all accessible tissue by the actual cautery as described, ringing the upper vagina with the cautery, and carrying out the earlier dissections from below, then opening the abdomen and separating uterine attachments, cautery methods being used whenever possible. Through the abdominal incision any accessible nodule of disease at or above the point where the ureter passes the cervix may be more readily reached. In cases of adenocarcinoma of the endometrium, the so-called cancer of the body of the uterus, and in very early conditions of epithelioma of the cervix, in my opinion the abdominal operation presents no advantages over the vaginal when properly carried out, except that it gives an opportunity for inspection higher up and for dealing with bowel or bladder disease. In other words, in a case so far advanced as to require extensive pelvic dissection for removal little benefit will ensue from any operation.

The limits of this paper will not permit further discussion of details of technic. The position is taken that each case must be managed according to its peculiarities, but in general both the vaginal and abdominal routes should be adopted as has been stated. The experience with some of my own cases of vaginal hysterectomy combined with cauterization has been so favorable that I do not share the pessimism which some operators express. This better experience is credited to the physicians who have referred to me early cases. In vaginal hysterectomy for very early cases of carcinoma of the cervix, in which the cautery can first be freely used, the mortality will be probably not over 2%, while the late results will be good.

Six illustrative cases may be cited, all private patients and carefully observed:

CASE I.—Mrs. H., aged 54; seven births, three miscarriages; epithelioma of the cervix. Operation April 4, 1896 (*Therapeutic Gazette*, October, 1896). Entirely well June, 1903, seven years afterward, as shown by examination. The epithelioma, which was microscopically demonstrated in the laboratory of the Methodist Hospital, was around the external os uteri, the furthest infiltration extending on the left side about a half inch into the lower lip. There were three easily bleeding warty projections just at the edge of the os. The vaginal portion of the cervix was not diseased except at these points. Thorough preliminary cauterization of the diseased area with the thermocautery was done, followed by vaginal hysterectomy, ligation method. Though the patient had a decided mitral murmur, the pulse at the close was 86. There have been no signs of recurrence, and the patient is now living in excellent health near Philadelphia.

CASE II.—Mrs. E., aged 39, one child. Referred by Dr. W. R. Hoch. Malignant adenoma of cervix uteri and of posterior vaginal wall at the point of contact with the diseased cervix. Operation: thorough use of thermocautery, followed by vaginal hysterectomy and excision of the diseased vaginal wall. Microscopic diagnosis by Drs. Edsall and Cattell. An area of disease 2 cm. in diameter involved both cervical lips. Operation February 13, 1897 (*Medical and Surgical Reporter*, April, 1897, case 29). A slight recurrence in the vaginal wall was cauterized nine months later with the Paquelin cautery without perforating the rectal wall. Since then she has remained in perfect health, now more than six years, and was examined recently. She weighs 160 pounds and performs the duty of postmistress in a small city.

CASE III.—Mrs. W., widow of a physician, six births. Sent by Dr. R. J. Phillips. Microscopic diagnosis by Dr. D. L. Edsall, squamous epithelioma of cervix. Vagina involved all around cervix, broad ligament slightly. Operation April 7, 1898: cautery to vaginal attachments and growth, followed by vaginal hysterectomy. An examination February 13, 1903, showed the patient entirely free from recurrence, five years later.

CASE IV.—X., aged 45, single. Microscopic diagnosis, malignant adenoma of cervix. Operation: cautery and vaginal hysterectomy, October 5, 1898. Frequently examined since. Now well, free from recurrence, and working as a trained nurse, four and one-half years later.

CASE V.—Mrs. S., aged 71. Microscopic diagnosis, carcinoma of body of uterus. Operation December 5, 1899, vaginal hysterectomy. Two months ago reported to be free from signs of recurrence. Private patient. Living out of city, constantly watched by physician; not examined by me. Time since operation over four years.

CASE VI.—Mrs. B., aged 66. Sent by Dr. M. K. Elmer, of Bridgeton. Persistent bleeding. Small growth of the cervix. Microscopic diagnosis, carcinoma (Pathological Laboratory, Presbyterian Hospital). Operation: combined vaginal and abdominal hysterectomy, June 19, 1901. Well. I had also removed a papillomatous cystoma of her left ovary in September, 1898.

Another class of cases may be cited as illustrating the prolongation of life in epithelioma of the cervix of apparently hopeless character:

Over four years ago Dr. Wm. G. Porter, of this city, sent to me the wife of a friend who had been under the care of other physicians for severe hemorrhage due to epithelioma of the cervix. The patient was in bed, extremely weak from long continued hemorrhage, suffering much pain; she had been advised against operation by her previous attendants, who were of another school. A large, soft, friable mass of cancerous tissue, more than three inches in diameter, tightly filled the upper vagina, making it impossible to outline the cervix uteri from which the growth took its origin. Profuse hemorrhage followed examination, and though it was impossible to determine the exact limits of the disease, the case was considered unfavorable for radical operation, both on account of heart weakness and of the probability of speedy recurrence. With the object of arresting hemorrhage and giving temporary relief, in January,

1899, with the assistance of Dr. Porter, I rapidly removed the fungating mass which sprang from the cervix, and thoroughly and deeply cauterized the uterine tissue up to the limit of safety of neighboring organs. When the parts had partly healed and contraction had occurred the uterus was found so movable, and so little infiltration of surrounding tissue was present, that hysterectomy, at first seemingly impossible, was determined upon. Owing to my illness it was carried out at my request by another surgeon, who used the vaginal method. I met this patient on the street a few days ago, looking entirely too stout for comfort, and, except for neurotic symptoms, in very fair health. She passed from under my care and has had various ups and downs in the four years since operation. She had at one time an abscess to the right of the uterus supposed to be appendicitis, but while no return of the cancerous growth has, I am told, been demonstrated, the chances are that she has it. That a patient apparently dying of cancer of the cervix should be fat and healthy looking four years after is in itself a vindication of the operative treatment of an apparently hopeless case. In my judgment the crucial element in the management of this case was the thorough use of the Paquelin cautery about two weeks before the hysterectomy.

Unfortunately, patients whose cases are as advanced as this usually die rapidly from hemorrhage or exhaustion in a few months no matter what treatment is adopted, but the case illustrates the point previously made that in certain patients, even with extensive disease of the uterine cervix, metastasis to neighboring glands has not occurred, and a radical local treatment will produce marvelous results. The cases in which these good results will follow cannot be determined beforehand, but they occur with sufficient frequency to encourage radical operation in all cases in which all visibly diseased tissue can be removed. It is an axiom in surgery to which I know no exception, that attempted radical operation confined within the limits of cancerous growth is harmful rather than beneficial to the patient. This does not apply, however, to the removal by the cautery of soft fungating, readily bleeding or sloughing masses from the cervix. This gives great temporary relief from pain, hemorrhage, and sepsis, and as it is not attended by shock or danger it may be repeated more than once during the downward course of the disease. No lymph spaces are thus opened which are not at the same time sealed by the cautery.

There remains for consideration the management of the later stages of recurrent or inoperable growths. The use of the x-ray as a palliative in the pelvis appears at the present time to be considerably limited by the deep-seated location of the parts. It may be tried, however, through various vaginal speculums and in some cases appears to give relief, at least temporary. In a case of fibrosarcoma (diagnosed by Dr. J. Dutton Steele) of the abdominal wall operated on for Dr. M. B. Hartzell six months ago, there was an involvement of the uterus, the left broad ligaments, the left tube, ovary and rectum which could not be surgically removed, and the abdomen was closed. Under the x-ray treatment by Dr. Newcomet at the Presbyterian Hospital the patient has shown marked improvement in the relief of pelvic distress and a surprising diminution of the superficial portions of the growth. As there was deep-seated pus in the little suprapubic mass it was at first hoped that the whole trouble was inflammatory, which accounts for the operation.

In late cases in which sloughing is going on nothing has given greater satisfaction for daily use in the hands of the patient than strong solutions of potassium permanganate. The surgeon may apply at intervals of several days strong solutions of formaldehyd, one to ten for example, with a decided influence in lessening the progress of superficial growths. This has served to delay a recurrent carcinoma of the uterus for two years in a patient for whom I performed hysterectomy for advanced disease of the corpus more than six years ago. She has little bleeding, has no odor, and suffers little pain, though the disease has slowly invaded the scar tissue between bladder and rectum and also the upper portion of the vagina.

The management of the comparatively rare cases of sarcoma does not differ from that of carcinoma of

the body of the uterus, and calls for early hysterectomy.

In conclusion, a strong plea is made for the early investigation of cases which show *any* of the symptoms of cancer. The method of operating must be determined by the case, but every patient should receive in some form thorough treatment by the actual cautery before any lymph spaces are opened by any other form of operation. Even apparently hopeless cases may show surprisingly satisfactory results. No patient should be denied the benefit of persistent intelligent palliation.

## CHLOROSIS.

BY

S. H. ROSENTHAL, M.D.,  
of Rochester, N. Y.

In the practice of medicine, many conditions arise which tax the greatest skill of the diagnostician and require a most thorough knowledge on the part of the therapist. Foremost among these conditions stand the various forms of the anemias. With the many varieties, the discouraging course of the disease and the bad prognosis associated with some of them, especially the pernicious type, surely no subject demands a more thorough study. My aim is to discuss only that form of anemia which if recognized early can be treated with the assurance of an ultimate cure. I refer to chlorosis. By chlorosis is meant that variety of the primary or essential anemias in which the blood change is a disproportionate hemoglobinemia without any modification of the leukocytes and which is associated with not only symptoms common to all anemias, but also with those peculiar to itself.

In order to render the study of this subject more simple I will discuss it under the following heads: 1. Etiology. 2. Morbid anatomy. 3. Symptomatology and diagnosis. 4. Blood examinations. 5. Prognosis. 6. Treatment.

*Etiology.*—Of the etiology little can be said, but nevertheless it is most important in arriving at our diagnosis. The disease is almost always found in girls between puberty and the age of 24. Many writers claim to have seen it in men, but the cases reported are very few. According to Tyson its occurrence is not impossible in men of feminine habits and occupations. Hermann Eichhorst especially mentions tailors. However, so closely is the disease connected with the female generative organs that we must almost doubt its very existence in males.

As to age, we also have deviations from the rule. Although the great majority of cases, as before stated, occur between the ages of puberty and 24, still we have that variety known as "chlorosis tardia" found between the ages of 30 and 40. More rarely it is seen in children. Niemeyer claimed that girls who menstruated at 13 or 14, in whom there was as yet no development of the pubes or breasts, almost always become chlorotic. Another important etiologic feature is bad hygiene; poor food, lack of sunshine, indoor life, and overwork all tend to increase the severity. Again there are repeated emotions such as arise from sexual excitement and masturbation. Flint mentions ungratified sexual desire, disappointment in love, loss of relations and crosses of various kinds.

We are but in the realm of supposition as regards the true exciting cause of chlorosis. Stevens states that the absorption of ptomaines from the bowel may act as an incentive for the onset, but in this I can hardly agree. The frequent association of constipation with chlorosis led Sir Francis Clark to suggest that it might be a copremia, an absorption of ptomaines or leukomains from the large bowel. Such poisons readily interfere with the proper development of the hemoglobin of the

blood disc, without destroying it to a great degree. Forcheimer also advanced this theory. This etiologic feature may be considered in pernicious anemia, but I doubt its plausibility in chlorosis.

The various gastrointestinal disturbances which I shall describe later have been proved to be secondary to the blood changes and in no instances have they been primary. If this absorption is the exciting cause then the intestinal signs would be primary.

*Morbid Anatomy.*—The study of the morbid anatomy of this disease is embryonic. So few cases come to autopsy that we are unable to get much data as to the real pathologic changes. We know, however, that all show a marked atrophy in the size of the uterus and its appendages.

Many years ago Virchow pointed out certain characteristic circulatory results—the heart was found invariably small, the right ventricle being dilated. This was undoubtedly due to the extra strain upon the heart which we note late in the disease. In the *British Lancet*, R. Wybauw, in discussing cardiac dullness in chlorosis, states that the increase of the ventricular space is generally due to actual dilation, but may sometimes be due to upward displacement of the heart by the diaphragm. The distinction is made that when there is only displacement the apex beat is pushed upward and outward. When dilation is present the apex beat is down and out. Virchow also found the aorta and its large branches poorly developed and thin-walled. Tyson claims that this state of the vascular system, when present, is probably an accidental coincidence. Gautier, in the *German Archives of Clinical Medicine*, denies this theory of Virchow and gives as his reason the fact that the heart returns to normal size when the patient improves. According to Gautier, a congenital narrowing of the arterial system being a permanent condition would bring about a permanent cardiac condition unless absolutely cured, which, as we easily can see, is impossible. Engelhart describes a case of chlorosis in a girl of 18, in which a diagnosis of tumor of the brain was made during life because of a bilateral optic atrophy and choked disc. Death occurred and autopsy showed no alteration in the brain excepting marked anemia. Engelhart believes that optic neuritis and the general symptoms which had given rise to the diagnosis of brain tumor had been the result of the chlorosis. We must admit that our knowledge of this phase of the subject is extremely limited at the best and until the necroscopist obtains more material, our conclusions along this line must be very limited.

*Symptomatology and Diagnosis.*—This is the most important part of the study of chlorosis. No disease has such typical pictures and no disease, when closely followed, runs a more uniform course, but notwithstanding this, the general practitioner makes his diagnosis more from guess than from a thorough inspection of his patient's condition. In a young girl at or near the age of puberty a peculiar pallor of the skin is first noticed. The lips, which especially in youth have such a fresh tint, gradually become more blanched than by the extremest emotions of fear. Unlike pulmonary tuberculosis, in which the skin is pale and the mucous membranes still retain their brilliant hue, the chlorotic girl shows a peculiar greenish-yellow condition of the skin, especially in the folds of the well-formed cheeks, and the lips and conjunctivas synchronously attain the exaggerated pallor before mentioned. Thomson claims that this is not a bleaching process, but a true discoloration. Noted in blonds as well as brunets, it gives us a picture never seen in any other form of anemia, whether it be febrile or nonfebrile. If it were a variety of jaundice, the conjunctiva would most certainly be involved, but this membrane remains absolutely colorless. No bile can be found in the urine or any other bodily secretions. I will admit, however, that the liver is a factor in the cutaneous change. The normal

destructive metamorphosis of the erythrocyte must be deranged, or there would not be the typical whitened stools. In patients under treatment this is not always seen and its disappearance can easily be explained when we recall the effect produced by the administration of iron even under normal conditions. Pepper describes a condition known as "chlorosis rubra," in which the lips and cheeks grow red upon exertion even when the so-called "valeur globulaire" is considerably diminished. These skin changes, together with the areas of pigmentation often noted about the joints and the pallor of the tips of the fingers present a typical picture of the well-known "green sickness."

Following these metamorphoses, the case is first brought to the attention of the physician. An anxious mother brings her young daughter who has never menstruated, or in whom the function has been long retarded. According to Strümpell, cases of menorrhagia are very rare. I can now recall several cases seen in hospital work in which the patient never menstruated until the age of 17, 18, or 19. I have one patient now under observation who menstruated twice when 14, after which the menses did not appear for several years. I do not mention this as the exception, but as almost the rule. When menstruation does begin it is very scanty and often attended with considerable pain. Some time ago there was quite a diversity of opinion as to whether these menstrual changes, together with the gastrointestinal ones, were primary to chlorosis or chlorosis primary to them. The latter is by all means so. Some years ago I consulted all the literature at my command to determine this, and became perfectly satisfied that chlorosis was the cause and not the effect.

Among the first subjective symptoms the patient complains of are malaise, headache, languor, vertigo, dyspnea, and palpitation. The perversion or loss of appetite then comes with many real or imaginary dyspeptic disturbances. She refuses food, but if suggested will eat almost anything. Often one who could not bear the sight of olives, pickles, vinegar, and other sour articles, will actually crave for these, and be satisfied with nothing else. Schoolgirls have been known to eat chalk, leadpencils, and even earth. The desire for sour food is easily explained when we remember that these girls cannot digest fats of any kind. The digestive symptoms which most trouble the patient at this time are borborygmus and tympanites. These are often intense, causing a marked sense of fullness in the epigastrium which is often hard to relieve. Severe cardialgia may be present. This is usually of purely nervous origin, but is sometimes produced by a gastric ulcer, existing as a complication of chlorosis. When this ulcer does exist there follows the localized pain, especially severe after the ingestion of food, and not relieved until the stomach is again emptied either by the food passing on into the duodenum or by being vomited. Often this vomitus is mixed with blood. When this complication is suspected there should be an examination made of the stomach contents after a test-meal, and if the diagnosis is correct there will be an excess of hydrochloric acid. This is almost pathognomonic. Of course there are many other conditions in which we will find this; in fact one writer claims that he determined by autopsies that 9% of all stomachs contain ulcers of some degree, most of them never having been suspected, before death. Pepper stated that when ulcer does exist and is accompanied by morning vomiting and amenorrhea, especially in a person who has indulged in recent sexual intercourse, he has often been called upon to decide if the patient is pregnant. Of course this can only be determined by thorough examination. I cannot elaborate in this condensed paper upon the symptoms associated with gastric ulcer complicating chlorosis, but I do want to caution against overlooking it and allowing it to go untreated. Upon this the prognosis of chlorosis often depends. Again, when the presence of an ulcer is known it must be

remembered that it is only secondary to the chlorosis and the chlorosis should not be ignored. I have given this warning because several persons, believing that chlorosis is secondary, have given their patients gastric lavage and claim to have obtained good results. Pick, of Prague, has made this statement, but does not substantiate it with sufficient proof. To me the lavage of an ulcerated stomach is extremely poor practice. Not knowing how extensive the ulcerative process is, the risk of filling the stomach with fluid and the introduction of a tube seems dangerous and uncalled for. An acute exacerbation of symptoms and even rupture of the stomach has been known to occur when lavage has been practiced, and this fact ought to condemn the procedure.

The differential diagnosis between chlorosis and many other diseases is apparently quite difficult, but when we consider each one individually it can most readily be seen that, notwithstanding the similarity, chlorosis still maintains its identity.

Organic heart disease is often mistaken for the hemic murmur of the chlorotic heart. In the former hepatic and renal complications often exist; in the latter but seldom. The character of the chlorotic murmur is generally a purely systolic one, mostly at the base or near the pulmonic valve, not transmitted, and generally of a blowing character. This ought to be sufficient to exclude any other valvular disease. Three explanations are given for its existence: (1) It is due to the rubbing together of the abnormally dry pericardial sac; (2) it is the result of interference with the movement of the cardiac valves, following fatty degeneration of the myocardium; (3) it is caused by relative insufficiency from dilation of the heart or imperfect action of the papillary muscles. Strümpell states that murmurs in the large veins of the neck are heard with or without cardiac murmurs. These are known as the "bruit de diable." A. Weil maintained, however, that they are found in healthy persons as often as in anemic. This Strümpell denies, but does not claim any diagnostic value even when they do exist.

Kidney trouble and chlorosis are at times confounded. In this form of anemia the urine is deficient in urea, has low weight, seldom contains albumin, and never casts. In kidney disease the two latter are generally present with their many complications, as seen in nephritis. The absence of jaundice and enlargement of the liver eliminates hepatic disorders. From carcinoma, the absence of cachexia, glandular involvement, loss of flesh and strength, the absence of a mass, together with the age of the patient, makes the distinction quite easy.

From the leukemias, chlorosis can only be diagnosed by a blood examination.

Pulmonary tuberculosis is often spoken of as simulating chlorosis, but the laboratory can easily settle this question.

Lastly, certain febrile conditions are named in connection with this disease. In the former there exists a destruction of fat, muscle, bone, and especially albumin of the blood, hence an emaciation. In the latter only the hemoglobin is destroyed, therefore no emaciation.

**Blood Examinations.**—We have now arrived at that phase of our subject which perhaps is the most important and the most interesting—the blood change. As I have previously mentioned, the impoverishment of the blood in chlorosis has reference chiefly to the red corpuscles and in less degree to the albuminous constituents of the plasma. Becquerel and Rodier found the albumin in the blood of six patients to be 72.1 per mm. instead of 57, the normal. There is a reduction in the quantity of hemoglobin with or without diminution of the number of the cells. According to Flint, cases have been noted in which the red cells were normal in number but the hemoglobin reduced 50%. This condition of disproportionate diminution of hemoglobin, known as oligochromemia is the distinguishing feature of the disease over all other anemias. If we make an examination of

a chlorotic's blood there will generally be found a slight, at times quite large reduction of the red cells. The white cells will be but little affected but the hemoglobin will be down to 30% or 40%. The blood is generally pale, the centers of the red cells especially so. These red cells may be normal in size or may be microcytes, while a few may be macrocytes. Here and there a poikilocyte will be found. Again the erythrocytes seldom form in rouleaux. In occasional instances there is a considerable number of so-called "granular bodies," the exact character and significance of which are not known.

**Prognosis.**—As I have already intimated there is a great variety in the course and prognosis of chlorosis. Complete cures in four to six weeks in cases which are quite severe at first are not exceptional. Other cases much more obstinate resist all our efforts for a long time and there are many relapses before a final cure is effected. The disease never endangers life except by complications.

**Treatment.**—The treatment of chlorosis is comparatively simple when complications do not exist. If we see the patient early, the bettering of hygienic surroundings will often do much. Outdoor life, exercise in moderation, withdrawal from school, no working in shops, good nourishing food, and the internal administration of iron practically completes the treatment. Just which preparation of iron to be used is not important, but I have seen the best results from Bland's, given in increasing doses. Tyson recommends a beginning dosage of .19 grams (3 grains) of Bland's after each meal. The iron should then be run up until the patient receives enough to establish results. Generally one to two grams (15 to 30 grains) daily will accomplish this, but if still unsuccessful, no hesitancy in still adding to it should be had. I recall one instance when 5.8 grams (90 grains) were given every 24 hours without any ill effect, and which brought about absolute cure. Some therapeutists advise the tincture of iron chlorid, but this is a matter of personal preference. Various proprietary drugs are for sale, some of them having exceptionally good qualities, but their chief virtue lies in the iron constituent. Arsenic, either in mass or as Fowler's solution, has been strongly recommended. When the disease is well advanced, the patient, beside this medicinal treatment, should have the absolute rest cure. She should not leave bed for several weeks; much nourishing food should be given, reinforced by massage and electricity if circumstances permit. Some authors suggest mud or sand baths, but of the virtue of this treatment I can not comment upon owing to lack of personal experience with it. When improvement becomes marked, allow the patient to sit up one-half hour daily, gradually increasing the time.

All complications should be met symptomatically and promptly treated. Under a treatment similar to this, Thayer states that in his most severe cases in four weeks an increase of from 40% to 80% of hemoglobin was noted. However, do not be too optimistic at the beginning. Cases often go for months before final cure is established, but persistence in proper treatment will ultimately bring about the very best results.

**New Hospital in Washington.**—On June 6 the cornerstone of the new Episcopal Eye, Ear, and Throat Hospital was laid, with appropriate ceremony.

**Grave Mortality from Pneumonia and Bronchitis.**—The Bulletin of the Health Department of Chicago for the week ended May 9 states that during the week previous there were 178 deaths from pneumonia out of a total of 672 deaths, and that pneumonia and bronchitis combined have caused more deaths since January 1 than all the other diseases combined. The bulletin states that some means for filtering the air consumed in public and private houses which will keep out the numerous pathogenic germs should be devised. It states that a device consisting of a screen of cheese-cloth, the upper edge of which is attached to the lower rail of the bottom sash of the window so that when the sash is raised the cheese-cloth is drawn up, completely filling the opening, has been found of value for this purpose.

## A NEW METHOD OF TREATMENT FOR CHRONIC ANTERIOR URETHRITIS, AND FOR THE DECLINING STAGE OF ACUTE URETHRITIS.<sup>1</sup>

BY

WILLIAM WARREN TOWNSEND, M.D.,  
of Rutland, Vt.

By the term chronic urethritis is understood an inflammatory process, involving the urethra subsequent to an acute invasion of that canal. It may be localized in any part of the urethra, that is to say, in the anterior or posterior portion.

However, as it is the purpose of this paper to treat of the form of urethritis that is the "bête noir" of the general practitioner, chronic anterior urethritis, I will merely mention the fact that chronic posterior urethritis often times exists independently for some time after the chronic anterior condition is cured, and very frequently coexists with anterior urethritis, but as that condition (chronic posterior urethritis) demands a separate and distinct form of treatment, I will confine my remarks to the treatment of that form which is most common—chronic anterior urethritis. This results from a previous acute, inflammatory condition of the urethra, and as acute urethritis has the natural tendency to linger indefinitely in the tissues, and with the inability to control the physical forces of one's patients, who most generally are obliged to continue at their usual vocations during the acute stages and who are apt at the first indication of the diminishment of discharge, to indulge in alcoholic and sexual excesses, it is not to be wondered at that the condition becomes chronic, especially when one stops to consider the virulence of the gonococcus and the great disadvantages that have to be overcome in the management of the cases.

Too protracted and energetic treatment in the early stage will tend to assist in the disease becoming chronic, and the popular habit of "seeking discharge" by stripping the penis prior to urination, and at various times during the day, adds materially in promoting chronicity by burying the germ-laden pus cells deep into the submucosa.

The condition of anterior urethritis is popularly known as gleet, and numerous are the preparations advertised to cure. Most of them consist of injections of zinc and copper, and the internal medicaments are as a rule, balsamic in character.

The pathologic appearances of the lesions as determined by the endoscope in chronic anterior urethritis vary. Follicular inflammation shows itself in small deep red pus oozing spots varying in size from that of a pin-head to a pea; likewise does inflammation of the lacuna magna and other crypts show itself. A deep red, purplish color of the thickened mucous membrane is the most constant morbid symptom, and may vary in extent, involving a segment of the canal, or simply cover a limited portion; associated with this form one will most generally find a generous pus secretion.

Another condition in which there is epithelial hyperplasia and a budding appearance of little eminences caused by the growth of new capillary vessels is common and is known as granular urethritis; and a further advancement of this hyperplastic and capillary condition has also been honored with the dignity of a name, and is described as a separate and distinct condition under the name of papillomatous urethritis.

This has always seemed to me to complicate the study of the pathologic condition of the urethra rather than to simplify. As stated, the papillomatous condition is simply a granular urethritis in an advanced and aggravated stage.

Erosions and ulcerations of the urethra are frequently the cause of chronic anterior urethritis. The mucous

membrane in this condition is thickened and red, and does not show the luster and shining appearance of the surrounding tissue, owing to the loss of the epithelial covering. While all these superficial lesions are observable by the endoscope, there is a deeper exudative process at work in the submucosa, and all the superficial appearances are a result of this deeper condition.

"The morning drop" or tear, as it is sometimes called, is the pus accumulation of the night before, and may be small in quantity. It is generally greenish-white in color, and in numerous instances there is just enough of it to seal the meatus; and a separation of these lips will disclose a drop of glairy mucus; and it is the alleviation of this symptom to which your patient looks to you, and in our attempt to do so we are frequently put to our wits' end. I do not believe there is a physician who has not had a case that has proved rebellious to every effort at treatment attempted by him, and it is for this class of cases that I wish to suggest a form of treatment that in my hands has proved most effective.

Hundreds of remedies have been vaunted in the treatment of gleet, and one can hardly pick up a medical journal without seeing this or that remedy suggested as being applicable with good results. It is not my purpose to extol the virtues of any given drug, but to offer

The Townsend Duplex Insufflator. Powder container attaches at E.

a method of application that, as stated before, has proved of value to me, and one which I have given a fair trial in a considerable number of cases in the past five years. The actual statistics I am unable to give, as I treat my patients symptomatically, and have been in the habit of using this form of treatment in a special way, rather than in a routine manner. However, to the general practitioner who is not familiar with endoscopy, and is too busy or has not the inclination to investigate it, the use of the instrument I present will accomplish more toward the cure of chronic cases and in a more scientific manner than the ordinary treatment by means of injections of varying strengths and internal medications.

The instrument consists (see cut) of a (D) glass rod 22, French bent at right angles perforated by a canal B bored through it from end E to air chamber C, and with another canal A extending from air chamber C and having an outlet at A1. The air chamber C, as will be seen, is perforated at its proximal end by the openings of the canals A and B, and its distal end is open except when in the urethra, at which time the urethral walls fall over the end, thus making a closed air chamber.

It is obvious that when this insufflator tube is attached to a powder container at E and the powder forced, it will follow the direction of the arrows, and reaching the air chamber C will become agitated and

<sup>1</sup> Read before the eighty-ninth annual meeting of the Vermont State Medical Society, October 9, 1902.

necessarily a portion will adhere to the moist mucous membrane of the urethral walls, forming the distal wall of the air chamber.

As the powder is forced from the container into the insufflator, the tube is gradually withdrawn, and the mucous membrane of the urethra is consequently covered with the medicament used. To this insufflator, I have given the name of "Duplex;" as will be seen it can be used in any cavity or sinus as well as in the urethra, and will, I believe, find a field of usefulness by supplying a means of thoroughly applying an impalpable powder to any region desired. It offers the advantage of being simple in construction and being easily cleaned.

Sterilization is accomplished by boiling, and it may be dried rapidly by passing through the flame of an alcohol lamp after shaking out any water that may be in the capillary tubes A and B. Special care should be given to the last mentioned detail, for if done carelessly the water will boil in the tubes, and by the generation of steam the tubes will crack. Therefore, keep it in motion while in the flame of the lamp, and be sure all water is out of the capillary tubes before applying heat.

The drugs that I have been in the habit of using are those that are astringent and antiseptic, and any other that suggests itself to me in each individual case. When there is a quantity of pus accumulation, I give several treatments with aristol prior to applying an astringent. It is impossible to set down any hard and fast rule as to the selection of drug or the number of treatments to be given. In my experience zinc, copper and aristol have accomplished the desired effect, and I treat my patients three to four times a week. I want it distinctly understood that I recommend this method of administration in chronic anterior urethritis and in the declining stages of the acute condition, and under no circumstances in the early stages, as nothing but harm could accrue from its use at this time; but in the two first-mentioned conditions I consider it a rational treatment as it is a wellknown surgical fact that astringents and antiseptics are indicated in conditions similar to those in chronic anterior urethritis; and the orthodox treatment for this condition depends upon the unreliable solutions of drugs which are injected into the urethra by the patient and to the ingestion of various balsams which do nothing but cause a bland condition of the urine and do harm by disarranging the assimilation, whereas the condition is a local one and should so be treated.

Those making genitourinary work a specialty treat the condition of chronic anterior urethritis locally with astringents and antiseptics by means of special instruments which the general practitioner is unfamiliar with, and it was to devise a means of easy access to the morbid urethra that prompted the idea of this little instrument which, as may be seen, has a twofold action. That of a sound, as by its passage into the urethra the "ironing out" process of the urethral folds is accomplished, and, at the same time, the drug used is being deposited upon any diseased area that may be covered by these folds.

## MAN'S RESPONSIBILITY IN STERILE MARRIAGES.<sup>1</sup>

BY

W. H. PRIOLEAU, M.D.,

of Asheville, N. C.

Before entering upon the subject-matter proper of this paper, I want to emphasize the fact that I shall not touch upon that class of childless marriages in which, for selfish reasons, children are prevented from coming into the world—unfortunately this state of affairs is alarmingly on the increase and the remedy is not yet in our hands.

The condition I propose to discuss is of that class of fruitless unions in which offspring is wanted and yet

fails to come—a true pathologic condition which in many cases can now be corrected and can also be prevented from happening in the future.

I shall endeavor in my remarks to remove the stigma from the barren woman and place the responsibility on the man, where it justly belongs in at least 70% of cases. Vedder says: "Out of 310 sterile marriages, 70% were due to the husbands, either through azoospermia, or impotence, or because of the wife's infection with gonorrheal disease from her male partner."

That the husband is more often the cause than the wife is easy to prove; but what is most pitiable in sterile marriages is that the man seldom ever questions his own potency, but allows the woman to consider herself the cause and to undergo manifold operations at the hands of gynecologists to relieve the situation.

The husband, not being aware that the sin has been or is in him, is frequently not only the cause of the wife not bearing him children, but too often is he the unconscious cause of her unsexing or death, he having infected her with a disease contracted before marriage. Writing of such infections, Valentine says: "It can not for a moment be assumed that the men who caused the death of their wives married with the knowledge that they would produce such disastrous results," and yet Noeggerath as far back as 1876 claimed that 90% of sterile women are married to husbands who have suffered from gonorrhoea either previous to or during married life.

Realizing the truth of such a statement, the medical profession as a body is to blame; and family physicians especially for having allowed such a condition of affairs to continue; certainly it was their duty to protect the daughters of the families whose physicians they were, and to advise the sons of those families as to the possible consequences of an uncured or latent specific urethritis. Even if the family physicians had gone only so far as to instruct the parents of daughters eligible for matrimony as to the danger to woman from an infectious disease latent in man, our graveyards would not now contain so many young wives, our gynecologists would have less to do, and there would be fewer barren women.

Statistics prove beyond a doubt that specific urethritis is most often the cause, directly or indirectly, of sterile marriages. When we realize the frequency of the disease the wonder is that all of us are not in the hands of the genitourinary specialist and our wives under the tender care of the gynecologist. Lawson Tait claimed that every man, at least once during his life, acquired specific urethritis. This I believe is too high a percentage, and Noeggerath came nearer the truth when he asserted that 800 out of every 1,000 men in large cities had gonorrhoea. Assuming that Noeggerath's estimate is correct we have then an existing state of society in which 80% of the men have had or now have specific urethritis, a disease in itself and in its complications most difficult to treat. A patient with gonorrhoea will undergo treatment only so long as the discharge continues. He rarely ever remains under treatment until all infection has been removed.

Once anterior specific urethritis is contracted the danger of the posterior urethra becoming involved is great—some authors claiming that in as high as 80% of the cases the posterior urethra is involved. The genital apparatus proper being so intimately connected with the posterior urethra we can readily see how easy it would be for infection to be transmitted from one to the other. The vas deferens, continuing as the duct of the epididymis and testicle, joins with the duct from the seminal vesicle to form the ejaculatory duct and to empty into the posterior urethra. The ducts of the prostate also empty into the posterior urethra. Such being the case the infection from a specific urethritis posterior might easily be transmitted to the prostate, seminal vesicles, epididymis, or testicles. These infections do occur more often than is generally known.

Frank remarks that of 651 cases of specific urethri-

<sup>1</sup> Presented at the fiftieth annual meeting of the North Carolina Medical Society, June, 1903, Hot Springs, N. C.

tis 210 showed involvement of the posterior urethra, and of this 210 the infection had traveled to the prostate in every case. The prostate becoming infected, the danger to the seminal vesicles becomes exceedingly great. The diplococcus of specific urethritis being once lodged in the prostate or seminal vesicles only the most careful treatment long continued can dislodge it.

As to the epididymis, Gouley states that it is involved in 30% of all cases of acute urethritis. The epididymis becoming infected, the natural sequence would be occlusion of the vas deferens on that side; and when there is a double epididymitis at least 50% of the patients will be absolutely sterile. A frequent cause of sterility, and one that is often overlooked, is stricture of the urethra. During erection the penis becomes congested, the lumen of the stricture closes, and although the semen may be potent, it cannot pass when ejaculated.

The danger of the man becoming sterile from specific urethritis, its consequences or sequels, as has been shown, is evident; but a more serious condition exists when the disease, although apparently cured, becomes latent; the germs remaining imbedded in some part of the genitourinary apparatus. Thinking himself cured, or at most only suffering from gleet, he marries. The excesses of early married life produce hyperemia of the sexual organs, and the diplococci of specific urethritis which have been dormant for so long are thrown from their nests and lodged in the virgin tissues of the new wife. The sequel is apparent to all, and unfortunately almost a daily sight in our practices. The woman becomes infected, pelvic troubles begin, and if she be so fortunate as to escape death, a condition ensues which to some is almost as bad, a childless marriage. Indirectly the husband has been the cause, and for the rest of her life the wife must remain barren—all due to the man to whom she has given herself body and soul.

Should a husband with latent gonorrhea not infect his wife, there yet remains in him a condition which might render him sterile. Where the gonococcus lives there must be destruction of tissue, and pus is deadly to spermatozoa. Inflammatory conditions of the sexual organs which produce pus, even though the cause be not specific may render the semen sterile.

I might here mention certain other conditions which cause impotency in the man, first by exhausting his strength and producing undeveloped spermatozoa, and afterward from disease, producing no spermatozoa at all. The conditions I refer to are masturbation, onanism, and sexual excess. To return, however, to gonorrheal urethritis as being the most frequent cause of sterility, I want to cite the following which bears out what I have said: "Benzler, investigating gonorrhea and sterility, followed the histories of 3,000 soldiers of the German army who were infected with gonorrhea during their term of service. Out of 474 authentic marriages of those who had been affected with simple gonorrhea, he found that 10% were without children after three years of married life; of 111 marriages of men who had had epididymitis on one side, 23.4% were sterile; of 24 marriages of men who had had epididymitis on both sides, 41.7% had no children and 52.5% had only one child." It is to be regretted that Benzler did not pursue his investigations so far as the wives of these soldiers were concerned. Had he done so, his statistics would have been doubly valuable.

Having shown how it is possible for specific urethritis to produce sterility, and having quoted statistics as to its frequency, we come now to syphilis, which although not so common as gonorrhea, still ranks high as a producer of sterile marriages. Unlike specific urethritis, it acts on the product of conception and not on the procreative germ. In all textbooks, syphilis is given as one of the principal causes of abortion, and as man is the aggressor in all sexual acts, it is just and reasonable to suppose that in the majority of cases he has infected the woman.

Being cognizant of the above facts as to gonorrhea and syphilis, it is our duty to prevent these diseases.

1. Lectures on venereal diseases should be a part of the curriculum of high schools and of colleges. It is not necessary for these lectures to be vulgar to be instructive. Every boy on reaching the age of 16 should be taught the physiology of the genitourinary apparatus. He should be told of the conditions which follow self-abuse and other unnatural sexual acts. Above all, it should be impressed upon his mind how serious are gonorrhea and syphilis, not only as to his own health, but as to his wife's, should he ever marry. I remember the most instructive lesson I ever received was from a visit to a dime museum when a college student. On either side of the hall, in glass cases, were wax-works showing syphilis and gonorrhea in their most repellent forms. I have never forgotten what I saw, and today whenever I see one of the demi-monde, I think how cruelly she may mark her prey—if she has the disease. I advocate school instruction because few parents ever appreciate the proper time for instructing their sons. It is hard for them to realize that their sons' ambitions rise in all directions at the same time. Putting off this important information from day to day is like playing with fire, for some day the boy of the family will "become a man" according to his playmates; he will have contracted either gonorrhea or syphilis.

2. No patient with venereal disease coming to a physician should be dismissed until there is positive evidence of cure. Patients with venereal diseases are too apt to discontinue treatment the moment all outward manifestations disappear. Because of this fact we have recurrent or latent gonorrhea, tertiary syphilis, etc.

3. Each patient with venereal disease should be instructed as to its possible result to himself and wife, if married. If single, he should be told how necessary it is for him to be cured before marrying.

4. Each family physician should inform the parents of marriageable daughters as to the seriousness of venereal diseases. He should counsel them not to consent to the marriage of a daughter unless the man can present a certificate from his physician declaring him free of any venereal infection. Advice given by public documents or leaflets does good, but much more real benefit is derived from a private conversation. No one can talk to a parent along such lines except his physician; he will listen to and follow the advice of his doctor when nothing else will appeal to him.

5. Establish State laws, making it a crime for a man or woman to marry while suffering from venereal disease. Already several States have passed such a law. All the States should pass it and, more important still, should enforce it.

6. When a husband of a fruitless union consults you, first examine him carefully before subjecting his wife to the ordeal. After several such examinations you will find in the great majority of cases that the man is directly or indirectly the cause of the sterile marriage.

**Pneumonia.**—The Chicago Bulletin of the Health Department for the week ended May 31, speaking of pneumonia, says: "A disease which has annually carried off nearly 13 in every 10,000 of the population of the country during the last few years and whose ravages are rapidly increasing year by year, is certainly worth talking about and preaching about, both to the profession and the public. The average pneumonia deathrate per 10,000 of population of 10 principal cities for a series of years prior to 1900 was as follows: Milwaukee, 10.40; Minneapolis, 11.84; Los Angeles, 12.49; Buffalo, 15.86; Chicago, 17.00; San Francisco, 18.12; New Orleans, 18.87; Philadelphia, 20.33; Boston, 25.20; New York, 26.67. Since 1900 these rates have enormously increased and are still increasing."

E. Souchon reports that on 12 fruit vessels, making 180 trips between New Orleans and Central America, and which carried medical inspectors for the purpose of capturing mosquitos that their variety might be determined, but 208 mosquitos were caught, of which only 5—that is, less than 2.5%—were stegomyia. In houses 40% are found. Females were enormously in the majority. Between Havana and New Orleans the percentage was 16. During 15 years, from 1886, fruit vessels were forbidden to have communication with the shore, and but 5 vessels arrived with yellow fever on board during the quarantine season. Only 1 of the 5 cases could not be positively traced to infection on the shore. He recalls the impunity of intercourse with noninfected vessels from yellow fever ports. During 10 years 50,000 laborers came in contact for 5 hours with mosquitos before fumigation of the holds, and yet not a case of yellow fever occurred in New Orleans. This was because the mosquitos were not infected. There is great improbability of stegomyia on infected vessels becoming infected before arrival because the percentage is so small, because the females must be impregnated before they will bite; the males are in very small number, the females must bite within the first 3 days. They cannot infect a human being until 12 days thereafter; they do not bite a second time until 5 days have elapsed; they do not breed on bilge or sea water; the bitten subject must be a non-immune. The cases on record are all primary, not secondary cases. It is impossible for a mosquito on an infected fruit vessel to carry yellow fever to the city because the vessels are not more than 6 days in transit, and are then thoroughly disinfected, the mosquitos being destroyed before the 12 days have expired. Mosquitos will not live in baggage without moisture for more than 3 to 5 days in summer. [H.M.]

