PUBLISHED WEEKLY AT 1321 WALNUT STREET, PHILADELPHIA, BY THE AMERICAN-MEDICINE PUBLISHING COMPANY

VOL. V, No. 1.

JANUARY 3, 1903.

\$5.00 YEARLY.

The rise in the typhoid mortality during the past year and continuing into the winter season, is unquestioned proof that water is the chief carrier of the contagium, and that our public water-supplies are contaminated. The existence of some 9,000 deaths a year in one city, 6,000 in another, and 4,000 in a third, is a biting commentary on the policies and the charities which devote so much attention and money to a hundred things of infinitely less importance than public hygiene and preventive medicine. Here is a truth no one disputes—the value of human life; and another as indisputable is that these hundreds of thousands of deaths are unnecessary. Medicine has shown the cause and the cure, and now all that remains is that the wasters of our public and private wealth shall make an end of the wellknown causes of the needless deaths. There are doubtless other means of the transfer of the typhoid germ except water—such as inhaled dust, flies, uncooked foods—but all together do not equal water as the agent. And we now know that it is perfectly possible to free our drinking water from typhoid germs; all that is needed is the public consciousness and conscience, the demand that water shall be pure. The present waste of life is shameful, a frank sacrifice to carelessness and consciencelessness.

**The Drinking Water Furnished by the Railways,**—who knows anything about it? What are the regulations of the different companies as to its purity, and the cleansing of the tanks and coolers in railway waiting-rooms, cars, steamboats, etc.? In the presence of the great fatality of typhoid fever and the recent increase of the disease all over the country the foregoing questions seem very apropos. Certainly the transportation companies do not generally furnish their patrons with boiled, filtered, or spring water, and just as certainly the water furnished by most of our cities, especially by Chicago and Philadelphia, is contaminated and dangerous. One constantly notices the engineer or fireman drinking from the tank of the tender, and the men who handle the freight trains, the station agents all along the road—is there any attempt, is there any company that makes any serious and thoroughgoing effort to supply these employes with pure water? Whose business is it to see that the railways do their duty in this respect? Can any of our readers tell us what laws have been passed or what regulations of city and State governments, and of

Boards of Health, exist concerning this important subject? Have we not here a source of frequent infection which has too much escaped the attention of sanitarians?

**Native and Foreign Elements in the Population of the United States.**—A writer in the *Nineteenth Century* for December shows what he calls “the weak spot in our republic,” consisting of the decrease in the rate of increase of the entire population, and the far greater relative decrease of the native in comparison with the foreign elements. The rate of increase is slowing up, the census of 1900 showing about 4,000,000 less than the previous rate of increase indicated. This is due to lessened immigration. In the typical New England State of Massachusetts the alien has increased four times as fast as the native, while in no New England State is the native American in a majority; and today the foreign birthrate is four to one of the American. Out of our 76,000,000 nearly 10,000,000 are Negroes, Indians, Chinese, etc.; more than 10,000,000 are foreigners; and 13,000,000 are born of foreign parents. Then comes the change of nationality of the immigrants. From 1820 to 1899 there were about 19,000,000 settlers from other countries—8,000,000 British, 5,000,000 German, and 1,250,000 Swedes and Norwegians. But since 1893 the bulk of immigrants has come not from western but from eastern Europe. The relatively small outflow to northwestern Canada has trebled in the last three years, while Canadian immigration has ceased. With sterile natives, prolific foreigners, lessened immigration and its changed character, it would seem as if a submerging of the original Anglosaxon stock and character is inevitable. If there is no way of avoiding this by legislation, the question must arise whether it may not be at least modified. France is the only country where attempts to increase prolificity have been consciously made. Failure there would seem to discourage any such a movement here. Our problem indeed is intimately bound up with our industrial and protective system. Will it be possible for the little leaven to leaven the whole lump? We have been accustomed to think the Anglosaxon character of our life its most precious element.

**The Greatest Number of Nontaking Vaccinations.**—In response to our request recently made for a record of the greatest number of nontaking vaccinations

occurring in the practices of any of our readers, Dr. D. N. Kinsman, of Columbus, Ohio, reports the following cases :

1. L. M. L., a professor in the Medical College of Ohio, told me he had vaccinated himself more than a score of times unsuccessfully. He attended smallpox cases during his whole professional life without infection.

2. M. Mc. was vaccinated 10 times unsuccessfully, the last by me while she was quarantined at home with her sister who had smallpox. She occupied the same bed as her sister, until the eruption was entering the vesicular stage. She did not take smallpox.

3. M. B., a medical student, I vaccinated the ninth time, unsuccessfully, while he was occupying the same room as his chum who had smallpox. He did not take variola.

4. B. was vaccinated by me during her first year. When she was five she was vaccinated 19 times in three months during a severe local epidemic of smallpox. From that time till now, more than 20 years, I have repeated the operation many times, so that the number of unsuccessful vaccinations amount to more than 40. The virus used was from the same lots successfully used on other cases.

Such cases, as Dr. Kinsman suggests, appear to show that in rare instances some persons are naturally immune to smallpox, unless the theory of Copeman is thought worthy of consideration, that, without producing any local manifestation, the repeated rubbing of the vaccine into the skin produces immunization. What number of unsuccessful vaccinations would Drs. Reynolds and Reilly, of the Chicago Department of Health, place as a safe limit? Would they go on revaccinating a pseudo-immune every day or week, or month of his life?

**A Sainly Defender of Patent Medicines.**—Some one sent us an editorial taken from a paper called the *New York Weekly Witness*, in which *American Medicine* was most severely criticised for attacking the widespread sale of alcohol under the guise of patent medicines. We had never heard of this "witness," but from the extremely patent stupidity and hypocrisy of the editorial we suspected it must be—well, just what it is! We ordered half a dozen numbers to be sure our suspicion was correct. The editorial says that no one knows anything about millions of dollars' worth of these alcoholic patent medicines being sold, and implies that it is not so; it ridicules the idea that they make drunkards; it says that the so-called "bitters" of the syndicates are not medicines, and so not classifiable with the patent medicines; it says that alcohol is harmless or harmful according to the other things mixed with it; it says that the doctors make more drunkards than the patent medicine men; it says that most of the medicines prescribed by physicians contain alcohol, etc. The language in which this is said is sometimes doubtful and always slimy with indirection and illogic, but we think this is what is meant and believed. The "fool of a doctor," in the opinion of this much-praying editor, is very common, in fact he says that a *good* doctor is "a priceless jewel,"—of which there are of course very few in the world,—perhaps not so many as of really religious editors. "Thousands of persons," he says, "have been greatly helped by patent medicines who have sought help from doctors in vain." "Some people are practically compelled to doctor themselves because they cannot find a doctor who will treat them intelligently." Turning to the actual pages of this defender of the faith

we find, as was to be expected, that a nauseating religiosity vies for space with patent medicine advertisements. The advertising and reading columns are mixed as badly as in a yellow newspaper or a ladies' journal. We find the reading notice, that dirty relic of barbarism which even irreligious magazines have spit upon. We find "Mrs. Pinkham," "Swamp Root," "Piles cured," "Actina," "Are your kidneys weak?"—with portraits of the testimonialists, and \$5,000 offers of rewards if the testimonials are not genuine. "Doctors and hospital physicians use it when all else have failed with their patients." Plainly, religion (of a certain kind) with advertisements (of a certain kind) pays. But what a way to make a living!

**The Fourth Manifesto of Physicians as to Total Abstinence.**—We gladly give place to the statement published in another column for the encouragement of the cause of total abstinence by physicians. We believe in total abstinence heartily and therefore endorse the preliminary part of the manifesto. But it seems a pity that some statements should not have been made less sweeping and more scientific. Had a wise conservatism guided the remonstrants the profession would have almost universally signed the document. We believe in total abstinence when it is founded upon a man's free and individual choice, and we believe as fully in keeping up all the agencies and arguments to convince every man that such a free and independent decision is both his duty and his self-interest. But we do not believe in compelling adults to be total abstainers by means of law and punishment. That is tyranny; it is false morality, and it increases the evils of alcoholism, etc., instead of diminishing them. It should have been made clear in the statement that total abstinence is aimed at by individual conviction and resolution, not by legislative enactments and punishments. The position taken in the first paragraph is, according to present science, not true. It is in many cases the reverse of true. The second paragraph is usually true, but not always so. The third paragraph is surely true. In the fourth the condition of health should have been noted. In some disease-conditions the majority of physicians believe that alcohol may be of service in improving bodily functions. The fifth paragraph is terribly true, and the conclusion is as indisputable. The manifesto should have contained the qualification that it excepts the use of alcohol under the advice of a qualified physician.

**Money Prizes and the Encouragement of Scientific Discovery.**—The award of the Nobel prizes, about \$40,000 each, has brought misgiving to thoughtful minds, so far at least as relates to stimulating scientific discovery. It would seem as if nothing is more needed than the instruction of the rich in the art of giving wisely, of doing what they desire, and of not utterly wasting their gifts. In his provisions Nobel made two or three fundamental mistakes, either of which alone in fact condemns his plan. He gave too much money to a single person; he gave it as a reward, not as an inciter of discovery; he mistook the essential nature of the great scientific worker. With \$40,000 he could have put 10

or 20 good scientific minds at work in genuine scientific research. For completed discovery the scientist finds all the reward he needs or really wishes. More than one great discovery will usually not be made by a single mind. What civilization needs is to provide the means for discoveries not yet made. There are thousands of men ready and willing to devote their lives to research if they could be assured the simplest necessities of material comfort. One of the first rules of the normal school for millionaire pupils would be, Give while you live! The second would be, Give your trustees the largest freedom as regards details. These two rules have enabled Mr. Carnegie in his Institute to avoid the great mistake made by Nobel.

**Antialcohol Prizes by the W. C. T. U.**—Four prizes (of \$12 and \$10) are offered by the superintendent of Nonalcoholic Medication for National W. C. T. U. for the best story, humorous article, poem, and oration. Prizes Nos. 1 and 3 are to show "the evils of the medical use of alcohol" exclusively. Prize No. 2 is to show "the evils and absurdities of the use of patent medicines containing alcohol, opium or cocain, or other dangerous drugs." Prize 4 is against both the professional and the patent medicine use of alcohol. We heartily commend the plan of Prize 2, but must protest against the lack of discrimination exhibited in the other offers of prizes. A common crusade against the use of the fluid extracts, tinctures, wines (of ergot, etc.), and spirits (some twenty-five in number) of our *materia medica*, and against patent medicines, is open to much criticism; it is mixing up two dissimilar things, the indiscriminate, unregulated self-doctoring of the patent medicine users with the scientific judicious treatment by the physician. It compares the extremely slight use of small amounts of an alcoholic by the physician with the wholesale guzzling of the patent-medicine and bitters drinkers. It presupposes that the medically untrained mind of the reformer has judgment superior to that of the great mass of physicians. It alienates the sympathies of physicians, who are usually and rightly believers in temperance, not seldom in total abstinence also, but who are well aware that their choice of therapeutic agents must not be limited by nonexpert advice, or by prejudice and dogmatism. The indiscrimination shown by the prize-offerers can only produce, as it is evidently designed to produce, the same feeling of popular antipathy and ridicule toward the physician who gives his patient a drop or two of tincture of aconite, as against the stomach-bitters maker who allows the self-drugger to take his 40% alcoholic concoction *ad libitum*. All reformers should conjugate the verb to *distinguish* in all its moods, tenses, persons, genders, and numbers, like a prayer, at least thrice daily.

**Alcoholism in Children.**—Dr. Max Kassowitz, professor of children's diseases in the University of Vienna, at the Eighth International Congress against Alcoholism pleaded that the use of alcoholic drinks, etc., by children produces a large number of serious diseases. The child organism, he showed, is particularly susceptible to injury from this cause. The truth of these statements cannot

be lessened by other contentions made by Dr. Kassowitz as to the food-value of alcohol, its antiseptic effect, uses in fever, etc., which may or may not be true, but which should not have been mixed up with the undeniable verity of the perniciousness of alcohol when used by children in drinks. In our country this is not seen so much as it is in Europe, but there is altogether too much of it even here, especially if one remembers the extensive use of nostrums in the families of the poor and ignorant. There is one method of bringing on alcoholism in children that is not alluded to by Dr. Kassowitz nor by the W. C. T. U. (which translates his article), and that is through the system of the nursing mother. The judgment of the individual physician in the exceptional case should, of course, rule, but in general alcohol must result in harm to mother and child.

**Unscientific Science.**—An excellent address before the School of Medicine of the University of Colorado by Professor Lee, of Columbia University, was marred by an unscientific materialism as to "vital force." A page was devoted to contempt of this term and of what it represents. Professor Lee's attitude is shown in these words:

"Through the latter part of the eighteenth and the early part of the nineteenth century the vital principle was still in control of the physiologists, but, as they learned more of the conservation and the transformation of energy in inanimate things, and more of the working of living bodies, the gulf between the inanimate and the animate gradually narrowed, and the supremacy of the laws of chemistry and physics in all things living became clearly recognized. It is true that at times in these latter days sporadic upshoots of a neovitalism raise their tiny heads, but these are to be ascribed to the innate aversion of the human mind to confess its ignorance of what it really does not know, and they do not receive serious attention from the more hopeful seekers after truth."

In our issue of April 19, 1902, pp. 624, 625, we showed that the dogmatism of the foregoing excerpt is absolutely untrue. Michael Foster, Professors Halliburton, Ewald, Gowers, Bunge, Lord Kelvin, John Haldane, Pflüger, G. N. Stewart, Wundt, Huxley, etc., would feel flattered when called "tiny heads" and "sporadic upshoots of neovitalism." And yet Professor Lee seems to assent to Virchow's "*Omnis cellula e cellula*." If all living cells are derived from living cells where is the "narrowing of the gulf between the animate and the inanimate?" The dogma of materialism is unscientific, and materialism never yields good science. Science in fact will not permit of dogmatism, materialistic or immaterialistic, and so long as spontaneous generation remains unproved so long should there be no bigotry as to the unity of life and matter.

**Empiricism and Medical Science.**—In this same address Professor Lee said that medicine had "from first to last been permeated by the pernicious influence of empiricism." He further says that from the earliest ages science and empiricism, like the good and bad principles of all natures and religions, have ever been contending. "Science," he says, "is sure to be victorious over empiricism." All of which seems to us an erroneous statement of the facts. It takes a false view, and from a dogmatic standpoint. Except in some branches of mathematics and physics, and these but sel-

dom, empiricism is the basis of all discoveries. In biologic investigations, and especially in medical matters, so-called empiricism almost always makes the discoveries which science afterward proves and generalizes. There is no more excellent demonstration of this than vaccination and serumtherapeutics. Our therapeutics are today nearly entirely empiric in origin, and "science," in the theoretic and laboratory sense, is only corrected and extended and rationalized empiricism. The faults of empiricism do not do away with the method. Do not let us throw the baby away with the bath. Moreover, science is not solely "good" and empiricism "bad"; the two methods of discovery and progress are not opposed; one will never have any "victory" over the other. It would be a sad day for civilization and for science itself if it should ever be "ultimately victorious." The mistakes of empiricism are indeed many and to be avoided, but they do not affect its value as a method of discovering truth. The truest scientist is the most careful and observant empiricist.

**The Increase of Insanity Among Negroes.**—In his report of the Alabama Insane Hospitals Dr. Searcy says that in 1870 there were 33 negroes in the State hospitals; in 1880 there were 71, in 1890, 241, and in 1900 there were 451. The inference is allowed that this represents an actual increase of the negro insane. But is there no fallacy in the figures? Was the increase in the number not due to the fact that the insane were previously cared for in the county almshouses, or in homes, and that there has in these years been an increase of hospital inmates only without a real, or so great, an increase of the insane in the State? Are there trustworthy data in reference to the increase of the negro insane in other States? If there is a genuine and general increase of insanity among the negroes of the South, as stated, the fact is profoundly serious, and presents a problem to the States concerned that will demand the study of legislators. The sudden transfer of the negro from conditions of slavery to those of freedom and competition certainly put a strain upon these ill-prepared and handicapped pupils of civilization which they can not bear; but is the mind giving way at the rate suggested by Dr. Searcy's figures?

## EDITORIAL ECHOES

**Cosmetics and Hair Restorers.**—Most of the advertised cosmetics and hair restorers—to begin with the beauty medicines—have mercury, lead, bismuth, or zinc entering very largely into their composition. "Madam Ruppert's Face Bleach," and Mrs. Harriet Hubbard Ayer's "Recamier Balm" and "Recamier Moth and Freckle Lotion" contain corrosive sublimate. "Laird's Bloom of Youth," "Hagan's Magnolia Balm," and "Bradford's Enameline" contain oxid of zinc. Professor C. F. Chandler analyzed eight of the best known hair "restorers" and "renewers" and reported to the New York Board of Health that they all contained lead, some as much as seven grains to the ounce. To the person who knows the action of these mineral poisons, comment is unnecessary, and we submit that they should not be used by persons who do not know their action.—[Dr. Edward Bumgardner, Transac. Col. State Med. Soc.]

## BOOK REVIEWS

**The New International Encyclopedia, Volume IV.**—This volume includes words from Canada to Colenso, and in medicine the principal subjects are cancerum oris, capsicum, carbolic acid, carbonic-acid gas, carbuncle, carotid artery, cartilage, castor oil, castration, catalepsy, cataract, cathartics, cattle plague, caul, cellulitis, chest, chigoe, chloral, chloroform, chlorosis, cholera, chorea, cinchona, circulation, circumcision, cirrhosis, clavicle, climate, club-foot, cocain, codliver-oil, colchicum.

We cannot forbear again expressing our admiration of the general excellence and the fullness of space allowed medical subjects in a popular cyclopaedia. For the first time, so far as we know, professional matters have obtained a proper recognition in such a work. We must note a few omissions which strike us, in order to keep the editors up to a high standard. One can never be certain that a subject apparently omitted has not been treated under another heading. In that case there should, of course, be a cross reference. We find no mention and no cross reference to caput succedaneum, chalazion, chancre, clonus, chloasma, chorion. Under Cheyne no mention is made of Cheyne-Stokes breathing, and Charcot's disease is not alluded to under Charcot. Under circumcision the medical and surgical significations should have been epitomized. The same may be said of charcoal. Caustic as a mathematic figure has a half column and as a medical term only one-eighth. The general public will agree, we think, that the proportion should have been reversed. The same overfondness for mathematics that disfigures some other cyclopedias is also illustrated by one-half column devoted to cassinian oval, while omitting chalazian, etc. The legal bias is illustrated in a column devoted to case as a legal term, with no mention of the equally important medical use of the word. We think it too much of a flattery of popular nomenclature to treat cantharides under blistering-beetle. Of the articles themselves, they are all that could be reasonably expected. The single column given to chest is altogether insufficient, and the space given to chorea ridiculously so. We have taken pains to test the accuracy of the cross-references given. Caustery is referred to bleeding, cantharides to blistering-beetle, and there they are found.

**Materia Medica, Therapeutics, Medical Pharmacy, Prescription Writing, and Medical Latin.**—A Manual for Students and Practitioners. By WILLIAM SCHLEIF, Ph.G., M.D. Series edited by BERN B. GALLAUDET, M.D. Second edition, revised and enlarged. Lea Brothers & Co., Philadelphia and New York.

This book is practically a syllabus of the lectures of Dr. H. C. Wood. It appears to be accurate. It is concise and clear, and should be of service to the student who desires a brief statement of the main facts covered by its title.

**A Textbook of Pathology and Pathologic Anatomy.**—By Dr. HANS SCHEMAUS. Translated from the sixth German edition by A. E. THAYER, M.D., with additions by JAMES EWING, M.D. Philadelphia and New York: Lea Brothers & Co., 1902.

The ideal textbook of pathology, if it is possible for any book to be such under the conditions of rapid progress which characterize this branch of medical science, should state clearly the present status of our knowledge, emphasize differences of interpretation when such exist, explain the reason for diverse views, and give well chosen references to original sources. The altered physiology resulting from changed anatomic conditions should be emphasized, and reference to the altered metabolism distinctly emphasized, especially when the change is one bearing on problems in clinical medicine. The illustrations should aid one in understanding the text; not the reverse. The book before us does not fulfill these requirements. It is the type of textbook that gives the student the idea that pathology is very simple, and he can get along without lectures and collateral reading. It is comprehensive in the sense that it covers many subjects, but many of these subjects are treated very inadequately. Much recent important work is not mentioned. Many descriptions are ridiculously brief; thus the histology of the intestine in typhoid fever is described in one sentence of 15 words. Although "its great popularity in

Germany" may have "brought it to a sixth edition," one gets the impression that not much care has been devoted to the revisions of these various editions, and regrets that the "editor has avoided, so far as possible, any changes in the subject-matter." Many of the illustrations are good, but many others are hardly intelligible, even with the aid of their legends. The publisher has done his work well.

**Clinical Methods.**—A Guide to the Practical Study of Medicine. By ROBERT HUTCHISON, M.D., and HARRY RAINY, M.A. Second revised edition. Chicago, 1902: W. T. Keener & Co.

The chief alterations in the second edition of this work are in the chapters relating to the blood, the nervous system, and to clinical bacteriology, although the entire book has been modernized. The chapter on clinical examination of the blood is valuable because of the minute instructions given for technic and for care of instruments. This attention to details characterizes the entire book and renders it useful to practising physicians. To this end another feature of the book is to be commended, viz., the omission of many recently proposed methods of clinical investigation. For this two reasons are given. First, some of these methods have not yet been sufficiently proved, and second, some of them, especially chemical analyses, are too complicated for clinical use when simpler, though less accurate, procedures will suffice. The binding of the book is entirely too flimsy.

**The Treatment of Tabetic Ataxia by Means of Systematic Exercise.**—By Dr. H. G. FRENKEL. Translated and edited by L. FREYBERGER, M.D. Philadelphia: P. Blakiston's Son & Co., 1902.

The editor of this edition states that it is not a translation of Dr. Frenkel's book but an adaptation of it to the requirements of physicians, whose chief need is the ability to treat the ataxia of their tabetic patients. Frenkel's method differs from that associated with v. Leyden and Goldscheider in that it lays greatest stress on practice instead of athletic strengthening of the muscles, and in requiring but little apparatus. The book under consideration is a very clear exponent of this method. Part I, 66 pages, consists of general considerations regarding the types, causation, and theory of tabetic ataxia, special attention being given to the handling of patients in the examination of sensibility and examination for ataxia. Part II deals with the mechanism of the movements of the human body and the classification of exercises for the improvement of ataxia. The illustrations of movements and the simple apparatus employed are highly explanatory. As a whole the book is very satisfactory.

**Transactions of the Colorado State Medical Society.**—Reed Publishing Company, Denver.

This volume of 452 pages contains the entire proceedings of the convention as well as the bylaws and list of members of the society. The scientific program includes 38 papers. The total active membership of the society is 340. The volume also contains the essay of Edward Bumgardner, M.D., that was awarded the prize by the committee on literature for the best essay on the subject, "Dangers of Self-Drugging with Proprietary Medicines."

**A Handbook of Materia Medica, Pharmacy, and Therapeutics.**—By SAMUEL O. L. POTTER, A.M., M.D., M.R.C.P. London. Ninth edition, revised and enlarged. P. Blakiston's Son & Co., Philadelphia, 1902.

The new edition of Potter is very welcome. It has all the merits of conciseness and lucidity which have characterized this work from the beginning, and have made it so valuable for ready reference; and the new developments in the fields of synthetic chemistry, serums, and organic extracts receive full but conservative treatment. The author's preface states that 40 new articles have been inserted in the section of materia medica, and 13 rewritten. In the section of therapeutics, new articles have been inserted on local anesthesia, beriberi, dhobie itch, tropical fevers, heatstroke, hemoglobinuric fever, lymphadenoma, millaria, bubonic plague, sprue, tinea imbricata, tinea versicolor, and toxemia. Many articles in this portion

of the book, especially those referring to tropical and epidemic diseases, have been rewritten, and many other articles have been expanded with items from current medical literature and from the author's personal experience. This experience has been enriched by a service of three years as army surgeon at the headquarters of the Department of the Pacific in the Philippine Islands, and Dr. Potter's known skill in diagnosis and therapeutics, with his proved accuracy in observation, should render its fruits especially valuable.

**The Principles and Practice of Gynecology.**—For Students and Practitioners. By E. C. DUDLEY, A.M., M.D., Professor of Gynecology, Northwestern University Medical School. Third edition, revised and enlarged, with 474 illustrations, of which 60 are in colors and 22 full-page plates in colors and monochrome. Lea Brothers & Co., Philadelphia and New York, 1902.

It is a pleasure to review this book, as it is one of the best in the English language. The writer has fulfilled his purpose in writing a practical treatise on gynecology. He has employed a rational division of subjects made from the pathologic and etiologic sequence, preserving so far as possible the unity of each pathologic process as it may affect consecutively the different pelvic organs. The illustrations are unusually good and numerous, adding much to the value of the book. In this third edition the author has made a thorough revision, which includes the recent advances in gynecology, and has rewritten, rearranged, and condensed many chapters. His characterization of the present status of electrolysis in the treatment of uterine myoma will undoubtedly meet the approval of practical gynecologists. He considers that the survival of the electric method in gynecology depends chiefly upon the patient's ignorance of its inadequacy and dangers, upon the worship of the mysterious, upon an unreasoning dread of operative measures, and upon a desire to grasp any other promising means of relief. The plates illustrating the operation of vaginal hysterectomy are exceptionally fine and give a better idea of the operation than pages of text. That the therapeutic value of the Röntgen ray is not mentioned as a palliative treatment for inoperable cancer is probably due only to the fact that this value has been so recently demonstrated. But undoubtedly in the future no textbook will be complete which does not state the value of the Röntgen ray as an agent in the treatment of inoperable or recurrent malignant disease.

The arrangement of the table of differential diagnosis in confusing conditions is of especial value to the student of gynecology. We are glad to note that Dudley advises the rational method of performing episiotomy recommended by Tarnier, which passes to one or the other side of the anus; and that he also avoids describing an unnecessary number of operations for perineorrhaphy. He considers immediate operation for puerperal laceration of the cervix is of questionable value, unless necessitated by profuse arterial hemorrhage, as the exact relations of the torn vaginal wall to the cervix are difficult to define and accurate adjustment of the torn surfaces often impossible. Only about one page is devoted to solid tumors of the ovary and no mention is made of the frequency with which they are complicated by ascites. Probably it would have been wise to devote more space to this subject. But the thoroughness with which the author has treated the important subjects of gynecology, the careful, conservative, and up-to-date treatment he has advised lead us unqualifiedly to recommend this book to students, practitioners, and specialists.

**Manual of Childbed Nursing, with Notes on Infant Feeding.**—By CHARLES JEWETT, A.M., M.D., Sc.D., Professor of Obstetrics and Diseases of Women in the Long Island College Hospital. Fifth edition, revised and enlarged. New York: E. B. Treat & Co., 1902.

In this little manual of 80 pages, originally prepared for the Training School for Nurses at the Long Island College Hospital, we have a valuable aid to the nurse in remembering the more important practical teaching of the hospital training. It does not presuppose too much knowledge on the part of the nurse, neither does it encourage her to rely too much upon her own responsibility, but indicates her duties during labor and the puerperal period, including the care of mother and child. We

are glad to see that the nurse is instructed to beware of alarming her patient with talk of her experiences in other cases. This is particularly a fault of the so-called monthly nurse, who delights to entertain her patient and friends with all the gruesome details of any horrible labor with unfortunate results which she may have chanced to witness. The nurse may do much to encourage and reassure her patient, and should never unnecessarily alarm her. The directions for the management of birth in the unavoidable absence of the physician are especially clear and safe for the nurse to follow. We can heartily recommend this little volume to nurses and teachers of training-schools, while medical students may read it with advantage to themselves.

**Blakiston's Quiz-Compend, No. 4: Human Physiology.**—By ALBERT P. BRUBAKER, A.M., M.D. Philadelphia: P. Blakiston's Son & Co., 1902. Price, 80 cents net.

We have always considered this number one of the best, if not the best, in this series of compends, and the latest edition serves to further confirm that view. Some revisions have been made and new paragraphs added. The book now contains 270 pages. We unhesitatingly recommend it to the medical student, and the busy practicing physician will find it an extremely handy and useful book of reference.

**Lessons and Laboratory Exercises in Bacteriology.**—An Outline of Technical Methods Introductory to the Systematic Study and Identification of Bacteria. Arranged for the use of students by ALLEN J. SMITH, M.D., Professor of Pathology in the University of Texas, Galveston. P. Blakiston's Son & Co., 1012 Walnut street, Philadelphia, 1902. 298 pp. \$1.50 net.

This is a thoroughly practical book, having crystallized as it were from the daily experience of the author in conducting laboratory exercises during a period of several years. The entire series of exercises outlined may be carried out in eight or nine weeks of 10 hours' work each week. Sufficient explanatory matter precedes the exercises proper to render clear every step in the technic, and in Chapter IX the student is provided with a simple but comprehensive key to the classification and identification of bacteria. The book is interleaved with blank pages for conveniently recording special instructions or notes of the outcome of special experiments, and there is furnished a blank form to be followed in recording the data ascertained in connection with the study of the various forms of microorganisms. The book is an excellent one and cannot fail to facilitate the work of both teacher and student in its special field.

**New Jersey State Board of Health: Twenty-fifth Annual Report, 1901.**

This report is a volume of 459 pages giving the report of the secretary, the location of smallpox outbreaks, reports of local Boards of Health, facts concerning water-supplies, lists of physicians in New Jersey, etc.

#### BOOKS RECEIVED.

[Prompt acknowledgment of books received will be made in this column, and from time to time critical reviews will be made of those of interest to our readers.]

**How to Succeed in the Practice of Medicine.**—By JOSEPH McDOWELL MATTHEWS, M.D., LL.D., President of American Medical Association, 1898-99, ex-President Mississippi Valley Medical Association, Kentucky State Medical Society, American Proctologic Society, Louisville Surgical Society, etc. Louisville: John P. Morton & Co., 1902.

**Alcohol. A Dangerous and Unnecessary Medicine; How and Why. What Medical Writers Say.**—By MRS. MARTHA M. ALLEN, Superintendent of the Department of Non-Alcoholic Medication for the National Woman's Christian Temperance Union. Charles C. Haskell & Son, Norwalk, Conn. L. N. Fowler & Co., London, 1900.

**The Mattison Method in Morphine.** A Modern and Humane Treatment of the Morphine Disease.—By J. B. MATTISON, M.D., Medical Director Brooklyn Home for Narcotic Inebriates. E. B. Treat & Co., New York, 1902. Price, \$1.00.

**A Textbook of Diseases of the Eye. A Handbook of Ophthalmic Practice for Students and Practitioners.**—By G. E. DE SCHWENITZ, A.M., M.D., Professor of Ophthalmology in the University of Pennsylvania, etc. Fourth edition, revised, enlarged and entirely reset. Octavo volume of 773 pages, with 280 text-illustrations and 6 chromo-lithographic plates. Cloth, \$5.00 net; Sheep or Half Morocco, \$6.00 net.

**Physician's Visiting List, 1903.** P. Blakiston's Son & Co., Philadelphia, 1902.

## AMERICAN NEWS AND NOTES.

### GENERAL.

**Smallpox in the Barbados.**—The epidemic is reported to be rapidly abating. From July 13, when the disease broke out, up to November 29 there were 1,368 cases, of which 1,063 patients were discharged cured and 110 died, leaving 190 still under treatment.

**Removal of Corpses in Cuba.**—A law which is operative in Cuba forbids the removal of corpses until two years after the date of the burial, and then special permission of the civil authorities and of the church is required, as well as two medical certificates to the effect that the public health will not be injured by such removal.

**Cholera in the Philippines.**—A fresh outbreak of the disease is reported to have occurred in Manila, with an average of 30 cases daily. Army surgeons who have arrived recently in the United States from the Philippines state that the death-rate in Iloilo is very heavy, and the authorities seem absolutely powerless to check the epidemic.

**Bubonic Plague in Mexico.**—A recent report says the disease which made its appearance almost simultaneously at Lapaz, Guaymas, Mnlje and Mazatlan, all situated on the Pacific coast of Mexico, has been pronounced by competent medical authority to be bubonic plague. At Mazatlan the death-rate from the disease is from six to ten persons daily. Every possible precaution has been ordered taken to prevent a spread of the disease.

**Miscellaneous.**—MCGILL UNIVERSITY, MONTREAL: Dr. P. G. Woolley has resigned the Governor's fellowship in pathology. Dr. H. Wolverstan Thomas has been appointed to a faculty fellowship in pathology, and Dr. A. H. Gordon was appointed demonstrator in physiology. PHILADELPHIA, PA.: Dr. Alfred Hand, Jr., has been appointed visiting physician to the Children's Hospital, in place of the late Dr. Frederick A. Packard.—Dr. Thomas L. Coley has been appointed visiting physician to the Methodist Episcopal Hospital, in the place of Dr. J. P. Crozer Griffith, resigned.

**Pure-Food Bill Passed House.**—The provision known as the Hepburn pure-food bill has passed the House as reported from the Committee on Interstate and Foreign Commerce. In its report the committee said: "The bill does not prohibit the manufacture or sale of any food product not deleterious, however it may be adulterated, nor does it lay its inhibition upon the sale of an adulterated drug; but it does provide that all adulterated food and drugs shall be placed on the market under their true names and in such a manner as to advise the purchaser of what he is getting. The measure is not drastic nor unreasonable. It simply enjoins upon manufacturers and dealers in products coming within the range of interstate commerce that they shall brand or tag or in some way so mark their goods as to show just what they are."

**The Committee on Scientific Research of the American Medical Association** (Alfred Stengel, chairman, 1811 Spruce street, Philadelphia; William Osler, Baltimore; Ludwig Hektoen, Chicago) is prepared to receive applications from gentlemen engaged in scientific research bearing upon practical medicine or surgery. Five grants of \$100 each will be given in support of such investigation. The results of the work in each case must be presented, either in abstract or complete, before one of the sections of the American Medical Association, preferably the Section on Pathology, at the next annual meeting, to be held in New Orleans, May, 1903. All applications should be accompanied by a full statement of the applicant's previous work and training and his present facilities, as well as by a sufficient indication of the proposed or partly completed work to enable the committee to decide upon the advisability of making a grant.

**Hospital Benefactions.**—NEW ORLEANS, LA.: The late A. C. Hutchinson, after enumerating and naming various beneficiaries in his will, has bequeathed the residue of his estate, said to amount to almost \$1,000,000, to the Tulane University, for the sole and exclusive benefit of its medical department. The object of this bequest is to create a fund to be used in increasing the efficiency of the medical department of the University as a medical school and to contribute to its usefulness in helping the sick and infirm. To further this purpose the fund thus created is to be used by the administrators of the Tulane University, under the direction and supervision of the medical faculty, for the purchase of ground and the erection of suitable buildings to be used in the establishment of a free clinic or dispensary and for a hospital which will include in its wards such a number of free beds as in the judgment of the faculty may be available within the limitation of the fund. It is also recommended that a part of the fund and interest shall be reserved for the purpose of maintaining a free clinic. Mr. Hutchinson requests that the structure be named after his late wife, Josephine. He has also bequeathed \$20,000 each to the Eye, Ear, Nose and Throat Hospital, St. Ann's Asylum, and the House

of Good Shepherd. **SOUTH BETHLEHEM, PA.:** The late Benjamin Barge, of Mauch Chunk, bequeathed \$5,000 to St. Luke's Hospital. **BOSTON, MASS.:** Under the will of the late Mrs. N. E. Rust the Children's Hospital receives \$5,000; the Massachusetts Eye and Ear Infirmary, Perkins Institute for the Blind, and New England Hospital for Women and Children each \$2,000; and the Addison Gilbert Hospital, Gloucester, Mass., \$10,000. About \$15,000 of the residuary estate is also left to this hospital. **CHICAGO, ILL.:** By the will of the late Rosa Buehler the German Hospital will receive \$1,000. **SOUTH BEND, IND.:** The relatives of the late Clem Studebaker have given \$50,000 to the Epworth Hospital, in accordance with the expressed desire of Mr. Studebaker. **NEW YORK CITY:** The late Anne Lawrence Coleman bequeathed \$5,000 to the babies' ward of the New York Post Graduate Hospital. **READING, PA.:** Col. G. S. Beck has given an entire new equipment, said to have cost several thousand dollars, to the surgical ward of the Reading Hospital.

#### EASTERN STATES.

The New Haven Medical Association will celebrate its one hundredth anniversary January 5 and 6, 1903. Dr. William Osler, of Baltimore, and Dr. Francis Bacon, of New Haven, will deliver commemorative addresses.

**Tuberculosis Hospital.**—It is proposed to build on Woodbridge Heights, Conn., a modern tuberculosis hospital, to be run on the fresh air system. The institution will consist of three cottages of eight rooms each, so arranged that the greatest circulation of air can be obtained. Physicians claim that the treatment of tuberculosis can be accomplished successfully in the dry altitudes of that State.

**Eyes of School Children.**—A systematic examination of the eyes of school children has been carried on in Boston during the past few years and statistics obtained of over 200,000 pairs of eyes. An analysis of these examinations shows that in the primary schools nearly all the children enter with normal eyes. In the higher grades 25% have become myopic, while in university life the percentage of myopia has increased from 60% to 70%, which shows that the number of nearsighted pupils increases from the lowest to the highest schools, and that the increase is in direct proportion to the length of time devoted to the strain of school life.

#### NEW YORK.

**Genuine Bubonic Plague.**—Dr. William H. Park, bacteriologist to the Department of Health, has made his report relative to the three sailors who were detained at Swinburne Island some days ago, suspected of having the plague. The report confirms the suspicion, and states that all are victims of true bubonic plague.

**Treatment of Trachoma.**—The Bellevue and allied hospitals have established a clinic for the treatment of trachoma. It appears that many children have been excluded from school on account of the disease, and the various hospitals having facilities for treating it are very much overcrowded. A ward is provided and patients kept over night and longer if necessary.

#### PHILADELPHIA, PENNSYLVANIA, ETC.

**Muhlenberg Hospital.**—The corner-stone of the new Muhlenberg Hospital, to be erected in Plainfield, N. J., was laid recently. The new buildings will cost \$125,000.

The University of Pennsylvania Hospital is to be enlarged and improved. It is proposed to spend \$300,000, and it is estimated that when the alterations are completed the capacity of the institution will be nearly doubled.

#### SOUTHERN STATES.

**Baltimore Health Department Receives Medal.**—A handsome bronze medal, the prize won by the Baltimore Health Department for having the best exhibition of health and mortality records shown at the Paris Exposition in 1900, has been received from Paris.

**Removal of Marine Hospital Contemplated.**—It is announced that a vigorous effort will be made to have Congress remove the marine hospital now located at Gallipolis, O., to Point Pleasant, W. Va. Advocates of the project contend that by placing the hospital at Point Pleasant, at the mouth of the Kanawha, it will be convenient to many more river men, and also that less expense and trouble will be entailed in reaching it.

**To Stamp Out the Hook-worm Disease.**—Dr. Charles Stiles, zoologist to the Department of Agriculture, has asked that literature bearing on the subject be freely circulated in the sand districts of the South, where the hook-worm disease prevails. He has shown that the disease, when properly diagnosed and treated, is very easily cured. A vigorous effort, with the cooperation of physicians in the districts, will be made to stamp out the disease.

#### WESTERN STATES.

**Plague on the Gulf of California.**—The Marine-Hospital and Public Health Service will send an expert to the Gulf of California, in Mexico, to investigate the reports regarding the appearance of plague among the Chinese immigrants there.

**Hospital for Contagious Diseases.**—At a conference of women's clubs in Chicago it was decided to erect a hospital for children suffering with contagious diseases. The project has been in contemplation for some time, and has been vigorously agitated during the past few weeks with the above results.

**Nurses to Fight Tuberculosis.**—The Visiting Nurses' Association, of Chicago, have organized a permanent tuberculosis crusade committee, consisting of medical and lay members. Literature will be disseminated and, so far as possible, hospital and sanatorium facilities extended and care provided for those suffering from the disease.

## FOREIGN NEWS AND NOTES

#### GENERAL.

**Miscellaneous.**—**LONDON, ENG.:** Dr. A. E. Wright has been appointed pathologist and bacteriologist to St. Mary's Hospital, and has resigned his position as professor of pathology in the Army Medical School.—Sir Michael Foster will resign his seat in Parliament, in which he represents the University of London.

**Mortality from Pulmonary Tuberculosis in Europe.**—According to statistics recently published by the Imperial Health office in Berlin, the deathrate per million of population in the various countries is as follows: Russia has more than 4,000 deaths; Austria-Hungary and France more than 3,000; Sweden, Germany, Switzerland and Ireland, more than 2,000; Netherlands, Italy, Belgium, Norway, Scotland and England, more than 1,000 deaths.

**Sleeping Sickness.**—A report issued by the School of Tropical Medicine states that this disease, which is now devastating the Uganda, has already killed from 20,000 to 30,000 persons, and is spreading to new areas with increasing virulence. It is said that the only scheme thus far devised for the prevention and spread of the disease is the isolation of new cases. It is rumored that the Medical Commission sent to Uganda from London has discovered the germ and cause of the disease.

#### GREAT BRITAIN.

The London Hospital for Sick Children has received \$250,000 from Mr. William Waldorf Astor to build a new outpatient department, which is to be dedicated to the memory of his daughter, Gwendoline, who died recently.

**Poor Hygiene.**—A report from London relative to the period of greatest prevalence of diphtheria says that year by year the returns show a remarkable decrease in the number of cases during the vacation and of increase after the scholars reassemble. The report for 1899 indicates a fall in notified cases, between the ages of 3 and 13, of 34.7%, and upward of 13, 11.9%. On the other hand, in the four weeks after the holidays there was a rise of 44% and 14%, respectively, for these ages. It is remarkable that in children under school age the rise of disease is greatest during the holidays and less after the vacation. The medical officer of the County Council pointed out these facts in 1894, and the returns since then appear to confirm his contention. Defective ventilation and dust in public and utterly unsuitable, overcrowded rooms in private schools are quite sufficient to make them nurseries of diphtheria.

**Eye Troubles in London Schools.**—According to the *London Truth*, in April last the London School Board appointed eight ophthalmic surgeons to pay 200 visits each to schools under its control, with the object of testing the vision of the scholars. They have submitted an account of their work up to the beginning of the summer vacation, and their report shows 17,245 children have been examined, and serious visual defects have been discovered in 8% of the boys and 11% of the girls, the proportion being about equally maintained throughout school life, though the percentage varies enormously in different districts, being small in the better-class districts and greater in the poorer. The work done, however, does not end with the production of statistics. Children with subnormal vision have been supplied with a green advice card on which treatment is recommended, while those with bad sight are given red cards to take home, giving instructions as to treatment. Unfortunately, the appointment of eight oculists seems inadequate under such circumstances, for, at the present rates of progress, five years will have elapsed before all the children will have been examined.

#### CONTINENTAL EUROPE.

**Apparatus for Taking Temperature of Fever Patients.**—According to a recent report, a curious medical device is in use in the Paris hospitals. It is a little apparatus which is put under the arms of the fever patient, and is so constructed that when the temperature reaches a dangerous height a bell rings.

**Teeth of School Children.**—A dentist of Germany states that out of 5,300 school children examined, only 4.37% had sound teeth.

**Women Physicians in Paris.**—Of the 3,600 physicians now established in Paris, 57 are women. No woman physician has as yet been rewarded with the Cross of the Legion of Honor, but one midwife, Madame Gross, holds this coveted order. It was conferred upon her for gallant conduct during the Franco-German war.

**Increase of the Opium Habit in France.**—The prevalence of opium smoking and opium eating throughout France, and the rapid increase of the number of victims, which in some of the cities may be numbered by thousands, has led the government to propose placing on this drug an absolutely prohibitive import tariff. In Marseilles and Toulon the habit is said to be especially general, there being whole streets where opium dens are found in every house, with men, women, and children passing hours under the influence of the drug.

#### OBITUARIES.

**Edward Strong**, a retired physician of Newton, Mass., died December 28, aged 78. He practised in Boston, Springfield and Philadelphia. He was for many years in charge of the bureau of vital statistics in the office of the Secretary of State, and was a recognized authority on this subject.

**James F. McCone**, of San Francisco, Cal., December 7, aged 31. He was graduated from the University of California, San Francisco, in 1892, and was a member of the American Medical Association.

**S. N. Landis**, of Boston, Mass., December 25, aged 73. He was graduated from the American College of Medicine in Pennsylvania and the Eclectic Medical College of Philadelphia in 1854.

**John B. Crombie**, of Allegheny, Pa., December 22. He was graduated at the University of Maryland School of Medicine, Baltimore, in 1883, and was a Founder of *American Medicine*.

**Thomas R. Veazy**, of Milan, Ind., died in Pittsburg, Pa., December 10, aged 45. He was graduated from the Kentucky School of Medicine, Louisville, in 1885.

**Dennis Nunan**, in Guelph, Ont., December 12, aged 63. He was graduated from the University of Michigan in 1867, and Trinity Medical College, Toronto, in 1867.

**Frank H. Green**, in Homer, N. Y., December 7. He was graduated from the Syracuse (N. Y.) University in 1882, and was a coroner of Cortland county, N. Y.

**William F. Penwarden**, of Grand Rapids, Mich., December 27. He was graduated from the Bellevue Hospital Medical College in New York in 1883.

**William W. Miller**, of Pittsburg, Pa., December 14, aged 36. He was a graduate from the Western Pennsylvania Medical College, Pittsburg.

**William B. Lindsay**, of Strathroy, Ont., December 9. He was graduated from the University of the Victoria College, Cobourg, Ont., in 1869.

**George M. Van Dyke**, in West Newton, Pa., December 13, aged 44. He was graduated from the Jefferson Medical College, Philadelphia, in 1888.

**Joseph Adolphus**, in Atlanta, Ga., December 9, aged 88. He was graduated from the Pennsylvania Medical College, Philadelphia, in 1849.

**Alfred J. French**, in Lawrence, Mass., December 1, aged 79. He was graduated from the Vermont Medical College, Woodstock, in 1848.

**John F. Hammond**, in Berlin, Md., December 6, aged 72. He was graduated from the Jefferson Medical College, Philadelphia, in 1852.

**D. B. Hall**, of Ithaca, Mich., December 22, aged 75. He was a graduate of the medical department of the University of Michigan.

**John McKinley**, in New Wilmington, Pa., December 12, aged 67. He was a graduate of the Jefferson Medical College, Philadelphia.

**Josiah W. Lash**, of Chillicothe, Ohio, December 12, aged 50. He was graduated from the Columbus (Ohio) Medical College in 1878.

**James Bartlett**, at San Antonio, Tex., December 13. He was graduated from the University of Louisville (Kentucky) in 1878.

**Edmond M. Landis**, of Chicago, Ill., December 14, aged 56. He was graduated from the Rush Medical College, Chicago, in 1875.

**Benjamin Benoit**, in Lowell, Mass., December 7, aged 55. He was graduated from the New York University (New York) in 1877.

**John W. Gaston**, of Troup, Tex., December 4. He was graduated from the Kentucky College of Medicine, Louisville, in 1890.

**William M. Fulkerson**, in Ingleside, N. Y., December 7. He was graduated from the New York University (N. Y.) in 1881.

**Edward D. Wright**, in Nashville, Tenn., December 9, aged 55. He was graduated from the University of Tennessee in 1882.

**George B. Beeler**, of Baltimore, Md., December 23, aged 49. He was graduated from the University of Maryland in 1876.

**E. B. Davis**, of Kirby, Ohio, December 12. He was graduated from the Western Reserve University, Cleveland, in 1881.

**C. E. Stevens**, of Baldwinville, N. Y., December 26, aged 35.

## CLINICAL NOTES AND CORRESPONDENCE

[Communications are invited for this Department. The Editor is not responsible for the views advanced by any contributor.]

### PHYSICIANS' TOTAL ABSTINENCE MANIFESTO.

*To the Editor of American Medicine:*—It will be new to many medical men to learn that three times during the last half century medical manifestos have been issued giving the opinion of physicians on alcohol. The first was issued in 1839, and was signed by 86 persons. The second in 1847, and was signed by 2,000 physicians, and the third appeared in 1871, with the signatures of over 4,000 physicians, including the names of many leading physicians in all parts of the world. A fourth declaration of opinions is now being circulated for signatures, and reads as follows:

The following statement has been agreed upon by the Council of the British Medical Temperance Association, the American Medical Temperance Association, the Society of Medical Abstiners in Germany, and leading physicians in England and on the Continent. The purpose of this is to have a general agreement of opinions of all prominent physicians in civilized countries concerning the dangers from alcohol, and in this way give support to the efforts made to check and prevent the evils from this source.

In view of the terrible evils which have resulted from the consumption of alcohol, evils which in many parts of the world are rapidly increasing, we, members of the medical profession, feel it to be our duty, as being in some sense the guardians of the public health, to speak plainly of the nature of alcohol, and of the injury to the individual and the danger to the community which arise from the prevalent use of intoxicating liquors as beverages.

We think it ought to be known by all that:

1. Experiments have demonstrated that even a small quantity of alcoholic liquor, either immediately or after a short time, prevents perfect mental action, and interferes with the functions of the cells and tissues of the body, impairing self-control by producing progressive paralysis of the judgment and of the will, and having other markedly injurious effects. Hence alcohol must be regarded as a poison, and ought not to be classed among foods.

2. Observation establishes the fact that a moderate use of alcoholic liquors, continued over a number of years, produces a gradual deterioration of the tissues of the body, and hastens the changes which old age brings, thus increasing the average liability to disease (especially to infectious disease), and shortening the duration of life.

3. Total abstainers, other conditions being similar, can perform more work, possess greater powers of endurance, have on the average less sickness, and recover more quickly than non-abstainers, especially from infectious diseases, while they altogether escape diseases specially caused by alcohol.

4. All the bodily functions of a man, as of every other animal, are best performed in the absence of alcohol, and any supposed experience to the contrary is founded on delusion, a result of the action of alcohol on the nerve centers.

5. Further, alcohol tends to produce in the offspring of drinkers an unstable nervous system, lowering them mentally, morally, and physically. Thus deterioration of the race threatens us, and this is likely to be greatly accelerated by the alarming increase of drinking among women, who have hitherto been little addicted to this vice. Since the mothers of the coming generation are thus involved the importance and danger of this increase cannot be exaggerated.

Seeing, then, that the common use of alcoholic beverages is always and everywhere followed, sooner or later, by moral, physical, and social results of a most serious and threatening character, and that it is the cause, direct or indirect, of a very large proportion of the poverty, suffering, vice, crime, lunacy, disease, and death, not only in the case of those who take such beverages, but in the case of others who are unavoidably associated with them, we feel warranted, nay, compelled to urge the general adoption of total abstinence from all intoxicating liquors as beverages as the surest, simplest, and quickest method of removing the evils which necessarily result from

their use. Such a course is not only universally safe, but is also natural.

We believe that such an era of health, happiness, and prosperity would be inaugurated thereby that many of the social problems of the present age would be solved.

This declaration has already received the signatures of over 1,000 physicians in all parts of the country. I have been appointed chairman to present this manifesto to American physicians for their endorsement. I should be very glad to receive the name, title and address of any physician who is willing to aid by his signature to correct public sentiment and assist in the prevention of one of the great evils of the age. This is purely a scientific effort for the purpose of having a general consensus of opinion of the leading physicians of the world, and it is assumed that American physicians are equally enthusiastic and prompt to lend their signatures to this statement as in the wine-drinking countries of Europe. A postal card with address and title is earnestly solicited from every medical man who would like to be represented in this great movement for a clearer comprehension of the subject. Address  
T. D. CROTHERS, M.D.,  
Hartford, Conn.

## THORACENTESIS FOLLOWED BY ALBUMINOUS EXPECTORATION.<sup>1</sup>

BY

WM. CLIFTON DREIN, M.D.,  
of Philadelphia.

I am indebted to my late chief, D. D. Stewart, for permission, to report the following case, which occurred at the Episcopal Hospital during his service. It is reported at the request of David Riesman,<sup>2</sup> whose recent exhaustive article on the subject leaves but little for me to say, except to report the case for record. I believe it is the only fatal case of this rare condition thus far reported in America.

J. S., aged 54, a ship caulker, was admitted to the Episcopal Hospital 11 a.m., January 29, 1902, and died 1.10 a.m., January 30, 1902. Diagnosis: pleural effusion.

*Family History.*—Parents both died of senility at advanced ages. One sister died in infancy. Two sisters and one brother are living and well.

*Personal History.*—In childhood he had measles, chicken-pox, mumps, and scarlatina. He had malaria while in the South in 1877 and 1890. He had rheumatism, but never severe enough to keep him from his work. He had diarrhea off and on since last summer. He has never noticed any edema.

*Present Illness.*—About 12 days ago he noticed a slight soreness at the left apex, which he thought to be rheumatism due to exposure while at work. Eight days ago he first noticed that he was slightly short of breath, and this symptom has steadily increased. He was able to continue at his work until one hour before admission, when the dyspnea became so severe that he had to stop. He walked from the shipyard to the hospital, but had to sit down and rest frequently on the way.

*Examination on Admission.*—He is a stout, well-nourished man, appearing to be a few years younger than age given. He has no pain or soreness in any region, but complains of a feeling of great oppression in the chest. Bowels have been regular for the past week, and he says he has been passing a normal quantity of urine. Dyspnea is very marked, all the accessory muscles being brought into action; expression is anxious; lips cyanosed; tongue slightly coated and tremulous; slight cough; no expectoration; no edema present. Right chest is clear, except for accentuated breath sounds. Left chest anteriorly; resonance impaired to apex. Dulness begins at the lower border of the third rib and shades off to absolute flatness at the base. Posteriorly, there is flatness at the base, and dulness to the midscapular region. Dulness is slightly movable. Breath sounds and tactile fremitus are absent at the base. There are distant breath sounds at the upper limit of dulness and harsh breathing at the apex. The heart is displaced to the right, and the apex is not palpable. Sounds are best heard one inch to the left of the sternum. No murmurs could be elicited. Abdomen is negative. Temperature is 99°, pulse 100, respirations 40. After being put to bed the patient seemed more comfortable. He was seen by Dr. Stewart who, after confirming the diagnosis, ordered thoracentesis. At 4.45 p.m. thoracentesis was done with a Potain-aspirator. The needle was introduced in the seventh interspace in postaxillary line, and 1,620 cc. of clear straw-colored fluid withdrawn. The patient stood the operation well, and did not cough during the whole procedure, but

coughed some after the needle was withdrawn. The fluid had a specific gravity of 1,020, and coagulated into a solid mass on boiling. There was no blood in it. At 7.30 p.m. it was found the patient had been fairly comfortable, with the exception of a slight, dry cough, until 20 minutes before, when he had a severe paroxysm of coughing with intense dyspnea, followed by the expectoration of about half an ounce of frothy, straw-colored fluid, resembling that obtained from the pleural cavity. The cough rapidly became almost continuous, and the dyspnea so severe that he had to sit up in bed. He has expectorated about two ounces in the last 20 minutes. Large gurgling rales are heard all over the left chest. There are no signs of pneumothorax. Temperature is 100.6°. Pulse 120, and very weak. Dry cups followed by wet ones were applied without relief and free stimulation and morphin ordered. At 10 p.m. the dyspnea had increased, and edema had spread to the right lung. He fills a sputum cup with expectoration every few minutes. Sputum on boiling coagulates into a solid mass. Temperature is 100.6°. Pulse 130. At 12 p.m. he will not respond to stimulation. Extremities are cold, skin clammy, pulse hardly perceptible. Fluid is gushing from the mouth and nostrils in a steady stream. At 1.10 a.m. the patient died. The relatives refused to allow a postmortem examination.

The usual cause given for this condition is either a too rapid or excessive withdrawal of fluid which does not permit a correspondingly rapid expansion of the lungs, and the veins having lost their tone from compression are unable to keep up the balance between the general circulation and the active congestion that ensues, consequently a leakage into the air vesicles occurs. This condition has been very aptly called "congestion by recoil." In the present case the fluid was withdrawn slowly, the patient allowed frequent rest, and the amount, although large, does not seem to me excessive, when we consider that he had no alarming symptoms during the tapping, and did not cough until the needle was withdrawn. Rosenbach<sup>1</sup> states that edema of the lungs has been observed after simple puncture without aspiration. An interesting feature of the case is the length of time that elapsed before the onset of expectoration—about two hours. According to Riesman, this is very rare, expectoration usually coming on within the first half hour after thoracentesis, and rarely, as in his case, during it. Owing to an unfortunate mistake, the fluid was thrown away before any chemical analysis could be made, except the simple boiling test applied to it while the patient was still alive.

## SOME OF THE SURGICAL USES OF CLOVE OIL.

BY

W. A. BRIGGS, M.D.,  
of Sacramento, Cal.

My earlier impressions of the value of clove oil in surgery and obstetrics, communicated to the California Northern District Medical Society in October, 1900, have now been confirmed by an experience extending over a period of nearly two years and embracing a large number and variety of surgical conditions. I shall briefly report the method and results of the use of clove oil in the various conditions, surgical as well as obstetric, in which I have employed it:

1. Disinfection of hands of surgeon, obstetrician and nurse: (a) Minimize danger of infection by wearing rubber gloves in all septic cases; (b) should the hands be accidentally or unavoidably infected, cleanse and disinfect them at once; (c) keep the skin smooth and soft and free from cracks and abrasions; (d) immediately before an operation file the nails short, clean thoroughly the subungual spaces, cleanse the hands, forearms and arms well above the elbows with a soft brush, tincture of green soap, and the very free use of warm sterile water; dry the hands and arms with a sterile towel and apply clove oil freely and thoroughly with soft brush to the entire surface; fill the gloves with sterile water and "float" them on without removing the oil.

This method is simple, expeditious, efficient, and possesses the advantage, which in my opinion is very great, of maintaining a positively aseptic condition of the hands during the entire operation.

2. Disinfection of operative field: Cleanse the surface thoroughly with soap, water and a soft brush; dry with sterile

<sup>1</sup> Read before the Northern Medical Association of Philadelphia, December 12, 1902.

<sup>2</sup> American Journal of Medical Sciences, April, 1902.

<sup>1</sup> Nothnagel's Encyclopedia of Practical Medicine.

towel; rub in with soft sterile brush a mixture of equal parts of clove oil and lanolin; cover with sterile gauze; repeat this process with pure oil just before the operation; cleanse well with ether. If the operation must be done at once cleanse with soap, water and soft brush, dry with sterile towel, rub clove oil well in with a soft brush and wash it off with sterile gauze and ether.

3. The need of a positive, nonirritant and continuous antiseptic in the treatment of infected wounds, whether surgical or accidental, is felt by every surgeon. For this purpose I know of nothing better than clove oil, variously combined or diluted. I have now used it in some 20 accidental wounds, lacerated and contused. In all but three of these primary union took place throughout. These three cases are of exceptional interest, partly because as exceptions they prove the rule.

The first of the three was the case of B., a millhand, who thrust the palm of his left hand against a wide set circular saw. The saw teeth entered just above the carpus, severing both the radial and ulnar artery, tearing out the flexor tendons from their muscular origins and excavating the carpus and metacarpus. Both arteries were tied, the ulnar and the radial; the second finger, the second metacarpal bone, fragments of the carpal bones and of other lacerated tissues were removed and the extensor tendons of the index finger and thumb were sutured as well as possible to the lacerated muscles of the corresponding side of the forearm. The wound was thoroughly cleansed with 20% clove oil, of which an excess was left in the wound. The wound was closed with difficulty, on account of the loss of tissue, and sutured with considerable tension. Notwithstanding this, however, primary union was complete except at the site of the gauze drains at the upper and lower angles. Unfortunately, on account of the tension drainage was not perfect and an abscess developed and was drained through the palm. Aside from this nothing occurred to mar the recovery, and a very useful hand resulted.

The second case was that of a young man whose hand had been caught in the gearing of an elevator; the little finger was amputated at the metacarpophalangeal joint, and the skin of the ulnar aspect of the hand was badly lacerated by the cogs. The wound, after careful disinfection with 20% clove oil was dressed in the same oil, and healed by first intention, excepting three pieces of skin that were practically gouged out. Enough of these pieces retained their vitality to prevent the considerable scarring that would have resulted from their sacrifice.

The third case was that of a fleshy girl of 10, who fell from a fence, catching the thigh on the head of a projecting nail and making a wound  $\frac{3}{4}$  inches in length, and from  $\frac{1}{2}$  to 1 inch in depth. The edges were badly lacerated, but after disinfection were brought together without trimming. The stitches were removed on the third day, when union seemed to be perfect, except at two or three points where narrow strips of lacerated skin had necrosed. Two days later, in consequence of a fright, the patient made a sudden and severe muscular effort and separated the edges of the wound, which then healed by granulation.

Punctured wounds should be thoroughly packed with gauze or absorbent cotton, saturated with pure clove oil. I have treated two nail wounds of the feet without any inflammatory reaction whatever.

4. I often pack abscess cavities, particularly when badly infected after evacuation, with gauze saturated with pure or diluted clove oil, and have had excellent results.

In obstetrics, rapid and perfect disinfection of the hands is imperative. Clove oil meets these requirements better than any other antiseptic I have used. Besides, by maintaining a positive and continuous aseptic condition, it reduces to a minimum the possibility of infection from the hands of the accoucheur.

5. One of the most useful applications of clove oil is as a dressing for the umbilical cord. Put dry and sterilized tapes, absorbent cotton, and rubber finger cot in pure clove oil, and have on hand sterilized scissors and hemostats. Tie the cord securely with tape an inch from the abdomen and sever it a half inch beyond; through an opening in the distal end of the cot, pass the jaws of the hemostat and seize the cord within an eighth of an inch of the body (leaving just room enough for the ligature); tie the proximal end of the cot firmly about the cord at its very end, being careful, of course, not to include the skin; withdraw the hemostat and insert in the cot a piece of absorbent cotton as large as a hazelnut, saturated with clove oil, and close the distal end of the cot with a ligature. Dress the enveloped cord by carrying it through several thicknesses of sterile gauze, which should be saturated with 30% clove oil in olive

or other indifferent oil, and folded over as in the usual dressing. Each day the gauze should be saturated with the same solution.

The advantages of clove oil for these purposes are these: 1. It is practically nontoxic. In an extensive experience I have never observed the slightest constitutional disturbance attributable to its influence. 2. Locally it is distinctly analgesic and powerfully antiseptic. Properly diluted, it is nonirritant or, in its purity, to the bare tissues, superficially escharotic, as may be desired. 3. It affords a quick, simple, and ready means of disinfecting the hands and of keeping them in an aggressively antiseptic state during the progress of operation. The skin at first is somewhat sensitive, but it soon acquires immunity, and thereafter remains in the best possible condition for surgical work.

## BROAD LIGAMENT CYST OF LARGE SIZE OCCURRING DURING THE COURSE OF PREGNANCY; ITS REMOVAL FIVE WEEKS AFTER DELIVERY.

BY

LEVI JAY HAMMOND, M.D.,

of Philadelphia.

On April 18, 1902, Mrs. R. M. M., aged 22, consulted me at my office. This was the first time I had seen her, and she was then at full term of pregnancy. She gave the following history:

When three months pregnant she detected for the first time in the right pelvic region a freely movable growth about the size and shape of a lemon. This gave her no concern, as she supposed it was the natural enlargement of the uterus, and her mother, whom she consulted, thought likewise. Its rapid growth, however, which, by the end of the sixth month had reached the height of the umbilicus, entirely filling the right abdomen, and extending well into the flank, made the patient apprehensive. Her alarm was further increased as the uterus could also be readily outlined by her; abdominal palpation in her particular case being readily accomplished because of the thin walls and entire absence of fat. She weighed only 97 pounds, her height being 5 feet 7 inches. She consulted a physician, who told her there was no reason for anxiety, as he believed her condition to be one of twin pregnancy. The tumor continued to grow rapidly, until by the eighth month it filled the entire right side of the abdomen and extended well to the left side, overlying a great part of the uterus.

She consulted another physician, who promptly recognized the presence of a growth, and advised her to be at once admitted to a lying-in hospital for treatment. This she did; but after remaining there a few days she decided she would prefer to be treated at home, and left the institution.

On the following day, accompanied by her mother, she called at my office. Examination disclosed the fact that she was then in labor, the cervix being dilatable to the extent that it would readily admit the index and middle fingers. Pelvic measurements taken at this time showed a normal pelvic outlet. The tumor was not difficult to outline separately from the uterus, palpation of it being rendered much easier by the fact that the uterus was then in a state of contraction. The growth, as before stated, filled the entire right side of the abdominal cavity, and fluctuation could be readily elicited. A diagnosis of ovarian or broad ligament cyst was not difficult to decide upon.

As the patient was already in labor and the tumor did not encroach upon the birth track, nor with the body of the uterus, it was decided that she should return home. Here, after the cervix was dilated, she was placed under ether and delivered by forceps of a perfectly healthy female child at full term. The uterus promptly retracted and remained so. There were no untoward symptoms following labor for about 48 hours, when I was hastily summoned. I found the pulse 140, and great pallor with marked blanching of the conjunctiva and lips. The uterus was still firmly contracted, there had been no post-partum hemorrhage, and the cyst was apparently not ruptured. After application of the usual restoratives, both hypodermically and locally, she began to rally, and continued to a perfectly normal convalescence.

Just what was the cause of this sudden shock was not apparent to me at the time, nor has it been since. A possible explanation for it, however, may have been a rupture of a small cyst, or a separation of the cyst wall from either adhesions to the intestines, or to the parietal peritoneum. There was no infection whatever. Temperature at no time during the entire lying-in period was above 99°.

Five weeks after delivery I opened the abdominal cavity and removed a broad ligament cyst (paroophoretic). There were considerable adhesions extending throughout and along the parietal peritoneum as high as a level with the umbilicus. It is possible that the presence of these adhesions may offer an explanation as to the cause of the profound systemic shock 48 hours after delivery. There was no twisting of the pedicle.

SOME CARDIORESPIRATORY PHENOMENA REVEALED BY THE RÖNTGEN RAYS.

BY  
ALBERT ABRAMS, A.M., M.D.,  
of San Francisco, Cal.

In this contribution I intend to discuss certain facts which have been elaborated as the result of personal observation. The rays have been epoch-making in exploding many statements in physiology which have heretofore been regarded as apodictic. The diaphragm does not flatten with each inspiration; on the contrary, its curve is always maintained unaltered, and in its excursions it plunges piston-wise up and down. The lines of the diaphragm on both sides are not on the same niveau, and the excursions of the diaphragm are slightly greater on the left than on the right side. The heart is not stationary during the phases of respiration, but with each inspiration there is a decided downward movement of the organ following the inclined plane of the central tendon of the diaphragm. Physiologists have taught that the central tendon is capable of only limited movement in respiration, hence the heart in its respiratory mobility is likewise restricted. Campbell<sup>1</sup> asserts that when the pulsating heart is felt in the epigastrium after deep inspiration, it is not due to an actual descent of the heart but to the lifting upward of the thoracic cage over the heart. The aphorism of Fowler, "The position of the apex beat is the key to the diagnosis of nearly all the affections of the heart and chest" is no longer infallible. The rays prove that the so-called apex beat may be palpated at a point remote from the anatomic apex, hence the impulse felt may be due to the impact of the ventricle against the chest wall. Finlayson<sup>2</sup> and others taught that the disappearance of the apex beat, when the breath is held after a deep inspiration, is caused by a dilated right ventricle pushing the left aside. My observations show that this maneuver causes no dilation of the right ventricle nor dislocation of the left. The real explanation of the phenomenon is that the triangular space in front of the heart widens and lengthens in deep inspiration and causes a slight recession of the apex beat from the chest wall. We must frankly concede that the rays have not fulfilled our expectations in cardiac diagnosis and, beyond demonstrating the fallibility of our methods of percussion, they have only rendered us a modicum of service.

THE POSITION OF THE HEART.

The site of the heart is normally influenced by attitude, respiration and the position of the diaphragm. Adhesions modify the amplitude and direction of physiologic dislocation.

*Attitude.*—In attitudinal dislocation my measurements show that in the left lateral posture the heart moves on an average 2.6 cm. to the left and 1.1 cm. upward; in the right lateral posture 1.5 cm. to the right and 0.5 cm. upward. In children suspended by the feet I found only slight heart dislocation which was toward the median line. As a rule attitudinal dislocation was less evident in children than in adults, and less marked in obese individuals than in lean ones. In the recumbent posture the triangular space behind the heart is still in evidence, a fact which would tend to disprove the theory of Kingscote<sup>3</sup> that the predominance of asthmatic seizures at night was caused by this posture which enabled a dilated heart to impinge on the vagi.

*Respiration.*—The heart descends during inspiration and ascends during expiration. During inspiration the silhouette of the heart becomes more defined, its transverse diameter diminishes and the heart inclines slightly toward the right. I have observed that repeated deep

inspirations will eventually darken the luminous area of the lungs and concurrently cause obscuration of the heart. This is probably dependent on the fact that repeated inspirations excite the respiratory center to send out expiratory impulses, thus putting the lungs in the position of expiration. During inspiration the cardiac pulsations show less amplitude than in expiration, a fact which may be referred to the stretching of the pericardium during inspiration. There is no reason to believe that an x-ray study of the heart pulsations supersedes in value the conventional physical signs, unless it is in the differential diagnosis between an enlarged heart and a pericardial effusion. In the former the pulsations may be discerned, but not in pericardial effusion.

*Aneurysm.*—As the pericardium is reflected on to the greater vessels at the cardiac base, there is during forced inspiration considerable stretching of these vessels; hence the area of an aneurysmal shadow would be diminished in inspiration and increased in expiration. Cardiac position is maintained by pulmonary suction. If this suction is diminished on one side, the heart will be drawn to the opposite side by predominant suction. This physiologic fact refers in a measure to the great bloodvessels and may be employed in a skiascopic study of suspected aneurysm. Diagnosis is based on such a multitude of little things that anything, however insignificant, is worthy of regard. In my initial investigations with the rays I frequently committed the error of making a diagnosis of aneurysm when it did not exist. Such errors, in the main, emanated from a failure to recognize the occasional anomalous course of the aortic arch. Even now I would hesitate to diagnose aneurysm with no other aid than the rays. Sagittal chest illumina-

tion shows a dense shadow caused by the sternum and spine; projecting from this shadow is a smaller round one, with a slight convexity outward, located in the second left interspace which belongs to the arch and descending aorta. Now, this small shadow may be brought into greater prominence either on the anterior or posterior chest surface by firm pressure sufficient to immobilize the right thorax. Such compression brings into play the unopposed suction of the left lung which tugs on the heart and bloodvessels, drawing them toward that side. I find that by oblique illumination of the chest, *i. e.*, by directing the rays from the posterior left side to the anterior right side of chest, the aortic arch may be brought out most distinctly. By this maneuver the heart silhouette appears suspended in space with a dark pulsating cord (ascending arch and descending aorta) rising from it. Two maneuvers in respiration are available in diagnosis, *viz.*, Valsalva's and Müller's experiments. The former consists in conducting forced expiration with closed mouth and nostrils, which so raises intrapulmonary pressure that the great bloodvessels and heart are firmly compressed. The effect of

such pressure on the heart may be seen in the accompanying fluoroscopic tracing. In Müller's experiment a vigorous inspiration is taken with mouth and nostrils completely closed. This maneuver diminishes the negative pressure on the heart and bloodvessels. If a shadow is a suspected thoracic aneurysm, the Valsalva experiment will diminish and the Müller experiment increase the area of the shadow.

#### POSITION OF THE DIAPHRAGM.

The area of cardiac dulness, as the rays show, is influenced by the position of the diaphragm; and per-

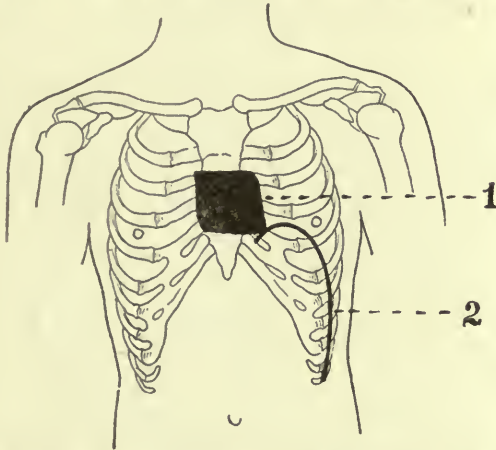

Fig. 4.\*—Effect of stomach insufflation on the heart: 1, radioscopic appearance of the heart, and 2, outline of the fundus of the stomach

cussion, however skilful, often yields erroneous results. When the diaphragm is high, the long axis of the heart becomes more horizontal than when it is low, hence the transverse diameter of the heart is greater during expiration than inspiration.

*Dislocation of Accommodation.*—We have long recognized the almost intelligent function of muscles whether displayed in fixing a diseased joint or spine or in protecting an inflamed serous membrane. Now the midriff will become fixed in the deepest inspiration when if for any reason there is any encroachment on the respiratory area

length of the aorta. If we make firm compression of the upper thorax in a child we may note the immediate descent of the heart. Dislocation of accommodation is observed in thoracic aneurysm if unaccompanied by aortitis. Cardiac dislocation in thoracic aneurysm is usually regarded as a result of pressure, but the fact is, it occurs in early aneurysm before the heart is capable of mechanic dislocation. In health during deep inspiration there is usually a free space between the heart and diaphragm, and the heart does not rest on the latter but is supported by the bloodvessels. In aortitis and aneurysm associated with anginous signs, the diaphragm

Fig. 5.\*—1, radioscopic appearance of the heart after administration of a Seidlitz powder; 2, outline of the fundus of the stomach.

lies high, as if to support the heart and diminish traction on the bloodvessels. It is only a question as to whether pain or dyspnea predominates in disease of the heart and bloodvessels; if the former, the heart lies high, if the latter, it is low.

#### THE STOMACH AND COLON ON THE POSITION OF THE HEART.

I have referred elsewhere<sup>4</sup> to the influence of a dilated stomach on the position of the heart. The accompanying illustrations show how easily the heart may be

Fig. 6.\*—Patch of dulness in dislocation of the heart upward. Patient in erect position.

Fig. 7.\*—Same case. Patient leaning backward.

Fig. 8.\*—Black areas, shadows cast by normal heart. Shaded area, shadow of dislocated heart.

in the upper thorax. With this descent of the diaphragm there is also a downward luxation of the heart, which I will refer to as the dislocation of accommodation. In old age this form of dislocation is present, and the low position of the diaphragm and heart is a mere accommodation phenomenon to compensate for the increased

\* Figs. 4, 5, 6, 7, 8, 11 and 12 are reproduced from blocks received through the courtesy of the New York Medical Record.

dislocated by artificial distention of the stomach. It is unnecessary to descant on the practical value of this observation. Heart dislocation from stomach dilation is associated with a circumscribed area of dulness in the left interscapular region. Over this area bronchial respiration is heard. When the patient leans forward dulness and bronchial breathing disappear, to reappear when the erect attitude is resumed.

Leaning backward increases the area of dulness. The phenomena in question are produced by a dislocated heart compressing the lung, which fact is easily verified by the rays.

The foregoing syndrome may be reproduced synthetically by artificial distention of the stomach. An enormously distended heart may produce identical signs. Artificial insufflation of the colon is incapable of producing the same degree of cardiac luxation.

*The Position of the Heart in Coughing and Laughter.*—A cough, by alternately elevating and depressing the diaphragm slightly, does not materially influence the position of the heart, although in one patient the organ was forced upward nearly three inches. Laughter, on the contrary, by putting the diaphragm in the position of extreme expiration, causes a decided elevation of the heart. When laughter is paroxysmal the rays show the heart to bob up and down like a rubber ball, thus inducing a veritable heart massage. I can easily conceive the baneful effects of prolonged laughter in cardiac disease by inhibiting the return of the venous circulation and causing the disintegration of a thrombus in the heart chambers.

*Amyl Nitrite.*—The inhalation of this drug will intensify feeble cardiac murmurs, but ordinarily it is not serviceable in diagnosis, owing to the creation of cardio-muscular murmurs, which have no reality other than in the delirious state of the organ. To bring out aneurysmal pulsations while the rays traverse the chest, it is indispensable. During the inhalation of amyl nitrite, in a certain percentage of persons, the transverse diameter of the heart will become diminished. This drug is

Fig. 9.

Fig. 10.

Fig. 9.—Dull area elicited after amyl nitrite inhalation.  
Fig. 10.—Action of amyl nitrite inhalation on the heart: A, area of heart before, and B, area after inhalation.

a specific in inhibiting the distress of angina pectoris, and if it reduces the cardiac area as the rays demonstrate, the theory of Heberden, that angina pectoris is a cramp of the heart muscle, must be wrong.

The theory of extreme tension of the ventricular walls in consequence of acute dilation seems to be corroborated by the action of the drug upon the heart. I have observed another phenomenon associated with the inhalation of amyl nitrite, and that is a limited patch of dulness which develops over the manubrium sterni, as seen in the illustration.

This patch of dulness may involve the entire manubrium and extend to the right as well as to the left side. The dulness in question is almost never reproduced after an immediate second inhalation of the drug. It is caused by a circumscribed collapse of lung. In some persons inhalation of the drug evokes dull areas in other chest regions, but the manubrium dulness is almost constant. The latter area of dulness may at once be dissipated by tapping the epigastrium, which provokes the counter lung reflex of dilation.

*The Action of Rarefied and Compressed Air on the Heart.*—I have sought to determine the modifying degrees of pressure of the external atmosphere on the heart by applying to the precordial region large cups

from which the air was exhausted. It could easily be observed while the rays were traversing the chest that the creation of a vacuum caused a decided dilation of the right cardiac auricle and ventricle, and that the cardiac area was restored to normal the moment such vacuum was removed. Similarly, increased pressure in the precordial region caused a recession of the cardiac area, likewise implicating the right chambers of the

Fig. 11.\*—Heart reflex in a boy aged 8. Duration of reflex, 2½ minutes.

heart, but the change in the cardiac area was not as great as in the previous experiment. These observations, elementary as they are, serve, nevertheless, as an index in determining the effects of altitude on the heart.

*The Heart Reflex.*—This phenomenon, first observed in 1896,<sup>5</sup> consists essentially of myocardial contraction resulting from cutaneous irritation in proximity to the precardium. It can only be observed with the rays. The degree of myocardial recession varies. In some it is scarcely perceptible.

In a previous contribution<sup>6</sup> I espoused the theory that the real factor involved in balneotherapeutics and mechanotherapeutics was not dependent on the baths and exercises as such, but to the cutaneous irritation provoked by these maneuvers and the resulting action

Fig. 12.\*—Heart reflex in a boy aged 14. Duration of reflex, 55 seconds.

on the myocardium (heart reflex). Time has only strengthened me in this conviction. Since my original contributions on the heart reflex, I have studied it as an index to the condition of the myocardium, and find in brief that when the cardiac muscle is beyond restitution in myocarditis and valvular diseases the reflex cannot be elicited. Heretofore this reflex was only observed in the transverse cardiac diameter, but it may also be noted

in the sagittal diameter. The recognition of the heart reflex will often aid us in excluding the murmurs of a relative insufficiency. Here vigorous rubbing of the precardium will temporarily dispel the latter murmurs. One may elicit the heart reflex by irritation of more remote regions. I refer in particular to the nose. Some years ago<sup>7</sup> I directed attention to the pulmonary neurosis of dilation which could be evoked in almost every healthy person by irritation of the nasal mucosa, and that such irritation was inoperative if the mucosa were

nance. The circumscribed dull area obtained by Cherchevsky corresponds precisely to that elicited by amyl nitrite inhalation. Dull areas may be obtained in other chest regions, especially in proximity to the sternum and spine if vigorous percussion is conducted. For this purpose, I use a large wooden mallet and a pleximeter of felt. The circumscribed dullness thus induced lasts but a few seconds but may be made to disappear at once by striking the epigastrium. Observed with the rays in a susceptible person, the phenomenon in

Fig. 13.

previously cocainized. Later<sup>8</sup> I demonstrated that in persons suffering from asthma of presumable nasal origin, impaction of cotton in one or both nasal cavities would induce a typical asthmatic paroxysm. One may easily observe by aid of the rays that when ammonia is inhaled there is a decided recession of the cardiac ventricles (heart reflex), especially the left, and that this heart reflex may be more pronounced than when discharged through the skin of the precardium. Ether and chloroform produce a similar though less pronounced effect. With the nose closed, a similar though less pronounced effect of the vapors may be obtained, presumably by their action on the pharyngeal and laryngeal mucosa. In a few instances the vapors produced a veritable heart inhibition. I could observe no diminution in the intensity of the heart tones during the inhalation of the vapors, yet the accompanying sphygmogram shows a decided difference in the output of blood into the general circulation before and after the inhalation of ammonia. These observations suggest the wise expedient of cocainizing the nasal mucosa before using an anesthetic, and further suggest the cogent necessity of anesthetizing the pharyngeal and laryngeal mucosa.

In another communication<sup>9</sup> I directed attention to inhibition of the heart as an aid in diagnosis. I then demonstrated the facility which certain persons possessed of inhibiting the action of the heart by voluntary contraction or stretching of the neck muscles.

During anesthesia, one may observe that this reflex act is accentuated, and there is no doubt, in my mind, that many a careless anesthetist has caused death by undue stretching of the neck during chloroform or ether anesthesia. The heart reflex may also be invoked by irritation of the gastric mucosa when the sponge of the gyromele is made to revolve against it. This fact may explain sudden death of gastric origin through reflex inhibition of the heart. The "vagus reflex" of May is practically the heart reflex. When the vagi are compressed and the heart observed by aid of the rays, there is an inhibition of the organ, retraction of the myocardium and lung distention.

*The Lung Reflex of Contraction.*—I wish finally to direct attention to the Cherchevsky<sup>10</sup> sign of early arteriosclerosis. This author contends that in normal conditions the diameter of the aorta varies at different times. It becomes dilated if the region over the arch is struck with the percussion hammer, while it shrinks in size if the blows are struck in the epigastrium. In arteriosclerosis it is impossible to produce these variations in diameter. The author has misinterpreted the phenomena obtained by his maneuver. What he really elicits is a circumscribed lung contraction adjacent to the part struck on the chest by the hammer and the blow on the epigastrium merely causes the collapsed lung area to dilate, thus supplanting dullness by reso-

question is a most interesting study. After the blow is struck the adjacent lung area becomes gradually dark, showing that the air has been expelled from the lungs, whereas in a few seconds the lung area becomes bright again. This reflex cannot be obtained if the nasal mucosa has been previously cocainized nor if the skin is irritated over the lung area, for then the counter reflex of lung dilation is elicited. The phenomenon just described I have

Fig. 14.—Mallet and pleximeter for eliciting the lung reflex of contraction.

called the lung reflex of contraction to distinguish it from a reflex described elsewhere<sup>11</sup> and which I will now specify as the lung reflex of dilation. The latter reflex is provoked by any cutaneous irritation, percussion of the epigastrium and the inhalation of irritating vapors. The lung reflex of contraction has the same value in diagnosis and therapeutics as the counter reflex, but I will reserve its consideration for a future contribution. Suffice it to say at this time that we must hypothesize two distinct functions of the vagus, one which will enable it to dilate and fibers which can

Fig. 15.—The lung reflexes of dilation and contraction: A, normal areas of heart and upper liver border respectively; LRD, region for eliciting lung reflex of dilation which, when struck, causes lung border to descend to B, and cover heart area almost to obliteration; LRC, regions for eliciting lung reflex of contraction which causes lung borders to recede to C.

contract the bronchioles. This is the only hypothesis which permits us to explain the lung reflexes. Aufrecht<sup>12</sup> has recently shown that the belief of only a circular layer constituting the musculature of the bronchi is wrong, and that by using the Biondi-Heidenhain stain a longitudinal muscular layer also exists. I contend, in

view of this histologic fact, coupled with a knowledge of the lung reflexes and observations of asthmatics, that the theory of asthma must not alone be based on a spasm of the circular fibers of the bronchi but on an inability of the weaker longitudinal fibers to expel residual air imprisoned by the circular fibers. In support of this theory I recall my observations with amyl nitrite. The primary effect of inhalation of this drug is to augment lung volume and then to diminish it so that its efficiency in arresting paroxysms of asthma is actually dependent on contraction of the longitudinal no longer antagonized by the circular fibers. This action has its analog in the bladder musculature when, in consequence of a spasm of the sphincter vesicæ, the weak detrusor vesicæ cannot expel the urine, and ischuria spastica results.

A CASE OF SUBACUTE COMBINED SCLEROSIS OF THE SPINAL CORD.

BY

CHAS. S. POTTS, M.D.,

of Philadelphia.

Instructor in Nervous Diseases at the University of Pennsylvania; Neurologist to the Philadelphia Hospital.

In 1887 Lichtheim<sup>1</sup> first described three cases of pernicious anemia, which, in addition to the usual symptoms of that disease, presented symptoms of affection of the spinal cord. From this time similar cases associated with pernicious anemia were described by others until in 1891 Putnam<sup>2</sup> described a number of cases presenting similar clinical nervous symptoms and pathologic changes which were not associated with pernicious anemia, but occurred in debilitated people past middle life, who, in most cases, had been subjected to some other form of toxemia, and in some of whom anemia occurred as a secondary symptom. Dana<sup>3</sup> very shortly afterward reported a similar case.

A considerable number of like cases most frequently occurring in women have since been reported by various observers, which either occurred in connection with pernicious anemia or other toxic and cachectic conditions, notably the acute infectious diseases, prolonged diarrhea, lead-poisoning and possibly shock; prolonged worry and poor nutrition. In the latter group anemia as a secondary symptom is also usually but not always present. To this group of cases somewhat differing names have been given by different observers, *e. g.*, subacute combined sclerosis of the spinal cord; subacute combined degeneration of the spinal cord (Russell, Batten, and Collier<sup>4</sup>); and diffuse degeneration of the spinal cord (Putnam<sup>5</sup>). The first symptoms are usually marked paresthesia, especially of the lower limbs, slight weakness of the lower limbs and some ataxia. As the disease progresses the legs become more spastic and the deep reflexes increased, after a varying period the paralysis changes from a spastic to a flaccid one and the deep reflexes disappear; finally the arms become affected, wasting of the muscles with changes in the electric reactions develop, and more or less complete sensory paralysis appears. In the later stages also incontinence of the sphincters, edema of the lower limbs, bed-sores and subcutaneous hemorrhages and slight dementia have been noted. An eruption of herpes sometimes occurs as

an early symptom and remissions in the symptoms for a greater or less length of time are frequent. While the disease may be confounded with either neuritis or tabes dorsalis, it can be distinguished from the first by the absence of tenderness over the nerve trunks, and in the early stages the occurrence of a spastic condition of the legs, Babinski's reflex and the absence of muscular atrophy; from the second by the rapid onset, muscular weakness, presence of Babinski's reflex, absence of ocular symptoms and, if in the early stages, increased knee-jerks. The pathologic changes in the nervous system may be summarized as follows: A diffuse degeneration of the posterior and lateral tracts of the cord, chiefly in the dorsal and lower cervical regions, freedom from involvement of the gray matter and nerve roots, and varying, usually slight, degrees of degeneration of the spinal bloodvessels.

The prognosis is bad, death usually occurring in two or three years at the latest. The treatment is essentially tonic and supporting.

The following case, in which unfortunately an autopsy could not be obtained, is so typical clinically that it seems worthy of report:

Catherine K., aged 56, was admitted to the Philadelphia Hospital in June, 1901. She had previously been in the Woman's Hospital, and for her previous history here given I am indebted to Dr. F. P. Henry, under whose care she was. She was first admitted there in December, 1899. Nothing special is noted in her family or previous history until a year previous (December, 1898) to her admission to the hospital; at that time she had an attack of influenza. She apparently recovered from this but about a month afterward she began to experience a sensation of numbness and tingling in the hands. Two months later similar sensations appeared in the legs, which soon also "became stiff and she could not use them well." She remained in this state until her admission to the Woman's Hospital. It was then noted that she dragged one foot and raised the other unusually high. Her appetite was poor, vomiting occurred at times, and she was very weak.

Examination of the blood at this time showed red corpuscles, 1,239,000; white, not given; hemoglobin, 44%. About two weeks later it was as follows: Red, 1,257,584; white, 4,071; hemoglobin, 40%. After two months' treatment she was discharged improved, but returned in a week with a return of the symptoms. Examination of the blood then showed red corpuscles, 2,362,500; white corpuscles, 6,719; hemoglobin, 50%. She was again discharged in six weeks, her condition being much better, and she was not seen until the following October. Examination then showed her legs to be weaker, but she could walk alone; knee-jerks much increased; no ankle clonus; station good; sensation normal, and eyes normal. A systolic anemic murmur was heard at the apex. Her blood count was: Red, 1,464,000; white, 2,600; hemoglobin, 43%. It was also noted at this time that the "red cells were anemic, many being mere shells; five nucleated red cells were seen, and many large grayish cells with very pale-blue nuclei." On November 20 a herpetic eruption appeared upon the back and right side. On January 14, 1901, she was again discharged much improved, her blood count showing red cells, 2,000,000; white, 2,400; hemoglobin, 66%. It was also noted that the numbness of the feet was much lessened, but her gait was the same. The diagnosis made was pernicious anemia.

After leaving the Woman's Hospital she states that she got about fairly well, although her legs were "stiff," until April, when she fell while trying to walk; she then went to bed and there remained until her admission to the Philadelphia Hospital in June.

At this time the patient was pale, but appeared fairly well nourished. She complained of inability to walk, shooting pains in both legs in the course of the sciatic nerves, burning sensations in the feet, tingling sensations in the hands, and frontal headache.

*Examination.*—There was ability to slightly adduct the thighs and to flex and extend them upon the pelvis; there was also slight power of plantar flexion of the feet and of flexion and extension of the toes. As the patient lay in bed, both feet were markedly plantar flexed. All movements of the hands and arms could be performed, but they were much weaker than normal. The grip of the right hand measured 12, the left 19. All the muscles of the legs were atrophied, those of the right being more so. The muscles of the arms were flabby, and there was decided atrophy of the intrinsic muscles of the hands also more marked upon the right side. Owing to the electric appliances being out of order, electric examination of the muscles could not be made. There was no paralysis of any of the cranial nerves. The knee and Achilles jerks were absent. The plantar reflexes were very active, and a marked

Babinski phenomenon present upon both sides. All other reflexes, both superficial and deep, were absent. Fibrillary twitching of the muscles was not present.

The patient had incontinence of urine, due to retention. She said that she was conscious of a desire to urinate but was unable to perform the act. This trouble began a month before entering the hospital. The bowels were obstinately constipated.

Marked paresthesia of the limbs, as before mentioned, was complained of. There seemed to be slight hyperesthesia of the right thigh, and passive movements of the legs caused some pain. There was no tenderness of the nerve trunks. Hypesthesia was present in both legs below the knees; pain and temperature senses were lost in the same area. Over the thighs either heat or cold was felt as heat. Sensation upon the trunk and arms was normal. There was incoordination in the movements of the arms, the patient being unable to touch the end of the nose or bring the index fingers together either with the eyes closed or open. Passive movements of the fingers or toes were not recognized. She recognized a pencil held in the left hand, but could not recognize a coin or key held in either hand (astereognosis). The extremities were not cold or cyanosed. Over the first metatarsal-phalangeal joint of the left great toe there was an area of hyperemia about the size of a dime; on the heel was a similar area the size of a fifty-cent piece. On both legs were a number of small red spots which disappeared momentarily on pressure. Some edema was present about the ankle-joints. No disorder of any of the special senses was present. Her memory had failed markedly.

The urine was examined several times and with the exception of containing sugar was normal. Examination of the blood showed: Red, 2,275,000; white, 7,000. Hemoglobin was not estimated. Owing to circumstances beyond our control further examination of the blood was not made. Examination of other organs was negative. At the time of admission her temperature was 99° F., and pulse 80 to the minute.

The patient steadily grew worse. On July 17, 1901, it is noted that the feet were markedly edematous. Along the outer margin of the sole of the left foot there was a large area of hyperemia in about the center of which was a small patch of gangrenous skin. Similar areas were present over the left internal and the right external malleoli. On July 22 diarrhea and vomiting set in, which continued until her death on July 31. Three days before death her temperature, which had ranged from normal to 101°, rose to 103° and just before death was 106°. For several days previous to her death the patient lay upon her right side in a semistuporous condition with the thighs flexed upon the body and the legs flexed upon the thighs.

There would seem to be no question as to the proper diagnosis of this case. The paresthesia as an early symptom, slight ataxia, spastic paralysis, with increased reflexes and no sensory paralysis, becoming later transformed into a flaccid paralysis, and with the exception of the Babinski phenomenon, absent reflexes, ataxia, and sensory paralysis are very characteristic.

The question of etiology is of some interest. There has been some dispute as to whether these cases attendant upon pernicious anemia should be classified with those attendant upon other toxic and wasting conditions. Authorities in this country believe, what seems evidently to be the common sense view, that they should. It will be noticed that in the case just reported the woman was well until she had influenza, after which the symptoms of disordered nervous system very soon (one month) appeared. She was not seen at the Woman's Hospital, when the diagnosis of pernicious anemia was made, until one year afterward. That she had pernicious anemia at that time there can be no question, the diagnosis having been made by a distinguished hematologist. While we cannot be absolutely certain, it would seem probable from the history that the degeneration of the spinal cord was caused by the toxins of influenza, and that the pernicious anemia was caused also by the same poison. A somewhat similar case in a woman in whom pernicious anemia and the spinal symptoms appeared, after an attack of grip, is mentioned by Putnam,<sup>6</sup> to show that in the cases which follow pernicious anemia it is probably the same agent that produces the blood changes that causes the degeneration of the spinal cord. Billings<sup>7</sup> well sums up the whole matter when he says: "There is marked similarity of the contributing causes of pernicious anemia and of the conditions which are mentioned as causative in the production of the spinal cord lesions of other conditions. The consensus of opinion, as stated, is that pernicious anemia is due to a hemolytic toxin, and it is the universal

belief, too, that the different conditions are due to a toxin. It is suggestive, therefore, that possibly a toxin which has its origin, perhaps, in the way suggested by Adami\* may be one which may have, in certain individuals, a predilection for hemolysis; in another for degeneration and sclerosis of tissue which, by election, affects the liver in one case, the kidney in another, and certain parts of the spinal cord in another."

THE ETIOLOGY OF UTERINE AND PELVIC DISEASE.<sup>1</sup>

BY

CLARENCE L. WHEATON, M.D.,

of Denver, Colo

Clinical Associate in Gynecology, Denver College of Medicine; formerly Clinical Assistant in Gynecology, Chicago Polyclinic, and Attending Physician Out-door Free Dispensary, St. Joseph's Hospital, Chicago, etc., etc.

With the progress of knowledge and the accumulation of facts relative to the etiology of disease, we are better able today than ever before to solve the intricate problems of pathology and bacteriology, advancing, as it were, more rational theories as to the cause of uterine and pelvic disease.

Any one who has had the opportunity of conducting a large charity clinic for the treatment of diseases peculiar to women must necessarily be impressed with the fact that pathologic conditions involving the uterus and adnexa are exceedingly common.

The quacks and nostrum mongers devote whole pages of the daily press to the exploitation of their wares for the treatment of uterine and ovarian diseases, and whether their remedies are efficacious or not, the ability of these various firms to meet their enormous advertising expenses proves the ready sale of the medicament.

The large attendance of suffering women at the gynecologic clinics of our free dispensaries, together with the vast number as already mentioned who seek relief for their ills at the hands of the vendor of patent medicines, enables us to form some adequate idea of the prevalence of diseases peculiar to women, involving the generative organs.

In the discussion of the etiology of uterine and pelvic disease, I shall draw my conclusions from observations made in private practice and at the charity clinics which I have had an opportunity of conducting.

The environment of the woman in America differs from that of her foreign sister in many countries of the old world. In Europe and other foreign countries women by thousands labor in the fields; in the various seaports of the Orient, ocean liners of enormous tonnage are coaled by women, and in the various tribes of Indians the female performs the drudgery incident to their mode of living. In the circus tent the woman, high aloft on the flying trapeze, twice daily performs acts requiring great physical strength, and her powers of endurance seem almost equal to the male. So we may reason that the female, if kept beyond influences physically depreciating in character may compete physically with the male of her race.

Is not the woman of modern society exposed to depreciating influences, particularly the woman of high social environment? Our ways and customs of civilized life have unquestionably depreciated her power of

\*In the intestines.

<sup>1</sup>Read at the thirty-second annual convention of the Colorado State Medical Society.

resisting disease, and, in fact, have created a predisposition to the development of disease most frequently referred to the generative organs. It would be absurd to endeavor to substantiate a theory that such conditions as prolapse of the uterus or bladder, cystocele, rectocele, malignant and benign tumors were unknown to the savage or to those not exposed to the environment of modern civilization. Yet these conditions are said by competent observers to be comparatively rare among savage tribes, or when present, excluding malignant disease, do not give rise to profound constitutional disturbance. I venture to say that hundreds of poor women in the city of Denver are today performing the drudgery incident to their lives of hard labor, with the uterus and bladder in a state of complete prolapse, yet this same condition in the woman of high social environment would completely incapacitate her physically.

As a remedy for all this I do not advise a return to savagery to increase woman's physiologic resistance to disease, nor do I advocate coal heaving, or wish that women might perform the labor that our decorum as gentlemen forbids and our true sense of gallantry as civilized men prevents, but I do advocate a radical change in various methods, at present seemingly inevitable to our civilization, and the consideration of other methods which will tend to improve the physical condition of the young girl approaching puberty.

Today there exists a disproportion between the development of the nervous and muscular systems. Young girls are sent away to boarding-school imbued with the idea that much of their future depends upon their high literary attainments; they apply their minds closely to their work at college, they master difficult studies and in many instances overtax their intellects—a loss of balance soon results between the nervous and muscular systems. The product is a refined girl, cultivated in the arts and sciences; but much of this has been derived at the expense of her physical wellbeing, and a predisposition to disease has been created.

Dr. Kelley Sabine points out that menstrual irregularities are present in 75% of the women in finishing-schools and colleges, these defects being dated back to the time when menstruation first takes place and the so-called habit neuroses are easily formed.

Dr. Byford's adage, although uttered many years ago, applies with as much force today. He said "six hours' study and two hours' play should be reversed; it should rather be eight hours' unrestrained exercise and two hours' study."

In a recent editorial in the *Journal of the American Medical Association* it was stated that labor laws regulating the time of work for minors had been passed in many States. Some observer has pointed out that the hours spent in study in and out of school by many of the pupils in high schools is in excess of that allowed by law for the labor of minors; then, again, the mental labor of the schoolgirl is more fatiguing than the manual labor of her working sister.

But the evil, we trust, is being remedied as parents observe that great mental attainments and culture purchased at the expense of the woman's physical wellbeing are not factors tending to fit their girls for the duties of wife and mother.

Out of door life and physical development have not, until comparatively recent years, been factors in the development of the young girl. Women are naturally more inclined to a sedentary life than men, and the out of door sports have not been encouraged sufficiently. Sanctioning such, it might be feared that the young woman would be robbed of a lady-like decorum, and her refined tastes and sensibilities become blunted. Fortunately, however, the physicians throughout the country have in a measure waged a successful campaign against this delusion and the fallacy of it all is being proved rapidly. The golf girl, the tennis girl, the oarswoman, are becoming familiar figures on the campus of many

educational institutions devoted to the teaching of women.

It is not the bodily influence alone of exercise, but the mental relaxation as well, from the close application incident to hard study that accomplishes good. The shackled prisoner eight hours a day on the rock pile may be violently exercising, but the benefits derived from such exercise are not to be compared to the benefits derived by the athlete, in the field one-fourth of the time. Exercise out of doors, as many observers have stated, increases the peripheral circulation; this increases cutaneous exhalation and equalizes the circulation. So in uterine and ovarian disease, when engorgement is a marked feature, the value of exercise out of doors, supplemented by Turkish baths, sea bathing, and massage must be evident to all.

In the consideration of this subject it seems quite proper to allude to the dress worn by the women of today, and especially those deluded victims of the fads or fashion. Tight-fitting clothing, especially at the waist line, seems to be the predominating style; the smaller the waist the supposedly more attractive the figure, until finally such fads of fashion result in malformation of the thorax and pelvis with an accompanying displacement of the abdominal viscera. A woman confined for 15 hours under such conditions must necessarily suffer. That most important respiratory muscle, the diaphragm, is practically thrown out of action, its lateral expansion fettered, and a downward pressure on the intestines, estimated at about ten pounds, exerted. Not alone a tendency to, but in fact a displacement of the uterus results, and its mobility is seriously influenced.

I have repeatedly demonstrated in my clinic at the Denver College of Medicine this effect of tight clothing on the uterus, and the marked deviations in its position and increased mobility upon releasing these mechanical constrictions about the waist line. Passive congestion of the uterus, flexions and versions with all their sequels may not infrequently be traced to improprieties of dress, and the paresis following constriction of the muscles of the thorax with its evil effects on respiration is too well known to need elucidation here. Mechanical devices, such as pessaries for the retention of the displaced uterus, will prove of little avail until the evil effects of heavy and tight clothing have been combated. The wasp-like figure following a distorted waist is sadly at variance with the Venus of Milo, the sculptured model of the perfect female form. As Dr. Anderson has said, if this beautiful Greek goddess came to life by her own breath, as did Pygmalion's Galatea, and donned the dress of the woman of this century, what would her less fair sisters say?

*Indiscretions at the menstrual period* must be recognized as a prolific source of uterine disease in young girls who have reached puberty. The so-called congestive dysmenorrhea or even endometritis has its origin in needless exposure to the varying changes of temperature, especially at a time when thin clothing is worn. The lining membrane of the uterine canal is usually first attacked, resulting in an endometritis tending to run a chronic course; finally the parenchyma of the organ becomes involved and sterility in a fair percentage of cases results, and it may be added that these sufferers are rarely free from pelvic pain.

*Imprudence While the Uterus is in Process of Involution.*—Lusk says that the puerperal state occupies the borderland between health and disease; though in a strict sense physiologic, it offers a variety of conditions which at other times and under other circumstances would be regarded as pathologic. The acute degeneration of the uterus presents a phenomenon which if it occurred in any other organ of the body would prove speedily fatal. The thrombus formation in the open placental vessels possesses no corresponding physiologic analogue. Again the torn vessels may lead to hemorrhage, while the traumas which even in normal labor

result from parturition, and the ease with which deleterious materials are absorbed by the wide lymphatic interspaces, the serous infiltration of the pelvic tissues, the exaggerated size of the lymphatics and veins, create a predisposition to innumerable forms of disease. The nicety of the balance between normal and morbid conditions renders it peculiarly necessary for the practitioner to make himself familiar with the physiologic limits of the phenomena of childbed.

Rest and absolute rest during the process of involution would seem indicated; women who rise too early when the lochial discharge is still present assume the risk of seriously interfering with involution and regenerative changes in the cavity of the uterus. Immediately after birth the uterus weighs upward of two pounds. The possibility of displacement of such an organ at this time should be seriously considered should the woman rise too early. Many of the followers of the christian science faith rise on the second and third days following delivery. Their conduct is not a criterion, however, and would lead us to believe that there is much truth in the old adage, "A fool for luck."

Binding the abdominal walls after delivery is a procedure popular with us all. A moderately tight-fitting bandage is unquestionably a source of comfort; but as Thomas states, "Uterine contractions should be secured by vital not mechanical means and no amount of compression by a bandage will cause the over-distended abdominal muscles, skin, fascia and areolar tissue to return to their original condition. In the application of a bandage to the abdominal wall care must be exercised not to force the uterus down into the pelvis and there retain it, usually in a position of retroflexion when involution is complete."

*Tears of the Perineum and Their Neglect.*—During the year 1901, 685 treatments were administered to women at the free dispensary of the Denver College of Medicine. In fully 40% of the cases coming under my observation injuries due to parturition were etiologic factors in the pathologic conditions treated. Tears of the perineum occur in the hands of the most experienced obstetricians; they may extend from the fourchet to the anus, but this does not imply ignorance or neglect on the part of the obstetrician. It is the nonrecognition, however, of such accidents, and failure to repair the same, that stands as a monument to his ignorance and neglect.

The lacerated areas about the perineal body are richly supplied with lymphatics and bloodvessels which may carry infective material from such a focus just as readily as from other abraded areas in the body. Here we have a focus of infection bathed for approximately 14 days in a fluid containing cervical and vaginal epithelium, blood and mucous corpuscles, bits of decidua, and sometimes shreds of membranes and of the placenta. In the vaginal lochia may be found a variety of microorganisms, such as the diplococci and streptococci, rod bacteria, the trichomonas vaginalis, and sometimes gonococci. It is evident that the possibility of infection from these sources cannot be eliminated, to say nothing of the failure of involution of these parts and the inevitable rectocele following destruction of the perineal body and the predisposition of the uterus and bladder to prolapse.

*Gonorrhoeal Infections.*—Donald Kennedy recently informed me that in 90% of the cases of gonorrhoea in the male there was a failure to effect a cure. This presumably is due to the fact that many patients treat themselves with some favorite prescription, or when the discharge ceases believe themselves cured and pass from under the observation of their medical adviser. Dr. Noggerath has undertaken to show that with very few exceptions the wife of every husband who at any time of his life before marriage had contracted gonorrhoea is affected with latent gonorrhoea, which sooner or later brings its existence into view through some one of the forms of disease. Noggerath further asserted that of

every 100 women marrying men who have previously had gonorrhoea scarcely 10 remain healthy. To sustain his assertions he gave the statistics in 81 cases, of which 31 patients only became pregnant; of the 31 only 23 went to full term, 3 were prematurely delivered, and 5 aborted. Of the 23 that went to full term, 12 had 1 child each during married life; 7 had 2 children each; 3 had 3; 1 had 4, and among the 23 women there were 5 abortions. Such statistical evidence may possibly exaggerate the true condition of affairs, but if authentic a healthy woman would be almost an exception. Dr. Noggerath's paper was published in 1873. Neisser did not discover the diplococcus of gonorrhoea until 1879. The possibility of an error in diagnosis made on clinical signs alone must be considered, especially in females.

We know, however, that gonorrhoea is one of the most widespread affections, and its sequels in the female so terrible that it merits our earnest consideration. The cases usually come under our observation late, after the development of an endometritis and beginning tubal involvement, when nothing but prompt surgical intervention may save the sufferer from the pitfall of chronic invalidism.

The crimes of the abortionist stand prominently before us as a prolific source of uterine and pelvic disease. The shrewdness by which these professional degenerates elude detection leads me to believe that the intelligence which they possess is sadly misdirected. The application of their professional attainments along more legitimate lines might prove them valuable citizens to a community, instead of criminals whose abode should be the State penitentiary rather than a fashionable office building in the down-town district. To their bungling methods we may attribute many inflammations of the genital mucous membrane, endometritis and salpingitis, inflammation of the uterine parenchyma and of the subserous and pelvic cellular tissue. Inflammation of the peritoneum covering the uterus and its appendages, pelvic peritonitis and diffused peritonitis, uterine phlebitis, with formation of thrombi, embolism and pyemia, and finally septicemia to close the scene.

It behooves us, as members of the medical profession and the confidential advisers of families in matters pertaining to their health, to educate our patients to the dangers following their indiscretions, to point out the pitfalls that menace their daily life, to do this at the right time, in a conscientious spirit and with the courage of our convictions. We have then done our duty and perchance may save many a sister from a life of invalidism, for I do not believe that woman was born to suffer as the sparks to fly heavenward.

## TRANSVERSE POSITION OF THE CHILD WITH PROLAPSE OF THE ARM AND IMPACTION.<sup>1</sup>

BY

STRICKER COLES, M.D.,

of Philadelphia.

Demonstrator and Clinical Lecturer on Obstetrics in the Jefferson Medical College; Assistant Obstetrician to the Jefferson Maternity.

This condition is invariably due to neglect; the child lying in transverse position with the advent of labor and rupture of the membranes will become impacted unless there is spontaneous version or evolution, which rarely happens when the child is of average size. When impaction occurs the child may lie in one of four positions, but clinically only two are of importance. First, when the child's back is anterior; it makes little difference whether the child's head is to the right or left side, and second, when the back is behind. When a careful examination is made the uterus will be found in tetanic contractions, the head with neck elongated and breech will be found

<sup>1</sup> Read before the Philadelphia Obstetrical Society, May 1, 1902.

about on the same level and with the upper arm between. This forms the base of the wedge, the prolapsed arm forming the point of the wedge. When the back is behind it is impacted under the promontory of the sacrum, which makes the position much more difficult to treat, for any manipulations at version require the entire child to be shoved up, which is often impossible without rupture of the uterus. When the back is anterior it can be shoved up and anterior without moving very much the head and breech and then a foot can easily be brought down. The danger of rupturing the uterus is very great and should always be borne in mind in attempting version. After delivery there is the danger of sepsis even when the greatest antisepsis has been observed and the uterus thoroughly emptied, as in cases in which there has been prolonged labor with rupture of the membranes for some days before there is often pressure necrosis of the uterine wall with the entrance of pathogenic bacteria before delivery, and this is greater in those cases in which attempts at delivery have been made. In treating these patients place them deeply under chloroform anesthesia, and while this is being done empty the bladder and rectum, and thoroughly scrub the external genitals and adjacent parts with soap and water, then plain water, then mercuric chlorid, then give a 2% lysol douche, washing out the vagina as well as possible, having the patient placed on a high table. The best method of delivery, especially when the back is posterior and the prolapsed arm gangrenous, is by decapitation, using Braun's hook; or, if the elongated neck can be reached by the fingers, decapitate with long blunt-pointed scissors. This should be done at once and no attempts at version made. As soon as the head is severed, by making traction on the arm, the body is easily delivered and the head can then be delivered by forceps. If the head is so far up that decapitation cannot be safely done, then the prolapsed arm should be amputated and the other arm brought down, which lessens the wedge at its base. It can also be amputated, and this will allow the head to move upward and inward and the foot can be brought down and delivery accomplished. When the back is anterior and impaction not very great the back can be shoved up in a rotary motion, sweeping along the anterior wall of the uterus, and then it is an easy matter to bring down the anterior foot or both feet.

After the child has been delivered the placenta and membranes should be removed and the uterus douched with 1% lysol solution and then packed with iodoform gauze, which will lessen the dangers of hemorrhage and drain the uterus. This will also lessen the dangers of sepsis. The gauze should be removed in 36 hours and another douche of 1% lysol given, but this is not necessary and may be omitted. Should there be a rise of temperature, and foul lochia, great care must be used if the uterus is washed out, for a curet or uterine douche tube will readily pass through the uterine wall if there is a slough, which is often present, being due to the prolonged pressure. The entire thickness of the wall may slough, leaving only the peritoneum separating the uterine and abdominal cavities.

CASE I.—Mrs. A. B., a Slavonian, aged 24, first menstruated between 14 and 15. It was always painful, keeping her in bed for two or three days. Last menstruation was in January, 1896. She has been pregnant once before, when she had in spontaneous labor a girl who is now 5 years old. She was attended by a midwife and remained in bed for four weeks, as she was feverish and weak. She has been well during the present pregnancy, except for constipation. Active labor pains began Monday, October 26, 1896, in the early afternoon, and soon afterward there was a copious discharge of amniotic fluid. The pains continued strong and frequent. She was seen by Dr. Wells late Tuesday evening and sent by ambulance to the Jefferson Maternity, where she arrived at 12.45 Wednesday morning. She was above the average size with flabby tissue. She was very weak and exhausted, the uterus in tetanic contractions, the bladder greatly distended. Strychnin and whisky were given at once and chloroform started. The bladder was emptied and the bowel irrigated. On palpation the child's

head was found in the right iliac fossa and back behind. After cleansing the external genitals and washing out the vagina with creolin, an examination showed the right arm prolapsed and gangrenous, the cord prolapsed, but not outside the vulva. The right arm was amputated with long scissors and an attempt made to shove up the head, but this was not successful, owing to the danger of rupturing the uterus. The left arm was between the head and hip. This was brought down and amputated. The head was then pushed up a little and the left foot caught and brought down, and the rest of the delivery was easily accomplished with the back of the child anterior. The placenta was delivered manually in five minutes. It was attached to the right anterior wall of the uterus high up. The uterus contracted well. Normal, not saline, solution was freely injected into the bowel, and by hypodermoclysis into the right lateral aspect of the chest and thigh. She was again stimulated with strychnin, whisky, and ergot. The patient reacted slowly and did well until the fifth day, when there was a sudden rise of temperature. The uterus was gently cureted and irrigated with a large amount of 1% creolin solution. The temperature soon fell to about normal, and the subsequent recovery was uneventful. The child, a boy, weighed 8 pounds 8 ounces, and was 56 cm. long. The other measurements were correspondingly large.

CASE II.—A. G., white, a stenographer, aged 24; had had diphtheria and measles during childhood. She menstruated first at 12; the flow was always regular, lasting four or five days. She was last seen on January 10, 1897, and she had continued well during her first pregnancy. She was brought to Jefferson Maternity in the ambulance at 6 p.m. on October 2, 1897. After being prepared she was chloroformed, and on examination the left arm was found prolapsed with a loop of cord. The head was in the left iliac fossa and back behind. The left arm was amputated and the head pushed up a little, the right foot caught and brought down, and delivery easily completed. The placenta was delivered manually and the uterus irrigated with creolin and packed with iodoform gauze. The patient was stimulated with strychnin and ergot. On October 4 the gauze was removed and a creolin douche given. The patient was in good condition and continued so throughout the rest of her convalescence.

CASE III.—L. H., colored, aged 28, was pregnant for the second time. The first pregnancy was normal. She had a contracted pelvis; all of the measurements were small; the external conjugate was only 17.5 cm. Dr. Royer was called to the patient when labor began, at 8 p.m. May 8, 1898, and while giving an enema the waters ruptured and the arm prolapsed. An attempt was made to do version, but it was not successful. Dr. Wells was sent for and another unsuccessful attempt at version made. I saw the patient at 5 a.m., and found the right arm and cord prolapsed, the child's head in the right iliac fossa and the back behind. The uterus was contracting strong and continuous; I could not get the fetal heart sounds or pulsations in the cord. The patient was placed under deep chloroform anesthesia, and by continuous pressure I was able to shove the child's head up a little and brought down the left foot, and then turned the case over to Dr. Royer, who completed the delivery and treatment. The patient made an excellent recovery. The child was stillborn.

CASE IV.—Mrs. S. B., a Russian Jewess, aged 28, has had two normal labors; after the first she had a breast abscess. She had active labor pains three hours before being seen, but the membranes had been ruptured only a short time. On examination the right arm was found prolapsed, the head in the left iliac fossa and back anterior. The fetal heart sounds were good and strong. The patient was placed under deep chloroform anesthesia and the head shoved up and the right foot brought down, but it turned posterior, and the left foot had to be brought down. The arms were extended, but easily brought down. The head could not be delivered manually, so forceps were applied and delivery accomplished. The child was asphyxiated, and was with difficulty resuscitated. The mother did well until the third day, when her temperature rose to 102° F. and there was considerable pain in the breast. When milk was well established the temperature dropped, pain left, and she was able to nurse her child from both breasts.

CASE V.—M. T., colored, aged 28, has a family history of insanity, her mother and sister both died insane. She menstruated first at 14, the flow has been regular and painless, lasting three days. The flow was last seen in April. She has had two pregnancies, both of which were normal. She has been well during the present pregnancy. The first stage of labor was very severe, lasting 24 hours. The second stage had lasted two days when first seen on January 16, 1897, at 3 p.m. The right arm was prolapsed and hyperemic, the head was in the left iliac fossa and back interior. I could not get the fetal heart sounds. She was placed under deep chloroform anesthesia, the back of the child shoved up, the right foot brought down and delivery easily accomplished. The child had apparently been dead for some hours. She was greatly exhausted after delivery and had to be freely stimulated, but did not respond very well, and on the twentieth day well-marked symptoms of puerperal sepsis appeared. She was sent to the Philadelphia Hospital, where she died of profound sepsis. The patient said she had been attended for two days by a physician who assured her she was doing well.

CASE VI.—A young white girl, a primipara, was seen with

the resident physician. She had been in labor for three days, being attended by a student. When seen the right arm was prolapsed and gangrenous, back anterior and the head in the left iliac fossa. She was advised to go to the maternity, but declined. She was placed under chloroform and the back shoved up and the right foot brought down and delivery easily accomplished; the child was slightly macerated. She was greatly exhausted, but reacted very well, but on the third day had a subnormal temperature and a weak and rapid pulse with evidences of profound sepsis. She was sent to the Philadelphia Hospital, where she died.

Another patient, seen with the resident physician last August while the Jefferson Maternity was closed, was so weak and exhausted and the surroundings so dirty that she was sent to the Philadelphia Hospital, where she died before delivery could be accomplished. She had been attended by two physicians for three days.

## TWO EXAMPLES OF PARASITIC HEMATURIA.

BY

L. NAPOLEON BOSTON, A.M., M.D.,

of Philadelphia.

Bacteriologist to the Philadelphia Hospital; Demonstrator in charge of the Clinical Laboratories of the Medico-Chirurgical College, Philadelphia.

The first case, the report of which follows, is doubtless one of extreme rarity, and its occurrence in connection with bloody urine appeared unique at the time of its discovery in the urine of an inmate of the Philadelphia Hospital, August, 1899.

The patient, a male of 61 years, presented nothing abnormal for one of his age, and gave no history of having ever before voided bloody urine. On rising in the morning he noticed that his urine resembled blood and it remained unchanged during the day. He suffered no discomfort and during the day did not void urine oftener than usual. A specimen taken from that passed

Fig. 1.

on retiring and during the night following was also bloody and contained a few parasites. The following morning the urine was normal in appearance; did not contain the parasite; and the centrifugated sediment showed but few blood discs. The urine, on standing, displayed a heavy sediment, a microscopic study of which showed it to be composed, for the most part, of blood discs, clots, few epithelial cells, and many blood casts. No crystals were present, but everywhere the sediment was found to contain many small worms, which are best described by the accompanying plate (Fig. 1). A drop of this sediment, when studied under a 2-3 lens, often presented from two to six of these parasites in a single field of the microscope. Their movements consisted in coiling and uncoiling, apparently reaching forward with the tapering extremity, the movements being repeated in such rapid succession that they were enabled to travel across the field of the microscope in a few seconds. The serpentine movement, as shown by the embryos of the filaria, was not observed. No attempt was made to photograph the parasite during its movements. They remained alive for 24 hours in a specimen of urine that had been placed in an incubator, at a temperature of 37° C. When kept at room temperature they were found to be motionless after a few hours. There appeared to be a great variation in the size of these worms, as is shown by the following measurements: Total length, 0.036 to 0.053 inch; diameter at greatest part, 0.003 to

0.0035 inch; diameter at the junction of the greater  $\frac{1}{2}$  with the remaining  $\frac{1}{2}$  of the body, 0.002 to 0.0025 inch.

It was extremely difficult for one to distinguish beyond question of doubt a capsule enveloping the parasite, and while the artist has made this very clear in the accompanying sketch, I regard its production, in a measure, as being dependent upon the change of focus. Several of the parasites were handed to Dr. Charles Wardell Stiles, of the Bureau of Animal Industry,

Fig. 2.—Scolex and hooklets, *Tenia echinococcus*, from urinary sediment. Obj.: Queeu 1/c, eye piece iv.

Washington, D. C., who, after having studied them, writes me in part as follows: "I regret to say that I am still unable to make a specific or even a generic determination. The size of the worm appears to disagree very radically with the embryos of *Filaria bancrofti* (*Filaria sanguinis hominis*). I also found one trichocephalus egg in one of the specimens."

During my term of service at the Pennsylvania Hospital, 1901, I studied a specimen of bloody urine, voided

Fig. 3.

by a male patient, in which many parasites apparently identical with those observed in connection with the previous case were found. Specimens of the parasites from this second patient were also handed to Dr. Stiles. Ova of *Trichocephalus dispar* were present in the urine of both patients. My second observation of the parasite was through the courtesy of Drs. H. W. Cattell and A. Scott, the latter of whom tells me the case was one

of special pathologic interest, and will doubtless be reported. An abnormal communication between the enteric and urinary tracts was not discernible in my patient, and for a period of several months, while he remained in the hospital, repeated examinations of the urine failed to detect anything abnormal.

The second case is one of hematuria resulting from the development of an echinococcal cyst, whose products were eliminated through the urine. A bottle containing about four ounces of bloody urine was found among

Fig. 4.—1, shreds of membrane; 2, clusters of scolices; 3, scolex, *Tenia echinococcus*. Obj.: Queen  $\frac{3}{8}$ , eye piece iv.

a number of specimens in the clinical laboratory of the Philadelphia Hospital; it bore no label and all efforts to determine the specimen's origin were of no avail. The urine was bloodstained, and displayed a heavy sediment composed, for the most part, of shreds of flocculent membrane.

Microscopic study showed it to contain shreds of a yellowish membrane, hooklets (Fig. 4), and scolices of the *Tenia echinococcus* (Fig. 2). Many blood casts were also present (Fig. 3).

## EXOPHTHALMIC GOITER: REPORT OF CASE.<sup>1</sup>

BY

K. S. HOWLETT, M.D.,

of Franklin, Tenn.

On June 21, 1901, G. H., white, male, unmarried, aged 34, applied to me for relief from "indigestion and torpid liver."

**History.**—He had run a wheat-thresher engine for a number of years and later an engine at a flouring mill; at both places the labor was heavy, the heat excessive and the hours long. His habits had always been good, and he had always boasted of his capacity to endure an almost unlimited amount of labor without fatigue or ill consequence, and from early life had been an excessively hard worker, allowing himself little rest and no recreation whatever. Four years ago he first noticed his strength and endurance were beginning to fail, and after a day of hard work he would feel considerable physical and mental depression, accompanied by pronounced muscular weakness and tremulousness. The following day he would feel indisposed or unable to resume his work. He also acknowledged some shortness of breath and spells of palpitation of the heart, which had increased in frequency and severity. During this period, however, he had not been confined to his bed for as much as an entire day, but had called on two or three physicians at various times for treatment and had been invariably told that he was suffering from biliousness and given calomel to correct it. His tongue, he stated, was usually dirty, and he had a bad taste and poor appetite with constant dull headache, somewhat throbbing in character. His digestion had not been good for a long time, his stomach feeling full and uncomfortable after meals, and he had several spells of acute indigestion or colic (which he con-

tinued to have during the remainder of his illness). Constipation was the rule, though it had not been very obstinate and was occasionally alternated with diarrhea. These disturbances seemed to me to be part of, and not the cause of the patient's general condition, and could be readily accounted for by the mental worry, change of habits, lack of exercise, etc., and at the time I saw him they certainly were not the most prominent symptoms. Sometimes for days, or even weeks, he would feel fairly comfortable and be able to keep at his work almost constantly, still he had been growing steadily worse and was now compelled to abandon work entirely.

**Examination.**—The patient's general appearance was that of languor and fatigue, his countenance indicative of discouragement as well as distress. The skin of the face was dark, almost bronzed, the coloration being much more marked immediately around the eyes. The complexion was sallow and the mucous membrane of the lips, mouth and fauces was a pale, bluish color, suggestive of leukemia. I noticed the thyroid was enlarged, but the patient had not mentioned it, and in fact seemed rather irritated and disgusted that I should give it so much attention. He stated that he had first detected it when he was about 20 years of age (14 years ago) and that it had never been sore nor given him any pain or discomfort. The enlargement was on the right side, was flat and not very prominent and upon mere inspection did not appear to be larger than a turkey's egg. Upon palpation, however, it proved to be much larger, extending downward toward and behind the clavicle and backward toward the vertebrae, and evidently exerting considerable pressure upon the trachea, bloodvessels, and nerves beneath. Breathing was labored, wheezing, and asthmatic in character, the respirations being 26. He had frequent, violent paroxysms of coughing, with scant expectoration of a thin, frothy, serous fluid. The pulse was 115 but increased to 130 after walking a few steps. It was quick, full, strong, forcible and regular. The cardiac impulse extended over a larger area than usual and was more perceptible; the epigastric pulsations were very distinct. The heart sounds were louder than normal but I could detect no murmur and the area of cardiac dulness was little, if at all, increased. I made no examination of the lungs at this time, and in view of subsequent developments this was unfortunate.