**12.—The Weight Wave of Menstruation.**—W. T. Belfield finds that during several days, especially the first, preceding the flow a progressive increase of from 2½ to 5 pounds occurs, which may be from 1¼ to 5% of the usual weight. Half of this may be lost in 8 to 16 hours. The flow begins during rapid loss, the blood often following immediately on the crest of the wave. It terminates about when the weight reaches the premenstrual level. The gain is due to diminished excretion, especially of water; the loss to rapid excretion of carbon dioxide and water, not to the trifling loss of blood. After the weight has fallen there may be another crescendo and diminuendo movement lasting several days, but less pronounced than the menstrual wave. Two cases of irregular habit exhibited the wave where the flow was nearly or quite lacking. For two days preceding the climax in weight there is often marked torpidity of the bowels and scantiness of urine, while with the decline, excretion by bowels, kidney, skin, and lungs is notably increased. A woman of 59 showed no characteristic weight wave. [H.M.]

2. Policephalomyelitis and Allied Conditions. E. W. TAYLOR.
3. Congenital Inspiratory Stridor. D. CROSBY GREENE, JR.
4. Avulsion of the Tibial Tubercle Occurring in a Girl of 13. FRANCIS D. DONOGHUE.

1.—See *American Medicine*, Vol. V, No. 23, p. 895.

**3.—Congenital Inspiratory Stridor.**—D. C. Greene has seen 5 cases in 3 years. In all these the epiglottis exhibited an infolding of the lateral borders backward so that they almost touched posteriorly, converting the epiglottis into a tube with a narrow slit behind. One child died of pneumonia, another developed rickets. One outgrew the stridor at 1 year, another at 1½ years, the fifth child still has it at 15 months of age. The weight of opinion favors locating the difficulty in the vestibule of the larynx. There is a lax condition of the cartilages at the attachment of the aryepiglottic folds which permits of abnormal approximation. This is always associated with deformity of the epiglottis. The stridor is always noted immediately after birth or within a few days, and is continuous during waking and sleeping. Infants do not appear uncomfortable, and under favorable conditions the health is good, though such children seem susceptible to pulmonary affections. At 1 year of age stridor becomes gradually less noisy and finally disappears. Laryngismus stridulous usually does not begin until dentition. In stridor due to pressure of enlarged thymus or glands the sound is heard in expiration as well as inspiration. Treatment is purely prophylactic. [H.M.]

**4.—Avulsion of the Tibial Tubercle.**—The cases previously reported have been those of active, athletic boys between 13 and 16. The author's case is that of a girl of 13, likewise muscular and athletic. While vaulting over a horse in a gymnasium she fell, striking the cushion with her knee. There followed swelling and pain especially noticeable on attempting to kneel. After five weeks she came under the writer's observation. There was swelling, stiffness, and some pain, especially in the region of the tibial tubercle. The patellas were of the same elevation. The Röntgen rays showed plainly the true condition—avulsion of the tibial tubercle. Under treatment by strapping the leg became almost perfect functionally. [A.B.C.]

## Medical Record.

3. Diagnostic and Prognostic Data in Nervous and Mental Diseases. WILLIAM BROADBENT FRITCHARD.
4. Autocutaneous Skin-grafting. H. F. MCCHESENEY.
5. Report of an Operation for Carcinoma of the Cecum and One of Carcinoma of the Transverse Colon. C. G. DARLING and DEAN LOREE.

**1.—Neurofibromatosis.**—Joseph Fraenkel and J. R. Hunt define this condition as the formation of one or more tumors in one or more cerebrospinal or sympathetic nerves. They may occur in any of the former except the optic and olfactory, which are essentially outgrowths of the brain and the supporting structure is glia. The tumors may vary in number from few to hundreds, and in size from a nut to a child's head. The condition is rare. Four cases are reported, one of which came to autopsy and another was operated upon. The pathologic findings and illustrations are given. The interesting article concludes as follows: We believe the following points deserve emphasis: 1. The possible diagnostic aid to be derived from the presence of skin fibromas or nevi in obscure lesions of the nervous system. 2. Choreiform muscular twitchings as observed in the first case. A similar condition was noted by Virchow and Thomas. 3. The absence of characteristic root pain in a case of extramedullary compression of the cord. 4. The fact that neurofibromatosis is occasionally the cause of increased intravertebral or intracranial pressure. 5. The presence of neurofibromas without giving rise to neural symptoms. 6. The indications for surgical interference are given not only by direct neural symptoms, but by the consideration of the fact that sometimes, although rarely, neurofibroma may assume a malignant character and undergo sarcomatous trans-

formation. 7. That the absence of neural symptoms may be explained partly by the presence of an interfibrillary edema and succulent myxomatous tissue within the hyperplastic fibrous tissue, thus diminishing and distributing the pressure, and partly by the absence of a tendency for this fibromatous tissue to contract, in contradistinction to inflammatory hyperplasia. [A.B.C.]

**2.—Bureau of Public Health and Marine-Hospital Service.**—Surgeon-General Wyman, in his address at the first annual conference of State and National Health Authorities, notes that while the conference is official it is advisory in character, being called in pursuance of a provision looking to cooperation between National and State governments. He describes the work of the six divisions of the Bureau—Marine-Hospitals and Relief, Domestic Quarantine, Foreign and Insular Quarantine and Immigration, Sanitary Reports and Statistics, Personnel and Accounts, Scientific Research. He reports the work accomplished by the Yellow Fever Institute, and announces that a national leprosarium and regulations relating to establishments for the production of vaccine, serums, and antitoxins, are now engaging the attention of the service. He advises the appointment on special committees of members of the conference especially interested in the several subjects to be considered, the reports of these committees to be read at the next full conference. He believes this will stimulate investigation and produce uniformity of effort, and coordination in different parts of the country, such as does not now obtain. [H.M.]

**3.—Diagnostic and Prognostic Data in Nervous and Mental Diseases.**—W. B. Pritchard holds that the neurologist must be an evolutionary development from the general practitioner. The collateral territory is larger than in any other specialty. He discusses the degree in which such factors as race, environment, temperament, occupation, age, sex, social, and educational status, heredity, etc., must be taken into account. Heredity is of more importance in prognosis than diagnosis. The facies alone of the neurologic patient at times decides the diagnosis. The perceptive faculties must be trained into association habits. The trained touch and trained ear often aid in identifying the disease. Prognosis in nervous diseases and insanities is far better than is generally supposed. All the nonorganic types are recoverable. Etiology is relatively unimportant in its bearing on prognosis. [H.M.]

**4.—Autoepidermic Skin-grafting.**—H. F. McChesney describes a method of skin-grafting which he has employed with success. The area to be grafted is cleaned with Tiersch solution and then irrigated with normal salt solution. The granulating surface is then dried with gauze. Where the granulations were firm and healthy the graft is placed directly on them; over areas of exuberant growth they are cut down and gently compressed with dry sponges until all bleeding ceases. Soft and flabby granulations are scraped away until a firm fibrous foundation is reached. Then the thin blue line of epithelial cells that has started to creep in along the edge of the wound is dissected up, and small pieces about  $\frac{1}{4}$  inch square are cut off and placed on the granulating surface. These are covered with pieces of oiled silk about an inch square, or are protected with sterile gauze. The limb is then put up in a Volkmann splint. The patient experiences little discomfort while the epithelial line is being raised and cut off. It does not disfigure or scar, and at each dressing several new islands can be started without discomfort to the patient. These newly developing epithelial cells are very active in their growth and the grafts take well. [A.B.C.]

**5.—Operations—One for Carcinoma of the Cecum, Another for Carcinoma of the Colon.**—C. G. Darling and D. Loree report the cases. A man of 46 had a tumor of the right iliac region, diagnosed carcinoma of the cecum. Operation confirmed the diagnosis. The technic of the operation is given. Three inches of the ileum and six inches of the colon were removed and end-to-end anastomosis accomplished by suture, the omentum being brought over the site of anastomosis. The wound was closed with drainage and the patient made a good recovery. Another case is reported, the condition being cancer of the transverse colon. The same method of anastomosis as above mentioned was used, five inches of the colon being

removed. On the second day after operation signs of obstruction appeared. All food by the mouth was withheld for five days, lavage and enemas employed and recovery followed. [A.B.C.]

8. Neuritis from Whoopingcough, with Report of a Case. CHARLES J. ALDRICH.

**1.—Aids to Cystoscopic Practice.**—F. C. Valentine has devised some aids to the practice of cystoscopy. The first is the *box phantom*, which consists of a small square box, at the bottom of which is a schematic circular device separated into segments. At the extreme of each radius is a figure just as it appears on a watch dial. Near the front of the picture are two holes intended to simulate the ureteral orifices. A lid is held at an angle of 45° to the open surface. The inner surface of the lid has a mirror. In the front of the box is a hole representing the urethral lumen. The manner of studying the location of points in the bladder by means of a ureteral catheter inserted into the Valentine cystoscopic phantom is given in detail. A *larger phantom* is also described, which consists of a heavy wooden stand containing a rubber hemisphere in which the lower two-thirds of the bladder are depicted as they appear in life. A movable mirror is so arranged that it will show the images of the lower part of the bladder just as this region appears through the cystoscope. Practice with this device is the same as with the smaller box. The *ureter-catheter simulacrum* is an instrument intended for the practice of ureteral catheterism without the dangers to the patient or the instrument that expensive cystoscopes would entail. It consists of a short metal tube somewhat resembling a female catheter with large rings attached to its proximal end and a straight tube with one ring at its proximal end. [C.A.O.]

**2.—Pyelotomy with Secondary Nephrectomy on the Left Kidney, Pyelonephrolithotomy on the Right.**—This case, reported by J. F. Erdmann was that of a woman of 31, who when first seen by him was in shock; pulse, 160; temperature, 104° F.; there was marked indications of tumefaction in the left side and an immediate history of obstruction for four days; agonizing pain, generalized, but most marked in the entire left half. There had been vomiting for three or four days. For 12 years the patient had suffered from attacks of pain limited to the left side and calculi had been passed several times. A diagnosis of nephritic colic with perinephritic abscess was made and immediate operation advised. The usual oblique incision for nephrorrhaphy was made, and about eight ounces of purulent fluid escaped. Examination revealed a large rent in the pelvis of the kidney, through which several small stones were removed. The cavity was packed and drained. There was still evidence of sepsis and five days later a nephrectomy was done. The patient gradually improved for four weeks, when she had an attack of pain in the right side, and a condition similar to that first seen, presented itself. For several months the attacks recurred at intervals, becoming more severe. A Röntgen ray picture showed a large calculus in the kidney pelvis and extending into the kidney substance, and several smaller calculi in the kidney substance. A pyelonephrolithotomy was done. The large stone, when dry, weighed three drams, while the four small ones weighed seven grains. Her convalescence was positive after the first day. [C.A.O.]

**3.—Blepharitis Marginalis.**—D. S. Reynolds divides these cases into three classes: First, those in which there is slight thickening of the borders of the lids, the anterior margins are dry and red, and the lash is thin, while the cuticle between the hairs is covered with minute scales of desquamating epidermis. Cases of this kind frequently disappear under correction of errors of refraction, of constipation, and of any form of

malnutrition or debility. The author believes that the fungus in the follicles in such cases may be entirely eradicated, and permanent recovery secured for many of them, by the periodic application of pure carbolic acid. The application is made about once in 10 days with a needle as direct and complete as possible to all the hair follicles of the margin of the lid. About the fifth day after each of these treatments a crust of epidermis exfoliates and should be removed and a little yellow oxid of mercury ointment applied. The second group of cases are those which present an excoriated, glazed, red, rounded appearance of the tarsal margin, with no sign of lash. Applications of phenol greatly reduce the thickening of the lid and a fair growth of lash appears. A third group is that in which an abundant accumulation of inspissated sebum mats the lashes together in groups. Reynolds says that in cases in which alopecia is present without ulceration or apparent desquamating conditions, or such as may be due to parasitic or microphytic causes, in persons who have neither syphilis nor leprosy the application of phenol often produces brilliant results. [C.A.O.]

**4.—Operations for Astigmatism.**—A. E. Davis calls attention to a case reported by G. J. Bull, in which complete tenotomy of the left external muscle relieved the muscular insufficiency and incidentally cured the astigmatism in the left eye. Another case is cited in which astigmatism was produced by tenotomy of the recti muscles. In each instance the operation was performed primarily to relieve an insufficiency of the ocular muscles. Other operations, such as paracentesis of the cornea, section of the cornea, and galvanocauterization of it, have been suggested as a cure for astigmatism. Davis believes that no one of these proposed operations for the cure of astigmatism is a justifiable procedure, except in the most extreme cases, as in keratoconus. [C.A.O.]

**5.—Summer Complaints of Infants.**—This paper by C. G. Kerley is based upon an observation of somewhat over 3,000 cases of summer diarrhea which were treated to a conclusion of the illness. Change in the diet is more important than all other measures in the management of these cases, that change being a substitution of a carbohydrate, in the nature of a cereal gruel, for the milk food. The milk must be removed entirely from the dietary and must be removed early, and must not be resumed until the temperature is normal, the stools thick and but two or three in 24 hours. One or two drams in each feeding may then be used noting the effect on the temperature and stools. The carbohydrates should be used in the form of barley or rice, gruel, plain, or dextrinized. When flavored with salt, sugar, or beef products, they furnish the best milk substitute. They should be given in the same amount as the child was accustomed to receive in ounces of milk in health, but at more frequent intervals. Half an ounce of the cereal to a pint of water is the usual strength. Raw starch, such as rice or pearl barley, should be cooked for three hours. Calomel in small, frequent, repeated doses is given, if there is a tendency to vomit. Two teaspoonfuls of castor-oil is given by preference on account of its prompt washing out effect. Bismuth subnitrate is of great value and must be given in doses of from .7 gm. 1.4 gm. (10 grs. to 20 grs.) every hour. In order to be of service it must be converted into bismuth sulfid in the intestines, forming black stools. Dover's powder in from  $\frac{1}{4}$  gr. to  $\frac{1}{2}$  gr. doses every two hours is indicated when there is tenesmus and straining with frequent stools. Irrigation is indicated in cases with high temperature and inactive bowel. Normal salt solution is the best irrigating fluid and may be used as cold as 70° F. in the high fever cases, and as hot as 110° F. in those with low temperature and extreme prostration. For the fever and restlessness, sponging with alcohol and water, equal parts at 80° F. is ordinarily employed. Kerley says the best prophylactic agent against summer diarrhea is a well baby properly fed all the year round. In the case of tenement children safe milk must be supplied, ice furnished, and the mothers taught the details of infant management. [C.A.O.]

**6.—See *American Medicine*, Vol. V, No. 21, p. 814.**

**7.—Torsion of the Testicle.**—A case is reported by W. W. Williams in a boy of 16, who had a sudden attack of pain in the right groin and testicle. A distention of the right inguinal canal and great tenderness of the right testicle was

found. The hernia was reduced, but the pain in the testicle continued. The epididymis was turned toward the front; upon turning the testicle about half way around on its axis the boy got immediate relief. A truss was put on the hernia and he had no further trouble for almost a year, when the pain suddenly returned more severe than before. The testicle was found enlarged and tender, and the epididymis turned to the front. The testicle could not be turned in either direction. An incision was made, and the testicle and lower portion of the cord were black, caused by the strangulation. The cord was ligated high up and the testicle removed. [C.A.O.]

**8.—A case of polynneuritis complicating whooping-cough** is reported by C. J. Aldrich in a boy of 4. The attack of whooping-cough was very severe. During the fourth week it was noticed that he was weak in his legs, and that he shortly began to complain of pain in the toes and ankles, which were slightly swollen and tender to the touch. Soon after this the patient manifested sensible loss of hand-grasp, with swelling and tenderness of the hands and fingers. Nasal speech developed and fluids were regurgitated through the nose. There was also diminution of the kneejerks, loss of both plantar reflexes, and some slight loss of touch and pain sense in the hands and feet. The palate was paralyzed. In about 12 weeks the boy appeared as well as ever. The kneejerks were absent for over four months. [C.A.O.]

### Medical News.

June 13, 1903. [Vol. 82, No. 24.]

1. Colchicum in the Treatment of Gout. CHARLES C. RANSOM.
2. Four Months' Experience with Antistreptococic Serum in Pulmonary Tuberculosis. S. G. BONNEY.
3. The Origin of the Eosinophiles and Their Diagnostic and Prognostic Importance. THOMAS R. BROWN.
4. The Morbid Anatomy and Pathology of Tabes. JOSEPH COLLINS.
5. Leukoplasmia in Secondary Syphilis. DOUGLASS W. MONTGOMERY.

**1.—Colchicum in Gout.**—C. C. Ransom reviews the history of the drug from ancient times and the diverse opinions as to its action. He concludes from his own observations that it does not augment urinary secretion and the uric acid and urea are unaffected. He invariably uses colchicin, and does not believe in pushing it to the point of purgation. Small doses should be given in the intervals between attacks. This relieves the discomfort of chronically affected joints and prevents acute exacerbations. Retrocedent gout is less likely to occur when colchicum is used. In cardiac degeneration it should be given with care. Nephritis is not a contraindication. [H.M.]

**2.—Antistreptococic Serum in Pulmonary Tuberculosis.**—S. G. Bonney has employed this as a last resort in desperate cases, the sputum containing large numbers of streptococci. The report covers 25 cases treated in four months in which a favorable climate and supervisory control failed to arrest the disease. One case presents improvement so remarkable as to insure permanent recovery. In another there was speedy termination of a streptococic pneumonia, another recovered from severe septic pneumonia following hemorrhage in tuberculosis, four others show marked improvement with probability of ultimate arrest, five cases exhibit definite improvement with uncertain prognosis, eight cases show some improvement, but not enough to modify an unfavorable prognosis; in three cases the effect was doubtful, in three there were no results. In many cases urticaria developed in three to ten days after injection. [H.M.]

**3.—See *American Medicine*, Vol. V, No. 7, p. 249.**

**5.—Leukoplasmia in Secondary Syphilis.**—D. W. Montgomery reports the case. A man of 37 came under observation, having contracted syphilis one year previously and had not been vigorously treated. Under treatment by the author several refractory and painful mucous patches in the mouth and on the tongue gradually healed and were replaced, particularly on the anterior dorsum of tongue, by areas of leukoplasmia. While the secondary syphilis was believed to be the prime factor in causing the condition there were local causes which doubtless contributed materially. These were alcohol, smoking, and ill-kept teeth. Rheumatism also doubtless played some part as a general cause. Of four previous cases of leukoplasmia hitherto reported as arising from secondary syphilis three were in women, though in general the condition is more fre-

quent in men. The patient is slowly growing better under mercury, but tobacco and alcohol have doubtless retarded the favorable progress of the case. [A.B.C.]

## CLINICAL MEDICINE

DAVID RIESMAN

A. O. J. KELLY

### REVIEW OF LITERATURE

**Diastolic Murmurs Without Lesions of the Aortic or Pulmonary Valves.**—R. C. Cabot and E. A. Locke<sup>1</sup> report four cases encountered during the past year in which a diastolic murmur during life led to the suspicion of aortic régurgitation, but in which autopsy proved the aortic valves to be normal. Detailed notes of the cases are given. The first is thought to belong to the group of cases in which the murmur is caused by genuine regurgitation, due to dilation of the valvular ring. The other three appear to belong to the class of cases studied especially by Sahli, when the murmur is supposed to be due to intense anemia. In one of the three there might have been temporary dilation of the aortic ring, because an accompanying chronic glomerulo nephritis caused high blood-pressure. For the other two there is no better explanation than that of extreme thinning of the blood, though this explanation does not seem to the writers by any means a satisfactory one. [A.G.E.]

**Acute Meningitis, with Recovery.**—O. Fischer<sup>2</sup> reports a case in which a young man of 19 presented a seropurulent discharge from the ear, with all the typical symptoms of acute meningitis. Lumbar puncture gave a cloudy fluid, which was rich in polynuclear leukocytes, but no microorganisms. The absence of bacteria in the cerebrospinal fluid is of no significance, according to Fischer; cases which at autopsy showed the presence of a virulent type of meningitis gave a sterile cerebrospinal fluid when lumbar puncture was performed. The author believes that because of the early discharge of the pus the infection of the meninges was too slight to cause death. Fischer concludes that a patient with a well-developed secondary meningitis is not always doomed to death. The primary focus of pus, whether it be acute or chronic, should be immediately evacuated. Even in well-established cases of meningitis the degree of infection may be so slight that death will not follow if further infection be prevented. [W.E.R.]

**Behavior of the Healthy and Diseased Animal Peritoneum.**—Clairmont and Haberer<sup>3</sup> have performed experiments on 200 rabbits to determine the absorbing power of the healthy and diseased peritoneum. The results of these experiments are as follow: 1. Increased peristalsis accelerates peritoneal absorption. 2. The absorptive power is not changed through one inflation of the abdominal cavity with air. 3. Intraperitoneal injection of sterile fluids, as urine, intestinal contents, do not interfere with peritoneal absorption; the same may be said of intestinal contents entering the abdominal cavity through a perforation. 4. At the beginning of peritonitis, serous absorption is accelerated; toward the later stages it is slowed. 5. After dry laparotomies, it is markedly retarded. 6. Moist laparotomies disturb absorption much less. 7. Narcotics influence absorption differently, depending upon the anesthetic used. 8. It is retarded very much when the diaphragmatic peritoneum is destroyed. 9. Transudation of the abdominal cavity is not markedly affected by laparotomy. [E.L.]

**Congenital Edema of the Left Arm.**—F. J. Collet and Maurice Beutter<sup>4</sup> report an example of this condition in a woman 27 years old. The family, previous and personal history, was unimportant. The condition was discovered accidentally when examining the patient's lungs. The circumference of the arm on the left high up was 23 cm.; on the right, 23 cm. At the lower third the circumference on the left was 29 cm.; on the right, 23 cm. The circumference of the forearm at the middle part was on the left 34 cm.; on the right, 20 cm. There was a true edema. Pressure, especially on the back of the hand,

caused a depression which persisted for a long time. The patient claimed that she had had the condition since birth. Congenital trophoedema is rare. The author found only the cases of Nouné, Tobiesen, and Rapin. [J.H.W.R.]

**Negative Features of Sterilized Milk.**—The use of sterilized milk for infant feeding is meeting with more and more opposition. A host of deleterious results are being attributed to the sterilizing process, which bids fair to become abandoned in the near future. N. P. Daniloff<sup>1</sup> has made a series of 175 analyses of milk subjected to high temperatures and draws the following conclusions: The alleged germicidal action of sterilization can only be obtained by temperatures of such height as to destroy the nutritive value of milk; milk subjected to sterilization undergoes quantitative and qualitative alterations which impair its digestibility and vital properties; these changes are physical and chemical in character and render the milk positively harmful as an infant food; such milk, when used over long periods, lowers metabolism, deranges digestion, and furnishes insufficient material for nutrition and growth. The result is frequently constitutional or metabolic disease. Sterilization is thus seen to be a noxious procedure. By means of scrupulous cleanliness in preserving and preparing the raw milk far better results could be obtained in artificial infant-feeding. [L.J.]

**Traumatic Pericarditis, Endocarditis, and Myocarditis.**—J. H. Pleasants<sup>2</sup> gives the clinical, and in one case the autopsy, notes of two cases of pericarditis and one of endocarditis in which the causal relation of trauma seems unquestionable. One of the first two patients was thrown from a carriage the other received a blow in the left axilla from a piece of scantling. The latter had also a myocardial infarct. Four other cases are recorded in literature. In one of the writer's cases the injury is believed to have resulted from *contrecoup*. The case of endocarditis occurred in a football player as the result of a kick on the chest. A tabulated summary of 14 reported cases of acute and chronic traumatic endocarditis, developing into valvular disease, accompanies the article. [A.G.E.]

**Immunization Against Albuminuria.**—Albuminuria follows subcutaneous injection of albumin in rabbits, and is also seen in man, if the diet is very markedly albuminous. It has been proved by specific precipitating serums that this excreted albumin is composed both of eggalbumen and serumalbumin, thus proving that this albuminuria is the expression both of an elimination of a strange, superabundant albumen as well as of actual injury of kidney cells. By means of repeated injections of albumen into rabbits, Hamburger<sup>3</sup> has found that the albuminuria gradually diminishes, to disappear completely after the fourth to sixth injection. An immunization of the kidney cells against this albuminuria may therefore be spoken of, inasmuch as albumen is found in the blood in sufficient quantities to produce albuminuria. Alimentary albuminuria may also be immunized against through subcutaneous albumen injection. He finds it impossible to explain this immunizing phenomenon. [E.L.]

**Influence of Fats on Gastric Digestion.**—K. Walko<sup>4</sup> finds that the administration of olive oil in small or large doses retards and diminishes HCl secretion. A retardation of gastric motility is also observed. Oil may therefore be used to advantage in the treatment of hyperacidity which is often associated with hypermotility. The presence in the stomach of a fat splitting ferment has been demonstrated frequently. The amount of this ferment is greatest after milk diet, less after meat diet, and least after administration of carbohydrates. The administration of oil does not influence proteid digestion and favors starch digestion. It also has a favorable influence on the constipation which so frequently accompanies hyperacidity. Bone marrow has the same good effect as olive oil, is pleasanter to take, and has a high nutrient value. The author has administered olive oil therapeutically and finds it of great and permanent value in almost all cases of hyperacidity. He has also used atropin and sodium bicarbonate but finds them to be of no benefit, and sometimes even harmful. Carlsbad salts are more useful

and give some permanent results. It seems not improbable that the cause of hyperacidity is to be found in a diet confined exclusively either to meat or to carbohydrates. Hence, a change of diet is of great benefit in the treatment of this condition. Milk and carbohydrates are badly borne but cream and butter are well taken by these patients. [B.K.]

A. B. CRAIG

MARTIN B. TINKER

C. A. ORR

### EDITORIAL COMMENT

**Methods of Intestinal Anastomosis.**—The *Lancet*<sup>1</sup> is authority for the statement that the earliest description of intestinal suture is found in a somewhat obscure passage in the Sanscrit Veda; that Celsus advises the use of sutures for wounds of the large intestine, but says nothing as to how they are to be employed; that Galen favored suturing the stomach and large intestine, but warned against usual death from suturing the small intestine. It is further stated that the Arabian physician, Abulcasis, recommended catgut for suture of the wounded bowel, and that Roger, of Parma, and Roland in the thirteenth century made use of a little elderwood tube, which was placed within the bowel and the edges of the wound were united with silk. All of this, together with much else that is recorded should serve to remind us that the principles involved in the present multiplicity of methods in intestinal anastomosis are old rather than recent. It was not that our medical forefathers did not appreciate the feasibility of intestinal anastomosis which prevented its becoming a customary surgical procedure, but rather that sepsis and death were almost universally consequent upon laparotomy. The first successful resection and anastomosis of the bowel was performed by Reybard in 1833, some three inches of the colon being removed. In 1836 Dieffenbach resected the gangrenous bowel involved in a strangulated hernia, did an anastomosis, and the patient recovered. These cases considering the condition of surgery at that time are phenomenal, and because of this and the rarely successful performance of laparotomy then, they remain conspicuous in surgical evolution. It was not, however, until surgical cleanliness made it reasonably safe to enter the abdominal cavity that intestinal suturing or anastomosis became more than a surgical curiosity. Since the attainment of this comparative safety an array of methods, which for variety and ingenuity are truly remarkable, have been introduced, each having its enthusiastic advocate. The authority previously quoted places the number at over 200. The multiplicity is a sufficient commentary upon the fact that no one method possesses many and distinct advantages over all others. Mayo Robson's bone-bobbins were ingenious and served a useful purpose, but are now rarely used; Senn's plates are less popular than formerly; Halsted's inflatable rubber cylinder is now not much employed; the ingenious methods of O'Hara and Laplace have never become widely popular; and Abbe's catgut rings are now no longer used. In this connection, however, distinction should be made between those methods which leave a foreign body within the gut to assist in the approximation, and those like the devices of Halsted, O'Hara, etc., which merely assist in effecting the operation. Among the former the mechanic apparatus which has undoubtedly achieved the widest popularity and use is the ingenious metal button of Murphy. It has served a most useful purpose and is still widely employed, but the evidence is plain that its popularity is distinctly waning. In the hands of the less skilful and in emergency cases it will remain an exceedingly useful device, but the present tendency among those skilled in visceral surgery is to discard any and all methods which require that a foreign

body be left within the intestine, unless speed, often an important factor in intestinal anastomosis, is urgent. There is an ever-present danger, even if not great, in leaving an extraneous body of considerable size in this situation. Of the various methods of effecting anastomosis by suture none appears simpler and easier than that of O'Hara, and yet complaint has been made that it leaves a diaphragm within the lumen of the gut, which practically amounts to a stricture. There are certain inherent disadvantages in relying on any mechanic device to assist in effecting the operation; it may not be at hand; it may be out of order—any one of many hindrances may occur. Manifestly then the fingers of the surgeon, together with needle and thread, are the only implements which can at all times he relied upon, and the progressive abdominal surgeon will cultivate his manual dexterity in this regard. What particular method of suture anastomosis he shall choose, whether lateral implantation, lateral anastomosis, circular enterorrhaphy, or the ingenious methods of Maunsell, Wiggin, Connell, and others, depends entirely upon the choice of the operator and the exigencies of the case. The probabilities are, however, that the near future will see a reduction rather than an increase in the number of methods and devices actually used, and that the suture alone will be the means chiefly employed by the skilful surgeon even when time is an important factor.

### REVIEW OF LITERATURE

**Actinomycotic Appendicitis.**—L. Therenot<sup>1</sup> reports the case of a patient of 18, a farmer, who was in the habit of chewing grass, wheat, corn, etc. He developed symptoms of appendicitis, which disappeared somewhat under medical treatment. In the right iliac fossa a mass remained, however, which was painless to the touch, movable and doughy; it was adherent below to Poupart's ligament. A diagnosis of actinomycotic appendicitis was made and confirmed at operation. The appendix was removed and drainage inserted; the intraappendiceal liquid did not contain the fungi, but they were found in the granulations lining the tract. The wound healed very slowly, until tincture of iodine was applied locally, and potassium iodide given internally in doses ascending to 6 grams (90 grains). The author recommends the latter treatment very enthusiastically. The differential diagnosis of ordinary and actinomycotic appendicitis is discussed at some length. [E.L.]

**Sarcoma of the Tongue.**—A. D. Fripp and R. H. J. Swan<sup>2</sup> tabulate 29 cases of true primary malignant connective tissue tumors of the tongue, the remainder of the 44 cases published under the title of sarcoma of the tongue being excluded because of insufficient proof, secondary involvement, etc. The age of the patients varied from 7 weeks to 65 years. There were 17 males and 8 females among the 25 cases in which age is stated. The small round-cell variety of sarcoma was the most frequent. Symptoms are usually not present until the growth interferes mechanically with mastication or deglutition. The mucous membrane covering a lingual sarcoma is in most cases thinned and healthy. The lymphatic glands in the submaxillary space were enlarged in six cases, three of which showed sarcomatous involvement. The submaxillary salivary gland was enlarged in three cases. In the two removed the swelling was found to be inflammatory. The other, left *in situ*, regained its normal size two weeks after removal of the lingual tumor. The enlargement in these cases is possibly due to pressure on Wharton's duct by the growth in the tongue. The general health of patients with sarcoma of the tongue remains good until secondary visceral deposits have appeared or the mass becomes large enough to interfere with deglutition or respiration. Of the 29 cases 25 were operated upon and 11 recovered, remaining well for varying periods ranging from 13 years to 6 months. Seven may be considered cured. [A.G.E.]

**The Transverse Incision in Laparotomy.**—Ignacio Plasencia<sup>3</sup> was the first to introduce this operation into Cuba.

<sup>1</sup> Gazette des Hôpitaux, 1902, Vol. lxxv, p. 1277.

<sup>2</sup> The Practitioner, May, 1903.

<sup>3</sup> Revista Medica Cubana, December 1, 1902.

The curved incision crosses the median line about four centimeters from the symphysis pubis, beginning and ending at the crest of the anterior superior spine of the ilium. The transverse incision passes through the skin and aponeurosis, but when the recti muscles are reached they are divided vertically. The fascia transversalis and the peritoneum are treated as in ordinary laparotomy. After opening the abdomen the patient is placed in Trendelenburg's position and the incision held open to give space for operation. The peritoneum, muscles, and aponeurosis are sutured with catgut, the skin with silk in separate places. Drainage tubes are inserted at the median line. The author used sterilized silver foil over the wound after suturing. When this method is used there is little danger of hernia, because the incision is transverse to the muscular tissue. The scar moreover does not show when the patient stands. An account of two clinical cases in which the operation was entirely successful follows. These present no important features beyond the uneventful and complete recovery of both patients. [G.C.D.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### EDITORIAL COMMENT

**Age Limit in Uterine Carcinoma.**—Although the maximum incidence for the occurrence of carcinoma of the uterus is between the fortieth and fiftieth years, yet the possibility of its development earlier should not be overlooked, and probably should be more frequently emphasized. This fact has been strongly brought to our notice recently by the observation within three months of three patients suffering from well advanced cervical cancer before thirty years of age. In two of them the disease was so extensive as to contraindicate surgical interference. As we have repeatedly said, eternal vigilance is required for the early diagnosis of this insidious disease; and these cases in point indicate the necessity for careful examination and early operation in bad lacerations of the cervix; for it is extremely rare for a nulliparous woman to suffer from cervical cancer unless she has been subjected to some operation or instrumental treatment. When the disease occurs early during the period of sexual activity, its extension is very rapid and recurrence almost inevitable, so that we are confronted by the melancholy truism that we know little about, and can do little for, well defined cases of uterine carcinoma. The chief prophylactic measure is the repair of lacerations of the cervix which are extensive enough to produce an eversion of the cervical mucous membrane, whether they are symptom producing or not.

### REVIEW OF LITERATURE

**Conservative Nonoperative Treatment of Women's Diseases.**—A. Pincus<sup>1</sup> gives an illustrated description of an apparatus which he employs in the conservative treatment of the female genital organs. He recommends the hot vaginal douche and its modifications in all cases in which the promotion of elimination favors the absorption of inflammatory masses. This method must not be used without precautions, but the physician must determine the indications for beginning the treatment by the control of the pulse and temperature, and the sensitiveness of the pelvic organs through bimanual examination. So long as there is the least rise in temperature present, or there is excessive sensibility of uterus or appendages, he advises to wait before treatment; as he believes that in the acute or subacute stages of such diseases there should be complete rest in order to obtain the best results, even to the omission of any examination. Even vaginal examinations, introduction of tampons, or irrigation, in an acute stage of the disease are to be avoided and cold applications should be used, such as an ice-bag on the abdomen, or in case of necessity opium suppositories. In suitable cases he uses tampons and massage in connection with other treatment. But massage is often used

most illogically and should never be employed for hysterical women. In such cases the hot water is the rational remedy. He has used what he calls the resorption cure successfully for the hematocele of extrauterine pregnancy, in many cases of perimetritis, oophoritis and salpingitis, and especially in long-standing pyosalpinx. Great care must be exercised that no exacerbation of tissues arises from the hot douches; constant watch must be kept over pulse and temperature. Pincus repeats in conclusion that he is not an absolute opponent of operative treatment; but it should be resorted to only after other methods in all suitable cases have been tried and have failed. [W.K.]

**Pregnancy and Labor Following Nephrectomy.**—J. F. Baldwin<sup>1</sup> reports two cases in which unilateral nephrectomy has been done, the women having afterward married and passed through a normal labor. The urine in Case II was normal throughout the pregnancy, and was also apparently normal in Case I. [D.R.]

**Therapy of Hematocele in Extrauterine Pregnancy.**—F. Schenk<sup>2</sup> says that we should operate usually not only in cases of uninterrupted extrauterine pregnancy, but also in interrupted pregnancy with the formation of hematocele, since another attack of hemorrhage, or long uterine bleeding, or appearances of decomposition may set in. In uncomplicated hematocele the waiting method without operation may be followed. The advantage of early operation is that the operation may be more conservative than if it has to be done later under unfavorable conditions. [W.K.]

**Treatment of Uterine Fibromyomas.**—F. W. N. Haulbain<sup>3</sup> reported nine years ago 20 cases treated by electricity. He has traced the subsequent history of 15. Of these 9 were cured, in 2 hemorrhage recurred, in 2 the tumor continued to grow, and in 2 others underwent active degenerative changes. In soft, edematous fibroids, removal of the appendages is valuable. Vaginal myomectomy may be performed for stalked growths or submucous polypi, especially when the cervix has already been dilated by the downward growth of the tumor or thinned by pressure. It is a debatable question how far conservative surgery warrants us in proceeding in the removal of sessile, subserous, and interstitial tumors by the abdominal route, as the risks of lengthened manipulation are great and the organs doubtfully serviceable. When symptoms call for hysterectomy, Haulbain prefers the supravaginal abdominal method as the quickest. He believes that electrical treatment is decried because it has been used in unsuitable cases, as submucous tumors, in which it tends to aggravate hemorrhage by stimulating uterine contractions. In interstitial tumors of medium size it seldom fails, and if it does, no harm is done. Diagnosis of the variety of tumor is important in all cases, and can be achieved only by dilation of the cervix and digital examination of the uterine cavity. [H.M.]

**Contemporaneous Extra and Intrauterine Pregnancy.**—K. Reifferscheid<sup>4</sup> relates the history of iipara, aged 26, strong and healthy, admitted to the hospital because of pain and persistent hemorrhage. Examination resulted in a diagnosis of left-sided ectopic gestation with a possible intrauterine three months' pregnancy. Median abdominal incision was made, left tube and ovary removed, the adherent parts of omentum resected and all done with the most careful consideration for the large pregnant uterus. Operation occupied 20 minutes. Convalescence was ideal, and the intrauterine pregnancy, undisturbed, ran on its normal course. [W.K.]

**Epidemic Parotitis with Metastasis to the Female Genitalia.**—A summary of the literature of the subject leads G. McNaughton<sup>5</sup> to state that the localization of the disease in the region of the ovaries is in mumps more frequent than commonly mentioned in textbooks. He reports the case of a girl of 18 who, as the parotitis began to subside two weeks after a menstrual period, experienced pain in both ovarian regions. After two days a bloody flow appeared. The pain was severe enough to require the use of an opiate for five days. The case

<sup>3</sup> Edinburgh Medical Journal, March, 1903.

<sup>4</sup> Zentralblatt für Gynäkologie, March 21, 1903.

<sup>5</sup> Pediatrics, May, 1903.

<sup>1</sup> Berliner klinische Wochenschrift, April 6-13, 1903.

is believed to be an illustration of the specific poison of parotitis affecting the female genitalia. The term genitalia instead of ovaries is used because the writer believes it impossible to exclude pelvic inflammation or engorgement beside that of the ovary. [A.G.E.]

**TREATMENT**

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPLEMAN

**REVIEW OF LITERATURE**

**Aftereffects of Aspirin.**—Unpleasant aftereffects, especially skin eruptions, are not so common after aspirin as after other compounds of salicylic acid. A patient of Otto's<sup>1</sup> took a 1 gram (15 grains) powder and shortly after was attacked with violent itching, followed by a board-like swelling of the skin of the entire body and the mucous membrane of the mouth, throat, nose, etc. After a second powder of 1 gram (15 grains) the symptoms of itching and tension of skin became almost intolerable; violent thirst, oppression, dizziness, and vomiting set in and later the entire body became covered with deep red elevated spots; the eyes were completely closed by edema of surrounding structures. A similar case is related by Meyer after 1 gram (15 grains) of aspirin. [E.L.]

**The Solution of Menthol.**—The value of menthol as a local anesthetic is sometimes interfered with on account of its insolubility in water. De Crescentignes<sup>2</sup> recommends for the proper preparation of menthol solution, or more properly emulsion, the use of soap bark, as in the following prescription:

Menthol . . . . .	.03 gram	(.5 grain)
Tincture quillaia . . . . .	5 cc.	(75 minims)
Glycerin . . . . .	9 cc.	(2.5 drams)
Water enough to make . . . . .	120 cc.	(4 ounces)

A tablespoonful at a dose.

The menthol is dissolved in the tincture of quillaia, the glycerin added first, and then the water with constant stirring. In this way there is formed a permanent emulsion.

It is counterindicated in gastralgia. For local use de Crescentignes recommends the following:

Menthol . . . . .	.13 to .32 gram	(2 to 5 grains)
Tincture quillaia . . . . .	9 cc.	(2 1/2 drams)
Water enough to make 150 cc.		(5 ounces)

For a gargle this prescription may be diluted with 6 to 8 times its volume of water. It must be remembered, however, that soap bark is a local irritant and that its active principle, saptoxin, is a powerful protoplasmic poison, and we believe the following formula recommended by Wilber<sup>3</sup> is therefore frequently preferable:

Menthol . . . . .	1 gram	(15 grains)
Chloroform . . . . .	5 cc.	(75 grains)
Spirit of camphor . . . . .	10 cc.	(2 1/2 drams)
Alcohol . . . . .	20 cc.	(5 drams)
Soft soap . . . . .	15 cc.	(4 drams)
Oil of wintergreen . . . . .	2 cc.	(30 minims)

Mix for internal use. [H.C.W.]

**Treatment of Simple Jaundice.**—A. Robin<sup>4</sup> reports the case of a young woman suffering from jaundice which came on as a result of fright. In such cases Robin begins treatment by placing the patient on a purely milk diet, which acts in two ways: It increases diuresis and causes the biliary and intestinal toxins to be more easily eliminated. It also lessens biliary secretion and in this way modifies hepatic activity. This diet should be continued until there is a modification in the urine as follows: In making Gmelin's test for biliary pigments in the urine, when it is noticed that the green discoloration is replaced by a mahogany discoloration it denotes the presence of urobilin or hemaphein which indicates that the biliary passages are open. The presence of urobilin indicates that there is insufficiency of the liver; it is then necessary to stop the milk diet and stimulate the hepatic functions by other food and by alkalis. In order to hasten the flow of bile, 10 mg. to 16 mg.