The patient seemed to be of fairly good weight, but stated that he had lost flesh decidedly during the preceding year. The muscles were large, apparently well developed like those of a laboring man, but were soft and flabby to the touch. Upon holding out the hand a fine tremor was very marked and presented an interesting and typical exhibition of the special symptom, said to be a constant and characteristic symptom of exophthalmic goiter.

The enlarged thyroid, tachycardia, and fine tremor, together with muscular weakness and general nervousness, induced me to make a diagnosis of exophthalmic goiter, notwithstanding the absence of exophthalmos, which if present at all was too slight to be of positive diagnostic value, and certainly would never have been noticed but for the other symptoms calling attention to it. Nor were there any other ocular symptoms at this time, although later Graefe's symptom (a tardy or defective descent of the upper lid when the eyeballs are directed downward) could occasionally be brought out. This, however, was not invariably present, and never well marked, although it did become more patent before his death.

I saw the patient on the street after this, and he said his cough had become more annoying, and he had some pain in his right side. On June 29, eight days after I had first seen him, and two days after meeting him on the street, I was called to see him at his home. He was complaining of a severe pain in the right side of the chest, which had been constant for three or four days, but had grown rapidly worse during the preceding night. It was acute, lancinating in character, and caused the patient to cry out in coughing. Examination showed a completely hepatized right lung, there being scarcely any expansion of that side, no vesicular murmur over any portion of the lung, no rales, and only slight crepitus at the lower portion, evidently pleuritic. The temperature was 103°, pulse 120, full and bounding. The cough was paroxysmal and violent in spite of every effort upon the part of the patient to suppress it. The expectoration was thin, watery and frothy, and neither at this time nor subsequently was there anything resembling the characteristic sputum of acute pneumonia.

Dr. D. B. Cliffe, Jr., of Franklin, Tenn., saw the patient with me in the afternoon of this day, and we were both impressed with the absence of so many of the general symptoms which would be expected from a severe pneumonic infection. There was no delirium, no general prostration more than had appeared on his visit to my office, and the condition of appetite and tongue were also about the same. There was an absence of the distressing dyspnea and cyanosis which would be expected when an entire lung had become hepatized. Physical examination of the heart and left lung rather indicated that the condition of the right lung must have existed long enough for nature to compensate to some extent for the loss of breathing space by increased power of the left lung. In fact, but for the temperature of 105°, the pain in the side and physical evidences of a solidified lung, there was no symptom present that could not be readily accounted for by my previous diagnosis. The pneumonia, if indeed it was a specific pneumonia as we at first thought, certainly did not run a typical

<sup>1</sup> Read before the Middle Tennessee Medical Society at Lewisburg, May 16, 1902.

course. The temperature was normal the next morning, and afterward ran an irregular course, usually going above normal at some time during the day, but at no time reaching 100° until the last two weeks of his illness, when it reached 101° and 102° a few times.

The lung never cleared up, although the patient lived two months longer. There was never during life any evidence of breaking down of lung tissue, nor of septic absorption. The autopsy showed a completely solidified lung, swollen, edematous, and filled with a whitish, semisolid exudate with pleuritic adhesions over the greater part of its area, but no abscess and no pus could be found.

In the beginning there was a moderate amount of pleuritic effusion, which disappeared within three or four weeks. The pain in the side disappeared in a day or two, and never returned.

From this time the patient's decline in general health, while slow and irregular, was sure. The thyroid did not perceptibly increase in size but the breathing remained much obstructed and grew more rapid. The expectoration became more profuse but retained its thin serous character. The pulse grew more and more rapid, reaching 180 or even more, sometimes becoming difficult to count, but it maintained its full, forcible beat even to the last. At times a heart-murmur could be distinctly heard at the apex, this was probably systolic but was not constant and we could not satisfactorily classify it. Rather distressing palpitation would nearly always occur when the patient attempted to assume the upright position and at such times he would complain of dizziness. The heart's action was regular until about 12 or 14 hours before death, when his condition grew suddenly worse.

The tremor remained about the same throughout; emaciation was rapid, and the muscular weakness became constantly more pronounced, the patient soon becoming unable to stand or walk; he received several falls in attempting to get up to stool. When lying down, however, he could move the limbs readily and freely and there were no evidences of paralysis. He complained considerably of bodily heat although the skin did not feel hot to the touch, being always moist and presenting a greasy appearance. Although the sweat glands were quite active all the time there were never any exhaustive colliquative sweats. At times there was considerable edema of the hands, face and trunk, but never of the lower limbs. In the earlier stages this would disappear under a little saline purging, but toward the last it became a more permanent feature.

The urine was amply sufficient in quantity, specific gravity 1,010 to 1,020, and sometimes contained traces of albumin. While the patient never grew hungry, yet he did take plenty of nourishment throughout his illness, and the digestive process was, as a rule, good. A little indiscretion in eating, however, would cause his stomach to distend with gas, and he would have acute indigestion and colic. He usually had to take medicine or an enema to get a movement from the bowels, though two or three times he had rather an alarming diarrhea, dysenteric in character.

The change in the patient's disposition was so decided as to amount almost to mental aberration. Before his illness he was said to have been a quiet, agreeable, even-tempered man of rather stolid, impassive temperament. He was now morose, irritable, impatient of contradiction, angry upon the slightest provocation, and suspicious. He would seem to be aware of this himself, and would apologize for it and make heroic efforts at better self-control. He frequently had a peculiar form of delirium, or more properly, mental delusion. He would imagine that he was at some other place than his home, that his mother was some other person, and he would maintain this idea with considerable warmth and stubbornness. Later he would seem to realize that he had been deluded, would speak of his mental confusion and seem much worried and depressed. He was sometimes hysterical, and toward the last showed symptoms almost maniacal in their manifestations. These mental disturbances were always transient and temporary, the patient being most always entirely rational.

Death seemed due to general weakness and heart failure. Twelve or 14 hours before this occurred, the pulse became very irregular, losing one or more beats at frequent intervals. The heart, however, still maintained its forcible, tumultuous action, as if laboring under undue stimulation.

*Autopsy.*—This was held a few hours after death. The thyroid was found much larger than had been suspected during life, the greater part of the enlargement being backward. It was larger at its upper portion than a man's closed fist, sending a projection downward behind the clavicle into the chest cavity. The pressure upon the trachea had been such that the rings were all softened, and it appeared as a collapsed tube throughout its entire length. The gland was very firm, hard, and appeared to contain (we did not use a microscope) an excess of fibrous tissue. Its cut surface was paler in color, and there was less exudation of colloid material than in health, and macroscopically there appeared to be an increased vascularity of the gland. No other pathologic condition except that of the right lung already mentioned was evident. The left lung was emphysematous and increased in size, but we could find nothing else wrong with it. The heart was probably slightly enlarged, dilated, but showed no valvular lesions. The liver, kidneys and spleen were of proper size and normal in appearance.

The tumor differed from that generally found in exophthalmic goiter, which is considered to be largely a vascular enlargement due to increased vascularity as well as to a general increase in the amount of secreting gland tissue, and is therefore softer than the gland of ordinary goiter, the change being aptly compared to that which takes place in the mammary gland during lactation. Just what was the true cause and the real pathology of the condition found in the right lung, what part the diseased lung played in the symptoms presented by the patient during life, and how much it hastened or contributed toward his death, what would have been the course and duration had this complication been absent, were puzzling questions throughout the patient's illness, and still remained unsolved problems after the autopsy. It was unfortunate that an examination of the lungs was not made upon his first visit to my office. No information as to this feature could be obtained from the physicians who had seen him before, as they stated that they had made no examination of the patient other than merely to look at his tongue. However, I think there is little doubt but that the lung complications developed between the time that I saw him at my office and when I was first called to see him at his home, although the well-known general symptoms always expected in the presence of a recently and completely hepatized lung were absent. I hardly think it was a genuine pneumonia due to an infection from the pneumococcus, for although the symptoms present on the first day of his confinement to bed were such as to induce us to make a diagnosis of acute pneumonia, yet the subsequent course of the case was certainly not typical of that disease. The condition of the lung and pleura at autopsy, together with the character of the exudate with which the air-vesicles and tubes were filled, clearly indicated that there had been congestion and inflammation, and yet it was most likely a passive congestion due possibly to some mechanical obstruction to the return flow of blood to the heart or to some other cause which could not be clearly demonstrated.

On the other hand, the case in its history, course, and duration did present a typical picture of exophthalmic goiter except for the absence of exophthalmos. We are told, however, that while this is the most conspicuous characteristic of this disease, yet it is the one most frequently absent. At the same time, barring the local evidences of a solidified lung, there was no symptom presented by this case throughout its course that could not readily be accounted for upon the theory of thyroid intoxication alone.

**Site Selected for Philadelphia Almshouse and Insane Hospital.**—The Philadelphia councils have been asked to pass an ordinance permitting the Department of Charities and Correction to use part of the House of Correction property in Holmesburg as a site on which to locate the City Almshouse and the Department for the Insane. The selection of this site was based on the favorable decision reached by the party of physicians, representing a number of hospitals and three colleges, after they had made a thorough inspection of the location. Councils are urged to provide for the immediate construction of the necessary buildings. By a recent provision there is \$250,000 available for the buildings and for a Municipal Hospital, and in addition there is a loan item of \$200,000 which can also be used. It is proposed to spend \$200,000 for the Insane Department and \$100,000 for the Almshouse. The site selected consists of 150 acres of healthy, high, and accessible ground, which is already owned by the city. Part of the tract consists of 40 acres of woodland, which will be used as a recreation park. The Pennsylvania Railroad runs through the northern section of the land, and patients from all parts of the city can readily be transported over this railroad and transferred to the institution without the slightest inconvenience. It is estimated that the buildings when completed will accommodate 4,000 persons. Mayor Ashbridge, in a message to councils, recommends that the new buildings be designated as the Philadelphia Hospital for the Insane and Philadelphia Hospital for Indigent, and the whole institution to be known as the Philadelphia General Hospital. The county hospital will be retained on the present site at Thirty-fourth and South streets, where all the buildings are now located.

## SPECIAL ARTICLES

THE GYNECOLOGIC EXAMINATION.<sup>1</sup>

BY

JAMES HAWLEY BURTENSHAW, M.D.,

of New York.

Adjunct Professor of Gynecology at the New York Polyclinic.

*General Observations.*—When a woman submits to a gynecologic examination, it must be remembered that she does so, in a majority of instances, with a full realization of what it implies, and with the hope that treatment will cure or relieve her condition. While the examination should be thorough in every sense, a conscientious effort should be made by the physician to respect her natural sense of modesty, and to spare her undue exposure. When possible, a specially trained nurse or other female attendant should prepare the patient, and should be present during the examination. Whether one is in attendance or not, the patient should always be allowed to arrange her clothing, before and after the examination, behind a screen, which preferably should be placed about or immediately adjoining the examining table.

The use of a sheet should never be omitted, and it should be scrupulously clean. All instruments to be used during the examination should be kept out of sight, and all unnecessary noise in handling them carefully avoided. Subsequent to the examination the instruments, towels, soiled cotton, and the like should be removed from sight before the patient is allowed to rise from the table. While it undoubtedly is a wise precaution to disinfect all instruments carefully, preferably by boiling, both before and after an examination, few gynecologists, in their routine office practice, attach to this procedure the importance it warrants. In every case they should be scrubbed clean with hot water and soap, and thoroughly dried before again being used or put away.

If the physician has the slightest reason to suspect the presence of recent venereal infection in the case of the patient to be examined, a thin, seamless rubber glove should always be used on the hand which examines the vagina, and the glove and all towels, instruments, etc., should be submitted to rigorous disinfection before being put aside. Rubber finger-cots under these conditions do not afford sufficient protection. In the case of malignant disease of the vagina or uterus, similar precautions are necessary.

The instruments used should be kept in warm water until required. Cold instruments should never be introduced into the vagina. If the instruments have just been boiled, the water in the basin need not be medicated, but otherwise it is best to add one of the mild antiseptics, such as creolin or lysol in the proportion of a dram to the pint. Mercuric chlorid will corrode the instruments and should never be used. Iodin, silver nitrate, or strong acids used in the course of local treatment ruin all fabrics with which they come in contact, and therefore all excess of these agents should be removed from the genitalia or from instruments with moistened absorbent cotton, rather than with a towel.

The time of election for the gynecologic examination is about midway between two menstrual periods. When possible, the patient should always have had a free bowel movement an hour or two previous to the examination, and to this end a saline cathartic should be taken the night before. Her bladder should be empty, or as near so as possible. If the examination is to take place under general anesthesia, she should have abstained from taking food for at least six hours previously. If apprehension is shown by a patient during the progress of the examination, a few words by the physician will often serve to distract her thoughts and render it less of a bugbear. Above all things the physician should never in any way express surprise, anxiety or consternation as a result of his findings. If the patient's condition is serious, it is probable that she will possess some understanding of its gravity, or of its consequences, and her mental state should not be made worse by any

remark or facial expression of the physician. Finally, it is to be remembered that levity or joking conversation on the part of the examiner at such a time is distinctly out of place.

*The Vaginal Examination.*—The routine practice which I have adopted in vaginal and combined vaginoabdominal examinations differs somewhat in detail from that of many gynecologists, and therefore I shall describe it with considerable minuteness.

Whether the digital examination of the pelvic contents is made with one or two fingers, or with the fingers of the right or left hand, is a matter entirely of preference or custom with the examiner. Every gynecologist should be able to examine equally well with each hand, but while the right side of the pelvis may be most readily explored with the right hand and the left side with the left hand, long experience usually enables one to obtain all necessary information with the fingers of that hand which he is most accustomed to use. Personally I use the index and second fingers of the left hand, the remaining two fingers being doubled into the palm, the thumb being fully extended. The right hand is thus left free for the handling of instruments.

The patient having loosened her corset and all waistbands, she is made to stand on a small stool at the foot of the examining table, facing the examiner. The latter, or the nurse, then holds a sheet folded in half before her at a level with her hips, and protected by the sheet she is told to raise her skirts behind to the level of the table and then to seat herself on the edge of the latter. The sheet is then laid over her lap and she is assisted to lie down, a hard pillow of moderate height being placed under her head. Still protected by the sheet, the examiner then adjusts her feet in the stirrups and she is directed to separate her knees widely. If she has slipped back on the table, she is drawn forward so that her buttocks extend slightly over the edge. The lower part of the sheet is then folded under the edge of her skirts, and after being pushed upward some distance the nurse folds skirts and sheet inward toward the abdomen, holding them in this position during the examination. By this method the patient is least exposed. If preferred by the examiner, however, or if a nurse is not in attendance, the skirts and sheet may be raised to the level of the knees or the skirts may be pushed above the knees, care being taken that the sheet covers the latter at all times. If for any reason the course of the examination is temporarily interrupted, the end of the sheet should at once be dropped, concealing the genitals from view. When the patient is in proper position she is directed to rest her arms quietly at her sides and to breathe regularly and deeply, preferably with the mouth open, in order to relax the abdominal muscles as much as possible. She should not be allowed to raise her head from the pillow until the examination is concluded.

The physician then proceeds to inspect the external genitals, standing somewhat to the left of the patient and separating the labia with the thumb and forefinger of the right hand, or while seated before her, in this case using both forefingers for the purpose of exposing the canal. A careful visual examination should never be omitted under any circumstances; it requires but a moment, and much valuable information may be gained. A textbook on gynecology of comparatively recent date states in this connection: "Inspection of the external genitals should not be made a routine practice. As a general rule it should only be made when there is local tenderness, when syphilis or gonorrhoea is suspected, or when it is said by the patient that something comes down at the vaginal orifice." Such teaching cannot be condemned too strongly. The physician owes it to his patient that the examination be as thorough and complete as lies in his power, and neglect of any advantage that may be gained by such a step will handicap him in his diagnosis and treatment. During the visual examination the physician should note the following:

1. The height and angle of the pubic arch, and the condition of the mons veneris. Scratch-marks on and in the neighborhood of the mons frequently are indicative of pruritus, or of the presence of pediculi. An extraordinary growth of hair in this region has been noted as sometimes occurring in connection with tumors of the pelvic organs.
2. The position and condition of the clitoris. Pronounced.

<sup>1</sup> Lecture delivered at the New York Polyclinic Medical School and Hospital, November 26, 1902.

hypertrophy or congestion and sensitiveness of the clitoris, especially in a neurotic subject, should give rise to a suspicion of masturbation. An adherent prepuce may be a causative factor in many hysteroneurotic conditions.

3. The urethral orifice. Redness and sensitiveness is most frequently due to the presence of caruncle, to urethritis, or to prolapsed walls. Pus at the orifice may be due to general urethritis, or to inflammation of Skene's ducts.

4. Position and condition of the vulva. A virgin vulvar orifice is usually small, and its labia are firm; a multiparous orifice is more or less enlarged, and the labia are less firm, or flabby. A ruptured or absent hymen is not necessarily an evidence of unchastity. Every gynecologist of experience has seen cases in which the membrane has been torn or destroyed as a result of a fall, or by the use of an unyielding nozzle while taking a vaginal douche.

5. The condition of the vulvovaginal glands.

6. The vaginal opening for presence of chancre, mucous patches, or condylomas; for prolapse (rectocele and cystocele); for laceration; for gonorrhoeal or leukorrhoeal discharge.

7. The anus for hemorrhoids, fissure, or fistula.

A curious fact which has very frequently been brought to my attention is the facility with which students at my clinics and in my operative classes diagnose the existence of a cystocele when none is present. This happens in the course of the visual examination, and in some instances, perhaps, is pardonable. The female urethra measures about  $1\frac{1}{2}$  inches in length, and is supported by the anterior wall and pubovesical ligament. The bladder, normally, then, is the distance mentioned from the vaginal orifice. Directly beneath the urethra, and especially at its junction with the bladder, the anterior vaginal wall is made up largely of erectile tissue. In women who lead an active sexual life this tissue is apt to become more or less hypertrophied, and I have frequently seen it enlarged to the size of a hickorynut. Under such conditions this so-called tubercle of the vagina is sometimes mistaken for a true cystocele, the examiner for a moment having become confused as to the anatomy of the parts.

The visual examination having been completed, the physician lightly anoints the finger or fingers with which he is to make the vaginal examination, and then with a towel wipes off the thumb by which the lubricant has been distributed, in order not to soil the patient's clothing. A very small amount of the lubricant will be necessary. The examiner's hands should be warm, scrupulously clean, and the nails should be cut short and rounded. A ring should not be worn on any of the fingers of the examining hand. The details of the digital examination demand close attention. The ability of the examiner to explore the pelvis without causing the patient unnecessary pain frequently determines whether he will be retained as her medical attendant. Aside from consideration for a woman's natural sense of modesty, no one feature appeals more strongly to her susceptibilities than absence of physical discomfort when undergoing an examination of this character. Three cardinal points should be borne in mind when introducing the examining fingers into the vagina: (1) Always pass the fingers into the canal from below—that is, over the perineal body—never from above; (2) always avoid touching the clitoris; (3) always avoid compressing the soft tissues under the pubic arch by making firm, steady pressure on the perineal body and rectovaginal septum. If the physician has been accustomed to examine with two fingers, and is confronted with the task of examining a nulliparous vagina of small caliber, it frequently is surprising how readily it may be accomplished without causing pain to the patient if these precautions are observed. On making firm downward pressure on the perineal body and avoiding as much as possible coming in contact with the pubic arch, I lay particular stress. At the introitus the vaginal canal is distensible to a very slight extent upward, due to its anchorage under the pubic arch, but to a marked degree downward, on account of the elasticity of the muscular walls and of the perineal body.

If the vaginal walls are relaxed, or the canal moderately capacious, firm pressure downward will not be so necessary, and the examining fingers may be introduced with a boring or worming motion; but if the orifice is small and the canal nar-

row much discomfort to the patient may be avoided if the fingers creep in, one after the other. The palmar surfaces of the fingers are always toward the perineum until the digits are well into the canal, when the hand is turned and the examination completed with it in that position. The manner in which it is turned is important. If the fingers are kept side by side and rotated together, if the orifice is small or the pubic arch narrow the index finger will impinge on the soft parts under the arch throughout the entire arc of the circle in spite of firm pressure downward being made at the same time, and considerable discomfort will result from the contact. A simple maneuver on the part of the examiner will almost completely obviate this difficulty. If the index finger is placed on top of the second finger before the rotation is made and kept in that position until the rotation is completed only a small portion of the soft parts under the arch will be compressed at any time.

The physician should invariably stand while conducting the digital examination. The labia are separated widely by the thumb and forefinger of one hand and are kept in this position until the examining fingers have been rotated. The tip of the second finger is introduced into the canal and firm, even pressure made on the perineal body. The end of the index finger follows, and likewise presses downward. Then the pressure made by the longer finger is relaxed and its tip is made to pass that of the index finger, and so on, pressure by each finger being made alternately until their second joints pass just beyond the introitus. Then the hand is rotated slowly, the two fingers being in the position described above, and the hand which has been separating the labia is placed on the abdomen in readiness for the bimanual examination.

As the fingers are passed along the vaginal canal toward the cervix the following points should be noted: The size and length of the canal; the presence or absence of rugæ; the amount of secretion present; the temperature (if raised); the sensitiveness; the state of the perineal body and vaginal floor—whether torn or relaxed; the presence or absence of fecal matter in the rectum. Small rectovaginal or vesicovaginal fistulas can usually be detected only on careful visual exploration of the canal, although if the induration surrounding such an opening is extensive it can ordinarily be detected by the fingers.

*Examination of the Cervix: Position.*—It has been very generally taught that the position the cervix occupies in relation to the long axis of the vagina is indicative of the position of the uterine fundus. This is distinctly incorrect. Normally, the long axes of the cervix and vagina form an angle slightly less than a right angle, the fundus uteri being forward. Three malpositions are possible in which the accepted teaching, as has just been said, can be shown to be incorrect: (1) The cervix uteri may be in its normal position, while the body may be bent forward, causing an acute flexion at the level of the internal os; (2) the body of the uterus may be in its normal position and the cervix be bent forward; (3) both cervix and body may be bent forward. In retrodeviation of the uterus, whether the case is one of flexion or version, the cervix is usually found more or less parallel with the vaginal canal. In lateral deviation the cervix may be drawn to one side by inflammatory contractions in the vagina or pelvic cavity, or pushed to one side by a pelvic tumor.

*Size and Consistency.*—A smooth, firm round cervix with circular ostium is usually indicative of nulliparity; a long, conical cervix with pinhole ostium generally denotes congenital sterility; a gaping ostium with more or less roughened or fissured edges denotes pluriparity. In pregnancy the cervix is enlarged and soft, due to congestion, but the same condition frequently prevails in acute metritis and acute cervicitis. In the latter case, it is accompanied by a more or less glairy discharge, often containing blood. A contracted, cartilaginous-like cervix may be indicative of a chronic or subacute inflammation which has progressed to the hyperplastic stage, or of the first stage of scirrhus degeneration. A cervix that is very much increased in size, that is of moderate hardness and more or less nodular, the enlargement extending to the body of the uterus, is nearly always cancerous, the disease being of the parenchymatous variety, while a cervix that is more or less immovable, and has a crater-like cavity with irregular edges, accompanied by a

foul-smelling, shreddy discharge, is in the ulcerative stage of the same disease. An epithelioma of the cervix is cauliflower-like in appearance, the organ is enlarged and soft, and it bleeds readily when touched.

Ulcers of the cervix are of rare occurrence, except when of syphilitic or tuberculous origin. The former are accompanied by pain, and yield readily to antisiphilitic treatment; the latter may easily be mistaken for the specific variety, or for carcinoma. Unless of considerable size, a specular examination is ordinarily necessary for their detection. Erosions of the cervix, on the other hand, are very common. The organ is enlarged, nodular, and usually soft, and when laceration is present, the lips are everted. When the inflammation is very marked, the condition may be mistaken for epithelioma. Small, nodular irregularities on the surface of the cervix are usually due to occlusion of the ducts of the muciparous glands, the so-called *ovula nabothi*.

Lacerations of the cervix, whether unilateral or bilateral, if of small extent, and especially if old, frequently are not recognizable to the sense of touch. A foreign body projecting from the cervical canal, or from one of the lips of the cervix, may be a mucous polyp or a pedunculated submucous fibroid or fibromyoma. The first are common, the second rare.

*Conjoined or Bimanual Examination.*—The examining fingers of the left hand having been brought in apposition with the cervix, the right hand should be laid flat on the abdomen, the roots of the fingers being just above the symphysis pubis. Firm pressure should be made with the fingers straight and close together and along their entire length, and the skin covering the abdomen should be pushed toward the navel. Then the fingers should be arched and their tips made to sink as deeply into the pelvis as possible, the pressure being firm and steady downward and toward the fingers in the vagina. Many gynecologists advocate arching the hand directly above the pubis and making the necessary pressure from that location. For many reasons this plan is not good, one being that frequently the bladder is not empty at the time of the examination, and pressure at this point, instead of facilitating the palpation of the uterus and adnexa, defeats the object by the bladder forcing the organs deeper in the pelvis. Pushing the loose skin upward with the flat of the hand before making deep pressure puts it less on the stretch when the fingers sink into the pelvis, and therefore gives less discomfort to the patient. To facilitate the examination of the pelvic organs, Winter<sup>1</sup> says:

It is very necessary to know what portions of the bony pelvis can be felt through the vagina. The posterior wall of the symphysis, the horizontal and descending ramus of the pubic bone, and the upper part of the ascending ramus of the ischium can be felt, whereas the tuberosity of the ischium can rarely be recognized, on account of the soft parts covering it. Of the descending ramus, the tuberosities can easily be made out, and are important in estimating the height of the *portio vaginalis*. The *linea ileo-pectinea* is easily recognizable in patients with relaxed vaginal walls, and under ether narcosis, as is the lower border of the sacrospinal notch. The promontory and upper portion of the sacrum can be reached if the pelvis is not too wide, but the posterior and most excavated portions can seldom be felt. At times separate muscles can be felt in the pelvis, especially if in a state of contraction. On the anterior surface of the sacrum the pyriform muscle appears to the touch as a faint welt; on the anterior pelvic wall, on the obturator foramen, the expanded internal obturator muscle can be made out. The broad belly of the iliopsoas can be felt high in the canal from within upward and from below outward.

In palpating the contents of the pelvis one very important precaution should be borne in mind: to endeavor to transmit all impressions to be gained by the examination from the hand on the abdomen to the fingers in the vagina, and not *vice versa*. The reasons are obvious. The vaginal fingers are necessarily closer to the organs to be palpated and the intervening tissues are thinner and more sensitive than the abdominal wall. To accomplish this end, the fingers in the vagina should be held firmly and steadily against the area to be examined, and the pressure transmitted from the abdominal surface. To press downward from above and make a series of jabs with the fingers in the vagina, as I have frequently seen done, is not permissible under any circumstances. Aside from adding greatly to the discomfort of the patient, the results from traumatism might

easily be serious, especially in the case of a thin-walled cyst or pyosalpinx.

The position of the hand on the abdomen, of course, will be changed as the examination progresses nearer the pubis and to each inguinal region, but the skin should always be pushed upward before deep pressure is made in each locality. A variety of movements by the hand will tend to facilitate the examination; thus, in addition to deep pressure, the muscles of the abdomen may be rolled under the fingers, or the abdominal surface sharply tapped, or successively pressed and released. At times a bimanual examination of the pelvis yields unsatisfactory results, owing to the rigidity of the abdominal walls, due either to the fact that pressure causes pain, or to nervousness on the part of the patient. If undue pain results from such an examination, the only recourse is complete anesthesia, but when nervousness and fear of being hurt is the cause of the rigidity, it frequently may be overcome by diverting the patient's attention to something not connected with the matter in hand. During the entire course of the examination she should be requested to breathe evenly and deeply, preferably with the mouth open.

*Position of the Uterus.*—Great diversity of opinion exists as to the normal position of the uterus. This is not surprising when it is remembered that the uterus is a movable organ, suspended in the pelvis by certain ligaments, and that it is susceptible of considerable variation within perfectly normal limits. The condition of the rectum, sigmoid and bladder, whether full or empty, one or all, naturally influences its position. For all practical purposes, the bladder being empty, it may be considered as being normally placed when, the woman being in the upright position, the plane of its long axis is slightly above that of the horizon, in other words, when it closely approaches the horizontal. Therefore, the patient being recumbent during the bimanual examination, the fundus, under these circumstances, will usually be found some two inches, more or less, back of the symphysis pubis.

The tips of the fingers in the vagina are placed directly under the cervix and steady pressure made by the hand on the abdomen. If the uterus is in its so-called normal position, and if the abdominal muscles are sufficiently relaxed, the organ can usually be brought between the fingers. If the uterus is not found in this position, the fingers in the vagina should be brought into the anterior fornix. If the organ is anterodisplaced, it will easily be outlined by the vaginal fingers through the walls of the bladder; if retrodisplaced, pressure should be made on the anterior portion of the cervix with the hope of raising the fundus so that it may be grasped. If this cannot be done, which is usually the case, the fingers in the vagina will recognize the condition when palpating the posterior culdesac.

*Examination Through the Posterior Fornix.*—The posterior vaginal fornix, normally, is about one inch in depth, and is concave in shape. It is separated from the Douglas culdesac by the reflection of the posterior vaginal wall covered by mucous membrane, by loose cellular tissue, and by peritonium. The examining fingers, palmar side upward, are passed to the end of the fornix and firm pressure made by the hand on the abdomen. The culdesac ordinarily is empty. Abnormally it may contain one of the following: (1) Fundus of the uterus, the organ being retroflexed or retroverted; (2) a prolapsed ovary; (3) a uterine fibroid; (4) a prolapsed coil of intestine; (5) fecal impaction or a tumor in the rectum; (6) an hematocoele, due to rupture of an extrauterine pregnancy; (7) ascitic fluid; (8) cellulitic or peritonitic exudate; (9) tumor of the sacrum.

The differential diagnosis in some cases is exceedingly difficult. The history of the case, with subjective symptoms, will frequently be of great assistance in determining the character of the tumor. In general the following characteristics will apply to the several conditions: A retrodisplaced uterus is of oblong shape, is soft, as a rule, elastic, and may be tender. The direct continuity of the cervix and uterine body may be traced. A fibroid growth is hard, and may be nodular. Unless bound down by adhesions, it is movable with the uterus. A prolapsed ovary is small, almond-shaped, and causes characteristic pain when compressed. An ovarian cyst is soft, presents a spherical outline, and is apt to be only slightly tender to the

<sup>1</sup> Gynäkologische Diagnostik, Leipsic, 1897.

touch. Prolapsed intestines, unless inflamed, are not sensitive, are compressible, and if not adherent may be made to leave the pouch by placing the patient in the knee-chest, and, at times, in the lateroabdominal or Sims position. Fecal impaction yields a doughy sensation, and cannot well be mistaken for anything else. A growth in the rectum will easily be diagnosed by rectal examination. An hematocele, the result of ruptured ectopic gestation, is soft, compressible, fills the entire pouch, and is painless to the touch. The history of possible pregnancy with sudden inguinal pain and collapse, along with other symptoms referable to the condition, makes the diagnosis comparatively easy. Ascitic fluid in the pouch is nonencapsulated, and its location will change with the patient's position. Cellulitic deposits may be found on one or both sides of Douglas' pouch, or through the lateral vaginal fornices, the result of inflammation in the laterouterine connective tissue between the folds of the broad ligament. In case this has gone on to suppuration, a smooth, convex tumor will be felt. If not of recent origin, it is apt to be hard, shrunken, and not tender; if recent, it usually will be soft, more or less boggy, and very sensitive. Enlarged lymphatic glands, presenting irregular flat surfaces, and which are tender to the touch, are frequently found in these localities.

**Examination Through the Anterior Fornix.**—The fingers in the vagina are now brought above the cervix, and steady pressure from the abdominal surface made with the other hand. The range of the examination here necessarily is limited. Abnormally, one of the following may be felt through the fornix: (1) An anteverted or anteverted uterus; (2) a fibroid growth springing from the anterior uterine wall or fundus; (3) a pedunculated fibroid (rare); (4) a prolapsed coil of intestine (rare); (5) a prolapsed ovary (rare); (6) anteuterine hematocele (rare); (7) cellulitic exudate. A stone of large size in the bladder has been mistaken for the fundus of the uterus.

**Palpation of the Tubes and Ovaries.**—The fallopian tubes are given off from each side of the uterine fundus, are contained within the upper free border of the broad ligaments, and vary from four to six inches in length. In other words, they are soft, easily compressible, soft-walled tubes of small diameter extending sinuously from the uterus to the ovaries. They cannot be palpated through the vagina when normal except, perhaps, at their junction with the uterus; first, because it is practically impossible to differentiate them from the surrounding tissues; and second, because the narrowness of the vaginal canal limits the area that can be palpated. Normally the tubes are not sensitive to the touch. The ovarian ligaments are frequently mistaken for them when felt through the vagina.

The ovaries are almond-shaped bodies measuring about  $1\frac{1}{2}$  inches in length,  $\frac{3}{4}$  of an inch in width, and are about  $\frac{1}{4}$  of an inch thick. Their size varies, depending on the ripening of the follicles and the development of the corpora lutea. They lie on the upper or posterior surface of the broad ligaments about  $1\frac{1}{4}$  inches from the uterus and beneath the tubes. Each ovary is attached at its lower end to the uterus by a ligament, the ovarian, measuring about  $1\frac{1}{2}$  inches in length, which is attached to the uterine fundus directly beneath the origin of the fallopian tube. According to Winter (*loc. cit.*), "the ovaries lie near the lateral walls of the true pelvis directly under the ileopectineal line. Their upper borders do not quite reach the iliac bloodvessels nor their lower borders the pelvic floor. Each is so suspended that its largest diameter is parallel with the long axis of the body, the hilus is directed forward, and the free convex border posteriorly, the flattened surface lying against the pelvic wall."

Palpation of normal ovaries should not be difficult in a majority of cases. If the vagina is small, or if the abdominal walls are rigid or contain much fat, skill and long practice, however, may prove unavailing in an effort to palpate them. The first requisite of success is an appreciation of the anatomy of the parts. My experience has shown me that almost invariably students and general practitioners search for them with the examining fingers placed *under* the cervix in the posterior vaginal fornix. No account is taken of their normal position, or of the resistance offered to the fingers by the laterouterine tissue or the uterosacral ligaments. Under these circumstances, of course, the effort will be fruitless, no matter what degree of

pressure is exerted by the hand on the abdomen to force the organs deeper into the pelvis and so within reach of the fingers in the vagina. The ovaries, when normally situated, cannot be palpated through the posterior vaginal fornix. It must be remembered that the uterosacral ligaments pass from the posterior surface of the uterus, at the junction of the body and cervix, outward and backward to the second sacral vertebra. They thus form part of the upper lateral boundary of Douglas' culdesac, and upward or lateral mobility of the fingers in the posterior vaginal fornix necessarily is limited by their presence. An ovary prolapsed into Douglas' pouch may easily be felt, the intervening tissues being only the vaginal wall covered by mucous membrane, some loose cellular tissue, and the peritoneum.

If the ovaries are not prolapsed the examining fingers should be brought from the posterior fornix to the side of the cervix, and the examination continued through the lateral fornices. Here steady pressure should be made in succession, laterally, upward, and perhaps more or less downward, the hand on the abdomen pressing the pelvic contents toward the fingers. An ovary from this position cannot be so readily felt, for the reason that in addition to the vaginal wall a portion of the bladder and the broad ligament will be between it and the fingers in the vagina, but nearly always it will be recognized as a moderately hard body, uneven in outline, which causes marked pain on pressure. Frequently the ovaries may be more easily felt by combined rectoabdominal examination, a fact that should not be lost sight of in difficult cases.

## THE WORLD'S LATEST LITERATURE

Journal of the American Medical Association.

December 27, 1902. [Vol. xxxix, No. 26.]

1. Obstetrics and the General Practitioner. M. H. FUSSELL.
2. Three Cases of Involuntary Movements in Locomotor Ataxia. J. H. W. RHEIN.
3. Sanitary Measures for the Prevention of Tuberculosis in New York City and Their Results. HERMANN M. BIGGS.
4. A Peculiar Case of Recurrent Bullous Eruption. WILLIAM S. GOTTHEIL.

**1.—Obstetrics and the General Practitioner.**—Fussell emphasizes the obligation of the general practitioner who handles the vast majority of obstetric cases to follow hospital methods so as to make private work without avoidable mortality. Failure to periodically examine the urine is criminal neglect. Among other duties which he discusses are regulation of daily life, attention to the breasts, abdominal examination, measuring of the pelvis in the primipara, instructions to the woman as to preparation for the lying-in period. [H.M.]

**2.—**See *American Medicine*, Vol. III, No. 25, p. 1056.

**3.—**See *American Medicine*, Vol. III, No. 25, p. 1047.

**4.—Recurrent Bullous Eruption.**—Gottheil reports a case in which without either general or local prodromal symptoms there would appear minute vesicles, increasing to walnut size in two or three days if not ruptured. After rupture the epidermis could be removed at once, as epithelial repair had taken place under it. It recurred in the fall of four successive years. Benign pemphigus is the name that suits it best, but Gottheil hesitates to use this on account of its periodicity and the absence of inflammatory areola. [H.M.]

1. On the Teaching of Physical Diagnosis. WILLIAM SYDNEY THAYER.
2. Two Cases of So-called Landry's Paralysis: Autopsies. E. W. TAYLOR and G. A. WATERMAN.
3. Obstetric Antisepsis. WARREN R. GILMAN.
4. Errors in the Estimation of Urea by the Hypobromite Method. ELLIOTT P. JOSLIN.

**1.—The Teaching of Physical Diagnosis.**—Thayer holds that the essential points in the teaching of physical diagnosis consist in the demonstration of these points in regional anatomy, an accurate knowledge of which is necessary to the diagnostician. Such demonstrations should first be had on the normal individual. It is desirable that the student should learn by actual observation and practice the physical causes for the

signs noted on inspection, palpation, auscultation, and percussion. A proper groundwork should first be had in pathologic anatomy, and frequent demonstrations should be had in the necropsy-room of the lesions in physical examination on the living. The student should be allowed no textbook on the subject until he has learned to detect on the living individual the important physical manifestations of disease. Proper instruction requires that a subdivision of the class into smaller sections be had. In learning the fundamental essentials of physical diagnosis nothing is more important to the student than experience in an outpatient clinic, or its equivalent under the direction of an instructor. No one is fitted to begin the actual practice of medicine who has not had actual bedside experience in the observation of the more important diseases which he is to meet in general practice. This is best had by service in a hospital under some capacity. After all, the method of instruction is perhaps the smallest part. Success depends to a much greater degree upon the instructor himself. [A.B.C.]

**2.—Landry's Paralysis: Report of Two Cases, with Autopsy.**—Waterman reports two cases of so-called Landry's paralysis. Detailed reports of the two cases, together with the findings at necropsy, are given at length. The author concludes that in view of the large number of articles previously published on the subject of Landry's paralysis and allied conditions detailed records of the pathologic anatomy is unnecessary. Nothing definite is added by the report of the two cases beyond a further demonstration of the general fact that a fatal disease of the nervous system is not uncommon, which is explained by the findings at necropsy. Speculation concerning the cause of death in such cases appears to be unavailing in the present state of our knowledge of the question of toxemia. Much preliminary work yet remains to be done before an adequate scientific explanation is had. In the meanwhile, accurate and exact reports of clinical and anatomic findings are highly desirable in this undefined class of cases. [A.B.C.]

**3.—Obstetric Antisepsis.**—Gilman appears to be of the belief that the principles of asepsis and antisepsis are much more vigorously preached than practised by the average obstetrician. The ones in charge of the case, especially if untrained, should be given explicit directions in writing as to the proper preparation of patient and paraphernalia. The patient herself should be given a few simple, concise orders in reference to the proper preparation of herself, clothing, bed linen, etc. The doctor engaged in general practice should take every precaution before assuming charge of the labor case that the hand and instruments are thoroughly disinfected. Rubber gloves are especially commended by the author, not only for the protection of the patient herself, but to the doctor and patients whom he must visit subsequently. The importance of providing sheets, towels, and napkins should be thoroughly impressed upon the patient about to be confined. [A.B.C.]

**4.—Errors in the Estimation of Urea by the Hypobromite Method.**—Joslin holds that this method is unreliable under certain circumstances. Urea is almost  $\frac{1}{2}$  ( $\frac{2}{3}$ ) nitrogen, and consequently the urea in 24 hours can never much exceed twice the quantity of nitrogen. In a case of diabetic coma he noticed on a given date that in round numbers the nitrogen was 24 grams, and the urea by Braunstein's instrument was 44 grams, and by Squibb's instrument 80 grams. On the succeeding day the figures were respectively 19 grams, 30 grams, and 48 grams. This great discrepancy led to an investigation, and the author found that in diabetic coma and allied conditions not much ammonia, acetone, etc., are present. The hypobromite method is wholly unreliable. Other bodies like creatin, uric acid, and urates also interfered with the test. Since acetone, oxybutyric acid, and ammonia are chiefly found in diabetical patients it is best not to use the hypobromite method in these cases. The simplest procedure to enable us to determine their presence is the ferric chlorid test for diacetic acid. When this is positive the above named substances are always present and an excess of ammonia is probable. [A.B.C.]

#### Medical Record.

December 27, 1902. [Vol. 62, No. 26.]

1. On Some of My Principles in Orthopedic Surgery. PROF. ADOLPH LORENZ.

2. What Can Be Done to Prevent the Spread of Syphilis. E. HARRISON GRIFFIN.  
3. X-light in Therapeutics. CLARENCE EDWARD SKINNER.  
4. Typhoid Gangrene. CHARLES E. NAMMACK.  
5. The Etiology of Relapse in Enteric Fever. H. N. RAFFERTY.  
6. Pasteurized and Sterilized Milk as a Cause of Rickets and Scurvy. E. M. SILL.

**1.—Principles in Orthopedic Surgery.**—Lorenz says so long as the bones are elastic enough he prefers osteoclasts to osteotomy, the latter being reserved for adolescents and adults. In cases of hip deformity he uses the chisel only in cases of complete ankylosis. Knee-contraction is corrected by intra-articular modeling redressment so long as the slightest mobility is found. In all deformities of the foot, both paralytic and congenital, he relies exclusively on modeling redressment of the foot; wedge-shaped excision of the bones of the foot is nothing short of a deplorable mutilation. On general principles he prefers bloodless operation so long as there is a possibility of securing the desired result. He opposes extirpation but commends subcutaneous myomectomy of the sternomastoid in persistent wry-neck. Caput obstipum is cured by modeling redressment of the cervical scoliosis combined with subcutaneous myomectomy of the sternomastoid muscle; and the congenital form may be thus cured without myomectomy but with myorrhexia of the sternomastoid. Another principle followed is that all deformities should be reduced after the so-called "central correction" method, which means that every deformity should be corrected in the vertex of its angle. Genuvalgum is usually treated by supracondyloid osteotomy; epiphysiolysis of the lower end of the femur is better, but is restricted to those between 5 and 16 years. Another principle is to save all the bone possible at the expense of the soft tissues, hence cuneiform osteotomies and resections *en bloc* should be avoided and linear osteotomy used; this is available even in bow-legs with anterior curvature. He has never resected a joint for tuberculous disease in a child. In tuberculous disease of the hip-joint he uses extension only so long as there is pain, and uses massage to prevent muscular wasting so soon as freedom from pain will permit it. His final aim is to secure solid, bony ankylosis of the joint together with good position, which is slight abduction of the leg. In cases of scoliosis he is wholly opposed to mechanical supports, especially those worn night and day. [A.B.C.]

**2.—Prevent the Spread of Syphilis.**—Griffin says in an active practice for many years as a nose and throat specialist, his records show that every thirteenth patient had syphilis in some form. He is fully convinced that it is caught and dispersed by the mucous patch more than by the primary chancre. The author cites many means, such as public drinking cups, cigarmaker's saliva, fruit vender's saliva, kissing, toys manipulated by the mouth, etc., by which syphilis is communicated extravenereal. The gist of this interesting and instructive article is that the public should be thoroughly informed as to the contagiousness and general character of syphilis, and that means should be adopted to prevent or greatly limit its extravenereal dissemination. Every dispensary patient should be supplied with a card on which is printed in the patient's language the general nature of the disease, and rules to govern his conduct. Cases of syphilis should be reported to the Board of Health the same as other infectious diseases. [A.B.C.]

**3.—Röntgen Light in Therapeutics.**—Skinner says the Röntgen rays have been found of value in the treatment of acne, psoriasis, eczema, rheumatism, some forms of neuralgia, neuritis, anthrax, lupus, and cancer. Its great interest naturally has to do with treatment of cancer, and in this affection it is used in both superficial and deep malignant growths. The length of time it has been used is too short for statistics to be of value, but so far only about 5% of superficial malignant growths "cured" by Röntgen rays have recurred, and about 80% of all the superficial cases subjected to treatment are cured or arrested. In the deep-seated growths prognosis is much less hopeful but not without some encouragement. In September, 1902, the author reported the condition of 33 patients with deep-seated malignant growths, which he had had under treatment for nine months. His further report on these is as follows: Out of 33 cases, we have up to the present time 3 apparent cures; 13 that have been permanently benefited and are still improving, with good prospects of ultimate cure; 12 that were

temporarily benefited; 2 that experienced no benefit; and in 3 the treatment was discontinued by the patient before enough applications had been made to indicate whether or not any results would have been produced. [A.B.C.]

**4.—Typhoid Gangrene.**—Nammack reports a case in which almost the whole of each lower extremity was involved. He believes the commonest time of occurrence is in the second and third weeks, though it may begin as late as the seventh week. It is possible in mild as well as severe cases. The onset is determined by a weak heart, sluggish circulation, general enfeeblement, obstruction of the bloodvessels from arteritis or autochthonous thrombosis, and the diffusion of bacilli and their products throughout the tissues. The latter probably set up a specific typhoid arteritis, which occurs more readily in those with arteriosclerosis, amyloid degeneration, syphilis, mechanical or chemic injury or an inflammatory process which injures the intima. With gradual arterial obliteration the gangrene is dry; when the vein is obstructed moist gangrene develops. [H.M.]

**5.—Etiology of Relapse in Typhoid Fever.**—Rafferty believes reinfection may occur by inoculation of healthy intestinal glands with sloughs from those first infected; by a deposit of bacilli in the gallbladder with or without cholecystitis, and later expulsion of the colony with bile into the duodenum, and by a colonization of bacilli in the spleen. Sequels apparently due to the specific organism have followed many years after the attack and living germs have been found in bodies three months after death. [H.M.]

**6.—Pasteurized and Sterilized Milk as a Cause of Rickets and Scurvy.**—Out of 179 infants fed for 9 months of the year on pasteurized and 3 months on sterilized milk Sill reports the occurrence of 97% of cases of scurvy and rickets. He states that a temperature much above blood heat disorganizes the albuminoids and mineral constituents. Pure milk should be secured by inspection of cows and utensils. [H.M.]

1. Endometritis. H. J. BOLDT.
2. Laryngectomy for Malignant Disease. FRANK HARTLEY.
3. Gynecologic Massage. BERNARD S. TALMEY.
4. Alexander's Operation. LE ROY BROUN.

1.—See *American Medicine*, Vol. IV, No. 22, p. 847.

**2.—Laryngectomy for Malignant Disease.**—Hartley reviews the various steps in the development of the present status of the operation, and narrates his personal experience with 5 patients. The first case was a man of 49; well 4 years after operation. The second case was a man of 60, who after 4½ years was free from recurrence. In the third case there was no recurrence at the end of 5 years. In the fourth case there was recurrence in the deep cervical glands 14 months after operation, it was then considered inoperable, and death occurred 3 months later. The fifth case was a woman of 41; no recurrence 10 months after operation. The author believes that statistics are much more favorable now than formerly, and calls attention to the remarkable development of a voice in some patients after a total excision of the larynx has been done. He lays special stress on the necessity of the most careful after-treatment in these cases. [C.A.O.]

**3.—Gynecologic Massage.**—Talmey believes that massage is a helping therapeutic agent in many gynecologic cases, and that it deserves more attention. The indications given are: Chronic perimetritis and parametritis, chronic metritis and endometritis, subinvolution and hyperemia of the uterus, uterine hemorrhages, and retroflexion and prolapsus. Massage should not be administered in acute inflammations. The general rules followed by the author are those laid down by Kellogg, and are as follows: (1) The treatment should not be employed until two hours after eating; (2) the bladder must be emptied; (3) the fecal accumulations must be removed; (4) the patient has to breathe deeply and regularly; (5) too much pain should not be caused; (6) all deep kneading movements should be slow; (7) the patient must be warned that she may feel some pains after the first sitting, and told that cold compresses will alleviate them. She must also be told that at the

second sitting the abdomen may be more sensitive than the first time. He believes that by applying massage in these cases the performance of a number of hysterectomies, dilations, curetments and oophorectomies will become unnecessary. [C.A.O.]

**4.—Alexander's Operation.**—Broun states that in suitable cases no operation can in his hands yield the same uniform clinical result. The danger is almost *nil*, and the operation is of far less gravity than other surgical means in use for the relief of the same symptoms. The anatomic result obtained is all that can be desired, and is effected without the establishment of new pathologic adhesions, the intentional formation of which form the basis of all vaginal fixations or ventral suspensions. He believes that the danger of inguinal hernia following this operation is greatly exaggerated, provided the operation is properly done, without laceration of the surrounding tissues in a long continued search for the ligament. If such laceration has taken place, hernia is impossible, if the operator continues his incision to the internal ring and does a Bassini operation, which does not prevent his shortening the ligaments at the same time. Patients having adherent retroverted uteri cannot be benefited by this operation unless the adhesions have been previously broken up. In such cases he prefers to open the abdomen, and after breaking up the adhesions to do either a ventral suspension or Bissell's operation, which consists in taking out a section of both round and broad ligaments sufficient to hold the uterus in a forward position. [C.A.O.]

1. Recent Advances in Electrotherapeutics. WILLIAM J. MORTON.
2. Imitation, Suggestion, and Social Excitements. JOHN BESSNER HUBER.
3. Cutaneous Angiomas and Their Significance in the Diagnosis of Malignant Disease: A Statistical Study Based Upon the Observation of Nearly 400 Cases. DOUGLAS SYMMERS.
4. The Rapid Microscopical Diagnosis of Fresh Tissue: With Special Reference to Staining. F. T. BILLINGS.
5. Indications for the Performance of the Mastoid Operation. WILLIAM C. BRAISLIN.

**1.—Recent Advances in Electrotherapeutics.**—According to Morton the elevation of the electromotive force and its oscillations or alterations make possible the electrification of the whole body at once, increasing oxidation and tissue metamorphosis. This is especially useful in diseases of perverted nutrition like rheumatism, obesity, etc. He briefly discusses the applications of the static induced current, the wave current, the Tesla and the D'Arsonval transformers, and the Oudin resonator, the brush discharge, the Geissler tube, and the Bequerel and Röntgen rays. The apathy of the profession toward this branch of therapeutics is incredible. [H.M.]

**2.—Imitation, Suggestion, and Social Excitements.**—In discussing this subject Huber states that the normal individual is governed by the higher brain centers, while in the savage conduct is unreasoning, passionate, impulsive, imitative and instinctive. The changes produced in an intelligent person by hypnotism illustrate these differences. According as the hypnotizer wills he gives expression to the basal emotions, fear, hate, blind reverence for unworthy objects, etc. Other factors produce the same results, mainly imitation, suggestion, and the force of social excitement, through which the power of calm observation and logical thought is lost. Huber illustrates the influence of these factors in Christian Science, the anti-Semitic mania, race riots, etc. The crowd is an entity not analogous in its psychism to that of the individuals composing it. All progress has been achieved mainly through the efforts of individuals who can withstand the hypnosis that has seized their fellows, and can influence them along moral, altruistic and religious lines. [H.M.]

**3.—Cutaneous Angioma and Malignant Disease.**—Symmers in examining nearly 400 patients found cutaneous angiomas as frequent among those without as with malignant disease. It was observed that their occurrences increase rapidly with each successive decade of life and the inference is that arteriosclerosis bears an important causal relationship. His conclusions are: That skin angiomas bear no relationship to malignant disease and that their existence, even in large num-

bers, is not to be viewed with any degree of alarm so far as cancer is concerned. That they form a frequent, practically an invariable, concomitant of the decay of advanced years, and in both young and old are probably significant of some form of well-marked arterial degeneration. [A.B.C.]

**4.—Rapid Microscopic Diagnosis of Fresh Tissue.**—Billings says that as a staining material hamalaun, a preparation of hematein, an oxidation of hematoxylin, is much superior to the latter. He sums up the different steps of hardening and staining sections of fresh tissue for microscopic examination: (1) Fresh specimen set upon freezing stage, frozen and cut; (2) sections are wiped off knife and placed in water; (3) alcohol, 50%, two minutes; (4) alcohol, 95%, three minutes; (5) hamalaun, three minutes; (6) wash in water; (7) alcoholic solution of eosin, 30 seconds; (8) alcohol, 80%, three minutes; (9) alcohol, 95%, three minutes; 10 carbo-xylol, two or three minutes; (11) mount in Canada balsam. The whole process, cutting included, should not take more than 25 minutes. The result as a rule is entirely satisfactory. At times the sections appear cloudy, but this is generally due to faulty technic and can be avoided. The rapid method is of great value in general surgical and gynecologic practice. [A.B.C.]

**5.—Indications for the Mastoid Operation.**—Braislin says the symptoms of greatest significance in leading one to undertake immediate operation are pain, continuous and severe, radiating upward along the side of the head to the vertex, backward to the occiput, or more rarely forward to the frontal region; the temperature even in children does not often keep at a high point after the first days of acute illness, but is often markedly irregular; a falling of the posterior superior wall of the external auditory canal, caused by edema of the periosteum and tissues over the mastoid cells, or it may be due to the actual burrowing of pus. It is possible to mistake this condition for furuncle of the canal. Tenderness over the mastoid is the rule in cases calling for operation, but there are exceptions. Other severe symptoms may be present pointing to perforation of the tegmen tympani. Some operators believe an exploratory mastoidectomy is justifiable at any stage of mastoiditis. But operations are thus often done in acute cases which would recover without operation. It is proper in his judgment to operate on cases in the quiescent states of chronic mastoid suppuration; both because the inflammation and irritating character of the discharge from the ear are producing destruction of the middle ear adnexas, with consequent progressive loss of hearing, and also because sooner or later the disease is almost sure to require operation. [A.B.C.]

## CLINICAL MEDICINE

DAVID RIESMAN

A. O. J. KELLY

### REVIEW OF LITERATURE

**The Influence of Soil, Fabrics, and Flies in Disseminating Typhoid Infection.**—Firth and Horrocks,<sup>1</sup> in consequence of experimental investigations, draw the following conclusions, which are equally applicable to typhoid bacilli recently isolated from stools as to old cultures that have been in the laboratory for many months: 1. There is no evidence to show that the typhoid bacillus when placed in soil displays any disposition or ability to either increase in numbers or grow upward, downward, or laterally. 2. The typhoid bacillus can be washed through at least 18 inches of soil by means of water, even when the soil is closely packed down and no fissures or cracks allowed to exist. 3. The typhoid bacillus is able to assume a vegetative existence in ordinary and sewage polluted soil and survive therein for varying periods amounting in some cases to 74 days. 4. The presence or absence of organic nutritive material in the soil appears to be a largely negligible factor, since the typhoid bacillus can survive in a soil indifferently well whether it be an organically polluted soil or a virgin soil, and whether it receive dilute sewage or merely rain-water. 5. An excess or great deficiency of moisture in soils appears to be the dominant factor affecting the chances of survival of the

typhoid bacillus in, or at least the possibility of recovering it from, soil. 6. From fine sand allowed to become dry the typhoid bacillus can be recovered on the twenty-fifth day after inoculation. 7. From fine sand kept moist with either rain or dilute sewage the typhoid bacillus cannot be recovered later than the twelfth day after fouling; this inability to recover the organism is due probably not so much to its death as to its being washed down into the deeper sand layers by liquids added. 8. In peat the typhoid bacillus appears to die out rapidly, as it cannot be recovered from it after the thirteenth day. 9. From ordinary soil kept damp by occasional additions of rain-water the typhoid bacillus can be recovered up to and on the sixty-seventh day. 10. From a similar soil kept damp by addition of dilute sewage the typhoid bacillus is recoverable up to the fifty-third day. 11. From a similar soil kept damp by occasional additions of dilute sterile sewage the typhoid bacillus is recoverable up to the seventy-fourth day. 12. In a similar soil after a heavy rainfall the typhoid bacillus disappears at once from the surface layers. 13. From a similar soil allowed after inoculation to become so dry as readily to be blown about as dust the typhoid bacillus can be recovered up to and on the twenty-fifth day, and typhoid infective material can be readily translated from dry soil and sand by means of winds and air currents. 14. In a sewage polluted soil recovered from beneath a broken drain the typhoid bacillus is able to survive up to the sixty-fifth day. 15. From a piece of khaki drill inoculated with an emulsion of typhoid bacillus and then allowed to dry, the bacillus is recoverable up to and on the seventy-fourth day. 16. From a piece of khaki serge similarly treated the typhoid bacillus is recoverable up to and on the seventy-eighth day. 17. From a piece of blue serge similarly treated the typhoid bacillus is recoverable on the seventy-eighth day. 18. From a piece of khaki drill fouled by liquid typhoid feces and then allowed to dry the bacillus is recoverable on the seventeenth day. 19. From a similar fabric fouled by solid or semisolid typhoid feces and then allowed to dry the bacillus is recoverable on the ninth day. 20. The typhoid bacillus is able to survive in surface soil an exposure to 122 hours of direct sunshine, extending over a period of 21 consecutive days. From a piece of infected serge the typhoid bacillus is recoverable after the fabric has been exposed to 50 hours of direct sunshine spread over a period of 10 days. 21. Ordinary house flies (*Musca domestica*) can convey typhoid infective matter from specific excreta or other polluted material to objects on which they may walk, rest, or feed. Such infective material appears to be attached not only to their heads (mandibles, probably) but also to their legs, wings, and bodies. It has not been proved that the typhoid bacillus passes through the digestive tract of the fly. [A.O.J.K.]

**Toxin of Tapeworm.**—Massineo and Calamida<sup>1</sup> prepared filtered extracts of all the common species of tapeworm, and with these extracts inoculated hypodermically guineapigs, rabbits and dogs, in all of which symptoms of intoxication were produced. The authors believe that the pathologic changes produced in the intestines of the hosts of tapeworms are due to a secretion of toxin rather than to mechanical action. [C.S.D.]

**Concerning the Pathogenesis of Typhoid Fever.**—Schottmueller<sup>2</sup> has isolated the typhoid bacillus in 182 cases (83%) out of 220 in which he made bacteriologic blood examinations. He has found them relatively oftener in adults than in children, but sex did not seem to affect the result. In a few cases he discovered them as early as the first 24 hours, and numerous positive results were noted about the fifth day. During the second and third week they were detected in every sample examined. The bacilli disappeared very quickly as soon as the temperature began to decline, and by the time the temperature was normal no case gave positive results. Relapse was always associated with a return of the bacilli and they occasionally reappeared for a short time in cases when there was no relapse but a rise in temperature. Nothing else accounted for this rise. In grave cases the number of colonies was high even at an early date, and as the case improved the colonies became fewer or vice versa. For the purposes of

<sup>1</sup> Journal Méd. Vet. et Zootech., September, 1901. Experiment Station Record, September, 1902.

<sup>2</sup> Münchener medicinische Wochenschrift, September 23, 1902.

<sup>1</sup> British Medical Journal, September 27, 1902.

diagnosis and prognosis, therefore, this method of examination is an extremely valuable one; it certainly is of much greater value than the Widal test. He considers the intestinal lesions not as primary lesions of typhoid, but rather as metastases, the typhoid bacilli being carried to the lymph follicles by way of the bloodstream. [E.L.]

**The Leukocytes in Malaria.**—Mallend<sup>1</sup> states that cases of malaria show constantly at some period an increased percentage of large mononuclear leukocytes. This is most marked at times when the patient is free from fever, though there may be actually an increase when the patient is in a rigor; but no positive conclusions can be drawn from the leukocytes either during the rise of temperature, or even shortly before its onset. It is believed that in a case suspected to be malaria the presence of 10%, or perhaps 12% or over of large mononuclear cells is strong presumptive evidence that the case is one of malaria, and that the presence of less than 8% is strong presumptive evidence that the case is not one of malaria. The consideration of the percentage of the characteristic large mononuclear cells is of more value than that of the aggregate of large lymphocytes and large mononuclears. [A.O.J.K.]

**Transmission of Tuberculosis from Human Beings to Cows.**—Fibiger and Jensen<sup>2</sup> report their observations of five fatal cases of tuberculosis, the original seat of which was the alimentary tract. The patients ranged in age from four months to 42 years. Autopsy corroborated the diagnosis in each case. Portions of caseating glands obtained after death were injected into calves and cows. All the animals thus subjected to the injection developed tuberculosis of varying degree. The authors conclude that their patients were infected with bovine tuberculosis, and lay stress upon the frequent occurrence of this disease following the ingestion of milk obtained from tuberculous cows. [W.E.R.]

**Glycosuria and Tabes.**—Meyer<sup>3</sup> reports a case of glycosuria and tabes, in which the excretion of sugar is absolutely independent of the carbohydrates in the food, as the assimilative power of the body for carbohydrates is not changed in the least. He proved this by giving the patients large amounts of grape sugar. He concludes from this that in this case of tabes the glycosuria is not the result of a primary alteration in metabolism, but that it is a symptomatic expression of a tabetic nuclear affection in the floor of the fourth ventricle. [E.L.]

**Indications for the Use of the Stomach-tube.**—Henry W. Bettman<sup>4</sup> believes that most of the gastric disorders can be overcome by a judicious regulation of the habits and diet of the patient. In more advanced or obscure cases, especially in those in which organic changes have occurred in the stomach, the stomach-tube offers a ready means of learning the exact pathologic condition. Furthermore, in conditions in which the stomach is in a constant state of irritation by secreted mucus, food remnants, fermentation products, etc., the tube is a rational and sure method of relieving the organ of its embarrassment and giving it a needed rest. [F.C.H.]

**The Histology of the Gastric Mucosa in Pathologic Conditions of the Stomach.**—Einhorn<sup>5</sup> tabulates 34 additional cases of disorder of the stomach in which he was enabled to examine pieces of the gastric mucous membrane, gives the details of the histologic findings, and his opinion of their significance. He believes that the secretory functional disturbances of the stomach are not based on a primary change in the mucous membrane of the stomach, but that they rather produce, if they last for a longer time, lesions of the mucosa of greater or less extent. The diagnosis of carcinoma of the stomach may under specially favorable conditions be made from a piece of gastric mucosa if a direct invasion of the gland substance by epithelial cells can be observed. Therapeutically attention must be directed principally toward the improvement of the general body state, and only secondarily by means of special measures against any secretory anomalies that may be present. [A.O.J.K.]

**Traumatic Nephritis.**—Curshmann, Jr.,<sup>6</sup> reports a case of

traumatic nephritis belonging to that group, where for a long time albuminuria and casts existed without the appearance, however, of other nephritic symptoms. The patient's injury was a severe one, producing numerous minor bruises and abrasions. He was nauseated and vomited; his abdomen was tender and distended; in the region of the right kidney could be felt a mass as large as a head. He suffered at first from total anuria, later, and for some time after, from oliguria and dysuria; there was no hematuria and albuminuria. Recovery was slow, and six weeks later the mass, somewhat smaller, could still be felt in the right side of the abdomen. During an examination 12 months later albumin and casts were discovered, both in small quantity, but they were found in every specimen of urine. No other renal symptoms existed, and the right kidney was not enlarged. Examination of all other organs proved negative; the blood-pressure was even below normal. All the symptoms point to a traumatic laceration of the kidney, limited to its peripheral portions as manifested by pressure of abdominal hematoma and absence of hematuria. As the picture changed to circumscribed interstitial nephritis, albuminuria and casts appeared in the urine. The absence of changes in heart, bloodvessels, and blood-pressure serve as differential points from other nontraumatic nephritis. [E.L.]

**On Spastic Constipation.**—Von Sohlern<sup>1</sup> considers the treatment of a chronic constipation as one of the most difficult and thankless chapters of internal medicine. The neurosis known as *obstipatio spastica* was first described by Cherahevski in 1883, and afterward by Fleiner, Westphalen, and Ebstein. It is undoubtedly more common than is generally suspected, and Kernig, of Petersburg, is referred to as having recognized it frequently through the years and as giving potassium bromid as a laxative. The affection is especially one of great cities and of the strenuous modern life which determines a neurotic condition in so many families. In the front rank of symptoms is the loss of ability to defecate correctly, the stoppage and the spasms which give rise to cramping pains before, during or after the passage. The feces are never normal, usually poor in water, thick, pitchy, or hard, and always of small caliber. The palpable, stiffened intestinal cord is the most essential symptom, though difficult of detection in patients with thick abdominal walls. *Obstipatio spastica* is not to be regarded as a disease *sui generis*, the condition is only a symptom, usually of a functional, at times of an organic disease of the nervous system, but it is to be recognized and treated as a disease since the patient comes to the physician not for his neurasthenia but for the spastic obstipation. Rest in bed is the most important point to be emphasized in the treatment. The patient should remain in bed for 14 days or four weeks, until defecation is painless and takes place spontaneously or with only slight help. The diet should be soft, nonirritating but very nourishing; rich milk, honey, butter, bouillon, with addition of roborant or sand-tropon, tender meats with rice, noodles, potato broth, macaroni, are suggested. The patient should be given all the water he will drink. Continuous warm applications to the abdomen during the day and a binder at night should be used. For medication von Sohlern recommends the officinal preparation of potassium bromid *mixture nervina*, a teaspoonful morning, noon and night. [C.S.D.]

**The Public Health Aspects of Summer Diarrhea.**—Newsholme,<sup>2</sup> pointing out that in 1900 summer diarrhea was responsible for 3.89% of the total deaths in England and Wales (as compared with 7.6% for the combined deaths from smallpox, measles, diphtheria, scarlet fever, pertussis, typhus, and typhoid fever) discusses the question from the public health aspect. Epidemic diarrhea is chiefly a disease of urban life, and as a fatal disease is a disease of the artisan and still more of the lower laboring classes to a preponderating extent. Towns with a high temperature and a deficient rainfall, especially in the third quarter of the year, suffer severely from diarrhea. This relationship is so close that the towns may be classified meteorologically in the order in which they ought to stand in reference to diarrhea, and their true relative position as to domestic and municipal sanitation may be ascertained when we

<sup>1</sup> British Medical Journal, September 27, 1902.

<sup>2</sup> Berliner klinische Wochenschrift, September 22, 1902.

<sup>3</sup> Münchener medicinische Wochenschrift, September 16, 1902.

<sup>4</sup> The Cincinnati Lancet-Clinic, September 27, 1902.

<sup>5</sup> American Journal of the Medical Sciences, Vol. cxiv, p. 471, 1902.

<sup>6</sup> Münchener medicinische Wochenschrift, September 23, 1902.

<sup>1</sup> Berliner klinische Wochenschrift, September 29, 1902.

<sup>2</sup> Practitioner, Vol. lxi, p. 161, 1902.

know whether they occupy a better or a worse position on the list of towns than that which their meteorologic place would indicate as rightly belonging to them. Among populations living on impervious and rocky soils diarrhea is not so prevalent, probably because polluting fecal and other organic impurities do not cling to or soak into such soils. Diarrhea is most prevalent where the systems of removal of sewage and house refuse are the least satisfactory. The exceptionally good position of certain towns in which pail-closets are largely used must be regarded as due to the favorable climatic and physiographic position of these towns, probably aided by efficient municipal scavenging; and it is almost certain that their position might be still further improved by the general adoption of a water-closet system. The fundamental condition favoring epidemic diarrhea is an unclean soil, the particular poison from which infects the air, and is swallowed, most probably with food, especially milk. Milk is not the actual cause of diarrhea; it is the vehicle of infection, just as mosquitos are a vehicle of malaria, or rats of plague. [A.O.J.K.]

**Concerning the Formation of Sugar in the Animal Organism.**—To determine if sugar elimination is increased after ingestion of fats, or which component parts of fats are the cause of this increase, Luethje<sup>1</sup> has experimented with dogs who had been made diabetic by the removal of their pancreas. Neither olive oil nor fats given subcutaneously were able to increase the amount of sugar excreted. When glycerin was given the glycosuria increased considerably; the yolks of eggs, and especially lecithin, produced the same results. Similar observations were made when these substances were fed to a diabetic patient. Therefore he thinks that substances rich in glycerin and lecithin should be withheld from the diet of a diabetic. [E.L.]

**On the Action of Alcohol on Human Metabolism.**—Arthur Clopatt<sup>2</sup> describes a research which he made upon himself in the Physiologic Laboratory of the Carolini Institute of Stockholm, in which he confined himself to a special diet of exactly ascertained value for a period of 12 days. A part of the fat was replaced by an isodynamic amount of alcohol for a second period of 12 days, which was followed by a third period of 7 days in which the alcohol was omitted with no corresponding replacement of fat. As the result of the examination of the feces and urine throughout the entire period, he arrives at the following conclusions: 1. Alcohol not only prevents waste of nitrogen free foodstuff, but also of albumin after the body has become accustomed to it. 2. Alcohol exerts no appreciable action on the absorption of foodstuffs by the intestine. [C.S.D.]

**A Case of Severe, Probably Pernicious, Anemia,** with marked general and coronary atheroma, in which many evidences of aneurysm were present without anatomic explanation for them, is reported by Edwards.<sup>3</sup> The pulsation present in the case was extensive, markedly expansible, and attended by a bruit, abdominal as well as thoracic, and still no anatomic explanation for it was found at the necropsy. [A.O.J.K.]

**Lobar Pneumonia in Young Children.**—J. A. Coult<sup>4</sup> gives statistics showing that croupous pneumonia is more frequent in the first two years of life than any other period. It is often difficult to distinguish it from the catarrhal form, which is frequently grafted on the other. In 60% of cases treated in two years, it was localized in the apex. This may aid in diagnosis. It generally runs a more typical course than when occurring at the base. Harm is done often by overfeeding. The child should have plenty of water. A temperature of 106° should always be actively treated, as also a sustained temperature above 104.5°. Pain or insomnia profoundly influence the temperature. Opium will control all three, except when these occur from exhaustion, accompanied by restlessness, dry mouth, excessive thirst, and rapid, feeble pulse, when alcohol is indicated. Small enemas at 75° F., or colder, reduce temperature more and longer than wet packs or sponging. Antipyrin may be guardedly used with alcohol, and quinin may be combined with it to prolong its action. Leeches are best for pain from pleurisy, or dry cupping may be used. The ice-bag may

cause collapse, and poultices interfere with chest movements. Insomnia may be relieved by laxatives, the ice-bag to the head or darkening the room. When alcohol and strychnin fail to relieve the heart, bleeding is indicated. Middle-ear disease should always be looked for. Simple incision is the best operation in empyema. [H.M.]

**A Case of Traumatic Pneumonia.**—Pneumonia is but rarely due to traumatism. Of 3,373 cases collected by Stern, only 44, or 1.3%, could be traced directly to trauma. Schild<sup>1</sup> reports the case of a 64-year-old man who fell on the ice, striking the right side of his chest. During the same evening he was taken with a chill, followed by fever, chest pain, dyspnea, cough, etc. He developed a typical croupous pneumonia of the upper right lobe, which diagnosis was verified at autopsy; there were no other injuries to the chest wall. [E.L.]

**Equine Malaria.**—A. Theiler<sup>2</sup> holds the pathologic organism of this disease to be distinct from that of human malaria and has, therefore, applied to it the name *Plasmodium malariae equorum*. The affection appears to be identical with that described in 1883 by Wiltshire under the name anthrax fever, and also with the disease ordinarily known as biliary fever. Theiler finds, however, that the number of parasites in the blood may be greatly diminished by the administration of quinin, as is the case in human malaria. [C.S.D.]

**Two Hairy Tumors in the Stomach.**—Ekehorn<sup>3</sup> reports two cases of hairy tumor (trichobezoar) in the stomach removed by operation, and gives an analytic survey of the cases hitherto reported. The principal characteristics of the condition are: More or less gastric disturbance, and a large, very movable tumor in the region of the stomach. Contrary to the general view, the author claims that hysteria and insanity very rarely cause these tumors. [D.R.]

**The Surgical Treatment of Cirrhosis of the Liver.**—Greenough,<sup>4</sup> from a study of the subject and a review of the literature, concludes: The condition known as biliary cirrhosis, with enlarged liver, jaundice, and fever and without ascites is accompanied in a certain proportion of cases by an infection of the bile ducts. The drainage of the bile ducts by cholecystostomy is a proper operation for the relief of this condition when evidence of infection is present and symptomatic treatment has failed to effect relief. Of 105 cases of liver cirrhosis which presented the symptoms of ascites 42% were improved and 58% not improved by Talma's operation or one of its modifications. The mortality within 30 days was 29.5%. Nine cases were improved in health two years after the operation. The nine cases of continued relief presented no marked differences from the general character of the cases. The cases in which the liver was enlarged gave a lower mortality and a higher percentage of improvement than cases of atrophic liver. Cases of suture of the omentum between the layers of the abdominal wall gave a lower mortality and a slightly higher percentage of improvement than cases in which only the peritoneal surfaces were brought in contact. Drainage increases the danger of septic infection and peritonitis and is to be avoided. If necessary tapping may be done after the operation. The presence of adhesions or perihepatitis is of good prognostic import as regards the success of the operation. The number ofappings before the operation and the presence of edema of the feet and legs are of less prognostic importance than the general condition of the patient, the size of the liver, and the functional activity of the liver cells. Talma's operation or one of its modifications is of proved benefit in a certain limited number of cases of liver cirrhosis, primarily for the relief of the ascites, and secondarily for the relief of other symptoms of portal congestion. The dangers attending the operation are mainly due to the weakened resistance of the patient rather than to the operation itself. The selection of cases suitable for operation demands more judgment than has been exercised hitherto. The operation is not indicated in cases of ascites due to causes other than cirrhosis of the liver. The operation is contraindicated in the presence of renal or cardiac disease and when good evidence does not exist

that sufficient functional liver tissue remains to maintain life. It is also contraindicated when complications exist sufficient in themselves to make the result of operation uncertain. [A.O.J.K.]

**Diphtheria and the Diphtheria Bacillus in Scarlet Fever.**—Schabad<sup>1</sup> has made extensive clinical and biologic studies regarding the relation of diphtheria and its bacillus to scarlet fever. From his experimental work and extensive clinical material he makes the following conclusions: The combination of scarlet fever with diphtheria is noticed not only during the convalescence from scarlet fever but also during the height of the disease, and even at its beginning. To make a diagnosis of this combination at the onset of the disease it is absolutely necessary for the clinical symptoms to correspond with the bacteriologic findings; that is, the clinical symptoms of diphtheria must be present as well as the diphtheria bacilli. The bacilli cultivated from the pharynx in cases in which the diphtheria arises during the convalescence from scarlet fever or during the acme of the disease possess normal virulence for guineapigs; at the beginning of the disease, although having all the other marks of true diphtheria bacilli, they are but slightly, if at all, virulent for them. This absence of virulence, however, does not exclude their etiologic activity in producing the combination pathologic process. In addition to these cases others were found in which diphtheria bacilli were present at the beginning of scarlet fever but without producing the symptoms of diphtheric sore throat. Comparing the results in these cases with those in which scarlet fever and true diphtheria were combined it must be supposed that in the former the diphtheria bacilli play the part of saprophytes and do not take any part in the pathologic process. To prevent the spread of diphtheria in the scarlet-fever wards of hospitals it is necessary to isolate all scarlet-fever patients having diphtheria bacilli in their throats. To bring this about the pharynx of every patient should be examined bacteriologically when admitted to the hospital. Diphtheria antitoxin should be used in all cases in which the diseases are combined, whether this be at the onset, during the fastigium or during the convalescence from scarlet fever. [E.L.]

**The Nature of Diabetes.**—Hess<sup>2</sup> gives a very good summary of the theories concerning diabetes, together with a description of some experiments to elucidate the pancreatic factor in the disease. There are two views regarding the connection between the pancreas and diabetes, one that the organ furnishes a glycolytic ferment that keeps the quantity of sugar at a certain level in the blood; the other, that it normally neutralizes a toxic substance that, when accumulating in the blood, causes diabetes. The author's experiments did not confirm the existence of such a neutralizing substance. One interesting feature in his experiments on dogs is that in every instance, after the extirpation of the pancreas, the animals developed an extreme fatty degeneration of the heart. [D.R.]

**Braxy.**—D. J. Hamilton<sup>3</sup> contributes a historic and descriptive account of this infectious disease, which he treats of as something distinct from anthrax, to which it is referred by many writers. [C.S.D.]

**Tuberculosis of the Parotid Gland.**—Scudder<sup>4</sup> reports a case of tuberculosis of the parotid gland occurring in a woman, aged 57, treated by excision and followed by recovery. At the time of the report, a year and a half after the operation, no recurrence was evident. [A.O.J.K.]

**Bone Metastases in Tumors of the Thyroid Gland.**—The following case is reported by Wagner.<sup>2</sup> A woman, 48 years of age, was suddenly seized with severe pain in the left hip. The only other complaint made by her was of a feeling of tension on swallowing. On examination, a number of nodules were found along the anterior margin of the sternocleidomastoid muscle, also a goiter just above the sternum and a deep-seated infiltration in the left inguinal region. The patient died in coma with the symptoms of a general intoxication. At the autopsy, a small, spindle-celled sarcoma was discovered in the thyroid gland, and a similar growth in the neck of the left femur. Thyroid tumors have a predilection for giving metas-

tases to bones, although more frequently to the flat than to the long bones. The metastases usually appear early, and are generally single. From an operative point of view they constitute a surgical "Noli me tangere." Von Eiselsberg has rightly said that in all cases of tumors of bones that are apparently sarcomas, the possibility of metastasis from the thyroid should be kept in mind. [D.R.]

**Glandular Cyst of the Pancreas.**—F. Villar<sup>1</sup> reports a case of glandular cyst of the pancreas operated upon three years ago. The patient had had two attacks of intestinal obstruction. Examination before operation showed a tumor in the epigastric region, dull on percussion, and enclosed above and below by two zones, which were sonorous on percussion. He complained of anorexia and loss in weight; his urine contained a notable quantity of sugar. After opening the abdomen, a cystic tumor was found between the stomach and transverse colon; being very adherent to the neighboring organs, it was removed by marsupialization. The patient made an uneventful recovery. [L.F.A.]

**Experimental Tuberculosis in Cows and Calves.**—Schottelius<sup>2</sup> fed human tuberculous sputum to one cow and two calves, mixing it with their food. They were killed four months later. All the glands of the body were enlarged; the submaxillary and mesenteric glands of the calves showed cheesy and calcareous degeneration. The cow presented tuberculous enteritis, cheesy pneumonia, and scattered miliary tubercles in the pleura, in addition to the glandular affections. Tubercle bacilli were isolated from all the lesions. [E.L.]

**On the Vitality of Certain Pathogenic Microbes in Ink.**—Enrico Calendoli<sup>3</sup> has supplemented the work of Beiere and Wolf on the "Occurrence of Bacteria and Molds in Writing and School Inks"<sup>4</sup> by a careful study of the relative endurance of different pathogenic bacteria to the action of ordinary inks made from iron or logwood. He finds that the vitality of the bacillus of typhoid and that of diphtheria is destroyed by ink within 15 minutes. The vitality of *Bacterium coli* and *Staphylococcus pyogenes aureus*, though no longer demonstrable in some inks after 15 minutes, remains in others unaffected for 8 hours. The *Bacillus tuberculosis* retains its vitality and virulence in most black inks for 4 days. [C.S.D.]

## GENERAL SURGERY

A. B. CRAIG                      MARTIN B. TINKER                      C. A. ORR

### REVIEW OF LITERATURE

**The Treatment of Rodent Ulcer.**—McFeely<sup>5</sup> says in substance when pathologists tell us what rodent ulcer is our treatment may be more systematic and uniform. As yet we do not know whether rodent ulcer is really malignant in the ordinary sense. If so it differs from all other forms of malignant disease in many respects. His treatment is as follows: In case the ulcer is not very large or easily accessible use, in the first instance, pure formalin; if a second or third application seems necessary later, formalin glycerin 30% to 50%. In case the patient objects to an anesthetic, local anesthetic, either cocain, eucaïn, or, better still, acöïn is used, giving a hypodermic of morphin 5 or 10 minutes after using the application if pain is very severe. In case the disease is of long standing and likely to involve bone or extensive destruction of tissue, he prefers to anesthetize the patient and remove by knife or curet all diseased tissues and apply as a styptic either powdered tannin or suprarenal gland extract, and then use formalin or formalin glycerin, keeping the patient fully under the anesthetic for about five minutes afterward. When the formalin is applied it should not be allowed to evaporate. If pure formalin is used in the first instance, he rarely finds a second or third application necessary, unless to some isolated patches. The blackish slough which forms should be allowed to separate spontaneously, and may be assisted by some nonirritating ointment.

<sup>4</sup> Centralbl. f. Bakter. u. Parasitenkunde, xxi, 276.

<sup>5</sup> British Medical Journal, November 8, 1902.

After, or very often before, this eschar has been separated, the granulations will sprout up and, if healthy, grow vigorously. The author reports a number of cases in which the above or similar treatment gave very satisfactory results. [A.B.C.]

**Operative Procedures for the Relief of Epilepsy.**—Doran<sup>1</sup> says at Craig Colony there were 29 cases that had been trephined before or after admission, of which 6 showed some improvement, 19 were unimproved, the results were doubtful in 2, and in 2 the symptoms were worse after the operation. None was cured. Doran states that operation may do good in some cases, may effect a cure in a very few, but in most cases the results are discouraging. [J.H.W.R.]

**Intestinal Anastomosis.**—Bishop<sup>2</sup> believes that some form of absorbable bobbin serves the best purpose for intestinal anastomosis. To this end he has devised a bone bobbin which is believed to possess certain advantages over Jessett's, Allingham's, and Robson's. The bobbin devised has the beveled conical ends peculiar only to Jessett's instrument, while in the center it has the groove peculiar to Allingham's pattern. The author has prepared three forms all on the same general principle. The first is suitable for end-to-end anastomosis of the intestine; the second is intended for ileocolostomy or gastroenterostomy; and the third for pylorotomy. Several cases are reported in which the use of the bobbin was satisfactory. [A.B.C.]

**A Point Regarding the Pathologic Anatomy of Cancer.**—Jaboulay<sup>3</sup> speaks of the refractile granules found in the cells of cancers and resistant to alkalies and acetic and sulfuric acids. These bear a resemblance to certain cells found in connection with varieties of parasitic cysts. Jaboulay believes that these granules are to the ordinary cancer what granules of melanin are to black cancers and specially colored granules are to the green cancer, or chloroma. The suggestion is made that these are forms, or containers, of the parasite of cancer. Attention is called to the fact that one species of protozoa, the hematoozon of malaria, produces an hepatic hyperplasia that is in effect an adenoma of the liver. Hence the probability that others of the species produce neoplasms. [A.G.E.]

**Radical Cure of Cancer of the Stomach.**—Mayo<sup>4</sup> reports his results in this line of work. He quotes Murphy, who collected 189 cases of radical operation; 26 of the patients died, and 17 survived three years. If the diagnoses were made earlier in these cases, the results of the operative measures would be more encouraging. When a small tumor at the pylorus associated with symptoms of obstruction is present, it is not unfavorable to an operation. Cancer of the pyloric region is the only form of malignant disease of the stomach which in Mayo's experience has been diagnosed sufficiently early to warrant operation. If the disease has extended to adjacent organs the operation is contraindicated, while extensive adhesions is an unfavorable complication. Lymphatic involvement is a hopeless complication. When there is secondary involvement of the viscera, an operation is contraindicated. Mayo and his brother operated on 126 cases of nonmalignant disease of the stomach with 5% mortality, and on 92 cases of malignant disease of the stomach with 10% mortality. In 7 cases they did Kocher's operation. In 20 cases they performed pylorotomy, with three deaths. One patient lived over three years, and died of secondary involvement of the liver. [J.H.W.R.]

**Value of Blood Counts in Abdominal Disease.**—Longridge<sup>2</sup> asserts that leukocytosis is a sign of acute inflammation, provided the resistance of the patient is capable of reaction, or provided the intensity of infection is capable of exciting reaction. Occasionally there is a case in which the toxemia is so intense that the reaction of the patient is overwhelmed. Again a thick wall of inflammatory material surrounding a collection of pus may prevent the escape of the toxins, which in some way cause the increase in the leukocytes. Leukocytosis is most marked between the ages of 30 and 40, and diminishes after 40. The author is of opinion that we cannot regard a leukocytosis as an absolute and infallible indication of the presence of pus;

but as an indication of toxemia its value is great. It is not possible at present to fix any definite relationship between the amount of the leukocytosis and the intensity of the toxemia, yet an increasing leukocytosis is, other things being equal, the most scientific means we have for gauging the increasing virulence of an appendicular infection. A decreasing leukocytosis is evidence of decreasing virulence or walling-off of the toxic products. He agrees with Da Costa in this: "The surgeon who attempts to use the blood count in appendicitis as a definite pathognomonic sign will soon run afoul of diagnostic disasters, but he who regards it as only a symptom invariably to be correlated with other equally, if not more, important clinical manifestations, cannot fail to find this method of inquiry of signal value in routine clinical surgery." [A.B.C.]

**Foreign Body Retained in the Eye for Thirty Years.**—From the eye of a man of 38 Lagrange<sup>1</sup> removed a foreign body consisting of a piece of wood  $\frac{1}{2}$  cm. (.2 inch) long and the thickness of a match. It had penetrated the eye when the patient was eight years old. At the time the eye was painful, shrivelled up, and became atrophic. Eight years ago a small abscess formed in it, another two years ago, and during the last few days the eye again became inflamed. After having been in the eye for thirty years the foreign body was removed without enucleation. Sympathetic ophthalmia was never present. [E.L.]

**Complete Excision of the Urinary Bladder.**—Mayo Robson<sup>2</sup> reports a case in which the urinary bladder of a woman became so thoroughly involved in a newgrowth as to demand its removal, all other means of treatment having failed. A vertical incision 10 cm. (4 inches) in length was made in the middle line of the abdomen extending to the pubes, and a transverse incision  $7\frac{1}{2}$  cm. (3 inches) in length above the pubes. The recti muscles were divided at their insertion into the pubes, and the bladder and peritoneum exposed. The peritoneal cavity was opened and the bladder found freely movable, forming almost a solid mass. The removal of the organ was commenced by stripping the peritoneum off the fundus and posterior aspect. This was continued until the uterus was reached, the organ being separated readily from it and the vagina. The stripping was continued on either side of the bladder, the superior and inferior vesical arteries being clamped and divided as they were reached. The ureters were exposed and divided close to their entrance to the bladder. The tumor was displaced backward and separated from the posterior aspect of the pubes. This was fairly easily effected, but there was considerable hemorrhage from a large number of small vessels. The bladder was then separated from the anterior vaginal wall mainly by blunt dissection with the fingers. The dissection was continued until the bladder was attached only by the urethra. This was seized in pressure forceps and divided. The whole bladder was then removed. The patient lost comparatively little blood, but many pressure forceps and ligations were necessary. No. 6 Jaques' catheters were now inserted into the divided ureters and secured in position by catgut stitches. A speculum was passed into the vagina by an assistant, and a small incision made in the anterior vaginal wall in front of the cervix uteri on the right side on to the speculum. A similar incision was made on the left. The rubber tubes and ureters were then passed through the openings thus made, and secured in position by two or three sutures of catgut. The peritoneum was closed by a continuous catgut suture. Normal urine passed freely from the right ureter, but that from the left was offensive, bloody, and scanty from the first. It was, therefore, clear that the left kidney had already become affected, and pain was complained of in the left renal region. In the course of the second week, although there were no abdominal symptoms nor any other sign of peritonitis, the patient's breath began to have a urinous odor, and though her temperature varied little from the normal, the pulse became rapid and feeble, and she died uremic on the thirteenth day. Had the patient recovered it was the author's intention to try to convert the vagina into a pseudobladder, and to make use of the urethra which had been left *in situ*. [A.B.C.]

<sup>2</sup>British Medical Journal, November 8, 1902.

**Circumcision and Venereal Diseases.**—Bellenger<sup>1</sup> has practised circumcision in cases of chancroid, herpes, and gonorrhoea successfully. He claims that the cases recover rapidly, and a spread of infection is rare. [J.H.W.R.]

**Radical Cure of Femoral Hernia.**—Nicol<sup>2</sup> exposes and clears the sac; opens it longitudinally and clears it of contents. He then separates it from parts surrounding its neck, including the transversalis and iliac fascia for 2.5 cm. (1 inch) around the abdominal aspect of the ring. He says next bisect the sac longitudinally from fundus to neck; make an aperture in one-half near the neck, and put the other half through the aperture and reduce the whole through the femoral ring into the abdomen, the mass blocking the aperture somewhat after the method of MacEwen in inguinal hernia. Part of the sac may be cut away if desired. The ring is closed as follows: Carry an incision (bone deep) from the femoral vein along the pubic ramus to the region of the pubic spine. This divides the pubic portion of the fascia lata, the origin of the pectineus, and the periosteum. Its length will depend on the extent to which the femoral vein has been displaced. Detach the periosteum to a limited extent and retract it. Drill the bone near its upper edge in two places, 1 to 2.5 cm. (.5 to 1 inch) apart. Pass through one of the apertures a loop of stout catgut. It is easily passed by threading it in the eye of an ordinary surgical probe. Divide the loop of ligature. Thread one end in a large curved surgical needle and pass it as a mattress suture through Poupart's ligament. Repeat this with the second end, carrying it through Poupart's ligament at a higher level, avoiding the deep epigastric artery to the outer side, and, in male patients, the spermatic cord above. By means of the probe withdraw both threads through the second drillhole in the bone. Tie the ends of each loop separately over the front of the bone, thus bringing Poupart's ligament down to the posterosuperior surface of the bone and fixing it firmly in contact with that surface constituting what is in effect an extension outward of Gimbernat's ligament, and absolutely closing the femoral ring to whatever extent may be desired. The degree of occlusion is regulated by the position of the sutures in Poupart's ligament, not by the tension with which they are tied. To make the closure doubly secure complete the operation by uniting, by interrupted catgut sutures, the detached margin of the pectineal origin and the pubic portion of the fascia lata to the "anchored" Poupart's ligament. [A.B.C.]

**Vesical Suture After Suprapubic Cystotomy.**—Hofmann<sup>3</sup> considers the primary suture of the bladder after suprapubic cystotomy the ideal procedure, and inasmuch as its results in selected cases are far more rapid and complete, always preferable to drainage where it can be employed. In many cases, however, it is absolutely impossible to close the bladder at once on account of cystitis, thickened walls, bruised edges, etc., and such cases must be either preceded by a course of systematic preparation (rest in bed, local applications, salol, vesical irrigation, etc.) or drainage must be used. Suturing the bladder to the anterior abdominal wall seems to him an advantageous procedure. Of the methods employed to suture the bladder he prefers that which closes the bladder with two rows of sutures. He uses catgut for the inner suture and silk for the outer suture. [E.L.]

**Complications of Gallstone Diseases.**—Moynihan<sup>2</sup> reports a series of cases of gallstone disease, together with a variety of complications which he has encountered. The complications placed in tabulated form are as follows: Impaction of stone in the cystic duct, followed by hydrops, empyema and cystoduodenal fistula; sloughing of the gallbladder from phlegmonous cholecystitis; perforation of the gallbladder and formation of a fistula between it and the stomach; impaction of stones in the hepatic and common ducts; impaction of stones in the common duct; impaction of stones in the ampulla of Vater; primary carcinoma of the gallbladder. The author says the above record gives some idea of the frequency and of the character of the difficulties met in operating for gallstones.

It is impossible to say beforehand what conditions may be encountered. The surgeon must be prepared to meet any complication. That some such complications as these are met with in approximately 20% to 30% of all gallstone operations is the best indication that earlier operations are desirable. As early uncomplicated operations are devoid of risk, and as, owing to improvements in the technic of the operations, a complete clearance of all the stones can be assured, the surgeon is entitled to ask that the patients be brought to him at a reasonably early period of the disease. [A.B.C.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### REVIEW OF LITERATURE

**Complications Following Celiotomy.**—Bowreman Jessett<sup>1</sup> thinks it is probable that in a large majority of cases of celiotomy subsequent adhesions are formed and pain is sure to follow; the surgeon should bear this in mind and pay especial attention to the toilet of the peritoneum. He should see that no blood clot is left in the Douglas sac, or between the intestines; and, above all, be careful to draw down the great omentum over the intestines, as less trouble will arise from adhesions to this than to the intestines. In case of ordinary ovariectomy the stump left should be carefully stitched over and buried so as to be completely covered with peritoneum; and for this work ordinary sterilized catgut should be used, not silk. These adhesions may not only cause pain but may become a serious peril to the patient, as in the various forms of intestinal obstruction resulting from adhesions. Another danger is the kinking or adhesions of the ureters and their possible inclusion in ligatures. This can be prevented by not ligating the uterine arteries until the anterior and posterior flaps of peritoneum have been reflected from the uterus, when the vessels are readily felt running up the side of the cervix and can be ligatured without including other tissues. The appendix sometimes becomes involved in these adhesions following removal of the appendages. A case of this kind is reported, in which a woman, three months after removal of the right appendage and ovary, was seized with acute pain in the right iliac region with all the symptoms of acute appendicitis. On opening the abdomen the appendix was found firmly adherent to the site of the first operation. It was removed and the patient recovered. Another cause of pain after hysterectomy may be that a remaining ovary has become adherent. To prevent these troublesome adhesions, Jessett now uses a specially prepared catgut for all suturing of peritoneum and ligating of vessels; he carefully buries all stumps of tumors and sutures carefully any torn or cut portions of the peritoneum. [W.K.]

**The Growth of the Placenta.**—Hitschman and Lindenthal<sup>2</sup> review at length and in detail the growth of the placenta from its earliest origin; and they express the view that upon the place in which the fecundation of the ovum occurs, which may be in any part of the tract between the ovary and the cervix, and upon the rapidity of the movements of the fertilized ovum, depends the point of implantation of the ovum, whether in the tube or in the higher or lower segment of the uterine cavity. There will be a normal development of the placenta when the ovum attaches itself at such a height in the uterus that the tension of the decidua vera in the unrolling of the serotina shall be approximately the same from above and from below. The implantation of the ovum lower than this in the cavity of the uterus changes the mechanic relations and there results a pathologic condition which explains the existence of partial placenta previa. The attachment of the ovary to any part of the lower one-third of the uterine cavity gives rise to some form of partial or reflex placenta, while central placenta previa occurs when the implantation occurs at the os uteri or even in the cervix. This is most likely to take place when there is a peculiarly narrow passage or the mucous membranes of the anterior and posterior uterine walls overlap each other. [W.K.]

**TREATMENT**

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPLEMAN

**REVIEW OF LITERATURE**

**Acute Urethritis.**—Situ<sup>1</sup> recommends the following for the early acute stage: Irrigation of the anterior urethra with

Potass. permanganate . . . . . 0.05 gm. (gr. j)  
Distilled water . . . . . 200 cc. (̄viiij)

followed by the introduction with a hand syringe of a 0.5% solution of protargol. This solution is retained in the urethra for from 5 to 10 minutes. These maneuvers are repeated three times a day. With this there is given by the mouth the following:

Boric acid  
Potassium bromid } of each . . . . . 4 gm. (̄j)  
Salol

Divide into 12 powders. One every hour.

As the discharge somewhat diminishes, the following is advised as a hand injection:

Carbolic acid . . . . . 0.25 gm. (gr. iv)  
Zinc sulfate . . . . . 0.75 gm. (gr. xij)  
Pulv. alum . . . . . 0.75 gm. (gr. xij)  
Water . . . . . 100 cc. (̄iiv)

S.—Used as injection three times daily.

For the declining stage, the following is used:

Zinc acetat . . . . . 0.75 gm. (gr. xij)  
Acid, tannic . . . . . 0.75 gm. (gr. xij)  
Water . . . . . 100 cc. (̄iiv)

S.—Use once at bedtime. [H.C.W.]

**Chloralose in Some Mental Affections.**—M. Bresson<sup>2</sup> draws the following conclusions from the study of this drug in mental affections: Chloralose is a good hypnotic, producing calm sleep without trace of fatigue upon awaking. It is indicated in rebellious insomnia, with or without agitation, especially in hysteria, and perhaps in general paralysis. In the vertiginous form of epilepsy, chloralose produces a temporary diminution in the convulsive seizures. The principal counter-indications are diseases of the respiratory apparatus, especially advanced pulmonary tuberculosis, and mental diseases with intense hallucinations. The dose of chloralose varies from .2 to .8 gram (3 to 12 grains). The effects of the latter dose should always be watched carefully. [L.F.A.]

**Apomorphin in Puerperal Convulsions.**—Kitchens<sup>3</sup> has employed apomorphin with very good effect in postpartum convulsions in doses of .003 gram (<sup>3</sup>/<sub>20</sub> gr.) hypodermically, and believes from its beneficial action in this condition that it would also be useful in eclampsia. [H.C.W.]

**Sodium Cacodylate in the Treatment of Mental Diseases.**—E. Pualet<sup>4</sup> has obtained good results with sodium cacodylate in acute melancholia and in other mental diseases. It should be continued for a considerable time. It is usually given hypodermically, as follows:

Sodium cacodylate . . . . . 6.4 grams (99 grains)  
Carbolic acid, 10% . . . . . 10 drops  
Distilled water . . . . . 97 cc. (̄3̄ ounces)

This should be brought to the boiling point for a moment, then placed in a sterilized flask. One cc. (15 minims) of this solution corresponds to the average dose for an adult in 24 hours. By this treatment the mental condition of the patient improves markedly, while at the same time the physical condition is benefited. [L.F.A.]

**Examinations Concerning Sublamin as Disinfecting Agent.**—Upon the strength of a large series of tests to determine the disinfecting properties of sublamin, Blumberg<sup>5</sup> concludes that it is as good as the best of the known disinfecting agents—corrosive sublimate; that it is preferable to this, as it does not act as an irritant to the skin even in highest concentration. On account of this absence of irritating properties it is possible in cases where our hands have come in contact with highly virulent infectious material to produce by increasing

the concentration of the solution a still greater disinfecting power than with corrosive sublimate. It is a disinfectant at much greater depth of the skin than is corrosive sublimate. It dissolves in high concentration as soon as it touches water; corrosive sublimate tablets require a longer time to do so. He describes Kroenig's method of disinfecting hands and sterilizing sutures. [E.L.]

**The Solubility of Quinin Salts.**—As information of possible interest to some of our readers we print the following table from *Merck's Archives*, August, 1902:

Name of salt.	Percentage of the alkaloid in the salt.	Solubility in cold water.
Sulfate.....	73.5	In 800 parts.
Hydrochlorate.....	81.8	" 40 "
Dihydrochlorate.....	72.0	" 1 "
Hydrobromate.....	76.6	" 45 "
Dihydrobromate.....	60.0	" 7 "
Bisulfate.....	59.1	" 11 "
Phosphate.....	72.8	" 78 "
Valerianate.....	75.7	" 110 "
Lactate.....	78.2	" 10 "
Salicylate.....	70.1	" 225 "
Hydrochlorosulfate.....	74.3	" 2 "
Arsenate.....	69.4	slightly soluble.

The salts most suitable for hypodermic injection are the hydrochlorate, the dihydromate, and the disulfate. [H.C.W.] [I find the double hydrochlorate of quinin and urea superior to all others. s.s.c.]

**Lumbar Puncture in the Treatment of Cerebrospinal Meningitis.**—J. Babinski<sup>1</sup> reports the case of a young girl aged 12, who was attacked 13 months previously with deafness which became complete in two days and which was accompanied by the characteristic symptoms of meningitis: stiffness of the neck, fever and very severe pains in the head. These symptoms persisted three months without being modified to any great extent. Lumbar puncture performed at the end of this time resulted in the expulsion of cerebrospinal fluid under strong pressure, cloudy in appearance and containing a great number of polynuclear leucocytes. This operation caused a marked improvement in the condition of the patient. Fifteen days later another lumbar puncture was made which showed a liquid having the same characteristics. The improvement following this second operation was even more marked than the first. In the course of one month, three other punctures were made, each followed by very marked improvement. After the last of these the patient appeared entirely cured, excepting that the deafness persisted. When the patient was seen six months later, there had been no return of the symptoms. [L.F.A.]

**Principles of Antisyphilitic Treatment.**—Duering<sup>2</sup> does not place much value on the statistics of Fournier and Neisser relative to the value of the long-continued, intermittent use of mercury in preventing syphilitics from reaching the tertiary stage. His own experience has shown him that many cases never reach the third stage although but little treatment is given, while others, especially individuals with debilitated constitutions and faulty methods of living, in spite of constant treatment are always suffering with relapses and pass through all the stages. The greatest number of tertiary patients are to be found among those combining low resistance, bad hygiene, and no treatment. He is convinced, therefore, that many cases can be prevented from reaching the third stage with much smaller doses than the chronic intermittent method of treatment requires. Not only, however, that he does not think that mercury will prevent a patient in all cases from reaching the tertiary stage, he actually believes that it is likely to induce it by weakening the organism to such an extent that it cannot resist the syphilitic poison. In some cases mercury protects against the third stage, but in spite of it anemia, neurasthenia, alcohol, irregular mode of life, mental worry and excitement are of the greatest importance in producing tertiary lesions. This refers especially to the so-called parasyphilitic diseases, which in his opinion are not due to the syphilitic poison but are engrafted onto nervous and neurasthenic individuals,

<sup>2</sup> Münchener medicinische Wochenschrift, September 16, 1902.

whose organism is further weakened by the abuse of mercury. His own method of treating syphilis is as follows: Sometimes he begins treatment with the first symptom, but usually he waits until he is absolutely certain about the diagnosis. He injects salicylate of mercury twice weekly, using  $1\frac{1}{2}$  to  $1\frac{1}{2}$  gr. (0.08 to 0.1 gram). He continues this until the patient has been without symptoms for 12 weeks. Two months later he prescribes potassium iodid in doses of 8 to 15 gr. daily (0.5 to 1 gram), and continues this for two months. He returns to treatment three months later, using half this dose; at intervals during the next three years he uses potassium iodid in gradually diminishing doses. He lays much stress on the use of Turkish baths during the active treatment, and attempts to regulate the life of the patient. [E.L.]

**The Treatment of Pulmonary and Laryngeal Tuberculosis with Hetol.**—Krause<sup>1</sup> reports 21 cases of tuberculosis of the lungs and larynx which were successfully treated with hetol. All of his patients were improved and many cured. This drug was administered by intravenous injections. During the first week subjective and objective symptoms of improvement were seen. In the early stages of tuberculosis all the pathologic symptoms disappeared with the exception of slight changes in the respiratory murmur. In the more advanced cases the tubercle bacilli, the expectoration, and the hemoptysis were cured. Krause believes the use of hetol with the proper hygienic, dietetic, and climatic treatment will cure many of the so-called incurable cases of tuberculosis. [W.E.R.]

**Treatment of Acne.**—L. Brocq<sup>2</sup> recommends that (1) the patient should abstain from taking coffee, tea, all alcoholic beverages, pork, fish, crustacean foods, venison, truffle, pastry, cheese, spiced food, tomatoes and uncooked food. He should not eat much butter or fatty food. (2) At the beginning of each meal he should take one of the following cachets:

Sodium bicarbonate . . . . .	0.3 gram ( $\frac{1}{2}$ grains)
Calcined magnesia . . . . .	0.2 gram (3 grains)
Powdered cascara sagrada . . . . .	0.13 gram (2 grains)
Benzonaphtol . . . . .	0.13 gram (2 grains)
For one cachet.	

(3) The diseased area must be cleaned with tampons of absorbent cotton dipped in very hot water which has been boiled with 10 grams ( $2\frac{1}{2}$  drams) of bran and one dessertspoonful of sodium baborate to the quart. (4) In the evening it may be washed with naphthol soap, then sponged with camphor water. (5) Before retiring, the eruption should be covered with a small quantity of the following ointment in which the amount of vaselin may be increased or diminished according to the effect produced:

Camphorated betanaphtol . . . . .	0.3 gram ( $\frac{1}{2}$ grains)
Resorcin . . . . .	0.2 gram (3 grains)
Black soap . . . . .	0.2 gram (3 grains)
Prepared chalk . . . . .	0.5 gram ( $7\frac{1}{2}$ grains)
Precipitated sulfur . . . . .	1.4 grams (22 grains)
Pure vaselin . . . . .	0.2 gram (3 grains)

(6) In the morning, after the toilet, the following should be applied to the parts:

Sodium borate . . . . .	10 grams (2 $\frac{1}{2}$ drams)
Camphorated sulfuric ether . . . . .	37.5 cc. (10 drams)
Rose water . . . . .	90 cc. (3 $\frac{1}{2}$ ounces)
Distilled water . . . . .	148 cc. (5 ounces)

[L.F.A.]

**Bilateral Ophthalmoplegia Interna as the Result of Extract of Ergot.**—Schneider<sup>3</sup> reports the case of a man who after taking 16 powders of extract of ergot each containing three grains complained of dizziness, general faintness, tremor, and bilateral internal ophthalmoplegia. All objects seen at a distance looked red and distorted. He was unable to read at all in the morning, but by 4 every afternoon all eye symptoms would disappear. The symptoms came on gradually, and after the discontinuance of the drug disappeared within a few days. [E.L.]

**The Internal Use of Carbolic Acid.**—Dessau<sup>4</sup> has obtained excellent results from carbolic acid in various catarrhal complaints of children. He has found it useful in the symptom-

complex of dry cough, frequently paroxysmal, and expectoration of a tenacious and viscid character, the lungs showing a few rales of a sticky quality and frequently harsh respiratory sounds in the interseapular spaces like the broncho-vesicular murmur of Flint. In this group of cases he has found carbolic acid to act more promptly and efficaciously than any other drug. He gives it to infants of one year in doses of one teaspoonful of a 1% solution. [H.C.W.]

**Thymol Urethane, a New Anthelmintic.**—Thymol urethane or thymolcarbonic ether occurs as a white crystalline substance having a slight taste, slightly soluble in water.<sup>1</sup> This drug is decomposed by the alkaline juices of the intestine, thymol being liberated and acting as an anthelmintic. Thymol carbonate is decomposed much less completely. Thymol urethane gives good results in the treatment of intestinal worms and ankylostoma. [L.F.A.]

**Tincture of Iodin Instead of Potassium Iodid in Syphilis.**—Richter<sup>2</sup> treated a number of syphilitic patients with the tincture of iodine instead of potassium iodid. The drug was given in 10 to 30 drop doses three times a day. Tincture of iodine is preferable to potassium iodid because of the smaller amount of iodine required and the longer duration of its effects. Richter proved that in 100 grams of the tincture of iodine there were 10 grams of iodine, while a like amount of potassium iodid represented 76.5 grams of iodine. Another advantage of the tincture is its cheapness. [W.E.R.]

**Chloretone as a Preventive of Postoperative Vomiting.**—Bickle<sup>3</sup> has used chloretone in some 40 cases of various surgical operations to prevent the nausea and vomiting that so frequently occur after the administration of an anesthetic. Of these 40 only three vomited and but one of these at all severely. He gives 1 gram (15 grains) two hours before the operation. [H.C.W.]

**Ethyl Iodid in the Treatment of Whoopingcough.**—Amat<sup>4</sup> reports two cases of whoopingcough in young children of the same family in which the paroxysms of coughing were frequent and very weakening. The usual remedies were given without beneficial result. Inhalations of ethyl iodid were employed at the beginning of each paroxysm, and resulted in a gradual diminution in the frequency and severity of the attacks; the bronchial secretions were rendered more fluid and were more easily expelled. Eight days later the paroxysms had almost ceased. [L.F.A.]

**The Intestinal Action of Atropin.**—Aronheim<sup>5</sup> considers atropin an excellent intestinal narcotic and anesthetic; he has found it especially useful in appendicitis, giving it hypodermically in daily doses of  $\frac{1}{75}$  to  $\frac{1}{25}$  gr. All the symptoms were very quickly relieved by it, and recovery was usually complete about the fifth to sixth day. [E.L.]

**Santonin in Neuralgia.**—Negro<sup>6</sup> used santonin in 16 cases of neuralgia with good results. Santonin has a special affinity for nerve substance. Its greatest use is to quiet the lancinating pains of neuralgia. The daily dose should be 1 gram (15 grains). [W.E.R.]

**Thyroid Extract in Painful Dysmenorrhea.**—Stinson finds thyroid extract very efficacious in the treatment of painful dysmenorrhea. He employs it in doses of .1 gram (1 grain) three times a day for two days before menstruation begins, and in double this quantity during the menstrual period. [L.F.A.]

**Lime Salts in the Treatment of Diabetes.**—Boigey<sup>7</sup> reports good results in three cases of diabetes treated by large doses of lime salts. One was a man of 64, who during coma was bled and given hypodermoclysis of sodium bicarbonate solution. The sugar remained above 40 gm. to the liter of urine. Two injections of 25 cc. of glycerophosphate of lime were then given, the drug being continued by the mouth in 2 gm. doses. The patient steadily improved, and the urine now contains but 1 gm. of sugar to the liter. Vision has improved, edema disappeared, and muscular strength is being regained.

<sup>1</sup> Berliner klinische Wochenschrift, October 20, 1902.

<sup>2</sup> Bulletin Général de Thérapeutique, Vol. cxlix, No. 13, 1902, p. 508.

<sup>3</sup> Münchener medicinische Wochenschrift, September 30, 1902.

<sup>4</sup> Pediatrics, 1902, 14, 212.

Excellent results were also obtained in two other less grave cases, the dose used varying from .5 to 1 gm. The results are explained by the theory that diabetes is an intoxication by organic acids. The appearance of large quantities of phosphate of lime in the urine of the first patient, and of a phosphatic concretion in the pus of an abscess formed at the point of one injection led to the conclusion that the larger part of the drug put in circulation in the economy is neither absorbed nor transformed. [A.G.E.]

**The Bloodless Treatment of Furuncles and Abscesses.**—Kaufman<sup>1</sup> treats furuncles and abscesses by applying 5% of stypticin in a lanolin ointment. These conditions heal very rapidly after this treatment. If the furuncle or abscess should be large in size, the necrotic center must be pressed out. [W.E.R.]

**Treatment of Hemorrhoids.**—Raynaud<sup>2</sup> believes that local application of cold for the relief of the pain of external hemorrhoids is too fleeting in its action, and that soon after its application the pain becomes worse because of the reaction and secondary congestion of the part. He prefers the application of dry heat as intense as can be borne. By this means immediate relief is obtained which lasts a long time. The applications may be made as often as desired. [L.F.A.]

**Concerning the Action of Atropin.**—Gebele<sup>3</sup> does not agree with Ostermaier, who advises the use of atropin in doses of  $\frac{1}{15}$  to  $\frac{1}{20}$  gr., hypodermically, in cases of strangulated hernia, believing that it excites peristalsis and narrows the caliber of the mesenteric bloodvessels. He quotes numerous authors, who state that atropin in small doses acts as an excitant to the intestinal muscle, but in large doses it paralyzes the nerve ganglion cells in the walls of the intestine upon which depends the motility of the intestine. He speaks of a number of cases in his own and other physicians' practice, showing that in such cases (strangulated hernia and other mechanical obstructions) atropin does harm by obtunding the symptoms and preventing operation until it is too late to save the patient. He concludes his article with the statement that atropin should never be used in cases of mechanical obstruction, and especially not in incarcerated hernias, where herniotomy is the only sure agent in bringing about the patient's recovery, hot baths and morphin injections having proved themselves without effect. Atropin should be used in all cases of fecal impaction, reflex intestinal spasms, intestinal atony, and paralytic obstruction; in the former in large quantities, in the latter in very small doses ( $\frac{1}{15}$  to  $\frac{1}{20}$  gr.). [E.L.]

**The Use of Ipecacuanha as an Emetic.**—Kobert<sup>4</sup> instituted a number of experiments on the internal use of ipecacuanha. He concludes that this drug is a great depressant of the heart, and therefore should not be given internally. To obtain vomiting the fluid extract or tincture of ipecacuanha should be used as a gargle. [W.E.R.]

**Caffein in Infantile Therapeutics.**—Rousseau Saint-Philippe<sup>5</sup> employs caffein in children only in certain well defined conditions which are grouped in the following classes: (1) Those in which the heart is feeble, temperature low, the pulse small and feeble, the urine scanty, and the child somnolent and weak; (2) in collapse and sudden danger in the course of infectious diseases. Caffein is used rarely in the acute febrile affections of children, as it may cause increased restlessness and elevation of the already high temperature. When caffein is indicated in cardiac feebleness and in collapse it should be given in small doses, not more than from .1 to .3 gram ( $\frac{1}{2}$  to 5 grains) in 24 hours. [L.F.A.]

**The Treatment of Neurasthenia.**—DeBlois<sup>6</sup> divides the treatment into: (1) Hygienic and moral; (2) therapeutics of the depression and nervous erethism; (3) injections of artificial serum. Under (2), hydrotherapy is the most efficacious, and the cold douche, lasting 5 or 10 seconds, the best form of application. This should be given on alternate days with other less heroic applications between. Static electricity also merits a

trial in conjunction with the hydrotherapy. Artificial serum may be given subcutaneously, two or three times a week, in doses of 5 to 20 grams. [A.G.E.]

**Chlorcalcium in the Treatment of Hemophilia.**—Wallis<sup>1</sup> reports a case of hemophilia in which the patient bled excessively after the extraction of a tooth. He administered chlorcalcium for eight days before extracting the other teeth. He found there was very little bleeding after this treatment. [W.E.R.]

**Agurin.**—Th. Solacolu<sup>2</sup> discusses in Thèse de la Faculté de Paris, 1901-1902, No. 579, the new drug *agurin*, a derivative of theobromin. In small doses the drug exhibits a diuretic action. It is soluble in water, and causes no disturbance of the gastrointestinal tract. [C.S.D.]

**FORMULAS, ORIGINAL AND SELECTED.**

**For Pruritus Ani.**—

Ac. carbolic	2 gm. (gr. xxx)
Calomel	4 gm. (5j)
Tar	6 gm. (5iss)
Menthol	1.2 gm. (gr. xx)
Zinc oxid	8 gm. (5ij)
Simple cerate	60 gm. (5ij)

Wash the parts with hot water and spread the ointment on a cloth. Apply and fasten with a T-bandage.—*Medical Record*. [H.C.W.]

**For Relief of "Neuralgic" and "Rheumatic" Pains.**—

Guaiacol, c. p.	2.5 cc. (40 mm.)
Menthol	2 gms. (30 grs.)
Oil of birch or synthetic methyl salicylate	7.5 cc. (2 drs.)
Woolfat	} each 15 gms. ( ½ oz.)
Cerate	

Mix. Dispense in a tin tube; a small quantity to be rubbed in over the seat of pain. [S.S.C.]

**OPHTHALMOLOGY**

WALTER L. PYLE

**EDITORIAL COMMENT**

**Lowered Blood-pressure in the Causation of Glaucoma.**—In a recent paper read before the French Ophthalmologic Society, Zimmerman<sup>3</sup> advanced the theory that decrease in blood-pressure, from mental or physical shock, cardiac disease, etc., is a prominent factor in the etiology of glaucoma, and in his explanation he utilizes both the theory of defective excretion and that of excessive secretion. When vascular pressure is lowered, even though intraocular tension is normal, the blood enters the eye only with difficulty, and pulsation of the intraocular arteries is noticed. Diminished intraocular supply causes denutritional changes and edema, with actual increase of intraocular tension. The sclera becomes distended, the intraocular veins are compressed, general edema of the inner tunics results, and the gross changes typical of glaucoma occur. Zimmerman believes that in certain cases in which intraocular tension does not rise above normal, glaucoma may develop from a relatively low vascular pressure, the result of profound and persistent cardiac disturbance. He also says that prodromal glaucomatous attacks do not necessarily indicate ocular disease. The eye may at first be healthy, but the blood-pressure greatly lowered. True glaucoma does not develop until repeated prodromal phenomena have produced such anatomic changes as cupping of the disc and closure of the filtration angle.

The practical application of these observations is that in simple glaucoma the treatment should include, primarily, measures to increase and maintain the proper blood-pressure. In 40 cases of subacute glaucoma so treated, Zimmerman had need to resort to iridectomy but once. As to the drugs employed, digitalis was found unsuitable on account of certain mydriatic effects. Strophanthus acting upon the heart-muscle rather than

upon the bloodvessels was very satisfactory, administered in doses of eight minims four times daily. Adonis vernalis was found equally effective.

This treatment, of course, is not indicated in secondary glaucoma following disease, injury, or operation, as here intraocular pressure is the primal cause, and the arterial pressure may not be disturbed.

**Primary Sarcoma of the Iris.**—Wood and Pusey<sup>1</sup> have made a very extensive study of this subject, and have reviewed practically all the available cases in literature. Their most important conclusion is that when a diagnosis of iris sarcoma is established the globe containing the growth should be immediately enucleated. The widely quoted advice of Fuchs, that iridectomy including the diseased tissue may be sufficient in cases in which the sarcoma is limited to the iris, they believe to be harmful teaching. They doubt that we can clinically determine with certainty that a particular growth is limited to the iris. In the histologic examination of 41 cases the enucleated globe showed involvement of other parts than the iris, and in reviewing the subsequent history of many cases treated by iridectomy, there is strong evidence of the continued growth of the tumor. Sarcoma in this location is exceedingly slow in growth, and no case should be reported as cured until more than three years has elapsed after operation.

#### REVIEW OF LITERATURE

**Metastatic Carcinoma of the Optic Nerve Without Ophthalmoscopic Evidence.**—Holden<sup>2</sup> describes an interesting case of a negress of 41, in which carcinomatous infection of the pylorus, lungs, and liver was associated with total destruction of a considerable longitudinal area of the left optic nerve posteriorly. There was total blindness for four months without paleness of the disc, and only the slightest microscopic changes in the nerve near the ball. There was a considerable defect in the infero-nasal portion of the field of the right eye, which was explained by a limited sclerosis of the right nerve, likely the result of affection of the vessels in the pial sheath.

**Cataract from Naphthalin Poisoning.**—Lecenius<sup>3</sup> reports a case in a druggist of 36, who after taking consecutive large doses of naphthalin and castor oil for enteritis, was seized with great vesical pain within 24 hours and noticed rapid failure of vision. There was diffuse opacity of the perinuclear region of the crystalline lens with a number of small white spots. The patient had always enjoyed good vision, but was now only able to count fingers at 1.5 meters. Ophthalmoscopic examination was unsatisfactory. The visual fields were much contracted, although there was retained normal color perception at the last observation. General health was recovered, and the urine contained neither albumin nor sugar, but the cataract remained.

**Shot in the Anterior Chamber for Eight Years.**—Bürstenbinder<sup>4</sup> has published an observation of a penetrating wound of the eyeball by a grain of lead, which had remained in the anterior chamber eight years without causing any inflammation. There was a prolapse of the iris adherent in the corneal cleatrix, a circumscribed opacity of the lens, and a rupture of the choroid and retina from contrecoup. Vision =  $\frac{1}{3}$ , with a defect in the superior field. Beside the lead in the anterior chamber, the skigram showed several grains in the orbit, which had wounded the right externus and levator of the eyelid, explaining the slight ptosis and convergent strabismus.

**Foreign Bodies in the Eye.**—Sweet<sup>5</sup> offers the following conclusions relative to the use of electromagnets in the extraction of foreign bodies in the eye: (1) The size of the splinter of iron or steel, and its approximate position in the eyeball, should be known before an attempt is made to extract it by either the medium-sized or the giant magnet; (2) the x-rays are the most certain method of diagnosis in injuries from all kinds

of foreign bodies; (3) the large and medium-sized magnets are of value in determining the presence of iron or steel, but negative findings can not be accepted as conclusive evidence of the absence of the metal in the eyeball; (4) the Haab magnet is superior to all forms of smaller magnets in extracting iron or steel from the vitreous chamber by way of the anterior chamber, but the great power of the instrument requires that it shall be used with caution; (5) when the body is to be extracted through an opening in the sclera close to the previously determined position of the metal the medium-sized magnets are shown by experiments to be as effective as the giant magnet; (6) the entrance of the magnet point into the vitreous is harmful, and should never be attempted except when other means of extraction have failed.

**Myopia of Nine Diopters from Ciliary Spasm.**—Fromaget<sup>1</sup> reports the case of a young man who was rejected from military service on account of high myopia. He was wearing concave lenses of six diopters, with which he could not read at a distance of 25 centimeters. Without lenses he read with difficulty at 10 centimeters. For distance vision he preferred concave lenses of nine diopters. Visual acuity was about 1/3. There were none of the common myopic fundus changes, but the papilla was greatly congested. Tonic spasm of the ciliary muscle was suspected. By skiascopy no more than 2.50 diopters of myopia could be made out. Under atropin cycloplegia he was found to have a small amount of compound hyperopic astigmatism.

**Iodin-vasogen in Corneal Infiltration.**—Duane<sup>2</sup> uses this solution of iodine in vasogen. It forms a nonirritant, syrupy, brownish liquid, containing either 5% or 10% of iodine. He believes that in all the cases of corneal ulceration treated by applications of iodine-vasogen the favorable outcome was hastened at least, if not actually determined, by the remedy. In several cases it succeeded in subduing extensive destruction of the cornea after other means had failed. His conclusions are: 1. Iodin-vasogen is a valuable application in infiltrated and spreading ulcers of the cornea, whether associated with purulent conjunctival secretion or not. It is particularly indicated in those cases in which the galvanocautery is contraindicated by the situation of the infiltrate. 2. It rarely causes pain, if not applied in excess, and never causes any unpleasant reaction or untoward effects. 3. Preliminary anesthetization of the cornea with cocaine is rarely required and in general is better omitted. 4. The application is best made every other day until the infiltrate begins to shrink decidedly, and then should be made every three or four days until the infiltrate disappears.

**Cuprocitrol and Itröl in Trachoma.**—Von Arlt<sup>3</sup> employs cuprocitrol by means of a glass rod over granulations in the conjunctival sac, followed by gentle but thorough massage. In advanced cases he uses a 10% ointment three times a day, decreasing the strength as the case improves or if the applications cause pain. In a few cases cuprocitrol is not tolerated, and in these von Arlt uses a dusting powder of itröl. He speaks favorably of this substance, but warns against its susceptibility to deterioration from exposure to light and to the products of combustion of illuminating gas.

**Eserin in Corneal Affections.**—Katz<sup>4</sup> recommends the employment of eserine in cases of peripheral ulceration of the cornea, scrofulous keratitis, etc. He uses a pomade composed of eserine sulfate, 0.03; iodoform, 0.12, and vaselin, 6.0.

**Ichthyol in Corneal Affections.**—Fedorow<sup>5</sup> used an ointment of ichthyol, 0.1; cocaine hydrochlorate, 0.15, and vaselin, 5.0, in 28 cases of corneal infiltration, and is of the opinion that resorption was hastened, and reestablishment of corneal transparency favored by the applications.