(1/8 gr. to 1/4 gr.) of belladonna extract may be given night and morning. The rectal injection of 1 1/2 quarts of water at the temperature of the room acts as a stimulant to biliary secretion, the biliary passages and the intestine. These injections should be given by means of a soft catheter inserted high into the rectum, and should be repeated twice daily. Vichy water is useful when taken in the morning and at night, or a solution of sodium bicarbonate may be substituted. The food should not comprise raw materials nor acids, fats, butter, sauces, or stewed articles. Constipation, if present, may be relieved by sodium sulfate. [L.F.A.]

**Adrenalin an Abortive Agent in Asthma.**—Aronsohn<sup>1</sup> used adrenalin in a solution of 0.5 gm. (7 1/2 grains) to the ounce to cut short an asthmatic attack. He applied it directly to several inflamed-looking spots in the nose, and the attack disappeared within five minutes. He employed it successfully in several recurrences with the same patient. He does not see a curative agent in it, but considers it superior to cocain as an abortive agent. By diluting it with two parts of oil vaselin it may be used as a spray in cases where the asthmogenic points can not be isolated. [E.L.]

**Anesthesin.**—Chevalier<sup>2</sup> gives the results of his study of anesthesin the ethylic ether of paraamidobenzoic acid. It is very slightly soluble in water, more soluble in alcohol, glycerin, and oils. It is a very stable preparation and is absorbed very slowly. Anesthesin is used as a local anesthetic in all such cases as those in which orthoform is employed. Hypodermic injections of anesthesin have not given very satisfactory results. Chevalier considers it superior to orthoform because its action is more pronounced and of longer duration. No toxic symptoms have been observed. [L.F.A.]

**The Value of Exercise in the Treatment of Pulmonary Tuberculosis.**—Trj  en<sup>3</sup> takes exception to the prevalent idea in the treatment of tuberculosis that all that is necessary is to have the patient gain weight. A large deposit of fat is neither a sign of health nor a source of strength. The use of properly modulated exercise is not only harmless but a very valuable aid in the cure of pulmonary tuberculosis. It increases the assimilation of food, brings about freer circulation of the air in the lungs as well as the blood through the body and heightens vital resistance. He is convinced that in his sanitarium the patients have done better since the introduction of regular exercise as part of the treatment. The exercise should not be begun until subsidence of the severer symptoms, and should be at first very light, a couple of half-hour walks along the level. Gradually the amount may be increased so that five or six hours daily may be spent in walking, preferably in "broken doses," with a portion of it in ascending hills. Sometimes "lung gymnastics" are useful. [H.C.W.]

**Yearly Variations in the Strength of the Official Digitalis Leaves.**—The variations in the strength of digitalis leaves have been known for a long time. Focke<sup>4</sup> concludes from his observations in practice that the greater part of these variations arise in the drug store and are connected regularly with the portion of the year in which the preparations are sold. The leaves used in July and August (immediately after harvest) are four times as strong as those displaced by them. Until the beginning of October they lose half the strength, until January two-thirds, and until summer three-quarters. After observing this in actual practice he demonstrated it also by animal experiments. Cases of poisoning are therefore more common, and occur with smaller doses in the second half of the year than in the first. When occurring in the first half the doses have invariably been found to be very large. [E.L.]

**Mercuriol.**—H. Dreesman<sup>5</sup> uses mercuriol, a combination of mercury and nucleinic acid, in leg and other chronic ulcers, in the form of a 2% to 5% ointment; in soft chancre and granulating wounds as a dusting powder; in gonorrhoea as a 1/2% to 2% injection; in syphilis internally in doses of 0.05-0.1 grains (1/4-1/2 grains) twice daily. Peru:	Callao.....To May 12.....	10	4

**Changes in the Medical Corps of the U. S. Army for the week ended June 13, 1903:**

MABRAY, WILLIAM C., contract surgeon, Columbus Barracks, ordered to San Francisco, Cal., with recruits, is granted leave for ten days, the leave to begin and end at San Francisco, when Contract Surgeon Mabry will return to his station.

PEASE, LOUIS W., contract surgeon, leave granted on surgeon's certificate is extended one month.

GREGORY, WILLIAM G., contract surgeon, leave granted on surgeon's certificate May 14 is extended one month.

PEDDICORD, HARPER, contract surgeon, will proceed, via Skagway, Alaska, and the White Pass Railroad, to Fort Gibbon, Alaska, for duty, to relieve Contract Surgeon Verdo B. Gregory, who will proceed to Vancouver Barracks, and report for temporary duty.

STEDMAN, CHESTER J., contract surgeon, now in Washington, D. C., will proceed to Fort Adams for duty.

HATHAWAY, First Lieutenant LEVY M., assistant surgeon, now at Vancouver Barracks, will proceed to Fort Davis, Alaska, by steamer, sailing from Sea tie, Wash., June 6.

VAN KIRK, HARRY H., contract surgeon, is granted leave for twelve days from about June 4.

WICKLINE, W. A., contract surgeon, is granted leave for one month, to take effect when relieved by Contract Surgeon H. L. Wood, with permission to apply for an extension of fifteen days.

HADRA, FREDERICK, contract surgeon, is granted leave for twenty-one days from about June 10.

JENKINS, FRED. E., contract surgeon, is granted leave for thirty days from about June 11.

GREGORY, WM. G., contract surgeon, is relieved from further duty in the division of the Philippines, and upon the expiration of his present sick leave will proceed to Fort Apache for duty.

BANISTER, Major JOHN M., surgeon, is relieved from duty at the First Reserve Hospital, Manila, P. I., and will report to the commanding general, department of Luzon, for assignment to duty.

RUTLEDGE, JAMES C., contract surgeon, is granted leave for one month, with permission to visit China and Japan, to become available when his services can be spared.

WILSON, ROY A., contract surgeon, is relieved from further duty at the Presidio and will proceed to his home, Dennison, Ohio, for annulment of contract at his own request.

WHITCOMB, First Lieutenant CLEMENT C., assistant surgeon, now at San Francisco, Cal., is relieved from further duty in the division of the Philippines, and will proceed to Governor's Island, N. Y., and report to the commanding general, department of the East, for assignment to duty pertaining to the Army and Navy maneuvers during the ensuing year.

ROBERTS, D. M., contract surgeon, leave granted May 6 is extended two months.

**Changes in the Medical Corps of the U. S. Navy for the week ended June 13, 1903:**

SPRATLING, L. W., surgeon, detached from the Navy Yard, New York, and ordered to the Columbia—June 6.

LEACH, P., surgeon, detached from the Columbia and ordered to the Massachusetts—June 6.

BLOCK, W. H., acting assistant surgeon, detached from the Naval Recruiting Station, Chicago, Ill., and ordered to Navy Yard, New York—June 6.

STEELE, J. M., surgeon, detached from the Massachusetts and granted leave for six months—June 8.

Surgeons Means, Cordelro, Wieber, Norton, Kite, Wentworth, Decker, Berryhill, Stone, Pickrell, Crandall, Harris, Urle, McCormick, Arnold, Wilson, Stokes, Stitt, Gates, Lowndes, Barber, Rothganger, Smith, Lung, Von Wedekind, Bogert, Spratling, Kennedy, Blackwood, Braisted and Evans commissioned surgeons, with rank of lieutenant-commander, from March 3, 1903—June 8.

Passed Assistant Surgeons Orvis, Kerr, Narr, Grow, Grunwell, Langhorne, Thompson, Benton, Carton, McCullough, Furlong, Agency, Bell, Curl, Bell, Holcomb, Parker, Wright, Plummer, Odell and Taylor commissioned passed assistant surgeons, with rank of lieutenant, from March 3, 1903—June 8.

MORGAN, D. H., passed assistant surgeon, detached from the Boston and ordered to Naval Hospital, Mare Island, for treatment—June 8.

RENNIE, W. H., VERNER, W. W., KOHLHASE, O., and ROSSITER, P. S., doctors, appointed assistant surgeons from May 25, 1903—June 9.

SMITH, W. B., and HOEN, W. S., doctors, appointed assistant surgeons from June 2, 1903—June 9.

GRAYATT, C. U., medical director, retired on account of disability incurred in active service—June 10.

ANDERSON, F., medical director, detached from the Alabama and ordered to the Brooklyn—June 10.

BYRNES, J. C., surgeon, ordered to the Texas—June 10.

DECKER, C. J., surgeon, ordered to the Alabama—June 10.

STOKES, C. F., surgeon, ordered to the Navy Yard, League Island, Pa.—June 10.

PICKRELL, G., surgeon, detached from the Texas and ordered to the Iowa—June 10.

SMITH, R. K., passed assistant surgeon, detached from the Independence and ordered to duty at the Naval and Marine Recruiting Stations, San Francisco, Cal.—June 10.

KINDELBERGER, C. P., passed assistant surgeon, detached from the Iowa and ordered home to wait orders—June 10.

FARENHOLT, A., passed assistant surgeon, detached from the Boston and ordered to the Concord—June 10.

ELMER, M. K., assistant surgeon, detached from the Ranger and ordered to the Independence—June 10.

HUNTINGTON, W. H., pharmacist, retired from active service on account of disability incident to service—June 10.

**Changes in the Public Health and Marine-Hospital Service for the week ended June 11, 1903:**

CARMICHAEL, D. A., surgeon, leave of absence for seventeen days from May 19, 1903, granted by Bureau letter of May 9, amended so that it shall be for thirteen days only—June 6, 1903.

EAGER, J. M., passed assistant surgeon, granted leave of absence for two months from August 1—June 9, 1903.

GARDNER, C. H., passed assistant surgeon, granted leave of absence for seven days—June 5, 1903.

PARKER, H. B., passed assistant surgeon, directed to report at Washington, D. C., for temporary duty—June 8, 1903.

VOGEL, C. W., assistant surgeon, granted leave of absence for one month from June 8—June 5, 1903.

LLOYD, B. J., assistant surgeon, reported to Passed Assistant Surgeon R. Blue, Plague Laboratory, San Francisco, Cal., for temporary duty—June 9, 1903.

BREADY, J. E., acting assistant surgeon, granted leave of absence for three days—June 6, 1903.

MCCONNELL, A. P., acting assistant surgeon, granted leave of absence for two days from June 10—June 8, 1903.

MASON, W. C., acting assistant surgeon, granted leave of absence for ten days from June 17—June 9, 1903.

RODMAN, J. C., acting assistant surgeon, granted leave of absence for thirty days from June 20—June 9, 1903.

WALKLEY, W. S., acting assistant surgeon, granted leave of absence for seven days from June 11—June 9, 1903.

ALLEN, G. C., pharmacist, granted extension of leave of absence for twenty-three days from June 5—June 8, 1903.

PUBLISHED WEEKLY AT 1321 WALNUT STREET PHILADELPHIA BY THE AMERICAN-MEDICINE PUBLISHING COMPANY

VOL. V, No. 26.

JUNE 27, 1903.

\$5.00 YEARLY.

**The Medical Charities of London.**—*The Lancet* of June 6 includes a supplement in support of the Metropolitan Hospital Sunday Fund, which shows at a glance the vast amount of work that is being done by the hospitals and dispensaries of greater London. One is astonished to find that there are 204 of these in all, 31 general and 60 special hospitals, 57 cottage hospitals and Convalescent Homes, and 56 Dispensaries. In 1902 these treated 128,974 in-patients, and 5,025,058 out-patients, and 406,108 accidents and emergencies. In all the institutions there were 8,692 deaths during the year. They received from the Hospital Sunday Fund award, \$289,045. The progress of this fund is shown in a table in which the total fund in 1873 was \$138,500, rising fairly steadily to \$313,345 in 1902. How many of these millions could have paid for the medical service would of course be mere guessing, but the constant increase of the total amount of such charitable work, the growing difficulty of securing voluntary support, the doubts and injustices contingent upon "bad years" bring always nearer the thought that some more stable manner must be devised of meeting the difficulty.

**The Newspaper Mouth Padlocked.**—We have noticed with satisfaction the extensive, continual, and habitual quotation from the columns of *American Medicine* by the lay press, but our interest has been more constantly excited by the fact that articles on one class of subjects is never quoted. Any facts or articles *e. g.*, upon patent medicines are received in utter silence, so far as the newspaper is concerned, and as Hans Breitman would say, are at once lost in die Ewig-Keit. A correspondent at last points out the reason. He called the attention of a "syndicate writer," one whose specialty was humorous articles on popular fads and fancies, to the field open to him in the exploitation of the nostrum drinkers, the electric belt men, the oil-of-mustard actina people, the women with wires about their ankles connected with a wonder-working liquid yonder, etc. In especial was pointed out the man who had taken 792 bottles of patent medicines, washed down with two gallons a week of a prized mineral water. He had failed to support his family, and had the ungratefulness to die. The fun-maker saw the opportunity and regretted his inability to work the vein. The newspapers and their writers could nag the Christian scientists, and such,

every day, because these do not advertise. But to touch the sacred alcoholic nostrum traffic, the magnetic belt business, and all that, that of course would be suicide, speaking from a newspaper point of view. And suicide is not in their intent at present. They, the solemn "guardians of public morality," prefer their mouths padlocked and the key given to the patent medicine syndicates.

**Medical Editors in Newspaper Offices.**—The newspaper accounts of the operations performed by famous foreign surgeons that have visited and are visiting this country have, in many instances, been entirely erroneous, and unjust to the visitors and to our American surgeons. The visiting surgeons have been credited with having performed operations that had never before been done in the United States, although they had never made such a claim for themselves. Such statements bring the visitors into disfavor with their American colleagues, and also lessen the respect in which our surgeons are held by the public. It appears to us that a reputable newspaper should have sufficient pride not to print accounts of operations that are the product of the uncontrolled mind of the imaginative reporter without submitting them to a medical man for revision. If it is impossible—and it seems that it is—to prevent the lay publication of medical items, every newspaper should have attached to its editorial staff a competent physician who, as medical editor, should revise all articles pertaining to professional subjects. Newspaper science would then, to some extent, be relieved from the contempt in which it is at present held. Every self-respecting newspaper should feel as much pride in accounts of medical matters as in those of financial, real estate, or other affairs.

**The no-breakfast fad** illustrates the fatal and foolish tendency of humanity to go from one extreme to another. If we have overeaten or overdrunk let us not eat or drink at all. If we have been hogs let us be angels. People without a sense of moderation and avoidance of extremism who have gorged themselves with animal food feel that they must be vegetarians. No-breakfast is their latest reaction. To the do-nothings and the fussers-about-themselves this nonsense may do no harm, but for people who work with muscle or brain the faddism can do nothing but injury. It will perhaps

end in coffeeism and drugism, or some other pernicious evidence of lack of balance and control. Many Europeans make merry or wax disgusted over "the American breakfast," but they are easily caught up by the observation that they eat late at night, so that in the morning the stomach or intestines are still filled with undigested and unassimilated food. Moreover, they do not fail to pour into the stomach a lot of coffee at breakfast time, and they will also take a late breakfast as one of their five or six meals a day. The stomach should be empty on going to bed, and if so the normal system demands a breakfast of good food soon after rising. Harm may result from the no-breakfast folly if people do not properly regulate their general dietary and personal habits.

**Concerning Antimony.**—The destructive properties of the salts of antimony have, during the past half century, been from time to time brought with painful prominence under the notice of our British confreres on the other side of the Atlantic. The physical properties of the element itself have long been known to possess great interest for the scientific chemist. Its history savors somewhat even of the romantic. This is in some degree indicated by the account of its—still problematic—etymology given by the great English lexicographer as: "the stibium of the ancients, by the Greeks called *στίμιμι*. The reason of its modern denomination is referred to Basil Valentine, a German monk, who, as the tradition relates, having thrown some of it to the hogs, observed that, after it had purged them heartily, they immediately fattened; and therefore he imagined his fellow monks would be the better for a like dose. The experiment, however, succeeded so ill that they all died of it; and the medicine was thenceforward called *antimoine*, *antimonk*." Johnson, with all his startling roughness, frequently displays a keen, as well as ponderous, appreciation of the ridiculous; and he very evidently could not resist the temptation which opportunity afforded of inserting on his page this preposterous item of mythologic therapeutics. The account is proved false by Basil Valentine's own references in the pages of his quaintly interesting "Triumphant Chariot of Antimony" (English version, 1678) to the very remarkable cures which he had effected by its employment in cases of otherwise desperate diseases occurring among his "Brethren." The medicinal value of the preparations of antimony have for several centuries aroused, at intervals, the very emphatic testimony of enthusiastic advocates. Dr. James, the friend of Samuel Johnson, and (nominal) author of the great Medical Dictionary, in the preparation of many of whose articles the latter is said to have taken a prominent part, was a votary of antimony; and the "powder" which bears his name is now better known than his great lexicon. But of recent years the poisonous properties of antimony have secured more attention than the medicinal.

**The Chemistry of Antimony.**—The history, as well as the physical properties of antimony, one of the best-known preparations of which was used in the perpetration of the horrible crime for which George Chapman was recently executed in London, is of peculiar interest.

Like other poisons, the preparations of antimony are extensively used in medicine; and always prove most valuable remedies when judiciously employed. The properties of antimony were first brought prominently under the notice of European scientists by the shadowy investigator, Basil Valentine, referred to in the definition of the great English lexicographer already quoted, "Monke of the Order of St. Bennet" (Benedict), whose remarkable work, "The Triumphant Chariot of Antimony," informs the reader that "The Life of no one Man is sufficient for him to learn all the mysteries thereof. It is Venome and a most swift poyson, also it is void of Venome and a most excellent Medicine; whether it be used outwardly or inwardly. Which is a thing hid from most men by reason of their own blindness; and they judge it an incredible, foolish and vain work, because (through their ignorance) it is unknown to them, who can no otherwise be excused, then that they deserve the name of Stupidity. Yet that is not to be suffered in them, because they desire not to learn or be better informed, either here, or elsewhere." The chemical classification of antimony was long regarded as doubtful, but the rapid advances of modern research have thoroughly established its position. It ranks, in the elementary form, as a "metal;" but like arsenic, many of whose properties closely resemble its own, it occupies a place close to the borderline of the "nonmetals." Like arsenic, it is an "irritant" poison, causing inflammation of the mucous membrane of the stomach and intestines when brought into contact therewith. Hence the prolonged use of its preparations in small doses causes the development of symptoms which simulate those of typhoid fever, as was shown in the investigation of the celebrated "Bravo case." Like arsenic, too, its combining power is that of a "pentad," that is to say, one of its atoms possesses the physical property of attaching to it, in the formation of a molecule, five atoms of one of the elements of single affinity, such as hydrogen. It is interesting in this connection to note in passing that when elements of such combining power unite with those whose affinities are of an even number, thus leaving some bonds unsatisfied, the resulting molecular compounds are often peculiarly unstable; they disunite rapidly when agitated; that is to say, they "explode." Nitrogen, which forms (approximately) four-fifths of the bulk of the air we breathe, is an element whose affinities correspond to those of antimony, and all the most violent "explosives" are essentially formed of its compounds. Hydrocyanic acid, too, which is the most rapidly acting—the most *explosive* in its effects—of all known poisons, is a compound of nitrogen.

**Newspapers and magazines "For the Home," and "For the Young."**—Among the samples of morbid serial literature that we have gathered we notice many that need the attention of the Postmaster-General. Depravity can go no lower than some of these illustrate. To appeal to the ignorant and innocent in the disguise of a "periodical for the home," and sneak into their hands the pollution of the abortionist and purveyor of obscene literature shows a depth of degradation meriting the punishment instead

of the support of the government by extending to the scoundrels the help of the mail department. The meanness of the debauchers is also shown in the fact that these periodicals are furnished at prices far below the cost of printing, the pay, and the profit coming from the filthy advertisements. Let us take one published at 25 cents a year. It has "Household Departments," "For Girls and Boys," "The Family Physician," "For Nurses," etc. In the interlarded advertisement columns are found the following disgusting headings:

"For ladies only. Private tips. Should the number of babies be limited? This book will bring you relief."

"A sure rheumatism-cure."

"Why suffer with kidney and bladder disease?"

"Ladies' never-failing monthly remedy."

"The folly of being good; 4 full-length pictures."

"How to be happy in love."

"An easy road to marriage life."

"A young girl's book of experience."

"Only a boy; for sports only; exposes the wiles of the libertine."

"Free clairvoyance."

"Ladies! Harmless; relief sure and certain."

"Ladies! Our regulators."

"Ladies! If you are afflicted."

"All troubled and despondent women."

"Your fortune free."

"Ladies! I have studied your menstrual periods."

"Gold and California oil stocks."

"Ladies! Our never-failing monthly remedy."

"Ladies! Our monthly-regulating tablets."

"The magic dice."

"Eyebright!"

"A test-medium."

"Catarrh cured!"

"Self-hypnotic healing."

"Ladies, when in need!"

"Stops earache."

"The social hell."

"Lost vitality."

"Weak men cured free."

"To mothers or daughters with female troubles."

"The Philomathean" describes itself as the official organ of the Society of Oriental Mysticism, and devoted to magic, mysticism, astrology, palmistry, hypnotism, spiritualism, occult science, and kindred subjects. It is a monthly, published at Union City, Michigan, at \$1.00 a year, although the editor begs earnestly for subscribers, without money, and says if they can't pay, he will never dun them. It is against the "so-called christian churches," "which have become as whitened sepulchres." There are about 22 pages in this issue of October-November, so we suppose a single issue would be perhaps 11 or 12 pages. There are 9 or 10 pages of advertisements, nearly all of which are "medical." The following are the principal: Olivene, the great female specific, positively cures, etc.; Dr. M. Rogers, the vitapathic healer, positively cures the worst cases of cancer, dropsy, Bright's disease, etc.; The great heart and nerve food cures all affections of the nerves, etc.; The little vitalizers; Dr. Rogers' rheumatic specific; How to live to ripe old age without doctor or medicine; Self-hypnotic healing; Medicine taught by mail; The science of psychraticism; Epilepsy positively cured by Dr. M. Rogers; The living fire, or healing by the power of the spirit; Water of life, a safe pleasant remedy, cures consumption, disease of the sexual organs,

etc.; Elixir of youth, for the cure of nervous debility, lost manhood, and the rest; Consumption positively cured; The magic belt of India gives health and 100 years of life; White magic; A new work on sexual debility. The larger part of the advertisements are by the New Union Publishing Company, which is the publisher of *The Philomathean*, or by the editors of that journal. The editorial page says this periodical is entered as second-class matter.

**Ruined Eyes from a Professional Error.**—In the private office of capable oculists there frequently appear patients, one of whose eyes has been ruined by a widespread error. The large hospital clinics get many more such cases, and altogether there are certainly thousands of such blunders every year. A child has strabismus or a high degree of heterophoria so that during several years one eye at least has been out of function. The mother reports the matter thus: "My doctor told me to let it go until the child is seven years old, and the eyes would then come straight, or they could be operated on then." There is a growing suspicion among patients that this advice is not all due to professional blundering, but is sometimes in the interests of the consultant operator, to whom the parents are urged to go. Three things at least are beyond question: 1. With every month of delay the disused eye is losing its power of vision, and at the age of seven it is often too late to save the vision. 2. The cure is not effected either spontaneously or by operation. 3. The prevention of the condition can be brought about without operation. The advice to postpone is inexcusable.

**Yellow Journal Lies.**—Is there not some way of stopping the lies of the newspaper dispatches as regards medical matters? Can not the readers of the papers do something to make the editors punish the egregious reporters and authors of their press-dispatches? For years there has been a constantly recurring outbreak (every summer especially, when news is scarce) of stories of triplets, quadruplets and even quintuplets born in some family in some far-away part of the country. There is always an exact giving of name, place and date. We have repeatedly investigated these reports and have never found even a rag of truth in them. Recently there has been republished all over the country such a circumstantial press-report of the adoption by Mr. and Mrs. John Shandrow, of South Haven, Mich., of twenty-two orphan children. There was no truth whatever in the report. Why does the ordinary yellow newspaper prefer lies to truth? To one of our hospitals there recently came, as a patient, a man who had made a fine income for years inventing such stories. He had an especial art in concocting medical and scientific nonsense and falsehoods with an air of truth about them intended to deceive the ignorant. His work was "syndicated" and illustrated. When taken sick he was writing an account of a new species of eels he had discovered that walked on their tails, he said, and he had told many absurd yarns about hospitals, medical men, etc., whose gratuitous aid he now sought. He said the newspapers that paid him for his stuff knew perfectly well what they were buying.

## AMERICAN NEWS AND NOTES.

## GENERAL.

**Pulmonary Tuberculosis in Hawaii.**—The mortality report of the Board of Health for the last month shows an unusual percentage of deaths from pulmonary tuberculosis. Almost 20% of the deaths were due to that disease.

**To Navigate the Air.**—M. Santos-Dumont is trying a 60-horse power motor airship, "No. 7," intended for the St. Louis exposition. He expects to make his first ascension in a fortnight, and says he will go to St. Louis unless the prize of \$100,000 is reduced, in which case he will not attend because of the heavy expense. He expects "No. 7" to be capable of making fifty miles and hour.

**Miscellaneous.**—CHICAGO, ILL.: Dr. Wm. L. Ballenger, has been elected professor of otology, rhinology, and laryngology, at the College of Physicians and Surgeons. He will fill the vacancy made by the resignation of professor M. R. Brown. Dr. J. Elliott Colbrun, has been elected professor of ophthalmology in the Eye, Ear, Nose, and Throat College, Chicago. Dr. U. S. Christopher has resigned as Professor of Pediatrics in the College of Physicians and Surgeons, Chicago.

**Philippine Opium Bill.**—Secretary Root has decided that nothing further shall be done regarding the proposed opium act of the Philippine Commission until it has had the most careful consideration in Washington. The Commission has been so informed by cable, and the opium bill, which had passed its second reading, will remain in its present condition until the Secretary of War reaches a conclusion. Many protests have been received at the department against the proposed law, and the Secretary has been urged to take steps to prohibit its sale.

**Shall Lepers be Divorced?**—From Honolulu comes the news that as a result of the report of the United States Senate Committee that visited here last fall, and local agitation, the Board of Health is trying to arrange about 60 divorces at the leper settlement of Molokai, and the assistance of the attorney-general has been invoked. In all the cases under consideration the husband or wife is at the settlement, while the other person is away. These partitions have resulted in conditions at the settlement that the Senate Committee strongly condemned, and it is the opinion of many that the moral situation would be greatly improved if the lepers were free to intermarry at Molokai. The plan has aroused much local opposition, chiefly of a religious nature.

**Oppose Patent on Drugs.**—The National Association of Retail Druggists has begun a movement looking to the repeal of the patent laws on drugs. An official of the Association gives the following reason for the attitude of the druggists: "Few people know that at present the patent laws of our country make it possible to levy a blood tax on many articles 'made in Germany,' and used by the sick, the very persons the government would naturally be expected to shield from imposition. Our laws should be so changed that no patent shall be granted on articles used for food or for medicine. It is beyond all reason that the inventive genius of Americans and the conspicuous ability of our chemists should be kept down by these laws, especially when the greatest sufferers from the injustice are those least able to bear the burden."

**Typhoid Panic in England.**—An editorial in the *New York Times* says: "A curious panic has been started in England by the discovery that a large number of infected army blankets from South Africa—many thousands, indeed—'swarming,' we are told, with the bacilli of typhoid fever, have been returned to Great Britain by the speculators who purchased them at the sales of condemned military stores, or acquired them less honestly, and widely distributed at retail. A great many thousands of these blankets have been sold in some 150 English cities, and the discovery of the fact has furnished the London newspapers a first-class sensation. According to British army regulations every discarded blanket condemned and sold at auction must be torn in at least four pieces and invoiced as rags, useful only in the manufacture of wool shoddy. Some of the army blankets found on sale had been neatly pieced together again, and the seams were difficult to distinguish, but many had obviously never been torn at all."

## EASTERN STATES.

**Myopia and School Life.**—Examinations of over 200,000 pairs of eyes and careful tabulation of the results in the Boston public schools show that nearly all children enter the primary schools with normal eyes. In the higher grades one-fourth of the pupils are myopic, and in universities this increases until from 60% to 70% of the students are myopic. In other words, nearsightedness increases steadily from the lower to the higher grades, and in exact proportion to the length of time devoted to the eyestrain of school life.—[*Annals of Gynecology and Pediatrics*, Boston, Mass., May, 1903.]

## NEW YORK.

**Children's Hospital on Randall's Island.**—Plans have been filed with the Building Bureau by architects for the city for a new Children's Hospital to be built on Randall's Island. It is to be a two-story building of brick and marble, 112 feet front and 44 feet deep, and will cost \$30,000.

**Tuberculosis Congress for St. Louis, 1904.**—At the annual session of the American Congress on Tuberculosis held recently in New York the new council provided for the revised constitution of last year was elected and was instructed to arrange for the Congress of Tuberculosis at St. Louis in 1904. Proper officers, embracing many of the wellknown physicians of the country, were elected.

**Changes at Columbia Medical College, N. Y.**—The announcement of courses for 1903-04 at the College of Physicians and Surgeons of Columbia University, just issued, shows a radical reorganization in the curriculum and teaching staff. President Butler is planning to place the medical school on a postgraduate basis similar to that of the school of laws. No student will be permitted hereafter to take medical work who has not completed three years' course in a scientific school or college, or who has not passed the Columbia entrance examinations. The course for the last two years will lay greater stress on bedside practice. The inclusion of laboratory work in chemical pathology with that in pathologic anatomy and plain pathology is an innovation. The fourth year man will spend most of his time in hospital and dispensary work.

## PHILADELPHIA, PENNSYLVANIA, ETC.

**The new home for the nurses of Cooper Hospital** (Camden, N. J.), erected by the board of trustees from endowment funds at a cost of \$30,000, has been formally opened.

**New Insane Hospital for Pennsylvania.**—The commission elected by the Legislature of Pennsylvania for 1901 to secure the site and erect a building for the Homeopathic State Hospital for the Insane has bought a tract of land containing 200 acres near Allentown, on which the hospital will be erected.

**Bill Giving Homeopaths Charge of Certain Wards in Philadelphia Hospital Vetoed.**—Mayor Weaver has vetoed the bill which was lately passed by City Council giving control of five wards in the Philadelphia Hospital into the hands of the homeopaths. The reason given by the Mayor for his action is because the bill provided that the physicians and surgeons to be appointed to take charge of these wards should be nominated by Hahnemann College.

**Smallpox in Bordentown, N. J.**—The State Board of Health has been called upon to assist in preventing the spread of smallpox in Bordentown. There are now 12 cases and a number of suspects. An appeal was made to the Trenton Health Board for the use of the municipal hospital, but the consequences to that city were feared. The Bordentown authorities have begun the erection of a pesthouse. The epidemic has caused almost a complete suspension of business in Bordentown.

**Kerosene Debauch.**—According to the police of the city it is not an unusual thing for boys to become intoxicated by inhaling the fumes from kerosene. The vicinity where these debauches have been observed is usually in the neighborhood of the railroad yards, where the empty oil cars are stationed. The method of obtaining the fumes is for the boys to climb upon the tank car, place their noses over the manhole and thus inhale the fumes. The effects produced are similar to those produced by alcohol: First a feeling of exhilaration, then a period of stupor, and following is the period of deep sleep. It is stated that in several instances boys, drunk from these fumes, have been taken to hospitals in the vicinity. From the meager amount of observation in such cases it is believed that the effects on the system are similar to those produced by alcohol.

**Red Bank Sanitarium.**—Dr. Martin, Director of Public Health, with his able staff of advisers, has discussed with Mayor Weaver the all important subject of milk supply in the city of Philadelphia, together with the best means of alleviating the suffering of the city's poor children in the slum districts during the summer months. The proposition to establish summer tents in Fairmount Park for the care of suffering children was abandoned in favor of the plan to establish tent hospitals at Red Bank, N. J., five miles below Philadelphia. Here a number of tents will be erected and 25 nurses employed during the summer months to care for the children. In this work the health authorities are working in conjunction with the Red Bank Sanitarium Association, whose boats run hourly to and from Philadelphia, carrying the children to the ample playgrounds, shaded lawns, and bathing places at Red Bank. The Red Bank Sanitarium Association has heretofore accomplished great work in thus caring for the poor children of the city during the summer months. In some instances as many as 5,000 children have been conveyed from the city to the associator grounds at Red Bank and returned in a single day. The cooperation during the present summer with the city authorities will doubtless vastly increase the good work accomplished in this particular line.

## WESTERN STATES.

**New Hospital for Englewood.**—A hospital which will be a four-story, brick building, 147 by 147 feet in dimensions, with a capacity for 150 patients, is to be built at Englewood in the near future. The cost is estimated at \$120,000.

**Notice to Milk Shippers.**—The Bulletin of the Chicago Health Department, week ended June 6, gives the following as a notice to milk shippers, from Dr. Reynolds, Commissioner of the Health Department: "Milk-cans must be clean inside and out. No matter how clean a can looks, before using it should be washed with hot soap suds, rinsed with clean water and then scalded. Milk shipped in dirty cans is liable to confiscation."

**Cheap Pasteurized Milk for Chicago.**—Nathan Straus, of New York, has offered to equip a plant in this city for the pasteurizing of milk. The offer of Mr. Straus was made to the Children's Hospital Society and was accepted. The plant will be situated somewhere in the West Side and pasteurized milk will be sold at cost, about two cents a pint. The hospital society is without funds and an effort will be made to raise \$5,000 to buy pure milk for poor children.

**Two Sanatoriums for Colorado Springs.**—An attempt is being made to secure funds to erect two sanatoriums in Colorado Springs, one for the poor who cannot afford the expense of treatment and another for those who are able to pay for their care. It is believed by those having the matter in charge that the receipts from the institution which receives pay for the treatment of patients will pay the expenses of both. The estimated cost for each hospital is \$200,000.

## FOREIGN NEWS AND NOTES

## GENERAL.

**Ozone to Purify Water.**—The Chemical Congress at Berlin has revived interest in the feasibility of purifying water by means of ozone. Just how this may be accomplished has not been made clear, but since scientists have already demonstrated that ozone may be liberated in water by a process of electrolysis it is assumed that some such means may be instituted for ozonizing the water. Should this be found practicable it may in time work a revolution in the process of purifying water. It is said that tests were made with water artificially impregnated with the most deadly germs, including cholera and dysentery, that the water was pumped through an ozonizing tower and then carefully analyzed. All the germs were found to be killed, while the passage of water through sand filters failed to kill many of them. Another feature of less importance is that the presence of the increased amount of oxygen in the water from the process improves the potable quality. It is said that Weisbaden already has a small ozonizing plant, and so far as reports go it appears to be successful. How the plan will work on a more extensive scale yet remains to be demonstrated.

## GREAT BRITAIN.

**Insurance Against Appendicitis.**—The recent increase in the popular knowledge of appendicitis has given rise to the idea that it occurs more frequently than is really the case, and in consequence a London Assurance Company now issues special policies guaranteeing to holders all the medical, surgical, and nursing expenses, up to the amount insured, incurred in an attack of this malady.

## OBITUARIES.

**Isaac N. Love**, of New York City, June 17, aged 55. He was graduated from the St. Louis Medical College in 1872. He was the city physician of St. Louis for a time, and an instructor in the St. Louis Medical College. He devoted special attention to the diseases of infancy and childhood. In 1887 he became secretary of the Pediatric Section of the Ninth International Medical Congress at Washington and president of the Mississippi Valley Medical Association. Two years later became professor of pediatrics in the St. Louis College of Physicians and Surgeons; he was also elected president of the Section of Diseases of Children of the American Medical Association, and one of the trustees of the American Medical Association Journal; he was also chosen president of the American Editor's Association. He was one of the charter members of the Marion Sims College of Medicine in St. Louis. In 1890 he issued the first number of the *Medical Mirror*, of which he continued editor until his death. Of late years, he devoted himself especially to editorial work. He moved to New York City three years ago, and became a member of the County Medical Association, and of the New York State Medical Association.

**Albert T. Henley**, in Birmingham, Ala., June 2, aged 54. He was graduated from the New York University in 1869 and had served as medical inspector of State convicts for twelve years. He had also served as President of the Jefferson County (Ala.) Medical Association and was senior councillor of the Alabama State Medical Association.

**Robert Boal**, of Lacon, Ill., in Peoria, June 12, aged 97. He was graduated from the Medical College, of Ohio, Cincinnati, in 1828. He was a member of the American Medical Association, founder and president of the Illinois State Medical Society, and was one of the trustees of the Deaf and Dumb Asylum at Jacksonville, Ill.

**Orpheus Everts**, of Cincinnati, O., June 19, aged 76. He was graduated from the Rush Medical College, Chicago, in 1876. Since 1880 he had been superintendent of the Cincinnati Sanatorium. He has made a number of contributions to medical literature on the use of stimulants and the treatment of the insane.

**Julius A. Crane**, in Santa Ana, Cal., June 6, aged 58. He was graduated from the Cleveland Medical College in 1870, and was formerly superintendent of the Agnew's California State Hospital for the Insane.

**Charles T. Pepper**, at Grasland, Va., May 28, aged 74. He was graduated from the University of Virginia, Charlottesville, in 1855. He had served as a surgeon in the Confederate Army during the Civil war.

**J. Robert Shaw**, in Ashland, Wis., June 2. He was graduated from the College of Physicians and Surgeons, Baltimore, in 1887, and was a member of the American Medical Association.

**John Gillespie**, of Warnersburg, N. Y., died at Silver City, N. M., May 26, aged 44. He was graduated from the University of Pennsylvania, Philadelphia, in 1880.

**Charles J. Wright**, of Glenville, Ohio, died in Cleveland, Ohio June 1, aged 28. He was graduated from the Cleveland Homeopathic Medical College, in 1898.

**John W. Sykes**, of Pittsburg, Pa., died at Ocean Grove, N. J., May 29, aged 76. He was graduated from the Hahnemann Medical College, Philadelphia, in 1855.

**Alden E. Bessey**, of Waterville, Me., June 15, aged 65. He was graduated from the Maine College of Medicine, Bowdoin College, Brunswick, in 1870.

**Theophilus J. Batchelder**, of Machias, Me., May 26. He was graduated from the Eclectic Medical College of Pennsylvania, Philadelphia, in 1871.

**Richard V. Cenn**, in Tacoma, Wash., June 1, aged 79. He was graduated from the Bellevue Hospital Medical College, New York City, in 1852.

**Hiram K. Jones**, of Jacksonville, Ill., June 16, aged 82. He was graduated from the Medical Department of the Illinois College in 1846.

**Eibert S. Miller**, in Johnson City, Tenn., June 6, aged 83. He was graduated from the Transylvania University, Lexington, Ky., in 1846.

**Lucius Nutting**, at Helena, Mont., June 22, aged 81. He had studied medicine in Chicago but gave up practice half a century ago.

**Curtis E. Marriot**, in New Kingstown, Wickford, R. I., May 29, aged 62. He was graduated from the New York University, in 1866.

**Madison A. Kelly**, of Lewiston, Idaho, May 27, aged 75. He was graduated from the Jefferson Medical College, Philadelphia, in 1876.

**Edwin K. Fernsler**, in Terre Hill, Pa., May 22, aged 61. He was graduated from the Jefferson Medical College, Philadelphia, in 1867.

**David McLellan**, of West Hoboken, N. J., June 1, aged 68. He was graduated from the Hahnemann Medical College, Chicago, in 1880.

**Joseph H. Hilton**, in Maywood, Ill., May 27, aged 67. He was graduated from the Miami Medical College, Cincinnati, in 1874.

**John M. Brooke**, of Portland, Ore., May 24, aged 37. He was graduated from the University of Virginia, Charlottesville, in 1888.

**Fiske H. Day**, at Lansing, Mich., May 30, aged 77. He was graduated from the Jefferson Medical College, Philadelphia, in 1849.

**David A. Pletts**, of Brunswick, Me., died at Portland, June 7. He was graduated from the McGill University, Montreal, in 1879.

**O. L. Watson**, in Montpelier, Vt., May 25, aged 75. He was graduated from the University of Vermont, Burlington, in 1861.

**L. F. Calhoun**, of Black River, La., June 2. He was graduated from the Kentucky School of Medicine, Louisville, in 1835.

**L. S. Rice**, of Springfield, Ohio, May 25, aged 72. He was graduated from the Medical College of Ohio, Cincinnati, in 1869.

**W. S. Wolfe**, of Shoemakersville, Pa., June 17. He was graduated from the Jefferson Medical College, Philadelphia, in 1897.

**R. P. Evans**, of Franklin, O., May 31, aged 74. He was graduated from the Yale Medical School, New Haven, Conn., 1850.

**I. Van Camp**, in Omaha, Neb., June 1, aged 74. He was graduated from the Eclectic Medical Institute, Cincinnati, in 1867.

**William Y. Thompson**, in Luzerne, Pa., May 28, aged 80. He was graduated from the Castleton Medical College, in 1844.

**William L. Bradley**, of New Haven, Conn., June 13, aged 66. He was graduated from the Yale Medical School, in 1864.

**L. V. Lacount**, in Merrill, Wis., May 25, aged 60. He was graduated from the Rush Medical College, Chicago, in 1868.

**Frederick W. Ruhe**, in Louisville, Ky., June 7, aged 37. He was graduated from the University of Louisville, in 1886.

**W. C. Baleman**, in Butler, Ga., June 5, aged 32. He was graduated from the Atlanta (Ga.) Medical College in 1891.

**Chester Howard**, in Dayton, N. Y., May 27, aged 35. He was graduated from the University of Buffalo, in 1879.

**Joseph L. Carr**, of Clarksburg, W. Va., June 9, aged 85.

## SOCIETY REPORTS

## SIXTH TRIENNIAL CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

Held in Washington, May 12, 13 and 14, 1903.

## ASSOCIATION OF AMERICAN PHYSICIANS.

[Specially reported for *American Medicine*.]

THIRD SESSION (CONTINUED).

**Studies in the Action of Alcohol Upon the Circulation in Fevers.**—RICHARD C. CABOT (Boston), in his experiments, had used the Oliver and Riva-Rocci instruments. Charts were exhibited showing the blood-pressure before, during and after the administration of alcohol. In 41 cases, mostly cases of typhoid fever, 1,105 measurements had been made. The blood-pressure showed no variations that could reasonably be referred to the action of alcohol; its action upon the circulation was nil. The same was found to be true in 309 patients suffering from a variety of diseases in which 2,160 measurements had been made. The writer drew no conclusions as to whether alcohol was useful or useless in disease. As a narcotic and vasomotor dilator it might be of use.