**The Pathology of Optic Atrophy.**—Harman<sup>5</sup> hesitates to accept the current views of the pathology of optic atrophy in retrobulbar neuritis. He believes them to be based upon an inaccurate appreciation of the ascertained facts of the development of the nervous connections of the eye, and of the

<sup>5</sup> British Medical Journal, November 1, 1902.

theory of the neuron. The retina is known to arise as an outgrowth from the brain. Within this outgrowth nerve cells give rise to axons which grow centrally to make connections with parts of the brain different from the site of origin of the evagination. Thus the trophic centers of the optic nerve fibers are the ganglion cells of the retina from which they are outgrowths. The case is parallel with the relation of a posterior root ganglion cell to its central axon passing into the cord. Thus degeneration of the optic fibers should be in the vast majority of cases ascending only, and we should look in cases of optic atrophy first to the retina for evidence of damage. He believes a rational classification could be arrived at as follows: 1. Primary damage in disease of the ganglion cells (*a*) from anemia due to spasm of retinal vessels from drugs as quinin, reflexly from cold, and to general anemia succeeding severe hemorrhages, febrile diseases, etc.; (*b*) from poisoning of the ganglion cells by drugs—tobacco, lead—a view directly supported in the antidote of tobacco blindness, strychnin, which was agreed to act directly upon nerve cells. In all these cases the changes at the disc are proportionate to the number of cells damaged; in cases of great loss of ganglion cells, it is probable the rapid destruction and swelling of the myelin sheaths of the degenerating fibers at the lamina cribrosa produces a mechanical choked disc. 2. Cases of damage to the optic nerve by contiguity of diseased structures or in general nerve changes producing islands of fibroid exaggeration, and followed by obvious atrophy of the disc. Here ascending degeneration should be the earlier result, with a later degeneration of the axon segment next the trophic ganglion cell from disuse, a process the more easy owing to the special myelin sheathing of the optic nerve fibers. In reply to the question as to how he could explain by ascending degeneration undoubted optic atrophy following section of the nerve in fracture at the optic foramen, Harman says in these cases there is nothing to show the damage was limited to the actual point of injury, exudation was just as certainly to be found within and around the optic sheath even to the disc, which would explain the early onset of atrophy in some cases; further, he allows the possibility of a degeneration of the segment between injury and trophic cell, both from disuse and by reason of the arrangement of the myelin sheaths of the optic fibers.

**Detachment of Corneal Epithelium.**—Menzies<sup>1</sup> describes two main types of the condition, with and without distinct blister formation; keratitis bullosa of traumatic origin is also included. In the majority of these cases a history of injury is obtainable; the detached epithelium does not become firmly reattached and is disturbed by movements of the lids causing great pain. If the case extends an ulcer may result. The diagnosis depends upon the history and careful inspection of the cornea under proper illumination. In some cases fluorescein may be useful. The treatment consists in tying up an injured eye until corneal healing is complete. In mild case massage with an ointment or oily substance is generally sufficient. When there is a distinct blister, the detached epithelium should be removed, the denuded surface scraped, an ointment applied, and the eye bandaged.

**Chestnut-bur Thorns in the Cornea.**—Meding<sup>2</sup> describes a most instructive case in a girl of 7, who was struck in the left eye by a falling bur. Eight thorns were seen transfixing the cornea, their points projecting into the anterior chamber, almost impinging upon the iris and lens. The bases of the thorns except one were broken off even with the surface of the cornea. It was found very difficult to seize the thorns with any instrument and slight pressure on the cornea brought the thorn-points in contact with the iris and lens. Atropin was instilled and expectant treatment was advised. Knapp in consultation advised no surgical interference unless especially indicated. One month later three central thorns were removed with a fine forceps. In another month two more thorns were removed, all the removals being possible on account of ulceration about the bases of the thorns. Within a few weeks the remaining thorns had disappeared, the last absorbed being the one which was first attacked. The only sequelæ to the injury

were two very faint scar-points, and one somewhat larger and denser opacity. The lessons drawn from this interesting case are: 1. The thorns were aseptic. 2. The curious tolerance of the cornea and absorptive powers of the aqueous, not generally believed to include vegetable matter. 3. The wisdom of retaining the thorns as plugs for the wounds they made, thus preventing infection. 4. The largest and most opaque scar was left at the site of the preliminary efforts at removal.

**Filamentous Conjunctivitis.**—An unusual case is reported by Coppez.<sup>3</sup> The patient was a child of 8, treated in 1900 for adenoids and follicular conjunctivitis. In 1902 the patient returned complaining of the appearance in the eyes of threads which obscured vision whenever he applied himself to work. Rubbing the eyes would enable him to extract thin filaments 3 cm. or 4 cm. in length. Examination showed the eyes to be practically normal except slight injection of the conjunctiva. The filaments could be seen, if the eyes were watched sufficiently long, to descend from the superior culdesac, traverse obliquely the cornea downward and inward to the internal angle of the eye, when they could be extracted. Microscopic examination of the filaments showed them to have no special structure, being composed of mucus containing leukocytes and desquamated epithelial cells. These filaments interfered so much with sight that the boy had to be removed from school. Treatment with acetic acid, zinc sulfate, yellow precipitate, etc., has been unavailing, as any irritant immediately causes an increased production of filaments. [A.G.E.]

**Concerning Cocain.**—Fuchs<sup>4</sup> does not approve of the routine use of cocain for every ocular pain. He himself never prescribes it in such cases. He says the pain of conjunctivitis is not sufficiently severe; in diseases of the deeper structures as Iridoeyclitis, glaucoma, it is of no benefit, as its action is only superficial, and in diseases of the cornea, in which it might be of benefit, it is not useful because of its evanescent action; its continued use is associated with clouding of the epithelium, abrasion and even ulceration; it has in some few cases been the active cause of glaucoma. He advises cocain in all operations on the eye, even in such a small one as removal of a foreign body. In strongly injected eyes, its anesthetic power being very low in such cases, he assists it with subconjunctival injections of cocain at the point of incision, with the use of adrenalin hydrochlorid, 1:1,000, or with hypodermic injections of morphin. He does not approve of Schleich's infiltration method. Cocain is useful in all cases of photophobia, especially when met with in children. He associates cocain with atropin for purposes of dilating the pupil. [E.L.]

**Congenital Nystagmus in Father and Child.**—Fisher<sup>5</sup> reports an instance of lateral nystagmus unassociated with disease of the choroid, lens, or retina occurring in a child aged 5 months. The condition probably existed from birth, as it was noticed a few hours after birth. The father, aged 21, was similarly affected, and had been so, it was reported, from his birth. His vision was good, and there was no disorder of the choroid or retina. There was no history of any nervous disorders in the family, but a child of a cousin was reported to be similarly affected. [A.O.J.K.]

**A Tubular Visual Field in Hysteria.**—Greef<sup>6</sup> reports a case of hysteria in a young girl who presented a tubular visual field. Various parts of her body showed the typical painful spots seen in hysteria; the whole body, and especially the left half, presented hyperesthesia. Her sense of smell, hearing and taste were somewhat impaired. Her vision was  $\frac{3}{4}$  yard, her visual field was concentrically limited. It was just as great at 5 meters as at  $\frac{1}{2}$  meter, and hence tubular. A venous and an arterial pulse were found on ophthalmoscopic examination. A venous pulse may be physiologic but an arterial pulse is pathologic; yet in this case no organic lesion was found. Greef was unable to account for this condition. He believes the tubular visual field to be of great diagnostic value in hysteria. [W.E.R.]

**The Suprarenal Gland in Ophthalmic Practice.**—According to de Schweinitz<sup>1</sup> the instillation of any of the various preparations of suprarenal gland into the eye is followed in from 30 to 60 seconds by a blanching of the mucous membrane due to stimulation of the vasoconstrictor apparatus. The smaller bloodvessels are more affected than the larger ones. The effect lasts from a half to two hours, according to the amount employed. These drugs have no effect upon the inner vessels of the eye, that is, of the retina or choroid. In the inflamed eye there is a blanching of the conjunctiva, but there is some dispute as to whether the suprarenal has any action upon ciliary congestion; de Schweinitz inclines to the view that the application of the drug removes superficial and lessens deep hyperemia. It is asserted that the visual acuity is increased by the drug. When the suprarenal extract is injected into the subconjunctival sac there is produced mydriasis and protrusion of the eyeball. The adrenalin preparations are useful to relieve congestion in conjunctivitis, to combat blepharospasm, to relieve trachomatous pannus, and similar conditions. They are also of value to enhance the action of other drugs, as cocain or eserin. It is not at all certain whether the use of adrenalin has any real curative effect; it is probable, however, that it has a favorable modifying influence upon the disease process in some cases. As a hemostatic in operative work this preparation, while preventing oozing, does not control bleeding from the larger vessels and is likely to be followed, de Schweinitz believes, by postoperative hemorrhage. Concerning the choice of preparation, he has obtained equally good results with a solution of dried extract and with adrenalin chlorid. Solutions of adrenalin chlorid have the advantage of being more easily sterilized, but de Schweinitz has observed that it is somewhat more irritating than the older preparations. [H.C.W.]

THE PUBLIC SERVICE

**Health Reports.**—The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended December 27, 1902:

SMALLPOX—UNITED STATES.

		Cases	Deaths
California:	Los Angeles.....Dec. 7-14.....	1

Changes in the Medical Corps of the U. S. Army for the week ended December 27, 1902:

The following-named assistant surgeons are relieved from duty at the places indicated, and will report to the commanding general, department of California, for transportation to the Philippine Islands on the transport to leave San Francisco, Cal., January 1, and upon arrival at Manila will report to the commanding general, division of the Philippines, for assignment to duty: First Lieutenant Milton E. Lando, discharge camp, Angel Island, Cal.; First Lieutenant Charles Y. Brownlee, Benicia Barracks, Cal.

STOCKARD, JAMES K., contract surgeon, now at Greensboro, N. C., will proceed to Fort Delaware for duty.

ADAIR, GEORGE F., contract surgeon, is relieved from further duty in the division of the Philippines, and upon the expiration of his present leave will report to the commanding general, department of the East, for assignment to duty.

VITOU, BENJAMIN, hospital steward, now at Akron, Ohio, having relinquished the unexpired portion of furlough granted him in the Philippines, is relieved from duty at Fort McDowell, and will report at Fort Thomas, to relieve Hospital Steward Theodore H. Connor. Steward Connor will proceed to Manila, P. I., for assignment to duty.

CORSON, JOHN M., hospital steward, now at Buffalo, N. Y., is relieved from duty at Fort McDowell, Cal., and will report on or before expiration of furlough at the General Hospital, Fort Bayard, for duty.

DALE, First Lieutenant FREDERICK A., assistant surgeon, is granted leave for ten days, to take effect upon the return to the United States General Hospital, Washington Barracks, of First Lieutenant James R. Church, assistant surgeon, from temporary duty at West Point, N. Y.

EDWARDS, First Lieutenant JAMES F., assistant surgeon, now at State-lick, Pa., is relieved from further duty in the division of the Philippines, and upon the expiration of his present leave will proceed to Fort Leavenworth for duty.

VAN POOLE, First Lieutenant GIDEON MCD., assistant surgeon, leave granted December 3 is extended ten days.

BACON, ALEXANDER P., contract dental surgeon, is granted leave for eighteen days.

WATSON, HARRY J., contract surgeon, is granted leave for one month, with permission to apply for an extension of one month.

Changes in the Medical Corps of the U. S. Navy for the week ended December 27, 1902:

BERTOLETTE, D. N., medical inspector, ordered to duty as fleet surgeon of the Pacific station—December 20.

GREEN, E. H., medical inspector, detached from duty as fleet surgeon, Pacific station, and ordered to the Wisconsin—December 20.

Changes in the Public Health and Marine-Hospital Service for the week ended December 25, 1902:

PARKER, H. B., assistant surgeon, granted leave of absence for fourteen days from December 22, 1902—December 20, 1902.

WHITE, M. J., assistant surgeon, granted leave of absence for fourteen days from December 23, 1902—December 19, 1902.

LLOYD, B. J., assistant surgeon, relieved from duty at the San Francisco Quarantine and directed to report to Surgeon A. H. Glennan, San Francisco, Cal., for duty—December 23, 1902.

BALLARD, J. C., acting assistant surgeon, granted leave of absence for five days from December 23, 1902—December 23, 1902.

GOLDSBOROUGH, B. W., acting assistant surgeon, leave of absence for three weeks granted by Department letter of November 22, 1902, amended so that said leave shall be for twelve days only—December 22, 1902.

LEONHARDT, S. C., acting assistant surgeon, granted leave of absence for one month from January 1, 1903—December 17, 1902.

VOL. V, No. 2.

JANUARY 10, 1903.

\$5.00 YEARLY.

**Conservatism in using the Lorenz method** is at the present time most advisable by American surgeons. There has been created such an alarming interest in the operation by the newspapers that there is danger that operations may be undertaken by the unskilled and the procedure itself brought into disrepute. The conditions that limit the choice of cases fit for the operation should be most carefully studied. It cannot be forgotten that even in the hands of one so experienced and successful as Lorenz himself only about one-half the operations are successful. It is, moreover, the opinion of some thoughtful men that the operation with the knife may finally prove preferable, even in patients of six years and less. It is also to be remembered that the primary success in getting the head of the femur into its socket still leaves the greater part of the work, and often the most difficult, to be carried out in the long and delicate manipulations and care required after the cast is removed. Whatever method may finally gain precedence in practice, nothing but harm can result from haste and recklessness on our part in undertaking operations in ill-advised cases. If to this should be added the misfortune of the poor operation, an over-revulsion will follow, and progress will more than ever be sadly delayed.

**Extremes in Theory and Practice.**—As regards therapeutics how common it is to find practitioners divided into two classes, those whose practice runs to treatment almost exclusively regardless of diagnosis, and those whose interest in a case at once ceases so soon as a diagnosis is made. Medicine exists not for the benefit of its practitioners, but for the good of its patients. In a recent set of ten examination questions for a graduating class by a professor of the "Practice" of Medicine, only one had any reference whatever to treatment. On the other hand, What do you prescribe in a case of —? shows the silliness of another extreme. But why should civilized men run to either extreme? If stolid empiricism and indiscriminate drugging characterizes the one set of extremists, a brutal and immoral therapeutic nihilism is equally disgusting. The patient does not come to us and pay us for our theories and diagnoses, but to be made well. He knows, and we all know, that drugs have power, and, intelligently used, have power for good. A correct diagnosis must precede correct treatment, but a correct

diagnosis does not do away with the need of treatment. There is a deal of anti-nonsense being scattered about, not only by the ranting quacks, but by many so-called "leaders" of the profession. Hygiene, nursing, diet, etc.—yes, but why not drugs also, if they can help? And help they can when used with skill. The practitioner of the future will unite both theory and practice, both diagnosis and treatment. Let the extremists take warning.

**The Prophylaxis of Color-blindness.**—Some time since we spoke of the success which may follow in educating those supposedly blind to see. It has been found that the remnants of function in those supposed to be blind may often be so improved as to take these patients entirely out of the blind class and make them enjoy useful vision. It is but a corollary of this that the deficiencies of vision called color-blindness are also preventable. Function, it must ever be repeated, depends upon education and exercise, and it is a necessary part of the great physiologic law that the perception of colors will be lost if the eye is not exercised in their perception. That the defect is dependent upon nonexercise is indicated by the fact that it is far less common in women than in men. In 10,000 men 369 are affected, while only 9 are found in the same number of women. The proportion among savage men is less than among civilized men. But of course the education and exercise must begin in early childhood. And there is some proof that this exercise in childhood does stimulate color-perception and prevent color-blindness. In the *Educational Review* Alida S. Williams recently reports having tested the color vision in 580 boys of the primary schools of New York. These boys had received careful systematic color-training. According to the teachings of statistics 24 should have been defective in their color-sense. But only one was so. It is impossible to estimate how many of the accidents to vessels and railway trains have been due to the color-blindness of employes. The proportion is higher than is usually supposed. Despite all the systems of testing many of these employes are still color-blind. Perhaps it will ultimately be found that prevention is cheaper than testing.

**Nontaking Vaccinations.**—The following reports have been sent to us by subscribers:

1. Dr. H. B. Young, of Burlington, Iowa, cites the case of his youngest daughter, always robust and healthy, who was

vaccinated twelve times between the ages of 7 and 12 years with virus (points and tubes) from different and most reliable producers and by four different physicians—but without result. When 12 years old she was vaccinated for the thirteenth time, and this was followed by a pustule. But as the area of inflammation was large and there was a slough about 5 mm. in diameter, I do not feel sure that it was a vaccinal pustule.

2. Dr. W. B. Jones, of Rochester, N. Y., gives details of the case of a dentist, whom twenty years ago, in boyhood, never having been vaccinated or had smallpox, a physician vaccinated seven times without success. Thereupon he took him to the bedside of a patient having that disease and vaccinated him with a scab removed at the time from one of the pustules. That was also unsuccessful, but last month vaccination was done in the ordinary manner and there was a typical reaction.

3. Dr. D. F. Manning, of Marshall, Mo., writes as follows: In the winter of 1900, during the prevalence of smallpox in our community, a gentleman and his daughter applied to me for vaccination, stating that he had had fourteen and his daughter four nontaking vaccinations. On inquiry I found that he had been twice vaccinated in early youth by the "arm to arm" method. During his army service of four years in the Civil war he was vaccinated twelve times. I vaccinated both him and the daughter twice at the time stated (1900), using the dried points first and the glycerinized virus in tubes the second time. But there was no result either time in either case, thus making the record sixteen and six nontaking vaccinations, respectively, in these cases. The gentleman is a truthful and highly respectable man. Five other members of the family, vaccinated at same time and with virus from the same package used with the father and daughter, proved susceptible. I am not persuaded that these are cases of insusceptibility, but if they are, might not the element of heredity be considered in the case of the daughter?

4. Dr. G., of New York City, says of himself as patient: My first vaccination in 1865 was a failure. Several other vaccinations in my family at the same time from the same scab were successful. The vaccinations, one each in 1871, 1872, and 1874, were failures, and in 1878 there were two failures. The last vaccination was by the then vaccine expert of the New York Health Board, who laughed at the idea of failure, but he did not succeed. Between 1878 and 1901 at least two vaccinations failed. In the last named year the eighth vaccination was mildly successful. On some of the dates named a second attempt was made as soon as failure was evident. To those studying this subject it may be of interest to state that I was exposed to smallpox without contagion during the time that I appeared immune to vaccination, also that I never contracted any of the diseases of childhood, with one exception, although frequently exposed in my own family. The one exception was a case of "mumps" after I began the practice of medicine. Further, my daughter resisted repeated attempts at vaccination until she was 8 years of age. Furthermore, she has reached adult age without contracting any of the contagious diseases of childhood, except chicken pox. Individual cases are of little importance, but in this instance tend to demonstrate the importance of persistent attempts at vaccination in cases apparently immune, as the time seems to come when the person apparently becomes susceptible and liable to contract smallpox even though he may have resisted its contagion before. The fact that one is not susceptible one year is no indication that he may not be the following year, and then he runs all of the risks as regards contagion, severity, and mortality, that all run who have never been vaccinated.

The cases reported in another column by Dr. Seilkovitch should also be considered a part of the series.

**The Lister Jubilee.**—Fifty years ago Lister took the Fellowship of the Royal College of Surgeons of England. To celebrate the jubilee the *British Medical Journal* of December 13, 1902, publishes a special number containing tributes to Lister's great services to surgery. There are articles by Professor von Bergmann, of Berlin; by Dr. Lucas-Championnière, of Paris; by Professor

Durante, of Rome; by Bloch, of Copenhagen; by von Mikulicz-Radecki, of Breslau; by Howard Marsh, of London, and others, together with an excellent editorial epitome of the Listerian system as practised in other countries and departments of medicine. We regret that among the contributions there are none from our own countrymen. This we are assured was not the fault of the editor of the *British Medical Journal*. Some of our American colleagues, it is inferred, were to blame. The fact by no means argues that we are not conscious of the splendid services of Lord Lister and keenly grateful for them. It is seldom that a man lives to see the results of any great revolution he has brought about in science and to be honored by the world he has so richly benefited; but even here the recognition was sadly and needlessly slow in coming. In a recent speech in London Lord Lister said that he had often thought that if he did deserve any credit it was at the time when perfectly convinced of the truth of the principle on which he acted, and persuaded also of the enormous importance to mankind of being able to carry out that principle in practice he worked for years together with exceedingly little encouragement from his professional brethren. These pathetic words remind us that the old tragedy is constantly being reenacted in our midst, even in our professional life—the tragedy caused by our dull neglect of those who today and every day are achieving the profoundest good for medicine and for humanity. When our benefactors most need help and sympathy we are wholly reckless of them, and even aid the common enemy.

**Forest Fires.**—The medical profession has always been practically unanimous in its support of all that is being done to check the wasting of the forests of the country. There now comes an opportunity for every doctor, and especially for the country doctor, to make his influence felt in that direction. The foresters, who may be supposed to know whereof they speak, have reached the conclusion that more timber is burned up in forest fires than the whole country uses. The subject has been studied in detail by members of the Bureau of Forestry at Washington, and will be presented to the public in a bulletin soon to be issued. No feature of the forest question is more important, and the country cannot be informed about the facts too soon. One statement that will be made is that nowhere, neither in Maine, in Washington, nor in the South, are the great fires chargeable to the lumbermen, but in most instances are the result of the carelessness of farmers and campers. The whole country is filled with a reckless indifference about fire in the woods, and no hope of maintaining the old forests or of growing new ones can be realized until the fires shall be stopped. What a denuded country means every physician knows. He knows, too, in how slight a degree ragged brush lands can fulfill the hygienic office of a full-grown forest. Therefore the opportunity—no, the *duty*, of the doctor as he goes his rounds is to report every fire that he sees and to exert all his influence against the habit of starting fires out of place and out of season. The money loss to the nation is estimated at a hundred millions a year. Are the lost health-giving tree influences worth any less?

**Curettage, Curettement, or Cureting?**—A correspondent asks us what is the correct or best form of word to use, *curettage*, *curettag*e, *curetment*, *curettement*, *cureting*, or *cureting*, etc. The sole "authority," of course, is that very despotic commander, General Usage. By his orders the most ridiculous words must be accepted, written, and spoken by all. But as to *curettage*, etc., the General has not made up his mind or given any orders. His subjects are therefore making use of all forms, but with doubt and indiscriminatio. No one form, indeed, is inherently better than the others, and the only value of discussion is to make the majority of physicians use one form to the exclusion of others. We think it better for many reasons to prefer American and English rather than foreign philologic fashions, and the history of many words shows that the English spirit of the language will finally conquer and the "outlandish" form will be neglected. For this reason we suggest that the French terminations, *-age* and *-ment*, be discontinued and the English *-ing* preferred. Let *cureting* displace *curettage*, *curettag*e, *curetment*, etc. If it should be asked why not *cureting*, we at once counter with a query as to leaving out the *e* of the French. If double *t* is demanded (*cureting*) the whole of the tail (as in *curetteing*) should be left. But in *quintet*, *etiquet*, *cullet*, *corset*, etc., we have curtailed the needlessly long tail (pace the "zoopholists"!); hence why not in *curet*, *fouret*, etc.? To demand the double *t* is to acknowledge that the instrument should be spelled *curet*, and not *curette*.

#### **Drunkenness in Itself a Punishable Offense.**—

We suspect that the greatest progress in reference to the alcohol question will result from the new licensing act which went into effect in England on January 1. Drunkenness, which for some time has there been a social misdemeanor punishable only if accompanied by disorder, is now a legal offense of itself. Moreover, the habitual drunkard becomes a fully labeled outcast of society. The police are drawing up a blacklist in each district of all persons who have been convicted thrice of drunkenness during the year. The lists and photographs will be supplied to all liquor sellers, who will be heavily fined, and, on repeated offense, will lose their licenses if they sell drink to those blacklisted. Persons treating habitual drunkards will be heavily fined, as also will be intoxicated persons in charge of infants. Combined with the various methods of supplying the drinker with substitutes for bad liquor, for limiting its sale, for offering pleasant places under good conditions for social enjoyments, there is no reason why the disease sequels of alcoholism may not be speedily lessened. The English act is wisely careful not to interfere with the liberty and free-will of an adult by legal prohibition which cannot be executed. Public drunkenness is of itself a public offense, and it is a strange oversight that reformers have so long allowed the criminal to go unpunished.

**The Association of Medical Librarians** is making noble progress in its noble work. Its library membership now numbers over 40, and there are some 30 individual affiliated members. In 1902 it distributed to libraries over 5,000 volumes, chiefly duplicates from the

larger libraries sent to libraries not possessing them. This noteworthy progress must be gall and wormwood to those firms of medical book and periodical publishers which have derided and discouraged the formation of public medical libraries. That the medical profession is Christian cannot be doubted if to love its enemies is a proof—and if in this case it really does love them. We have no doubt that the *Association* has not realized the thousandth part of its coming usefulness. Physicians and their heirs should make it the legatee of their valuable medical books, and medical publishers should be shown the impolicy and stupidity of the selfishness of hating public medical libraries. The greater the number of such libraries the more books will be sold to individuals. Authors of medical books should remember to bargain with their publishers that a copy should be presented to each library on the list of the Association. Professional medical journals of the country give yearly subscriptions to these libraries. Commercial medical journals do *not*. Are you a subscriber or contributor to commercial medical journals?

**Mark Twain on Eddyism.**—When a solemn ignoramus turns philosopher and takes himself seriously we often have the perfection of humor. But when a professional humorist turns into a solemn prophet, we have as a result neither sense nor humor. Mark Twain seems to be determined to carry the latter thesis to the bitter end of realization. In the *North American Review* for December he plainly implies that eddyism is destined in 25 years to become the new religion of the world, and to stand second only to Rome in power and numbers. He says it now has 500 churches and 1,000,000 members in America. It offers a new personage to worship. More than four-fifths of the pain and disease of the world, he adds, is purely imaginary, and eddyism, we are assured, can rid the world of all of this; and no other force can. All of this reminds us that last year Mark testified before the Committee on Public Health of the New York Legislature that he had been treated by osteopaths, and that not to license them was to interfere with one's personal liberties, that he had a right to do with his own body as he pleased, and that the Legislature had no right to say who should treat him, or how it should be done, etc. It is a pity that the gay sense of the ludicrous is lost in old age, and sane logic gives place to senile fantasy. In 25 years eddyism will be as powerless as the Perkins' tractors, and Twain's successor with the cap and bells will make merry over the vaticinations and sociology of Mark himself.

#### **Lemon Juice and the Typhoid Fever Germ.**—

In its latest *Bulletin* the Chicago Health Department advises the use of lemon juice upon raw oysters, and cites the fact that the use of acids was advised nearly 30 years ago by the present assistant commissioner of the department as a prophylactic against cholera. It is also said that a cablegram from London announces that Dr. Asa Ferguson has demonstrated that lemon juice has the power of destroying the bacillus—in the proportion of one teaspoonful to half a glass of typhoid-infected water, says the department *Bulletin*. Further investigations are

being made to show how small an amount will suffice and whether it will be equally destructive to other germs, especially of the colon group. The report of Dr. Jaques, the director of the laboratory, says:

The following experiment was made in the laboratory to test the value of lemon juice in destroying the typhoid bacilli: 120 cc. of bouillon was inoculated with the bacillus typhosus. The flask was placed in the incubator at 90° for 12 hours. At the end of this period 4 cc. of lemon juice was added. At the end of four hours plates were inoculated from this flask. The plates at the end of 24 hours showed no growth. Control plates showed abundant growth.

In view of the fact that typhoid fever has often been traced to oysters and the bacilli found in them, this method of prophylaxis is worthy of serious attention and further testing.

**A Nonrecurrent Epidemic.**—One of the strange things one finds in the history of medicine is the appearance of a peculiar disease which does not again recur. A writer in the *Nineteenth Century and After* for December, 1902, cites such an epidemic of disease among animals which occurred in Italy in the last century before the Christian Era. The fact is also noteworthy for another reason, viz., that it was made the subject of a poem by Virgil. Lord Burghclere gives a translation of the part of the *Georgics* containing it. Many attempts have been made in modern times to describe the conditions of disease in poetic language, but all have failed; just why, no one seems to understand. Virgil certainly did not fail, and he gives a description as accurate as was then possible of the symptoms of the disease. It was not our modern rinderpest; it was called by elder writers "murrain and blain;" it was a black and putrid fever. The only thing that seemed to check the ravages of the disease was that advised in the poet's words, *continuo culpam ferro compeisce*—"spare not the steel, but stamp the mischief out." The doctors were of no avail—

"Men called on Medicine: and her healing art  
Proved but a bane. Great masters of the craft,  
Chiron the Centaur, born of Philyra,  
And wise Melampus, Amyphaon's son,  
Stood by with helpless hands and baffled lore."

## EDITORIAL ECHOES

The deathrate of New York City in 1902 was 18.74 per one thousand of population, as compared with 20.02 for 1901. The difference in the two rates represents a saving for 1902 of 4,649 lives. These figures are taken from the annual report of Dr. Lederle, president of the Board of Health, who has a perfect right to be gratified over the showing which he is able to make. It is not pretended that the splendid administration of the Health Department is wholly responsible for the improvement. Deaths from heat prostrations were at a minimum last summer; there chanced to be fewer deaths from old age in 1902 than during the previous year, and other conditions, over which nobody asserts any control, happened to be favorable. But a decrease of 582 in the number of deaths from tuberculosis, a decrease of 100 in the deaths from smallpox, and of 35 percent in the diphtheria deathrate, can properly be ascribed to enforcement of sanitary regulations by the Health Board and by the Street-Cleaning Department. That so much has been accomplished in a single year is gratifying indeed.—[*N. Y. Evening Post.*]

## AMERICAN NEWS AND NOTES.

### GENERAL.

**Miscellaneous.**—PHILADELPHIA, PA.: Dr. James Tyson has been appointed visiting physician to the Pennsylvania Hospital in place of the late Dr. Frederick Packard.

**Insufficient Hospital Accommodations.**—Surgeon-General O'Reilly, of the Army, is anxious to have constructed at Fort Riley, Kan., a modern hospital of 100 beds. It has been found that the present hospital cannot be enlarged to the required capacity, and the constant growth of the garrison necessitates better hospital facilities.

**Medical Clerks.**—The United States Civil Service Commission announces that the Commissioner of Pensions would like to provide for the appointment of 25 young students of medicine as clerks or copyists in the Pension Office. Examinations for the position will be held January 27, 28, 1903, in Washington, D. C. Only graduates of recognized medical schools will be examined.

**Good Sanitation Must Continue in Cuba.**—The lower House of the Cuban Congress has voted \$400,000 to aid the city governments in the island to continue the high sanitary standard achieved under American occupation. Contrary to current reports it is claimed that no retrogression had occurred in Havana, but this was not true of the interior and east coast towns. This was, it was claimed, not due to apathy, but to lack of funds. Now that a sufficient sum has been granted it is believed the former efficiency will be restored.

**Hospital Benefactions.**—ORANGE, N. J.: A fully-equipped bacteriologic and pathologic laboratory, to be known as the Graves Laboratory, has been presented to the Orange Memorial Hospital by Dr. William B. Graves, of East Orange. DERBY, CONN.: It is announced that the \$50,000 which had been bequeathed by George Griffin, of this city, for the construction of an emergency hospital, has become available for use. MR. GRIFFIN died three years ago. PHILADELPHIA, PA.: The late Mary Drury, of this city, bequeathed \$300 to the St. Vincent's Home and Maternity Hospital, and \$100 to the Free Hospital for Poor Consumptives.

**Pension Money of the Insane in the Government Hospital.**—It is probable that new legislation will be inaugurated to effect a more equitable distribution of pension money given to those committed to the Government Hospital for the Insane. Under the present regulations this pension money for each individual, of whatever amount, is placed in the hands of the superintendent and goes into the general fund for maintenance as an offset for the patient's expenses in the institution. It is asserted that in some instances this pension money is in excess of the actual expenses of the patient, and many things are withheld from the patient which under the present regulations the government institution cannot supply, whereas, if his pension money were used for his special needs greater justice would be done. The reform will probably consist in placing each pensioner's money in a separate account at the institution with the pension.

**Birthrate.**—The *Chicago Tribune* is authority for the statement that in Boston the birthrate among people of foreign parentage is 39 per 1,000; among people of native parentage it is only 8 per 1,000; while in New York the corresponding figures are 42.5 per 1,000 and 11 per 1,000. The *Tribune* is of the opinion that the reason for the present situation is a shrinkage in our native birthrate, due to conditions which are not physiologic, but are social and industrial. The native American population is at the top of the social and industrial ladder in this country, and the consequence of that position is exactly what it would be in a similar position in any other part of the world. The higher the comparative position of a family the lower its birthrate. The richer families of Europe have fewer children than the poorer families. This is not due to physiologic conditions, but, as stated above, to sociologic, industrial, and economic conditions.

**Plague in Mexico.**—Late reports state that the disease has spread in Mazatlan and that the alarm which had somewhat abated has returned with increased strength. People are fleeing from the city at the rate of 300 a day, and it is estimated that nearly 5,000 have already left. Strenuous measures have been adopted to improve the sanitary condition of the city. Streets are to be kept scrupulously clean, and the city government has appointed an inspector for each block, whose duty it is to enter every house in the block at least once during the day, make a thorough inspection and report any suspicious sickness. Fifty pavilions are being constructed for the use of persons who have been exposed to the disease. The houses and personal effects of all who died, as well as of those stricken with the plague, have been burned. A strong cordon still protects the interior towns, and persons from Mazatlan are prevented from entering.

**Seasickness.**—Mayor Des Planches, Italian Ambassador to the United States, writes to a physician in New York giving his experience in seasickness. He says: "After having found by experience that one way not to suffer from seasickness was to lie in a horizontal position, I happened to notice that fixing my eyes upon a mirror while dressing, even when the sea was stormy, was sufficient to relieve the unpleasant sensation of seasickness. During my last ocean trip I tried this accidentally discovered remedy and always with good results." This is explained by an authority who asserts that the eye of the observer when on the rough sea changes every few seconds to a different horizon, and has in consequence the sensation of the lack of equilibrium. We call that vertigo, which in its highest form manifests itself in pallor, cold perspiration, weak pulse, nausea and vomiting, the symptoms of seasickness. The relief of the symptoms as observed by Mayor Des Planches is explained on the ground that the eyes and the mirror form one body, and the changing of the horizon being reflected by a surface equal in every plane the eye loses the consciousness of the different changes and equilibrium is maintained.

**"Index Medicus."**—From Robert Fletcher, M.D., editor-in-chief of the revived *Index Medicus*, comes the following: The *Index Medicus* was established in 1879, under the editorship of Drs. John S. Billings and Robert Fletcher, and was discontinued in 1899. The present publication, which is undertaken by the Carnegie Institution, will be known as *Index Medicus*, Second Series, Volume I, commencing in January, 1903. It consists of the titles in full of books, pamphlets, theses, contributions to cooperative works and original articles in journals, transactions of medical and scientific societies, arranged under subject headings. It is issued as early as possible after the first day of the month, and it represents the literature of the preceding month. A table of contents accompanies each number, and on the completion of the volume an "Annual Index of Authors and Subjects" is issued. The subject part of this annual index is elaborately subdivided, the classification closely resembling that of the Index Catalogue of the Library of the Surgeon-General's office. The titles in certain languages, as Russian, Polish, Swedish, Danish, Finnish, Hungarian, Bohemian, Roumanian, and Japanese, are translated into English. The *Index Medicus* publishes no advertisements and does not exchange copies with other journals.

**The Appointment of Assistant Surgeons in the Army.**—The difficulty of obtaining young men graduates of medical colleges who are able to pass the examination for appointment as assistant surgeons in the Army must, sooner or later, engage the attention of the authorities. Surgeon-General O'Reilly has a plan in contemplation which he hopes to see realized before he finishes his term of office. It is his idea to take graduates and, after examining them as to their general qualifications, admit them to the Army Medical School in Washington and give them a training in special branches for a year or more, subjecting them to examinations as they progress and at the end of the term select from among them those who are deemed competent to fill the vacancies in the medical corps. Such as do not find a place in the regular establishment would be of use in the national guard organizations, which latter will be benefited by having available young men who are specially trained in military medicine and surgery, hygiene and sanitation. In this way the State troops would have at their bidding surgeons who have a practical knowledge of their military as well as professional duties. Surgeon-General O'Reilly is also in favor of requiring that the young men who enter the medical department after this preliminary education shall be required to serve at least five years.—[*Army and Navy Register.*]

#### EASTERN STATES.

**Smallpox in Massachusetts.**—During the year 1902 there were 2,263 cases of smallpox in the State, and of these Boston furnished 1,015 cases or nearly one-half. For the year 1901 there were but 778 cases.

**To Assist in the Treatment of Tuberculosis Among the Poor.**—An organization which aims to improve the condition of poor persons suffering with tuberculosis and finally to stamp out the disease has been formed by several society women of Cambridge, Mass. In order to make the work practical all of the physicians in the city have been asked to cooperate with the organization by sending to the members designated the names of those who lack the means to provide themselves wholesome and nutritious food. The dietary which the doctor prescribes will be indicated by a diet card, and this food will be supplied at the expense of the organization. The organization will also be aided by district nurses, who will visit the patients in their homes. The principles now in vogue in the Rutland Sanatorium will be followed out as nearly as possible, thus making the work educational as well as remedial.

#### NEW YORK.

**Trachoma in School Children.**—According to a recent report in the first ten days after the old Gouverneur Hospital had been placed at the disposal of the Health Department for

use as an eye hospital, 2,128 cases of trachoma in school children were treated, and in 116 of these operations were necessary.

**Births in Manhattan.**—According to the records of the Health Department, during the year ended September 30, 1902, there were 51,688 births in the borough of Manhattan alone. This exceeds the figures of last year by 1,460 and indicates that on an average one child was born every 10 minutes. There were 29,406 births reported by physicians and 22,282 by midwives.

**Decrease in Deathrate for New York.**—Dr. Lederle, president of the Board of Health, in his annual report states that the deathrate for New York City for 1902 was 18.74 per 1,000, which is considerably the lowest rate ever reported for this city. The rate in 1901 was 20.02. The statement is made that the epidemic of measles during the first four months of the year increased the number of deaths over the year 1901, for the same months, by 1,100; but the decrease in the number of deaths from sunstroke, there being 1,244 less than in the previous year, made the rate about even.

**Alien and Domestic Insane in New York.**—Investigation carried out for a committee of the United States Senate by two experts from the lunacy institutions in New York shows a condition differing to some extent from what was expected, especially in regard to the proportion of insane furnished by the foreign countries. It appears that prejudice against foreigners from Italy has been the foundation for false and exaggerated statistics relative to the number of Italian insane. The New York Commission on Lunacy reports the number of patients admitted to the State asylums from 1888 to 1900, which amounted to 59,603, of whom 30,529 were native Americans. This does not include the native insane who are confined in private institutions. During the period above mentioned the number of British insane numbered 10,770; and the German insane, 6,901; while Italy contributed but 830 patients, a very favorable showing for the Italians.

**State Hospital Reform.**—At a recent meeting of physicians on Ward's Island papers were read and discussed relative to the aims and plans of the Pathologic Institute of the New York State hospitals. Dr. Adolph Meyer said: "We must make the work of the physician as medical as possible, abolish all regulations which derange their work; in short, all and everything that makes a young assistant put frivolities above medical accuracy. We must investigate how large a force is required to reach a standard of work on which we can agree. We must make somebody responsible for the accuracy and efficiency of the medical work which the superintendent cannot possibly supervise well enough when he is responsible for all the administrative burdens, and this person or these persons, let us say the older members of the staff, must be official helpers to the younger members, that is, sources of instruction and stimulation." Arguments were adduced to show that medical schools do not provide the necessary training for actual hospital work and that the assistant members of the hospital come unprepared for special work. A congress of conferences has been appointed in connection with the Pathologic Institute of the New York State Hospitals and many subjects relative to the improvement in hospital management will be discussed. At these conferences such matters as the following are to be discussed: Improvements in the training-school for nurses; better facilities for the admission of emergency cases of insanity and for voluntary patients; the organization of a department in the State hospitals for the more effectual treatment of acute diseases; the construction of pavilions for isolating tuberculous patients; and the issuance of a new textbook for nurses in the training-school.

#### PHILADELPHIA, PENNSYLVANIA, ETC.

**Cause of Typhoid Fever in Atlantic City.**—After thorough investigation of the typhoid fever cases which occurred in Atlantic City last summer, it has been found that the entire trouble was caused through a break in the sewer pipes which crossed Penrose Canal, which vicinity was used by the three largest oyster dealers in the city for freshening oysters for market. The total number of cases was 72.

**Smallpox** is reported to be increasing throughout Pennsylvania. This increase is especially noticeable in Philadelphia. In the former there are now under treatment 509 cases of smallpox, while in the latter there are between 70 and 80 cases of the disease, 13 cases occurring within the past week. A corps of vaccine physicians, numbering 36, has been appointed in Philadelphia to make house-to-house visitations for the purpose of vaccinating the inmates, and \$25,000 has been appropriated to combat the disease.

#### SOUTHERN STATES.

**New Hospital for Tampa, Fla.**—Plans are now under consideration for the erection of a new city hospital. The building proposed will cost about \$10,000 and will be maintained by the city.

**Memorial to Major Walter Reed.**—At a recent meeting of the American Association for the Advancement of Science resolutions were adopted on the death of Major Walter Reed and a committee of nine members appointed to carry out plans for the erection of a memorial to his memory.

**Diphtheria on the Training Ship "Buffalo."**—From Pensacola comes the news that the training ship "Buffalo," with several hundred naval apprentices, has put in at Pensacola on account of the number of cases of diphtheria on board and in order that the sufferers may receive proper medical attention. The "Buffalo" was on a cruise of several months in the Gulf, but the discovery of diphtheria among the apprentices required a rearrangement of her voyage.

**Site for City Hospital.**—The *Baltimore Sun* states that the Health Department officials have selected a site near the Bay-view Asylum for a city hospital for infectious diseases. It appears that in addition to the hospital for infectious diseases other municipal institutions will be established upon this property. Among the more important buildings contemplated is the Home for Consumptives, to be built entirely of iron and glass, largely on the general plan of a conservatory. A building is also contemplated which will serve as a parental home for the care of certain classes of boys now at the Colored House of Reformation at Cheltenham.

**Quarantine to be Relaxed.**—The *Louisville Courier-Journal* states that as a result of the discovery announced by physicians and sanitary experts that the mosquito is the sole agency for the transmission of yellow fever germs it is likely that the stringent quarantine regulations between Cuba and the southern part of the United States will be greatly modified, which will mean many thousands of dollars annually to the South. Dr. Bailey, of Louisville, is authority for the statement that the yellow fever epidemic of 1878 cost the South many millions of dollars at the time, and the strict quarantine which has been enforced has debarred much traffic from its ports. That the work of the sanitation of Cuba under American methods has proved to be beneficial is apparent when it is considered that the city of Havana was not free from yellow fever for 140 years until 14 months ago, and during that 14 months not one case of yellow fever has developed in the city. The work of the sanitation of the city has only begun, and when the additional building facilities are completed and the water supply is purified Havana will be free from a curse which has held it in bondage for more than a century.

#### WESTERN STATES.

**Medal Awarded.**—It is reported that a medal has been awarded to St. Paul, Minn., by the directors of the Paris Exposition, showing it is the healthiest city in the world and has the lowest deathrate. It was also decided that this city has the best system of sanitation in the world.

**Prison Reform in Illinois.**—It is believed that the report soon to be submitted by the State Board of Health will make some startling disclosures and recommend sweeping reforms in the various insane asylums and prisons of the State. It is claimed that insane prisoners have been kept in isolated retreats because of lack of accommodations elsewhere. The sanitary conditions in many of the county jails of the State is said to be in a deplorable condition. Since the State Board of Health under the present regulations has no authority to enforce reforms the coming Legislature will be requested to enact such measures as will give the board the proper and legal authority for the necessary government of these State and county institutions.

**Chicago's Deathrate.**—The *Chicago Tribune* is authority for the statement that for the seventh consecutive year Chicago's deathrate has been lower than that of any other city of first magnitude, and that, too, in the face of the fact that 1902 was a year of frequent grave concern over conditions affecting the public health of the city. With the exception of the year 1901 the rate is the lowest in the records of the Health Department. Computed on an estimated midyear population of 1,820,000 the unrevised total of 26,384 deaths from all causes in 1902 gives the rate 14.49 per 1,000 of population. Appended figures of the deathrate in the other cities of first magnitude are given:

Cities.	Population.	Total deaths.	Rate per 1,000.
New York City.....	2,189,632	41,034	19.18
Boston.....	588,730	10,950	18.58
Greater New York.....	3,682,501	67,450	18.28
Philadelphia.....	1,350,000	24,108	17.85
Chicago.....	1,820,000	26,384	14.49

#### CANADA.

**Hospital for Contagious Diseases for Montreal.**—News comes that the authorities of Montreal are favorable to a plan agreed upon between one of the English hospitals and the Notre Dame Hospital, that each shall erect a pavilion for the treatment of contagious diseases. The city is to grant to each the sum of \$10,000, which would provide for 20 patients per

day, the contract to be for a period of 20 years. When the number exceeds this number the city shall pay \$1 a day for each adult and 75 cents a day for each child.

## FOREIGN NEWS AND NOTES

### GENERAL.

**Cancer in Germany.**—It is claimed that 70% of male and 68% of female cancer patients suffer from cancer of the digestive organs.

**Miscellaneous.**—The Nobel prize for natural science and chemistry has been awarded to Dr. Emil Fisher, of the University of Berlin.

**Light-cure Treatment of Lupus.**—It is announced that Professor Niels Finsen, of Copenhagen, has completed a short account of the results he has obtained in this treatment. Since 1895 about 800 patients have been benefited by it, having wholly or partly recovered. Professor Finsen contemplates publishing a large work on the light cure next year.

### GREAT BRITAIN.

**Decreased Deathrate from Cancer.**—According to statistics published by the London County Council, the mortality from cancer in London during 1902 shows a slight decrease, the percentage being .93 per thousand as compared with .95 in the previous year.

### CONTINENTAL EUROPE.

**Sanatorium for Women Alcoholics.**—It is reported that a special sanatorium is to be erected in St. Petersburg for the treatment of women alcoholics.

**Intemperance in Absinthe.**—It is asserted that alcoholism in France is steadily increasing and that the use of absinthe and other deleterious liquors is rapidly undermining the French constitution and is one of the main factors in the decrease of the French population every year. A volume might be written on the strange hallucinations which absinthe drinking develops in its votaries. The enormous increase in France of late years of pulmonary tuberculosis and other tuberculous diseases is said to be due to the abuse of absinthe, and the present Cabinet is credited with the resolve to introduce stringent legislation against its sale at the next session of the Chamber, opening in January.

**Factory Legislation.**—In Germany, children under 13 may not be occupied in workshops or factories, and above that age they can only be employed after they have finished their course in the schools. Children and young women may not be employed in such factories regarded as dangerous to health and morality. This latter regulation now includes glassworks, wire-drawing mills, sugar refineries, rolling mills, brick works, coal mines, tin and lead mines, etc. Children under 14 must not work longer than six hours per day, and young people between 14 and 16 years can not be employed longer than 10 hours per day. Their work shall not begin earlier than 5.30 in the morning, and shall not be continued later than 8.30 in the evening, and must be interrupted by regular intervals of rest. Similar regulations are in force regarding females, and even if they are over 16, they must not be employed more than 11 hours per day, or 10 hours on Saturdays and the days preceding holidays.—[*Public Health Reports.*]

### OBITUARIES.

**Samuel Fenwick**, of London, Eng., consulting physician to the London Hospital, and assistant physician to the Hospital for Diseases of the Chest, died December 11, aged 81. He obtained a wide reputation as a diagnostician and his "Students' Guide to Medical Diagnosis" has been translated into many languages. He was especially interested in the study of disorders of the digestion and contributed to literature many valuable works on this subject. During the last four years he evinced much interest in the preparation of a series of monographs upon diseases of the stomach, and he saw the completion of the first two volumes, which deal with simple ulcers and tumors of that organ.

**Karl Nicoladoni**, professor of surgery, died at Gratz, December 4, aged 55. He is known as the originator of the method of restoring a missing thumb by utilizing the second toe as a substitute. One of his first contributions to science was the successful relief of paralytic contractures by the transplantation of tendons. His research on the spine in scoliosis is the basis for our knowledge on the subject, and he was also the first to describe the syndrome caused by the torsion of the seminal cord, and to suggest orchidopexy.

**Professor Richard von Kraft-Ebing**, the wellknown neurologist and alienist of Vienna, died at Gratz, December 22, aged 62. He was professor of physiology and nervous diseases at the University of Vienna. His manuals on criminal psychology, psychiatry, and foren-

sic psychopathy have passed through numerous editions and his contributions to medical literature are widely quoted. Credit is due him for the general recognition of the close relationship between psychiatry and neuropathology.

**John F. Couch**, of Somerville, Mass. He was graduated from the Harvard Medical School in 1872. Later he took a course in obstetrics at the Rotunda Hospital, Dublin, Ireland, remaining there 6 months. For 3 years he was city physician to Somerville and also served as a member of the Board of Health. He was a member of the Massachusetts Medical Society, and a former president of the Somerville Medical Society. He was a trustee of the Somerville Hospital and one of its visiting physicians.

**Joseph R. Laine**, of San Francisco, Cal., December 15, aged 56. He was graduated from the University of Buffalo in 1876 and was a member of the American Medical Association. For 8 years he was a member and secretary of the State Board of Health, and was also one of the organizers of the College of Physicians, being its president until 1899. He was a lieutenant-colonel and assistant surgeon-general in the National Guard of California.

**Jacob M. Kraus**, in Buffalo, N. Y., December 19, aged 36. He was graduated from the University of Buffalo in 1889, and was a member of the Buffalo Academy of Medicine, of the New York State Medical Association, and of the American Medical Association. At the time of his death he was on the medical staff of the German Hospital and physician to the Erie County Penitentiary.

**Julius Kohl**, of Belleville, Ill., January 4. He was graduated from the Washington University, St. Louis, Mo., in 1859. He was a member of the Illinois State Board of Health, and was a United States delegate to the National Congress of Physicians at St. Petersburg in 1900. He was also a delegate to the American Tuberculosis Congress, held in New York in 1902.

**David Jacobson**, of New York City, December 31, aged 38. He was graduated from the medical department of the New York University in 1887. He received a special diploma for physical diagnosis in 1886 from Dr. Alfred L. Loomis, of Bellevue Hospital. He was connected with the Eastern District Hospital.

**Frederick L. Brady**, in New York City, December 20, aged 30. He was graduated from the College of Physicians and Surgeons, New York, in 1899. He was a member of Troop B of Roosevelt's Rough Riders during the Spanish-American war.

**Louis Wheat**, of Richmond, Va., December 29, aged 46. He was graduated from the Medical College of Virginia, Richmond, in 1881, and was professor in diseases of the genitourinary organs and syphilis in the University College of Medicine.

**Robert H. Moore**, of Hot Springs, Ark., December 15. He was graduated from the University of Louisiana, New Orleans, in 1861. He served as a major-surgeon in the Confederate States Army and was for 6 years coroner of Garland county.

**S. S. Cornell**, of Athens, Ont., December 2, aged 37. He was graduated from the Faculty of Medicine of Queen's University and the Royal College of Physicians and Surgeons, Kingston, Ont., in 1886.

**William B. Stevens**, of Nelson, Pa., at Hartford, Conn., December 11, aged 37. He was graduated from the Jefferson Medical College, Philadelphia, in 1891.

**Carl Schumacher**, in Syracuse, N. Y., December 15, aged 51. He was graduated from the Homeopathic Medical College, Cleveland, Ohio, in 1883.

**Francis M. Davis**, of Houston, Tex., December 16. He was graduated from the Texas Medical College and Hospital, Galveston, in 1874.

**William A. Kidd**, in Independence, Pa., December 11. He was graduated from the Western Reserve University, Cleveland, in 1897.

**A. Wilber Hoon**, in Pittsburg, Pa., December 16, aged 25. He was graduated from the Jefferson Medical College, Philadelphia, in 1902.

**William P. Armstrong**, at Jamestown, Cal., December 16, aged 73. He was graduated from the University of Louisville (Ky.) in 1857.

**John M. Bowser**, in Goshen, Ind., December 19, aged 53. He was graduated from the Medical College of Ohio, Cincinnati, in 1878.

**Henry Bauer**, in Brooklyn, December 13, aged 27. He was graduated from the Long Island College Hospital, Brooklyn, in 1896.

**J. K. Barney**, in Weir City, Kan., December 12, aged 60. He was graduated from the Washington University, St. Louis, in 1874.

**Hugh E. Ward**, assistant professor of bacteriology in the University of Illinois, died in Grand Rapids, Michigan, December 30.

**George R. Weeks**, in Los Angeles, Cal., January 2, aged 76. He had held several State and municipal positions in Arkansas.

**William S. Harding**, of St. John, N. B., December 19, aged 88. He was graduated from the University of Edinburgh in 1836.

**John S. Mason**, near Waverly, Va., December 16, aged 85. He was graduated from the University of Maryland, 1836.

**Jacob Hays**, of Chicago, January 3, aged 62. He was graduated in medicine at the Vienna University in 1863.

**George W. Rhodes**, of Boston, Mass., December 31, aged 71.

**Joseph A. Huff**, of Pittsburg, Pa., December 30.

**S. Choppin**, of New Orleans, La., December 29.

## SOCIETY REPORTS

### WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Twelfth Annual Meeting, Held at St. Joseph, Mo., December 29 and 30, 1902.

[Specially reported for *American Medicine*.]

FIRST DAY.

The following officers were elected for the ensuing year: President, Dr. Alexander Hugh Ferguson, Chicago, Ill.; first vice-president, Dr. C. H. Wallace, St. Joseph, Mo.; second vice-president, Dr. C. W. Oviatt, Oshkosh, Wis.; secretary and treasurer, Dr. George H. Simmons, Chicago, Ill.; members of the executive council, Dr. James E. Moore, Minneapolis, Minn., chairman; Dr. A. F. Jonas, Omaha, Neb.; Dr. O. B. Campbell, St. Joseph, Mo.; Dr. C. H. Mayo, Rochester, Minn., and Dr. J. R. Hollowbush, Rock Island, Ill. Denver, Colo., was selected as the place for holding the next annual meeting; time, December 28 and 29, 1903.

**Evolution of the Treatment of Cancer of the Rectum.**—C. H. MAYO (Rochester, Minn.). To sum up the main objections of the past operations, the author stated that we have:

1. Ineffectual removal with local recurrence, so common in the perineal type.
2. The extensive mutilating character of the Kraske before operative conditions were known.
3. The frequent failure of all methods of union of proximal and distal portions of the bowel, which, when united with the destruction of the levator ani and internal sphincter, and anus saved, represented but one-third of the controlling apparatus of the bowel.
4. The frequent formation of stricture, either cicatricial or cancerous, after operation, necessitating inguinal colostomy.
5. The loss of the fecal continence in straightening the sigmoid. That sentiment, and not chance, has proved the main reason for continuing to place an uncontrollable anus in an inaccessible situation. The gain in the combined operation has been in a selection of the operation to the case, radical removal *en masse*, with all glands, fat, and connective tissue, or colostomy for palliation, the retention of the sigmoid as a fecal container, the peculiar formation of the anus, giving a fair control in an accessible situation.

**Carcinoma Uteri.**—H. C. CROWELL (Kansas City, Mo.) believes that nothing is gained by hysterectomy for carcinoma of the cervix unless very early discovered. Later operations may avail in carcinoma of the body of the uterus. In cases well advanced his individual experience leads him to believe that more days or months, as the case may be, are added to the life of the patient than by any attempt at extirpation, by cutting and scraping away the necrotic tissue down to solid tissue, burning that surface with the thermocautery, and treating subsequently by touching the surface occasionally with 4% formalin. By this treatment disintegration is retarded, hemorrhage and discharges are checked, enabling the patient to recuperate sometimes to a remarkable degree. The suffering is lessened and the patient is relieved of the shock and dangers attending more radical procedures. The essayist urged frequent early examinations of parous women, who should be advised of the expediency of such as a routine safeguard after the age of 36.

**Oblique Inguinal Hernia.**—A. E. BENJAMIN (Minneapolis, Minn.) described an operation for which he claimed the following advantages: 1. There are no sutures for the tissues to absorb. 2. There is no additional culture media in which infectious microorganisms may grow and cause deep abscesses. 3. There are no buried, nonabsorbable sutures left to irritate the tissues and cause further trouble. 4. There is no necrosis from tight sutures, therefore few, if any, stitch abscesses. 5. The gauze rolls act as elastic cushions, which prevent scars from the sutures. 6. The operation completely closes the breach and makes a firm wall. 7. All sutures, after serving their purposes, are removed, leaving only the natural supports.

**Rupture of Gallbladder or Duct from Vomiting, with Rupture of the Appendix in the Same Patient.**—W. W. GRANT (Denver) reported two recent cases of appendicitis because of the interest connected with drainage and phagocytosis. In connection with these cases, he states that he is satisfied of having saved some patients after peritoneal extravasation by the liberal use of gauze for drainage. In abdominal operations, drainage imperils the integrity of the abdominal wall, therefore predisposes to hernia. It should consequently be dispensed with as soon as possible. But in the enthusiasm for new theories and facts, in a justifiable belief in the efficacy of hyperleukocytosis, he believes it is not wise to hastily discard surgical procedures which have stood the test of abundant experience. He also reported a case of acute yellow atrophy of the liver. Whether the condition is primarily a general infectious disease of a rare and unusual nature, or primarily a local infectious disease of the liver, is not known. The suggestion of an intestinal origin has no distinct foundation. The resemblance to phosphorus poisoning is striking, though differing in important particulars. While the urine of both may contain leucin and tyrocin, they are more constant in the former disease. Evidently the disease is rapidly diffused through the circulation, and future investigations will probably disclose a bacterial origin and nature.

**Chronic Pancreatitis and Pancreatic Cyst.**—B. B. DAVIS

(Omaha, Neb.) reported two cases, one of pancreatic cyst, the other chronic pancreatitis, both of which had previously been subjected to exploratory abdominal section, and the diagnosis of malignant disease of the pancreas made. In diagnosis, the clinical symptoms will have to be depended upon. Glycosuria, fatty stools and muscle fibers in the stools, which theoretically ought to be diagnostic factors, in pancreatic disease, practically have usually been found absent. In cases in which glycosuria was present, destruction of the islands of Langerhans has been found to exist. Cases in which infection is the causative factor, prolonged drainage of the gallbladder was recommended.

**Gunshot Wounds of the Stomach.**—J. W. ANDREWS (Mankato, Minn.) reported a case of a boy of 11, upon whom he had operated. The patient rallied from the shock, and did well for the first three days after the operation, when he began to fail, and died on the eighth day. A necropsy showed that death was from septic peritonitis. Since surgeons of international reputation do not agree as to an immediate operation, he prefers to accept that which may seem less conservative, namely, an immediate operation in all cases where it is reasonably certain that the stomach has been perforated.

**Fowler's Position in Abdominal Surgery.**—VAN BUREN KNOTT (Sioux City, Iowa) has employed this position in the treatment of cases of septic peritonitis, and he reported five recoveries from diffuse septic peritonitis. These successes were not consecutive, however, no two of them having occurred without an intervening failure. Brief histories of the five successful cases were given, as they are the only cases of diffuse septic peritonitis that have been operated upon by the author successfully. The Fowler position was maintained for 24 hours, unless some special reason for continuing it was present. He says that the head of the bed should be raised from 18 to 20 inches from the floor. He hoped that those present who had neglected to employ the Fowler position would be induced to do so, for he believes that it can do no harm, and in many cases will prove of much value.

**Old Irreducible Dislocations of the Shoulder-joint.**—A. F. JONAS (Omaha, Neb.) referred at length to the literature of such cases, and reported seven in his own practice. His method of dealing with these cases consisted chiefly of (1) manipulation, using the forearm as a lever, rotating outward and inward, abduction and adduction, never forgetting for a moment a possible accident to the axillary vessels and nerves, and the possibility of fracturing the humerus. (2) If this plan fails the capsule is incised, and all cicatricial tissue is extirpated. All muscular attachments that offer restraint are severed, the axillary vessels are protected with a broad, flat retractor, and the head of the bone is brought into place by means of an elevator, assisted by manipulation and traction. To avoid infecting the wound, in this last maneuver, it is advisable to firmly wrap the entire arm and hand with wet sublimate towels. Dry towels are liable to slip and become displaced, making it possible for the operator's hand to become infected. If the head cannot be replaced, then (3) the head of the humerus should be resected, an operation to be avoided, when possible, on account of the resultant flail-like condition of the arm, and yet must be done (a) when the humeral head and neck become too extensively stripped of their attachments, experience having shown that necrosis may occur in 16% of the cases; (b) when osseous union has occurred between the head and the ribs; (c) when, after a division of all restraining soft parts, the head rests against the point of the acromion process.

**End-to-End Anastomosis of the Popliteal Artery for Gunshot Injury.**—ALEXANDER HUGH FERGUSON (Chicago) gave a history of the injury, described the physical findings, and the operation which he did.

**Natural and Logical Treatment of Injuries of the Pelvic Floor Occurring During Parturition.**—WILLIAM E. GROUND (West Superior, Wis.) concluded that almost every woman during her confinement suffers injuries from which she does not recover unless she is subjected to a secondary operation for repair of lacerations of the pelvic floor; that immediate suture of apparent lacerations does not restore pelvic support in the vast majority of instances; that from one to two months after labor the woman should be subjected to a thorough examination and any relaxation corrected before it has had time to impair her health.