**Discussion.**—WELCH (Baltimore) called attention to the great diversity of results in experiments upon animals, but said there was one point on which there was uniformity of opinion—that was that alcohol administered to the point of intoxication increased the susceptibility to infectious disease. He thought the selection of the colon bacillus in Hare's experiments unfortunate because of the fact that that particular organism was so readily killed by human blood. He considered that there was no relation between the susceptibility to infection and the bacteriolytic power of the blood as determined in this manner. Great caution, he thought, should be used in applying to the treatment of disease the results of these experiments. JACOB considered the results of Hare's experiments as very conclusive and thought they taught a great deal about the effects that had been-observed clinically for a long while. He had always believed and taught that alcohol should be given in large doses in a number of the infectious diseases. Large doses of alcohol undoubtedly had a most beneficial effect on these cases. ABBOTT (Philadelphia) had found in his experiments that the administration of alcohol to rabbits diminished the hemoglobin complement at first, but later it increased it. Wherever such increase was produced there was found an inflammatory action in some part of the body, which was suggestive of a compensatory action. SHATTUCK (Boston) had had a uniform experience that alcohol did good in infectious cases and thought it capable of saving many of these lives. The clinical proof was so striking, he thought, that until stronger evidence against its value might be produced it was a duty to use it in such cases. MUSSER (Philadelphia) thought its routine use in typhoid fever was not justified. In a series of 80 cases, with no death, he had not used it at all. He used it, however, in cases of septicemia and with good results always. DOCK (Ann Arbor) had not used it for a good many years, and said often the most desperate cases of sepsis would pull through without its use. CABOT (Boston) thought that if the use of alcohol on the principles referred to by Hare and Jacobi was right, then it should be used in a routine way, and not simply in selected cases. If the bacteriolytic power of the blood was increased by the administration of alcohol then large doses should be given in every case. He thought the number of those who use alcohol on the ground that it does increase the protective power of the blood was increasing.

**The Morbid Changes in Hereditary Ataxia.**—L. F. BARKER (Chicago) considered the brain and spinal cord of two brothers dead of hereditary ataxia, the morphology of the gyri and sulci being described, with a microscopic study of the cord, cerebellum, brain stem and cerebral cortex. The principal changes were extensive atrophy of the direct cerebellar tract and of Clarke's column, on both sides; an elective degeneration of the dorsal funiculi involving the fibers that correspond closely in distribution to the so-called third fetal system of Trepinski. Illustrations of the lesions were shown.

**Discussion.**—STARR (Philadelphia) said the work had thrown a good deal of light upon the physiology of the muscular centers and established the fact that there were two independent and separate systems controlling the muscular centers.

**Autolysis in Lobar Pneumonia.**—SIMON FLEXNER (Philadelphia) studied the capacity for autolysis in a number of instances of lobar pneumonia, the special purpose being to throw some light upon the unresolved pneumonias, of which several examples were found to undergo autolysis slightly or not at all. A revision of existing views upon the absorption of exudates seemed necessary.

**Discussion.**—JACOBI thought that when uncomplicated absorption in lobar pneumonia was always rapid, as it was a surface affection; when complicated with interstitial connective tissue absorption did not occur so rapidly.

[To be continued.]

## AMERICAN SURGICAL ASSOCIATION.

[Specially reported for *American Medicine*.]

THIRD SESSION.

**The Significance of Albumin and Casts in Surgical Patients.**—JOHN C. MUNRO (Boston, Mass.) stated that while he believed that there was no doubt that there was danger in operating on a patient whose kidneys are incapable of sufficient elimination and where there are secondary organic changes, because a patient exhibits a small amount of albumin, hyaline, and fine granular casts with renal cells, the conclusion should not be hastily reached that he is not a fit subject for operation; on the other hand the presence of any of these symptoms should be sufficient to cause a thorough examination. He reported a series of 500 cases showing albumin and casts in the urine, not including those, however, that showed renal degeneration, glycosuria, genitourinary diseases, burns, erysipelas or similar diseases, most of whom were subjected to ether anesthesia, and in none of them was it noticed that any renal damage was inflicted. Out of the series of 500 cases 63 died; 8 from shock; 2 after operation for general peritonitis; 5 from pneumonia; 3 from tuberculosis; 19 from sepsis or severe peritonitis; 4 from senility, and in addition there were deaths from embolism, malignant disease, cardiac disease, skull fractures, and pancreatitis where the role of the urinary organs must have been insignificant. Of the 4 cases in which death was ascribed to senility 1 with cellulitis of the arm had 0.25% of albumin and casts; 1 with intestinal cancer had profuse diarrhea; 1 had a strangulated hernia, and the fourth died one month after fracture of the femur, showing only the slightest possible trace of albumin with hyaline and granular casts.

**The Treatment of Aneurysm of the External Iliac Artery by Digital Compression, with Report of a Case.**—FRANCIS J. SHEPHERD (Montreal, Canada) referred to the great dangers of surgical interference with the tumor, making amputation of the extremity preferable in many cases to trying to remove the aneurysm. He gave a careful review of the literature on the subject. The advantages of digital compression are that no apparatus is necessary, the finger being the sole means by which the artery is controlled above the aneurysm. This, of course, requires quite a number of assistants, and does not usually require to be kept up more than 24 hours, in the case reported the pulsation ceasing at the end of 12 hours. This case occurred in a man 43 years of age who had strained himself by lifting a heavy weight, and some months afterward a swelling appeared in the left groin, which pulsed; was at first soft and painless, but gradually became harder and seemed to grow upward into the abdomen. The patient objected to operation and it was decided to put him on palliative treatment until the session opened, so that relays of students could be secured. He was put on Tuffnell's treatment and ice-bags applied over the tumor, potassium iodid being given internally and very little fluid. At the end of 12 hours pulsation had entirely ceased, the pain having been severe after the first 4 or 5 hours until the end of 12 hours, being controlled by hypodermic injections of morphin. After 12 hours the patient had no excessive pain but compression was continued in a moderate degree for 12 hours more, when the leg was wrapped in cotton wool and carefully bandaged, he being kept in bed for a couple of weeks more, and six months after the operation, although the tumor could be easily felt, there was no pulsation and it was very hard.

**Strangulated Left Duodenal Hernia, in Which the Sac Contained the Entire Small Intestine, the Cecum and a Portion of the Colon.**—LEONARD FREEMAN (Denver) referred to the fact that the abdominal viscera and peritoneum are subject to various malformations and malpositions, sometimes acquired and often congenital, and unless the surgeon be familiar with these unusual phenomena his diagnostic ability will be curtailed by confusing conditions, for which he can find no adequate explanation. The peritoneal fossas may be responsible for the most remarkable forms of hernia, and this is especially true of the duodenal fossa. He carefully reviewed the anatomic formation in this region, and reported a case of strangulated left duodenal hernia in a strong, well-developed man 39 years of age. He had always enjoyed good health, with the exception of occasional indefinite abdominal pains, and five days before the author saw him he developed a severe ileus, with the usual symptoms of acute intestinal obstruction, with a pulse of 120, temperature subnormal, and capillary circulation poor. Immediate operation was performed. On opening the abdomen the cavity was found to be occupied by an immense tympanitic tumor, resembling an ovarian cyst, which could be outlined on each side by passing the hand between it and the abdominal walls. Upon opening the membranous sac it was found to contain the entire small intestine, together with the cecum and some six or eight inches of the colon. There was considerable foul and bloody serous fluid, no traces of which existed outside the sac, showing how completely the inner cavity was separated from the outer. The cecum, which was distended with fluid feces to the size of an infant's head and largely gangrenous, lay in the left upper quadrant of the abdomen, just beneath the spleen, in the vicinity of which the swollen appendix was attached by recent inflammatory adhesions. In attempting to relieve the

condition it was necessary to resect the gangrenous cecum, together with some six inches of the large intestine and a considerable portion of the small bowel. In doing this the gut was crushed with an angiotribe, the cut ends invaginated, and the opening closed with an over-and-over suture. A side-to-side anastomosis was then made with the Murphy button between the lower end of the ileum and a loop of the colon in the right iliac fossa, but the patient's resisting powers were so poor and the operation so complicated that death resulted.

[To be continued.]

## THE AMERICAN CLIMATOLOGICAL ASSOCIATION.

Twentieth Annual Meeting, Held in Washington, D. C.,  
May 12, 13 and 14, 1903.

[Specially reported for *American Medicine*.]

**Complications of Pneumonia.**—THOMAS D. COLEMAN (Augusta, Ga.) gave increasing mortality from pneumonia as about 21%. The complications discussed were pleurisy, which was stated to be almost a part of the disease; endocarditis, myocarditis, meningitis, venous thrombosis, cerebral and pulmonary embolism and uremia. Illustrative cases were given. Regarding venous thrombosis Da Costa's investigation was referred to in which he could collect only nine cases in medical literature. Steiner, in 1902, collected 38 cases and added three. The latter occurred among the 500 cases treated at the Johns Hopkins Hospital. Dr. Coleman's case occurred in a white male, aged 17. He was admitted to the Augusta City Hospital with the diagnosis of secondary anemia; on physical examination his heart and lungs were found to be normal. Eleven days later he had a chill, the temperature rose to 105° F., and lobar pneumonia was found at the base of the right lung, and extended to the upper lobe. On the sixteenth day phlegmasia alba dolens began in the left leg, and on the twenty-eighth day the right was similarly affected. Recovery took place.

**Treatment of Lobar Pneumonia.**—GLENTWORTH R. BUTLER (Brooklyn, N. Y.) said that in considering the efficacy of any particular form of treatment we must not forget the very considerable natural variations in the duration of the disease. As it is quite impossible to foretell the probable duration of the individual case the claims of certain over-enthusiastic observers who claim to have aborted the disease are "not proved." Dr. Butler insists on abundant ventilation, light bed-clothing, plenty of water by the mouth or by normal saline rectal injection, and liquid diet, to which is added lactose. Calomel is given at the outset and seven or eight grains of quinin on the first and second day by hypodermic method. Dr. Butler uses the carbonate of creasote, believing that it has been useful in 40 cases to which he has employed it in moderating the fever, diminishing the intensity of the toxic symptoms, the delirium, tremor, and cardiac symptoms. He uses occasionally for pain a tight chest bandage and small doses of morphia or Dover's powder. He has not been favorably impressed with heroin. Unless the temperature is continuously at or over 105° F. it is probably not worth while to attempt to lower it. For this the hypodermic use of quinin is useful and the ice-bag may be applied to the head and chest. Dr. Butler does not sympathize with the therapeutic nihilism commonly observed.

**Deathrate of Acute Pneumonia.**—THOMAS J. MAYS (Philadelphia) said the disease has not been so fatal during the last five or six years as popular accounts would lead one to suppose. Compared with heart diseases as a death menace pneumonia ranks rather low, judging from statistics. Heart disease seems to be progressing at a much more rapid rate. In the composite chart, which was prepared from reports from 14 States and cities, the total increase of pneumonia deaths is not quite 10%, while those from heart diseases increased 85%. Dr. Mays showed that the natural average decrease in the deathrate of tuberculosis is between 2% and 3% a year. It was shown that the deaths from pneumonia are decreasing; that deaths from disease of the heart are increasing, and that deaths from tuberculosis decreased until five years ago, but have markedly increased since that time. Elaborate charts were exhibited, showing the course of these affections during the last 20 or 30 years in various communities in the United States.

**Bronchiectasis in the Tuberculous.**—S. E. SOLLY (Colorado Springs) states that the presence of marked bronchiectasis in a case of pulmonary tuberculosis indicated an old chronic case of fibroid phthisis, in which the fibrosis is so extensive as to cause dyspnea upon even moderate exertion. The case reported was that of a woman of 48 years, who had a tendency to catch cold in the spring. Dr. Solly saw her in July, 1902. She had lost about ten pounds in weight, and was anemic and had a moderate leukocytosis. She had afternoon fever, and about a month later tubercle bacilli were found in the sputum. A month after this she had a violent eruption of fetid purulent sputum, scarcely ceasing coughing for several hours. The temperature then dropped from 104° F. to 99° F. These eruptions of pus were repeated and varied in quantity from 16 to 5 ounces in 24 hours. After the eruption there was a partial clearing of the consolidation of the middle lobe. There was no evidence of a cavity, but a dilated bronchus was recognized by

the fluoroscope on the right side. This probably began during the recurrent attacks of bronchitis, or it may have ensued in consequence of the pressure of bronchial glands.

**The Cyrtoneter; a Neglected Instrument of Pulmonary Diagnosis and Prognosis.**—CHARLES L. MINOR (Asheville) strongly advocated the cyrtoneter and a demonstration of its application was made. Minor used a tape of sheet lead 2 feet long  $\frac{1}{8}$  of an inch thick and  $\frac{1}{8}$  of an inch wide. It was covered with calfskin and applied to the chest just below the scapulas with the aid of anterior and posterior points fixed by the callipers. Charts were shown which added value to the clinical record of cases observed during the past five years.

The following officers were elected: President, James C. Wilson, M.D., 1509 Walnut street, Philadelphia; vice-presidents, Thomas Darlington, Jr., M.D., King's Bridge, New York City, Thomas D. Coleman, M.D., Augusta, Ga.; secretary, Guy Hinsdale, M.D., 3943 Chestnut street, Philadelphia.

## AMERICAN MEDICAL ASSOCIATION.

Fifty-fourth Annual Meeting, Held at New Orleans, La.,  
May 5 to 8, 1903.

[Specially reported for *American Medicine*.]

### Section on Surgery and Anatomy.

#### SIXTH SESSION.

**The Use of Plaster-of-paris in the Treatment of Fracture of the Femur.**—SEXTON (New Orleans) strongly advocated the use of plaster-of-paris in the treatment of fracture of the femur, and reported a case in a child in which he had used this method with great success. An adult patient was presented before the meeting in whose case a very good result was obtained by treatment in this way. The femur had been broken about the middle of the shaft by jumping from the cab of a moving locomotive.

**Discussion.**—LORD (Omaha) was not prepared to advocate this method of treatment for all fractures of the femur. He believes that we cannot depend upon plaster-of-paris alone in the treatment of fractures in muscular men. On the other hand, the treatment by extension has proved successful nearly everywhere. Fractures of the femur in children are simpler and much more readily treated than in adults. GRANT (Denver) referred to Arbuthnot Lane's treatment by operation and wiring the bones, and believes this to be the method of choice in some bad cases. The old method of treatment by Buck's extension has not yet been improved upon for the treatment of the average cases, however. Grant considers potassium silicate preferable to plaster, as the weight of the dressings is very much less. MAURY (New York) referred to Sayre's chair method of treating fractures of the femur, which has the advantage of permitting the patient to be up if very old. He mentioned dextrin, 10% solution by weight, as a substitute for plaster. If a single layer of dextrin bandage be put on over plaster it makes the cast as hard and firm as steel. It is so much stronger that fenestra can be readily cut in it if it seems desirable in any case.

**The Closure of Wounds.**—MILES F. PORTER (Fort Wayne, Ind.) Priority or originality was not claimed. Porter finds adhesive strips superior to stitches in the closure of skin incisions, though through-and-through sutures should be used in cases where either tension or sepsis coexist. The advantages of adhesive plaster as compared with stitches are that it can be so much more rapidly used, no stitch holes are left, the approximation is better, there is no danger of carrying infection from the surface to deeper parts of the wound. The plaster is easily rendered sterile by formalin. The especial desirability of avoiding scars about the face, as in harelip operations, was mentioned. The usual methods of using nonabsorbable sutures are not always the best. Porter advises inserting the sutures in such a way that the ends of deep subcutaneous sutures are left out, and they can be withdrawn after healing has taken place. Permanent nonabsorbable sutures he does not find necessary, save in intestinal work. There is especial necessity for avoiding sutures if possible in presence of infection. Other substitutes for stitches are inferior to adhesive plaster.

**Discussion.**—SUMMERS (Omaha) considers Porter's method ideal for the treatment of skin wounds but in deeper wounds he thinks that stitches are desirable. He would hesitate to depend upon plaster alone in closing the abdomen. PEARCE (Kansas City) called attention to those cases in which the skin of an abdominal incision holds perfectly while the deeper part of a wound may be widely separated. These form a large proportion of the cases in which ventral hernia occurs and through-and-through sutures is necessary to avoid this. MORTON (San Francisco) believes that while the adhesive plaster approximates the skin and possibly the muscles, the fascia, which gives the main strength in healing of wounds, retracts and the edges are widely separated. Sutures through the fascia are necessary to prevent such retraction and give strength to the wound. The danger of inserting sutures under tension causing resulting necrosis was emphasized. PERKINS (New Orleans) called attention to the difficulty of checking hemor-

rhage in such cases as scalp wounds by use of adhesive plaster and the maceration of the skin which would surely follow if plaster was used in hot climates as disadvantages of Porter's method. PORTER, in conclusion, stated that he had no intention of advocating closure of wounds by plaster alone, but only as a means of approximating the skin readily without resulting scar.

[To be continued.]

### Section on Obstetrics and Diseases of Women.

#### THIRD SESSION (CONTINUED).

*Discussion.*—MASSEY (Philadelphia) expressed belief in the necessity of getting rid of infection previous to operation, and of toning up all the parts by electrical treatment. In retroversion he has never failed to get results. He has usually relieved the symptoms of retroflexion. LEWIS (New Orleans) remarked that before displacement is relieved it is necessary to remove other pathologic conditions. Postural treatment and artificial support often relieve inflammation. As to operative measures he prefers ventrosuspension. DORSETT (St. Louis) said that he had never abandoned the pessary and never expected to do so. It is applicable in retrodisplacement without adhesions. In doing ventrosuspension he opposes attachment of the posterior wall of the uterus to the peritoneum. He has seen no harm by attachment of the anterior wall between the round ligaments. MILLIKIN (Dallas, Tex.) believes that all use the pessary, its use being dependent upon the ability to replace the uterus. THEINHAUS (Milwaukee) insisted that the uterus is a pelvic organ, and that ventrosuspension is not in accordance with physiologic principles. He practises vaginal suspension and usually succeeds in substituting it for a pessary. CARSTENS (Detroit) has used Dührssen's method, but if the organs are once dragged down, vaginal operation does not relieve. He emphasized the necessity of applying the operation to the condition. All operations are sometimes good, sometimes bad. MARCY (Boston) believes that opening the abdomen is usually the best procedure. Then only can the pathologic factors be determined. Shortening of the round ligaments and suspension are both believed to accord with physiologic principles. RICKETTS (Cincinnati) favors opening the abdomen for the treatment of this condition. Suspension he regards as a serious procedure. The dangers of pregnancy should be explained to the patient. As to the use of the pessary, it is often impossible to diagnose diseased ovaries except by sight. LAWRENCE (Columbus, Ohio) believes that unless an operation is based upon philosophic principles it is not successful. One factor of success is the restoration of the tension of the broad ligaments and of the support from below. Pelvic massage has its place. HALL (Kansas City) referred to the fact that nothing had been said of nature's way of correcting these cases. He treats them in the puerperal period by postural method. First in the prone position, later by the knee-chest posture, several times daily. The patient is kept in bed for weeks. He has thus cured, by nature's way, many cases. DUDLEY (New York) quoted from his paper. He has had case after case of pregnancy go to term following ventrosuspension. In doing suspension, the central point between the entrance of tubes is attached loosely to the peritoneum; thus a small ligament is formed. Ventrofixation is considered pernicious. DUNNING wished to consider treatment in all its bearings. He would not trust a member of his family in the hands of a man with nothing but operation in his head. He knows of no accident in labor resulting from ventrosuspension. He has had 10 or 12 cases confined, and has repeatedly examined such cases. BOVÉE opposed the putting of sutures through the skin. He pointed out the special uterine support of the uterosacral ligaments and of the uterovesical attachment, and emphasized the necessity of maintaining this diaphragm. He uses postural treatment, but would hesitate to employ the knee-chest posture soon after labor. The methods he suggests are along the line of physiologic repair.

#### FOURTH SESSION.

**Sarcomatous Degeneration of Myomas.**—T. S. CULLEN (Baltimore) says that clinically these cases are not easily recognized. If myomas grow rapidly, have a suspicion of sarcomatous degeneration. The disease is more frequent than heretofore suspected. The sarcoma usually develops in one of several myomas, and may be in the subperitoneal, interstitial or submucous nodule. Formerly supposed chiefly in submucous myomas. Gross changes are characteristic, the firm cross-grained myomatous tissue being replaced by a homogeneous yellowish-white growth, devoid of fibrous arrangement, closely resembling raw pork. Frequent degenerations. Histologically, these develop from: 1. Connective tissue. 2. Myomatous muscle. Those of connective tissue origin may consist of: (a) Spindle-shaped cells. (b) Round cells. In those derived from muscle a direct transition from muscle into sarcomatous fibers can be followed. Clinical history is significant: Myomatous uterus dormant for years, then history of rapid enlargement. If the myoma has been submucous, portions have been expelled, and there is a free offensive discharge. Patient becomes cachectic. Operative significance of laboratory investigations: 1. Whenever sarcoma or carcinoma may coexist with myoma, panhysterectomy is imperative—not amputation

through cervix. 2. Bisection of uterus is contraindicated if malignant growth possible. 3. In every hysteromyomectomy, have assistant open uterus immediately. If carcinoma or sarcoma exist, cervix can be removed without delay, and should be done.

[To be continued.]

### Section on Sanitary Science and Hygiene.

#### THIRD SESSION (CONTINUED).

F. J. MOYER (Lafayette, La.) concluded with a paper on the necessity of establishing a national institute of hygiene on the Chautauquan plan of correspondence, lectures, and summer institutes, as contemplated by House bill No. 63, of 1900, and House bill No. 73, of 1902. This institute would cooperate with those States which would provide for such institutes. He offered the following resolution, which was subsequently unanimously passed by the section:

*Resolved,* That the Section on Hygiene of the American Medical Association recommends the passage of a resolution by the House of Delegates, endorsing the principle of public education in the fundamental principles of hygiene and the true nature, cause and prevention of contagious and infectious diseases, and the establishment of a national institute of hygiene which would cooperate with the States in popularizing such instruction, and that a special committee of five be appointed to carry out the intent of the resolution, to promulgate a plan toward this end, and to report at the next annual convention of the American Medical Association.

**Leprosy from a Sanitary Standpoint.**—ISADORE DYER (New Orleans), after giving a general review of the disposition of the leper from the ancient times down to the present, spoke of the methods in vogue at the time of the Berlin Conference in 1897, and showed what the world is doing today with especial reference to particular colonies. Leprosy is undoubtedly communicable, but apparently much more so in some sections than in others. Most countries at the present time are taking measures to prevent the spread of the disease. The bacillus is found in the nasal and buccal cavities, in the ground where lepers have been buried, and it invariably spreads through the community if once admitted. There is no doubt of its being communicable and the most common sources of infection are the nasal and buccal secretions and the genitals. The bacillus is not always found, but the disease exists in spite of the failure to find the bacillus, and these patients, if left to themselves invariably develop the characteristic tubercle. In the past 10 years he has noticed cases where the disease has been communicated to the child from the father. There are various opinions as to the measures to be employed in preventing the communication of the disease. The victim of the disease should either be segregated, or if he lives at home he should have his own room, should wash his own dishes, and should live entirely alone. There is no reason why a new infection could not be grafted on the nervous type of leprosy. The victims should bathe frequently and the public should be educated so that the disease can be recognized and the importance of segregation should be insisted upon.

*Discussion.*—SWARTS (Providence, R. I.) said that leprosy is seldom brought to the attention of the health officer in the East, but occasionally it does appear. An inhabitant of Providence for five years developed leprosy in the city, and the health officer was at a loss to know what to do with him. Dr. Dyer's paper clearly demonstrates what should be done. BRACKEN (Minneapolis, Minn.) stated that the lepers of Minnesota are almost all Scandinavians, and they came to this country with the disease. There was no case of American born leprosy until two years ago, and since then there are many cases. The disease is without doubt communicable. In Minnesota they are not segregated. There are 14 cases in Minnesota, 2 or 3 in Wisconsin, and 2 or 3 in Iowa. T. G. FRENCH (Hawaii) said that in Hawaii leprosy is epidemic rather than endemic. It was not known 50 years ago, and is supposed to have been introduced into the islands by the introduction of Chinese laborers 50 years ago. The native name for the disease is "mai pake," which translated means "Chinese sickness." Twenty years after the introduction of the disease, one native out of every 30 had the disease. Thirty-five years ago all the lepers were isolated upon one island, Molo Kai, and the disease continued to spread for five years until 30 years ago, when it reached the maximum. Since then the number of lepers in Hawaii has remained about the same. There are 12,000 lepers in Molo Kai. The reason why the disease has not subsided, but has remained stationary, is that suspects are allowed to live in their neighborhood, but must present themselves before the judge of that district once a month for inspection, and he is not segregated until the disease is well defined. There is a hospital in Hawaii for girls of leperous parents, and the development of the disease in these inmates is rare. DYER closed the discussion by saying that a case came under his notice which proved beyond doubt the communicability of the disease: A young woman consulted him for a trophic ulcer of the ball of the great toe, but with no other evidence of the disease. His predecessor, the late Dr. Blanc, had recorded the case seven years previously as one of leprosy. Eight years later the father contracted typical tuberculous leprosy. The nerve type can be communicated as well as the tuberculous type.

ORIGINAL ARTICLES

THE RELATION OF NEURALGIC HEADACHES TO STORMS.<sup>1</sup>

BY

S. WEIR MITCHELL, M.D.,  
of Philadelphia.

It is interesting to call attention to the fact that the only scientific studies of the relation of disease and pain to the weather have been made by Fellows of this college. Among these are my own essays on traumatic neuralgia, aided by Captain Catlin; Morris Lewis' and my own examination of choreas as related to storms; Wharton Sinkler's paper on "The Causal Relation of High Temperatures to Infantile Palsy;" Morris Lewis on "Acute Rheumatism and Storms"—a model paper. I should add Mills on "Choreas," and many minor studies of my own, where efforts were made to determine how far the pain of posterior sclerosis is due to weather.

I desire at present to call attention to the connection between neuralgic headaches and storms. I have many times tried to induce patients to accumulate material for such a study, but so far I have failed.

It is indeed rare to find a sufferer as able and as willing to deal scientifically with his case as was Captain Catlin. His charts now lie on the table to remind you of a study unique in medical research.

The originating causes of hemicrania are as yet unknown. The determining causes of the separate attacks have never yet been made clear enough to enable the victims to avoid them by precautionary measures.

I asserted long ago that eyestrains are rarely the primary trouble, but may add to the number and exaggerate the force of attacks. I have seen no reason to change my belief. Freedom from fatigue, or, rather, from exhaustion of mind and body, is most apt to lessen the number of headaches; hence changes of place and consequent idleness are likely to relieve for a time, and so also is whatever permanently lifts the level of general health. We see this very often when, after a successful rest treatment, the customary headaches vanish or become rare.

Among the influences which produce this form of pain it is very probable that atmospheric conditions have a potent share.

As in traumatic neuralgia, so in headaches, it is only required to come within the outer limits of storm conditions. The sky may be cloudless and the rain or cloud areas two or three hundred miles away, and yet the sufferer be within the area of barometric depression.

I have at different times been able to convince myself that certain migraines were due to storms, but not, as a rule, to the summer electric storms, which, however, in some hysterical women are sure to occasion a general headache, distinct in character from hemicranial attacks.

I shall not trouble you with details of cases, nor do more than observe that in two of them the subjects, who were physicians, became well assured that the months of storm frequency were those in which they suffered most often and most severely.

Mr. H., of Maine, aged 39, manufacturer, when 23 years of age began to have hemicranial pain at intervals, which, at first long, became more and more brief. The pain was preceded by the sense of being unusually well. Commonly for three mornings he awakened with slight transient pain, resulting, at last, in a violent left-side migraine, with vomiting. There were no eye troubles, paresis, or aphasia. The headache was followed by the usual free flow of pale urine; in other words, it was a

typical case of hemicranial neuralgic headache without notable flushes or pallor. It had one rare, but not exceptional, symptom—an ache in the left crural region, with sensations of numbness. There was no ill health; all the organs were sound; all secretions normal.

For seven years this gentleman kept a record of his attacks and of the means used to aid him. As usual, I asked, "What will cause an attack? What will make attacks severe?" To this he answered, "Overwork, fatigue, much worry or anxiety, severe storms, but not electric storms."

The conditions favoring freedom from pain were absence from home and relief from work.

Dr. Alfred R. Allen has been so kind as to make a curve representing the relation of this man's headaches to the time of year.

As the storm curves of the eastern coast vary little from New England to the Chesapeake, I have set below the pain curves the storm curves of our own locality for three years.

As Mr. H. was at times away from home during a month, the pain curves may be thus modified; nor is it possible to be secure of our conclusions until a number of persons shall have kept note of their headaches for two or more years. Nevertheless even the small knowledge we here gain is valuable.

You will see how far the pain curves follow the storm curves; also, how close they are to the chorea curve, which is so clearly related to the storm curve.

March and April are the worst months and October

Jan. Feb. Mar. Apr. May June July Aug. Sept. Oct. Nov. Dec.

Monthly average of headaches for seven years (1893-1899). The upper curve is the headache curve.

and February the best. If we could add a curve of business worry and of other causes of anxiety, it would further assist us.

The books have many statements concerning the relation of weather to headaches. It is needless to state them in detail, since, for the scientific study of this matter, the term "headache" is used too vaguely. There is, however, among the later writers a quite general belief that the storm winds favor the production of headaches.

Since, in the books, much is said of barometric pressure as determining headaches, it may be well to state that in Catlin's case low barometer alone had no tendency to bring on his form of neuralgia, and I incline to the belief that the grouped atmospheric conditions which constitute a storm will be found to be in hemicrania, as in traumatic neuralgia, essential to the causation of migraine. It is a question of practical moment and should be readily settled.

Our problem is this: Given a human instrument capable of evolving a group of symptoms, of which pain is the most surely present, what are the agencies which evolve attacks? How far are climatic conditions responsible?

<sup>1</sup> Read May 2, 1903, before the College of Physicians of Philadelphia.

Many of the Fellows must see cases of habitual migraine. If some of their patients could be induced to note on a calendar the dates of headaches during two years, the question of connection between storms and this kind of pain could be surely ascertained. For obvious reasons men should be chosen rather than women.

## A CASE OF ENDOTHELIOMA OF THE MAMMARY GLAND.<sup>1</sup>

BY

J. CHALMERS DACOSTA, M.D.,  
of Philadelphia.

The patient, M. L., was admitted to the Jefferson Hospital, February 2, 1903. She is 31 years of age, resides in Philadelphia, and was sent to me by her family physician, Dr. Kevin. The patient is white, married, a native of this city, and a housewife by occupation. She has had one child, which was born 10 years ago, and there was no trouble whatever with either of her breasts during the period of pregnancy or of lactation.

Both of her parents are dead. The father died of an injury and the mother of pneumonia. Two brothers and two sisters are living and well. There is no family history of tuberculosis or of malignant disease.

Mrs. L. states that she had always been in good health until after the birth of her child. Since that time she has suffered more or less with indigestion. Her menstrual periods are regular, but painful.

Three months ago she detected a nodule the size of a pea in the upper and inner quadrant of the left breast; and this nodule has been progressively enlarging. At first there was no pain connected with it, but during the last month there has been a dull, aching pain in the tumor itself. There has never been a discharge from the nipple. She thinks that she has lost some weight during the past year, but she is not certain.

Examination at the present time discloses a nodular tumor the size of an English walnut, which feels as if it were just beneath the skin. It involves the inner quadrant of the left breast and passes almost under the nipple. The tumor is somewhat irregular in outline, and the center of the mass is distinctly harder than is the periphery; but it is only the central hard mass that attains the degree of density usually encountered in a carcinoma of the breast. The skin is healthy in appearance and freely movable over the growth. There is no dimpling and no pigskin appearance, such as we should expect in a carcinoma of this size so near to the skin. There is an appearance of very slight retraction of the nipple; although it is probable that this is more apparent than real, the growth having raised up about the nipple, rather than the nipple having been pulled in by the fibrous tissue of a growth. No enlarged glands can be palpated in the axilla or about the clavicle. The heart and lungs are normal, and the urine report is negative.

To sum up: A woman of 31, with no record of injury to the breast, or of abscess or inflammation, develops a tumor that in three months has grown to a considerable size; is accompanied with a dull, aching pain; is somewhat irregular in outline, being indistinct at the margins, but having one part at the center that is hard and nodular; the tumor seems to lie directly beneath the skin and the areola.

The form of tumor we are dealing with is a matter of some uncertainty. If there were a history of discharge from the nipple, if the center of the growth fluctuated, or if it were softer than the margins, I should think it probable that we were dealing with a cyst rapidly filling up; but I do not think that this is a cyst. It is not an area of mastitis; the pain is not of the character encountered in that disease, and the tumor lacks the irregularly knobby condition met with in mastitis. It has grown too fast for an innocent tumor. To my mind, it is evidently a malignant growth, but of what character I am uncertain. Thirty-one is an early age for cancer, although it may occur at that age; in fact, I have operated upon one case in a woman of 26. The growth is very rapid for a scirrhus carcinoma, and a carcinoma of this size so near the surface should be adherent to the skin. There should be the evidences of dimpling of the skin or a pigskin appearance, and with a growth right below the nipple it is almost certain that the nipple would be distinctly retracted. The

inability to palpate enlarged glands counts for nothing; they might readily be there, even though we could not palpate them. The rapidity of this growth suggests sarcoma, although in the sarcomas of the breast that I have seen there has been no pain. The immobility of this tumor in the breast tissue and its free mobility under the skin suggest a case of sarcoma.

In view of the uncertainty of the diagnosis before proceeding to operate I make an exploratory incision into the growth. The incision is accompanied by an extraordinary amount of hemorrhage and the growth seems of a sarcomatous nature. I close up with sutures the wound made for exploration, wash the part and my hands, and take a fresh knife for the radical operation, because I am afraid I might transfer embryonal cells into the wound that I intend to make and thus disseminate the disease.

The radical operation of Halsted was performed. The specimen was sent to the laboratory. The report shows that I was not dealing with either a sarcoma or a cancer, but with an endothelioma of the breast of the type known as hemangioendothelioma. The following is the report of Dr. L. H. McKinnie, verified by Professor Coplin:

The specimen consists of a human breast with the adjacent tissues. One surface is covered with apparently normal skin. The nipple is very slightly retracted. The mass is soft, with the exception of a small area near the nipple, where there is a hard nodule 5 cm. in diameter. The specimen cuts with ease, except through the previously mentioned hard nodule. The cut surface of the nodule is greenish-yellow in color, firm in consistency, and markedly granular in appearance. The sections made of this specimen are found to be composed of fibrous tissue cells of various kinds and of muscle. Along one edge of some of the sections are many layers of squamous epithelial cells, the outer ones being stratified and keratinized. The deeper ones are polyhedral, with small nuclei and granular cytoplasm. Beneath this margin is a stratum of connective and elastic tissues, within which are found a few hair follicles and distorted sweat-glands. This edge is practically unaltered skin. The greater portion of the section is composed of a curiously fibrillated connective tissue stroma and nests of endothelial cells. The cells are of various shapes and sizes, but most of them are round or oblong, with smaller deeply staining basophilic nuclei and granular cytoplasm. Within these nests of cells are many sinuses having no distinct walls, but marked by closely packed cells of the type already described. Many of the spaces are empty; some contain blood. Near the center of many of the larger cell collections is found a detritus composed of red blood-corpuscles and fragmented endothelial cells. Within the stroma are quantities of bloodvessels filled with unaltered blood as well as many collections of free blood. The tumor is not encapsuled. The muscle in the sections is of the normal striped variety.

As to whether or not it would have been possible to make a diagnosis of this growth I am not sure. It was reasonably certain that we were not dealing with cancer, and possibly the free hemorrhage on incision, the absence of any history of injury, the presence of pain, and the undefined margin with the hard center should have separated this growth from the distinctly outlined breast sarcoma, which—in its earliest stages at least—is more or less encapsuled.

## ERYTHROPLÆUM: A CLINICAL STUDY.<sup>1</sup>

BY

REYNOLD WEBB WILCOX, M.D., LL.D.,  
of New York.

Professor of Medicine and Therapeutics at the New York Postgraduate Medical School and Hospital; Physician to St. Mark's Hospital.

In 1876 there was brought to France from Africa the bark of a tree which was later recognized as the *Erythroplœum guineense*, one of the *Leguminosæ*. From the red color of the solutions made from the bark the name is seen to be appropriate. This is also known as the gidu, mancona, doom, ordeal, casca, saucy, and sassy bark. It occurs in flat or curved pieces of irregular size, about 6 mm. thick, covered externally with an uneven, warty and fissured corky layer, or deprived of the same, of a

<sup>1</sup> Read before the Medical Society of the State of New York at its ninety-seventh annual meeting, at Albany, 1903.

dull brown color. It is hard, brittle, of a fibrous texture internally, with pale, yellowish spots, inodorous, of an astringent, somewhat bitter, acrid taste, and when powdered excites sneezing. Its active principle is a colorless alkaloid, erythroplein, which is soluble in water and alcohol. The only preparation of the bark is

condition persists until the heart becomes irregular, when it falls. The respiratory movements are at first slower and fuller, but when the heart becomes feeble they are accelerated, and during the period of irregular and feeble heart action they produce the so-called respiratory oscillations and increased blood-pressure. Large doses produce vomiting and increased peristalsis. Moderate amounts increase diuresis; poisonous doses induce convulsions and later marked weakness of all muscles, and finally death.

The mode of action may be summed up as that of a muscle-poison acting upon the heart earlier because it receives a larger quantity of poisoned blood. Upon the vagus its action resembles digitalis. It is a vasoconstrictor by acting on the vessels themselves, the vasomotor nerves or on some vasomotor center not contained in the medulla but probably in or around the vessels themselves. The respiration is influenced through the

the 10% tincture adopted by the British Pharmaceutical Conference, of which the dose is 5 to 10 minims.

During the five years after its introduction the chemistry and physiologic action of the drug were investigated in England by Brunton and Pye, and in France by Gallois and Hardy, and by Sée and Bochefontaine. With considerable uniformity in various reports its physiologic action may be stated to be as follows: The heart is slowed at first, later it becomes rapid. The ventricles contract regularly, but after large doses irregularly and stop in systole, while the auricles may continue to beat. This slowing is remarkable (1) from the regularity and energy of the systoles, and (2) from the fact that during this slowing the uniform blood-pressure is not altered by respiratory movements. The blood-pressure rises because (1) of the increased energy of the heart, and (2) of the contraction of the bloodvessels; this

pulmonary branches of the vagus. It is sternutatory, because the powdered bark is an irritant to the nasal mucous membrane, causes vomiting by reason of its solutions possessing the same property, and is diuretic for the same reason and under the same conditions as is digitalis.

The alkaloid has been investigated by Lewin, Égasse, Liebreich, Theobald, Onodi, Alt, and others. In 1 to 2 per mille solution it is locally anesthetic. This anesthetic condition may last several hours, but practically it is inferior to cocaine. It produces myosis, dims the cornea, causes headache, giddiness and even syncope. Its employment for this purpose has been abandoned.

The field of use for erythropleum would seem to be limited to the heart and bloodvessels when cardiac disease is or is not accompanied by dropsy. Its ability to slow the heart is rather greater than that of digitalis, but it is more decidedly a gastric irritant. Its vasoconstrictor properties are practically those of digitalis and ergot combined. It is rather less cumulative than is digitalis, using this term in the same sense that it is applied to digitalis.

My laboratory work done upon this drug in Paris in 1882 left a desire to investigate it clinically, for which no opportunity has presented itself until recently. The following are the cases which illustrate its action:

**CASE I.**—Mr. B. June 6, slight arterial (interstitial) nephritis, mitral regurgitation, dilated left heart, slight anasarca. (Fig. 1.)

June 21, moderate diuresis was observed, cardiac first sound of better quality. (Fig. 2)

**CASE II.**—Mr. D. March 14, marked dilatation of left ventricle, mitral regurgitation, renal congestion, confined to bed. (Fig. 3.)

April 25, considerable improvement in heart-sounds, aortic second well defined, some diuresis. (Fig. 4.)

**CASE III.**—Mr. J. December 12, old fibromyocarditis, dilatation, mitral obstruction and regurgitation, moderate congestion of kidneys, anasarca. (Fig. 5.)

December 17, marked diuresis, murmurs distinct, anasarca lessened. (Fig. 6.)

December 25, considerable improvement; pulse slow and hard. (Fig. 7.)

**CASE IV.**—Mrs. T. June 1, aortic stenosis and mitral regurgitation, fibromyocarditis. (Fig. 8.)

July 7, but little improvement in subjective symptoms. (Fig. 9.)

July 24, feels much better, and heart-sounds distinct. (Fig. 10.)

**CASE V.**—Mrs. G. July 9, fatty heart, with some mitral regurgitation, edema of ankles, attacks of syncope. (Fig. 11.)

August 3, cardiac first sound of lower pitch, no edema, some diuresis. (Fig. 12.)

**CASE VI.**—Mr. E. December 16, aortic stenosis, mitral stenosis, considerable regurgitation and dilatation; no anasarca. (Fig. 13.)

December 26, condition somewhat improved, hands and feet warmer. (Fig. 14.)

January 16, subjective symptoms markedly improved. (Fig. 15.)

**CASE VII.**—Mrs. M. May 31, aortic stenosis and regurgitation, mitral regurgitation, with marked ventricular dilatation, syncope. (Fig. 16.)

June 16, dilatation lessened, murmurs more distinct. (Fig. 17.)

June 29, no attacks of syncope since last report, marked diuresis. (Fig. 18.)

**CASE VIII.**—Miss E. March 1, mitral regurgitation, anemia, renal and pulmonary congestion. (Fig. 19.)

March 20, cough has disappeared, cardiac first sound louder. (Fig. 20.)

April 29, much improved, marked diuresis. (Fig. 21.)