**Lung Surgery: Historical and Experimental.**—B. MERRILL RICKETTS (Cincinnati, Ohio) illustrated his lecture by lantern slides. His conclusions were: 1. Severing one or more of the larger pulmonary bloodvessels results in instant death. 2. If death does not result within a few minutes bleeding will be slow and gradual. 3. If bleeding is slow and gradual it may require hours or days to cause fatal exhaustion. 4. If death does not occur until after the end of the second day following severe bleeding infection is its cause. 5. All, or a part of the escaped blood, may pass through the opening in the chest into the bronchus or alimentary tract. 6. The blood may escape into the pleural cavity or cavities, pericardial or peritoneal cavity, or all, and thereby become concealed. 7. *Pneumonotomy.* More definite knowledge of conditions and symptomatology is necessary that surgery of the lung may be perfected and made more aggressive in general. 8. Abnormalities, congenital or acquired, must always be considered in dealing surgically with the lungs. 9. Atelectasis and apneumatosi should be cared for by relieving the compression by removing the cause. 10. The same surgical principles can be applied to the lung as other organs of the living body. 11. The bony chest may be opened

for exploration of the lung with as little danger as opening the abdomen, cranium, articulating capsule, kidney, liver, pancreas, spleen, stomach, gut, or hepatic duct. 12. Hermetically closing the chest is irrational, unscientific, and dangerous. 13. Closing the chest wound by any means does not prevent the escape of blood from injured pulmonary vessels into the pleural cavity. 14. All wounds of the chest wall, whether penetrating or nonpenetrating, should be treated aseptically and with reference to drainage. 15. No instrument or needle should be made to enter the lung tissue for exploration, or the removal of fluid, unless the bony chest has previously been opened. 16. Foreign bodies in the bronchia or parenchyma of the lung may be detected with a fine exploratory needle through an open chest, with the lung contracted. 17. Foreign bodies in the lung and bronchia, when causing serious symptoms, should be removed. 18. Some small foreign bodies become encysted and remain harmless. 19. The position of a foreign body in the lung changes with expansion and contraction of the lung. 20. Hemorrhage, when due to pulmonary tuberculosis, should not be allowed to become fatal without opening the bony chest, and the application of pressure by forceps, gauze or otherwise. 21. Bleeding of the lung from any cause will, in many cases, cease when the lung is allowed to contract upon itself, with an open chest. 22. Blood clots within the pleural cavity should be removed at the time they are discovered, whether infected or not. 23. Blood clots in the pleural cavity may become organized with or without adhesions of the parietal and visceral pleura, or they may become infected and cause more serious consequences. 24. Hemoptysis may be absent in the most severe lacerations of the lung. 25. If bleeding from larger pulmonary vessels results, forceps should be applied; if not, gauze should be securely packed in the cavity. 26. Drainage of pulmonary cysts of any character can be effected with the same success as in any other organ. 27. Incision for drainage should be done with or without the presence of adhesions. If without adhesions, the opening in the chest should be at the lowest point of the pleural cavity for drainage by gravity. 28. Many incisions of the lung may and should be made with and without even local anesthesia. 29. It is probable but a few that will necessitate the use of general anesthesia. 30. Abscess of any character and of any location in the lung should be found and opened. 31. Gangrene of the lung demands most radical surgical measures, such as opening the chest, drainage, and the removal of all necrotic tissue. 32. Polyps of bronchia seldom necessitate removal, but they may cause conditions which may require surgical intervention. *Pneumorrhaphy.*—1. Silk, silkwormgut and animal tendons are the most desirable materials for lung surgery. 2. Absorbable sutures and ligatures, as a rule, are not to be relied upon as to strength and durability. 3. Silk and silkwormgut may become encysted in the lung and remain harmless. 4. The tug, and a combination of the tug and tobacco pouch sutures constitute the most desirable ones for use in the lung. 5. Ligatures and sutures may be dislodged by sudden expansion of the lung due to sudden closure of the opening in the chest wall. 6. The blood vessels, bronchia and lung tissue should be ligated separately, great care being used not to include too much tissue of any kind in one ligature. 7. Needles to be employed in lung tissue should be round, with a rounded point. They should never have a sharp point or sharp edges. 8. Not all ruptures, punctures or lacerations of the lung require sutures, or any surgical intervention whatever. 9. Many lacerations of the lung without fracture of the bony chest can and should be treated by suture, compression with gauze or forceps. 10. Puncture of the lung from any cause, such as stab and gunshot, resulting in hemorrhage, should be treated by opening the chest and applying ligature or compression. 11. Rupture of the lung should be treated as a laceration. *Pneumonectomy.*—1. A portion of all of one lobe, or the entire right or left lung, may be removed without causing death. 2. For complete or partial lacerated portions of the lung, when severe, pneumonectomy is necessary and should be done. 3. Gangrene of the lung requires in many cases the removal of all necrotic tissue. 4. Hernia of the lung, when sudden and of but few hours' duration, should, as a rule, be amputated, and the stump fixed in the chest wall, as there is no sac. 5. Hernia of the lung coming on gradually has a sac, and should be returned to the pleural cavity, if possible, without amputation. *Pneumonopexy.*—1. This is the safest and most rapid way of dealing with the stump of lung tissue in the majority of cases necessitating excision for any cause. 2. Adhesions of the parietal and visceral pleura have without exception taken place whether there have been lacerated or incised wounds, with or without suture. 3. The degree of adhesion corresponds with the degree of injury. 4. Cysts of the lung of any character can best be drained through visceroparietal adhesions. In the absence of adhesions the wall of the cyst may be sutured to the edges of the opening in the chest wall, drainage to be at once accomplished or at some subsequent time.

SECOND DAY.

**The Pathology that Remains After the Nonsurgical Treatment of Peritonitis.**—H. D. NILES (Salt Lake City, Utah) states that 95% of all the survivors of the nonsurgical treatment of peritonitis are left with infection without the peritoneal cavity and adhesions within the peritoneal cavity. The greatest amount of infection comes from a sudden rupture of an appendiceal or tubal abscess, or a perforation of the stomach,

an intestine, or the gallbladder. The most virulent infection is either appendiceal or from a pyosalpinx, following a puerperal endometritis; the mildest is from a cholangitis, or a gonorrhoeal salpingitis. He believes that about 40% of the possessors of infection and adhesions suffer from recurrent attacks of acute and subacute peritonitis, and less than 1% from mechanical obstruction of the bowels. It is to the remaining 50% that he invited particular attention, for while it has been customary to point to these cases as sufficient proof of the efficiency of the drug treatment of peritonitis, he believes that all fair-minded, thoughtful observers are learning to regard the pathology these patients carry within their abdomens as responsible for much distress and many deaths that were formerly attributed to other causes, or physicians were unable to trace to any well-defined cause.

**Surgical Treatment of Tuberculous Peritonitis.**—D. S. FAIRCHILD (Clinton, Ia.) stated these conclusions: 1. If an intraabdominal focus of tuberculosis is diagnosed or is suspected, an abdominal section should be made with the view of a more efficient treatment. 2. If a chronic tuberculosis of the peritoneum with ascites is diagnosed, or believed to exist, a laparotomy is indicated as soon as it is found that medical and hygienic treatment has failed. 3. In fibrous tuberculosis of the peritoneum the same course should be pursued, and if cheesy degeneration has not commenced, or progressed too far, a certain percentage of recoveries will follow. 4. In acute tuberculous peritonitis, with ascites and high temperature, laparotomy is useless. 5. In extensive adhesive tuberculosis, with matting of the intestines, laparotomy is useless, and an attempt to separate the adhesions is dangerous in its immediate results.

**Injury to Nerves Following Fractures.**—A. L. WRIGHT (Carroll, Iowa) reported a fracture of the humerus through the middle third, with injury to the musculo-spiral nerve, or rather the incorporation of this nerve between the ends of the bone, or to its being caught and pressed upon by the callus thrown out during the reparative process. The literature is replete with cases reported in which various nerves, especially the ulnar and median nerves, have been severed by a stab or the falling of glass. The case he presented had the typical clinical picture of injury to a nerve found at the end of a siege with a fractured bone, and taught a very valuable lesson regarding the prognosis and treatment.

**Treatment of Nevi.**—JOHN P. LORD (Omaha, Neb.) said the hot water treatment of cavernous angiomas, as suggested by Wyeth, is under trial, and will doubtless have a place in the treatment of selected cases. The treatment of port wine marks by electrolysis is too tedious and painful for large areas. The results are not perfect in that they are seldom complete, and leave some scarring. The x-ray promises better, and hot air would seem to have possibilities. Electrolysis occupies first place in hairy nevi, and will probably continue to do so unless the x-ray will produce permanent atrophy of the hair follicles. The operation of excision of very large tumors will probably never be supplanted by anything less radical, and hitherto inoperable tumors are rapidly yielding to the control of the operators of the new century.

**Hypernephroma.**—H. L. HARRIS (Chicago) said that it is only during the last few years that knowledge of tumors of the suprarenal capsule has made any material progress. Previous to this period, tumors were variously described as adenomas, sarcomas, carcinomas, mixed sarcoma and carcinoma, endotheliomas, etc. The essayist referred to the literature of this subject, and after reporting a very interesting and instructive case presented the following conclusions: 1. The hypernephromas are tumors of adrenal tissue, and therefore probably neither sarcomatous nor carcinomatous. 2. Such tumors may or may not form metastases. When they do, they are distinctly malignant. 3. When they are within the kidney capsule, or have perforated it by extension, the kidney should be removed. 4. When they originate in the adrenal tissue proper, they are usually separated from the kidney tissue by a connective tissue capsule, and however much the kidney may be flattened or fixed to the tumor, a line of cleavage may usually be found which will allow of the kidney being separated from the tumor and saved to the patient.

**Two Cases of Acute Intestinal Obstruction Following Contusion of the Abdominal Walls.**—J. E. SUMMERS, JR. (Omaha, Neb.). In the first case there was traumatic paresis of the lower part of the small intestine following kicks upon the abdomen. The patient was a man, 26 years of age, and of good physical development. The second case was one of retroperitoneal hemorrhage following a contusion of the abdomen, resulting in a hematoma, which compressed the descending and transverse portions of the duodenum from behind, so as to cause intestinal obstruction. The patient was a rugged young man, 20 years of age, and a farmer by occupation.

**A New Method of Shortening the Round Ligaments Intraperitoneally for Retroversion of the Uterus.**—HENRY T. BYFORD (Chicago). The operation consists in folding the ligaments anteriorly, according to Dudley, but in stitching the loop to the abdominal parietes about opposite or behind and a trifle above the internal inguinal ring. The ligament is grasped with hemostatic forceps and pulled out of the abdominal incision until it is drawn as far out of the inguinal ring as possible without doing violence to the tissues. Then a medium-sized catgut suture is passed through the center of the ligament about  $\frac{1}{4}$  inch from the uterine end and the same suture is passed through the ligament about  $\frac{1}{2}$  inch from the internal inguinal

ring. The suture is then drawn tight and tied like an ordinary ligature, except that it includes only half of the ligament in its grasp. The inner edges of the loop thus formed should now be touched with a chemical irritant, such as Monsell's solution or 1:5,000 mercuric chloride, in order to destroy the endothelium and secure firm adhesions. The irritant is then wiped off and the edges sewn together by fine catgut, which entirely closes in and covers up the irritated peritoneal surfaces. The end of this fold is then touched with the chemical irritant and stitched forward beside the bladder about opposite and a little above the level of the external inguinal ring. This, of course, will be only a peritoneal attachment and should be rather high, because the peritoneum is held in place here rather loosely. Thus there are practically two round ligaments on either side, one going from the uterus partly through the first catgut ligature to the attachment behind the external inguinal ring, and the other from the uterus to the ligature and from there to the internal inguinal ring, etc. The uterine  $\frac{1}{2}$  or  $\frac{1}{4}$  inch, or inch, according to the place where the ligament is transfixed, is common to both of the newly-formed round ligaments. When there is a tendency to uterine prolapse he sutures the whole side of the fold of the ligament to the peritoneum beside the bladder, or even sutures the portions of the round ligaments external to the folds of the parietal peritoneum in front. When there is decided prolapse he also stitches the infundibulo-pelvic ligament forward, the fundus uteri itself, and even takes folds in the sacrouterine ligaments. When there is cystocele he separates the remains of the urachus with a narrow strip of peritoneum, and after loosely twisting the flap thus obtained and drawing up the bladder attaches the flap into the abdominal wound.

**Dermoid Cysts of the Intestinal Tract.**—WILLIAM JERSON (Sioux City, Ia.) reported an interesting case. The cyst occupied the anterior internal wall of the colon about three-quarters of an inch above the ileocecal valve. It was covered by peritoneum, through which the cyst wall was plainly manifest. It was removed by making an elliptical incision through the serosa and dissecting out the growth. Recovery was uneventful. In explanation of the development of congenital cysts in the intestinal tract, the following theories have been advanced: 1. Imperfect obliteration of the omphalomesenteric duct. 2. Torsion of a portion of the intestinal wall by the products of a previous peritonitis, etc. 3. By sequestration or implantation of epiblastic or hypoblastic structure leading to the later development of an ontodermoid or ectodermoid. The points of interest which these cysts have for surgeons are: 1. That in a large percent of the cases the cysts, although innocent in themselves, ultimately lead to a fatal issue, either through obstruction of the intestinal lumen, or because of their contents becoming infected from the intestinal canal, terminating in peritonitis. 2. If their removal is undertaken before such complications have resulted, a favorable termination can be looked for.

**Appendicitis: Operation and Indications.**—A. C. BERNAYS (St. Louis, Mo.) laid stress on the fact that we can know nothing definite about the pathologic process which would warrant delay in operating. We cannot know enough before opening the abdomen to warrant us in following an expectant plan. He believes many lives are lost because the physician is lulled into hopeful security by an amelioration of symptoms. The amelioration cannot be depended upon to last; it may change without a moment's notice into a sad picture of collapse and sepsis, and the favorable time for operation be missed. In so-called intermediate cases a waiting policy is justified because the system is immunizing and fortifying itself against the toxins. An operation after the body has been immunized, which means that the pus has been made less virulent, is less dangerous. Dr. Bernays thinks that an operation is likely to be less dangerous on the seventh or eighth day than on the third or fourth, but pleads strenuously for operation on the first or second day of the attack, and claims that 98% of all cases operated on at that early period will be saved. Operations done the first day or second day of the attack are as safe as interval operations. Most brilliant and satisfactory results followed prompt operations in cases of severe appendiciteal peritonitis.

**Hyperplasia of the Uterus.**—C. C. GEIGER (St. Joseph, Mo.) mentioned three distinct stages of hyperplasia, hyperemia, hypertrophy, and sclerosis. It is impossible to determine at the bedside exactly when the state of subinvolution commences to merge into that of hyperplasia, as it is a slow and insidious development. The two affections in clinical appearance resemble each other, and apart from the history, differentiation is difficult. Chronic hyperemia and hyperplasia may involve any portion of the uterus, neck or body, or certain portions thereof. For manifest reasons the neck of the uterus is the favorite focus of disease. The treatment of the various conditions of enlargement is so dependent on their causation that each individual case demands a separate investigation. The ideal way of approaching this subject lies in the direction of prevention, which in a great many cases the attending physician is able to do. But gynecologists must meet the disease already developed and devise methods which, if not curative, are palliative. Iodin and caustics in the hands of the essayist have not been of much service. He believes that caustics do more harm than good. In neurotic patients nothing is better than a change of climate and scenery. In some cases a change in the surroundings accomplishes much good. The patient should be given rest, the cause removed, the diseased organ depleted, and, if possible, the patient's general health improved.

## CLINICAL NOTES AND CORRESPONDENCE

[Communications are invited for this Department. The Editor is not responsible for the views advanced by any contributor.]

## TREATMENT OF HEMOPTYSIS.

BY

H. A. HARE, M.D.,  
of Philadelphia.

To the Editor of *American Medicine*:—I have read with interest the posthumous article of Dr. Fenn upon the treatment of hemoptysis in the issue of *American Medicine* of December 27, because of the importance of the subject and the fact that it was written by one who had personal experience in this dangerous complication of pulmonary tuberculosis. In the course of Dr. Fenn's article the statement is made that I recommend ergot in the treatment of this condition. Evidently the sentence which is quoted is an imperfect one, so I am unable to trace its origin; but as this statement is in direct antagonism to what I firmly believe I take the liberty of quoting the following paragraph from the article on ergot in my book on therapeutics and another from that upon hemoptysis in the same volume:

"In hemorrhages from the lungs and kidneys or other unapproachable parts ergot is thought by some to be very useful when given by the mouth, but it is improbable that it really achieves any real good. Particularly is this the case in pulmonary hemorrhage, since the vasomotor system practically does not exist in the pulmonary vessels, and the increased pressure caused by the ergot in the general systemic circulation may increase the pulmonary leakage. The truth is that in pulmonary hemorrhage very little real good can be obtained by internal medication, and again, the life of the patient depends in reality more upon the rapidity with which a clot naturally forms than upon the skill of the physician. Some physicians advise that the patient should swallow 1 to 1.5 drams of the fluid extract of ergot, but it is difficult to understand how it can be of service."

My object in writing this note is, therefore, not to call attention to an error in quotation in Dr. Fenn's article, but to emphasize the fact that when hemorrhage takes place from a bloodvessel of any size, ergot is not only powerless, but may do harm. In capillary and uterine hemorrhage the proposition is quite different, and here, of course, it is of great value.

## AN IMPROVED ROUND-POINT NEEDLE FOR INTRA-ABDOMINAL USE.

BY

GEORGE ERETY SHOEMAKER, M.D.,

Gynecologist to the Presbyterian Hospital, Philadelphia.

The development of abdominal surgery, and especially conservative surgery, has brought out many occasions for sewing in soft and vascular tissue. The uterus, tube, broad ligament, bladder, ovary, meso-appendix and the mesentery, the kidney, liver, and stomach are frequently stitched nowadays, while there is no better way of checking troublesome bleeding anywhere in the depths of a wound than by a catgut stitch beneath the oozing point. Indeed it is the proper use of the catgut stitch which makes possible the dry closure of the abdomen without drainage in many cases of modern surgery. A needle which has a cutting edge is undesirable for this work. Its puncture may bleed. It often cuts too widely.

The full curved needle with round shank and without a cutting edge has been used somewhat for this work, but when grasped by the necessary needleholder it has proved unreliable and apt to shift or roll at a most critical time, especially when the sewing is done deep in a dark, narrow, blood obscured cavity. To make this grasp more secure the writer has had needles made with the half toward the eye flattened a little. This does not alter the character of the round puncture, as it does not make a cutting edge, but it does facilitate sure con-

trol. As the *straight* round-point needle can be best used without a holder the flattening is not required. When the part is readily accessible the ordinary ladies' straight sewing needle with an oval eye cannot be improved upon, especially for bowel sewing. No full curved needle, however, can be used without a holder, especially deep in a narrow cavity. Therefore the need for the improvement described.

A word as to a suitable holder for full curved needles. The essential feature is that the beak or jaw must be narrow, particularly for small-sized needles, otherwise so long a curved section is grasped that breakage of the needle is favored. The well-known Reiner needleholder, the jaws of which are here figured,

admirably suits this purpose. It may be used for the half-inch needle as well as for the largest sizes. If the round point needle is flattened where grasped the necessity for using a broad jawed holder in order to get holding power is eliminated. The making of needles appears to be an industry new to America. The J. Ellwood Lee Company appear to be the only manufacturers of surgical needles in the United States. They have listed four sizes of the improved needle described and illustrated.

## INSUSCEPTIBILITY TO VACCINATION.

BY

S. SEILIKOVITCH, M.D.,  
of Philadelphia, Pa.

To the Editor of *American Medicine*:—Last year a patient came to my office to have his child vaccinated, stating that she was unsuccessfully vaccinated six times by four different physicians, and that her teacher would not let her come to school. Had she been vaccinated by the same physician, I should have suspected either that the technic of the operation was at fault, or the virus was no good. I vaccinated her in the usual way, and, as it did not take, in 12 days I revaccinated her, again unsuccessfully. I gave a note to her teacher stating that the child was "immune," but she was still refused a seat in school. The child's father asked me to try once more. Being sure it would not take, I refused, but I advised him to bring the child in two weeks, tiring her out by fasting for five hours and a long walk before entering my office. I vaccinated her the ninth time, and at last I got the "split pearl on the rose leaf." Now, why did it not take the first eight times, or the seventh and eighth times, when the virus, operation, and precautions were the same as in the ninth time? I, myself, was vaccinated last year five times with different "brands" and none took. Why is it? I have seen a case in which a healthy child was with his brother, who had scarlet fever, in the same room for two days, playing and eating, and he did not catch the disease. The same healthy child a year later contracted scarlet fever, after being for a half-hour in the sick-room of his relative. Another child, suffering from diphtheria, spat a piece of membrane in his mother's mouth; she rinsed her mouth with plain water and did not suffer in the least; eight months later she contracted the disease from her other child, though all precautions were taken by her.

Adults do not contract chicken pox, measles, diphtheria, and scarlet fever so easily as children; we find in the nose, throat,

and mouth different pathogenic germs; to-day we are well, to-morrow we develop any special disease these special germs may produce. Do we not say we are "insusceptible" or less susceptible to measles or chicken pox? and, vice versa, that the pathologist says: the soil is not fertile for the growth of the given germ; well enough! but to-morrow, or some other time, for some reasons, the soil may change, and the pathogenic bacteria find it suitable for their development; so we see the same individual at some time may, at other time may not be susceptible to the same disease. Whether the explanation of "susceptibility" we base upon Metschnikoff's theory of phagocytosis, or germicidal action of the blood plasma, or other theories, matters very little. That worryment, an exhausted mental or physical state, etc., predisposes one to be more susceptible to diseases is also a fact. Now, why not in the same way think of "insusceptibility" to vaccination? I do not see any line of demarcation. In my case, the child was "insusceptible." By tiring her out I depressed her vitality, thus lessened the power of resistance to the vaccination and made her less insusceptible. How much less or how much more susceptible, I could not say before seeing the result of the *ninth* vaccination. If in a given case the vaccination does not take, say, the first three times, "*Vaccinate until it will*" is not good reasoning, as we do not know when that "*until*" may come, and so we may "*scrape*" the individual more than nine times with the same result. The question is, whether the one who is insusceptible to vaccination is also insusceptible to smallpox? It must be so, so long as vaccination is a protection against smallpox! And in the bank cashier's case (*American Medicine*, p. 957) "who tried four times and then trusted to the theory of insusceptibility . . ." and "died on the seventh day . . ." I do not see any proof, and any illustration to disapprove "insusceptibility to vaccination."

Taking for granted that the vaccine lymph was fresh and good, and the operation was performed *lege artis*, it is a question how soon after his fourth trial he contracted smallpox (we know on which day he died) and in what state of health was he at that time. We know that even natural immunity may be temporarily destroyed; take, for instance, the exhausted white rat and anthrax; we know that acquired immunity is not constant—immunization with diphtheria antitoxin will hold good not longer than four or five weeks.

## REPORT OF THREE UNIQUE CASES OF APPENDICECTOMY.

BY

ANDREW B. GLONINGER, M.D.,  
of Lebanon, Pa.

The following is the record of what is, perhaps, the youngest subject upon which the operation of appendicectomy has been performed:

CASE.—Congenital umbilical hernia in a male child. The child was delivered October 7, 1902, after a normal labor, by Dr. James Harris, of Jonestown, Pa. When about to ligate the cord he noticed what seemed to be an enlargement at the base, but on holding it up before the light a coil of intestine could be seen distinctly. I saw it in consultation 12 hours later. The tumor was increasing in size, the place was ten miles in the country, and there were no instruments at hand with which to operate, so a trial of gentle taxis was made, resulting in a partial reduction of the hernia. A compress and binder were applied to prevent its return. The next morning I went prepared to operate. The patient was then 41 hours old. The hernia had enlarged very much during the night in spite of the compress, and was dark in color with an offensive discharge from the stump of the cord. The prognosis was very grave. Strychnia sulfate .5 mg. (1/120 gr.) was administered hypodermically and the dose repeated during the operation. Fearing to injure the child if it struggled, it was decided to anesthetize it, using plain ether. The sac was opened the entire length. A considerable amount of dark fluid escaped. The intestines were spread out over the abdomen. The greater part of the small intestine, the cecum, the transverse colon were contained in the sac; all were highly congested and almost black in spots. The appendix, two centimeters in length, stood up straight and stiff and was also inflamed. The intestines were firmly adherent to the sac and were freed with difficulty; the hemorrhage was checked with hot salt solution. Upon enlargement of the ring instant

relief of strangulation was shown by the restoration of the normal color. The appendix, which had no meso-attachment, was excised, and the opening closed with a suture of fine catgut. The sac was cut away and the peritoneal cavity also closed with fine catgut. The umbilical vessels were ligated, but there was troublesome oozing from the surrounding tissue. This was controlled by adapting the skin surfaces with Thiery's clamps. The child reacted quickly, was given brandy grt. xv in 2 drams of hot water, which it swallowed readily. The next day the temperature rose to 102°, but was quickly reduced by the application of an ice poultice to the abdomen. The clamps were removed on the fourth day, the wound was entirely healed, and the child's health normal.

In contrast to the above, on the same day, by a curious coincidence, I operated on a man of 67, at the Good Samaritan Hospital, of Lebanon, Pa. I found a general adhesive peritonitis with an enormously enlarged appendix filled with fecal concretions. In this case also I used the Thiery clamps for an external suture, resulting in perfect union in one week.

On January 22, 1900, I was called in consultation by Dr. Chas. Strickler, of Lebanon, Pa., to a woman in the fifth month of pregnancy who presented all the symptoms of acute appendicitis with obstruction. She was removed at once to the Good Samaritan Hospital and prepared for immediate operation. Incision in the right iliac revealed local peritonitis, which had formed a mass of adhesions, from which the engorged appendix was released with difficulty and excised. Two inches above the ileocecal juncture the caliber of the gut was constricted by a strong band and an impaction of fecal matter at that point caused an entire obstruction. The adhesion was freed and the impaction relieved by manipulation, the bleeding points were ligated and the cavity irrigated with hot saline solution. The deep tissues were adapted by continuous sutures of fine catgut, the external with silk-worm-gut. The patient made an uneventful recovery and was discharged from the hospital in three weeks. Four months later she was safely delivered of a healthy female child.

## SECONDARY HEMORRHAGE OF THE UMBILICUS.

BY

RAMON D. GARCIN, M.D., A.B.,  
of Richmond, Va.

President Church Hill Medical Association.

I desire to place on record the following case, as I have never in my experience in hospital and private practice had one like it, and I have officiated or assisted in upward of 1,000 obstetric engagements:

October 23, 1902, I delivered Mrs. P. of a healthy boy after a natural labor. The case progressed satisfactorily, the cord coming off October 29, 1902 (there was no oozing even from the cord after it was first tied), and the surface underneath was smooth and healthy. October 31, 1902, at 6 a.m. I was hurriedly summoned with the information that the infant was "bleeding to death." On arriving I found the baby just alive. The hemorrhage was controlled promptly with a compress of sterile gauze saturated with a solution of suprarenal extract; hot salt solution was given by rectum; brandy, etc., were tried with no effect, death occurring in a few minutes. The nurse informed me that she dressed the baby at 9 p.m. October 30 after an action; examined the umbilicus and there was no hemorrhage. The hemorrhage was not observed till I was summoned, the father discovering blood on the bed on arising to go to work. The baby literally bled to death from secondary hemorrhage of the umbilicus, due to detachment of a clot of blood over the seat of the artery. Its occurrence so late after birth is unique in my experience.

## A TREATMENT OF TYPHOID FEVER BASED UPON THE SUPPLY AND DEMAND OF THE ANIMAL ECONOMY.

BY

CHARLES FRANCIS, M.D.,  
of Brooklyn, N. Y.

The demand of the animal economy in typhoid fever is based on the diminution of taurin and glycozin with their producers. The chemicals that produce taurin are sulfonic acid, alcohol and ammonia turning into amidoethylsulfonic acid. To produce taurin in the economy, mix sulfur and potassium nitrate equal parts in a capsule, this, in contact with alcohol and ammonia, produces taurin. In this disease there is a sufficiency of ethyl alcohol and ammonia in the body, therefore it is not necessary to add them. Glycozin is produced by acetic acid, chlorin and ammonia. The chemicals most dimin-

ished in proportion that produce glycozin are chlorin and acetic acid, when ammonia is present in sufficient quantity, to produce glycozin, acetic acid dilute and chlorin water (separately). The production of these chemicals, or proximate principles, is in accordance with the law of abhorrence of rest. Nature is ever willing to work, or help herself, if the proper conditions surround her. The compounds taurin and glycozin should be added to the economy on the law of demand. All chemicals and compounds beget their kind by preventing the production of the opposing ones. Hence, if a chemical, etc., is overproduced the system is out of equipoise; when this equipoise is displaced, chemical changes arise that we call disease; his equipoise sets up conditions necessary for living organisms; or else produces chemical changes again in the organism. I presume some will question, How does this overproduction and underproduction take place? By ingesta, environment and also animal activity. In using the proximate principles or producing them in the animal organism, give or produce them at short intervals. The best method of using producers of glycozin and taurin is:

Potassium nitrate, .3 gram (grs. v) } chlorine water,  
Sulfur, .3 gram (grs. v) } 2 to 4 cc. (5½ to 51)  
To make one capsule.

Dilute acetic acid.....15 cc. (3½)  
Capsules first two hours; chlorine water the next two hours. Dilute acetic acid in between.

Also I use vinegar and water baths. This treatment I use for 72 hours and as a general rule convalescence is produced. On this line of philosophy I have practised medicine for some years, believing a physician is an assistant to nature in overcoming disease. What better assistance can be given than what nature most craves?

## THE GAUZE TAMPON IN POSTPARTUM HEMORRHAGE.

BY

R. E. SKEEL, M.D.,  
of Cleveland, Ohio.

An article appearing in *American Medicine* of August 2, 1902, by Dr. J. F. Baldwin, in which the question is raised as to the value of the gauze tampon in postpartum hemorrhage, invites reply. Many of the criticisms therein contained are unquestionably true, and after some experience, both in the use of this and other means of controlling hemorrhage after delivery, the following statements are felt to be at least approximately correct: Postpartum hemorrhage, as is well known, may arise from two sources: First, a deeply lacerated cervix, and second, failure upon the part of the uterus to contract and thus close the vessels emptying into the placental site.

In the absence of proper facilities and surroundings for suture of the cervix a firm vaginal gauze packing unquestionably exerts enough pressure, and sufficiently contributes to the formation of clot by removal of serum to enable one to control completely hemorrhage due to deep cervical laceration. Bleeding from this source is far more common than is generally recognized. I think I am perfectly safe in asserting that intrauterine gauze tamponade alone and unassisted by other measures never could control the worst form of postpartum hemorrhage from a large flabby uterus whose power of contraction appears to be entirely in abeyance. Neither can it be applied with sufficient rapidity and thoroughness, under these circumstances, to be of any avail; but there is a class of cases in which, after the primary hemorrhage is controlled and the uterus has been made to contract, relaxation and renewed bleeding take place so soon as the method of stimulation of the uterus, whatever it may be, is discontinued. In just these cases there is no furious haste, and sufficient time can be taken to proceed methodically and aseptically to pack the uterus, and it does not need many square yards of gauze to accomplish the end desired. In other words, one method of stimulation, whether it be hot water, pressure of the hands, or friction over

the fundus, which cannot be continued indefinitely, is substituted by another one, gauze packing, which can be continued for an indefinite length of time without special discomfort to the patient or undue tax upon the physical powers of the attendant.

I think that no one would seriously insist that this method is one of checking hemorrhage by pressure, but rather a strictly physiologic one of stimulating the uterus by the pressure of a foreign body in its cavity. Gauze packing in the pelvic cavity checks bleeding in another manner also, that is, by keeping that cavity dry, and it probably acts in the same manner in the uterus, draining out the serum and retaining the fibrinous portion of the blood to clot and assist nature in thus occluding the mouths of the uterine vessels. This method of controlling bleeding is not such a contradiction to the old and well-tried dictum to remove all clots and fragments from the uterus, as it might seem. The criticism is sometimes made that we simply substitute one foreign body for another equally as bad. Blood clot in the uterus does not cause severe hemorrhage and when such clot is removed the good that is done is not so much by the removal of the clot as by the irritation of the agent removing it. Another factor still more important is that severe hemorrhage is frequently caused by the retention of a portion of placenta, acting not as a foreign body, but sufficiently adherent to the uterine wall to prevent retraction of the contiguous denuded placental site and when the blood clot is removed the placental debris comes with it. A loose piece of placenta or blood clot does not cause free bleeding unless large enough to prevent symmetric contraction of the uterus. It rather causes uterine contraction, as witnessed by the severe after-pains under these circumstances as well as the relief obtained after removal. Accidental hemorrhage without rupture of the membranes is in no way a parallel case, as the question here is entirely one of intravascular versus intrauterine tension. No uterus after labor is as large as a full-term uterus, and there is always some diminution in the caliber of the vessels after delivery even with the most severe bleeding.

I do not entirely agree with Dr. Baldwin that operative obstetrics is a part of the practice of surgery but insist rather that obstetrics as a whole is a surgical specialty and should be taught as such. Making operative obstetrics a part of general surgery leads to the performance of hysterectomy and ablation of the tubes and ovaries following cesarean section for minor degrees of contracted pelvis when other measures could as well be utilized for sterilization if necessary, without depriving the patient of healthy organs necessary for her physical and mental welfare. It is general surgery also which ignores the fact that induction of premature labor, in the future will render such mutilation unnecessary in any but marked forms of contraction. The great mass of obstetric practice is in the hands of the family physician and when he recognizes the fact that operative interference is necessary an operator is apt to be summoned who has the greatest number of amputated legs to his credit and thus the patient finds herself upon both horns of the dilemma which presents itself, a regular attendant without specialized surgical knowledge and a surgeon without specialized obstetric knowledge. Teaching obstetrics as a surgical specialty would obviate this difficulty and the practitioner who found himself unable to deliver by the ordinary method would then know not only what should be done but how it should be done, even if he is unable to do it himself.

The greatest good done by this teaching would be in the thorough inculcating of a knowledge of the principles underlying the practice of surgical asepsis and a consequent banishment from the lying-in room of the lard dish, vaselin jar and douche bag and their replacement by the hand brush, rubber gloves and sterile dressing material.

"Medical Library and Historical Journal."—The first number of this new publication, "Devoted to the Interests of Medical Libraries, Bibliography, History, and Biography," will appear on January 15. It will be the only magazine published in the English language devoted to the subject of medical history. A bibliographic feature will be the publication of a complete index medicus of every current medical book, both English and foreign. The journal will be published quarterly.

## ORIGINAL ARTICLES

THE TREATMENT OF EPILEPSY BY THE GENERAL PRACTITIONER.<sup>1</sup>

BY

WILLIAM P. SPRATLING, M.D.,

of Sonyea, N. Y.

Medical Superintendent of the Craig Colony for Epileptics; Secretary of the National Association for the Study of Epilepsy and the Care and Treatment of Epileptics; Member of the American Medical Association, New York Academy of Medicine, New York County Medical Society, American Medico-Psychological Association, Rochester Pathological Society, Buffalo Academy of Medicine, etc.

## EPILEPSY CURABLE IN MANY CASES.

I have no hesitancy in declaring that epilepsy is curable in many cases if taken in time and an accurate course of treatment laid down in the most minute detail and faithfully observed a sufficient length of time in every case; nor can it be denied that the privilege and duty of treating the disease when most can be done for it in a medical way belongs oftener to the general practitioner than to any other class of physicians.

First of all, we ought to remember that recent convulsions in themselves do not necessarily imply the presence of epilepsy. Nor do we think it best to speak of such convulsions at first as epileptic, but rather as epileptiform, telling the patient that he may not yet have the genuine disease. At the same time, we ought to remember that all convulsions, no matter how simple or what their cause, are to be seriously regarded, and that treatment once begun should in no case be discontinued under two or three years.

Habit epilepsy is universally recognized; that is, a convulsion having once occurred may, under the most trivial provocation, recur time and again until the final establishment of the true disease.

## THE TWO PRIMARY CAUSES: HEREDITY AND STRESS.

The only true philosophy in the treatment of any disease lies in trying to recognize and remove the cause, and if we cannot find out the first time we examine an epileptic patient the cause of his trouble, we ought to keep repeating the examination until we do, for we may rest assured there is one.

The primary causes of epilepsy are just two, heredity and stress, and we broadly characterize the manner of their action by saying that heredity always acts first from the brain; stress, toward the brain, being in one primarily central, in the other primarily peripheral.

Heredity is of two kinds, similar and dissimilar; the former meaning that the potentialities of epilepsy descended from parent to child; the latter that alcoholism, insanity, tuberculosis, chorea, and diseases of a like character were changed in type in transmission from parent to child so as to appear as epilepsy in the latter.

Similar heredity is the cause of the disease in about 16% of all cases, while dissimilar heredity causes it in about 40% of the rest, making a total of 56% due to heredity.

For ease of illustration we divide the second great cause, "stress," into two forms, initial and mechanical, placing under the former all cases in which the cause originated within the individual as the result of some act on the part of that individual, such as taking a chemically poisonous drink, drinking too much alcohol, producing an intestinal ptomain from improper food, the acquisition of syphilis, etc.; the second, or mechanical, acts of violence suffered beyond the control of the individual, such as hemorrhage or tumor within the brain, thrombosis or embolism, or a blow that injures the skull in a manner to interfere with the functions of the brain.

Now let us note for a moment the amount of influ-

<sup>1</sup> Read before the Keuka Lake Medical and Surgical Association, Keuka Lake, N. Y., August 20, 1902.

ence that has to be exerted by each to produce epilepsy in a given case, and take for the purpose a girl or boy who is passing through the disturbing epoch of puberty and whose parents had epilepsy, and let us say that the acquiring point—the point at which the patient acquires disease—is represented by 75, 50% of which is already present under heredity, it is easy enough to see that 25% of added strain or "stress" will bring to light the disease to which the system is already attuned—already ripe for, because its elements were in the child at its birth.

Or, on the other hand, suppose we take a child of 6 or 7 years, of good heredity and vigorous health, and whose resisting power is 100; it would require the full stress of the poison of one of the specific fevers, like measles or scarlet fever, to bring on the disease, all of the cause in this case being under stress, heredity having nothing to do with it. But if the parent of that child had been alcoholic, or insane, or infirm from some other neurotic disease, less would be required of stress, because heredity had already done its work in lessening the child's powers of resistance.

So plain, indeed, is the action of the principle here involved that we may formulate a law of origin—not an absolutely accurate one, to be sure, but one that will do for a working basis—something like this:

Epilepsy being always due to two primary causes, heredity and stress, its immediate development will depend either on the action of great stress in cases of little or no heredity, or on little stress in cases of great heredity.

## IMPORTANCE OF HEREDITY.

So firm, indeed, has become my conviction concerning the part played by heredity in epilepsy that I deem it of the utmost importance to look carefully for it in some form in every case that arises, knowing that if it can be excluded the chances of cure are infinitely greater, and that if it is present the knowledge will greatly aid in treatment, and in giving a prognosis when one is required.

The first thing, therefore, I would urge is that a systematic attempt be made in every case to find out two things:

1. What is the cause of the disease in this case? Is it heredity in greater part, or stress in greater part?

2. If it is stress in greater part, what is the stress, what its form of action, and how soon can it be removed? If it is heredity in greater part, what is its form? And so far as I am aware at this time, the best way to get this information is through the use of some questions covering the patient's family history, his personal history, and the history of his disease, combined with thorough personal examination of the case.

The questions in the blank we use at the Colony are so formulated that specific information is obtained on points that the patient or his friends under direct questioning might evade or deny; and we believe the use of some such form by physicians generally would be useful both for treatment and for the preservation of valuable scientific data.

## THE COMMONER FORMS OF STRESS.

To enumerate in detail the causes under stress in such a paper as this is out of the question, for they range from emotional shock to the grossest animal indulgences; but I think we are prone oftentimes to overlook the little thing actually causing the disease for the big thing we feel ought to cause it.

A man once came under my care in a State hospital who had marked delusions of persecution: he heard people talking about him all the time, threatening to kill him, and to burn his house. On testing his hearing it was found defective on one side, and when the ear was washed out with a warm soap solution several pieces of hard, dried tobacco as large as a grain of corn came away, with the result that the voices ceased in 24 hours, and some months later, when the man was discharged, had not returned. Here was the strongest possible demonstration of the

connection between a very simple material cause and a far-reaching, disastrous effect.

A woman of 37 entered the Colony with a history of epilepsy since about the time of puberty. Her ancestry was good and the disease had not affected the mind. A careful examination showed the uterus to be impervious, the menstrual flow appearing vicariously, mostly in the groin. The uterus and ovaries were removed without incident, with the result that for 2½ years now she has not had a seizure, and I believe she is permanently cured.

A man of 28, who had been an epileptic of the very worst type for 18 years, was admitted to the Colony in February, 1896, having twice been committed to hospitals as insane and twice discharged as hopeless—incurable.

During the 18 years his attacks averaged 110 to 125 a month. He had been dosed with the bromids so long and liberally that he was suffering from what might be termed bromid dementia. He was listless, inert, and without ambition; feeble, emaciated, quarrelsome, and fault-finding in disposition, and had numerous unstable delusions. He also had a slight limp, due, we found out, to a partial exhaustion paralysis, and not organic. After repeated examinations we could not find he had any organic disease of any kind, and based his treatment on the belief that he was having convulsions because he was systematically poisoning a naturally weak system, further vitiated by long neglect and unhygienic habits, with improper food. There was an utter absence of the nutritive rhythm.

He was put under vigorous treatment against his will, and at once began to improve, his progress soon exciting his interest. During the first month he had 110 attacks; the second, 98; the third, three, and during the two remaining years he lived at the Colony did not have another convulsion.

He left the Colony 4½ years ago, cured, and has remained entirely well ever since, and is now supporting himself and his mother as a printer, a trade he learned at the Colony while he was under treatment. It is only fair to add, however, that he still lives the abstemious life he learned at the Colony, and which he is compelled to live in order to keep well. Should he ever go back to the old manner of living he would almost surely be an epileptic again.

A strong, vigorous, professional man of middle age consulted me five years ago for what he termed "fainting spells," that came on only in the morning after he had indulged too liberally in good things to eat and drink late the night before. I warned him to let alcohol alone, telling him that so often as he applied the match the powder of badly balanced nervous energy would explode; but he kept right along dissipating and suffering the same way after each spree, until he had two or three attacks in one day in a place that embarrassed him exceedingly. Then he quit his bad habits, submitted to proper treatment, and for three years now has been perfectly well.

There are today a number of adult male epileptics at the Colony who have no convulsions simply because they can get no alcohol.

When a man of middle age, who seems robust and well-to-do and to enjoy life generally, comes to you for "fainting spells" he never had before, you may set these spells down in 75 cases out of a 100 as being due either to alcohol or syphilis, or both, and you will find that proper treatment will bear out the assumption as to cause every time. Further than this, if you can get the faithful cooperation of the patient in carrying out treatment, you can look for the most flattering results.

These are fair illustrations of the commoner forms of stress acting at the middle age period of life, and about 20% of all cases belong to that period; for 80% or more of them all begin long before middle age. Such accidental forms of stress as lead poisoning, injuries to the skull, etc., need only be mentioned, and the same is true of the changes in the blood and central systems that come late in life and cause the rather infrequent forms of old age epilepsy.

#### THE MORE ACTIVE CAUSES IN EARLY LIFE.

Now, let us look for a moment at the causes most active under 20, and we have just noted that 80% or more of them come before that period.

It is in this class of cases that heredity shows its hold; for, as a rule, inherited cases come to light early, and it is safe to say that 80 of the 100 persons under 20 who have epilepsy have it more from the results of heredity than from any form of stress. But this still leaves 20 out of every 100 under 20 years of age in whom it is due to other causes, and the causes here are the same to some extent as later in life, including disturbances in the nutritive system, accidents to the brain, the specific fevers that belong to this period of life, and cerebral

palsies, which latter alone is active in about 10% of all cases.

If you want to do much of value for the epileptic whose disease is largely the expression of some inherited taint, you must begin with him literally at the hour of his birth; and I venture to say that when the time comes for us to sum up the exciting causes of epilepsy in a fairly conclusive way we will find that accidents at birth play a part far in excess of the importance we attach to them now.

So firmly does Dr. Abram Jacobi feel that asphyxia of the newborn sometimes causes epilepsy that he aptly advises that in postpartum hemorrhage, where the child at the same time is threatened with asphyxia, that the doctor "sit on the woman's abdomen, if necessary, to check the bleeding while he uses both hands in resuscitating the child."

Some day, too, when surgery has gone a step further in its marvelous advance, the general practitioner will call on the surgeon to remove bloodclots from the brains of young children that occur with such distressing frequency, and that now go unrelieved only to cause painful bodily deformities, epilepsy, and other affections of the mind that generally last through life.

In 1,070 cases admitted to the Craig Colony, 117 had epilepsy as the result of a brain palsy, and while none of them have been entirely cured, many have been vastly improved.

The thing to do, it seems to me, and as I hope we some day shall, will be to remove bodily the clot from the brain before that organ becomes permanently impaired, and it would seem to us that the initiative in this matter will have to come from the attending physician—the general practitioner—he being the supreme family medical adviser in the case at the time. And while speaking of the child's liability to epilepsy at this early period, do not forget that of the mother, for puerperal infection, phlebitis, and other causes produce the disease in the latter, and the general practitioner may in such cases prevent as well as cure.

#### PRINCIPLES OF TREATMENT.

Because of the time limit on this paper I cannot possibly specify all the things of value in the treatment of epilepsy, but will try to state what seems to me to be the true principles that should govern our efforts at cure in every case, summarizing them briefly as follows:

1. We should consider every patient that comes under our care a particular case in its own right, and institute a searching examination along the lines above specified, that we might bring to light the especial cause in each case; then set out to treat the patient and his disease as a unit, as one and the same thing, never dissociating or separating the one from the other; never, for instance, giving the bromids simply for the fits and doing nothing for the individual, whose moral and physical stamina is so frequently impaired and even destroyed by the remedy itself, and which, after all, in my opinion, only smothers or suppresses the attacks for the time being, never effecting a cure unaided.

2. Before writing a prescription for medicines of any kind, write out a dietary for each case and make the patient stick to it absolutely, if possible. It won't pay to give general directions in this matter. The patient must clearly understand what he is to eat at each meal, and he ought to have a printed card as a general guide, with stated things for breakfast, dinner, and supper, the principle of epileptic dietaries being the use of bread-stuffs, eggs, milk, butter, fruits and vegetables, to the entire exclusion of rich, highly-seasoned things, pork, veal, pastry of all kinds, and all drinks that have an alcoholic basis. The diet card we use also has a place for keeping a record of all seizures, specifying each kind on the date it occurred.

3. For more than 50 years the bromid salts have been more largely used in epilepsy than any other single

remedy, but in all earnestness I again give it as my firm belief that this drug unaided never yet cured a case of genuine epilepsy.

That the bromids have a place of value in brain therapy I do not deny, especially when rationally administered, and given in this way they may even do a great deal of good. I think the practice of giving epileptics doses of 30 to 40 grains of potassium bromid three times a day in a routine way altogether wrong, and especially so when we fail to make any effort to counteract the poisonous effects of the drug on the system generally, being chiefly interested in the temporary suppression of the convulsions.

Illogically used, the bromid salts impair and may even destroy the mind, cover the body with unsightly sores, destroy the functions of the digestive apparatus, the one function in epileptics above all others that should be kept in proper condition, and produce general disorders that recent methods of administration have taught us how to avoid.

If we want to use bromids it is best to employ either the hypochlorization method, that is, to withdraw all salt from the patient's food, salting it with any one of the bromids, preferably sodium bromid, or use bromipin, which is a 10% solution of pure bromin in the oil of sésamum, the former method being much the less expensive of the two, the cost of the latter being considerable.

Bromipin does not produce acne; does not impair the digestive or assimilative functions in any way; does not suppress or pervert any of the faculties or functions of the mind or body, and with it all is a very good reconstructive in feeble and run down cases if given in the form of an emulsion. In rare cases it may be worth while to try some of the coal-tar derivatives in conjunction with the bromids, but generally they will prove a disappointment.

I recall several cases in which *solanum carolinense* (horse-nettle berries) worked remarkably well after about everything else known had failed.

The Fleischzig treatment that seemed at first to promise much has had its day, and never in our opinion had much value, because it was based on the belief that epilepsy could be cured in a few months' time.

Besides the drugs and the employment of other measures that seem especially to suppress convulsive phenomena there are a host of others that act beneficially in correcting conditions that may underlie the disease, and which ought to be used under these principles:

If the heart is weak or diseased, treat that particular organ.

If the kidneys are faulty in action, try and make them right.

If the eyes under careful examination of a good oculist show refractive or other errors they should be effectually and permanently corrected, but not through surgical intervention.

The use of proper glasses should be educational to the eye and to those parts of the brain that periodically discharge or explode under slight abnormal stimuli.

If there are foreign growths in the nose, remove them.

If the patient has a phimosis or a stricture of the urethra, correct it.

If the stomach and intestinal tract are in disorder, take prolonged and especial pains to correct both, for along this tract, beginning with the stomach and ending with the rectum, lies the cause through bacterial and ptomain poisoning of many cases of epilepsy.

Intestinal lavage and the free use of internal antiseptics will do wonders in selected cases, but even in these it is best to begin with the proper diet and so avoid the need for such treatment later on.

Finally, combat with appropriate treatment every ailment that can be discovered, keeping the patient mentally and physically employed all the while and

not permitting him to get the idea that he is an invalid and cannot do like other folks, and in two or three years you will be gratified with the results in the majority of cases you treat.

## REPORT OF TWO CASES OF TRANSVERSE POSITION OF THE FETUS WITH PROLAPSE OF AN ARM AND IMPACTION.<sup>1</sup>

BY

CHARLES S. BARNES, M.D.,

of Philadelphia.

Assistant Demonstrator and Instructor in Obstetrics, Assistant Demonstrator of Gynecology in the Jefferson Medical College.

Both cases occurred in the out-patient service of the Jefferson Maternity Hospital.

CASE I.—E. C., colored, a primipara, aged 20, was first seen December 20, 1900. The patient had been in active labor for from 6 to 8 hours. Labor pains were strong and frequent. Palpation and vaginal examination showed the fetal position to be transverse, with the head in the left iliac fossa, the back anterior, the membranes ruptured, and the right arm prolapsed. The child was dead, very probably as a result of the great birth pressure to which it was being subjected. There was no personal or family history of interest. The patient's health had been remarkably good. I can assign no plausible cause for the fetal malposition except the disproportion between the child and the pelvis. The former was large, and the latter contracted and somewhat deformed. Pelvimetry, taken some time after delivery, gave the following pelvic measurements: A. S., 26 cm.; crests, 25.5 cm.; troch., 30.5 cm.; L. O., 20.5 cm.; R. O., 20 cm.; E. C., 18.5 cm. It will be noted that the pelvic diameters are all two or more centimeters less than normal, but that the conjugate and crestal measurements are disproportionately lessened, the latter being shorter than that between the iliac spines, — a typical rachitic flat pelvis. I could, however, get no history or other evidence of rickets.

Dr. B. F. Royer gave chloroform as an anesthetic, and Dr. Coles assisted me in the delivery. The bladder was emptied, the hair clipped from the external genitals, and the parts surgically cleansed with soap and water, plain water, and mercuric chlorid solution, 1 to 2,000, and the vagina was douched with 1% lysol solution. It was thought advisable to excise the prolapsed arm, thus reducing the size of the fetus, and avoiding the introduction of the infected part into the uterus. Guarding the maternal tissues with the left hand, with the right using heavy-bladed, blunt-pointed scissors, I amputated the arm at the shoulder. Then manipulating with the left hand internally and the other externally, it was comparatively easy, by slightly pushing up the body of the fetus, to pass the left hand and arm over its ventral surface, to grasp the lower foot and to bring it down. By gentle traction internally and careful manipulation externally, the fetal back was made to rotate upward along the anterior uterine wall, the head was pushed in the direction of the fundus, and the breech made to engage so as to bring the leg which had been grasped anterior in the pelvis. By traction on the leg downward and backward, delivery of the body was easily accomplished, and the remaining arm, extended over the head, was readily reached and delivered. The delivery of the after-coming head gave but little difficulty. The latter was done by Wigand-Martin's method, namely: the maintenance of flexion of the head with a finger in the mouth, and by suprapubic pressure upon the head, the body of the child being brought, at the moment of extraction of the head, well over the mother's abdomen. To guard against possible infection and relaxation of the uterus and hemorrhage, the organ was douched with 1% lysol solution and packed with iodoform gauze. Lacerations of the pelvic floor, which were slight, were repaired. Recovery of the patient was prompt and complete. I recently delivered this patient of a 6 months' macerated fetus.

CASE II.—M. B., aged 30, was also colored, but evidence existed of a large proportion of Caucasian blood. The pregnancy was her fifth; two children were living and healthy. Patient's mother had died of cancer. She gave a history of having commonly had good health, although she appeared anemic, and naturally of poor, weak, muscular and nervous development, and when seen at the dispensary, a month or more before delivery, she was poorly nourished and had a troublesome nausea, with some evidence of mild toxemia. Calomel, gr. ̄, with sodium bicarbonate and Basham's mixture, 2 drams, were prescribed, each three times daily. As is the custom at the dispensary, a thorough examination of the patient, including pelvimetry, was made. The measurements were as follows: A. S., 23 cm.; C., 26.5 cm.; troch., 30 cm.; R. O., 20 cm.; L. O., 19.5 cm.; E. C., 17.5 cm.; circumference, 83 cm.; a just-minor pelvis, it will be noted. The condition of transverse position of the fetus, the back toward the ventral surface of the mother, head in the left iliac fossa, existed. The small pelvis

<sup>1</sup> Read before the Philadelphia Obstetrical Society, May 1, 1902.

may have been an etiologic factor in this condition, but I think the relaxed, flabby character of uterine and abdominal muscles were chiefly accountable. From the history and examination, the pregnancy was thought to be of about eight months' advancement, which was confirmed by delivery little over a month later. A few days after first seeing the patient I took with me, as is our plan, two undergraduates to visit the patient, and we examined her together. At this time external version was carefully tried, but without success, the patient being nervous. We left her with the oft-repeated injunction that we should be informed at the first signs of labor, thinking that perhaps, in the beginning of labor, external version could be performed; or if not that the attendants could be in readiness to use at any time whatever procedure was demanded for the sake of mother or child.

The first word received was early in the morning of June 13, 1901, when the husband of the patient came, saying that his wife had been in labor all night and that an arm was "sticking out." The patient was found much exhausted from long, ineffectual efforts at fetal expulsion, and from loss of considerable blood. The same condition of the fetus existed as in the first case. The state of the patient was evidently a serious one; the friends were so informed, and the suggestion made that the patient should be treated in a hospital; but her friends objected, wishing her to be treated at home. Through deference to their wishes and because the Jefferson Maternity was about to close for a period, I reluctantly consented (the surroundings being the worst) to treat the patient where she was. The friends were told that a careful attempt would be made "to turn" the child, with the understanding that if this did not readily succeed the patient was to be taken to a hospital. Assisted only by an undergraduate of medicine and an ignorant old negress, after giving some hypodermic stimulation, a small quantity of chloroform was administered, and, by the foregoing method (except that the prolapsed arm was not amputated), I readily and with comparative ease performed podalic version and extraction of the dead fetus. The uterus was douched and packed. Though the whole procedure was short, perhaps not over 20 to 30 minutes, yet before completion, the pulse became accelerated and weak, showing shock. The patient regained consciousness and there was some slight reaction from the shock; but in spite of active treatment with many of the familiar measures, she died in an hour and a half or two hours after delivery. Necropsy failed to reveal any lesion or cause of death, except that there was a general anemia, and flabbiness and friability of tissue, indicating little power of resistance. The cause of death was evidently exhaustion from prolonged labor, with shock necessarily attending anesthesia and delivery.

Conclusions cannot be drawn from two cases only, but every case suggests thoughts which should be weighed, and from which even inferences may be deduced. The trite fact that conditions of transverse position should have vigilant care is emphasized in these two cases. If they had been seen early in labor, the chance of saving both children would have been good, and the life of the mother, in the latter case, would not, in all probability, have been sacrificed. Possibly more persistent effort should have been made when external version was attempted. But had not the trifling, unreliable nature often manifest in the negro race and the presence of an ignorant old midwife caused the friends of the patient to neglect summoning proper assistance at the first signs of labor, the result would likely have been different. Innumerable babies and mothers will rise up in judgment against midwives; but meanwhile faulty legislation and careless and indifferent officials allow the slaughter to go on. The marked difference in the muscular and nervous fiber of the two mothers, and especially the fact that the former was not exhausted, while the latter was profoundly so, are the plausible reasons for the opposite results. The fatal ending may serve as a warning against major operations in exhaustion unless they are done with plenty of assistants, fair surroundings, and with all the essentials at hand for most active combat against shock.

As to the frequency of the occurrence of transverse position, it has been estimated at 1 in 150 to 1 in 300 of all cases of labor. Galabin, in reporting the statistics of 22,900 cases of labor occurring in Guy's Lying-in Hospital, gives the percentage of this condition as .32. As to the causes of this malposition, contraction of the pelvis and relaxation of the abdominal and uterine walls are the most common. The former of these etiologic factors was present in the first case reported, and both were present in the second case. Any abnormality of fetus or pelvis, in structure, size, or proportion, may

be a predisposing cause. The diagnosis is made by the usual methods of physical examination in pregnancy, and often may be done without difficulty. A physician owes it to himself, to his profession, and especially to his patient, to make it a routine measure to know her pelvic measurements and the position and presentation of the fetus in the latter months of pregnancy. It is only by such painstaking care that the fatal complications of obstetrics, such as result in neglected cases of transverse position, may be minimized. In the studies of Churchill, he found that in 235 transverse presentations, one-half of the children were lost. The only proper method of treatment recognized is some form of version; but the child, if dead, may, of course, properly be delivered by embryotomy. Brothers states that out of 125 cases delivered by spontaneous evolution, 111 children were born dead. While I have not been able to find any specific information as to the maternal mortality, yet in neglected cases it must be considerable; whereas, if the condition be diagnosed early, and intelligent assistance be rendered at the proper time, the prognosis for the child is a fair one and for the mother good.

### GASTROSIA FUNGOSA.\*

BY

MARK I. KNAPP, M.D.,

of New York City.

Organacidia gastrica is a disease—not a symptom—due to the presence within the stomach of relatively large quantities of organic acids, which may have been introduced as such into the stomach or may have formed there. It is a disease *sui generis*, having a definite and distinct cause which elicits definite, distinct, and invariable symptoms. Of course, the symptoms vary with the degree of the cause. The greater the irritation, and the greater the quantity of the injurious agent, the stronger, the more pronounced, and the more violent are the symptoms. Slight indistinct soreness and severe spasms and, possibly, tetanus, are the extremes between which are painful sensations corresponding to the degree of irritation. Organacidia gastrica permits of subdivision into three distinct classes: (1) Organacidia gastrica simplex, a pathologicochemic condition of the stomach in which the organic acids have been introduced in fruits, salads, etc.; (2) gastrosia fungosa, in which the organic acids are due to mold vegetation in the stomach; and (3) zymosia gastrica, in which the organic acids are due to the presence in the stomach of growing, sporulating, budding yeast.

The occurrence of mold in the stomach must now be admitted an established fact, since many have seen it, although it has been looked upon rather generally as being a curiosity merely. I believe Einhorn was the first who thought its presence in the stomach of pathologic significance. My own investigation of mold dates back to the latter part of last year, independently and in absolute ignorance of Einhorn's article. Other interesting communications bearing on this subject are those of Kühne<sup>1</sup> and of Pettersson.<sup>2</sup> Kühne has observed the spinach-green vomit and finds that the green color is not due to bile, an assertion I had previously made.<sup>3</sup> But he is not yet sure whether that green color is due to algæ or something else. Pettersson describes mold in the stomach.

Mold is introduced into the stomach chiefly through the mediums of food and drink, although the nose and the open mouth might readily prove available channels. As a rule moldy foodstuffs are rejected. But, unfortunately, in a few cases, as in certain varieties of cheese, food is prized because of the piquancy which they owe to the mold. All foodstuffs are apt to have mold in

\* Supplementary to my monograph on organacidia gastrica, published in the New York Medical Record, September 6, 1902.

spore form and in microscopic quantities. That mold grows in the stomach is proved by the fact that it is aspirated in occasionally very large patches and clusters. As the patient takes the mold unawares, unconsciously, in microscopic quantities, and as large clusters, readily seen with the naked eye, are aspirated, it must be accepted as conclusive that the transformation of the microscopic quantity into macroscopic size could have been accomplished by no other process than growth. We must needs infer that such parasitic growth of vegetable matter within the stomach undoubtedly has some influence upon the stomach. Growth is synonymous with the process of assimilation and elimination, and the process of growth and of life is ultimately a process of chemic action. The process of mold growth is, now one of oxidation, again one of reduction, and again of hydration, and dehydration. It needs for its growth nourishing material, needs the elements which constitute its anatomic existence. It does not import its life elements, it simply abstracts them from the stomach and its contents. Can there be any doubt that mold growth has a decided influence upon the stomach and its contents, and that such influence could not be wholesome? It would require exceptional reasoning to assume that vegetation, foreign and unnecessary to the body, could be of value to it. Mold is a recognized parasite of the flora; could it possibly change its relation when acting as a parasite of the fauna? From these premises the association of mold vegetation in the stomach with distressing subjective symptoms reaches beyond hypothesis. It is undeniable that suffering attributed by the patient to the stomach, and mold vegetation within the stomach are found associated. It remains only to be proved that the mold vegetation and the symptoms complained of are to one another in the relation of cause and effect. Of direct proofs I cannot add anything to what I have said in my original paper, but I have an abundance of indirect proofs. With the disappearance of mold vegetation the symptoms disappear. Considering, therefore, that mold grows in the stomach; that the growth of mold means chemic changes, the production of highly irritating, volatile, organic acids which are demonstrated; that with the disappearance of the mold the irritating acids and the distressing symptoms disappear, sufficient proof would seem adduced to hold the presence of mold vegetation as the cause of the misery of the patient.