June 1, anemia better, no circulatory symptoms. (Fig. 22.)

**CASE IX.**—Mrs. X. June 5, fatty heart, mitral regurgitation, dilatation, pulmonary congestion. (Fig. 23.)

June 27, all pulmonary symptoms have disappeared. (Fig. 24.)

July 11, still improving, heart-sounds distinct and dilatation now but slight. (Fig. 25.)

The dose employed has generally been 10 drops in a wineglass of water after each meal. The dates given are those upon which the sphygmographic tracings have been made.

The indications for the use of the remedy are those which Withering laid down in the eighteenth century for digitalis, namely, a rapid, low tension pulse with venous congestion. As compared with digitalis it is decidedly more active in slowing the pulse; it also irri-

tates the stomach more, and, therefore, is more likely to cause vomiting, and possesses a more disagreeable taste. As a vasoconstrictor it has greater effect than digitalis; in fact, as great as digitalis and ergot combined. It is less cumulative than digitalis. It seems to act rather upon the inhibitory than on the muscular system. As to constancy of effect in slowing the heart, strengthening the pulse, and promoting diuresis, digitalis is rather more reliable. The use of this remedy, then, should be confined to those cases of fairly competent heart with low vascular tension, in which it will show its effects more rapidly and markedly, and to those cases in which digitalis has lost its usefulness or has utterly failed.

## CHRONIC CYANOTIC POLYCYTHEMIA, WITH NOTES UPON TWO CASES.

BY

J. N. HALL, M.D.,  
of Denver, Col.

I offer the title as a tentative designation for certain cases recently reported of chronic cyanosis with immense increase in the number of red cells, and without cardiac disease, two cases of which I have observed recently. The first case I studied in Denver, and reported at the Denver Clinical and Pathologic Society, March 13, 1903. The patient was also seen by Drs. S. D. Hopkins, H. R. McGraw, and A. Zederbaum. The second I examined with Turk in Neusser's clinic in July, 1902.

**CASE I.**—Mrs. M., a Jewess, aged 61, who was born in Germany, has lived in Denver 18 years. She is of a strong family, and has had no serious illness. She has borne six children. Menstruation ceased at 50. She has no history of alcoholism, syphilis, nor tuberculosis.

As a girl and young woman she was very strong, delighting in long walks and other vigorous exercise. Only since the menopause have the dyspnea and palpitation of which she complains manifested themselves. It is because of these symptoms that she applied for treatment. Her condition has changed gradually for the worse for eight or ten years past.

The patient stated that she slept and ate well, suffered no pain, and was always thirsty. There was no constipation. Her lips were tremulous. Her dyspnea was very marked upon the exertion of removing her clothing for examination of the chest.

The most striking feature in her appearance is a cyanosis of such intensity as to be startling, giving her lips and tongue the shade of a ripe Concord grape. It is slightly less marked upon the hands, and still less upon the trunk and lower extremities. Over the face are to be seen tortuous veins which are almost black in appearance, and 2 mm. to 4 mm. in width. Although I noticed no especial change in her color at my examinations, her daughter stated that she showed a dusky flush at certain times, especially after excitement, which was very noticeable. The fingers are not clubbed. Her height is but little over five feet; her weight, 160 pounds.

The respirations were 30 while seated, the pulse beats 84 per minute, the temperature normal. Pulse strong, regular and of increased tension as compared with the normal; arteries moderately atheromatous. The heart was, if anything, slightly larger than the average upon percussion, the sounds all sharp and clear, the aortic second sound moderately accentuated. The examination was less satisfactory than usual because of her obesity, but of the points enumerated there could be no doubt. The lungs were negative excepting for a few crackles in the bases, probably, in the light of the edema of the legs and the condition of the urine, edematous in character. There was no evidence of emphysema.

The thick abdominal walls made the examination of the spleen very difficult. Enlargement was especially sought for, but I could not find it. The organ was certainly not greatly enlarged. The abdominal examination was otherwise negative. No enlarged glands were detected. There was moderate edema of the feet and legs, and had been for years. None elsewhere except as noted in the lungs. Knee-jerks were normal.

The urine amounted to nearly 2,000 cc. in the 24 hours. Specific gravity 1,012, albumin estimated by Dr. McGraw at .5% by weight. A moderate number of epithelial casts were found in the centrifuged sediment, but curiously scarcely any hyalin or granular ones.

The right pupil was slightly dilated, but both reacted normally to light and to accommodation. Dr. Edward Jackson reported that the eyes, beyond their extremely bloodshot condition, showed little but dilation of the retinal veins.

Dr. H. R. McGraw reported upon the blood as follows:

The drop obtained by puncture was extremely dark in color

Fig. 25.

and coagulated so quickly that it could scarcely be removed from the capillary tube for the blood count. Reds, 9,949,600; normal in character. Whites, 6,500; normal in variety and proportion. The hemoglobin was estimated at 170 on the first examination, January 8 (Von Fleischl), and 200 on March 6. Dr. McGraw found it necessary to dilute the blood twice as much as usual before making the estimation.

CASE II.—The brief notes of this case I obtained from Turk. I have not found it reported since my return.

Female, aged about 40. History not obtained, but she was extremely neurotic. She presented a reddish-blue hue of the face, which somewhat resembled the cyanosis of advanced emphysema, but was less slaty in color. This cyanosis was not constant, but became deeper and redder upon eating, upon examination, and upon excitement of any kind. The color was much less noticeable elsewhere, but was fairly marked in the hands. She was well nourished and able to move about actively and without distress. The physical examination showed a greatly enlarged spleen, but no other especial features. The heart was negative.

The blood contained on June 30, 9,935,000 red cells, and on July 1, 8,400,000. On the former date the whites were 22,000, on the latter 6,500. The hemoglobin was estimated at between 160 and 170 by Von Fleischl's instrument. The blood would hardly flow because of its thick consistency. There was no especial departure from normal in the blood cells nor in the relative proportions among the white cells.

There were strikingly large and dark veins upon the face, many being 2 mm. or 3 mm. in width.

Turk stated that these large veins appeared in another patient whom he had seen, upon the chest also. He laid especial emphasis upon three features, the polycythemia, the dilated veins, and the enlarged spleen. He believed the dilation of the veins to be paralytic in nature and intimately connected with the neurotic temperament. He suggested the possibility that the enlargement of the spleen arose from venous stasis. In his experience there was great variability in the number of cells found in the blood from different parts of the body and on different days.

In the report of the autopsy of Cabot's<sup>1</sup> case, which he has kindly furnished me, no enlargement of the spleen is noted—in fact, nothing characteristic, excepting the marked passive congestion of all internal organs. No other reports are accessible to me at present, but we may note that in Turk's case only, of the three mentioned herein, was the enlargement of the spleen a prominent feature. A French author, the reference to whose report I cannot now obtain, reported finding tuberculosis of the spleen in one of these cases postmortem.

The dyspnea and palpitation seem to be more striking symptoms in my own case than in the other two quoted. I can explain them only on the ground of insufficient oxygenation in spite of the increased number of red cells, for notwithstanding this increase, the result to the tissues in this disease seems to be that same paucity of oxygen noticed in many other conditions, as in the anemias. It seems possible that the increase in the reds may be a compensatory process—an attempt to make up the deficiency in oxygen-carrying capacity in individual cells by an increase in the number of cells. I know of no explanation of this deficient capacity of the red cells. Although not especially prominent in my own case, the neurotic manifestations in Turk's and Cabot's cases should lead to careful investigation along this line.

My own case is the only one that I know of in which a well defined chronic nephritis with cardiac manifestations seem to have been present. I am not at all sure that this is anything more than an accidental complication. I associated the high pulse-tension rather with the nephritis than with the disease proper. I have no record of the condition of the urine in Turk's case. In Cabot's the trace of albumin and the few hyaline casts seem nothing more than the results of the passive congestion. I believe the quantity of albumin, the character of the sediment, and especially the increased area of the heart, the increased pulse-tension, and the aortic accentuation in my own case suffice for a diagnosis of a definite nephritis.

I make this imperfect report because all of these cases should be put upon record for collective study, and regret my inability to obtain the reports of other cases at this time for comparison.

## A FURTHER STUDY OF THE INFLUENCE OF THE CONTENTS OF THE LARGE INTESTINE UPON STRYCHNIN.

BY

WILLIAM SALANT, B.S., M.D.,

of New York.

Fellow of the Rockefeller Institute, New York.

(From the Departments of Pathology and Physiological Chemistry, Columbia University.)

In a previous communication to this journal<sup>1</sup> "On the Influence of the Contents of the Large Intestine Upon Strychnin," it was reported that small quantities of strychnin (2 mgs.) added to the contents of the cecum and colon of normal rabbits could not be detected when examined according to the method recommended by Haines.<sup>2</sup>

In a number of control experiments, however, with 1 mg. of strychnin mixed respectively with gastric contents, liver, crushed brains or urine, carried out with the same method, strychnin was easily found. The conclusion was therefore drawn that the contents of cecum and colon of normal rabbits contain something which interferes with the detection of strychnin by the methods at our disposal. Beside the method referred to, other methods, such as those of Draggendorff and Otto Stas, were employed at first, but were abandoned in favor of the Haines' method. I have recently made use also of Blyth's method,<sup>3</sup> with similar results.

A study of the physiologic effect of a mixture of strychnin and contents of cecum and colon of normal rabbits was next undertaken. A quantity containing a maximum of  $\frac{1}{20}$  mg. of strychnin nitrate and injected into a frog of about 30 gms. induced a typical tetanus shortly after. This certainly proves that strychnin is not destroyed by the contents of the large intestine of normal rabbits. The failure to detect strychnin could be due, therefore, either to its destruction by heat used in the process of separation or to loss during the numerous manipulations involved in the various methods I employed. The first suggestion was put to an experimental test. A mixture of strychnin and contents of large intestines of normal rabbits was heated on the water-bath for four to five hours at a temperature of 75° C. to 80° C., and injected into frogs. The results obtained, although not constant, have shown that this temperature does not destroy strychnin in the presence of the contents of the cecum and colon of normal rabbits. I therefore set out now to simplify the method of obtaining strychnin. This was accomplished as follows:

After adding strychnin to the contents of the cecum and colon of a normal rabbit the mixture was acidified with acetic acid. To this 95% alcohol was added and both were digested on the water-bath for several hours at 75° C. to 80° C. Strong alcohol was now added again, and the whole filtered, the residue washed with alcohol several times. A second extract was made by treating the residue with alcohol and filtering as before. The two filtrates were united and evaporated to about 2 ounces at the same temperature as before. This was now shaken up with chloroform in the separatory funnel and the chloroform drawn off. Chloroform was then added again and the solution made alkaline with KOH. After shaking vigorously the chloroform was drawn off. A second chloroform extract, to insure complete removal of the strychnin, was made, the two extracts united and evaporated. The residue was dissolved with acetic and water and filtered. The filtrate was made alkaline and shaken up with chloroform, which on evaporation gave

<sup>1</sup> Boston Medical and Surgical Journal, December 7, 1899.

a typical strychnin reaction with potassium bichromate and concentrated sulfuric acid. I found, however, that when the original mixture is digested at room temperature for 24 hours and the filtrate evaporated at 30° C. to 40° C. a much purer chloroform extract is obtained. I never failed to detect strychnin, even 2 mgs., in the contents of cecum and colon by the method as outlined when the operations were carried on at a low temperature. It is, therefore, the method that was at fault in the failure in the early experiments to detect strychnin in the contents of the cecum and colon of normal rabbits. Why should a simplified method give different results? This may be explained as follows: If a careful study be made of the various methods I have employed, such as the Otto Stas, Draggendorff, Haines, and Blyth, it may be seen that in all of them the number of manipulations is quite large. The solution is filtered many times and shaken up in the separatory funnel a number of times successively with several reagents before the alkaloid is ready for the final test. As only small quantities of strychnin were experimented with, the loss of even a small portion during any of these processes would be sufficient to prevent its detection. But the same method was successfully employed for the separation of even smaller quantities of strychnin (1 mg.) from gastric contents, liver, brain, urine, etc. This may be explained by the fact that the organic impurities are not so numerous, and filtration much better; hence fewer manipulations with less loss of substance. While the acid solution of the large intestine had to be shaken up many times with amyl alcohol, benzin, etc., one extraction with amyl alcohol was all that was necessary for the purification of gastric content, etc. As amyl alcohol takes up water, it is not at all improbable that some of the strychnin was lost in this way. This would also explain why in many cases of strychnin poisoning the alkaloid has not been found. The large number of manipulations involved in the methods generally employed probably interfered with the detection of strychnin.

## A RAPID AND EASY METHOD FOR THE STERILIZATION OF CATGUT LIGATURE AND SUTURE MATERIAL.

BY

JOHN MILTON GARRATT, M.D.,

of Buffalo, N. Y.

Since the introduction of catgut as a ligature and suture material by Lister, efforts have been directed to perfect and simplify the method for its sterilization. The delicate structure of the material will not permit of harsh treatment, therefore sterilization must be accomplished with great care, otherwise the tensile strength will be impaired. Usually the technic leading to the desired result is complicated, costly, and time consuming.

The various methods for the sterilization may be summarized under the following heads:

**Dry Heat.**—The process consists in baking the material at a temperature of about 220° F. Properly the temperature should be raised gradually and be maintained for from one to two hours, depending upon the size of the catgut. The process should be repeated twice at least, allowing an interval for germ development from spores. Even with every care weak spots are likely to develop in the catgut prepared with this method of sterilization.

**Moist Heat.**—The sterilization in the majority of methods coming under this head depends upon the high boiling points of certain liquids in which the catgut is

immersed. The liquids commonly used are mixtures of the hydrocarbons, such as cumol (cumene), B. P. 152°-153° C.; zylene (xylyl), B. P. 136°-143° C.; benzin and alcohol, B. P. 50°-60° C., and about 78° C., respectively. It may be said, however, that the boiling point of the latter two is far from being high enough to kill even the less resisting spores. All of these liquids are inflammable and require, as a rule, complicated and expensive apparatus to carry out the sterilization safely.

**Chemicals.**—Those commonly used are: Carbolic acid, chromic acid, creolin, formalin, and mercuric chlorid. The latter heads the list for efficiency, and is found in the majority of formulas. It is known to kill the most resisting spore—that of anthrax—in a few minutes, using a solution 1-1,000. Lately iodine has been used. The theoretic objection to the use of a chemical germicide is its supposed effect in lowering tissue resistance and thus favoring infection. Mercuric chlorid is said to increase wound secretion, thus producing a favorable culture-medium for the growth of pus-forming bacteria.

The object of this article is to give to the profession a rapid and easy method for the sterilization of catgut, which has proved its reliability in practical tests, having been used in some 3,000 operations. Wounds in which catgut so prepared has been used have healed rapidly, and suppurations following have been unusually rare and could not be traced to the material. It has also been tested bacteriologically, always with negative result.

**The Technic.**—Have ready one two-quart and one one-quart clean fruit jar for each size of the material used. It is well to have an extra one-quart jar for use in preparing a fresh batch when one on hand is nearly used. The jars must be thoroughly cleaned beforehand and sterilized by boiling or dry heat. The various sizes of catgut can be purchased from any reliable firm dealing in surgical supplies. The sizes found most convenient are 00, 0, 1, 2, and 3. The first three sizes are cut into lengths of about ten inches and used for ligatures and sutures; the last two, 20 inches—used for pedicles, etc. For convenience, a piece of wood 10" x 3" x 1/4" is obtained, and both ends cut to a point and notched at intervals of one-quarter of an inch for catching the ends of the strands. After winding lengthwise, cut the smaller sizes at both ends of the board; the larger at one end only. Three strands of a similar size of the short lengths are placed in an envelope of unglazed paper, a convenient size being 3" x 1 1/4". Two strands of a similar size of long lengths are likewise placed in envelope. Seal and mark with an indelible pencil the size number on the outside of the envelope. The number should be made large enough to be plainly seen. It does away with the necessity of putting germ-catchers on the outside of the jar. Envelope and contents of similar size are kept in a two-quart jar until wanted.

Sterilization is accomplished by placing 40 or 50 envelopes and contents in a one-quart jar and completely filling it with the following germicidal solution:

Mercuric chlorid.....	1.	(15 gr.)
Tartaric acid.....	5.5	(75 gr.)
Columbian spirits.....		
Ether.....	of each	473. (1 pint.)

Put on the cover and screw it down tightly. Allow size 00 to remain in the solution for four hours; size 0, six hours; size 1, eight hours; size 3, twelve hours. After the material has been immersed for the desired time pour off the solution and drain, then cover envelopes and contents with columbian spirits, screw on the cover, and put away in a clean place until wanted. It is essential that columbian spirits be used. Ethyl alcohol cannot take its place, even when the absolute alcohol is used. Columbian spirits is a pure methyl (wood) alcohol practically free from water. It is inexpensive, costing less than the ordinary alcohol. It can be obtained usually at paint stores. It serves to toughen the catgut, acting much the same way as does formalin. In removing the envelopes from the jar use a pair of vulsella forceps kept expressly for this

purpose. Thread the needles, then place in recently distilled water. Catgut prepared by this method possesses all the requisites of a good ligature and suture material—strength, pliability, and most important, asepsis. The technic of sterilization is easy to carry out and it is inexpensive. The very minute quantity of mercuric chlorid remaining in the material overcomes the theoretic objections to its use.

It will not be out of place here to relate an experience with an infected ready-prepared cocain solution. Nearly all of our ordinary operations for the cure of hernia, varicocele, phimosis, removal of skin growths, etc., are done under a local anesthetic—cocain solution. The solution was prepared with distilled water, using every care. It was a rule to fill the hypodermic syringe from a clean glass and never return unused solution to the bottle. Some time ago suppuration followed in four out of five operations. The catgut and cocain solution were at once under suspicion, both were subjected to bacteriologic examinations. The catgut was found sterile. In the cocain solution was found *Staphylococcus pyogenes* with putrefactive bacteria. How the solution became infected is a mystery, but it is not unlikely that it was done in the operation of filling a syringe by inserting the needle into the bottle or that an unused solution was returned.

At the suggestion of Dr. Lee H. Smith the solution is now prepared from dry ingredients. Two dozen clean glass-stoppered one-dram bottles were obtained and sterilized. Into each bottle were placed the following dry ingredients:

Cocain mur.....	.062	(1 gr.)
Morphin.sulf.....	.002	( $\frac{1}{32}$ gr.)
Nitroglycerin.....	.000162	( $\frac{1}{625}$ gr.)

Just before an operation the bottle is filled with boiling decinormal salt solution.

When a bloodless field of operation is desired a 1-10,000 solution of adrenalin chlorid is used in place of decinormal salt solution, the nitroglycerin being omitted. In operations requiring more than one bottle of the solution, one-half of the solution from a full bottle is poured into an empty bottle and both filled with decinormal salt solution; the one-half strength solution works well. Bottles are to be sterilized before each refilling.

The small bottles are kept in a specimen jar tightly covered until wanted.

Since using this solution and the catgut ligature and suture material prepared as above some 200 operations have been performed without a single suppuration.

**For Quick Delivery of Milk.**—The Chicago Bulletin of the Health Department for the week ended May 31 says: "Referring to Chicago's problem and the inevitable rise of infant mortality as summer temperature obtains, and more quickly 'sours' the 36 to 60 hours' old milk, *American Medicine* urges that 'with the trolley lines now running into every part of the neighboring country the abuse of long-kept milk should be instantly abated. There is no reason why cold and pure milk should not be delivered at the doorstep within a few hours after milking. This is one of the greatest possible blessings of the development of the trolley system. Let our health boards at once set about its utilization.'"

**Chicago's Mortality.**—The Bulletin of the Chicago Health Department for the week ended June 6, says: "A remarkable and a gratifying feature of the five months' mortality—and one which still obtains, as shown in the above figures of deaths among the young—is developed in a comparison of the deaths under 5 years of age this year and last. In the five months of 1902 there were 3,325 such deaths out of a total of 11,233 deaths at all ages, or 29.5% of the total. In the five months of this year there were 3,644 such deaths out of a total of 13,159 deaths at all ages, or 27.5% of the total. These figures show a decrease of 7.2% in the proportion of under 5 year deaths this year. The greatest decrease—14%—is in the deaths of under 1 year of age. On the other hand, there has been a comparative increase of 3.5% in the deaths between 1 and 60 years and of 0.9% of those over 60 years of age. The "murderous mortality" has been principally among those at the most valuable age-period of life; but it is some satisfaction to know that the better safeguarding of infant life, the growing intelligence of mothers in the care of their young—especially in the poorer districts—shows tangible results."

### Boston Medical and Surgical Journal.

June 18, 1903. [Vol. CXLVIII, No. 25.]

1. The Need of an Institution for the Education of Nurses Independent of the Hospitals. FRANCIS P. DENNY.
2. Hemostasis by Compression and Heat. JOHN W. KEEFE.
3. Poliencephalomyelitis and Allied Conditions. E. W. TAYLOR.

**1.—Education of Nurses Independent of the Hospital.**—F. P. Denny points out the disadvantages of the present system, hospitals furnishing the training chiefly for economic reasons. To the small general hospital and the special hospital the didactic instruction required is a real burden, and even in the larger schools it is inadequate and not in the most competent hands. The nurse in the effort to get the routine work done has no time to digest the experience and teaching she is receiving. The changes urgently needed are leisure for study, instruction in the principles of nursing before beginning practical work, instruction by those especially fitted to teach, improved methods of instruction. The apprenticeship system does not develop powers of observation, clear reasoning, and sound judgment. Hospital experience should come at the end as in the medical profession. A single plant could provide for a number of hospitals, and hospitals could require all candidates to furnish a certificate of having taken such a course. [H.M.]

**2.—Hemostasis by Compression and Heat.**—J. W. Keefe reports 50 cases in which the electrothermic angiotribe was used. Its advantages are exclusion of the ligature, hemostasis *en masse* or of isolated vessels, aseptic gastrectomy, gastroenterostomy, resection of intestine, appendectomy, salpingectomy, extrusion of septic material during operation being rendered impossible; sterile occlusion of the fallopian tube, absence of irritable and painful stumps, less tendency to post-operative adhesions, rapidity of operation, no secondary hemorrhage from slipping of ligatures, nor suppurating sinuses due to ligatures, no puckering nor dragging on the tissues, no danger of inoculation with cancerous material during operation, as the heat destroys the cancer cells beyond the point of application of the clamps. [H.M.]

**3.—Poliencephalomyelitis and Allied Conditions.**—E. W. Taylor believes that a large group of affections of the central nervous system exists, provisionally to be regarded as inflammatory, in which may be included encephalitis, polienccephalitis (superior and inferior), poliencephalomyelitis, poliomyelitis, encephalomyelitis and, with reservations, Landry's paralysis, and possibly myasthenia gravis, and certain peripheral nerve infections. These should be regarded as essentially identical, differing only in symptomatic expression. The evidence for this lies in the simultaneous involvement in individual cases of various portions of the nervous system, a notable example of which is given in polienccephalomyelitis. We should gain in our understanding of these and other affections if we adopted a classification based on pathologic altera-

tions and on etiology, whenever possible, rather than on clinical symptoms determined by anatomic subdivisions. Admitting a somewhat definite pathologic alteration of the nature of inflammation as a fairly constant factor, we may assume the existence of a common exciting, probably toxic, cause. The nature of this cause is practically unknown, its manifestations are not always uniform, and our final understanding of the distribution and prognosis of these affections must depend, first, upon our knowledge of these exciting causes, and second upon the nature of individual susceptibility and resistance. [H.M.]

### Medical Record.

June 20, 1903. [Vol. 63, No. 25.]

1. Infantile Insanity in Its Relation to Moral Perversion and Crime. ALLAN MCLANE HAMILTON.
2. Gastric and Intestinal Crises. C. A. EWALD.
3. Intravenous Infusion in Puerperal Septicemia. EDWARD WAITZFELDER.
4. The Correlation of Alcoholism, Crime, and Insanity. C. A. DREW.
5. The Medical Officer of the United States Navy. GILBERT TOTTEN MCMASTER.

**1.—Infantile Insanity, Moral Perversion, and Crime.**—A. McL. Hamilton points out the difficulty of determining responsibility in children. Cruelty, theft, incendiarism, and even suicide may not bring with it any suspicion of mental disease. They simply do not understand the significance of these things. Many of their crimes are merely imitative. Certain neurotic children, as early as the third year, may develop peculiarities in which moral defects are constant, thus differing from the occasional acts of sane children. A form of useless lying, with defiance of authority, waywardness, sexual perversion, intolerance of restraint, and cruelty is nearly always present. The children are dull so far as systematic work is concerned, but sharp and precocious in other ways. Many forms of adult insanity are found including paranoia, parietic dementia, and circular insanity. Appreciation of consequences sometimes exists, but there is no dread of the obsession as in adults. There is apparent absence of the moral sense, especially when homicides are committed, the subjects often being flip-pant and boastful. Insane criminal perversion is due to (1) idiocy, imbecility, or an epileptic psychopathic condition; (2) to primary delusional insanity; (3) to a degenerative state, with delusive ideas and obsessions; (4) to parietic dementia and other adult diseases. Correctional institutions are needed where children are not stamped as felons; farms and trades' schools, and removal from malodorous tenements and association with older criminals. There should be government regulation of newspapers and injurious publications, with enforcement of existing laws for the protection of minors. [H.M.]

**2.—Gastric and Intestinal Crises.**—Gastric crises are only in small degree, if at all, the expression of disease of the stomach itself, but are reflexes from other organs. C. A. Ewald discusses those attacks originating from a lesion or functional disturbance of the central nervous system, leaving aside those due to kidney or gallstones, movable kidney or liver, intoxications, worms, uterine or ovarian troubles. He describes the early manifestations of tabes dorsalis necessary for a diagnosis, based on the study of 89 cases. The duration of the disease varies, the average is 2 years and 10 months. The attacks return always at shorter intervals and may last from one-half to 48 hours. Usually the attacks come as quickly as lightning and so disappear. It is surprising how long they precede tabetic symptoms. Sub-acidity prevails over other conditions, Intestinal, especially anal crises are less frequent. There is desire for stool, with constipation and sensation of a knife or hot iron in the rectum. It is difficult sometimes to separate tabetic crises from nervous vomiting due to organic or functional disturbances of the nervous system and from idiopathic vomiting without demonstrable disease. We are in the dark as to the nature of the crises. It is most likely an auto-intoxication by a substance which has no influence on normal nerves, the attacks increasing as degeneration progresses and ceasing when the line of transmission has been destroyed. In grave cases morphin must be given, never allowing the patient to use the syringe himself. Epidural injections of cocain have also been tried by the author.

In idiopathic vomiting tonic treatment will accomplish a great deal. [H.M.]

**3.—Puerperal Septicemia.**—Ed. Waitzfelder reports two cases treated by intravenous infusion. Case I was a primipara, aged 26, and brought to the hospital three weeks after normal labor, with well-marked puerperal septicemia. After following the usual treatment in such cases for about two weeks, including repeated hypodermoclyses of decinormal saline solution, pneumonia developing in the left lung, she gradually grew worse until her condition seemed hopeless. At this time he used the formalin infusion after the plan of Barrows. The result of the infusion was all that was looked for, but the improvement did not last, and after 48 hours, a second intravenous infusion was given, this time of decinormal salt solution; the result was identical in every way, the temperature-curves being a repetition of the other, the chills and sweating being exactly the same. The second bacteriologic examination of the blood showed a marked decrease in the streptococci present; and a later one, made just before death, showed their entire absence, but there was never any improvement in the condition of the lungs, and the persistent high temperature of the last few days, and the subsequent death were ascribed to pneumonia rather than septicemia. Case II was that of a multipara who had aborted in the fourth month of pregnancy, eight days before admission to the hospital with fully developed symptoms of septicemia, and a temperature of 103½°. She received at once an intravenous infusion of 1,200 cc. of decinormal saline solution at a temperature of 110°. During 12 hours there was a fall of temperature to 99½°, and from this time pulse and temperature remained practically normal until her discharge on the sixth day after her admission. Waitzfelder was impressed by his experience with the idea that the results obtained were due, not to the germicidal properties of the formalin, but to the transudation following the overdilatation of the blood vessels. [W.K.]

**4.—Alcoholism, Crime, and Insanity.**—C. A. Drew finds total absence of moral sense not uncommon in those whose parents were both inebriates, though the patient has never used alcoholics. Moral imbecility or instinctive criminality due to a neuropathic or inebriate heredity is usually incurable. It is difficult to get a history of a mother's intemperance. The writer's observations in the State asylum lead him to believe that the offspring of some temperate parents are less likely to suffer from alcoholic insanity, though heavy drinkers, than the second generation who may not drink half so much. The most highly organized tissues suffer first, so that from alcohol in the blood the normal sense is first affected. [H.M.]

**5.—Medical Officer of the Navy.**—G. T. McMaster discusses the sort of man required for the position, and gives a summary of the various duties devolving upon him. [H.M.]

7. Do Our Present Ways of Living Tend to the Increase of Certain Forms of Nervous and Mental Disorder? CHARLES E. ATWOOD.

1.—See *American Medicine*, Vol. V, No. 24, p. 946.

**3.—The New York Eye and Ear Infirmary.**—Gorham Bacon in this address delivered at the opening exercises of the Schermerhorn Pavilion gives a historical sketch and review of the growth of the aural department of the infirmary from 1864 until the present time. [C.A.O.]

**4.—Combined action among the various medical specialties** is advocated by J. W. Putnam. He believes that by joining researches and making a united effort in investigating the causes of diseases and new methods of treatment, the helpless condition of those for whom the prognosis has hitherto been unfavorable, may be improved and in other instances that

the deplorable results which are to be found in our homes for the epileptic, the feeble minded and the incurable paralytics, may be diminished. [C.A.O.]

**5.—Report of Some Surgical Cases.**—The first case reported by W. M. Smith is that of a woman of 59 who was thought to have a malignant tumor of the liver. An exploratory incision revealed a very large, hard and nodular right lobe. A needle was stuck into the mass, which encountered a hardness that was supposed to be a nest of gallstones in the liver tissue. An incision into the liver was then made and 71 stones removed, mostly of large size, with characteristic facets. Uneventful recovery followed. The second case is that of a woman of 63 who had suffered from a series of attacks of gallstone colic. She was very much jaundiced and thoroughly septic. An operation was urged but was promptly refused. Later she had hard septic chills, free sweats and a subnormal temperature for several days. About five weeks from the beginning of the illness the friends consented to an operation. An abscess was found involving the lower part of the gallbladder and including the ducts at their junction. This was incised and found to contain a great quantity of foul-smelling pus. The cavity was drained and recovery followed. The third case reported is that of a woman of 35 who had been suffering for several weeks with colic and transient jaundice. At operating 48 gallstones were removed, the bladder was found very much contracted with thick, brittle walls. Two of the stones were packed into the cystic duct. Recovery followed. Another case proved to be one of hematoma of the ovaries. That of the left ovary was about the size of a fetal head and was ruptured during the operation. The hematoma of the right ovary was small. An interesting feature of the case is that although both ovaries were completely removed the patient continued to menstruate at from two to four weeks' interval for some time thereafter and then stopped for five months, but at the time of reporting she was still menstruating. [C.A.O.]

**6.—Spermaturia.**—A. R. Elliott has found seminal elements in the urine a frequent confusing element in testing for albumin. In a review of 1,000 recorded analyses of male urines, seminal elements were present in 56 instances, in all of which spermatozooids were features of the microscopic sediment. In 44 of these cases the albuminous reaction was obtained. In 20 of the 44 cases no other morbid elements were present that would account for the albuminuria. As instances of the clinical confusion which may arise from the presence of these bodies the author reports three cases. [C.A.O.]

**7.—Ways of Living and Nervous Disorder.**—C. E. Atwood says that the tendency of our too rapid mode of living is to bring on neurasthenia or to develop a neurosis or mental disorder in those predisposed, or to jeopardize the future being, by establishing a faulty heredity. Overindulgence in eating and drinking tends to develop arterial sclerosis and may tend to cause apoplexies at an earlier age than formerly, and to conduce to senility and senile conditions. The effects of our rapid mode of living are perhaps greatest in the immigrant. Two-thirds of the insane of the State of New York are either foreign born or of foreign parentage. The causes of insanity and neurasthenia in these immigrants are chiefly faulty heredity, poverty and attendant evils, physical stresses, emotional excitement, intemperance and sexual excesses. [C.A.O.]

#### Medical News.

June 20, 1903. [Vol. 82, No. 25.]

1. The Need of Public Toilets in American Cities. EDWARD H. WILLIAMS.
2. The Morbid Anatomy and Pathology of Tabes. JOSEPH COLLINS. (Concluded.)
3. The Proper Recognition of Electrotherapeutics. A. R. RAINEAR.
4. A Contribution to the Pathology and Prognosis of the Diseases of the Bladder. ROBERT HOLMES GREENE and HARLOW BROOKS.
5. "Impressions of the Nonheredity of Acquired Characters": A Rejoinder. LAWRENCE IRWELL.

**1.—Public Toilets.**—E. H. Williams points out the embarrassment to strangers unaccustomed to our ways, as well as to citizens, especially women, from the absence of such places. In order to avoid disfigurement of the city they could be placed underground, as in London. The initial cost would be great, but could be materially lessened by their being constructed in

conjunction with present underground structures now building or projected. The saloonkeepers would find it more profitable for their business not to have them. He discusses and illustrates cheaper structures for outlying districts. [H.M.]

**2.—Morbid Anatomy and Pathology of Tabes.**—Joseph Collins concludes his interesting article on this subject. His remarks are based on the analysis of 140 cases of tabes and on the microscopic examination of three cords, together with a review of the status of the pathogenesis of tabes and a consideration of the theories which have been adduced to explain its phenomena. The theories that have been advanced to explain the degeneration of the posterior columns and the posterior roots are: 1. The vascular theory. 2. The theory of primitive degeneration of the posterior columns. 3. The theory that the essential lesion is (a) primary, (b) secondary degeneration of the posterior roots. 4. The theory that primary lesion is of the cells of the ganglia of the posterior roots. 5. The neuritic theory: the theory that the peripheral nerves are first attacked and that the lesions that finally overtake the posterior roots and columns in a secondary manner. These theories have been found insufficient to explain the lesions of tabes and have all, save the third, been abandoned. Though none of the hypotheses are adequate, that recently suggested by Marie and Guillain would seem to be most in accord with what we know of the etiology of tabes. Adopting their theory it is probable that the lesions of tabes are the results of the activity of a poison generated by syphilis acting primarily upon the intramedullary distribution of the posterior roots; that the essential lesion of tabes is an elective progressive degeneration, segmentary in type (in contradistinction to Wallerian), of the posterior columns of the spinal cord. [A.B.C.]

**3.—Electrotherapeutics.**—A. R. Rainear calls attention to the fact that quacks have availed themselves of the application of electricity to disease and are harvesting returns that should belong to the general practitioner. The majority of physicians are ignorant as to its action, forms, and dosage. The curriculum of all high grade medical colleges should have a department of electrotherapeutics. [H.M.]

**4.—Diseases of the Urinary Bladder.**—R. H. Greene and H. Brooks say that the increased frequency and ability with which medical men now recognize that diseases of the bladder often have their origin in the central nervous system has its hopeful aspect. Late improved methods in cystoscopy have added much to our knowledge in this field. In 500 necropsies in connection with various New York hospitals they found 107 instances of bladder lesion. The most constant lesion was acute dilation, this being present in 64 of the 107 cases. There were 4 instances of rupture of the bladder. Hypertrophy of the prostate may cause thickening of the bladder wall with contraction or thickening with dilation. Whether dilation or contraction takes place depends on the rapidity with which the prostate has enlarged. Extensive pathologic reports are given of a number of different lesions. Their conclusions are as follows: 1. The most frequent cause of diseases of the bladder is: (a) Lesions of the central nervous system, causing dilation; (b) septic processes of various varieties; (c) hypertrophy of the prostate. 2. In all conditions in which the spinal cord or central nervous system is involved frequent and early catheterizations should be resorted to. 3. Conditions of the bladder must greatly modify the prognosis in operative procedures for the relief of obstructions of the urinary flow, therefore the importance of cystoscopic and other examinations. 4. Hypertrophy of the bladder wall is due to four different processes, separate or combined: (a) Inflammatory infiltration; (b) increase of the fibrous connected tissue; (c) smooth muscle hyperplasia; (d) infiltration by new growth; (e) the clinical symptoms in hypertrophy of the bladder depend on which of these factors predominate. [A.B.C.]

**5.—Impressions of the Nonheredity of Acquired Characters.**—L. Irwell discusses the distinction between congenital conditions and heredity. Neo-Darwinians and neo-Lamarckians agree that congenital characters are hereditary. The alcohol diathesis is a congenital trait, and is undoubtedly transmitted. He has never asserted that acquired characters cannot be transmitted, but merely asserts that there is no reliable evidence that any acquired trait is transmitted. [H.M.]

## CLINICAL MEDICINE

DAVID RIESMAN A. O. J. KELLY

## REVIEW OF LITERATURE

**Bony Changes in Gonorrhoeal Arthritis.**—R. Kienbock<sup>1</sup> has observed after injuries and inflammatory processes of extremities, especially after grave gonorrhoeal metastatic arthritis, changes arise in the skeleton, usually spoken of as "inactivity atrophy" of the bones, but more correctly considered as acute osseous atrophy. It also occurs after injuries and acute diseases of the nervous system. Pathogenetically this atrophy is in line with other trophic changes, such as muscular atrophy, synovial changes, etc. It begins four to eight weeks after the onset of the disease, nearest the area of inflammation, radiating from it in different directions. It usually affects only the spongy bone at first, the radiographic picture showing this through lighter shadows, and slight changes in contour; the greater the absorption of limesalts, the lighter the picture. The diaphysis, cartilage and the surrounding soft parts are affected later. The treatment should consist of massage, passive and active movements, faradism and artificial passive congestion. Numerous photographs illustrate the stages of the condition. [E.L.]

**Congenital Hypertrophic Stenosis of the Pylorus.**—A quaint and interesting clinical and postmortem record is furnished by H. Beardsley,<sup>2</sup> with the following note by Dr. William Osler: "Cautley and Dent in a recent paper (*Lancet*, December 20, 1902) state that the first record of this disease, which is now exciting a good deal of interest, dates back to 1841. The report here given by Dr. Beardsley of a very clearly and accurately described case is, I think, worth publishing. It appears in the earliest volume of medical transactions issued in this country, entitled 'Cases and Observations by the Medical Society of New Haven County in the State of Connecticut,' New Haven, J. Meigs, 1788." F. W. Shaw<sup>3</sup> details three cases, one of them being confirmed by autopsy. The duration of the fatal case was nearly eight years, but the fact that vomiting had persisted practically from birth excluded it from similar cases in adults not of congenital origin. It also shows that stenosis may be partial for a time and then become complete. Shaw gives a general review of the subject. [A.G.E.]

**Tuberculosis of the Aorta.**—S. v. Simnitsky<sup>4</sup> reviews the literature on the subject of tuberculosis of the aorta and reports two cases. There are three varieties of aortic tuberculosis: 1. Extension of the tuberculous process from some adjoining organ. 2. Primary infection from the passing blood. 3. Infection by way of the vasovasorum. No case has as yet been reported as occurring in the latter manner. The author's two cases were found at the postmortem examinations of 155 cases of tuberculosis. Both of his patients suffered from acute miliary tuberculosis. Simnitsky considers this variety to be the most common cause of tuberculosis of the aorta. [W.E.R.]

**The Innervation of Digestion.**—O. Cohnheim<sup>5</sup> relates entertainingly some of his experiences in Pawlow's laboratory in St. Petersburg. The experiments are performed solely to study the nervous mechanism of digestion and are carried on on a large scale. Dogs with large gastric and esophageal fistulas are used for the purpose. Mechanical irritation of the gastric mucous membrane does not produce secretion of gastric juice, but if the dog is permitted to chew his food the stomach begins to secrete 5½ minutes after the onset of this, although none of the food reaches the stomach. The gastric juice runs from the fistulas into vessels. The odor and the sight of food is sufficient to start up the secretion. Through separation of the stomach into two compartments he has been able to determine the quality of the gastric juice. He finds that depending upon the variety of the food given the stomach secretes varying quantities and different qualities of juice. Other experiments have demonstrated facts concerning the pancreatic and duodenal digestion hitherto unknown. Taken all in all, Pawlow's work, according to Cohnheim, is the most brilliant ever done in this

line of physiologic chemistry and the results are entirely due to Pawlow's genius, brilliancy, exactness, and perfect surgical technic. [E.L.]

**Chronic Hydrocephalus Associated with Gigantism.**—G. G. Lempe<sup>1</sup> reports a case that presented features not usual in connection with chronic hydrocephalus. The patient died at the age of 18. When 10 years old he complained first of headache. This was followed later by ataxic gait, vomiting, almost total loss of sight and speech and control of the sphincters, and general swelling. Improvement then began and lasted until the age of 15, when the boy was 5 feet 6½ inches tall. Gradual failure followed return of the headache, and death occurred at the age stated. At that time the patient was 6 feet 7 inches tall and weighed 193 pounds. Only the brain was removed at autopsy, the pathologic conditions found being those of chronic hydrocephalus with a small hematoma in the roof of the fourth ventricle. The orbits were not abnormal in size, the frontal sinuses not enlarged, the jaw not prognathous. The feet and hands were small when compared with the height. The pituitary body was virtually normal in size and construction, excepting a slight hyperplasia. Lempe considers the case, in addition to chronic hydrocephalus, as one of gigantism, not acromegaly. It might have formed eventually into a true case of acromegaly with pituitary enlargement, of which the slight hyperplasia was an early indication, if chronic hydrocephalus and its fatal results had not intervened. [A.G.E.]