The symptoms the patients detail are due to the presence within the stomach of highly irritating, volatile, organic acids, which conform to the general physical laws of the expansibility of gases, spreading in all directions. As their injurious influence upon mucous membranes is everywhere the same the organs whose mucous membranes are thus irritated give unmistakable evidence of their existence. Thus the symptoms are not always confined to the boundaries of the stomach, but are painful manifestations of the irritated organs, and are severe in proportion with the quantity of the organic acids. A summary of the symptoms mostly encountered is: heartburn, uneasiness, soreness, pain, pyrosis, sour eructation, occasional vomiting, sour taste, spasms, cramps either of the pylorus or of the cardia or of both. In the first case the patient relates the pain to the immediate neighborhood of the umbilicus, in the second case the pain is indicated on the left side of the ninth dorsal vertebra, giving respectively pyloric and cardiac spasms. The extragastric symptoms are: soreness and burning behind and along the sternum and between the shoulder-blades (due to the irritation of the esophagus), a choking sensation, the globus hystericus (due to the irritation and contraction of the sphincter-like portion of the beginning of the esophagus), dryness in the throat (due to the irritated, dehydrated condition of the pharynx). This latter condition in turn becomes the cause of a train of symptoms. Dryness of the pharynx manifests itself, symptomatically, as thirst, varying in degree and duration with the irritation, and

necessitating the consumption of frequent and often large amounts of liquids. In these cases, if liquids containing carbonic acid are imbibed the introduced carbonic acid increases the irritation. The excessive amount of liquid introduced into the system must be eliminated by the emunctories and thus excessive perspiration and polyuria are added to the already annoying train of symptoms. For a like reason there may be an increased number of movements, which are necessarily soft. This latter condition must not be confounded with diarrhea, due to irritation of the bowels, which, of course, might be coexistent. Patients often complain that they get dizzy, get headaches, get fainting sensations if they do not take food at once on feeling hunger. This must be recognized as a false appetite by the attending physician. The increased, ravenous appetite is found in patients who have both a normal quantity of hydrochloric acid and a very large amount of organic acids. The headache associated with this disease and especially with this appetite is very significant, and is due directly to the same cause as the appetite. Both are the immediate and direct effects of the volatile, fatty, acrid, organic acids. These acids ascend to the esophagus, here through pharynx, through posterior nares to the nose and middle meatus, through the infundibulum and ethmoidal cells to the frontal sinuses. Tortuous as is this route it nevertheless is an unobstructed (unless by pathologic changes) direct course between stomach and frontal cells. This is the reason why the patients mostly suffer from supraorbital headaches and why there is often severe pain on each side of the root of the nose—the mucous lining of the frontal and ethmoidal cells is irritated in the same manner and by the same agents as is the mucous membrane of the stomach. Another form of headache, intense in character, is the one corresponding to the course of the superior longitudinal sinus. Very characteristic is the way the patient points to the location of this headache. He puts the tips of his fingers, which are usually held in close approximation, right over the region of the superior longitudinal sinus. The pain is usually described as of a bursting nature and is apparently due to the direct absorption of the noxious gases through diffusion by the veins that lead from the nose to this sinus. Buzzing in the ears is an occasional symptom, in which case the eustachian tube undoubtedly plays the intermediary channel for the introducing of the organic acids from the pharynx to the ear. The organic acids entering the intestines produce there very unpleasant symptoms in the shape of pain, colics, griping, etc.

The diagnosis made from these symptoms must be corroborated by the test-breakfast. As all these symptoms are due to the irritation of the mucous membranes by the volatile, fatty organic acids, which may as well have their origin in the intestines—organacidia enterica—it is evident that in cases of organacidia enterica, complicated by pyloric insufficiency (a quite common combination) there will be present not only the intestinal symptoms but likewise the entire picture of organacidia gastrica. From this it is apparent that an absolute diagnosis is of very vital importance. Treating a gastric disorder which requires an acid medication is one thing, and managing an intestinal disease which requires alkaline therapy is quite another.

In a typical case of gastrosia fungosa the physical appearance of the aspirated chyme is very characteristic. There is usually a large quantity, soon dividing into a thin, watery, upper layer with the very finely divided solid part—the “floury layer”—at the bottom.<sup>4</sup> The watery layer is usually of some shade of green. The odor is sweet, sour, pungent. Mold clusters, mostly yellowish or grass-green or dark-red or blackish, or possibly of even other colors may be seen floating on top of the aspirated chyme. The green-colored chyme should not be taken for containing bile nor the dark-red chyme for a hemorrhage unless bile and blood are *absolutely*

demonstrated beyond the shadow of a doubt. Upon the color and quantity of the mold may depend the color of the chyme. The microscope shows mold life in its different and manifold phases: mycelium, spores, gonidia, asci, single young mold segments, which look exactly like crystals, and microorganisms. Staining and decolorizing<sup>5</sup> bring out the mold very distinctly.

The chemical examination must be made for organic acids, especially succinic acid, the presence of which is demonstrated as follows:

Extract in a Strauss separatory funnel 1 cc. of filtered chyme with 4 cc. of ether. This, the chyme and ether, are well shaken in the separatory funnel, a short time is allowed for the chyme to settle at the bottom, which after settling is allowed to run out, and then the clear ether extract is floated on a weak iron solution. At the plane of contact between the ether and the iron solution a dark-red ring denotes the succinic, also propionic acids. A sulfur-yellow ring indicates lactic, malic, oxalic, tartaric acid and alcohol; acid phosphates show no ring. The iron solution is made by adding one drop of a 10% ferric chlorid solution to 2 cc. distilled water in a narrow test-tube. How to differentiate between the individual acids is described in my former article.<sup>6</sup> For the quantitative analysis, by titration, three indicators are used: a supersaturated alcoholic solution of tropæolin 00.; a 0.5% alcoholic solution of dimethyl-amidoazobenzol and a 1% alcoholic solution of phenolphthalein. The first indicates free inorganic acids—free HCl—the second shows the organic acids, and the third demonstrates the general acidity. For the entire titration only 5 cc. of chyme is needed. The indicators are not added all at once, but, for sharper differentiation of the resulting colors, 2 drops of each indicator is added in the order mentioned. The end-reaction of the tropæolin is evidenced by the turning of the cherry-red color, produced by tropæolin in the presence of inorganic acids into an amber color. The addition of the second indicator proves the organic acids by the appearance of a rather carmine-red color, which is turned into a lemon-yellow color by the titration with the decinormal soda solution, when all organic acids have been neutralized by the alkali. After this the third indicator is added and the titration resumed until a carmine-red appears. That the dimethyl reacts not only with free inorganic but also organic acids I have satisfactorily proved in my last quoted article, and will be seen from the table given in this paper. When only a few drops of chyme are aspirated I proceed to find the presence of inorganic and organic acids in this way: a piece of clean filter paper is moistened with the chyme and a drop of tropæolin is allowed to come in contact with the moistened filter paper. The tropæolin reaction results in the presence of free inorganic acids; amber color signifies the absence of free HCl. Should tropæolin prove negative, we can in the same way ascertain the presence of organic acids.

The gastric complications and sequels of gastrosia fungosa are those of organacidia gastrica in general. The constant irritation of the vicinity of the pylorus ultimately causes a chronic inflammatory condition of this part. This again is followed by pyloric insufficiency. Enterosia fungosa is but a natural sequel and complication very often seen, especially in children. Hemorrhagic erosions, ulcer, affection of the esophagus, etc., have been mentioned in the original monograph.

The therapeutic principles are to clean out the existing mold, and to give drugs to destroy the organic acids, which in combination with the diet prevent conditions favorable to the growth of mold. The first is accomplished by lavage. As drugs the mineral acids should be given. The burning sensation is caused by the organic acids, and the sour eructation is produced by the spastic contractions of the stomach ejecting and projecting some of its contents into the pharynx. The mineral acids destroy, decompose, dissociate the organic acids. Soda bicarbonate neutralizes the acids present, it is true, but by so doing it creates favorable conditions for the further development of the organic acids. Organic acids are developed from, and enhanced in their growth by saccharin mediums and mold grows readily on starchy and saccharin matter. Sodium bicarbonate enhances the diastatic action, this results in sugar, and this in turn is oxidized to organic acids. That is the reason why bicarbonate usually gives but temporary relief if any. When bicarbonate has given good results the condition undoubtedly was organacidia enterica and, most likely, accompanied by pyloric insufficiency. Should gastrosia fungosa be complicated with other affections the treatment will also necessarily become complicated.

The dietetic treatment entails comparatively few restrictions: no introducing of organic acids and no introducing of sweet mediums, which favor the development of mold and of organic acids. Food should be cooked and eaten soon after the cooking. Those who pervertedly advocate the eating of raw food are not sufficiently familiar with physiologic chemistry, nor have they evidently ever seen, with an eye open only to unbiased knowledge, the difference between raw and cooked food under the microscope. Vegetables should be washed thoroughly in plenty of running water. At the beginning of the treatment fruit should be entirely eliminated from the diet. Grapes especially are very dangerous because they harbor on their surface an enormous quantity of mold; they are sweet, and they contain a large amount of organic acids. If eaten, they should be plucked off the stem, then washed repeatedly in plenty of water, and before eating, each grape dried with a clean napkin. While pies, cakes, and other pastry should be sedulously avoided, there is absolutely no reason why other farinaceous articles and potatoes could not be permitted. Cereals must be well cooked. Whole grain bread and cereals cooked with their cellulose skin should be avoided. Strong coffee, strong tea, strong cocoa and alcoholic liquors should be forbidden at the beginning of the treatment, but later on may be used in moderation. To prepare coffee place the ground coffee into a receptacle, cloth or perforated metal, and pass the boiling water through it. The coffee infusion, thus prepared, must never come in contact with the coffee grounds. Only about a teaspoonful of such an infusion is needed to impart its delicious aroma to a cupful of milk. Soda water, seltzer, vichy and similar beverages containing CO<sub>2</sub> are likewise excluded.

In the histories of the following 10 cases, the symptoms of gastrosia fungosa are illustrated. In the first case only the qualitative test for organic acid is made, as at that time I could do no more.

CASE I.—Morris G., 28 years, Hungarian, painter, September 10, 1901. Has had heartburn for the last five years; enormous appetite, feels like vomiting, chiefly in the morning; when he gets hungry, sees spots before the eyes; buzzing feeling in the head after heartburn; loose bowels—five times daily for the last five years; urinates quite frequently; feels very bad after drinking coffee. Diet—when at work: occasionally eggs or oatmeal in the morning, but often nothing; at nine, sandwich and beer; at noon, regular dinner; between three and four, sandwich and beer; supper, meat, soup and beer; about nine p.m., sandwich and beer; very often eats something before going to bed. When he is not at work, he eats every two hours, because he gets a gnawing sensation in the stomach. Perspires very freely. The physical examination showed nothing abnormal in the chest; left kidney prolapsed in the third degree but right kidney scarcely palpable and tender; albuminuria. The fasting stomach yielded 55 cc. (some was spilled) greenish yellow, mucoid fluid; general acidity 56; free acids (Topfer's solution) 26. After the test-breakfast some 80 cc. yellowish-green contents was obtained, of a sweetish sour odor; pretty well reduced to chyme, but with some few coarse pieces present; general acidity 72, free acids (Topfer) 46; succinic acid present. No microscopic examination was made.

CASE II.—Joseph M., 34 years, Hungarian, fruit peddler, came to consult me December 11, 1901, especially for pain in the lumbosacral region, from which he suffered for the last six years, especially on getting up from his seat; bowels hard. Gets up at five; breakfasts at nine on coffee and rolls; dinner, meat, soup and some pastry; supper, goulash or sausages; eats fruit between meals. Two years ago had hemorrhages, lasting for three days, which were understood to come from the lungs and patient was sent to Colorado, where he stayed for six months, and, feeling better, he returned. After his return he had another attack of hemorrhage. His physical examination showed nothing abnormal in his chest (which was subsequently corroborated by others); both kidneys prolapsed in the first degree; spleen enlarged; slight resistance and tenderness at McBurney's point. The fasting stomach contained nothing. After test-breakfast 35 cc. was aspirated, of a pungent odor, coarse particles with little floury layer. *Microscopic examination*: Long curved bacilli, bead bacilli, prismatic crystals (single sections of mold), gonidia. Free HCl 24, organic acids 38, general acidity 82; floating test shows succinic acid; acid phosphates absent; urine normal. In this case the stomach tube was arrested in the esophagus both times: when entering the fasting stomach and when introducing the tube for test-meal aspiration. Both times the tube was arrested for possibly only a minute or so and then proceeded. This caused me to inquire

of the patient for any previous history, which at first he did not care to mention. The answer was the history of his hemorrhages and his being sent to Colorado. I therefore concluded that the arrest of the tube was due to the irritation of the cicatrix after an ulcer of the esophagus which was mistaken for pulmonary tuberculosis.

CASE III.—Mrs. Jennie S., 42 years, born in New York; three children. January 18, 1902. Is very thirsty and has to drink much (seltzer); feels very dry, burning in the lower part of sternum; belching; sour eructation; very often experiences a sharp, miserable taste of onions, of which she does not partake at all. Last night had cramps in the right epigastrium; coryza for a long time; irregular supraorbital and frontal headache; occasional spells of dizziness; never vomited. Had stomach trouble at times, but the present attack has lasted for the last nine months. Appetite not so good; dry parched taste; drinks three to four bottles of seltzer even the coldest day; bowels move only once daily, without medication; lost nine pounds within the last six to eight weeks; drinks three to four large cups of coffee daily. For the last seven months has been under treatment for diabetes. Got the treatment outlined. Eight days later came for test-meal examination, but at the same time reported feeling better. The fasting stomach contained about 45 cc. of yellowish-green contents. Test-meal aspiration gave 165 cc.—thin fluid above and floury layer below. Free HCl 24, organic acids 22, general acidity 59; floating test, succinic acid; acid phosphates absent, urine normal. This case has been mistaken for diabetes, but the patient made an excellent recovery in about five to six weeks.

CASE IV.—Mrs. Lena S., 28 years, Russian, two children, pregnant five months. Pressure in the stomach, especially at night about 3 o'clock. It "catches" her with pain in the stomach and palpitation, and then she cannot fall asleep for some two hours; has vertigo and fainting spells; had epileptic fits at night quite often for the last three years; appetite is usually good; must urinate frequently; gets calls for moving the bowels at night which "catch her." When she gets attacks of palpitation she must sit up, stem her feet against another chair, bend forward and with her hands press upon the epigastrium; is easily excited; bad and bitter taste. Coffee, two and more glasses about 8 a.m. For the last two or three years cannot eat any sweets; was treated for asthma. Both kidneys and spleen palpable. On March 11, 1902, came for an examination on an empty stomach after an attack of nocturnal epilepsy, having had three fits the night before. The fasting stomach yielded about 75 cc. of dark-red contents which from physical appearance could be taken for a hemorrhage. The odor was pungently sour. The color was due to the enormous mass of mold of the dark-red variety. Under the microscope there were seen very fine-beaded bacilli, greenish-yellow mold, circular purple bodies, no sarcinas, very few isolated yeast cells. The patient was so very much exhausted and somnolent that she fell asleep while I was examining the aspirated contents under the microscope; she was entirely dazed. Under such conditions I did not care to give her any test-breakfast. Her urine showed albumin. March 16, fasting, stomach no contents, lavage. March 17, fasting, about 10 cc. mucus; tropæolin positive; test-meal, about 10 cc. imbedded in mucus; tropæolin positive. March 18, fasting, no contents; test-meal aspirated half an hour after eating gave 75 cc., mucus present, no special odor, no tropæolin reaction, acidity with dimethyl 32, general acidity 70. On March 23 she came complaining of having premonitory signs of the coming of epileptic fits; had milk and roll about 10 a.m. I now (2 p.m.) aspirated, but found stomach empty; admits having had beer and grape wine yesterday. On March 24 she came to report of having had a very bad night, could not sleep at all, but had no epileptic fits. Had only a cup of milk this morning; aspiration (at 2 p.m.), no contents. On April 5 she reports not having had any epileptic fit last week, although she expected it. April 7, feels bad and slept till 11 a.m., after which she took hot milk and water. Aspirated (at 2.30 p. m.) about 120 cc., which gave free HCl 36, organic acids 28, general acidity 132. On May 2 it "caught" her very badly in the daytime, but she had no epileptic fit; this came after drinking "barshch," a sour beverage made from red beets. She was delivered of a healthy boy June 16, and has felt good all the time.

CASE V.—Miss Sara N., 18 years, Hungarian, works on neckties. On April 13, 1901, she visited me for the first time and then complained of trouble with her bowels and stomach lasting about a year. Could eat no eggs because the taste of them lingered after eating. Then came sour eructation, choking in the throat (pointing with the finger immediately above the sternum); severe constipation for the last three years; occasional headache. She came about one year after and on April 20, 1902, the fasting stomach contained about 120 cc. greenish-yellow (mold) fluid. One hour after the test-breakfast 250 cc. chyme was aspirated of greenish-yellow color. The solid part was very finely divided, forming at the bottom the "floury layer." On top of the fluid floated one large green cluster (mold) of a size one inch by one-half inch; also a few red brown streaks (red-brown mold) were present. The odor was sweetish. Free HCl 18, organic acids 26, general acidity 66. No microscopic examination.

CASE VI.—Mrs. Sara B., 30 years, Galician, three children; April 29, 1902. Pain in the epigastrium, headache, pain between shoulder-blades, bitter and sour taste, constipation, dryness in

the throat at night, troubled after meat; would like to eat every minute. The fasting stomach was empty; aspiration after test-meal about 50 cc., mucus; tropæolin negative, organic acids 20, general acidity 50. No microscopic examination was made.

CASE VII.—Samuel F., 33 years, Hungarian, hat maker; April 29, 1902. His suffering dates back three years; has no movements without drugs; after taking the first bite feels feverish; feels too heavy after meals, frontal headache; can eat only sour things. The physical examination shows enlarged spleen. The fasting stomach contained about 10 cc. greenish contents (mold). After the test-breakfast 100 cc. was aspirated. Green clusters floated on top; odor, sour sweet; "floury layer" after a little standing. Free HCl 26, organic acids 52, general acidity 114; no microscopic examination made.

CASE VIII.—Harris D., 36 years, cloak operator during the season, but keeps a stand in Coney Island during summer season. This patient was sent to me July 1, 1902, by another physician for diagnosis. His present illness dates back six to seven weeks. It began with a burning sensation "under the heart," which was most severe in the afternoon. Five weeks ago cramps appeared in the afternoon, which kept up since. In the last few days the cramps occurred also in the forenoon. Usually the cramps would cease on lying down, but in the last few days the cramps did not cease on lying down. During these five weeks he vomited five times, about two hours after dinner. The last time he vomited, on June 29, a half hour after the dinner, which latter included prunes. While usually the cramps ceased after vomiting, this last time they did not cease. His appetite is very good even during the cramps. No special taste; no headaches. Occasionally feels as if his throat burned him and at times has a sensation of pressure behind the sternum. The examination showed 5 cc. of greenish looking contents in the fasting stomach. The test-meal aspiration gave 68 cc.; the solid portion of the chyme consisted of coarse particles and of the floury layer; odor, that of roll but not pungent; mold and different bacilli present but no yeast chains. Free HCl 18, organic acid 24, general acidity 62. Floating test gave succinic acid reaction. Left kidney enlarged, prolapsed and somewhat tender on palpation; albuminuria.

CASE IX.—Mrs. Tillie S., 35 years, Galician; October 9, 1901. Headache, diarrhea, anorexia, bad taste. Came back July 16, 1902, for examination. The fasting stomach contained about 2 cc. Test-meal aspiration 68 cc.; green mold patches floating on top of the aspirated chyme, some mucus present. The solid portion consists of the floury layer with some coarse particles; odor slightly sour, salty and sweetish. The microscope shows few mother and daughter yeast cells, no yeast chains, bacilli, mold patches. No free HCl present (to both tropæolin and Guinzburg), organic acids 24, general acidity 52.

CASE X.—Miss Rose B., 18 years, born in New York, shirtwaist operator; September 2, 1902. For about the last two years would vomit every morning after her breakfast, which consists of roll with either cocoa or coffee, and occasionally a tomato with it; for lunch has a sandwich, fruit and tea; some fruit in the afternoon; for supper, soup, meat, seldom potatoes or vegetables. For the last few days has been vomiting constantly after everything. Occipital headache, dizziness, choking, bowels regular, flashes of heat and cold, ringing in the ears, fullness in stomach. Fasting, no contents. Test-meal, 150 cc., plenty of grass-green and yellow-green clusters floating, odor not disagreeable, floury layer; the fluid portion of the chyme is yellowish-green, no mucus. Stomach distention with CO<sub>2</sub> shows no enlargement or prolapse. "Stiffening of the stomach" (the "Magensteifung") of Boas present. Free HCl 12, organic acids 20, general acidity 52.

In the following I have tabulated the results of the quantitative analyses for better review, leaving out the first case, as at that time I knew only of the qualitative test for the organic acids:

Case.	Free HCl (tropæolin).	Organ. acid (dimethyl).	All free acids (dimethyl).	General acidity (phenolphthalein)
II	24	38	62	82
III	24	22	46	59
IV	0	32	32	70
V	18	26	44	66
VI	0	20	20	50
VII	26	52	78	114
VIII	18	24	42	62
IX	0	24	24	52
X	12	20	32	52

From this table we see that in no case was the actual amount of the free HCl excessive. On the contrary, it was at best nearer the lower limit of what is now accepted as normal. Should I have interpreted the dimethyl as indicator for only free HCl, Cases II and VII would have to be recognized as hyperchlorhydria, while Cases III, V and VIII already exceed the normal maximum limit. Case X should, according to the dimethyl, pass as containing a very fair amount of HCl. Likewise could Cases IV, VI and IX not explain the cause of the

patient's suffering, as Töpfer's solution gave good coefficients. But this table shows how absolutely wrong it is that the dimethylamidoazobenzol should be taken as an unqualified indicator for only the free HCl. My paper on "Some New Facts in the Chemistry of the Stomach" covers the ground and proves that the dimethyl, also congo, react as well with the organic acids. Bad as it would be to treat Cases II and VII for hyperchlorhydria it would be much worse for the therapy to overlook the facts that Cases IV, VI and IX had no free HCl at all (in Case IX the absence of the free HCl was also corroborated by Guinzburg, in the other two Guinzburg was not tested) and needed it very much. These last three cases show how absolutely fallacious must be the treatment based upon a very erroneous diagnosis which in turn is the result of a fallacious indicator. I can here but repeat the sentence of my paper on organacidia: "Fallacious tests lead to fallacious diagnosis; fallacious diagnosis to fallacious treatment, and fallacious treatment lead to the recognizing of the frequent occurrence of neuroses of the stomach." This table shows the marked preponderance of the organic acids in every case but in Case III, in which the organic and the inorganic acids are about the same. I very strongly recommend the tropæolin solution.

This is prepared by adding, in excess, the powdered tropæolin 00 to strong or absolute alcohol. It is then left alone for two or three days. The solution, a dark cherry-red, is then ready for use. To the novice the end-reaction of the tropæolin may cause some consternation, but practice makes perfect. The best way to judge the change of the chyme into an amber color is to hold the beaker which has the chyme inclined and look down at the angle formed by the wall and the bottom. A white sheet is held underneath the beaker. For practising, I would advise the titrating of a mixture of HCl with an organic acid—acetic acid—both solutions to be of known acidity. This is done: A weak solution of HCl is made and its acidity determined with phenolphthalein as indicator. In a like manner we proceed with the acetic acid. The acidity of each solution being known, we mix the two solutions, taking equal parts of each. If the HCl solution has an acidity of 20, and the acidity of the acetic acid is 40, and if of the mixture of the two 10 cc. is used for titration, actually only 5 cc. of each, the red color of the mixture, after adding tropæolin, will turn amber color when the buret gives an acidity of 40. This acidity of 40 means only 20, as only half of the mixture in the beaker is HCl. We can now add the dimethyl when the amber-colored mixture turns red again. This experiment can be used to prove both the color change of the tropæolin and its value as an indicator for free inorganic acids.

Of great interest in the histories given is the fact that Cases I, III and especially V show considerable gastrosuccorria and that the contents were yellowish-green (moldy). Some contents of a like color we also note in some other cases. That some shade of green is the almost accepted color in gastrosuccorria is well known. But whether gastrosuccorria is caused by *Gastrosia fungosa* is a contention yet to be demonstrated; present facts seem to lead my thoughts in that way.

Cases I and VI show the enormous appetite. Case II illustrates ulcer of the esophagus, as a sequel of irritation by organic acids which in this case were presumably introduced, mostly, with the fruits which were eaten frequently. Case III represents organacidia being mistaken for diabetes. Case IV is the banner case of the series. Here we find three well-marked facts: 1. The patient had oft recurring, crises-like attacks of nocturnal epilepsy. 2. Soon after an attack of nocturnal epilepsy the patient comes to me and I aspirate some 70 cc. from her fasting stomach. These contents are reddish, chocolate brown and prove to consist wholly of the dark-red mold variety. 3. With the disappearance of the mold from her stomach her epileptic attacks ceased. A further instance worth noting in this case is that the patient's stomach had been entered repeatedly for lavage and test-meal aspiration without in the slightest interfering with the progress of her pregnancy. Of course, I know of but one contraindication to the introducing of the stomach tube, and this is if one has not yet mastered the simple technic of introducing the tube. But then he might

use the director<sup>7</sup> I invented for that purpose. Was the variety of mold found in Case IV the cause of her nocturnal epilepsy? Her epileptic seizures were at certain and definite intervals; she knew the date of coming or she imagined she knew when the attack was due, and "felt" it coming. Were these nocturnal seizures, which the patient alleged to the influence of the full moon, synchronous with the "ripening" of another crop of mold? So striking and certainly extremely pleasing to the unfortunate woman was the absolutely immediate effect of the proper understanding and treatment of her highly melancholy malady that one cannot help associate the presence of the mold in question with her epileptic seizures. It is hoped that conscientious men will give their thoughts to this history. The patient is a very poor and densely ignorant woman, living in the heart of the slums and coming from a country where benighted ignorance and abundance of superstition are not great exceptions. Even the best food she could procure with the meager means at her disposal cannot be very good. Her treatment was a constant battle between the corruptedly spicy and saucy food in vogue in her environs and the rigorous instructions given by me. In that unequal skirmish, science was not always victorious and, of course, whenever I was clandestinely victimized the patient's stomach sided with me in open rebellion.

Cases V and X present "stenosis pylori ab irritatione." In these are aspirated large quantities of chyme, a condition usually interpreted as "atonic dyspepsia," to which diagnosis both Boas<sup>8</sup> and myself<sup>9</sup> take exception. The presence of large quantities of chyme at the end of one hour after the test-breakfast of which the solids are represented by the "floury layer" signifies not atony but the very contrary, hypertony, due to the stenosis pylori which is occasioned by the presence of the organic acids. The presence of mold vegetation in these cases is certainly very evident, especially in Case V, in which a very large piece of a mold colony, one by one and a half inches in size, was aspirated.

Case VII enlightens us greatly on the cause of the organacidia: he "likes only sour things," besides green clusters were aspirated. In Case VIII it is observed that the cramps disappeared on lying down. This is explained that upon lying down the irritating chyme gravitates away from the stomach openings; thus the cramps, cardiac and pyloric spasms ceased. Case IX shows *Gastrosia fungosa* complicated by gastritis.

It might be argued that the cases here reported are ill chosen to demonstrate *Gastrosia fungosa*, that the aspirated contents do not show uniformity in all 10 cases. Neither have I intended to illustrate here *Gastrosia fungosa* by exactly the same pictures. *Gastrosia fungosa* produces one picture when it just begins and different pictures as it progresses.

**Disease in Brooklyn Schools.**—Since September 18 last 6,347 children have been excluded from attending the schools on account of disease. Of these 1,979 were excluded because of eye diseases; 2,920 for diseases of the head and body; 75 for diphtheria; 14 for measles; 40 for chicken-pox; 879 for skin diseases, 74 for whoopingcough, and 336 for mumps. A strong plea is made by Dr. Raymond, assistant sanitary superintendent, for the appointment of more inspectors who shall devote their time exclusively to the schools. It is stated that 4,000 pupils were found who had never been vaccinated and 41,000 children whose first vaccination had "run out."

THE CAUSES OF DEATH IN DIPHTHERIA.<sup>1</sup>

BY  
BERNARD KOHN, M.S., MD.,  
of Philadelphia.

Perhaps no disease, certainly none of an infectious nature, has so uncertain a prognosis as diphtheria. Its possibilities are numerous, and its more frequent complications are among the most dangerous that may arise in the course of any disease. Even when convalescence is apparently established, the danger is not passed; for death may occur suddenly in various ways.

In a general way it may be said that death in diphtheria is due (1) to mechanical causes, (2) to the action of the toxin on the system, or (3) to one of the complications.

Mechanically, death may be caused by asphyxia, which occurs as a result of closure of the glottis in laryngeal diphtheria. Northrup and others maintain that when asphyxia occurs in the early stages of the disease spasm plays the most important role in the production of the laryngeal stenosis. It is a common experience at autopsies on children who died of asphyxia to find little or no membrane in the larynx, although there is a certain amount of congestion and swelling. Further, attacks of dyspnea are so readily excited by the slightest cause, and come on so suddenly, that Northrup is led to the conclusion that they are of a spasmodic nature, and are caused by contraction of the hypersensitive laryngeal muscles. But as the disease progresses, the effects of swelling and exudate become more and more marked, playing a constantly increasing part in the production of dyspneic symptoms; until finally in the last period of the disease, asphyxia is due entirely to the presence of false membrane and edema, and spasm is no longer a factor.

The toxemic form of death in diphtheria is produced through a general depression of all bodily tissues, caused by the poisonous action of the toxalbumins elaborated by the diphtheria bacillus. In such cases the fatal termination occurs at the height of the local process. There is a malignant form in which the infection is so virulent that the system is very rapidly overwhelmed by a profound intoxication, and death takes place within 24 to 48 hours. But such cases are fortunately rare, and usually, if the patient dies from diphtheric toxemia, the fatal termination occurs between the fifth and tenth days.

Often the action of the diphtheria bacillus is complicated and aided by a streptococcus infection, forming what is called septic diphtheria. In such cases the course of the disease is most severe. Death is probably more often due to the streptococcal septicemia than to the action of the diphtheric poison. It is in these cases of mixed infection that the severe complications of diphtheria are most likely to occur.

Of all these complications, bronchopneumonia is the one most to be dreaded. It occurs especially when the larynx is involved, but may follow any case of mixed infection, whether the larynx is affected or not. Some statistics, notably those of institutions, show it to be the principal cause of death in the majority of cases of diphtheria. At autopsy the streptococcus, pneumococcus, and diphtheria bacillus have all been found in the lung lesions. Wright and Stokes believe that the diphtheria bacillus may cause the pneumonia in many instances. Councilman, Mallory, and Pearce maintain that the pneumococcus must be regarded as the principal agent in producing the lung infection. Most authors, however (notably Prudden and Northrup), attribute its occurrence to the streptococcus, which finds access to the lung by inspiration of the foci of disease in the upper air passages. Bronchopneumonia usually occurs at the height of the disease, and is naturally most fatal then, although it may come on at any period, even in conva-

lescence after the membrane has entirely disappeared from the throat.

The kidneys are more or less affected in almost every case of diphtheria of moderate severity, but the nephritis of diphtheria usually runs a favorable course. However, it happens occasionally that the kidneys become extensively diseased, in which event all the symptoms of acute uremia may develop, and the case may end in death that is directly attributable to the renal condition. Fatal nephritis is most likely to occur in cases of septic diphtheria.

Perhaps the most distressing mode of death in diphtheria from the physician's point of view is that due to heart failure. This complication may occur early in the disease or late, even after convalescence is seemingly established. It may happen in cases of great severity or in the mildest cases. When heart complications develop early they occur in patients suffering from a severe form of the disease. In late cases they may make their first appearance in the third or fourth, or as late as the sixth or seventh week, after the disappearance of all traces of local disease. Holt, in his textbook on "Diseases of Infancy and Childhood," vividly describes the onset of heart failure in such cases as follows:

"It often happens that the patient is regarded as convalescent, and the great vigilance of the previous days or weeks has been relaxed. The physician has ceased his frequent visits and looks in once a day to satisfy himself that the patient is doing well and all congratulate themselves that the danger is over. If the pulse is carefully watched it is one day discovered that it is weaker than formerly and occasionally there is slight irregularity. It is usually slower, but may be more rapid than normal. On inquiry it is found that the patient does not take his food so well, that he has refused stimulants, and perhaps has vomited once or twice. Slight dyspnea is noticed and the face is paler than usual. Sometimes within 24 hours from the beginning of such symptoms the patient is dead. The changes for the worse occur very rapidly. The pulse becomes weaker, more irregular, often abnormally slow, but very rapid on slight exertion, and there may be a sense of precordial weakness or distress. There are dyspnea without cyanosis, anxiety, and great restlessness, but the mind is clear. There is vomiting if food and stimulants are taken. The extremities are cold. Auscultation shows feeble and indistinct heart sounds, but no murmur. The pallor is extreme. Death results from sudden syncope, sometimes during an attempt to administer food, sometimes from such slight exertion as turning in the crib."

Occasionally death from heart failure may occur without warning or previous symptoms. But usually if the patient is watched carefully some such premonitory symptoms as have been described will be observed.

The explanation of heart failure in diphtheria is not the same in all cases. Not infrequently cardiac thrombi play an important part in producing the fatal result. This was found by Hibbard to have occurred in 3 out of 21 cases of death due to heart complications which were examined by him. This author thinks a possible explanation of such cases is the occurrence of endocardial degenerations, which act as foci for the formation of the thrombi. When death occurs suddenly, following some muscular effort or excitement, without premonitory symptoms, it is in all probability the heart muscle which is most at fault. If the heart failure is ushered in by prodromal symptoms, it is probably the result of a toxic neuritis of the vagus nerve, and is thus a form of postdiphtheric paralysis. Changes in the heart muscle, however, occur in so large a proportion of cases of diphtheria that it is probable both pathologic conditions will be found at autopsy; and it is difficult, often impossible, to distinguish between the symptoms caused by each lesion.

The pathology of these myocardial changes has been extensively worked up, notably by Romberg, and by Councilman, Mallory, and Pearce. The results of these investigations are fairly uniform. Fatty degeneration is the simplest change found, and occurs alone in the severe cases of short duration. In more prolonged cases the fatty degeneration accompanies and seems to precede more advanced forms. In the latter there is complete destruction of the muscle tissue, which is converted

<sup>1</sup> Read before the Northern Medical Association of Philadelphia, June 13, 1902.

into hyaline masses. Accompanying these parenchymatous changes there is an interstitial myocarditis, consisting of a round-cell infiltration of the heart walls, which may, in advanced cases, lead to fibrous changes. The cause of these degenerations in the heart and its nervous supply is undoubtedly the action of the toxalbumins generated by the diphtheria bacillus.

In some cases of sudden death, apparently from cardiac paralysis, it may be found at autopsy that there is a hyperplasia of the thymus gland, lymph nodes, spleen, and other lymphoid tissues, associated with a hypoplasia of the heart and the aorta. These changes form what has been called the "lymphatic constitution." They have been found frequently in cases of sudden death from various causes, and are believed by many to indicate a diminished vital resistance and a special liability to cardiac paralysis. The study of this condition has been especially directed toward deaths under chloroform narcosis. But it is maintained that some sudden fatalities in the course of certain infectious diseases, markedly those occurring in convalescence from diphtheria, may be in part referable to the presence of the lymphatic constitution. We know little, however, of the chain of events leading to the fatal result, and, as Ewing says, we are compelled to content ourselves with the statement that the subjects of the lymphatic constitution, for some unknown reasons, are specially susceptible to reflex cardiac paralysis.

Changes in the nervous system, due to the action of the diphtheric poison, are of quite frequent occurrence. Here, as in the case of heart complications, paralytic sequels may follow either a mild case or a severe one, although, of course, more likely to occur in the latter. The lesion produced is a peripheral neuritis. From our present standpoint, the most interesting forms of diphtheric neuritis are those which cause cardiac or respiratory paralysis. Cardiac paralysis has already been mentioned. Respiratory paralysis may be due to involvement of the phrenic or the intercostal nerves, most frequently the former. Death is rarely, if ever, sudden. The symptoms may extend over two or three days, and consist of dyspneic attacks of gradually increasing frequency and severity. They are attended by extreme anxiety, distress and apprehension on the part of the patient. There is a constant dread of impending suffocation, which dread is unfortunately only too well founded, for death is the usual termination.

Finally, diphtheria may be complicated with other infectious diseases, and in very many cases the combinations are most deadly. This is especially true of combinations of diphtheria with measles, scarlet fever or typhoid fever. In such cases death may be caused by the development of bronchopneumonia or of a general sepsis, or it may be due to the overwhelming effects of the combined toxins of the diseases in question.

**Stringent Inspection of Immigrants.**—The Immigration Department has drawn up regulations for the guidance of the medical superintendent stationed at St. Johns, N. B., relative to the health of immigrants. Passengers bound for the United States or Canada will be rigidly inspected, and under the new regulations many will be refused admission on account of dangerous and contagious diseases. Heretofore it is said the rules have been loosely enforced.

## PERTUSSIS, WITH SPECIAL REFERENCE TO ITS EARLY DIAGNOSIS FROM THE BLOOD FINDINGS.

BY

ALFRED WANSTALL, M.D.,

of Baltimore, Md.

During the past 10 years Weill and Pehn<sup>1</sup> have devoted special attention to the period when the patient may transmit the disease. They state that the specific organism disappears rapidly when the patient develops the paroxysmal cough; and they hold that the contagious period is during the bronchial or catarrhal stage. When the characteristic cough develops, the likelihood of contagion is rapidly lessened, and by the eighth day of the paroxysmal period the possibility of a child infecting others is no longer present.<sup>2</sup>

That whoopingcough is very contagious during the catarrhal stage is well known, but that it is progressively less contagious during the spasmodic stage is not so well known, and will be something of a surprise to most older physicians. The diagnosis of whoopingcough, during the stage of its greatest contagiousness, is often difficult in the absence of positive knowledge that the patient has been exposed to the disease. There is very little to go upon with the exception of the patient's age and the more or less incessant and purposeless cough often following a more or less pronounced coryza, until the spasmodic stage begins to develop; and even then, in regard to many patients that do not develop the characteristic "whoop," one may remain more or less in doubt whether the child has had whoopingcough or not. In the presence of these difficulties and doubts, any aid that will render a diagnosis certain earlier in the disease, or even more certain in the doubtful cases, will be a great satisfaction to the physician, and of more than passing value to the public from a hygienic or prophylactic standpoint.

H. Mennier<sup>3</sup> states that

In pertussis of children there is a constant leukocytosis which far exceeds the leukocytosis which is found in other afebrile affections of the respiratory tract, due probably to a specific virus associated with this disease. The leukocytosis is found comparatively early, even before the clinical symptoms are well marked; reaches its height during the period of the paroxysms, and then gradually subsides as the stage of the decline of the disease progresses. In the beginning of the convulsive stage the number of leukocytes averages 25,000, and may reach 40,000. Complications, as otitis, bronchitis and bronchopneumonia, seem to have no influence on the number of leukocytes. The increase of the white cells is both relative and absolute, more intensive in younger than in older patients. The chief increase is in the lymphocytes, but all forms are increased to some extent. While the cause of the leukocytosis is unknown, it is probably due to the intense congestion of the tracheobronchial glands. The constancy of the leukocytosis in pertussis, its preponderance over all other spasmodic respiratory affections, and its early appearance before the typical paroxysms, make the blood examination a valuable aid in differential diagnosis and a decided advantage in prophylaxis in schools and hospitals.<sup>4</sup>

The practical interest in Mennier's observation lies in the statement that the leukocytosis consists chiefly in an increase in the lymphocytes, because if it has to do with a lymphatic leukocytosis, on account of its distinctive character it can be determined by the differential leukocyte count without the necessity of resorting to the whole white blood count in the wet preparation. It is useless to attempt to minimize the difficulty and inconvenience of making complete blood counts in young children, especially in private practice; and while not without its difficulties it is much simpler and more convenient to obtain smears for staining and differential counting, and this permits a much more economic distribution of one's time. Therefore the purpose of the present short study is to see how far differential counting will serve to establish the existence of a lymphatic leukocytosis in the early stages of pertussis, and its diagnostic value.

In the healthy human adult the number of leuko-

cytes in the cmm. of blood is about 8,000, and they are distributed in the following proportions: Polynuclear neutrophilic leukocytes, 62% to 70%; lymphocytes (small mononuclear leukocytes), 20% to 30%; large mononuclear and transition forms, 4% to 8%; eosinophiles, 1% to 4%; mast-cells, 0.5%.

The leukocytes are greater in number at birth than in the adult, with a still further increase during the first 48 hours, then a decline, though the count still remains higher during the first and second year than in the adult. After the second year the number gradually declines to that found in adult blood, and the percentage of the various forms of leukocytes becomes normal. Engel found in infants 12% to 20% of polynuclear cells; after the first few months up to the end of the first year, 40% to 50%; at 12 years of age, 60%. It may be stated in a general way that higher percentages of lymphocytes are found in the blood of children up to the twelfth year than in adults.

I have examined the blood of 19 children, ranging from 7 months to 11 years of age, all of them at the time suspected of being in the catarrhal stage of whooping-cough. Fifteen of the 19 cases, from their subsequent course, proved to be cases of pertussis, and 4 of them not. The whole number of leukocytes were counted in 5 of the cases that afterward proved to be cases of pertussis; they ranged from 4,288 in the lowest to 12,000 in the highest, the average of the five counts being 6,698. A differential leukocyte count was made in all of the 19 cases. There was no evidence whatever, from the apparent number of leukocytes on the cover-slips or from the time consumed in counting a given number, that any of the cases had a hyperleukocytosis of any marked degree, while several of them showed decided evidence of a leukopenia. In 11 of the 14 cases of pertussis the lymphocyte percentage exceeded that of the polynuclear neutrophilic leukocyte, the average percentage of the various elements of the 15 cases (18 counts) being:

Polynuclear neutrophilic leukocytes, 43%.  
Lymphocytes, 49.9%.  
Large mononuclear and transition forms, 4.9%.  
Eosinophiles, 1.7%.  
Mast-cells, 0.3%.

In all of the 4 cases proving not to be pertussis the polynuclear neutrophilic leukocyte percentage exceeded that of the lymphocytes, the average of the count of the 4 cases being:

Polynuclear neutrophilic leukocytes, 56.5%.  
Lymphocytes, 33%.  
Large mononuclear and transition forms, 7.8%.  
Eosinophiles, 1.9%.  
Mast-cells, 0.3%.

One of the cases of pertussis, the first I examined and the results of which linked my attention to the subject, is as follows:

The patient was an extremely well-nourished child of 5 years. At the time of the examination, just before the Christmas holidays, she had been coughing between two and three weeks. Her mother was very anxious to know whether it was whooping-cough, as upon the answer depended whether she should be isolated or not at a time when she would come in contact with other children at her own home and their homes during Christmas week. Her blood count gave the following results: Whole number of leukocytes, 11,000; polynuclear neutrophilic leukocytes, 44%; lymphocytes, 51%; large mononuclear and transition forms, 2%; eosinophiles, 2.5%; mast-cells, 0.5%.

On the strength of the lymphocytosis I diagnosed whooping-cough. The course of the cough was, in regard to its duration and general character, typical of the disease, but the child did not "whoop," so far as her family could say, although the nurse said she heard her "whoop" once. My mind would have rested easy in regard to the original diagnosis, in spite of the mild character of the attack, if I had not examined her blood again a month or six weeks after the cough had ceased, when the differential count resulted as follows: Polynuclear neutrophilic leukocytes, 34.6%; lymphocytes, 54.9%; large mononuclear and transition forms, 7.7%; eosinophiles, 2.5%; mast-cells, 0.3%—a more characteristic picture of a lymphatic leukocytosis than she had during the catarrhal stage of the disease. A still later count, five months after the disease, shows 35% of polynuclear neutrophiles, and 60% of lymphocytes, with very few leukocytes on the slide.

Cases XIV and XV are of interest.

The patients, brother and sister, aged 9 months and 4½ years, respectively, began to cough simultaneously. The coughs were characterized by their spasmodic character from the beginning. At the end of the first week the baby's differential blood count was: Polynuclear neutrophilic leukocytes, 40%; lymphocytes, 50.5%; large mononuclear and transition forms, 6.2%; the girl's corresponding elements, 57.3%, 33.6%, and 4.5% respectively. The girl's cough stopped completely by the end of the second week, the baby's cough continuing unabated. At the end of the third week the baby's cough, while very suspicious, was not absolutely characteristic; isolated shocks of cough at intervals, always one, sometimes two paroxysms a day, which resulted in gagging and finally vomiting. At this time the girl's cough began anew (after more than a week of complete suspension), a hard, dry, spasmodic cough, with no marked paroxysms; at this time her differential count was as follows: Polynuclear neutrophilic leukocytes, 47.3%; lymphocytes, 40.5%; large mononuclear and transition forms, 8%. At the end of five weeks both children were still coughing, but improved; the baby had one paroxysm a day, the girl's cough was unchanged in character but less frequent. Both cases are in all probability pertussis, although neither of them have "whooped." The doubt lies in the family history and the absence of positive blood findings. Three older children had whooping-cough some years ago, and had it severely; there is a fifth child, intermediate in age, that did not have it then and is free from it now. The whole number of leukocytes in the case of the baby was very small. It took longer to count 600 in his case than it did to count twice that number in the case of his sister. The question naturally arises whether the baby's tender age may not account for the excess of lymphocytes in his blood, and is answered in some degree by the case of a 7 months' old baby, whose cough turned out not to be whooping-cough, and whose differential count gave: Polynuclear neutrophilic leukocytes, 55.7%; lymphocytes, 38%; large mononuclear and transition forms, 8%.

The results of the differential count of the blood of three adults, two of them with whooping-cough, the other, who had been repeatedly exposed to it, and suffered with a severe, intractable, spasmodic bronchial cough, with all the characteristics of the disease without actually "whooping," show an interesting contrast. Two of them had normal adult percentages: 62.4% and 70% of polynuclear neutrophiles, 31% and 23% of lymphocytes, and 5.2% and 5% of large mononuclear and transition forms, respectively. The other, one of the pronounced pertussis cases, had 88% of polynuclear neutrophiles, 6.5% of lymphocytes, and 5.5% of large mononuclear and transition forms.

It remains to compare the results obtained in whooping-cough with those of other diseases of children. The material for this purpose is at hand in a paper by Alfred Stengel, M.D., and C. Y. White, M.D., on "The Blood in Infancy and Childhood."<sup>5</sup> Before proceeding to the comparison, a few words must be said in regard to the classification of the mononuclear leukocytes. In 51 of Stengel's and White's 55 counts, the large mononuclear and transition forms are above normal; in 1 case as high as 50%, and in 35 of the 55 counts the lymphocytes are below normal. The average of the 55 counts is 15.5% of large mononuclears and 23% of lymphocytes, together 38.5%, which is very close to the normal. As the normal percentage of the large mononuclear and transition forms is given by the books as from 2% to 8%, and they rarely exceed the latter figure, the average percentage of 15.5% of Stengel's and White's cases is too high, is not in keeping with their other figures, and must have resulted from a failure to discriminate the large lymphocytes from the large mononuclear and transition forms by ignoring their staining and morphologic characteristics.

The large concentrically-situated basophilic nucleus surrounded by a narrow rim of more intensely basophilic protoplasm (eosinate of methylene-blue), regardless of the size of the whole cell, serves to distinguish the lymphocyte from the feebly basophilic and eccentrically situated nucleus within the larger and still feebler basophilic mass of protoplasm of the large mononuclear leukocyte, and the indented or constricted nucleus of the intermediately basophilic nucleus and protoplasm of the transition form. Individual cells frequently occur, from poor staining or other reasons, that have to be classified at random. For instance, in one of my cases (No. 5 of

the first series) it was impossible to classify any of the large mononuclears as large lymphocytes, although two specimens were gone over carefully for the purpose. As a matter of interest, in another case (No. 9 of the first series) all of the large mononuclears were distinctly transition forms.

In order to utilize the material of Stengel and White it is necessary to classify the lymphocytes, the large mononuclear leukocytes, and the transition forms under one heading, simply as mononuclear leukocytes. I do this the more readily, as I believe it would be good practice to do it always in order to simplify counting and reduce the liability of error. Therefore, hereafter only two forms of leukocytes will be referred to: the polynuclear neutrophilic leukocyte, and the mononuclear leukocyte, the latter including the lymphocytes, the large mononuclear leukocytes, and the transition forms, the combined percentage of which would hardly reach 35% in the healthy human adult and in children would not exceed 40%.

Dividing Stengel's and White's 55 counts in various diseases of children into two classes, one in which there is an approximately normal leukocytosis, and the other in which there is a hyperleukocytosis, including all cases with 10,000 leukocytes and less in the former, and all cases with more than this number in the latter, there are 14 counts with an average leukocytosis of 7,072, showing differentially polynuclear neutrophilic leukocytes, 62.1%; mononuclear leukocytes, 34.3%.

There are 41 counts with an average hyperleukocytosis of 23,430, showing polynuclear neutrophilic leukocytes, 58.6%; mononuclear leukocytes, 38.4%.

The average of the whole 55 counts shows a hyperleukocytosis of 19,267, with polynuclear neutrophilic leukocytes, 60%; mononuclear leukocytes, 38.5%.

It will be noticed how uniform these percentages are under the varied conditions, the presence or absence of a hyperleukocytosis not affecting them very appreciably.

Among Stengel's and White's cases are 3 of pertussis, to which I add 5 of my own, in all of which the total white blood count was made; it ranged from 4,288 in the lowest to 34,667 in the highest, and gave an average hyperleukocytosis of 13,315. There are 18 cases (21 counts) in which a differential count was made, 3 of Stengel's and White's and 15 of my own. The percentage of the mononuclear leukocytes is higher than the polynuclear in all but 3 of the cases, the average being: Polynuclear neutrophilic leukocytes, 41.4%; mononuclear leukocytes, 55.4%.

It is particularly interesting that the mononuclear leukocyte percentage exceeds the polynuclear neutrophilic in these cases of pertussis almost as much as the polynuclear neutrophilic exceeds the mononuclear in all the other diseases of children.

Among Stengel's and White's cases there are a number, beside the cases of pertussis, in which the percentage of the mononuclear leukocytes exceeds that of the polynuclear neutrophilic; notably 1 of 10 counts of pneumonia, 2 of 10 counts of typhoid fever, 2 of 4 counts of varicella, 1 of 3 counts of enteritis, 2 of rickets, 1 of eczema, 1 of focal epilepsy, 1 of convulsions, 1 of spastic cerebral palsy, and 1 of pleural effusion. There are 16 such counts, with an average whole number of leukocytes of 17,448; polynuclear neutrophilic leukocytes, 39.8%; mononuclear leukocytes, 59.9%. The remaining 39 counts have an average hyperleukocytosis of 19,987, divided as follows: Polynuclear neutrophilic leukocytes, 68.6%; mononuclear leukocytes, 29.7%. It is interesting to note how nearly reversed the figures are for the two kinds of leukocytes, and that they confirm the occurrence of a lymphatic or mononuclear leukocytosis.

Other causes contributing to an increase of the lymphocytes (aside from lymphatic leukemia) are cholera infantum, rickets, intestinal diseases, scurvy, the anemias of children, inanition, and hereditary syphilis.

Calmette<sup>6</sup> states that a relative mononuclear leukocytosis is found in the blood in chronic diseases, as leukemia, pertussis, sarcomatosis, tuberculosis, syphilis, malaria, smallpox, varioloid, varicella, and the mineral poisons. Chronic diseases of the nervous system cause lymphocytosis (tabes, general paralysis, syphilitic meningitis, etc.).<sup>7</sup>

The disease with which whoopingcough is most likely to be confounded is bronchitis. Stengel and White report 6 cases; their average leukocytosis is 12,911, divided as follows: Polynuclear neutrophilic leukocytes, 68%; mononuclear leukocytes, 29.9%. A marked contrast to the blood findings in pertussis.

Their 10 cases of pneumonia (as in pneumonia in the adult) have an average hyperleukocytosis of 40,420, with the same distribution of the leukocytes as in bronchitis, namely: Polynuclear neutrophilic leukocytes, 68.1%; mononuclear leukocytes, 31.2%.

Contrast these figures with those prevailing in 2 cases of pertussis pneumonia observed by Cabot, presenting the most marked absolute lymphocytosis known to him (excluding leukemia); 1 had white cells up to 94,600, 69% of which were lymphocytes; the other, white cells 103,000, 64.5% lymphocytes.

These few cases of pertussis do not confirm the existence of a hyperleukocytosis as a constant characteristic of the catarrhal stage of the disease, although almost all of them confirm the presence of an increased percentage of lymphocytes. It is very probable that the condition of the child's nutrition is the potent factor influencing the presence or absence of a hyperleukocytosis, and that a moderate falling off causes a change in the relative distribution of the various forms of leukocytes themselves more readily than it does a marked increase in their numbers, and for this reason results obtained from patients in private practice are not always in keeping with those in dispensary and hospital practice. There seem to be good grounds to conclude that an increased percentage of lymphocytes, at least equaling or exceeding that of the polynuclear neutrophilic cells, is a valuable diagnostic aid in whoopingcough before the character-

SIXTEEN CASES OF PERTUSSIS.

No. of case.	Age.	Whole number of leukocytes.	Polynuclear neutrophils.	Lymphocytes.	Large mononuclear and transition forms.	Eosinophils.	Mast-cells.
1	5½ years.	11,000	44.0%	51.0%	2.0%	2.5%	0.5%

istic symptoms of the disease make the diagnosis easy. But like the doctrine of polynuclear leukocytosis in general, the figures are more convincing in the mass than when considered individually. Individual cases always occur showing exceptions to the general rule, and for this reason the results of blood examinations cannot be taken as an absolute diagnostic factor, but must always be considered in connection with all the other features of an individual case.

Since this paper was written I have examined an additional case:

A boy, aged 3, a child of well-to-do parents. He had been coughing for a week. Polynuclear neutrophiles, 31.7%; lymphocytes, 65.4%; large mononuclear and transition forms, 2.1%; eosinophiles, 0.6%; mast-cells, 0.2%. This is the only one of my cases in which cover-slips showed decided evidence of a hyperleukocytosis. He had since developed a typical whoopingcough.

A CASE OF INFECTION WITH THE DOUBLE-PORED DOG TAPEWORM (DIPYLIDIUM CANINUM) IN AN AMERICAN CHILD.

BY

CH. WARDELL STILES, PH.D.,<sup>1</sup>  
Zoologist, Bureau of Animal Industry.

Among the specimens of parasites recently sent to the Bureau of Animal Industry for examination is one (B. A. I., No. 3,305) which is of considerable interest. This is a double-pored tapeworm which was passed by a child, and which belongs to the species *Dipylidium caninum*, a very common parasite in dogs and cats, but comparatively rare in man. According to Dr. George Duffield, of Detroit, Mich., to whose courtesy we are indebted for this specimen, the worm was discharged by a child 16 months old.

The parasite in question belongs to the family Tæniidae, subfamily Dipylidiinæ, and is characterized as follows:

SUBFAMILY DIPYLIDIINÆ STILES, 1896.

*Subfamily Diagnosis.*—Tæniidæ: Suckers unarmed, Rostellum armed, rarely absent. Genital pores lateral, single, or double and opposite. Genital organs of each segment in single or double series. Uterus usually divides up into egg sacs, or disappears entirely so that the eggs lie free in the parenchyme. Eggs with thin transparent shells, with or without appendages. Larval forms (cysticeroides) in arthropods or mollusks. Strobila in mammals, birds, and reptiles.

Type genus: *Dipylidium* Leuckart.

Fig. 1.—Adult strobila of the double-pored dog tapeworm (*Dipylidium caninum*). Original.  
Fig. 2.—Mature segment of same, showing the anatomy: c., cirrus (penis); c. p., cirrus pouch; ov., ovary; r. s., receptaculum seminis; t., testicles; u., uterus; v., vagina; v. d., vas deferens; v. g., vitellogene gland. x 25. After Neumann in Rallillet, 1893, page 239, Fig. 188.  
Fig. 3.—Gravid segment of same, lettering the same as in Fig. 2. After Diamare, 1893, pl. I, Fig. 1.

GENUS DIPYLIDIUM<sup>2</sup> LEUCKART, 1863.

*Generic Diagnosis.*—Dipylidiinæ: Rostellum retractile, armed with several rings of alternating hooklets

<sup>1</sup> Transferred Aug. 16, 1902, to U. S. Public Health and Marine-Hospital Service as Chief of Division of Zoology.  
<sup>2</sup> Synonyms: *Dipylidium* Leuckart, 1863; *Microtenia* Sedgwick, 1884.

which usually possess a discoidal base. Suckers unarmed. Genital pores double and opposite. Genital organs in double series. Testicles very numerous, in median field. Ovary bilobed. Vitellogene glands distal of ovary. Uterus at first represents a reticulum, in the meshes of which are situated the testicles; later it breaks

up into egg-sacs enclosing one or several eggs. Eggs with double shell. Adults parasitic in mammals.

Type species: *Dipylidium caninum* (Linnaeus).

DIPYLIDIUM CANINUM<sup>1</sup> (LINNAEUS, 1758).

*Specific Diagnosis.* — *Dipylidium*: Strobila 15 to 35 cm. long; head small, globular; rostellum club-shaped, with 3 to 4 transverse rows of hooks (about 60 in number) of rose-thorn form; the anterior hooks 15 $\mu$ ; the posterior hooks 6 $\mu$ ; suckers relatively large, rather elliptical. Segments 80 to 120 in number; gravid

Fig. 4.—Head of same, showing four rows of rose-thorn hooks on the rostellum and four unarmed suckers. Original.

segments 8 to 11 mm. long, 1.5 to 3 mm. broad, often reddish brown in color. Genital pores at equator or in posterior half of segment; uterus forms egg-capsules, each containing 8 to 20 eggs; eggs globular, 43 to 50 $\mu$  in diameter; eggshell thin; oncosphere 32 to 36 $\mu$ .

*Hosts.*—Adult in dogs, cats, and man; larva in lice (*Trichodectes canis*) and fleas (*Pulex serraticeps*, *P. irritans*).

While this is one of the smaller tapeworms, it cannot be looked upon as harmless, for it sometimes burrows into the intestinal mucosa making a tunnel-like channel, through which the segments are pulled much like a train of cars passing through a tunnel.

*Clinical Diagnosis.*—In diagnosis, search should be made

in the feces for the peculiar elongated elliptical tapeworm segments. Microscopic examination of the feces for eggs is less certain than in case of infection with *Tenia saginata*, *T. solium*, or *Dibothriocephalus latus*, since *Dipylidium* is much smaller and less prolific than any of these three forms.

Fig. 5.—Egg packet of same. Greatly enlarged. Original.

Fig. 6.—Egg of same. Note the six hooks in the embryo. Greatly enlarged. Original.

Fig. 7.—*Cryptocystis trichodectis*, the larval (infection) stage of *Dipylidium caninum* as found in the flea. After Leuckart, 1886, page 847, Fig. 318.

The eggs of *Dipylidium caninum* are entirely different from those of any *Tenia*. In the genus *Tenia* we find a thick striated inner shell (embryophore), while in *Dipylidium* the inner shell is thin. The six-hooked embryo, characteristic of all tapeworms, is observed in the egg.

Physicians who wish to become familiar with *Dipylidium caninum* can easily obtain specimens by examining several cats or dogs, as this tapeworm is very common in these animals. For a zoological discussion and bibliography of the genus *Dipylidium*, the reader is referred to Diamare, 1893, II genre *Dipylidium* Lt. (Atti R. Accad. fis. e mat. di Napoli, 2. s., v. 6 (7), presentata 13 maggio, 1893. Reprinted as separate, 31 pp., pls. 1-3, with 50 figs. 4°. Napoli, 1893.)

## SPECIAL ARTICLES

### HOSPITAL WORK OF DR. CARL LAUENSTEIN.

BY

NICHOLAS SENN, M.D.,  
of Chicago.

One of the best known names in the medical and social circles of Hamburg is that of Dr. Carl Lauenstein. As a surgeon his name is familiar wherever surgery is practised. His contributions to surgical literature have been many and of great scientific and practical value. His voice is heard at every annual meeting of the German Surgical Society, and never fails to command earnest attention. Nearly every volume of the transactions of this society contains an account of his activity as a surgeon and scientist. He speaks French and English fluently, and is well versed in everything pertaining to foreign medical literature. His personality is a striking one. He stands six feet four in his stockings, erect as the fir tree of his native home, and is endowed with the physical strength of a giant. A man of ordinary size standing or walking aside of him experiences a keen sense of his physical insignificance under the shadow of his towering height. He is a typical blonde, and his large azure-blue eyes reflect the nobility of his soul. He has reached the fifty-second milestone of his busy, useful life. The son of a clergyman, he received the most careful training from early childhood for the profession of his choice. He studied medicine at the University of Göttingen, and was the favorite pupil of the late Professor William Baum. Lauenstein respected and loved his teacher of surgery. The genuine piety, profound learning and honest convictions which characterized the life and work of Professor Baum made a deep and lasting impression on his pupil, and undoubtedly had much to do in molding his subsequent professional career. Lauenstein loves to relate little incidents in the life of his master. Many of these little stories reflect the surgical practice of those days. On one occasion an assistant had used a probe in exploring a foul abscess; the professor, who wished to examine a recent wound, called for the instrument, and wishing to impress his assistants with the importance of surgical cleanliness, wiped the probe between his lips and then with a clean and easy conscience used it upon his patient. Lauenstein's early student days were eventful. At the outbreak of the Franco-Prussian war he was a medical student at Göttingen. He, like most of the university students, promptly volunteered

Carl Lauenstein and his smaller brother as privates during the Franco-Prussian war.