**Gastric Digestion in Chronic Enteritis.**—This element of chronic enteritis has not, according to W. P. Bajouff,<sup>2</sup> met with the attention it deserves, when we consider the frequency of gastric complications in enteritis. He reports five cases in detail, and sums up the result of his studies in these conclusions: 1. The subjective gastric disturbances accompanying enteritis or enterocolitis are due in most instances to an atrophic gastric catarrh. This catarrh is probably the result of extension from the intestines—ascending gastritis. 2. The subjective gastric phenomena do not, as a rule, correspond to the severity of the anatomic lesions. Advanced atrophy of the stomach walls may coexist with mild dyspepsia, especially when the pylorus is weakened. 3. The prognosis depends on the severity of gastric involvement, which serves as an index of the intestinal lesions. 4. Objective gastric data may be utilized in regulating the diet. In the absence of HCl, meat diet is contraindicated. Frequently the patients themselves select the proper food combinations; however, examination of the stomach contents supplies us with a scientific basis for our treatment. [L.J.]

**Gelatin by Mouth in Hemophilia.**—Hesse<sup>3</sup> reports the case of a boy 8 years of age, whom he has known since birth to be weak, pale, and of slender build. He bruised very easily and his feet often showed blue spots. After each fall he had extensive ecchymoses especially if he struck his buttocks. His teeth fell out spontaneously and he had profuse bleeding from his gums; he bled profusely from slight wounds and often had bloody effusions into his joints. Many things were tried but without result. About a year ago gelatin treatment was begun; he was given 200 grams (6½ ounces) daily in a 10% solution mixed with raspberries or lemon juice. The improvement was noticeable from the first day; for months he has not had epistaxis, gum or joint hemorrhage. Blows and knocks produce only slight ecchymoses. His general health is much better. [E.L.]

**The Value of Lemon Juice as a Prophylactic for Typhoid Fever.**—W. Johnson<sup>4</sup> gives the results of experiments to determine the effect of lemon juice upon typhoid bacilli. Results from agar and bouillon as test media were about equal, and showed that a strength of lemon juice equal to 50% of the whole solution killed the germ in less than 10 minutes or at least inhibited its growth. In a 9% solution the bacilli were capable of increase after 20 minutes and in a 2% solution after 24 hours. The results were entirely opposed to the newspaper statements of disinfection by a 1% solution in an hour or less, and which are helping establish a false sense of

<sup>1</sup> Wiener klinische Wochenschrift, January 15 and 22, 1903.<sup>2</sup> Archives of Pediatrics, May, 1903.<sup>3</sup> Brooklyn Medical Journal, May, 1903.<sup>4</sup> Prager medicinsche Wochenschrift, February 12, 1903.<sup>5</sup> Münchener medicinsche Wochenschrift, December 30, 1902.<sup>1</sup> Albany Medical Annals, May, 1903<sup>2</sup> Medizinskoje Obosrenie, lix, No. 6.<sup>3</sup> Therapie der Gegenwart, September, 1902.<sup>4</sup> Northwest Medicine, May, 1903.

security. Heat is the only safe method, and water need not be made unpalatable by having the air boiled out, as it can be rendered absolutely safe by merely bringing it to the boiling point or even many degrees below—140° F. [A.G.E.]

**Pathogenicity of *Balantidium Coli*.**—Altogether 89 cases of persistent diarrhea, due to *Balantidium coli*, have been previously reported. The cachexia caused by this condition often resembles that seen in the last stages of cancer of the stomach. *Bothriocephalus latus* is also found in many of these cases, the catarrh caused by this parasite evidently predisposing the alimentary tract for the invasion of the balantidium. Twelve fatal cases have been reported, the primary cause of death usually being an ulcerative colitis. E. Ehrnrooth<sup>1</sup> reports still another fatal case, occurring in a woman who had digestive disturbances for 20 years, and suffered from vomiting, diarrhea, and abdominal pains for four months before her death. Autopsy showed that the whole gastrointestinal tract was the seat of chronic inflammatory and degenerative processes. Partial atrophy of the mucous membrane was found in the stomach, and an extensive atrophy in the lower part of the ileum. There were no evidences of a general toxemia caused by the parasite, neither degenerative nor inflammatory processes being found elsewhere in the body. [B.K.]

**A Case of Fusiform Dilation of the Esophagus.**—P. Zinsser<sup>2</sup> reports the case of a man of 39, who since his twelfth year complained of his food sticking in the esophagus. At first he was able to wash it down with small quantities of liquids but later it required more. Unless he did this he always vomited his food later. He devised a diet for himself, which permitted him to eat with comfort, but each meal had to include 1½ pints of liquid. His death was due to pulmonary tuberculosis. The autopsy revealed a spindle-shaped esophagus, the largest diameter of which was 4 inches; its walls were very much hypertrophied. As the cardiac orifice showed neither organic constriction nor a valvular mechanism the only feasible explanation for the dilation was spasm of the cardiac orifice, which required a definite weight from above to overcome it. There were no signs of hysteria or nervous disease. [E.L.]

**Blood Cultures in Lobar Pneumonia.**—E. C. Rosenow<sup>3</sup> considers (1) the frequency and time of general pneumococcus invasion of the blood stream and the diagnostic and prognostic value of blood cultures in croupous pneumonia, and (2) the agglutinating and bactericidal action of pneumococcal blood-serum. He has studied 83 cases, positive results being obtained in 77, and cultures secured in 74 of these. Positive results were obtained in all stages of the disease. Friedländer's bacillus was never obtained. The conclusions reached by Rosenow are: (1) With improved technic, using for inoculation large quantities of blood, the pneumococcus can be recovered in all cases of pneumonia, and in obscure cases of pneumococcus infection blood cultures may be a diagnostic method of positive value; (2) pneumococemia in pneumonia does not mean a specially unfavorable prognosis; (3) on account of the difficulties involved agglutination of the pneumococcus is at present of scientific rather than practical value; (4) normal and pneumonic blood and serum appear to have no bactericidal influence on the pneumococcus; (5) the interesting question whether lobar pneumonia is the primary result of a direct local infection of the lung, or a secondary localization in the lung of pneumococci in the blood, is as yet hardly ripe for final discussion. [A.G.E.]

**Isoagglutination of Human Blood, Especially in Childhood.**—J. Langer,<sup>4</sup> as the result of his investigations, arrives at the following conclusions: 1. In human serum there is a variety of agglutinins, the erythrocytes of one individual being capable of agglutination by several kinds of serum. 2. The serum of the newborn seldom contains isoagglutinins, but the erythrocytes are as capable of agglutination as those of older children. 3. The acquisition of agglutinins occurs in the first months of life. It is still undetermined whether they arise by simple absorption of the isoagglutinins found in colostrum and milk, or whether their formation is incited by other means. 4.

The formation of isoagglutinins is unaffected by the absorption of hemorrhagic effusions (contusions, cephalhematoma, etc.), or by acute or chronic infectious diseases. 5. Isoagglutination is a phenomenon which has nothing in common with isohemolysis. [B.K.]

**Agurin, a New Diuretic.**—Agurin is a combination of sodium theobromate and sodium acetate. It is neither irritating to the stomach nor poisonous, and as it contains 60% of theobromin, as compared with 50% in diuretin, possesses greater diuretic powers than this drug. Its especial field of usefulness is to be found in cases of lost cardiac compensation, edema disappearing very quickly under its use. While not contraindicated in parenchymatous nephritis the results from it are not nearly so good, as its action is exerted only on healthy renal epithelium. A. Nusch<sup>1</sup> reports the clinical data of four patients, in all of whom the amount of urine was very much increased. He has also tried it in exudative pleurisy with good results. He recommends 15 grains (1 gram) three times daily, as the dose. [E.L.]

**The Dangers of an Exclusive Milk Diet in Nephritis.**—A. C. Croftan<sup>2</sup> says if it were not for the pronounced prejudice in favor of an exclusive milk diet in nephritis it would seem almost trite to adduce what he considers self-evident arguments against the use of this method of feeding, which (excepting possibly in very acute cases of nephritis, and then only for a few days) is directly harmful and dangerous. In selecting a dietary for patients having kidney lesions three indications must be met: (1) General nutrition must be maintained; (2) the renal epithelium must receive a minimum of irritation; (3) the functions of other organs must not be overtaxed. Regarding the first point, too little iron and too much albumin is supplied by an exclusive milk diet. As to the second, much water, much urea, and much phosphate, all elements that act as irritants to the renal epithelium, are carried to the kidney in large quantities when nephritics are fed exclusively on milk. Third, the digestive and cardiovascular organs are impaired by this diet when continued for a long time. In the present state of our knowledge we are not able to formulate any fixed rules in regard to the feeding of nephritics. Hence clinical experience and the reaction of the sick *individual* to treatment, not laboratory findings, and the reaction of the kidney function alone, must be our guides. [A.G.E.]

**Malaria, Diseases and Conditions on the West Coast of Africa.**—A. A. Loeb<sup>3</sup> details four cases of malarial fever which he saw while on the west coast of Africa. He also describes various diseases and conditions found among the inhabitants. He would advise any one visiting the west coast of Africa for the purpose of study to provide himself with a mosquito net, an abundance of light clothing, and a large helmet. As fresh food is often scarce, a good supply of the best canned foods should be always on hand. It is advisable to live as far away as possible from the villages. Proper covering will be required for the rainy season. [F.C.H.]

**Tremor and Urinary Intoxication.**—A. Horn<sup>4</sup> calls attention to various symptoms of intoxications observed in patients with urinary retention, and which in some cases have so obscured the clinical picture, as to give rise to mistakes in diagnosis and treatment. He reports the case of a man, who was referred to him on account of nocturnal enuresis and a tremor thought to be senile; he complained of great thirst, loss of appetite, constipation and great weakness. The urine which was voided very frequently, and in large amounts, was perfectly normal. Examination revealed a very large prostate and over a pint of residual urine. Under the treatment, which consisted of regular catheterization, and the use of urinary antiseptics the patient improved and the tremor disappeared completely. If at any time he neglected himself, the tremor was among the first symptoms of the autointoxication to return. [E.L.]

**Myelogenous Leukemia with Absence of Eosinophilic Leukocytes.**—This case is detailed at length by C. E. Simon.<sup>5</sup> Briefly, the patient, a man of 42, became markedly anemic

<sup>1</sup> Zeit. für klin. Med., Bd. xlix, p. 321.

<sup>2</sup> Münchener medicinische Wochenschrift, December 30, 1902.

<sup>3</sup> Medicine, June, 1903.

<sup>4</sup> Zeit. für Heilkunde, Bd. xxiv, 1903, Heft v.

<sup>1</sup> Münchener medicinische Wochenschrift, December 23, 1902.

<sup>2</sup> Medicine, June, 1903.

<sup>3</sup> Philadelphia Medical Journal, June 6, 1903.

<sup>4</sup> Deutsche medicinische Wochenschrift, December 25, 1902.

<sup>5</sup> American Journal of the Medical Sciences, June, 1903.

without apparent cause, steadily declined and died at the expiration of 17 months after the anemia began. No subjective symptoms appeared until late in the disease and then consisted only of shortness of breath and general weakness. The spleen was markedly enlarged, the glands but slightly. Hyperleukocytosis, absent at first, was marked at last. Neutrophilic myelocytes were present from the first in notable numbers. Eosinophiles were absent. The unusual features of the blood were the low grade of hyperleukocytosis, the absence of eosinophiles, and the decided increase of mononuclear elements devoid of granules which occurred toward the end of the disease. Simon says there is a growing tendency to attach only secondary importance to the actual number of leukocytes in the diagnosis of myelogenous leukemia, the characteristic feature of the disease being the presence in the blood of foreign elements, the myelocytes. Regarding the absence of eosinophiles this seems to be the only case recorded, Ehrlich stating positively that they are increased in every case. Unless the diagnosis be abandoned in this case, and Simon sees no reason for so doing, our conception of the disease must be extended to comprise the type under consideration. The large mononuclear cells present in such numbers are classed by Simon with the lymphoid cells of Michaelis and Wolff. Their true nature is not determined. There seems to be good ground, as suggested by Reed, for the recognition of three forms of leukemia—the myelogenous, the lymphoid, and the mixed-cell varieties. [A.G.E.]

**Some Observations on Tuberculous Patients Sent to Colorado.**—S. Simon<sup>1</sup> considers that incipient and first stage patients do well as a rule, provided they are placed under favorable environment and receive proper medical advice immediately upon arriving there. Those patients having the earliest symptoms of tuberculosis and the symptoms are rapidly progressive, have their lives shortened by being sent to Colorado. Many of the patients in the second stage of the disease get well, providing they can afford proper care and accommodations. Cases in the third stages or those patients presenting cavities should not, with rare exceptions, be sent west. Many of the patients sent west do badly because they arrive there penniless and are unable to obtain proper food, care, and attention. [F.C.H.]

**Subcutaneous Gelatin Injections in Childhood.**—Zupinger<sup>2</sup> considers gelatin injections in the treatment of hemorrhage from any source, one of the greatest boons of modern medicine. Where from 50% to 100% of all cases of internal hemorrhage in children used to die on account of the lack of an efficient hemostasis very few need do so now since the introduction of gelatin. He briefly reports three cases, in which the bleeding was so severe as to leave the patients almost bloodless. Hypodermic injections of from 1% to 5% solutions of gelatin in varying quantities were used and all of them recovered. Two were cases of scurvy, the third of purpura hemorrhagica. He has also tried it in melena neonatorum, epistaxis, pulmonary hemorrhage, etc., and always with the same result. He warns against the use of commercial gelatin, as this was often found to contain tetanus bacilli. If carefully sterilized few unpleasant after-effects will be noted. [E.L.]

**A Case of Cyanosis of the Extremities.**—The case reported by A. A. Eshner<sup>3</sup> was in a man of 72, who was at first treated for myalgia, with relief. Later the heart was found to be arrhythmic and the hands intensely cyanotic, presenting a variegation in hue between deep purplish-red and leaden. The discoloration was more marked in the left hand which was cool. Pulsation of the right radial was distinct, of the left very faint. The feet presented a lesser degree of cyanosis but there was no palpable pulsation of the left dorsal artery. The nose and adjacent portions of the cheek were cyanotic. No eye lesions were present. The case conforms with the clinical description of Raynaud's disease in the symmetrical and local distribution of the cyanosis and in the absence of anesthesia and atrophy. The difference in the intensity on two sides of the body is not unusual. Eshner believes that the cyanosis is dependent upon the vasomotor atonicity and that the case fits best into the parietic type of vasomotor ataxia of Cohen. [A.G.E.]

MARTIN B. TINKER  
A. B. CRAIG C. A. ORR

## EDITORIAL COMMENT

**Tetanus and the Fourth of July.**—The week following Independence day celebration will doubtless be marked by the usual increase in the number of cases of tetanus. The deaths and suffering will be one item in the cost of celebration. Where records have been kept, as in the larger cities, they show that more than one-third of the annual deaths from tetanus occur during the month of July. This fact has an interesting exception in the city of Washington whose records show that July furnishes no more than its proportional number of cases. Enforcement of the legal requirements in the capital city readily accounts for the practical absence of Fourth of July tetanus, for on that day, in addition to the usual restriction upon the carrying of concealed weapons stringent measures are enforced against the use of blank cartridges, firecrackers, and other explosives within the District of Columbia. How different are the records under such restrictions from those in cities like New York and Chicago, where H. G. Wells<sup>1</sup> has shown that July furnishes 38.7% of the year's mortality from traumatic tetanus. With but few exceptions the Fourth of July cases of tetanus arise from blank cartridge wounds. Numerous and careful examinations of these cartridges prove conclusively that they do not contain the tetanus germs. The child playing in the street has his hands plentifully soiled with dust and dirt, the favorite habitat of the germs, and the powder and wadding from the blank cartridge carries fragments of this soiled skin deep into the lacerated tissues. This forms the almost perfect anaerobic condition necessary for the growth of the tetanus germs. The organisms do not enter the blood, and, in fact, Kitasato has shown experimentally that they disappear from the tissues at the point of inoculation within ten hours. They are supposed to elaborate toxins in the vicinity of the wound, which rapidly enter the circulation and are believed to have a special affinity for certain cells in the spinal cord. The time elapsing before symptoms arise is thought not to represent the period of incubation, but rather the time necessary for chemic union to take place between the toxins and certain substances of the body. The mortality in acute tetanus is variously estimated at from 80% to 95%; whereas in the chronic form, that appearing after 10 days from the time of injury, it is about 30%. The most important feature in the treatment of tetanus is, of course, its prevention, and this can be done only by following the example set by the District of Columbia; until then we shall have the usual Fourth of July increase. One would suppose most of the fatal cases were among those treated by laymen or self-treated, but H. G. Wells<sup>1</sup> says the histories of 35 fatal cases showed that the vast majority of the victims were treated by a physician soon after the injury, and in not a single instance was a reasonable attempt made to secure proper surgical conditions. The case, reported by Bain,<sup>2</sup> is unique, and it indicates the proper and necessary treatment. The powder-burned and lacerated tissue of a blank cartridge wound was thoroughly and freely excised soon after the injury. The child did not develop tetanus in spite of the finding of numerous tetanus bacilli in cultures made from the removed tissues and wadding. Every wound of a suspicious nature, especially if made by a blank cartridge, should be promptly treated by thoroughly excising all the lacerated tissue, opening it widely, and using the cautery. This should be supplemented by the hypodermic or spinal intermedullary injection of not less than 5 cc. of tetanus antitoxin, as discovered by Tizzoni and

<sup>1</sup> Philadelphia Medical Journal, June 6, 1903.

<sup>2</sup> Annals of Surgery, March, 1903.

Cattani. The prophylactic use of the antitoxin has been attended by most encouraging results, whereas if it is used after the development of the symptoms the toxins of tetanus are already far advanced in their deadly work and the prognosis is exceedingly grave. In the treatment of cases in which symptoms have developed mention should be made of the method of Baccelli, who injects 10 cc. to 20 cc. of a 2% carbolic solution hypodermically three or more times daily. According to Italian reports, this has been attended by most remarkable results. We may with some shadow of excuse neglect the tetanus antitoxin and the carbolic solution, but certainly no physician who deserves the name should neglect the proper surgical treatment of the wound, for herein lies comparative safety—open, cleanse, cauterize, and drain.

#### REVIEW OF LITERATURE

**Operative Treatment of Enlarged Prostate.**—William Thompson<sup>1</sup> gives a historical review of the literature on the subject and the various operations which have been introduced. The method practised and advocated by the writer is essentially that of Freyer. The bladder is opened in the suprapubic region, after first being thoroughly washed out and distended with boric solution. The catheter is allowed to remain in as a guide to identify the urethra. Reaching the prostate the mucous membrane is snipped or scraped through. Two fingers in the rectum raise and fix the prostate, the forefinger of the other hand shells out the structure in two or more masses. This is sometimes difficult but can be accomplished. Bleeding is controlled by hot boric solution. A large drainage tube remains in for 48 hours. The bladder is frequently washed out. The wound usually closes in about four or five weeks. He objects to the perineal route from the fact that it is impossible to thoroughly explore the bladder by this route and even for successful removal of the prostate it requires a surgeon with a forefinger whose working length is three inches or over, and even then only two-thirds of the cases can be dealt with through this route. The combined perineal and suprapubic route is unnecessary since the suprapubic will give all the necessary working room. He reports a number of cases in all of which he successfully enucleated the prostate. [A.B.C.]

**Surgical Intervention in Stenosis of the Esophagus.**—H. Lindner<sup>2</sup> discusses the surgical treatment of esophageal strictures, which he divides into malignant and benign. The treatment for the former consists in feeding the patient as long as possible through the natural passageway. When the constriction becomes too tight for food to pass a gastrostomy should be performed; he prefers Witzel's method. It is only a palliative measure, but is the best that can be done; it prolongs life for from six months to two years. Removal of the tumor is almost impossible, especially so if the thoracic part of the tube is involved. It may be attempted if the cancer seems circumscribed to the neck, but even here the results are not encouraging. Benign strictures yield better surgical statistics. Foreign bodies producing stenoses may be removed by esophagoscopy and extraction; many other stenoses are overcome by gradual dilation; if this is impossible and the nutrition of the patient is suffering a gastrostomy followed by retrograde catheterization is often successful. If diverticulae are diagnosed and the patient's life is in danger gastrostomy or resection of the diverticulae, if they are high, may be resorted to. [E.L.]

**Bilateral Fracture of Heads of Fibulas.**—This unique fracture is reported by W. W. Sender.<sup>3</sup> It occurred in a working man, who was caught in a machine and dragged along by a revolving wheel. When the machine stopped he struck the floor with his heels. He was conscious, but could not rise to his feet, and was therefore taken to a hospital where during four weeks the treatment consisted in baths and massage. On admission to the clinic the fractures were discovered. The severed fibular heads could be felt on the femoral condyles; the right fragment had the size of a hazelnut, the left was somewhat

smaller; the fragments were but slightly movable in a lateral direction. The distance of the fragments from the shaft of the fibula measured two fingerbreadths on the right and one on the left leg. On flexing the knees the broken parts were approximated. Pain and crepitus present. Motor and sensory disturbances corresponding to paralysis of the perineal nerves are also present. These findings were largely confirmed by a radiogram. An operation was performed and the fragments united with aluminum bronze wire sutures. Six weeks later the man could walk, though his feet continued to hang in the equinovarus position. A later radiogram showed that the sutures had cut through and the fragments were again separated. Orthopedic appliances will therefore become necessary. The nervous disturbances also remain unchanged. [L.J.]

**On Syphilis.**—According to J. Hutchinson<sup>1</sup> there is no such thing as a pure culture in syphilis. It is introduced in a mixed state and it is owing to the mixture of pus and other secretions that there is the multiplicity of appearances in the primary sores. He warns every one not to tell a patient a sore which may possibly have been contracted from a venereal source is not syphilitic until a month has elapsed; the syphilis may be absolutely latent, or may be concealed by something else. Multiplicity is one of the features by which the nonindurated sore differs from the indurated. The secretion of pus is another. But an indurated sore may also be multiple and non-indurating sores single. Syphilitic virus produces nothing until at least three weeks have elapsed. If you find hard glands in the groin the inference is there has been a chancre on the anus, perineum or genitals; if in the armpit that the hand has been infected. There is such a thing as syphilis without any obvious chancre, but in most such cases some trivial sore has been overlooked. If the sore is inflamed and ulcerated the bubo is inflamed and tends to suppurate. While a primary chancre may never ulcerate it is sometimes nothing but an ulceration. The secondary stage will often begin while the primary one is still existent. Generally two months elapse before secondary symptoms begin. Fruit and green vegetables should be forbidden while taking mercury to prevent diarrhea. [H.M.]

**Syphilitic Fibrous Stricture of the Stomach and Intestines.**—H. Gross<sup>2</sup> describes syphilitic fibrous intestinal strictures as the product of an infection, which characterizes itself mainly through the formation of pure connective tissue. The intactness of the mucous membrane and the cylindrical form of the stricture speak for the syphilitic process causing them as belonging to the simple, irritative, and not to the gummatous form. He relates the details of two cases, in which the diagnosis of pyloric stenosis was made and operations performed. The first patient died suddenly 10 days after the operation, and at the autopsy multiple strictures of the intestines were found. The second patient died several months after the performance of a gastroenterostomy. It presented the same picture as the first case. Microscopic examination in both cases showed the process limited to the submucosa, and composed of inflammatory tissue, rich in cells, and not neoplastic. Scars and syphilitic infiltrations were to be found in the peritoneum surrounding the various abdominal organs. [E.L.]

**Giant-cell Sarcoma of Bone.**—The case reported by J. C. Bloodgood<sup>3</sup> is that of a man of 29 who had a giant-cell medullary sarcoma of the upper end of the tibia, probably dating from trauma received nine years previous. The upper end of the tibia was greatly expanded, containing a bony cavity 7 cm. by 4 cm. (3 by 1½ inches), which was occupied by the new-growth. The knee-joint was not involved. The tumor was removed and the entire bone cavity cureted, swabbed with pure carbolic acid, followed by alcohol, and then irrigated with 1:1,000 bichlorid solution, followed by normal salt solution. The bone was found to be perforated by 25 or 30 vessels as large as the temporal artery, each of which had to be plugged with Horsely wax. Three months after operation the cavity is filling with granulation tissue and no sign of recurrence is present. Bloodgood says he felt justified in attempting a cure by cureting instead of amputation because of the facts brought

<sup>1</sup> British Medical Journal, April 18, 1903.

<sup>3</sup> Johns Hopkins Hospital Bulletin, May, 1903.

out in a recent study of bone sarcoma. Among 42 cases of bone sarcoma in Professor Halsted's clinic, 7 were giant-celled, 4 medullary, and 3 periosteal. These cases are detailed, and the facts regarding them are believed to justify the removal of these tumors without destroying the continuity of the bone. [A.G.E.]

**Early Diagnosis in Cancer of the Stomach.**—Mayo Robson<sup>1</sup> reports in detail a number of cases, and says that removal of even a considerable portion of the stomach may be at times more than a mere palliative operation, and though early diagnosis is very important we may not conclude with some surgeons that a manifest tumor shows the condition too late for surgical interference. His conclusions are: That it is desirable to make an early diagnosis of cancer of the stomach in order that a radical operation may be performed at the earliest possible moment; that it may be needful to perform an exploratory operation in order to complete or confirm the diagnosis; that such an exploration may be done with little or no risk in the early stages of the disease; that even when the disease is more advanced and a tumor perceptible, an exploratory operation is as a rule still advisable in order to carry out radical or palliative treatment; that when the disease is too extensive for any radical operation the palliative operation of gastroenterostomy, which can be done with small risk, may prolong life and make it more comfortable; that some cases thought at the time to be cancer, too extensive for removal, may after gastroenterostomy get well; that in cases of disease of the cardiac end of the stomach too extensive for removal, the operation of gastrostomy may considerably prolong life and prove of great comfort; that even when the disease is too extensive either for removal or for a gastroenterostomy being performed with a fair chance of success, the operation of jejunostomy may occasionally prove of service to the patient; that when a radical operation can be performed the thorough removal of the disease may bring about as much relief to the patient as does the operation for the removal of cancer in the breast, uterus, and other organs of the body, and that in some cases a complete cure may follow. [A.B.C.]

**Enterocystoma as a Cause of Intestinal Obstruction.**—Enterocystoma is the name given to a retention cyst arising in the intestinal end of the omphalomesenteric duct. Eighteen cases have been reported, in four of which the cyst has caused symptoms of intestinal obstruction during life. A. Krogus<sup>2</sup> adds to the latter still another case in which a six weeks' infant showed a steadily increasing degree of constipation, vomiting, later fecal in character, and all the signs of intestinal obstruction. Operation revealed a cystic tumor enclosed between the longitudinal and circular muscle coats of the ileum at the ileocecal junction. The cyst was lined with intestinal mucous membrane. The operation was done in two stages to avoid too severe a shock to the already weakened infant, who, however, died of an unfortunate secondary hemorrhage from a mesenteric artery. [B.K.]

**Provisional Hemostasis in Operations upon the Head and Neck.**—George R. Fowler<sup>3</sup> comments upon the various methods of securing provisional hemostasis, and reports three cases of temporary carotid occlusion—one in a case of gunshot wound of the neck, the other two being intracranial neurectomies. In the first case the common carotid artery was occluded by the twisting of a ligature at the same site on two occasions during the control of hemorrhage. The common carotid was finally ligated at the second operation, but no disturbance followed the first occlusion. In one case of neurectomy hemostasis was practically complete. Slight sensory aphasia followed, but there is doubt as to whether this was due to an embolus or to injury inflicted by the elevator in lifting the central mass of the brain. Circular constriction was used in occluding the artery, but a flat clamp as used by Crile is believed to be a better means, especially in atheromatous vessels. The second case of intracranial neurectomy was accompanied by considerable venous oozing, this probably being due to compression of the internal jugular vein by a compress placed within the loop of the tape to prevent injury to the artery. [A.G.E.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### REVIEW OF LITERATURE

**Accidental Perforation of the Uterus.**—A. Brothers<sup>1</sup> divides these cases into three classes. The first class includes those in which during the passage of the sound or curet the uterus is perforated, and the accident is revealed by the fact that the instrument passes to a depth beyond the length of the uterus. The prognosis is good if the field of operation is aseptic. Internal manipulation should cease at once, and no intrauterine irrigation should be made. If the curetage or sounding was preliminary to an intraperitoneal operation, this may be proceeded with and the injury repaired with several catgut sutures. No drainage is necessary. Otherwise the patient ordinarily can be safely put to bed with an ice-bag over the hypogastrum and given morphin or opiates. 2. If the uterus has been injured and the operator has irrigated the uterine interior, three sets of conditions may arise. In the first a mild peritonitis may call for nothing more than the same line of treatment. In the second set an acute septic peritonitis may call for an immediate hysterectomy (usually vaginal) with drainage per vaginam. The third set of cases may be less virulent and more chronic, are apt to terminate in local abscesses and rarely require hysterectomy. 3. In those cases in which the uterus has been injured and the intestine has been dragged through the wound and become strangulated, laparotomy must be done as soon as possible. If the strangulation has been fatal to the vitality of the bowel, this must be excised. The uterus may then, according to the judgment of the operator, be repaired or removed. Bovée believes that hysterectomy and curetage should be resorted to far less frequently than at present is the case. [W.K.]

**Hepatoptosis.**—N. Saweljew<sup>2</sup> gives a comprehensive description of movable liver in regard to etiology, symptoms, diagnosis and treatment. Whatever leads to a relaxation of the abdominal ligaments, and whatever lowers the intraabdominal pressure may be a direct or indirect etiologic factor. Hepatoptosis occurs much more frequently in women, owing to the relaxing influence of pregnancy and labor. Tight lacing can hardly be considered as an important accessory factor. The displacement of the liver may be sudden, following trauma for instance, or its development is gradual. The symptoms will be acute or chronic, accordingly. Generally speaking, the elements entering into the clinical picture are dragging and fullness of the abdomen, pains, nausea, vomiting, dizziness, constipation or diarrhea, ascites, a peculiar "hepatic" cough, and other allied disturbances. The combination of symptoms are numerous and give a varying picture. The diagnosis rests on palpation and percussion in conjunction with the subjective phenomena. The liver dullness is found to change in different positions, and the organ may be felt in its new location. Movable kidney is excluded without difficulty when its smaller size, different contour, etc., are kept in mind. Hepatoptosis gives a tolerably good outlook *quod vitam*, especially under appropriate treatment and regimen. The patient must be instructed to avoid exertion, succussion and the like; his diet should be regulated with a view toward increasing the fat of the body. The direct treatment consists in replacing the displaced organ by manipulations, and retaining it in the proper situation with the aid of a broad abdominal bandage. These mechanical devices generally afford the sufferer great relief. In the event of their complete failure, however, operative interference may become inevitable, and consists in attaching the liver to the abdominal wall. Hepatopexy has been performed no less than 39 times since its introduction in 1887, and the results justify future resort to the operation. [L.J.]

**Fetal Retention After Rupture of Pregnant Uterus.**—Lajos Goth<sup>3</sup> gives the history of a case in which the fetus was retained two months after uterine rupture. The woman, aged 29, in the latter part of her sixth pregnancy received from a calf a thrust in the abdominal region, resulting in her keeping

<sup>1</sup> American Gynecology, April, 1903.

<sup>2</sup> Medizinskoje Obosrevie, Hx, No. 1.

<sup>3</sup> Zentralblatt für Gynäkologie, April 4, 1903.

her bed for three days, though without any alarming or severe symptoms; but no fetal movements were felt afterward. She then returned to her household duties, but six weeks later, at about term, abdominal pains set in, though without the intermittent character of labor pains or other indication of labor, and ceasing in a few days. A week later there was a hemorrhage of seven days, followed by return of pain with rise of temperature, and the patient was sent to a hospital. Examination showed that the uterine cavity contained pieces of bones, evidently parts of a decomposed fetus. In emptying the uterus there was found a gaping laceration in the anterior cervical wall, which contained the greater part of the fetal remains. No placenta or place of placental insertion could be found. The bones were in size those of a seven months' fetus. Goth believes that this was an instance of interstitial pregnancy, and that the rupture occurred at the time when the patient suffered the blow from the calf, and that because of this rupture the uterus became incapable of labor activity, and acted simply as an ectopic fetal sac, holding the fetal parts without any effort at expulsion. The patient 50 days after the operation was able to leave the hospital. [W.K.]

**The Recognition of Fetal Syphilis.**—Hecker<sup>1</sup> has made thorough examinations of 62 still-born children, and has found 33 (53%) syphilitic, and 6 (9.7%) doubtful. Many of the cases (15 of the 33) could not be definitely considered syphilitic immediately at autopsy, but had to be examined histologically before the diagnosis could be made certain. A macroscopic diagnosis was made only when at least two organs showed undoubted signs of syphilis. The spleen was the organ oftenest affected; then the bones, liver, kidney, etc. For histologic examination the kidneys are the most suitable organs, as they are the last to show signs of maceration, and are found more frequently diseased microscopically than any other organ. They were found involved in 90% of cases—spleen, 61%; thymus, 50%; pancreas, 46%; bones, 43%; liver, 23%; lung, 17%; navel, 16%. The so-called macroscopic syphilitic bone lesions were often found microscopically to be only irregularities due to maceration. He discusses at length the macroscopic and microscopic syphilitic lesions, dividing the former into pathognomonic, probable, and uncertain signs, and considering the latter from the standpoint of the bloodvessels, the connective tissue, the epithelium, and the disturbances of development. He concludes his valuable article with the dictum: Does the autopsy of a mature or immature fetus leave the presence or absence of syphilis in doubt, a microscopic examination should be resorted to. If frozen sections cannot be stained, small pieces of kidney spleen, thymus, pancreas, lung and liver should be hardened. The kidney should be examined first, and in case of negative results, the other organs in the order named. The round cell infiltration about the renal bloodvessels will usually make the latter superfluous. Congenital syphilis may with certainty be said to be absent, only when microscopic examination of all the organs mentioned has shown that none of the pathologic lesions of syphilis were present. [E.L.]

**Labor After Symphysiotomy.**—Otto Ihl<sup>2</sup> contends in opposition to some writers that symphyseotomy usually has a favorable influence upon later deliveries; in many cases indeed the birth passage is permanently enlarged, and in others it is more readily distensible during labor. This is especially true in those cases in which after symphyseotomy there is not a primary union of the parts and a loose joint is formed. He gives the history of a patient who after this operation had three normal deliveries. Whether this advantage in such cases outweighs the disadvantage in walking which results from such a loose reunion of the parts, may be questioned, but Ihl is of the opinion that in many instances such women learn to adapt themselves to changed conditions and regain their power of locomotion, while with others some support, as with a cane, is always necessary. [W.K.]

**Hour-glass Contraction of the Uterus in Breech Presentations.**—According to R. de Bovis<sup>3</sup> but 14 such cases have been reported, to which he adds a fifteenth. The complication, however, has been more frequent with vertex presentations.

The author's case was that of a healthy multipara of 38, who had been in labor 24 hours without apparent progress. Examination under chloroform revealed a left sacroanterior breech presentation partly engaged in the superior strait. The thighs of the fetus were firmly grasped by the contracting ring of Bandl which presented a cartilaginous consistence. In some cases the whole fetus lies above the ring and in others the infant's neck has been caught in the constricting band. The condition is usually accompanied by violent pain. The chief function of the ring of Bandl is to afford a point of insertion for the longitudinal muscle fibers of the uterus. If the circular fibers composing the ring are subjected to excessive strain, as from too frequent or prolonged labor pains, a degree of contraction results varying from simple spasm to tetanization. In the latter condition the elasticity and contractility of the muscle are lost. The contractions of the ring of Bandl may or may not be accompanied by a corresponding contraction of the uterine fundus. Treatment should consist in employing moderate forces to dilate the uterus, bringing down a foot, if possible, to aid in traction on the fetus. If these measures fail, the question of cesarean section should be considered. [B.K.]

**Degenerations and Complications of Fibroid Tumors.**—C. P. Noble,<sup>1</sup> after making a statistical study of 258 cases of fibroid tumors in his own experience, with their degenerations and complications, and reviewing the reports of C. J. Cullingworth, C. C. Frederick, and A. Martin, upon a series of numerous cases, concludes that it is a conservative statement that upward of one-third of women having fibroid tumors will die if not subjected to operation. The contrast with the results which can be secured by operation is very striking. It probably will not be disputed that the mortality of myomectomy and hysterectomy is between 2% and 10%, depending upon the gravity of the case, upon the operator, and upon the environment in which the operations are done. It seems a fair conclusion that the resort to early operation will effect a saving of from 25% to 30% in mortality, in addition to the perhaps greater saving in the morbidity which follows operation, as compared with that which is incident to the history of fibroid tumors. Early operation in the case of young women having one fibroid or a few small fibroids affords the truest opportunity for conservatism by curing these women of their disease and at the same time retaining their organs of reproduction. It seems to him that the attitude of the textbooks should be reversed, and that the rule of practice should be to remove all fibroids which come under observation, unless in a particular case there seems to be some good reason for temporizing, due either to the small size of the tumor, or to the advanced age, or to the general health of the patient. [W.K.]

**Phleboliths in the Female Genitalia.**—K. Czerwenka<sup>2</sup> reports the case of a woman of 40, suffering from metrorrhagia. The walls of the vagina contained numerous dense nodes as far up as the center of the cervix. Upon excision they were found to be phleboliths composed of calcium phosphate and carbonate. They, as well as the uterine hemorrhage, were probably due to stasis in the pelvic veins the result of a previous pregnancy. [E.L.]

**Comparative Examination of Maternal and Fetal Blood and Liquor Amnii and of Fetal Urine.**—W. Zangemeister and Th. Mussl<sup>3</sup> having made a study of this subject conclude that the number of red corpuscles is mostly greater in fetal than in maternal blood; that the white ones are somewhat less, and the red corpuscles of the infant blood are richer in hemoglobin. The maternal blood coagulates more rapidly and more completely, the blood-clot being firmer and the serum of a lighter color. The serum of the mother's blood contains more albumin, hence its specific gravity is greater; also the amount of nitrogen is greater. The chlorids in both kinds of blood are about the same and also the point of coagulation. The liquor amnii has a somewhat less specific gravity and less albumin and chlorids, but the amount of nitrogen is larger than that of either maternal or fetal serum and the point of coagulation is somewhat lower. The molecular concentration of the urine of the newborn is scarcely half as great as that of the blood, and

<sup>1</sup> Deutsche medicinische Wochenschrift, November 6 and 13, 1902.

<sup>2</sup> Münchener medicinische Wochenschrift, April 21, 1903.

<sup>3</sup> La Semaine Médicale, May 20, 1903.

<sup>1</sup> American Gynecology, April, 1903.

<sup>2</sup> Wiener klinische Wochenschrift, January 8, 1903.

<sup>3</sup> Münchener medicinische Wochenschrift, April 21, 1903.

the writers conclude from their extended investigations that the comparatively small molecular concentration of the liquor amnii is caused by the inflow of fetal urine, and that the fetus, at least during the last four months of pregnancy, discharges urine regularly into the liquor amnii. [W.K.]

**Prognosis and Treatment of Puerperal Eclampsia.**—According to W. E. Fothergill<sup>1</sup> when the condition is threatened the prognosis depends on the result of prophylactic treatment. Edema is frequently absent in serious cases. Too much importance must not be attached to the number and severity of the fits which depend not only on the quantity and nature of the poison but on the nervous equilibrium of the patient. The poison may be so virulent as to destroy the irritability of the nervous system. Morphin and other sedatives may mark the true condition. Convulsions after labor is over, point to a grave condition. The most favorable cases are those in which the convulsions are initiated by obstetric manipulations. The quantity of albumin is a false guide, that of urea is much more reliable. If anuria is complete things cannot be much worse. Only 1% of urea points to serious disorganization of metabolism; with 1½% or 2% the prognosis is favorable. During pregnancy signs of toxemia indicate active treatment including rest in bed and eliminatives. Thyroid extract to increase metabolism and promote diuresis is worthy of trial. Should the patient fail to respond to treatment the pregnancy should be terminated. With convulsions and coma saline transfusion and bleeding should be added to the other measures. There is a reaction against active obstetric treatment during eclamptic seizures. Slow induction of labor before any attack has occurred, or after one attack has been tided over is daily becoming more popular. [H.M.]

**The Use of Bossi's Dilator.**—Jentzer<sup>2</sup>, trained in the fear of rapid dilation in accouchement forcé, was so influenced by the warm recommendation of Bossi's dilator that he decided to test its value on the first favorable case. The history of the case is fully given, being that of a primipara brought to the hospital after two attacks of eclamptic convulsions. Others followed and the prognosis for the mother being very bad, he made a rapid dilation by means of Bossi's instrument and with forceps delivered a living child. The uterus contracted well; the placenta was manually delivered and two small lacerations were sutured. The patient, however, died the next day, death being ascribed to the eclamptic poisoning and not to the rapid dilation which at least saved the life of the child. Jentzer concludes that the dilators may be of great service in cases of incomplete abortion. [W.K.]

**The Prevention of Puerperal Eclampsia.**—J. T. Wheeler<sup>3</sup> speaks of the difficulty confronting the physician in general practice if he attempts to give a thorough supervision of the renal condition of his pregnant patients. To obviate this he would teach the laity the insidious nature of the kidney disease of pregnancy and as an object lesson teach the women to examine their own urine at stated intervals for albumen. They should make the test twice a week from the sixth month onward. That this might make the woman nervous or that she might become careless are not considered to be valid objections. Among the poorer classes it would help extend the benefits of prevention to those otherwise utterly deprived of it. Wheeler speaks from an experience of 20 years with this method. [A.G.E.]

**Prolapse of Ureter.**—E. V. Hibler<sup>4</sup> reports that a child 6 months old was brought to the clinic by its mother because of frequent urination. Examination showed in the vulva what appeared to be a thin-walled cyst about the size of a hen's egg attached to a pedicle protruding from the urethra. The cyst collapsed upon being emptied of the fluid and the necrosed part hanging from the urethra was cut off and preserved for examination. The condition of the child, good at first, soon became feverish and uremic and death quickly followed. The autopsy showed that the apparent cyst was a portion of the ureter, which had prolapsed through the bladder and urethra into the vulva. [W.K.]

## TREATMENT

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPELMAN

### REVIEW OF LITERATURE

**Treatment of Local Tuberculosis.**—Ed. Desesquelle<sup>1</sup> has obtained good results in the treatment of suppurating wounds and particularly in tuberculous cervical adenitis by means of injections of iodoform dissolved in camphorated betanaphthol. The quantity of liquid employed depended upon the size of the ganglion, but he never injected more than eight drops. Desesquelle believes that the good results obtained by this treatment were in a great measure due to the hardening action of the naphthol. [L.F.A.]

**Mesotan, a Preparation of Salicylic Acid for External Use.**—Mesotan, the methoxymethylester of salicylic acid, is a light yellow fluid of aromatic odor, soluble in ether and in aryl fluids, and mixable with oil; it is nonirritant for the skin, and after absorption is excreted in the urine as salicylic acid. Roeder<sup>2</sup> has used it 54 times in 150 patients; in cases of subacute rheumatism the results were excellent; they were almost as good in acute polyarticular rheumatism, but less so in rheumatoid arthritis. In peripheral neuritis, especially of gouty origin, no benefit was noticed, and several times dermatitis followed its use, probably due to the action of salicylic acid on inflamed nerves. His method of application consists in painting equal parts of mesotan and olive oil over the affected area, and covering it with cotton or silk. He warns against rubbing it in. [E.L.]

**Pustular Acne of the Face.**—Leredde<sup>3</sup> points out that in the treatment of acne it is necessary not to confound an acne developed on a sensitive skin, as in women, with an acne which appears on a hard skin which is but slightly sensitive. Sulfur is the remedy usually employed; but its action depends not so much on any special property of its own as upon the excipient with which it is incorporated. To this end two sorts of excipients are distinguished; first, agents which congest the skin, obliterate the glands and prevent cutaneous perspiration; the fats; second, the agents which decongest the skin and facilitate cutaneous perspiration: powders and pastes. Pastes are employed when the skin is sensitive. The following paste may be used in profound acne:

Precipitated sulfur . . . . .	20 grams. (5 drams)
Black soap . . . . .	10 grams. (2½ drams)
Pyrogallie acid . . . . .	5 grams. (1 dram)
Zinc oxid . . . . .	30 grams. (1 ounce)
Vaselin enough to make . . . . .	100 grams. (3½ ounces)

The application should be preceded by washing the skin carefully with salicylated soap. The paste should be applied in the evening and left in contact all night when the skin is hard; in women it should be removed at the end of one or two hours. Large quantities of sulfur are borne better when prescribed in this form than when prescribed in ointment in smaller quantities. The following ointment may be used when the skin is not sensitive:

Precipitated sulfur . . . . .	5 grams. (1 dram)
Calomel . . . . .	2.5 grams. (½ dram)
Lanolin . . . . .	20 grams. (5 drams)
Vaselin . . . . .	75 grams. (2½ ounces)

General treatment should be instituted at the same time to correct any gastric disturbance which may be present. [L.F.A.]

**The Influence of Digitalis on Blood-pressure.**—In an interesting dissertation P. I. Tsiplajew<sup>4</sup> details his observations on the action of digitalis in cardiac disease with loss of compensation. He summarizes his conclusions as follows: (1) Digitalis at first increases arterial pressure in uncompensated heart affections; (2) this increased pressure, after having reached its maximum, gradually falls in favorable cases independently of further administration of digitalis; (3) the fall of arterial pressure is preceded by an increased difference between capillary and venous pressure and by slightly marked diuresis; (4) the increase of the difference between venous and capillary

<sup>1</sup> Medical Chronicle, March, 1903.

<sup>2</sup> Zentralblatt für Gynäkologie, May 9, 1903.

<sup>3</sup> Albany Medical Annals, June, 1903.

<sup>4</sup> Wiener klinische Wochenschrift, April 23, 1903.

<sup>1</sup> Bulletin Général de Thérapeutique, Vol. cxlv, No. 8, 1903, page 299

<sup>2</sup> Münchener medicinische Wochenschrift, December 16, 1902.

<sup>3</sup> Journal des Praticiens, Vol. xvii, No. 11, 1903, page 168.

<sup>4</sup> Dissertation, St. Petersburg, 1903.

pressure corresponds closely to an increased daily quantity of urine; a diminution in the pressure difference is accompanied by diminished urine excretion; (5) in unfavorable cases neither the increased difference of pressure nor the diuresis nor the arterial pressure fall have been noted; (6) in favorable instances arterial pressure falls secondarily below its original level; this pressure is originally increased above normal during loss of compensation, while the difference between venous and capillary pressure is diminished in these cases; (7) during attacks of dyspnea blood-pressure rises; (8) digitalis shows its effects in the first 24 hours of treatment; (9) the drug exerted its best influence in organic mitral lesions, which also presented the least difference between venous and capillary pressure; (10) the beneficial action of digitalis cannot be attributed to its stimulating effect on arterial blood-pressure; (11) palpation of the pulse gives no reliable account of the blood-pressure. Under digitalis administration the pulse-curve shows higher excursions. [L.J.]

**Treatment of Ozena.**—Vaquier<sup>1</sup> recommends copious douches of hot water containing sodium chlorid, sodium bicarbonate, lysol, gomenol or naphтол in solution in order to detach the crusts. A small quantity of one of the following ointments may then be introduced:

- Menthol . . . . . 0.3 gram (4½ grains)
- Boric acid . . . . . 2 grams (30 grains)
- Vaselin . . . . . 30 grams (1 ounce)
- or,
- Gomenol . . . . . 5.0 grams (1 dram)
- Resorcin . . . . . 1 gram (15 grains)
- Vaselin . . . . . 30 grams (1 ounce)
- or,
- Diiodoform . . . . . 5 grams (1 dram)
- Vaselin . . . . . 20 grams (5 drams)

The injection of antidiphtheric serum has been used to aid the catarrhal secretion which eliminates the crusts. Local application of iodine or the iodids after cocain anesthesia has given excellent results. The following may be used twice a week by means of a cotton applicator:

- Iodin,
- Potassium iodid of each . . . . 1 gram (15 grains)
- Distilled water . . . . . 6 grams (1½ drams)

The internal administration of from 1 gram to 2 grams (15 grains to 30 grains) of potassium iodid daily for 15 days causes an increase in secretion and acts as a stimulant to the nasal mucous membrane. [L.F.A.]

**Theocin, a New Diuretic.**—Theocin, a new synthetic caffeine compound, is twice as effective in increasing the flow of urine as theobromin is. It is easily soluble, less poisonous than theobromin, and is used in powder form in doses of ½-1½ grams (7½-18 grains) daily. It acts much quicker than theobromin, but as its effect is lost quickly it cannot entirely displace this remedy. It cannot displace caffeine, as it has no stimulating action for the heart; it also does not influence blood-pressure. It is indicated in cases where a large edema must be removed quickly. C. Doering<sup>2</sup> reports his results in seven cases, which were uniformly favorable. [E.L.]

**The Action of Methylene-blue on Tuberculous Ulcerations.**—Louis Rénon and E. Geraudel<sup>3</sup> have treated five tuberculous patients suffering from ulcerations of the tongue and of the soft palate by daily local applications of powdered methylene-blue. These patients were nearing the last stage of pulmonary tuberculosis and the results of the treatment were remarkable. In all the cases there was a very marked diminution in the pain which had rendered eating almost impossible, and the local condition was much improved. The ulcerations became clean; they diminished in depth and extent, and cicatrized from the bottom and from the sides, the yellow points disappeared. In three cases cicatrization was complete and remained so until death. [L.F.A.]

**Action of Electric Baths.**—A. P. Rosen<sup>4</sup> has studied the action of electric light and light-heat baths on healthy men. He publishes a few preliminary conclusions, of which we shall

only note the marked improvement of appetite and sleep that followed a series of 12 baths. A gain in bodily weight was also recorded after the light-heat baths. These favorable changes seemed to be lasting. The manner in which the blood reacted to the baths, showing now a numerical increase, now a diminution of the cells, is also mentioned by the author. The subject will receive a more thorough future exposition at his hands. [L.J.]

**Anesthesin in Rhinology.**—A Courtade<sup>1</sup> reports his results from the use of anesthesin in rhinology. This substance is a paraamidobenzoic ether which is slightly soluble in cold water, and readily soluble in chloroform, acetone, oils and fats. It is also soluble in hot glycerin but precipitates when the temperature is lowered. A mixture of anesthesin and pure carbolic acid when heated forms a very limpid liquid which solidifies upon cooling; if, when the mixture is still liquid, hot water is added, there is a separation of a powdery product which consists of anesthesin, if, on the contrary, glycerin is added, the solution remains liquid and clear, even at the ordinary temperature. Courtade employed the powdery product in his clinical work. Its local application by means of a cotton probe produces anesthesia of the area to which it is applied. Several cases are reported in which anesthesin was successfully employed in the removal of enlarged tonsils, for the relief of the pain and dysphagia accompanying tuberculous laryngitis, and in syphilitic ulceration of the larynx. In laryngitis accompanied by painful dysphagia Kessel employs anesthesin in solution in olive oil, as follows:

- Anesthesin . . . . . 20 grams (5 drams)
- Menthol . . . . . 10 to 20 grams (2 to 5 grains)
- Olive oil . . . . . 100 grams (3½ ounces)

The menthol may be omitted if it is badly tolerated or is useless. In these cases, Courtade prefers to use the drug by insufflation or by means of a cotton applicator. No symptoms of irritation or intolerance have followed its use. Anesthesin may also be used internally for the relief of pain due to gastric ulcer. [L.F.A.]

**Death Following Benzine Poisoning.**—Racine<sup>2</sup> reports the case. A child of 2 years, who shortly after drinking between 10 and 15 grams (2½-4 drams) of benzine lost consciousness. Her pupils dilated and became fixed, she became cyanosed, and the skin was cold to the touch; her respirations became more and more rapid and shallow, her pulse small and galloping; clonic cramps set in later and death followed within two hours of drinking the benzine. Ether injections produced no results; lavage was not attempted. The autopsy performed two days later revealed an almost identical picture with carbon monoxid poisoning. The cadaveric lividity was of a marked light red, the blood very fluid and cherry red, and almost all the red blood-corpuses were broken up. Petechia and hemorrhagic extravasations were found in all the internal organs; there was follicular gastroenteritis and hyperemia of the brain and its membranes. [E.L.]

**Collargol in Therapeutics.**—Netter<sup>3</sup> reports good results from the use of collargol in the treatment of endocarditis, bronchopneumonia and diphtheria. In two cases of rheumatic endocarditis in which a mitral murmur was heard, two intravenous injections of 5 cc. (80 minims) of a 1% solution of collargol caused this to disappear in a few days. In bronchopneumonia, the injection of collargol produced marked improvement in the general condition of the patient and at the same time lowered temperature. Its employment in diphtheria, associated with serum therapy has greatly lessened the mortality in grave cases of this disease. No dangerous symptoms have followed the intravenous injection of collargol in doses of from 4 cc. to 9 cc. (1 dram to 2½ drams) of a 1% solution. In using collargol externally, Netter insists on previous careful cleansing and antiseptic of the skin as in preparation for an operation. An ointment containing 15% of collargol in benzoinated lard with 10% of wax is applied daily or twice daily accompanied with active friction for 10 minutes. The area is then covered with gauze and oiled silk. [L.F.A.]

**Changes in the Medical Corps of the U. S. Army for the week ended June 20, 1903:**

BARRON, First Lieutenant NOEL I., assistant surgeon, now at Fort Wright, will remain at that post until the departure of Cos. K and M, 17th infantry, for San Francisco, Cal., which organizations he will accompany to San Francisco, Cal., where upon arrival he will report to the commanding officer 17th infantry, to accompany that regiment to the Philippine Islands.

HUNTINGTON, First Lieutenant PHILIP W., assistant surgeon, now at Vancouver Barracks, will proceed to Boise Barracks in time to report to the commanding officer of that post June 20 to accompany Co. I, 17th infantry, to San Francisco, Cal., where he will report to the commanding officer 17th infantry to accompany that regiment to the Philippine Islands.

BAILEY, Contract Surgeon EDWARD, now at Vancouver Barracks, will proceed to Fort Canby for duty to relieve Contract Surgeon James E. Miller, whose contract is annulled to take effect June 2.

PARKMAN, Contract Surgeon WALLACE E., is granted leave for one month, from about June 30, with permission to apply for an extension of one month.

BROOKS, Contract Surgeon JOHN D., is granted leave for one month from about June 10.

FIELD, First Lieutenant PETER C., assistant surgeon, leave granted April 9, is extended 15 days.

SHORTLIDGE, First Lieutenant EDMUND D., assistant surgeon, having completed the duty for which he was ordered to Washington, D. C., June 3, will rejoin his proper station at the United States general hospital, Presidio.

So much of orders of December 29 as direct Captain PAUL F. STRAUB, assistant surgeon, to proceed to San Francisco, Cal., for duty to accompany troops to the Philippine Islands is so amended as to direct Captain Straub upon the expiration of his present leave to proceed to Camp Monterey, Cal., for duty.

WATKINS, V. E., contract surgeon, is granted leave for one month, from return to Fort Huachuca of Contract Surgeon I. W. Brewer from duty at Whipple Barracks.

APPEL, Major DANIEL M., surgeon, is placed on waiting orders at headquarters department of the Colorado for the convenience of the government.

HOLMES, THOMAS G., contract surgeon, is granted leave for one month, from about June 15.

SHORTLIDGE, First Lieutenant EDMUND D., assistant surgeon, is granted leave for one month.

WILSON, ROY A., contract surgeon, is granted leave for two months.

SMITH, First Lieutenant R. M. KIRBY, assistant surgeon, is granted leave for 20 days, from about June 20.

BOSLEY, JOHN R., contract surgeon, will proceed from Washington, D. C., to Governors Island, N. Y., and report to the commanding general, department of the East, for assignment to duty.

**Changes in the Medical Corps of the U. S. Navy for the week ended June 20, 1903:**

PARKER, J. B., medical director, retired from active service, from June 20, 1903, under provisions of section 1454, R. S.—June 13.

ANDERSON, F., medical inspector, commissioned medical inspector, from January 31, 1903—June 13.

TAYLOR, J. S., passed assistant surgeon, commissioned a passed assistant surgeon, from November 8, 1902—June 13.

MANCHESTER, J. D., DESSEZ, P. T., and WOODWARD, J. S., appointed assistant surgeons, from June 10, 1903—June 15.

DICKSON, S. H., medical inspector, ordered home and to wait orders—June 18.

MORRIS, L., passed assistant surgeon, detached from the Puritan and ordered to the Florida—June 18.

KEENE, W. P., acting assistant surgeon, detached from the Truxtun and ordered to duty with the second torpedo flotilla—June 18.

**Changes in the Public Health and Marine-Hospital Service for the week ended June 18, 1903:**

GLENNAN, A. H., assistant surgeon-general, detailed as assistant surgeon-general in charge of the domestic quarantine division in the Bureau of Public Health and Marine-Hospital Service—June 10, 1903.

STONER, J. B., surgeon, granted leave of absence for one month from June 30—June 18, 1903.

ROSENAU, M. J., passed assistant surgeon, to proceed to Greenpoint, N. Y., for special temporary duty—June 18, 1903.

NYDEGGER, J. A., passed assistant surgeon, relieved from duty at Cincinnati, Ohio, and directed to proceed to Sault Ste. Marie, Mich., as inspector of immigrants—June 13, 1903.

SPRAGUE, E. K., passed assistant surgeon, granted leave of absence for seven days from June 4, 1903, under paragraph 191 of the regulations.

GRUBBS, S. B., passed assistant surgeon, bureau telegram of May 13, 1903, granting leave of absence for one month, amended so that said leave shall be for one month from May 23—June 13, 1903.

DECKER, C. E., assistant surgeon, granted extension of leave of absence, on account of sickness, for twenty-two days from June 9—June 17, 1903.

LORD, C. E. D., assistant surgeon, relieved from duty at Galveston, Texas, and directed to report to medical officer in command at San Francisco Quarantine for assignment to special duty—June 18, 1903.

SIBREE, H. C., acting assistant surgeon, granted leave of absence for six days from June 16—June 15, 1903.

CARLTON, C. G., pharmacist, granted leave of absence for thirty days from June 1—June 6, 1903.

*Boards Convened.*

Board convened for the examination of Assistant Surgeon M. K. Gwyn to determine his fitness for promotion to the grade of passed assistant surgeon. Detail for the Board—Assistant Surgeon-General L. L. Williams, chairman; Assistant Surgeon-General W. J. Pettus, and Assistant Surgeon V. G. Helser, recorder.

Board convened for the examination of Assistant Surgeon W. C. Hobby to determine his fitness for promotion to the grade of passed assistant surgeon. Detail for the Board—Assistant Surgeon-General L. L. Williams, chairman; Assistant Surgeon-General W. J. Pettus, and Passed Assistant Surgeon L. E. Cofer, recorder.

# INDEX

Abbott, M. E.: On the classification of museum specimens, 541.

Abdomen—gunshot wound, 527; operating through in pyosalpinx, 858.

Abdominal—affectious, obscure, exploratory celiotomy, 772; aorta, traumatic rupture, 368; cavity, foreign bodies in, 855; disease, blood-counts in, 33; hysterectomy, with bisection of uterus, 813; hysterectomy for uterine fibroids, 234; incision, method of closing, 216; operations, peritoneal saline infusions, 984; pain in enteric fever, 152; pain in pleurisy and pneumonia, 771; pain, obscure, operative treatment, 194; pregnancy, primary, 356, 759, 928; pregnancy, secondary, 511; rigidity, 110; section for pelvic disease, 527; surgery, complications, 508; surgery, Fowler's position in, 48; wall, foreign body in inflammatory tumor, 276; walls, contusion, intestinal obstruction following, 49; wounds, in war, 76.

Abortion, recurrent, 758.

Abrams, Albert: Some cardiorespiratory phenomena revealed by the Röntgen rays, 11.

Abscess—bloodless treatment, 37; brain, otitic, 507, 840; cerebellum, 857, 863; ischioanal, and retention of urine, 434; liver, 115, 274, 352, 434, 716; pelvic, following osteomyelitis, 252; peridoneal, 249, 430; perisinal, of lateral sinus, 868; periurethral, in female, 636; Pott's, 981; pulmonary, 671; retrocecal, 70; retroperitoneal, 836; splenoid, 335; subcutaneous, due to gonococcus, 271; subphrenic, 190, 511; temporo splenoid, 857.

Absorption, influence of nephrectomy upon, 131.

Absstinence, total, manifesto of physicians, 2, 8.

Accessory thyroid tumors at base of tongue, 170.

Accidents—deaths due, 482; life-cost, 847.

Accouchement forcé, Bossi dilator in, 886.

Acetanilid poisoning, chronic, 352.

Achondroplasia, 432.

Achylia gastrica and pernicious anemia, 388.

Acid—boric, abuse of, 275; carbolic, vinegar as antiseptic, 719; oxalic, in urine, 239; salicylic, substitutes, 673.

Acids, and acid salts, influence on cells, 515.

Acne, treatment, 36, 1038.

Aconite—limitations, 781; toxic agent in aino arrow-poison, 674.

Acroparesis following traumatism, 72.

Actinomycosis—in America, 115; of bones of tarsus, primary, 754.

Actinomyotic appendicitis, 1011.

Actinotherapy—in neurasthenia, 903; practical results, 112.

“Adamkiewicz” cancerin, 236.

Addison's disease and genital tuberculosis, 517.

Adenitis, acute suppurative cervical, of infancy, 777.

Adenocarcinoma of rectum, 755.

Adenoids—and enuresis nocturna, 509; and malaria, 508; and trachoma, 70.

Adenoma—of rectum, 755; of stomach, benign, 237.

Adenosarcoma, embryonal, in kidney, 816.

Adhesions in nose, to prevent, 388.

Adiposis dolorosa, 191.

Adrenal tumors, 516.

Adrenalin, 474, 630, 758.

Adult and child, anatomic and physiologic correspondence, 777.

Adulterated wines and meats, to prohibit, 892.

Adulteration—and adultery, 283; of foods, Queensland and United States, 320.

Advertisements—in newspapers, indecent and fraudulent, 977; quack, imaginary Bright's disease, 363.

Advertiser, big and little, 362.

Advertising dodge, 642.

Africa, west coast, diseases on, 1033.

Age—limit in uterine carcinoma, 1012; old pride in, 123.

Agglutination in differentiating of bacilli, 353.

Agglutinins, effect of, on bacteria, 897.

Agrin, 37, 159, 1003.

Air—compressed, in remedies acting on cerebrospinal axis, 529; dry hot, as therapeutic agent, 626, 822.

Air-tracts, emphysema of, from vomiting, 417.

Akromegaly, chronic, 752.

Albuginotomy in chronic orchitis, 754.

Albumen preparation, new, myogen, 842.

Albumin—digestion with and without carbohydrates, 353; in surgical patients, 1020; in urine, 231; in urine, Pollacci's test, 175; of blood-serum, carbohydrates of, 238; on coagulation of blood, 237.

Albuminuria—122 cases at University of Pennsylvania Hospital, 694; immunization against, 1010; in diabetes, 900; orthostatic, 593.

Albumose—452; Bence-Jones, rapid reaction for, 238, 488.

Albumosuria—747; Bence-Jones, 473.

Alcohol—and proprietary foods, 469; effect on circulation in fevers, 1020; germicidal action, 881; in infectious diseases, 980; legitimate therapeutic use, 781; mental dissolution, result 395; methyl, toxicity, 113, 150, 801; pathologic effects, 31, 781.

Alcoholic—beverages, consumption, 562; epilepsy, 395; insanity, mental states in, 547.

Alcoholics, psychic disturbance in, 972.

Alcoholism—and meat-eating, 639; crime, and insanity, 1030; forms of, 641; in children, 3; “patent medicines,” “bitters,” and nostrums, cause, 441.

Aldrich, Charles J.: Chorea and eyestrain, 728: The psychic nature of some disturbances of the acts of urination and defecation 489.

Alexander's operation, 28.

Alimentary canal—iron absorption from, 780; operation, in, and rest, 433.

Alopecia, treatment of, 119.

Altitude—high, and increased blood counts, 747; high, and nervous cardiac symptoms, 261; high, anomalies of respiration in, 838; high, typhoid at, 772; hypercythemia, effect of in producing, 760; low and high, impressions of differences of practice at, 592; mortality of pneumonia, 836; on heart disease, 942; on pneumonia, 947; various, increase in erythrocytes and hemoglobin, 761.

Amblyopia—tobacco, 858; toxic, from wood alcohol, 801.

Amblyopic eye, treatment, 905.

Ambulatory automatism, 862.

Amebic abscess of liver and amebic dysentery, 115.

Amebic dysentery—at Johns Hopkins, 771; clinical history and pathology, 771.

American Italy, 748.

American Medical Association—and ethics, 763; medical ethics of principles, 796.

Ammii, liquor, 1037.

Amoeba coli, in dysentery, 193.

Amputation—interscapulothoracic for sarcoma of brachial plexus, 668; of limb in arteriovenous aneurysm, 962; painless, leg, 749.

Amygdalotomy, 547.

Amyotrophic lateral sclerosis, 534.

“An honest pensioner,” 978.

Anal—diseases, treatment, 906; fissure, no operation, 927.

Analgesia, spinal, 756.

Anastomosis—intestinal, 33, 76, 590, 757, 1041; ring, 800.

Anatomy—how to study, 69; of gallbladder surgery, 748; of pancreas, 810, 996; of perirenal fatty tissue, 171.

Anders, J. M.: Social conditions in America in their relation to medical progress and disease, 735.

Anderson, C. L.: Atypical variola, 369.

Anemia—and chronic enlargement of spleen, 940; and occlusion of artery of retina, 472; pernicious, 101; pernicious and achylia gastrica, 388; pernicious, following enlarged thyroid, 672; primary and secondary pernicious, and Bothriocephalus latius, 192; severe, probably pernicious, 31; splenic, 71, 714; treatment, 154.

Anencephalus, 476.

Anesthesia—chloroform, death in, 355; dangers in, 803; ether, for appendicectomy, emphysema following, 417; ether or chloroform, nitrous oxid as preliminary to, 263; general, improvement of; anesthetic, 427; general, shock from, 747; local, cocaine in, poisoning following use, 369; local, in inguinal hernia, 306; preparation of patient for, 845; pulmonary, 389; spinal, 271; ultraviolet ray, in minor surgery, 648.

Anesthetin, 118, 1013, 1039.

Anesthetic—general, ethyl chlorid as, 69, 279; in nose, throat, and ear operations, 607; new, narcotile, 980; primary to ether, ethyl bromid as 392.

Anesthetize, how shall we?, 355.

Anesthol, 427.

Aneurysm—191; aortic, 155, 353, 379, 593, 884; arteriovenous, of femoral vessels, 962; femoral of, external iliac treatment, 800, 1020.

Angina—pectoris and allied conditions, 115; syphilitic pseudo-membranous, 74; unusual case, 729.

Angioma—cutaneous, and malignant disease, 28; multiple, 942; of liver, large, 595.

Angioneurotic—erythema, neurectomy in, 972; purpura, 616.

Angiosclerosis of intestinal arteries, 311.

Angiotribe—Downes' electrothermic, 109; electrothermic, in varicocele, 548.

Animal—bones, differentiation, 553; cell and staining mixtures, 236; organism, effect of adrenalin on, 630.

Animals—cruelty to, 204; wild, performing case of, 602.

Ankylosis—bony, excision of knee for, 817; cicatricial, of jaws, 983; cricoarytenoid articulation due to inflammation, 188.

Ankylostomiasis, 68, 604, 822.

Anomalies of respiration in high altitudes, 838.

Anorectal diseases, treatment, 906.

Anthelmintic, new, thymol urethane, 36.

Anthracoosis, 884.

Anthrax toxin, 781.

Anthropometric signalment, x-light in, 799.

Antidiabetic diet, 780.

Antienzymes, 855, 941.

Antimalarial prejudice not chief cause bad ventilation, 933.

Antimony, chemistry of, etc., 1016.

Antipyresis in children, 353.

Antirennene, 782.

Antisepsis—intravascular, 477; obstetric, 27; systemic, 713.

Antiseptic—intestinal, ichtholbin, 931; surgery, 116.

Antiseptics—in hand disinfection, 331; intestinal, 781; on bacteria in intestines, 753.

Antistreptococci serum, 73.

Antisyphilitic treatment, principles, 35.

Antitoxic—serums, 512; veratrum viride as, 111.

Antioxin—and pharmacopeia, 747; diphtheria, 311; diphtheria, in infantile bronchopneumonia, 91.

Antituberculosis—campaign, 747; serum, 445.

Antityphoid serum, 484.

Antivivisectionists—as self-describers, 848; attention of is call'd, 765.

Anuria, 159, 314, 815.

Anus—artificial, after repeated operations, 981; peculiar etiology, rare localization, 157.

Aorta—abdominal, traumatic rupture, 363; compression, in postpartum hemorrhage, 368, 568, 987; descending, aneurysm, 379; embolism of, in typhoid, 631; tuberculosis of, 1042.

Aortic—aneurysm, 155, 332, 598, 884; insufficiency, functional, in Hodgkin's disease, 802; valve, rupture of, accidents, 673.

Aphthæ in children, 821.

Apomorphia, 486, 648.

Apparatus for application of local cold in genital tract, 158.

Appendicectomy—emphysema following ether anesthesia, 417; three unique cases, 51.

Appendicitis—307, 407, 510, 1011; cases, simulating, 700, 757; clinical manifestations and pathologic findings, 390; diagnosis, 191; early operation, 749; first operation in Warren county, Pennsylvania, 606; from gynecologist's standpoint, 775; gangrene after operation, 981; hemorrhagic, and purpura hemorrhagica, 271; insurance for, 166; leukocytes in, 475; mortality in, 749; operation, 49, 194, 860; prophylaxis, 389; recurrent, 550; retrocecal, with pelvic abscess, 836; subphrenic abscess in, 190; toilet of peritoneum in, 812, 994; toxicity; black vomit in, 711; unusual cases, 51, 882; when to operate, 76.

Appendix—gangrenous, constriction of small intestine by, 632; rupture, 47; sarcoma of, primary, 757.

Aristochin, 316.

Arizona, tuberculosis in, 312.

Army—cartridge belt, 271; assistant surgeons in, 45; drink in, 165; nurse corps, 561; arrow-poison, aino, 674.

Around the world via Siberia, 643.

Arsenic in animals, 443.

Arterial tension, routine for determining, 428.

Arteries—division of, in chronic simple glaucoma, 675; intestinal, angiosclerosis of, 311; ovarian and hypogastric, ligation of, for inoperable uterine carcinoma, 551.

Arteriosclerosis, 154, 250, 589, 677.

Arteriovenous aneurysm of femoral vessels, 962.

Artery—external iliac, treatment, 801, 962, 1020; middle meningeal, hemorrhage from, 313; superior temporal of retina, occlusion, 472.

Arthritis—and gonorrhœal conjunctivitis, in newborn, 676; deformans, 900; gonorrhœal, 194, 235, 1032; infective, 194; pneumococcus, 157, 605.

Ascites—chylous, from occlusion of thoracic duct, 229; chronic obliterative pericarditis with, 190; disproportionate, in serositis, 273; fibroma of ovary with, 415; in cirrhosis of liver, 801; surgical treatment, 748, 843.

Asepsis—operative, 634; ophthalmic, 905.

Aseptic—labor, 969; method of Lister, 116; surgery, 116, 194, 390.

Asphyxia, lumbricoid worms obstructing larynx, 929.

Aspiration in empyema, 925.

Aspirin, aftereffects, 1013.

Asthma, 448, 844, 1013.

Astigmatism—and wet packs, 283; corneal, 591, 840; high, 676; operation in, 306, 1009.

Ataxia—hereditary, 865, 1020; locomotor, treatment of, 79, 396, 397.

Atheroma of Hodgkin's disease, so-called functional, aortic insufficiency in, 802.

Athletic—habit, 343; overstrain, 383.

Atmospheric pressure in hip-joint, 627.

Atony—of duodenum, 927; of rectum and anal sphincters, 906.

Atrophy—of hand muscles, 945; of optic nerve, 662, 822; of skin, progressive idiopathic, 108; of uterine mucosa, 158.

Atropin—action, 37; unexpected effects, 987; in intestinal obstruction, 36, 312, 313; poisoning from ocular instillations, 528.

Aural fibroma, 899.

Auscultatory resonance and percussion, 747.

Autopidermic skin-grafting, 1008.

Automatism, ambulatory, 862.

Autres temps, autres meurs, 204.

Avulsion—of tibial tubercle, 1007; of scrotum, skin of penis, left testicle, 815.

Axis, cerebrospinal, remedies upon, compressed air to enhance and prolong action, 529.

- Babies, we are killing fewer, 682.**  
 "Baby-killers," two industrious, 639.  
 Baby, the murdered, and physician, 561.  
 Baccelli's method in traumatic tetanus, 79.  
**Bacilli**—differentiation of diphtheric and pseudodiphtheric, 353; in dysentery, 816; pathogenic, and Chicago drainage canal, 975; tubercle, and acid-proof saprophytes, 753; tubercle, from tuberculous foci in man, virulence of, 750; dysenteric and allied, in normal intestine, 816; war waged by, 889, 898.  
**Bacilluria** in typhoid, 473.  
**Bacillus**—aerogenes capsulatus, 545; chancreoid, 897; coli communis, 516, 743, 781; colon, suppurative meningitis due to, 192; epidemic dysentery, 516; from fatal diarrhea, 807; influenza, 387; of bubonic plague, 533; Shiga, in diarrhea epidemic, 545; tubercle, bacteriolysis of, 897; tubercle, isolating from body fluids, 515; tubercle, morphology, 897; typhoid, dissemination, soil, flies, and fabric, 514; typhoid, in urine and sputum, 270; typhus, chemistry, 781; typhus in peritonitis in typhoid without perforation, 700; typhus, intracellular substance, toxicity, 781.  
**Backache, 969.**  
**Backenstoe, M. J.:** Influence of marriage and pregnancy on diseases of the heart, 461.  
**Bacteria**—and corrosive sublimate solution, 710; cell substance of, products of metabolism in, 236; flagella and bodies of, agglutinins upon, 897; in conjunctiva, cornea, and other eye parts, 905; in eye inflammations, 905; in intestines, antiseptics on, 753; pathogenic, intracellular toxins of, 545; saprophytic, proteolytic enzymes and so-called hemolysins of, 816; to give light, 845.  
**Bacterial**—agencies in endocarditis, 94; intoxication and fatty degeneration, 239.  
**Bacteriologic**—blood examination in surgery, 631; diagnosis in medicine, 513; diagnosis of typhoid, 843, 884; studies of skin and throat in scarlatina, 609.  
**Bacteriology of blood in typhoid, 753.**  
**Bacteriuria and Weil's disease, 970.**  
**Bad personal characteristics and official positions, 847.**  
**Baker, Albert R.:** Eyestrain as a cause of chorea, 410.  
**Balantidium coli;** pathogenicity of, 1033.

Charities, medical, in London, 1015.  
Charity, prosthetic, trials and humors, 362.  
Chaulmoogra oil, administering, 552.  
Check, slate pencil in, 368.  
Chemical—pathology, 189; structure, is pharmacologic action determined by?, 780.  
Chemistry of antimony, 1016.  
Chest—accidental gunshot wound of, 290; pain, 259.  
Chestnut-bur thorns in cornea, 39.  
Cheyne-Stokes, breathing, 753.  
Chicago's drainage canal—and sewer system, 442; and pathogenic bacilli, 975; and waterborne infection, 975; recent typhoid epidemic, 764.  
Chickenpox, 482, 863.  
Child—and adult, anatomic and physiologic correspondence, 777; illegitimate, mother, physician, etc., 479; labor and disease, 282; labor, illiteracy, etc., in different states, 764; labor reform, 202; labor, sober second thought, 849; lobar pneumonia in and acute pemphigus, 312; nervous, over school, study of, 766; school, a typical, 281.  
Childhood—early, in rphin poisoning, in 311; infectious or bacterial bronchopneumonia of, 91; subcutaneous gelatin injections, 1034.  
Children—alcoholism in, 3; amyotrophic lateral sclerosis in, 534; antipyraxis in, 353; aphthæ in, 821; artificially fed, quantity of milk to be given, 275; catarrhal pneumonia in, treatment, 903; clubfeet in, treatment of, 197, 199; cry of, answered, 320; deaf, training in speech of, 284; development and care, 777; diabetes mellitus, in, 509; employed in factories, certificate of fitness to, 72; epilepsy in, causes, 408; feeding, 219; female genitalia in tuberculosis of, 435; flatfoot in, 667; fracture of femoral neck in, 882; gonorrhœa in, 234, 302; heart disease in, 751; hernia in, 634, 749; heppes in, 821; homeless, homes for, 481; hardening, so-called of, 309; influenza in, 861; joint disease in, chronic, described by Still, 753; leukemia in, 753; liver abscess in, 434; measles and scarlet fever in, blood in, 238; osteomyelitis in, 157; pleuritic effusion in, new sign, 310; polyarthritis in 669; pulmonary edema in, 885; school, care of eyes of, 264; school, examined for spinal curvatures, 199; scleroderma, pathology and treatment, 714; summer diarrheas, pathology, 820; tetany, diagnosis of, 193; therapeutics of, 308; tuberculosis peritonitis in, treatment, 842; typhoid in, 274; typhoid mortality in, 884; urine of, safranin reaction, 908; vomiting in, (cyclic), 114, 545; vulvovaginitis in, 469, 973.  
Chinatown, work in, 726.  
"Chiro" and "chiropractics," 562.  
Chloroform—anesthesia, nitrous oxide as preliminary to, 263; in gynecologic practice, 76; in labor, 487; oxygen narcosis, chemistry, 756.  
Chlorophyl, Nenckl's researches on hemoglobin in relation to, 237.  
Chlorosis, 154, 1001.  
Cholecystectomy, 355, 773; vs. cholecystorrhaphy and cholecystostomy, 860.  
Cholecystotomy for stone in common duct, 355.  
Cholelithiasis—434; and pancreatitis, 883; pancreatic disease simulating, 632.  
Cholera—287, 725, 850; infantum, antitoxin to combat, 405.  
Chorea—and eyestrain, 410, 728; of pregnancy, recurrent, 636; treatment of, 816.  
Chorioepithelioma of uterus, 151.  
Choroid, leukosarcoma, 900.  
Choroiditis, types, 508.  
Christian, Henry A.: Secondary carcinoma of the liver, with report of a case in which the liver weighed 15,110 gms. (33 $\frac{1}{2}$  lbs.), 131.  
Christian—hospital scheme, 805, 935; science, 402.  
Chromatopsia following labor, 408.  
Chyme, routine examinations of, 298.  
Cicatrical—ankylosis of jaws, 983; contractures of upper extremities, 250, 578; ectropium, 746.  
Ciliary—muscle, cramp of, and eye-stain, 905; spasm, myopia of nine diopeters from, 38.  
Circulation—chronic states of, simulating heart and kidney disease, 593; collateral, failure of in arteriovenous aneurysm, 962; in fevers and alcohol, 1020; in puerperal eclampsia, 883.  
Circumcision and venereal disease, 34.  
Cirrhosis—of liver and splenic leukemia, 940; classification, 113; operative treatment, 929; pancreas in, 312; surgical treatment, 31; with ascities, 801; with splenomegaly, hypertrophic, 672.  
Cities, deserted, 320.  
Clavicles, congenital absence, 569.  
"Cleaning by vacuum," 480.  
Cleanliness and public health, 559.  
Cleidocranial dysostosis, 569.  
Clemens, J. R.: Colchicum in diabetes mellitus, 449.  
Cleveland, tuberculosis in, 308, 322.  
Climatotherapy of functional neuroses, 931.  
Clinical notes, 323.  
Llave oil, surgical uses of, 9.  
Clubfeet in children, 197, 199.  
Coal famine—and increased mortality, 163, and public health, 209.  
Cocain—among laity, 548, 948; concerning, 39; hermitism, 969; incompatibility of camol with, 196; in local anesthesia, poisoning following use, 369; in nose, 884.  
Cocaineization of superficial cervical nerve, 510.  
Coffee—intoxication, 182; "wheat," 732.  
Cold—and disease, 69; local, application in genital tract, 168.  
Colds—common, 307; etiology of, 471.  
Coles, T. Stricker: Transverse position of the child with prolapse of the arm and impaction, 18.  
Colic, hepatic, peritonitic pathogenesis and painful epigastric crises, 593.  
Colitis, ulcerative, 114, 901.  
Collargol, 552, 1069.  
College—bred, families of, 285; courses, shortening, 121; graduation, increase of age, 891; of physicians of Philadelphia, 203.  
Collins, Joseph: A clinical report of nine cases of Friedreich's disease: hereditary or family ataxia so-called, with comments on noteworthy symptoms, 865.  
Colloidal—silver, preparation, 552; substance of thyroid, putrefactive processes, 557.  
Colon—bacillus, suppurative meningitis due to, 192; carcinoma of, 1008.  
Color-blindness, prophylaxis, 41.  
Colorado—climate, 151; law as to practise of medicine, 520; tuberculous patients in, 1034.  
Colored people, hospitals and nurse training-schools for, 724.  
Colpeurynter in incarceration of reflexed gravid uterus, 844.  
Colpohysterectomy for retroverted, incarcerated, gravid uterus, 595.  
Coma, terminal, in diabetes, 628.  
Compression, hemostasis by, 1029.  
Conception, imperative, 590.  
Conduct, unprofessional or dishonorable?, 204.  
Congenital—absence of eyeball, 948; absence of inferior recti muscles, 581; absence of clavicles, 569; absence of uterus, 886; acholous chronic icterus, 154; criminal, 671; defect of pectoral muscle, 802; diabetes insipidus and epilepsy after insolation, 312; dislocation of vertebra, 90; edema of left arm, 1010; elephantiasis, 472; goiter, 701, 803; hip dislocation, 786, 823, 856, 870, 872; inspiratory stridor, 1007; lateral ventral hernia, 312; muscular wry-neck, 475; myxedema, 309; occlusion of vagina, 470; pyloric stenosis, 1032; scoliosis, 198; torticollis, treatment of, 199.  
Conjunctiva—neoplasms of, 905; tuberculosis of, 858.  
Conjunctival flap in cataract extraction, 676.  
Conjunctivitis—filamentous, 39; follicular, and trachoma, 189; gonorrhœal, in newborn, and arthritis, 676; purulent, 249, 926; treatment of, 79; venereal, 783.  
Connell, F. Gregory: The effect of altitude upon pneumonia, 947; Through-and-through intestinal suture, with report of additional cases, 135.  
Connell suture, modification, 427.  
Consanguinity, effect of on organs of special sense, 782.  
Constipation, spastic, 30.  
Constriction of small intestine by gangrenous appendix, 632.  
Consultations, concerning, 763.  
Consumption and occupation, 640.  
Consumptive-cure companies, quack, 559.  
Consumptives—King's sanatorium for, 162; tents for, 937, 982.  
Contagious disease, struggle of mankind against, 184.  
Contractures, cicatricial, upper extremities, 578.  
Contusion of finger or toe, serious infection following, 790.  
Convulsion, third left frontal, destruction, 355.  
Convulsions—in hystero-traumatism, cured by excision cutaneous scar, 551; puerperal, treatment of, 35; unknown origin, treatment, 295.  
Convulsive diseases, common cause of, most, 330.  
Coplin, W. M. L.: Congenital dislocation of the hip: report of a bloodless reposition, followed by death, with an analysis of 23 cases in process of treatment, 786, 823.  
Cord—spinal, subacute combined sclerosis, 15; torsion of, strangulated testicle from, 815.  
Cornea, chestnut-bur thorn in, 39.  
Corneal—affectations, treatment, 38; astigmatism, 591; cicatricial, calcareous degeneration, 986; epithelium, detachment of, 39; infiltration, treatment, 38; trauma, astigmatism cured by, 840.

 Embryomas, ovarian, or so-called ovarian dermoid cysts, 277.  
 Emerson, Linn: Care of the eyes of school children, 264.  
 Emetic, ipecacuanha as, 37.  
 Emotional disturbances, treatment, 985.  
 Empyema—following ether anesthesia for appendicectomy, 417; curious case, 276; subcutaneous, 592.  
 Empiricism and medical science, 3.  
 Empyema—Bulau's aspiration drainage in, 802; chronic, of sinuses, 311; necessitatis, pulsating, 840; of accessory sinuses of nose, 351; treatment of, 313, 748, 925.  
 Encephaloscope, 858.  
 Endochondroma of spinal column, 812.  
 Endemic of paratyphoid, 72.  
 Endocarditis—94, 924; malignant, and typhoid and paratyphoid infections, 800; malignant gonorrhoeal, 928; rheumatic, treatment of, 119; traumatic, 1010; ulcerative, 928; vegetative, 509.  
 Endometritis, 356.  
 Endometrium, in uterine myomata, 782.  
 Endotheliomas—941; occurring in nasal fossa, 749; of kidney, nephrectomy for, 475; of mammary gland, 1024; of ovary, 277.  
 England, typhoid panic in, 1018.  
 Enterectomy for malignant disease, 634.  
 Enteric fever—abdominal pain in, 152; hemorrhage in, 153.  
 Enteritis—chronic, gastric digestion in, 1032; membranous, treatment, 637.  
 Enterocystoma and intestinal obstruction, 1036.  
 Enterorrhaphy, single cuff method, circular, 774.  
 Enterostomy—in cancer of stomach, 635; in intestinal obstruction, peritonitis, and typhoid perforation, 550; in peritonitis, 550, 860.  
 Entropion, operations for, 946.  
 Enuresis and adenoids, 509; treatment of, 234, 974.  
 Enzymes—and antienzymes, and antibody of rennet, 941; intracellular, 855; proteolytic of saprophytic bacteria, 816.  
 Eosinophilia—and verminous parasitism in man, 514; in pelvic lesions and in vermiform appendix, 275.  
 Epidemic, nonrecurrent, 44.  
 Epidural abscess of otitic origin, 840.  
 Epigastric crises, 593.  
 Epigastrum, sternocardial pain in, 310.  
 Epitatory, hydrogen dioxide water as, 512.  
 Epilepsy—306; after isolation and congenital diabetes insipidus, 312; alcoholic, 395; and chronic gastro-intestinal diseases, 862; and lead-poisoning, 752; clinical study, 778; cortical cell changes, 711; in young, causes, 408; menstrual, 356; treatment of, 33, 53, 79, 151, 235, 241, 395, 397, 437, 727.  
 Epileptic, criminal responsibility, 394.  
 Epinephrin (suprarenalin) powder in asthmatic paroxysm, 844.  
 Epiphysitis, acute, of head of femur, 901.  
 Epispadias, modification Cantwell's operation in, 914.  
 Epistaxis, treatment of, 79.  
 Epithelioma—contagious of fowls, 237, multiple cystic face, 904; treatment, 900, 941.  
 Epithelium, corneal detachment of, 39.  
 Eponymic terms in medical literature, 122.  
 Eponyms, misuse by medical writers, 242.  
 Epsom salts, 931.  
 Erosion of knee-joint, operative substitution for, 198.  
 Erck, Theodore A.: Fibroma of ovary with ascites, 415.  
 Ergot, 36, 607.  
 Eructations, hysteria, following anesthesia, 417.  
 Eruption—drug, of iodoforn type, 942; recurrent bullous, 26; scarlatiniform during diphtheria, 311.  
 Erysipelas, treatment of, 75, 279, 478, 842.  
 Erythema, angioneurotic necrotomy in, 972.  
 Erythrocytes—degeneration, 571; increase in at various altitudes, 761.  
 Erythropleum, 243, 1024.  
 Escherich's pseudotetanus, 275.  
 Esophageal carcinoma—simulating clinical picture of aortic aneurysm, 353; treatment of, 194.  
 Esophagus—diverticulum of, 971; excision for carcinoma, 156; foreign body in, 212; fusiform dilation, 1033; idiopathic dilation, 930; stenosis, electrolysis in, 549; surgery of, 1035; traumatic stricture, 117.  
 Esophoria, tenotomies for, 900.  
 Ether—anesthesia, nitrous oxide as preliminary to, 263; respiratory inhibition from, 882.  
 Ethics—and American Medical Association, 763; medical, of American Medical Association, principles of, 796.  
 Ethmoiditis—545, 779; syphilitic, pathologic histology, 428.  
 Ethyl bromid, 392, 667.  
 Ethyl chlorid as general anesthetic, 69, 279.  
 Eukinae, 552.  
 Euquinin, 317.  
 Eustachian salpingitis with stricture, 223.

 Examination, the gynecologic, 23.  
 Examining boards and licenses, 556.  
 Exanthems—differential diagnosis, 927; postvaccinal and vaccination, accessory pox marks in, 884.  
 Exercise in heart disease, 781.  
 Exophoria, tenotomies for, 900.  
 Expectorant, oxalic acid as, 597.  
 Expectoration, fetid, treatment of, 358.  
 Exophthalmic goiter, 21, 395, 510.  
 Expectorate and spit, 977.  
 Expressions, threadbare and stilted, 409.  
 Extrophy of bladder following operation, 233.  
 External preparations, 625.  
 Extirpation—of prostate, 314; of septic puerperal uterus, 234.  
 Extradural hemorrhage, 748.  
 Extruterine—pregnancy, 277, 1012; specimens, early histology of villi from, 77.  
 Extremities—cyanosis of, 1034; lower, rachitic deformities, 817; traumatic gangrene of, 626; upper, cicatricial contractures, operation for, 578.  
 Extremity, lower, fractures of, through indirect violence, 634.  
 Eye—affectations from rheumatism, 629; and general disease, 970; and sympathetic physiology, 822; anterior segment of globe, postoperative infection, 783; complications of smallpox, 906; diseases in white and negro races, 858; foreign bodies in, 33, 38; inflammations, bacteria in, 905; parts of, bacteria in, 905; radium rays in, 677; troubles in London school 7; tuberculosis of, localized, 858.  
 Eyeballs—congenital absence, 946; enucleation, paraffin injections after, 676.  
 Eyebrows, etc., traumatic lesions, 946.  
 Eyelids, skin-grafting on, 946.  
 Eyes—of school children, 7, 261; ruined, from professional error, 1017.  
 Eyesight, damage for loss, 554.  
 Eyestrain—669; and chorea, 410, 728; and cramp of ciliary muscle, 905; and headache, 249; of institutional inmates, duty and policy of state to relieve, 600.  
 Face, lupus of, phototherapy in, 235; pustular acne of, 1088.  
 Facial—canal, surgical relations, 899; orthomorphia, orthodontic, 784.  
 Factory legislation, 46.  
 "False cardiacs," 750.  
 Faradic current in retinal hemorrhage, 149.  
 Fat—assimilation of, 275; metabolism following straightening of limbs, 802; metabolism in organism, 237; necrosis, and acute pancreatitis, 188; necrosis, experimental, 513; necrosis of kidney, 773; perinephric, 210; in gastric digestion, 1010.  
 Fat-splitting ferment of stomach, 432.  
 Fatty—degeneration and bacterial intoxication, 239; tissue, perirenal, anatomy of, 171.  
 Fecal—accumulation, unusual case, 192; fistula, treatment, 595; incontinence, operation for, 756.  
 Feeding—by breast, from obstetrician's point of view, 821; infant, 219, 429, 752, 820, 861, 919; infant, milk modification, 919.  
 Feet, painful, 149.  
 Felon, treatment, 546.  
 Female, pelvic suppuration in, 971.  
 Femoral—aneurysm, surgery for, 800; neck, fracture of, in children, 892; vessels, arteriovenous aneurysm of, 962.  
 Femur—epiphysitis of, head of, simulating congenital malplacement, 901; neck of, fracture, 68, 928; sarcoma of, treatment, 594, 748.  
 Fenn, C. W.: *Emanio mensium*, 488.  
 Fertilization and ectopic pregnancy, 476.  
 Fetal—circulation, thrombi containing tubercle bacilli in, 897; syphilis, 1037.  
 Fetus—retention of, after rupture of uterus, 1036; transverse position of, with prolapse of arm and impaction, 53.  
 Fever—continued, neither malarial nor typhoid, 770; hemoglobinuric, 943; undulant, 802; yellow, transmission, 819; eruptive, treatment of, 478.  
 Fevers—circulation in, and alcohol, 1020; in infancy, doubtful, 428; southern, 770.  
 Fibrillar substance produced by connective tissue cells, 897.  
 Fibroids, uterine, 234, 277, 717, 1037.  
 Fibroma—aural, 899; molluscum, 782; ovarian, 110, 276, 415; uterine, near meropause, 928.  
 Fibromyoma, uterine, 315, 1012.  
 Fibrosarcoma, treatment of, 407.  
 Fibrosis of larynx and trachea, 668.  
 Fibrous obstruction of superior and inferior cavas, 882.  
 Fibulas, heads of, bilateral fracture of, 1035.  
 Filipinos, teaching them vices of civilization, 936.  
 Filters, cleanse and sterilize, 848.  
 Filtration, water, 903.  
 Finger—puncture of, serious infection following, 790; snap or trigger, 755.  
 Finsen light—in lupus, 627; in tuberculosis of bones and joints, 860.  
 Fissure, anal, no operation, 927.  
 Fistula—between gallbladder and stomach, 626; carcinomatous gastrocolic, 629, 635; cranial, operation in, 714; fecal treatment, 595; rectal, 271; salivary, 528, 672; vesicovaginal, obstetric indication, 595.

- Open air treatment for consumptives, plans for cabin, 982.
- Operating—for hemorrhoids, 843; through vagina or abdomen in double pyosalpinx, 853.
- Operation—abdominal, peritoneal saline infusions in, 984; Alexander's, 28; Bottini's, results, 633; exploratory, in gallbladder region, 773; extrophy of bladder following, 233; for abdominal pregnancy, 928; for appendicitis, 194, 606, 860, 981; for astigmatism, 306, 1009; for carcinoma of cecum, 1008; for carcinoma of colon, 1008; for cicatricial contractures upper extremities, 578; for entropion, 946; for incontinence of feces, 756; for inguinal and femoral hernia, 981; for myoma, 436; for nephropexy, Penrose's, 341; for obscure abdominal pain, 194; for proctitis, 625; for reproduction of sacrotuberine ligaments, 596; for trigeminal neuralgia, 812; for varicocele, 809; gynecologic, and diabetes mellitus, 476; in absence of temerosphenoidal lobe, 857; in appendicitis, early, 749; in cranial fistula, 714; in chronic gastric ulcer, 157; in diabetes, 474, 896; in diseases of alimentary canal, 438; in extradural hemorrhage, 748; in fibromyoma of uterus, 315; in fibrosarcoma, 407; in fracture of ischiopubic ramus and rupture of bladder, 837; in habitual dislocation of shoulder-joint, 469; in intestinal obstruction, 170; in intracranial tension, 508; in malignant disease of testicle, 607; in ruptured urethra, 410; in undue prominence of ears, 434; in varicocele, 548; in varix of inferior mesenteric vein and chronic ulcerative colitis, 901; Lorenz, 101; mastoid, 29, 470; modification, Cantwell's, in epispadias, 944; Mules', plastic artificial vitreous in, 429; nose, throat and ear, anesthetics in, 507; of cleft of lip, 370; on gallbladder and bile-ducts, 370; of cleft of lip, 370; on female genital organs, parotitis following, 803; on gallbladder and bile-ducts, 370; Roux's, in femoral hernia, 195; Talma's, 801; pelvic, mortality in, 149; performed in cavities of body, plugging with iodoform gauze in, 117; surgical, list, and modern aseptic surgery, 447; surgical, self-performed, 648; upon head and neck, provisional hemostasis, 1036.
- Operative—asepsis, 634; treatment cicatricial ankylosis of jaw, 983; cirrhosis of liver, 929; treatment of cystocele and proclivencia uteri, 589; treatment of enlarged prostate, 1035; treatment of fracture of patella, 548; treatment of pulmonary tuberculosis, 813; treatment of uterine carcinoma, 803; substitution for paralyzed quadriceps femoris, 198.
- Ophthalmia in Egypt, 565.
- Ophthalmic—asepsis, 905; practice, suprarenal gland in, 40; referee and transportation, 249; referees, railway, 508; specimens, 864; surgery, giant magnet in, 507.
- Ophthalmology—oscillatory ophthalmology for interocular diseases, 128.
- Ophthalmology, 783; in New York State Reformatory, 600.
- Ophthalmoplegia—exterior, 662; internal, bilateral, 86.
- Ophthalmoscope and physician, 248.
- Opie, Eugene L.: The anatomy of the pancreas, 996.
- Opium—habit in France, 8; in surgery, 591; poisoning, treatment of, 512; smokers, and others, badges for, 807; traffic in Philippines, 937.
- Optic—atrophy, pathology, 38; nerve, atrophy of, 662; nerve, metastatic carcinoma, 38.
- Optician and shirtmaker, 244.
- "Optometry" in Pennsylvania, 561.
- Oral cavity, Röntgen rays in, 784.
- Orbital cellulitis, following scarlatina, 960.
- Orchitis, chronic, albigneotone in, 754.
- Organ, innervation of and influence, suprarenal extract, 216.
- Organacidia gastrica, 548.
- Organism—biologic overexertion of, in natural vs. artificial nourishment, 630; infecting, of variola, 679.
- Organotherapy, ovarian, 317.
- "Original Articles," 84.
- Orr, H. Winnett: Use of cocaine among the laity, 948.
- Orthomorphia, orthodontic facial, 784.
- Orthopedic surgery—principles in, 27; therapy of, 229.
- Orthostatic albuminuria, 593.
- Os, spasmodic contraction of, obstruction to delivery, 158.
- Ossiculectomy, 390.
- Osteitis deformans—190, 193, 981; of knee, tuberculosis, operative treatment, 817.
- Osteoarthritis, treatment, 981.
- Osteomyelitis, 75, 150, 157, 252, 855, 819, 857.
- Osteopathy fined, 557.
- Osteopathic bill vetoed, 984.
- Osteopathy, 163, 642.
- Osteoplastic carcinoma, 513.
- Otitis media—acute, 156, 357, 863; suppurative, etiology, etc., 151; suppurative, chronic, 96; suppurative, complications, 151, 152; treatment, 152, 156; with sinus thrombosis, 858.
- Outrage, authorized or not, 641.
- Ova—mammalian, papillary cysts in, 816; syncytium and ectopic, 816.
- Ovarian—dermoid cysts, so-called, 277; fibroma, 110, 276; organotherapy, 317; tumor, anuria in, 314.
- Ovaries, dermoid cysts of, showing cerebellar tissue, 759.
- Ovariectomy—after vaginal hysterectomy, 277; and impacted tumor, 436; during pregnancy, 803.
- Ovary—and tube, obturator hernia, 511; calcification, 596; entothelioma of, 277; fibroma of, with ascites, 415; primary carcinoma of, 636.
- Overstudy and nervous school child, 766.
- Osium, attachment to atypic places, 511.
- Oxalic acid as expectorant, 597.
- Oxaluria, significance, 591.
- Oxygen—etheral, 719; tension, lowered, effect of, on producing hypercythemia of altitude, 760.
- Ozone—effect of, on blood, 770; to purify water, 1019.
- Ozena, treatment, 78, 1039.
- P**ain—abdominal, in enteric fever, 152; abdominal, in pleurisy and pneumonia, 771; intermenstrual, 111.
- Palpation of pylorus, 812.
- Palsy—birth, suture of brachial plexus for, 392; lead, nervous system in, 941; peripheral, following replacement of congenitally dislocated hip, 898.
- Pancreas—accessory, 667; and islands of Langerhans, 941; anatomy of, 996; cysts of, 32, 47, 810, 919, 972; diseases of, 751; diseases, symptomatology and diagnosis, 907; etiology and pathologic anatomy, 810; cirrhosis of liver, 312; in diabetes mellitus, examination, 112; inflammation, with hemorrhage and necrosis, 757; injuries and inflammatory processes, 810; physiology and physiologic chemistry, 810.
- Pancreatic—cyst, 32, 47, 810, 972; diabetes and movable right kidney, 592; disease simulating cholelithiasis, 632; lithiasis 115.
- Pancreatitis—acute, 117, 757; acute, with fat necrosis, 188; and cholelithiasis, 883; chronic, 47, 117, 291; hemorrhagic, 252.
- Pancreatokinase, 552.
- Panophthalmitis following dissection of capsular cataract, 900.
- Paracentesis of tympanic membrane in acute otitis, 156.
- Paraffin—in deformities, 193, 676, 756, 779; treatment in bowel prolapse, 632.
- Paraldehyde in disease, 393.
- Paralysis—brachial, after pneumococcal meningitis, 114; general, with tabes, syphilitic nature, 671; Landry's, 27; of recurrent laryngeal in mitral stenosis, 74; postanesthetic brachial, 799; post-diphtheric, 307; spastic, 199, 942.
- Paralytic talipes, operative procedures, 817.
- Paralyzed sphincter ani, 756.
- Parazyoclonus multiplex, 395.
- Paraplegia, syphilitic spasmodic, treatment of, 397.
- Parasites—human, 782; intestinal, clinical diagnosis, 771; tropical, 430.
- Parasitic hematuria, 20.
- Parasitism, vermiform, in man, 514.
- Parasyphilitic affections, 111.
- Paratyphoid, 72, 270, 631, 800.
- Parenchymatous—gastric hemorrhage, 233; pulmonary tuberculosis, chronic, 713.
- Park, Roswell: On cysts and other neoplasms of the pancreas, 949.
- Paronychia, treatment of, 628.
- Parotid—duct, stenosis of, 523; gland, tuberculosis of, 32.
- Parotiditis—chronic bilateral in insane, 179; epidemic, 514, 546, 1012; following operations on female genital organs, 803.
- Parturition—pelvic tumors complicating, 511; injuries of pelvic floor during, treatment, 48.
- Pasteur and Lister, 194.
- Patella, fractured, treatment of, 195, 210, 548.
- Patent medicine—trust, 639; and alcoholism, 441; testimonials, 682; saintly defender of, 2.
- Patents for drug, 1018.
- Pathogenic bacteria—and Chicago drainage canal, 975; intracellular toxins of, 545.
- Pathology—chemical, 189; surgical, instruction in, 880; surgical of genu varum and valgum, 817.
- Patient—consent of necessary, 364; or doctor, 473; point of view of, 480; who is not advised, etc., 470.
- Pauperism, hereditary, 283.
- Pearce, F. Savary: The nervous cardiac symptoms due to high altitudes, 261.
- Pectoral muscle, congenital defect, 802.
- Pedagogy and medicine, 806.
- Pediatrics—sanatogen in, 549; study of, 777; xeroforn in, 549.
- Pedicle, twisted, and hematosalpinx due to tubal pregnancy, 930.
- Pediculus capitis, 904.
- Pelvis, narrow, labor in, 476.
- Pelvic—abscess, 252, 836, 837; and uterine disease, etiology, 16; disease in young girls, 902; disease, surgery for, 527; lesions, eosinophilia in, 275; operations, mortality in, 149; support, inefficiency of immediate suture of lacerations to restore, 923; suppuration in female, 971; tumors, 356, 511.
- Pelvis—contracted, 429; funnel, 839; ureteral, 927.
- Pemphigus—chronic, 864; consecutive acute, 312.
- Penis, avulsion of skin, 815.
- Pennsylvania—annual subsidization scramble in, 319; "optometry" in, 561.
- Pensioner, an honest, 978.
- Penosuria, 74.
- Penrose's operation for nephropexy, 341.
- Pepsin, value, 803.
- Percussion—auscultatory, 747; tidal, of lung apices, 549.
- Perforation—duodenal, 968; gallbladder, gastric, 968, 435; typhoid, 152, 270, 550, 626, 700, 749; uterine, 1036.
- Pericarditis—chronic, obliterative, and ascites, 190; preventive treatment, 279; traumatic, 1010; typhoid, 672; with effusion, treatment of, 357.
- Pericardium—adherent, 390; primary sarcoma of, 239.
- Periduodenal abscess from duodenal ulcer, 430.
- Perigastritis, adhesive, secondary to gastric ulcer, 116.
- Perineal—prostatectomy, instrument for, 947; prostatectomy, conservative, 815; structures, repair, 860.
- Perineorrhaphy tetanus after, 886.
- Perinephric fat, 210.
- Perineum, the, 71, 551.
- Perineral fatty tissue, anatomy of, 171.
- Perisinusal abscess of lateral sinus with, 863.
- Peritoneal—infection, typhoid perforation with, 626; saline infusions, 984.
- Peritoneum—animal, diseased and healthy, 1010; in appendicitis, toilet of, 812, 994; in spreading and diffuse peritonitis, 812; in tuberculous peritonitis, 811; in typhoid, operations, toilet of, 812; toilet of, in operation, on stomach, 811, 812.
- Peritonitic pathogenesis of hepatic colic and painful epigastric crises, 593.
- Peritonitis—enterostomy in, 860; gonorrhoeal, in children, simulating appendicitis, 980; in typhoid without perforation, 700; pathology after non-surgical treatment, 48, 668; spreading and diffuse, treatment, 812; treatment of, 550, 812; tuberculous, 49, 78, 176, 672, 811, 842, 943.
- Periurethral infiltrations and abscesses in female, 636.
- Pertussis—and early diagnosis from blood findings, 62; 55 fatal cases, 273; treatment, 845.
- Peruna habit and other alcoholism, 641.
- Perversion, moral, 1030.

- Pharmacology, research problems, 780.
- Pharmacopeia—and diphtheria antitoxin, 399; and shock, 747; revision, 404; the new, 839; United States, 822.
- Pharmacy laws, to be discussed, 938.
- Pharyngeal—diphtheria, chronic, 75; mucopus, bacillus of Eberth in, 516; tonsil, inflammation of, 232.
- Pharyngitis, membranous, 779.
- Pharynx, lymphoid ring of, hypertrophy of, surgical treatment, 150.
- Philadelphia, 315 new cases of typhoid, 934.
- "Philomathean," 1017.
- Philippines—government laboratories for, 665, 721; civil sanitarium at Baguio, Benguet in, 601, 624; opium traffic, 937; proposed leper colony in, 500.
- Phimos, bloodless reduction of, 276.
- Phipps institution, 84, 86, 161, 166, 245, 988.
- Phebitis, septic, of roots of portal vein, 811.
- Phebloliths in female genitalia, 1037.
- Phosphaturia, 357, 392.
- Phototherapy—in lupus, 235; in skin diseases, 68; present status, 982.
- Phtisis, and factory and workshop conditions, 112.
- Physical—characters, pharmacologic action determined by?, 780; "Culture's" expose of Koch's consumption-cure frauds, 682; degeneracy and environment, 432; training, briefs on, 300, 342, 383, 413, 463.

- Physician—and murdered baby, 561; and ophthalmoscope, 245; and pharmacopia, 111; aspiration of, 84; exception to fee of, 556; fee of, privilege of increasing, 557; illegitimate child, etc., 479; prison, 560; verdict for, 556.
- Physicians—and correct registration of vital statistics, 776; and mortality statistics, 679; and preventive medicine, 442; and society, relation, 763; free, 246; records made and preserved by, 764; women, 686.
- Physiologic apparatus, 822.
- Physiology and invention, 124.
- Pigments, biliary, reaction for, 517.
- Pituitary body, gangrenous destruction of, 431.
- Pityriasis rosea, 904.
- Placenta—growth, 34; prævia, 356, 435, 551, 589, 590; tuberculosis of, 897.
- Plague—484, 524, 526, 590, 685, 725, 727, 766, 767, 808, 850, 978, 979; and rats, 209; bubonic, bacillus, 533; concealment of, 244, 281; conference, 127, 167; deaths of laboratory workers from, 975; in California, 88, 122, 209, 976; germs, government prohibition against, 979; in Sydney, 429; infection, 858; memorandum, 366; prophylaxis, 859; question, and public press, 439; serum, \*6, 109; situation at San Francisco, 681; transmissibility of, 142.
- Plaguy condition in California, 439.
- Platt, Charles: The metric system in use, 212.
- Pleura—echinococcus of, 434; hydatid cyst of, 355.
- Pleural effusions in heart disease, 300.
- Pleurisy—abdominal pain in, 771; chronic, treatment, 579; productive tuberculous, 74; to produce reexpansion after, 845; with effusion, treatment, 154.
- Pleuritic effusions in children, new sign of, 310.
- Plexus, brachial, suture of, for birth palsy, 392.
- Pneumococci—arthritis, 605; infection, severe, 752; meningitis, recovery, 114.
- Pneumococcus—in animals and pneumonic processes, 897; reaction, with certain normal and immune sera, 816.
- Pneumonia—391; abdominal pain in, 771; acute croupous, thrombosis, 841; altitude effect upon, 947; captain of the men of death, 387; catarrhal, in infants, 902; chronic, 970; complications, 1021; contagious disease, 162; croupous, 514, 629; deaths from, 245; desquamative obliterating, 751; epidemic, 850; increased mortality from, 161; hypodermoclysis in, 221; infectious disease, 509; leukocytosis in, 114, 514; lobar, 31, 312, 539, 1020, 1021; lobar, blood-cultures in, 1033; mortality, and altitude, 536; mortality, present day, 537; 125% more fatal than tuberculosis, 848; postoperative, 716; prognosis, 549; serum for, 166; traumatic, 31, 771; treatment of, 275, 308, 843; unresolved, new treatment, 761; with sepsis, pneumococcus of Friedländer in, 237.
- Pneumonic exudations, fat of, 855.
- Pock marks, accessory, in course of vaccination and of postvaccinal exanthems, 884.
- Poisoned wounds, 668.
- Poisoning—atropin, from ocular instillations, 528; carbolic acid, artificial respiration in, 409; chronic acetanilid, 352; fatal benzine, 1039; forage, in horses, 941; following use of cocaine in local anesthesia, 369; illuminating gas, 929; lead, 714, 752; morphin, serum for, 474; opium, treatment of, 512.
- Poisons—and poisoning, 976; sale, 639.
- Poliacephalomyelitis and allied conditions, 1029.
- Poliomyelitis in infancy, acute anterior, and amyotrophic lateral sclerosis, 534.

- Tropeins, chemistry of, 349.
- Tropical—diseases, 190, 231, 272, 308, 390; diseases, doctors to be instructed in 405; dysentery, 772; lands, surgery in, 436; parasites, 430.
- Trypanosoma—in blood of man, 239; lewisii, 782.
- Truneczek's serum, 509.
- Twins, joined, 483.
- Tubal pregnancy—hematosalpinx due to, 930; twin, in same tube, 595.
- Tube—carcinoma of, 158; obturator hernia of, 511.
- Tubercle—bacilli, 782; bacilli from tuberculous foci in man, 750; bacilli in sputum, 349; bacilli, isolating from body fluids, 515; tibial, avulsion of, 1007; tibial, lesions of, during adolescence, 229.
- Tuberculin—259; new, influence on cell metabolism, 73; treatment according to Goetsch, 478.
- Tuberculosis—208, 245, 473, 943; and calcium excretions, 637; and community, 983; and Dr. Robin, 81; and education, 443; and heredity, 970; and immigration, 306; and local sanatoriums, 942; and lupus erythematosus, 108; and milk, 82; and sanitary legislation, 355; and "sure cures," 245; and tanner's trade, 275; and typhoid, 113; Arizona in, 312; bovine and human, 153; bovine, in milk, 895; bovine, transmissibility to man, 192, 715; bovine, transmission to man, accidental reinoculation into calf, 630; bronchial, 110; bronchiectasis in, 1021; compulsory notification, 727; contract in hospital wards, 75; cutis, 856; dispensary for, 590, 943; expense of, 81; experimental, artificial immunity, 895; experimental, in cows and calves, 32; extinction, 519, 688; following dermatitis blastomycetes, 928; genital, and Addison's disease, 517; human and bovine, 153, 472, 715, 895; human, transmission to cattle, 74, 112; immunity and infection 391; in Cleveland, 308, 322; in Germany, 440; in Illinois, 86; in negro, 943, 983; incipient, diagnosis and treatment, 629; infection as factor in, 618; influence on duration of life and earning capacity, 715; inoculation, 232; joint, malignancy, 108; laryngeal, 36, 357, 672, 863, 930; miliary, and leukemia, 311; mountain sanatoriums for, 747; of aorta, 1032; of bones and joints, treatment, 860; of bronchial glands, 259; of eye, localized, 858; of female genitalia in children, 435; of mammary gland, 983; of middle ear, primary, mastoiditis following, 471; of parotid gland, 32; of placenta, 897; of pericardium, involvement of myocardium, 787; of spleen, vegetative endocarditis following, 509; of thyroid, 353; of tonsils, 895; Phipps institute for, 161, 166; plans for cabin for open air treatment, 982; pneumonia more fatal, 848; prophylaxis, 311; pulmonary, 111; pulmonary, chronic parenchymatous, 713; pulmonary, diazo-reaction, 591; pulmonary, exercise in, 843, 1013; pulmonary, mixed infections in, 839; pulmonary, origin, 714; pulmonary, prevention, 491; pulmonary, tent life in, 944; pulmonary, weights in, 653; recent literature of, 389; serum diagnosis, 881; surgical, to combat, 633; transmission from man to cow, 30; treatment of, 69, 159, 294, 310, 312, 313, 315, 316, 317, 387, 393, 472, 491, 512, 579, 596, 845, 941, 944, 970, 1009, 1038; urogenital, 970.
- Tuberculosis—bone-and-joint disease, treatment, 109; cavities of lung, surgery of, 156; cerebrospinal meningitis, 669; chest flat?, 746; department of Boston dispensary, 943; disease, treatment of, 317; excluded from California, 484; home treatment vs. sanatoriums, 350; hydrocele and rheumatism, 117; infection, 546; laryngitis, 306; lesion of genitourinary tract, treatment, 816; lungs in early infancy, 313; meningitis, 516; osteitis of knee, 817; patient, microbe-laden spray, 519; patient, should he know truth, 943; patients in Colorado, 1034; peritonitis, 176, 943; peritonitis, treatment, 49, 78, 672, 842; pleurisy, productive, 74; prisoner, 721; the care of, 310; ulceration, 1039.
- Tuboabdominal, pregnancy, unruptured, at end of six months, 234.
- Tufts, Stewart W.: The control of mouth-breathing at night, 169.
- Tumor—fibroid, cesarean section in, 276; fibroid, pregnancy with, 813; impacted, and ovarioectomy and cesarean section, 436; inflammatory, of abdominal wall, foreign body in, 276; multiple thyroid, of bone and glands, 941; obstruction of common bile duct, 939; of bladder, in, 434; of cauda equina, 514; of fourth ventricle, 397; of prostate, 972; of stomach, syphilitic, 354; ovarian, anuria in, 314.
- Tumors—accessory thyroid, 170; adrenal, 516; bissection in abdominal hysterectomy, 813; brain, and chronic hydrocephalus, 755; fibroid, degeneration, 1037; hairy, in stomach, 31, 115; lateral retroperitoneal, 632; malignant, karyokinesis in, 145; malignant, Röntgen rays, in 231; multiple primary, 69; neck, excision of, 391; of breast, doubtful, early removal, 758; of breast, 841; of thyroid, bone metastases in, 32; of uterus, fibromyomatous, 315; pelvic, complicating parturition, 311; pelvic, removal of, hemorrhage in, 356; teratoid, neuroglia and ependymal epithelium of, 782; transplantation of, 412; vascular treatment, 819.
- Tunica vaginalis, hematocele of cord into, 70.
- Tuning-fork in fracture diagnosis, 635.
- Turpin, Thomas J.: Early operation in appendicitis, 666: Use of the magnesium ring in uniting severed bloodvessels, 488.
- Tympanic membrane, paracentesis of, 156.
- Typhoid—770; and animal economy, 51; and malignant endocarditis, 800; and mortality, 483; and surgical suppurations, leukocytes in, 752; and tuberculosis, 113; at Boston City Hospital, 270; at Ithaca, 325, 766; at high altitudes, 772; at Massachusetts general hospital, 270; bacilli in respiratory diseases during typhoid, 353; bacillus in urine and sputum, 270; bacillus, dissemination, soil, flies, and fabrics, 514; bacteriologic diagnosis, 843, 884; bacteriology of blood in, 753; cerebral symptoms, treatment of, 781; complications, surgical, 712; cystitis and bacilluria in, 473; diagnosis, laboratory aids in, 308; diet in, 270; embolism of aorta in, 631; epidemic in Chicago, recent, 764; fewer drugs in, 629; fly carrier of, 387; gangrene, 23; in children, 274; in Philadelphia, 315 new cases, 934; infection in, 859; infection, soil, fabrics, and flies in disseminating, 29; intestinal perforation from, erroneous surgical decisions in, 152; lemon juice in, 43, 1032; leukocyte counts in, 237; mortality in children, 884; mortality, rise in, 1; panic in England, 1018; pathogenesis of, 29; pericarditis, 672; operations, toilet, peritonium in, 312; perforation in, 152, 270, 550, 626, 634, 749; prophylaxis, 859; relapse, 28, 883; statistics, 286; treatment of, 74, 316, 588, 761; trigeminal neuralgia complicating, 391; with unusual complications, 367; without perforation, with peritonitis, 760.
- Uhlenhuth test for differentiation of human blood, 469.
- Ulcer—gastric, 116, 157, 237, 274, 511, 773, 775, 968; leg, treatment, 673; of duodenum, perforative, 249, 430, 634, 968; single, of urinary bladder, 812; perforated, in typhoid, 749; rodent, treatment, 32; varicose, treatment of, 393.
- Ulcerations, tuberculous, 1039.
- Ulcerative endocarditis, 928.
- Ultraviolet-ray anesthesia in minor surgery, 648; rays and cathode, 927.
- Umbilical cord, kidney in, 759.
- Umbilicus, secondary hemorrhage of, 51.
- Uncinaria duodenalis in dysentery, 193.
- Uncinariasis, 68, 73, 628, 771, 772.
- United States—medical education in, 731; pharmacopeia, 822.
- University—extension of, medical, 399; of Pennsylvania hospital, albuminuria and eclampsia at, 694; president on football, rowdism and scholarship, 891.
- Unprofessional or dishonorable conduct?, 204.
- Urea estimation—hypobromite method, 27, 391; by mercuric nitrate, 925.
- Uremia, and treatment, 2'0, 692, 839.
- Uremic—origin, hemiplegia of, repeated attacks, 593; state, pathogenesis of, 188; state, therapeutic management, 250, 692, 839.
- Ureter—prolapse of, 1038; traction of, and ureterocystostomy, 474.
- Ureteral—orifices, compression of, separation of urine by, 156; pelvis, 927; surgery, 757.
- Ureterocystoscopy, 854.
- Ureterocystostomy, 474, 896.
- Urethra—gonorrhoeal induration, 636; permeability for certain salts, 815; rupture of, 391, 410.
- Urethral—diseases, Janet's method in, 75; irrigator, glass, 882; sound, uses and abuses, 791.
- Urethritis—acute, 35, 305, 308, 1004; chronic, 1004; gonorrhoeal, 234, 388, 668.
- Urethrotopy, internal, 314.
- Uric acid calculi, treatment, 545.
- Urinary—analysis for general practitioners, 969; anti-septic, helmitol, 477; bladder, diseases of, 1031; bladder, ruptured, 756; chemistry, 714; intoxications and tremor, 1033; signs in hepatic insufficiency, 841; tract, diseases of, treatment, 78, 983.
- Urination, disturbance of, psychic nature, 489.
- Urine—albumin in, 251, 592; detection and distinction of albumoses from other proteids found in, 432; freezing point, and kidney diseases, 517, 753; hyperacidty, 591; nocturnal elimination in heart disease, 593; of children, safranin reaction in, 903; oxalic acid in, 239; of infants and blood, comparative examination, 1037; Pollacchi's test, 175; residual, 351; retention of, 434; segregation, 112, 156, 157; spider, venom effect upon, 515; suppression, decapsulation of kidneys, 772; typhoid bacillus in, 270.
- Urogenital tuberculosis, 970.
- Uroin, 931.
- Uterine—and pelvic disease, etiology, 16; carcinoma, 314, 352, 551, 803; carcinoma, age limit in, 1012; fibroid, 234, 277, 717; fibroma near menopause 928; fibromyomas, 1012; hemorrhages, treatment, 118; inertia, 470; inversion and prolapse, 596; mucosa, atrophy of, 158; monoma, rare specimen, 718; myomas, 718, 759, 782; polyp, fibrous, histologic structure of, 436; prolapse, 551; rupture, 118, 157, 356, 511; rupture, is cesarean section indicated in succeeding pregnancy?, 596.
- Uterus—bicornis, 711; bissection, in abdominal hysterectomy, 813; cancer of, 111, 351, 814; chorioepithelioma of, 151; congenital absence, 886; double,

- 277, 711; fibromyoma of, for, 315; hour-glass contraction, 1037; hyperplasia of, 49; invagination, due to ventral fixation, 118; malignant disease, treatment, 671, 999; nonpregnant, muscular insufficiency of, 77; perforation of, 1036; procidentia, 758; prolapse, 551, 596; reflexed gravid, incarceration of, 844; retrodisplacements of, 49, 595, 873, 984; rupture, 118, 157, 356, 511, 596, 1036; septic puerperal, extirpation, 234; should it be removed when operating through abdomen or vagina in double pyosalpinx?, 833.
- Vaccinal syphilis**, 154.  
**Vaccinated**, never been, 724.  
**Vaccination**—470; and postvaccinal exanthems, 884; and vaccine, 243; by "variolinum," 321; compulsory, declared constitutional by Massachusetts Supreme Court, 933; during menstrual period, 485; insusceptibility to, 41, 50, 82, 130, 409; malpractice in, 557; or ostracism, 444; primary, 988; technic, 88; tetanus following, 113, 151; unsuccessful, 488.  
**Vaccine**—laboratory inspection, 710; virus, 855; virus, actinomycetes obtained from, 855.  
**Vacuum**, cleaning by, 480.  
**Vagina**—congenital occlusion, 248, 470; double, 277, 711; operating through in double pyosalpinx, 853.  
**Vaginal**—and abdominal section for pelvic disease, 527; celiotomy, 188; cesarean section, 158, 195, 636; hysterectomy, ovariectomy after, 277; section, scope, 390, 547; tear during expulsion, 718; wall, anterior, repair of cystocele, 861.  
**Valsalva**, right sinus of, true aneurysm of, 472.  
**Valves**, aortic or pulmonary, diastolic murmurs without, 1010.  
**Van Meter**, S. D.: The importance of mechanical manual training to the surgical student, 304.  
**Vapor** and verbiage, 164.  
**Varicella** and variola, 354.  
**Varicocele**, operating for, 548, 800.  
**Varicose ulcers**, treatment of, 993.  
**Variola**—agglutination properties of blood-serum, 855; and streptococci, 855; and varicella, 354; atypical, 369; bactericidal properties of blood-serum in, 855; bacteriolytic complement-content of blood-serum in, 855; etiologic factor, 855; etiology and pathology, 855; in ape, 855; infecting organism of, 679; ocular complications, 615; skin lesions, 855.  
**"Variolinum,"** vaccination by, 321.  
**Varix** of inferior mesenteric vein and chronic ulcerative colitis; operation, 901.  
**Vascular tumors**, treatment, 819.  
**Vasomotor system** of pulp, 784.  
**Vegetables**, desiccated, nutritive value, 521, 688.  
**Vein**—inferior mesenteric, varix of, 901; internal saphenous, surgery of, 351.  
**Veins**, hepatic, primary obliterative inflammation, 238.  
**Vena cava**, inferior, ligation of, 276.  
**Veneral**—disease, and circumcision, 34; infection, penalizing transmission, 442; peril, boys', 770; prophylaxis, 228, 404.  
**Venesection**, 233, 926, 968.  
**Venous hum**, 509.  
**Ventilation**—bad, antimalarial prejudice not chief cause, 933; night-air, prejudice, 933.  
**Ventricle**—fourth, tumor of, 397; left, gunshot wound of, 233.  
**Ventrofixation**, disadvantages, 356.  
**Veratrum viride**, 111, 781.  
**Verdict** of \$100,000 damages, 557.  
**Vermiform appendix**—eosinophilia in, 275; primary carcinoma of, 250.  
**Vernal conjunctivitis**, 783.  
**Vertigo**, malarial, 270.  
**Vesical**—appearance in renal suppuration, 149; calculus, unusual dimensions, 854; diseases, Janet's method in, 75.  
**Vesicovaginal fistula** as obstetric indication, 595.  
**Vesiculitis**, acute, and treatment, 854.  
**Veto**—splendid, one governor's, 934; strabismic, 889.  
**Vices** of civilization, teaching Filipinos, 936.  
**Vichy waters**, 308.  
**View**—bad point of, 480; patient's point of, 480; point of, 479.  
**Villi** from early intrauterine and extrauterine specimens, histology of; syncytium, 77.  
**Virchow**, 351.  
**Viscera**, transposition, 154.  
**Visceral ptoses**, treatment, 112.  
**Visual**—disturbances in brain injury, 778; field in hysteria, tubular, 39; field, sector defects, and cortical hemianopsia, 389.  
**Vital statistics**—225, 265, 303; correct registration, and physicians, 776; medical education in, 680; registration, legislative requirements, 679.  
**Vitality** of certain pathogenic microbes in ink, 32.  
**Vitreous**, plastic artificial, in Mules' operation, 429.  
**Volumetric testing** for sugar, 649.  
**Volvulus**—of cecum, 511; of small intestine, 234.  
**Vomit**, black, 711.  
**Vomiting**—after ether anesthesia, 417; cyclic, in children, 114, 545; postoperative, chloroform in prevention, 36; rupture of gallbladder and from appendix, 47; to prevent, 553.  
**Vulva**, primary carcinoma, 814.  
**Vulvovaginitis** in children, 469, 973.
- Wallace**, Raymond: Angioneurotic purpura, 616: Bloods spreads as a routine measure, 568.  
**Walsh**, James J.: Obstinate subacute rheumatism, 411.  
**Wanstall**, Alfred: Pertussis, with special reference to its early diagnosis from the blood findings, 62.  
**War**—abdominal wounds in, 76; waged by means of bacilli, 889, 893.  
**Ward**, Archibald Robinson: The significance of the presence of streptococci in market milk, 256.