<sup>1</sup>Synonyms: *Tenia canina* Linnaeus, 1758; *T. moniliformis* Pallas, 1781; *T. cucumerina* Bloch, 1782; *T. elliptica* Batsch, 1786; *T. (Dipylidium) caninum* (Linnaeus) Leuckart, 1893.

and entered the military service as a private of a musketeer regiment. During the short, historic military career he wrote one and often two letters every day to his anxious, devoted, affectionate parents. These letters were preserved, and in 1895 he published them in book form and presented this souvenir of the war to his mother on Christmas day. How his aged mother appreciated this gift only a mother can describe who has passed through the same bitter experience. Lauenstein was a faithful, heroic soldier. He was in action eleven times, and had many narrow escapes, but Providence deviated the bullets aimed at him. His patriotism and sense of duty knew no bounds. On his return home one of his friends furnished the explanation why he escaped uninjured. He said that during one of the battles a Frenchman drew his bead on him at close range, the next moment he dropped his musket lower, fully convinced that other comrades had selected the same conspicuous target, and not wishing to waste ammunition, fired at a man of ordinary size. In one of his letters to his parents he said that if he were permitted to return home alive he would never return to France, where he experienced all the privations meted out to the private soldier during a forced campaign under the most distressing climatic conditions. He failed to keep this promise. He recently made a bicycle tour through France with his oldest son, a law student, and visited all of the familiar battlefields where he served his country so well 32 years before. Such men should be rewarded with a jeweled cross of gold instead of one of iron. Dr. Lauenstein's opportunities for making practical use of his surgical knowledge and skill have been immense. He is surgeon-in-chief to two of the Hamburg hospitals and at the same time enjoys a lucrative private practice.

*Bethesda Hospital.*—This is a private hospital in charge of deaconesses. It contains 100 beds, of which 50 are occupied by surgical patients. Lauenstein is the very soul of this institution. It is here where his surgical methods can be studied to greatest advantage. A new addition is nearly completed and will afford the necessary additional room for the increasing demands on the hospital. The patients are divided into three classes. The first class patients pay eight marks a day, the second five. Many of the third class are received as charity cases. The wealthy citizens contribute liberally toward the improvements and running expenses of this excellent institution. The operating-room is small, unpretentious, but the plain, simple facilities for asepsis are utilized in such a practical manner that the visitor becomes convinced that the patients who are operated upon have received all the essential prophylactic care that modern surgery can offer against infection. Lauenstein places more weight on air infection than most surgeons. One of his requirements in entering the operating-room is careful wiping of the shoes, a task which is performed in a most conscientious manner by a male servant. Gloves are used in operations upon septic cases, and then only for the purpose of protecting the hands against contamination. Instead of a mask the hair and beard are washed and are kept moist with an antiseptic solution. The operator is assisted by the house surgeon and three Sisters. One of the Sisters administers the anesthetic, usually chloroform, by the drop method; another has charge of the instruments, and the third one handles the gauze, sponges and dressing material.

*Lauenstein's Method of Hand Disinfection.*—Lauenstein has made disinfection of the skin a special study for several years. Some three years ago he reported upon the results of his scientific investigations on this subject. He made use of all then known methods of disinfection and then removed a small particle of skin from the disinfected surface and under strict aseptic precautions transferred it to a nutrient medium. Without exception microbes developed, which led him to the conclusion that absolute asepsis cannot be obtained by any of the methods so far employed. These observations taught him the necessity of combining aseptic with antiseptic measures. He irrigates wounds with a 2% solution of lysol. His directions for hand disinfection are the following:

1. Softening and washing of the hands without brush in warm water with soap, frequently changed until the water remains clean.
2. Cleansing and trimming of finger nails.
3. Renewed washing in warm water without brush.

4. Final cleansing in warm water and soap with use of sterile brush.

5. Drying with sterile towel.

6. Thorough immersion and scrubbing of fingers and hands with 96% alcohol with use of sterile gauze sponges with special reference to finger nails and subungual spaces continued for three minutes. The field of operation is prepared the evening before operation and the surface covered with a compress saturated with a solution of salicylic acid. Before the operation the final disinfection is made.

*Lauenstein's Method of Catgut Sterilization.*—Lauenstein has given the different methods of catgut sterilization a fair trial and after finding them unsatisfactory has adopted the following method:

The catgut, free from fat and sterilized by dry heat, is immersed for eight days in 50% creolin-vasogen. In this very active bactericide the catgut softens and swells and is saturated with the creolin-vasogen throughout. It is then placed in 2% salicyl-alcohol to which 10% of glycerin is added. In this solution the threads are often turned over and in this solution it retains its firmness and tensile strength. Before use it is immersed in .5% formalin-alcohol. He has used catgut prepared by this method for six years with perfect satisfaction. The bacteriologic examinations of this catgut made frequently by Professor Dunbar have always proved its absolute sterility. Silk used for superficial sutures is sterilized by boiling. Dr. Lauenstein regards reliable catgut as the ideal material for ligatures and buried sutures. He has in his service a large gynecologic material. One day he examined three patients under anesthesia and dictated the following diagnoses: Subserous myofibroma, solid tumor of ovary, large ovarian cyst. All of these patients were operated upon three days later. On the day of my visit to this hospital he performed the first operation after his return from his summer vacation.

Dr. Carl Lauenstein.

*Tuberculosis of the Knee-joint; Amputation of Thigh After Resection of Joint had Failed.*—The patient was a woman, aged 56, who entered the hospital two months ago, suffering from advanced tuberculosis of the left knee-joint. Typical resection was made with faint expectation of a successful result owing to her advanced age and the extent of the disease. The wound healed only in part and the extensive recurrence left no doubt concerning the propriety of resorting to a mutilating operation. Patient was anemic and considerably emaciated; chloroform anesthesia; elastic constriction at base of thigh; long anterior and short posterior cutaneous flaps; remaining soft tissues were divided down to the bone with one sweep of the knife; soft tissues were retracted with two folded gauze bandages. After reflection of periosteum with elevator cross section of bone with a bow saw, the femoral artery and vein were isolated separately and tied with catgut. Careful search was made for the intramuscular branches, which were seized with hemostatic forceps. So thoroughly was this done that when the constrictor was removed no further use of the forceps became necessary. The flaps were united with silk sutures leaving both angles of the wound open for gauze drainage. The wound was thoroughly flushed with a 2% solution of lysol before and after suturing. A few layers of loose sterile gauze, next a thick layer of aseptic absorbent cotton, a cushion of wood wool and a second layer of cotton held in place with a gauze roller, which also included the pelvis, constituted the dressing.

In the absence of unfavorable symptoms the first dressing is not disturbed for two weeks. With the methods he now employs Dr. Lauenstein looks with confidence to his results.

*Harbor Hospital.*—This is a government hospital built and supported by the city of Hamburg. Dr. Lauenstein is the surgeon-in-chief, assisted by four salaried resident physicians. The hospital is intended for emergency cases, and its interior construction corresponds with this purpose. The wards are well furnished, well lighted, and well ventilated. It contains a

motley population, as it is likewise the refuge for the sick and injured sailors of all nations who frequent the great mercantile harbor of Hamburg.

This is the place in Hamburg to make a practical study of accidental surgery. Among the injuries brought here almost daily are fractures, dislocations, sprains and burns; stab and gunshot wounds are comparatively rare.

The dressing and operating-rooms are constructed upon the most improved plans, and are splendidly equipped. With all such conveniences it must be a source of gratification and pleasure to practise emergency surgery. The Röntgen apparatus and rooms are in constant use, and in charge of an expert. A complete outfit for photography turns out daily the most interesting illustrations of fractures, dislocations, and other injuries. Dr. Lauenstein is now making a special study of spiral fractures. He has the requisite material at his disposal to elucidate this subject from a scientific as well as a practical standpoint. Much has been said and written concerning this particular anatomic form of fractures, but more light is needed to comprehend fully the mechanism of their production. A number of beautiful Röntgen illustrations were shown of spiral fracture of the tibia and fibula. In fracture of both bones, the seat of the injury involved the lower part of the tibia, while the fibula yielded near the upper extremity. Reduction and retention by proper means of fixation offer no particular difficulties, and the results are usually very satisfactory. Dr. Lauenstein intends to present the paper he is preparing on the nature and treatment of this fracture on the occasion of the eightieth birthday of his Excellency Professor von Esmarch, which will be celebrated in the birthplace of that distinguished surgeon next January. The paper will be profusely illustrated, and will be looked for with interest by the profession, as it will clear up a number of doubtful points in the etiology of spiral fractures. The nursing in this hospital in the male wards is done exclusively by trained male nurses. The scrupulous cleanliness throughout the entire institution reflects credit upon the director as well as upon the efficient and well-organized nursing force.

The city morgue is located in the hospital grounds. Here is a good place to make a practical study of legal medicine, as a number of postmortems are made daily by an expert, and the causes of death, accidental and otherwise, are investigated with a view of satisfying all legal requirements.

The detention department is an interesting part of the hospital. This serves as a temporary asylum for cases of acute insanity, delirium tremens, etc. Violent patients are confined in single rooms having an iron door, which is locked. The room contains nothing but a leather-covered mattress for a bed. About six cells are always occupied by delirium tremens patients. In one cell we found a man in shirt sleeves facing the rear wall reaching with trembling hands for red currants which he saw distinctly on the bare white wall but always eluding his greedy grasp. Lauenstein has abandoned the use of alcoholic stimulants in the treatment of delirium tremens after a trial of over 20 years. He has become satisfied and firmly convinced that recovery takes place more speedily without than with alcohol. He looks upon the disease as an intoxication and reasons very properly that the sooner the cause is removed the more sure and prompt will be the recovery. So long as the patients are violent they are confined in a cell. Small doses of morphia and chloral hydrate are given to procure sleep. Much stress is laid on the administration of concentrated fluid nourishment. If on admission of the patient there is reason to believe that the stomach contains alcohol it is evacuated by siphonage. The acute symptoms usually subside in three or four days, when the patient is transferred to an adjoining ward, where with other convalescents he receives the appropriate after-treatment and where he remains until recovery is complete. It is said that most of these patients return about every six months with the same disease and pass through the same course of treatment. In Germany, like elsewhere, delirium tremens is caused by the excessive use of spirits; beer drinkers seldom succumb to this disease.

The medical tourist visiting Hamburg should not neglect to make a visit to the Harbor Hospital, as he will be sure to find here many things of the utmost scientific and practical interest

and will always meet a cordial reception by its genial medical director, Dr. Carl Lauenstein.

On board S. S. "Blücher," August 25.

## THE WORLD'S LATEST LITERATURE

Journal of the American Medical Association.

[January 3, 1903. [Vol. XL, No. 1.]

1. A Contribution to the Subject of Radiotherapy and Phototherapy in Carcinoma, Tuberculosis and Other Diseases of the Skin. JAMES NEVINS HYDE, FRANK HUGH MONTGOMERY and OLIVER S. ORMSBY.
2. Notes on X-ray Treatment of Cancer, with Report of Cases. G. E. PFAHLER.
3. The Technic of X-ray Therapy as Applied to Diseases of the Skin. LOUIS E. SCHMIDT.
4. Treatment of Fractures of the Neck of the Femur. CHARLES E. THOMSON.
5. The Treatment of Transverse Fracture of the Patella by Subcutaneous Purse-string Sutures. JOHN B. ROBERTS.
6. Uncinariasis or Ankylostomiasis, with the Report of a Case. JOSEPH A. CAPPS.
7. Prognosis in Mental Diseases. FRANK PARSONS NORBURY.

**1.—Radiotherapy and Phototherapy in Diseases of the Skin.**—Hyde, Montgomery, and Ormsby briefly discuss the phenomena of heliotropism in plants and animals, and the technic of radiotherapy, and report cases, illustrating them by a large number of cuts. They believe radiotherapy and phototherapy superior to any other treatment in tuberculosis of the skin, and phototherapy has given them the most satisfactory results in lupus erythematosus. In superficial carcinoma over a large area they prefer radiotherapy to all other methods of treatment. For circumscribed growths they recommend excision, followed by x-rays. If inflammation is excited it may encourage extension of the growth. The value of radiotherapy has been established in hypertrichosis, psoriasis, acne rosacea, folliculitis, and suppurating wounds. It should be reserved, however, for cases in which other treatment has failed. In tuberculosis phototherapy acts as rapidly as radiotherapy and with better cosmetic effects. [H.M.]

**2.—Röntgen Ray Treatment of Cancer.**—Pfähler briefly reviews the histories of a few cases, two illustrating the danger of doing too much instead of giving nature a chance when repair has been well started. He prefers the coil somewhat to the static machine, a low vacuum tube for superficial and a higher for the deeper structures, placing the tube near the part and carefully watching it. Exposure should be from 5 to 20 minutes every second or third day. Lead foil between layers of adhesive plaster best protects the surrounding tissue. The skin should be carefully reddened without causing ulceration. The time required to cure superficial cancer is two to six months. The open surface should be dusted with equal parts of starch, boric and salicylic acids. [H.M.]

**3.—Technic of Röntgen Ray Therapy in Skin Diseases.**—Schmidt discusses the preparation of the patient, trials to detect idiosyncrasy, how to measure the energy, how to judge the strength of a tube, the vacuum and its regulation, the relation of heat rays to Röntgen ray, and the position of the tube. The dosage may be regulated by increasing or decreasing the rays or applying them in a more or less intense manner. The former depends on the tube, the latter on the distance. [H.M.]

**4.—Fracture of the Neck of the Femur.**—Thomson thinks surgical authors have been rather discouraging to the general practitioner on this subject, that firm union and useful limbs may be anticipated, that age is not a counterindication to this, that the best treatment is reduction and immobilization, that this is best accomplished under anesthesia by the plaster-of-paris spica, that immobilization should last for a long time, and three months elapse before allowing weight on the limb. Operative treatment in old and neglected cases has succeeded beyond all expectation. [H.M.]

**5.—See American Medicine, Vol. III, No. 25, p. 1042.**

**6.—Uncinariasis or Ankylostomiasis.**—Capps describes the species affecting the lower animals and man, and reports in detail the first case of *U. duodenalis* infected in Panama, and in brief the 51 cases heretofore noted in the United States. The disease is common in our new possessions. It was probably imported into Panama by Italian laborers. Infection usually

occurs by eating with unclean hands. Examination of the feces is the only certain method of diagnosis. He emphasizes the importance of prophylaxis during the building of the canal. [H.M.]

### Boston Medical and Surgical Journal.

January 1, 1908. [Vol. CXLVIII, No. 1.]

1. Notes on Multiple Primary Tumors. PAUL G. WOOLLEY.
2. Percentage Modification of Milk in Infant Feeding. MAYNARD LADD.
3. Foot-and-Mouth Disease. LANGDON FROTHINGHAM.
4. Chlorid of Ethyl as a General Anesthetic. CHARLES GREENE CUMSTON.

1.—**Multiple Primary Tumors.**—Woolley gives a technical discussion, which while interesting and philosophic, does not lend itself to valuable abstract. The pivotal idea is that primary tumors, malignant, benign, or mixed, may arise independently in the paired organs of the body, in functionally unrelated organs, or in the same organ. That tumors arise secondarily by metastasis is of course beyond a doubt, but it is too generally assigned as a cause for separate tumor growths. In conclusion, he begs observers to watch for cases of multiple primary growths, and record with them careful studies of the general conditions, as well as of the special ones surrounding the patients. Such records in cases of tumors in paired organs, such as the breasts, adrenals, ovaries, etc., would be of the greatest interest and value in determining whether metastasis or biologic change is the more obvious factor in the production of such cases. [A.B.C.]

2.—**Modification of Milk.**—Ladd gives tables which put the percentages of the ingredients in various combinations in simple and practical form in order that intelligent percentage feeding may be more generally adopted. As breast milk varies from feeding to feeding its average analysis is of but little aid in adapting cow's milk to the individual infant. Each case is a problem in itself. The tables given are those used by the writer in teaching and in his hospital work and which he has had printed on cards that can be carried in the pocket. [H.M.]

3.—**Foot-and-Mouth Disease.**—Frothingham describes this most contagious of all animal diseases, recently reintroduced into this country. Where it is prevalent the financial loss may reach far into the millions. The vesicles which form contain the virus. Men who have been much exposed become infected. The mortality is low in animals and is seldom fatal in man, except among children. The special organism of the contagion is unknown. A temperature of 80° C. will render milk harmless. Infected straw will preserve virulence for two months. Birds may carry infection to distant localities. Immunity left by the disease is of uncertain duration. Immunizing serum has not as yet proved satisfactory. It requires 240 cc. (30 ounces) to protect a cow 14 days. Better results have been obtained with sheep and swine, as 5 to 20 cc. (1½ to 5 drams) will give immunity three or four weeks. [H.M.]

4.—**Ethyl Chlorid as a General Anesthetic.**—Cumston says Newinan used this drug for general anesthesia in 1867, with one death, and necropsy showed a fatty heart in that case. The names of many other surgeons are mentioned as having used it. Malherbe reports having used it in 170 cases, in 140 of which it alone was used, but in the remainder it preceded chloroform; and his enumerated points of advantage are: Small quantities of ethyl chlorid, from 2 to 4 grams (½ to 1 dram) are sufficient for producing a narcosis lasting four minutes, and can be renewed indefinitely; rapidity of the anesthesia (from 25 to 40 seconds); practically no congestion of the face or conjunctiva; never any cyanosis; the period of excitement is reduced to a few defensive movements, and these only in neurotic or alcoholic patients; contraction in the beginning rarely exists and immediately disappears; no trismus, no salivation. Occasionally emission of urine; the age of the patient is indifferent, and no disturbing symptom occurs; vomiting after administration of ethyl chlorid alone does not occur; vomiting occurring after a mixed anesthesia is not frequent, and if present rapidly subsides; rapid return to consciousness. Cumston agrees in the main with the conclusions of Malherbe, and he reports having

used ethyl chlorid preliminary to ether in 153 cases without the slightest accident. For examinations requiring an anesthetic, reduction of dislocations, curetment, etc., the drug is desirable when used alone, but for longer operations its use is in preceding the ether. Usually 10 cc. (2½ drams) are required for complete anesthesia, administered on a close-fitting cone. Only "kelene" or some other pure product should be used. [A.B.C.]

### Medical Record.

January 3, 1908. [Vol. 63, No. 1.]

1. How to Study Anatomy. STEPHEN SMITH.
2. Headache in Its Relation to Disorders of the General Health. WILLIAM M. LESZYNSKY.
3. Why the Open-air Treatment of Tuberculosis Succeeds. M. D. VEEDER.
4. Cold and Disease. H. RANDOLPH TUTHILL.
5. The Close Analogy of Trachoma to Adenoids. RALPH OPDYKE.

1.—**How to Study Anatomy.**—Stephen Smith holds that the present plan of teaching anatomy is without system, is unscientific, and calculated to befog the mind of the student. His plan is to have the student first recognize the necessity for an important organ structure or function, and then follow out a plan for devising mechanical arrangements to supply the necessity. The shape and method of locomotion in man presupposes a framework or skeleton, and this in turn a central point first created, and this is assumed to be the seventh dorsal vertebra. The histologic structure of the osseous system is mastered. Next the same appropriate reasoning with reference to the muscular system, the nervous system, digestive and circulatory systems. Considering the subject in this light he has found it a source of delight to the student and instructor. [A.B.C.]

2.—**Headache and General Health.**—Leszynsky describes functional headaches resulting from toxemia or reflex irritation in indigestion, from renal disease, from suboxidation or autotoxemia in rheumatism, from gout, diabetes, the infectious and other fevers, from alcohol, coffee and lead poisoning, from neurasthenia, epilepsy, errors of refraction and insufficiency of the ocular muscles, from nasopharyngeal and uterine disease, from hyperemia or passive congestion of the intracranial circulation, and from anemia. The most important element in treatment is recognition of the cause. [H.M.]

3.—**Why Open-air Treatment of Tuberculosis Succeeds.**—According to Veeder the only attribute of air that concerns us in connection with this subject is its temperature. The sharpness of limitation of temperature effects is well defined as to the tubercle bacillus, its ability to form colonies beginning almost precisely at the temperature of the body and extending to a few degrees above is well known. Feverishness may light up dormant infection, a cold or other slight ailment thus becoming the starting point of the disease. Cattle and birds whose temperature is above that of man are very susceptible, and horses whose temperature is below are immune. The activity of the bacteria keeps up the temperature disturbance and this activity is checked by cold. The use of drugs, etc., for reducing fever should be restudied in connection with the critical temperature points in the growth of bacilli in various diseases. Small variations may have very decided effects. Habitual outdoor living causes large temperature variation so far as the lungs are concerned and small variation as to the rest of the body. It is corroborative of this theory that the greatest benefit from open-air treatment occurs when the disease is in the lungs, and least when it is confined to the bones and other deep-seated tissues. As the tissues are invaded superficially at first entire recovery follows in a considerable proportion of cases. Furthermore, fresh, cool air is bracing, improving nutrition, deepening respiration, thus promoting the local effect and increasing resistance. Warm clothing is of service by enabling colder air to be taken into the lung without depressing effect. [H.M.]

4.—**Cold and Disease.**—Tuthill says cold lowers resistance through its effect on mucous membranes which sift out injurious bacteria. Probably the secretion of the mucous glands exercises a destructive or inhibitive action, and during arrest of secretion the germs develop, the local congestion stimulating growth. When reaction sets in and the glands pour out their

secretion it is too late, the intruders having gained so much headway. When chilling occurs, in addition to stimulants to insure reaction and cathartics to aid elimination of toxic material, an antiseptic spray seems advisable. [H.M.]

**5.—The Close Analogy of Trachoma to Adenoids.**—Opdyke found that two out of every three "operative" cases of trachoma had adenoids. This was true not only among the children of the East Side, in New York, but likewise on the West Side. This led the author to study the relation between these two affections. Histologically the trachoma nodule is lymphadenoid tissue, which later undergoes fatty degeneration and is replaced by cicatricial tissue. Since adenoid growths precede trachoma, and since the same general hygienic conditions conduce to the production of both, he thinks it fair to assume the relationship, and that the hygiene which cures or prevents adenoid growths of the nasopharynx will likewise prevent trachoma; or as the author aptly states: We have two distinct diseases in different parts of the body and adjacent to different organs, and with their etiologic and pathologic factors very closely analogous. We have proved the adenoid vegetation to be the primary factor, and we should give the benefit of the doubt to the trachoma as being its true sequel. If such is the case, active measures should be undertaken to stamp out, or at least to lessen the prevalence of trachoma by preventing its inception. [A.B.C.]

3. Personal Experience with McGraw's Method of Gastroenterostomy. SAMUEL LLOYD.

1.—See *American Medicine*, Vol. IV, No. 20, p. 766.

**2.—Retrocecal Abscess.**—Cullen reports a case of retrocecal abscess in a boy of 17, developing three years after the removal of the appendix. An abscess was evacuated and drained at the time of the first operation but recovery followed. About three years later he was injured by a fall and soon had symptoms of an abscess in the right iliac region. At the operation fully 100 cc. (3½ ounces) of offensive pus was evacuated. The abscess lay between the lower surface of the cecum and the parietal peritoneum. [C.A.O.]

#### Medical News.

January 3, 1903. [Vol. 82, No. 1.]

1. Disappearance of Yellow Fever from Havana, Cuba. MAJOR W. C. GORGAS.
2. Tabes Dorsalis: A Study of 140 Cases of Locomotor Ataxia. JOSEPH COLLINS.
3. A Case of Supernumerary Breast in the Axilla of an Adult Male. FREDERIC GRIFFITH.
4. The Diuretic Action of Rectal Irrigation: The Specific Action of Normal Saline Solution in the Production of Diuresis. ROBERT COLEMAN KEMP.
5. Hematocele. W. C. BOWEN.
6. Why Chloroform Should be Used in Puerperal Eclampsia. DOUGLAS H. STEWART.

**1.—Disappearance of Yellow Fever from Havana.**—Gorgas runs over the history of yellow fever and points out some of its prominent characteristics, the impossibility of its being carried by fomites, accounting for its absence from Asiatic countries, from high latitudes, and from altitudes in which the *Stegomyia* does not thrive. The disease is either epidemic or endemic, according as to whether the human host becomes exhausted. The disease can be stopped by destroying the *Stegomyia* or getting rid of nonimmunes or preventing infecting mosquitoes from biting the nonimmune, or noninfected *Stegomyia* from biting infected men, or by immunizing all the population. In Rio Janeiro and Havana the disease has been endemic because a large foreign immigration is constantly coming in. Gorgas describes the methods used in Havana to prevent infection of mosquitoes, to destroy those infected, to exterminate the species and to inspect nonimmunes, and the remarkable success attending these measures. With Rio and Havana gone as foci of infection, yellow fever would gradually become extinct. [H.M.]

**2.—Tabes Dorsalis.**—Of the 140 patients on whom Collins' study is based 124 were men and 16 women; 7.5 to one. The average age at which symptoms appeared was 38½. 68% of the men and 70% of the women gave a definite history of syphilis, and in a large proportion of the others it was probable. Exposure to cold and wet, sexual excesses, occupations that contribute to leg weariness, trauma, alcoholism, poisoning by ergot and lead, the arthritic and neuropathic constitution play an unimportant part in etiology. Syphilis stands out above all others, yet it is not a syphilitic disease in the true sense of the word, either clinically or pathologically, and is not amenable to syphilitic treatment in the slightest degree. Yet the contrast statistics of other nervous diseases seem to show beyond doubt direct pathogenetic relationship to it, tabetics having had syphilis ten times oftener than patients with other nervous diseases, excluding general paresis. It is impossible to determine how many syphilitics develop tabes as the interval is from 5 to 25 years. Its infrequency in prostitutes is probably due to their having reached their destiny before the age at which it usually develops. [H.M.]

**3.—Supernumerary Breast in Axilla of a Man.**—Griffith presents cuts showing this anomaly in a Bushman. A review of the literature fails to reveal any other well authenticated case. [H.M.]

**4.—Normal Saline Solution and Diuresis.**—Kemp calls attention to the fact that normal, or decinormal, saline solution has a specific effect on the kidney cells in promoting diuresis and that this occurs, whether the solution is administered by infusion, by hypodermoclysis, or enteroclysis. This takes place even when the quantity used is too small to cause any increase in arterial tension. He describes his experiments upon a dog, by which it was shown that one quart of normal saline solution, plus 5 cc. (1½ drams) of a 5% solution of ferrocyanide of potassium being employed through a recurrent irrigator, and the urine being tested every minute with ferric chlorid, in 20 minutes the Prussian blue reaction occurred, proving the rapidity of absorption from the intestines and the period when renal secretion begins. A small enema, or an enteroclysis of the above solution at 99° or 100° F. increased the amount of urine synchronously with the blue reaction, there being no rise of pressure, but the increased secretion being due to the specific action of the kidney. The normal salt solution given by any one of the three methods also causes a diminution of renal congestion. Even in cases of high arterial tension, though an irrigation at 110° to 120° may cause an evanescent increase, it will soon be followed by a rapid fall due to the profuse diuresis and diaphoresis. Experiments prove that the general average of absorption is one quart out of 13. In one case of oliguria with double pleurisy and effusion, with rectal irrigation alone in the space of four days, the urine increased from 12 to 20 ounces and in two weeks it increased to 70 ounces per day and the effusion had disappeared. Kemp emphasizes the fact that one cannot afford to wait for slow results in such a disease as puerperal eclampsia, but with frequent small venesection, combined with properly administered irrigations, one may turn the scale in the patient's favor in one-half hour—10 minutes for the venesection and 20 minutes for diuresis to follow the enteroclysis. [W.K.]

**5.—Hematocele of the Cord or Into the Tunica Vaginalis.**—Bowen recites the usual causes given for hematocele and says an important point in diagnosis is to differentiate it from hydrocele. Hydrocele is usually of rather slow growth and may exist a long time without serious inconvenience; while hematocele is usually of traumatic origin, of rather rapid growth and tends to trouble by seeking an outlet. Hydrocele is translucent to light and hematocele is not. The treatment of hematocele is by daily application of ice, elevation and rest, later hot applications supplant the ice. Open and turn out the blood-tumor if it fails of absorption, or if of such size as to render absorption improbable. Of course, in no case is the testicle to be sacrificed. [A.B.C.]

**6.—Toxemia of Pregnancy.**—We know, writes D. H. Stewart, that one of the many elements in the toxemia of puerperal eclampsia is the changing of urea into ammonium carbonate. This salt is demonstrable in the feces in eclampsia, and it is the result of the principal change in that complex blood poisoning which, by its effects on the nervous system, gives

rise to the convulsions which are so characteristic. It is also well known that chloroform produces a temporary glycosuria; hence we may readily assume that we must have glucose in the blood. If we admit the presence of this sugar in the blood, we can easily demonstrate by our test-tube that it does prevent the changing of urea into ammonium carbonate. Hence chloroform, with its accompanying glycosuria, is the anesthetic indicated in puerperal convulsions. Not that it will inhibit the development of all the poisons in the toxemia, but it will limit the production of the chief one. [W.K.]

### Philadelphia Medical Journal.

December 27, 1902. [Vol. x, No. 26.]

1. Influenza and the Nervous System. SMITH ELY JELLIFFE.
2. A Case of Acute Intestinal Obstruction Caused by a Gallstone; Necrosis of the Bowel; Operation; Death. J. A. SCOTT.
3. The Surgical Treatment of the Enlarged Prostate. GEO. E. ARMSTRONG.
4. Sore Throat. B. F. RANDOLPH CLARK.
5. Neurasthenia. T. W. KEOWN.

1.—See *American Medicine*, Vol. III, No. 25, p. 1047.

2.—**Intestinal Obstruction Caused by a Gallstone.**—Scott details the case of a woman of 67 in whom the intestinal obstruction was due to an unusually large single gallstone in the jejunum. The patient was operated upon and 12 inches of the necrotic bowel resected. The woman died several hours subsequently from cardiac exhaustion. Several cases are cited of obstruction by abnormal intestinal contents which have been reported during the past two years. In the case which he reports the pains were paroxysmal; there was no vomiting until about 18 hours after the first symptoms; no evidence of collapse but a flushed face, with normal urine; no evidence of either localized or generalized peritonitis. These are considered as important points in obstruction caused by one or another of the abnormal contents of the bowel. [F.C.H.]

3.—See *American Medicine*, Vol. IV, No. 15, p. 567.

4.—**Sore Throat.**—Clark discusses sore throat from its various etiologic standpoints. Not every patient who complains of sore throat is actually suffering from angina. In popular phrase the name sore throat is used loosely to describe any pain or discomfort about the mouth, fauces or larynx. Various conditions are detailed in which the patient may suffer from a reflex sore throat. [F.C.H.]

5.—**Neurasthenia.**—Keown details certain points which he has observed in cases of neurasthenia. He considers that all cases are curable, if properly treated in time. The best results are obtained by a combined treatment; the general nervous system being placed at rest, and special treatment instituted for the organ which seems to be the source of the trouble. [F.C.H.]

January 3, 1903. [Vol. XI, No. 1.]

1. Gastroptosis: A Critical and Clinical Study; with Reference to 100 Cases. ALBERT P. FRANCINE.
2. A Report of a Case of Chronic Splenic Anemia. JAMES ELY TALLEY.

4. A Local Electric Light Bath. C. C. F. NIESCHANG.
5. A New Reducing Cyrtometer. ROBERT POTTER ELMER.
6. A Case of Traumatic Rupture of the Bladder; Recovery. EDWARD A. SCHUMANN.

1.—**Gastroptosis.**—Francine details the etiology, physical signs, diagnosis and treatment of gastroptosis. The indications for treatment are to relieve the stagnation and fermentation and to increase the motor power or peristaltic activity of the stomach; to furnish support to the stomach and other abdominal viscera, thus relieving local congestion and weight, and to tone up the general health and mental attitude of the patient. [F.C.H.]

2.—**Chronic Splenic Anemia.**—Talley details a case of chronic splenic anemia occurring in a married woman of 34, who was born in the West Indies. The lower border of the spleen extended fully to the anterior superior spine of the ilium, its upper border was some inches above the costal arch, the anterior border was to the right of the mammary line, and the posterior border extended to a line drawn perpendicularly through the inferior angle of the scapula. On palpation the spleen was smooth, firm and not tender. [F.C.H.]

3.—**The Perineum.**—In order to prevent perineal lacerations Love prefers to deliver, especially primiparas, in the

left lateral prone position. The advantages of this position are that the obstetrician is in a measure master of the situation; the expulsive forces can be modified; undue expulsive efforts can be counteracted by pressure on the fetal head; the head can be kept well flexed and the soft parts can be better protected with the accoucheur's hand and the parts can be kept under better observation than in any other position. In proper selected cases episiotomy is of value, especially when the perineum has previously been seriously lacerated, and in which the sphincter has been torn and the lesion successfully repaired. All lacerations, if possible, should be immediately repaired; and it is not necessary to douche the vagina nor use the catheter subsequent to the repair of perineal lacerations. [F.C.H.]

4.—**A Local Electric Light Bath.**—Nieschang describes a portable electric light apparatus which consists of an insulated cone, lined with asbestos sheeting. The edges of the cone are protected by a rubber cushion. It also possesses a handle, connecting cord, plug and lamp. The article is illustrated. [F.C.H.]

5.—**A New Reducing Cyrtometer.**—Elmer has devised an instrument which is not expensive or clumsy, and which will rapidly make a graphic record of the thoracic outline. The instrument is accurate and of convenient size. The article is illustrated. [F.C.H.]

6.—**Traumatic Rupture of the Bladder.**—Schumann details the case of a male of 41 who had a traumatic rupture of the bladder which was successfully operated upon. At the time of operation, 24 hours subsequent to the injury, an area of necrosis was found in the fundal portion of the anterior vesical wall, elliptical in shape and with a rent about three-quarters of an inch long in its center. [F.C.H.]

## CLINICAL MEDICINE

DAVID RIESMAN

A. O. J. KELLY

### EDITORIAL COMMENT

**Splenic Anemia.**—For a number of years discussion has been rife as to whether or not there exists an independent disease to which, for want of a better term, splenic anemia is applicable. This term has been used by a number of writers to designate a symptom-complex characterized especially by grave and progressive anemia and enlargement of the spleen, but unassociated with leukocytosis or enlargement of the lymphatic glands—a symptom-complex variously described in the literature under the terms splenic cachexia, splenic pseudoleukemia, splenic lymphadenoma, idiopathic hypertrophy of the spleen without leukocytosis, primitive splenomegaly, Banti's disease, etc. The subject is now brought prominently to the attention of the profession by the recent paper by Osler,<sup>1</sup> who, to provoke discussion at the recent meeting of the Association of American Physicians, proposed that from among the conditions with which anemia and enlarged spleen are associated one may separate a well-defined disease which may be termed chronic splenic anemia, and which he defined as follows: A chronic affection, probably an intoxication of unknown origin, characterized by a progressive enlargement of the spleen which cannot be correlated with any known cause, as malaria, leukemia, syphilis, cirrhosis of the liver, etc. (primary splenomegaly); anemia of a secondary or chlorotic type (leukopenia); a marked tendency to hemorrhage, particularly from the stomach; and in many cases a terminal stage, with cirrhosis of the liver, jaundice, and ascites (Banti's disease). He reports a number of illustrative cases that have come under his personal observation and that of his colleagues in the Association: 12 cases of acute anemia, under one year's duration with enlarged spleen; 26 cases of chronic anemia with enlarged spleen; and 2 cases of simple splenomegaly. Directing attention to the chronic cases, he gives an excellent account of the symptom-

<sup>1</sup> *American Journal of the Medical Sciences*, 1902, cxxiv, 751.

atology of the affection which is characterized by, 1. the remarkable duration of the disease—10 years, 12 years, even 25 years. 2. The splenomegaly which forms a special feature of the disease, the spleen being unequaled in size in any other disease except, perhaps, leukemia. 3. Hematemesis, which often is profuse, and which, in the majority of the cases, is due to conditions associated with the enlarged spleen, and not to accompanying cirrhosis of the liver. The hemorrhage may result from (a) a general diapedesis from the gastric mucosa, (b) small erosions of the gastric mucosa, (c) rupture of a varicose vein of the esophageal plexus, or, (d) as suggested by Rolleston, a large wandering spleen pulling on the gastrosplenic omentum and causing torsion of the veins, or a kink in the splenic vein, and consequent intense venous engorgement of the stomach. 4. Anemia, characterized by a moderate grade of corpuscular anemia, low hemoglobin, and leukopenia. 5. Pigmentation of the skin, which is present in many of the cases. 6. Certain liver symptoms in the late or terminal stages of the disease—symptoms, such as ascites, that suggest cirrhosis of the liver. This relation of cirrhosis of the liver to enlargement of the spleen is discussed in detail, and attention is directed to the conditions in which splenomegaly and cirrhosis of the liver are associated: atrophic cirrhosis of the liver, syphilis of the liver, hemochromatosis, Hanot's cirrhosis, and a simple cirrhosis occurring in children. Especial interest attaches to the splenomegalic cirrhosis of the liver—a cirrhosis that may develop after the splenic anemia has existed for some time, and a condition to which Banti first called attention, whence Banti's disease. The splenomegaly may exist for a long time without leading to cirrhosis; in one of Osler's cases, after 13 or 14 years, the liver was only moderately cirrhotic. As insisted on by Osler, the enlargement of the liver, in adults at least, is not very great, the splenic features dominate the case throughout, and the ascites and hematemesis do not necessarily indicate that the liver is involved. Concerning the nature of this interesting disease but little can be said; its morbid anatomy throws no light on its origin, and whether it be due to some form of intoxication, or to hemolysis produced by an enzyme, is at present pure speculation. The important and practical deductions seem to be that splenic anemia is an independent disease entity, and that the spleen itself is a most important factor in it. Doubtless the discussion will continue as to whether the disease is a primary or a secondary anemia—and well it may; the most important and suggestive fact remains, however, that cure has followed removal of the spleen in some cases. A searching inquiry into and a renewed study of all cases of anemia is imperative.

#### REVIEW OF LITERATURE

**Cretinism Unsuccessfully Treated with Thyroid Extract.**—Mörl<sup>1</sup> reports a case of myxedema in a woman 37 years of age. When six years old the patient developed cervical adenitis; from this time on the typical symptoms of cretinism appeared. Thyroid extract was administered, and in six days there was marked improvement. This treatment was continued for six months, when all the old symptoms reoccurred in greater severity and the medicine had to be stopped. The patient rapidly became worse, and died in two months. Mörl believes that the excessive use of thyroid extract hastened her death. He thinks this drug is of no therapeutic use in long standing cases of cretinism. [w.e.r.]

**Rectal Temperature in Experimental Tetanus.**—Klee-feld and Pinchart<sup>2</sup> have made a study, in dogs and rabbits, of the temperature changes caused by tetanus under varying conditions. The results show (1) that tetanized adult dogs die with elevated temperature. Young dogs may show a lowered temperature. Tetanized rabbits show considerable hypo-

thermia. This difference in thermic reaction is constant whatever toxin is employed; (2) the blood serum of dogs tetanized by the toxin of Tizzoni produces in both dogs and rabbits a temporary hyperthermia. The blood serum of rabbits tetanized by the toxin of Tizzoni produces in the two species of animals a hypothermia equally as transient as the hyperthermia caused by the serum of dogs. These phenomena are not produced if the toxin of Behring is used to tetanize the animal from which the serum is taken. Hypothermia is not produced in rabbits if the injection of tetanic serum is preceded 24 hours by the injection of the immunizing serum of Tizzoni; (3) muscle extract of tetanized dogs produces hyperthermia in both dogs and rabbits, while that of rabbits produces hypothermia in both species. [A.G.E.]

**The granting of certificates of fitness to children and young persons employed in factories and workshops** was discussed at length by Greaves<sup>1</sup> at the recent meeting of the British Medical Association. He stated that the objects aimed at in requiring the examination and certification of young persons for employment may be divided into: 1. Avoidance of injury to health, development, or bodily capacity of the individual inspected. 2. Protection to the fellow workers, of whatever age or sex. 3. Maintenance of legality (which directly protects the employer). 4. Checking unfair competition and protecting the more conscientious manufacturers from the less scrupulous. (The discussion was participated in by a number of other wellknown members of the association, Alexander Campbell discussing in particular the system of half-time employment.) [A.O.J.K.]

**An Endemic of Paratyphoid Fever.**—De Feyfer and Kayser<sup>2</sup> publish their observations and bacteriologic examinations of an endemic paratyphoid fever occurring in Eibergen, Holland. Four families were affected, in all 14 individuals. The prodromal stage in all cases was short, lasting from one to four days, and was characterized by irregular temperature, anorexia, and pain. No matter how violent the onset the termination was always favorable, convalescence short, and with very few sequels. It is infectious and marked contagiousness. The temperature-curve is typical, first remittent and later intermittent; occasionally the disease ended in crisis. The pulse maintained a parallel relation with the temperature. It was regular, soft, and sometimes small. Vomiting, coated tongue, abdominal pain, gurgling in the iliac fossa, enlarged spleen, and diarrhea were the symptoms on the part of the intestinal tract. Occasionally albuminuria existed. Diazo and indican reactions were fairly constant. Roseolas were common, also angina and bronchitis. The Gruber-Widal reaction was usually absent, but a positive agglutination in all examined cases was obtained with the paratyphoid bacillus of type B. They believe that the cases had their origin in the water of a neighboring creek, of which all the families partook. [E.L.]

**Acroparesthesia Following Traumatism.**—Sommer<sup>3</sup> reviews the literature concerning acroparesthesia, and reports two cases following injuries. Acroparesthesia depends upon an irritation of the vasomotor centers. The arteries become contracted and the nourishment of the nerve endings in the extremities is diminished. The main symptom is an unpleasant feeling in the hands, and more rarely in the feet. It is worse at night and morning. Occasionally these feelings change to acute pain. It is rarely limited to the peripheral distribution of any one nerve. The skin presents but slight or no disturbance in sensibility. There is no pain on pressure over the nerve, and no gross changes occur in motion. Its development is gradual. The etiology is not clear. This disease occurs most commonly in women at the menopause. Sommer advises that when paresthesia occurs after an injury, the possibility of acroparesthesia should be considered, and thus spare the patient the accusation of simulation. [w.e.r.]

**Leprosy in Cuba.**—R. Gutiérrez Lee,<sup>4</sup> in a communication to the recent Sanitary Congress in Havana, refers to the rapid extension of leprosy which is without doubt taking place in cities of Spanish America generally. Of the 117 lepers in the

<sup>1</sup> British Medical Journal, September 13, 1902.

<sup>2</sup> Münchener medizinische Wochenschrift, October 14 and 21, 1902.

<sup>3</sup> Berliner klinische Wochenschrift, October 6, 1902.

<sup>4</sup> La Escuela de Medicina, October 1, 1902.

<sup>1</sup> Prager medicinische Wochenschrift, October 2, 1902.

<sup>2</sup> Journal Médical de Bruxelles, October 16, 1902.

Hospital de San Lázaro in Havana, 36 are women, 10 children, and the rest men; they are mostly Spaniards, natives of the Canary Islands, and Africans, though it is to be noted that the 10 children are Cubans, and the 36 women, for the most part, foreigners. In the hospital of Santa Clara there are 36 cases, mostly men and foreigners. The total estimated number of cases in the island is 403, and taking the population of the island at 1,600,000, this gives 2½ cases for each 1,000 inhabitants. The author estimates that in Colombia there are 27,000 lepers, or about 50 for each 1,000 inhabitants. In Brazil, Venezuela and Ecuador he estimates 12 per 1,000. The Central American republics, as well as Chile, Peru, and Argentine, furnish abundant cases. In the Tierras calientes of Mexico and the Antilles cases are frequently met with. This is also true of Yucatan, Tabasco, and Campeche. The author pays generous tribute of praise to the splendid work that has been done in Cuba by the American sanitary commission, and suggests the need for the establishment of leprosy hospitals located in the country where the lepers may be segregated under the most favorable sanitary conditions and furnished with healthful and agreeable outdoor employment in farming and horticulture. He advocates the enactment of laws to prevent the immigration and the intermarriage of lepers. [C.S.D.]

**The Relation of Metabolism to Lymph Formation.**—Bainbridge,<sup>1</sup> pointing out that the lymph serves as a sort of middleman between the blood and the tissues, states that the question of lymph formation may be considered from two points of view, namely, the relation of the blood to the lymph and the relation of the lymph to the tissues. During the last few years an enormous amount of work has been done on the former aspect of the question, and the present position may be summed up in the statement of Starling that "lymph formation depends upon two factors—changes in the capillary blood pressure and changes in the permeability of the capillaries." Directing attention to the relation of the tissues to the lymph, to the relation of metabolism to lymph formation, he details the results of a number of experiments that go to show that the influence of metabolism on lymph formation is of very great importance. Any attempt to explain how metabolism increases lymph production, however, is beset with difficulties. There can be no doubt that in the course of metabolism metabolic products are set free by the tissues, that these metabolites have a comparatively small molecular weight, and that many of them are of a crystalloid nature. Any sudden increase of metabolism (for example, secretion of bile) would lead to the rapid formation of these metabolites in the tissue cells. Thence they pass most probably by diffusion into the surrounding lymph spaces, where they raise the osmotic pressure of the lymph. As a result water passes by osmosis from the blood to the lymph, whereby the former becomes more concentrated and the latter more dilute; at the same time the lymph flow becomes increased. Assuming this explanation to be true, the process is analogous to the hydremic plethora induced by the injection of strong sugar solutions. In the case of sugar, the blood and lymph take up fluid at the expense of the tissues; in metabolism, crystalloids are suddenly formed in the tissues, and the lymph and the tissues take up the fluid at the expense of the blood. [A.O.J.K.]

**The Influence of the New Tuberculin on Cell Metabolism.**—Mitulescu<sup>2</sup> has performed a number of experiments to test the influence of Koch's new tuberculin on cell metabolism and expresses his results as follows: If used as a therapeutic agent in small and cautiously increased quantities, and only in suitable cases, it does not produce cellular degeneration, but rather a beneficent cell irritation and a gradual formation of specific immune bodies, which diminish the vitality of the tubercle bacilli and neutralize their toxins and proteins. Locally is produced a perituberculous irritation favoring a limitation and encapsulation of the tubercle through sclerotic tissue. [E.L.]

**Concerning Streptococci and Antistreptococccic Serum.**—Aronson<sup>3</sup> reviews the literature and reports his own

experiments on streptococci and antistreptococccic serum. Cultures were obtained from cases of scarlet fever, diphtheria, erysipelas and acute rheumatic fever. While many of these microorganisms originally possessed different characteristics, yet after repeated inoculations these differences were lost. After much experimentation Aronson obtained a culture of streptococci that was fatal to the larger animals, and he was then able to obtain an antitoxic serum. His serum shows the phenomenon of agglutination which is seen in none of the other antistreptococccic serums. He concludes that a very close relationship exists between the different varieties of this microorganism. He assumes this fact to be true since the serum from the horse will immunize against all forms of streptococci. He hopes soon to prove the value of his serum in immunizing the human body against streptococci. [W.E.R.]

**The injurious influence of fast aniline black dyeing processes** was the subject of a paper by Dearden<sup>1</sup> at the recent meeting of the British Medical Association. He pointed out in detail the injurious influences pertaining to the different stages of the process, as follows: 1. In the making of the "liquor" from aniline oil. 2. Impregnating and mangling the cloth. 3. Passing the impregnated material over drying cylinders. 4. Oxidation in the "ageing" room; and 5. "Chroming" or "fixing" the dye. [A.O.J.K.]

**Uncinariasis in Cuba.**—Aristides Agramonte,<sup>2</sup> having had his attention directed to the subject by the articles of Drs. Guitéras and Stiles in *American Medicine*, May 10 and July 19, 1902, undertook a more careful examination of the cases of persistent anemia of obscure origin which were admitted to Hospital No. 1, Havana, and encountered numerous cases of uncinariasis the existence of which had not been suspected. Of the 16 cases 5 were women and 11 men; the diagnoses, made before the discovery of the parasites in the feces were, in 3 cases paludic hydremia, in 2 cases chronic paludism, in 7 cases paludic cachexia, in 3 cases splenic anemia, and in 1 case intestinal tuberculosis. The article includes a description of the cases and illustrations of the parasites. [C.S.D.]

**The Rhodan Reaction of the Saliva in Diseases of the Ear.**—To determine the question whether the rhodan reaction of the saliva is of diagnostic and prognostic value in ear diseases, Alexander and Reko<sup>3</sup> examined the saliva of 85 persons suffering from different varieties of ear disease at different periods. In middle-ear disease, either acute or chronic, they usually found rhodan absent, or there was only a trace of it present. Some time after the operation, usually about the fourth week, the reaction returned again, indicating an uncomplicated recovery. Diseases of the external ear and parotid gland did not affect the reaction. When the tympanic membrane was destroyed on both sides, rhodan was permanently absent. The cause of the diminution is believed to be due to an irritation of the nerves of the tympanic membrane, the unilateral irritation having a bilateral effect. There is no prognostic significance to be derived from the reaction. [E.L.]

**The Heart in Diphtheria.**—After mentioning the cardiovascular changes in ordinary cases of diphtheria, Girard<sup>4</sup> considers at length the cases in which the heart lesions are so marked as to form really a cardiac type of the disease. Pallor of the face and the mucous membranes is of great value as a premonitory symptom of grave cardiac trouble. Vomiting of the cerebral type is present. The pulse becomes soft, arrhythmic, accelerated. In some cases there is cardiac erethism shown by the exaggeration of the intensity of the heart sounds as contrasted with the extreme feebleness of the pulse. Hemorrhages, as epistaxis, hematemesis and ecchymoses appear. Sometimes a singular apathy of the patient is a premonitory symptom of cardiac involvement. Pain is sometimes very violent, diarrhetic crises rarely occur. Convulsions and modifications of respiratory rhythm are frequent. Prognosis is most grave when these symptoms are marked. The pathologic anatomy of the heart is given, as also are the histologic lesions. Diphtheric endarteritis is exceptional. Nerve lesions play a capital role in the cardiac symptoms of diphtheria. The treatment is the early

<sup>1</sup> British Medical Journal, September 13, 1902.

<sup>2</sup> Revista Medica Cubana, September 1, 1902.

<sup>3</sup> Wiener klinische Wochenschrift, October 16, 1902.

<sup>4</sup> Gazette heb. de Médecine et de Chirurgie, October 2, 1902.

employment of large doses of antitoxic serum. The patient must be kept at absolute rest during the disease and during convalescence. For the symptoms cardiac tonics, especially caffeine, ergotin, and strychnin are indicated. [A.G.E.]

**The Systematic Examination of Workers in Dangerous Trades.**—Alcock,<sup>1</sup> opening a discussion on the value of systematic examination of workers in dangerous trades—lead, mercury, etc.—at the recent meeting of the British Medical Association, stated that we may assume the official aid in instituting these examinations to have been: 1. Elimination of the unfit. 2. Early recognition of dangerous symptoms, and consequent diminution in the amount and character of trade diseases. 3. Improvements in the treatment of lesions—in certain trades, for example, bichromate. 4. Accumulation of statistics. In actual practice, so far as his own district is concerned, the following results are being secured: 1. Gradual elimination of the unfit (whether from inherent debility, or from illness produced by occupation). 2. Better standard of hygiene, consequent upon repeated warnings, etc. 3. Accumulation of valuable statistics concerning the original and acquired characteristics of workers—for example, age limit, relation between pregnancies and miscarriages, order of development of symptoms of poisoning, etc. He believes that (1) the type of worker is decidedly improved; as a rule they are cognizant of danger, and some are glad to cooperate with the certifying surgeon in his search for warning symptoms; (2) that the rules governing personal hygiene are obeyed better and more automatically, it being significant, for instance, that neglect to clean the teeth and nails is held now to justify suspension; (3) that complaints from workers, treated confidentially, lead to improvements—for instance, the history of an illness has sometimes disclosed structural or other defects in a factory which can then be dealt with by the factory inspector. (The discussion was continued by a number of other wellknown members of the association.) [A.O.J.K.]

**Productive Tuberculous Pleurisy.**—Erben<sup>2</sup> reports the case of a woman of 24 in whom two years previously tuberculosis of the left apex had been diagnosed. Shortly afterward a left-sided pyopneumothorax developed. Since then the lung process remained quiescent, but the pleura became infected with tubercle bacilli; caseous granulation tissue formed, with the result of a productive tuberculous pleurisy, the necrotic cheesy masses of which became mixed with the pleural exudate. Ever since the development of the pleurisy (probably a year) the exudate was found to be rich in tubercle bacilli. The fluid was withdrawn four times, each specimen showing an enormous number of tubercle bacilli. At the point where the second puncture was made a small tumor the size of a walnut developed, which when excised was found to be a tuberculoma, the origin of which must be traced to an infection from the hypodermic needle while it was being withdrawn. [E.L.]

**Syphilitic Pseudomembranous Angina.**—Bellan<sup>3</sup> considers at length the historical and clinical aspects of this condition, and gives points in the differential diagnosis between it and ten other anginal affections simulating it. Diagnostic characteristics of the syphilitic variety are the long duration of dysphagia, the constancy of ulceration beneath the false membrane, and the fact that the breath is not fetid. The principal diseases considered in the differential diagnosis are pultaceous angina, diphtheria and herpetic, streptococcal and pneumococcal anginas. In diphtheria, bacteriologic and clinical studies are equally important, though the latter is often sufficient, the bacteriologic findings only confirming the diagnosis already made. [A.G.E.]

**Hematology of Cancer of the Stomach.**—Mouisset and Tolot<sup>4</sup> publish an extensive study of the blood in cases of cancer of the stomach. They find that the diminution in the number of the red corpuscles is proportionate to the general state of the patient's health. The diminution of the globular value (*i.e.*, the ratio of the hemoglobin percentage to the red corpuscle percentage) is an important sign of cancer of the stomach; but it may be absent, owing to the slow development of the lesion or

on account of a sudden disturbance in the number of red corpuscles. Leukocytosis is a late phenomenon, and does not appear until the period of cachexia, unless as the result of inflammatory complications. They note that it is impossible to base the diagnosis of cancer of the stomach upon the differential count. A detailed account of the clinical history and the blood studies of eight cases accompanies the article. [D.R.]

**Transmissibility of Human Tuberculosis to Calves and Goats.**—Moeller<sup>1</sup> has performed a number of experiments with calves and goats to test the transmissibility of human tuberculosis. He formulates his results as follows: Calves do not develop tuberculosis when human tuberculous sputum is fed to them or is given by subcutaneous injections; when tubercle bacilli are given in pure cultures by inhalation, by intraperitoneal and intravenous injection, or when rubbed into their skin; nor when human tubercle bacilli are injected into the peritoneal cavity after having been passed through goats. Goats are not made ill even if they are fed enormous quantities of sputum; if very large quantities are injected intraperitoneally, a nodular condition of the peritoneum resulted, but in no single instance was a spread of the disease throughout the entire body produced. [E.L.]

**Paralysis of the Recurrent Laryngeal in Mitral Stenosis.**—A patient of Hofbauer's<sup>2</sup> was ill for two months, complaining of a feeling of pressure within the chest, made worse by motion, and dyspnea upon exertion, when he developed hoarseness. This was more marked whenever the patient leaned forward or reclined toward the left, less marked when he would lie upon his back or right side. Examination showed the case to be one of very early mitral stenosis, without any of the ordinary causes of paralysis of the recurrent laryngeal. A Röntgen picture showed dilation of the auricles, and upon the strength of that and the fact that the case was a very early one, Hofbauer believes the paralysis to be due, not to compression by the auricles, but rather to crossing and pulling of the recurrent nerve by the ligamentum Botalli, this being worse when the heart falls forward, better when it falls backward. [E.L.]

**A Leukemic Lymphatic Lymphadenia.**—Under this title Weil and Clerc<sup>3</sup> discuss adenia and its nosologic relations. They consider briefly four cases in which the findings were analogous, *viz.*, glandular tumors, localized in one; general in three cases, inconstant splenic hypertrophy, and alterations in the blood characterized by anemia and a notable lymphocytosis, ranging from 66% to 92% of the leukocytes. The total number of leukocytes were from 2,400 to 20,000, thus ruling out leukemia. With these cases are compared cases of sarcoma and tuberculosis of glands which resemble lymphadenia clinically but which show an increase of polynuclear leukocytes. Hence cases of generalized glandular tumors not showing leukemia or cancer are placed by the writers in two classes: (1) for those showing lymphocytosis is reserved the term adenia. This is closely related to lymphatic leukemia, but the blood lesions are incomplete, due either to abortive processes or to the fact that the condition is an early stage of leukemia which will develop later on; (2) those which do not show lymphocytosis but in general an increase of polymorphonuclear leukocytes are not lymphadenia but sarcoma tuberculosis, or other chronic infections. [A.G.E.]

**Lactophenin in Typhoid Fever.**—Schuler<sup>4</sup> reports his experience with the use of lactophenin in an epidemic of typhoid fever. On account of circumstances baths could not be given to lower the temperature. The author resorted to lactophenin with excellent results in 450 cases. The temperature was decreased from two to four degrees in a few hours. This drug had no untoward effects on the pulse and respiration, nor did it show any of the bad results following the use of other antipyretics. It is administered in 15 grain doses three times a day. Lactophenin is also useful in the treatment of the nervous and abdominal symptoms in typhoid fever. [W.E.R.]

**A Contribution to Pentosuria.**—Kaliski's<sup>5</sup> experience

<sup>1</sup> British Medical Journal, September 13, 1902.

<sup>2</sup> Wiener klinische Wochenschrift, October 16, 1902.

<sup>3</sup> Gazette heb. de Médecine et de Chirurgie, October 23, 1902.

<sup>4</sup> Rev. de Méd., October, 1902.

<sup>1</sup> Deutsche medicinische Wochenschrift, October 2, 1902.

<sup>2</sup> Wiener klinische Wochenschrift, October 9, 1902.

<sup>3</sup> Gazette heb. de Médecine et de Chirurgie, October 19, 1902.

<sup>4</sup> Berliner klinische Wochenschrift, October 13, 1902.

<sup>5</sup> Deutsche medicinische Wochenschrift, October 9, 1902.

teaches him that to determine the question whether a pentosuria or glycosuria exists, the fermentation test is not alone sufficient; to make the diagnosis of pentosuria a certainty, tests with phloroglucin hydrochlorate and orcin must be performed. Bial's modification of the orcin test is especially appropriate, as it can be performed in a few minutes. In addition he permits the boiled urine solution to cool down somewhat; at this stage he adds ether in considerable quantity, when even small quantities of pentose give a marked orcin reaction. [E.L.]

**A Study on Diphtheria.**—Josias and Tollemer<sup>1</sup> give statistics of 580 cases of diphtheria treated in the hospital Bretonneau during 1901-02. The great majority of the cases corresponded clinically and bacteriologically. Attention is called to the necessity of making inoculations from the nasal mucosa in doubtful cases. Of 196 cases in which the bacillus of diphtheria existed in the throat, it was found in the nasal mucosa of 78. Among the complications were slight albuminuria in 95 cases; severe in 18; cardiac involvement in 14; diphtheric paralysis in 16; convulsions in 9; slight otitis in 2; neither pericarditis nor endocarditis occurred. Treatment consisted in the use of the serum of Roux, 10 cc. to 30 cc. on admission. This was repeated the following day if necessary. It is considered deplorable that only 33 of the 580 children had received serum at home before the attending physician had sent them to the hospital. No complication imputable to the serum was observed, except serum erythema, which appeared in 102 cases. The value of preventive inoculations is strongly emphasized. The mortality in the series of cases reported was 76 or 13.1%. Of these 18 were *in extremis* when admitted, making the mortality of the remaining cases 10%. The writers conclude that the only way to lessen this deathrate is for physicians to use serum early in every suspected case. [A.G.E.]

**Is the Active Agent of Hemolytic Fluids Derived from the Mononuclear Leukocytes?**—Metschnikoff's theory that hemolysins originate in mononuclear leukocytes is reexamined by Doemeny<sup>2</sup> in a series of experiments. He made use of the methods prescribed by Tarrassewitsch, who worked under Metschnikoff's guidance and upon whose results the hypothesis was based. Extracts were made of organs (pancreas, spleen, retina, mesentery glands) rich in mononuclear cells and they were brought in contact with a concentrated mass of red blood-cells. In the greater number of experiments there was no hemolysis, and in the remainder the hemolytic action was so inconstant as to rob it of all its value. He concludes that Metschnikoff's hypothesis is not aided by his experiments and that the origin of the substances producing hemolysis is still veiled in obscurity. [E.L.]

**Carbolic Acid in Erysipelas and Acute Osteomyelitis.**—Mencièrè<sup>3</sup> has employed carbolic acid in two cases of erysipelas and one of acute osteomyelitis, with very satisfactory results. A 5% solution was applied to the involved areas in the first cases for three or four minutes, followed by washing with alcohol. Cotton saturated with alcohol was then applied and covered with oiled cloth, this dressing being left on for two days. In the osteomyelitis pure carbolic acid was used, with the result of limiting the infection, as the author believes, better and more rapidly than could have been done by the chisel and mallet. [A.G.E.]

**Chronic Pharyngeal Diphtheria.**—Nelsser<sup>4</sup> traced a house infection of diphtheria to the throat of a girl of 22, who had been more or less hoarse and afflicted with cough ever since her eighth year, when a brother had diphtheria. She had never had the disease. The mucous membrane of her throat was dry, shiny, somewhat atrophic, and covered with some glairy mucus. Cultures from this mucous revealed true virulent diphtheria bacilli. She was employed as wetnurse to a child in the house for one month, then artificial feeding was instituted, she being retained as an attendant to the child. Three months later, during an exacerbation of her sore throat, her charge and another child in the family developed diphtheria. When the children recovered the house was thoroughly disinfected and the family left the house in charge of this nurse and another

servant. Upon their return the girl's duties consisted in caring for a third child. After a short time this child as well as the girl's bedfellow developed diphtheria. This was followed by an examination of the throats of everybody in the house and the discovery of the innocent culprit. She was isolated and subjected to a rigid treatment for two months, but she could not be freed of the bacilli. Examination of her blood showed the presence in it of 2,000 units of antitoxin, which explains her immunity to the disease. [E.L.]

**Contraction of Pulmonary Tuberculosis in Hospital Wards.**—Parisot<sup>1</sup> has observed patients showing chronic affections, as pulmonary emphysema, myocarditis, paraplegia, and rheumatism, who before their entrance to the hospital Saint Julien had been for six months to five years in medical wards of civil hospitals, where they were in more or less direct contact with tuberculous patients. Of seven patients not exposed before admission to civil hospitals, three were found to have pulmonary tuberculosis when admitted to the Saint Julien. The conclusion is that medical wards containing the tuberculous are foci for the contraction of the disease by chronic cases, who afterward carry it to homes for the incurable where they are admitted. [A.G.E.]

**The Treatment of Scarletina with Scarletina Streptococcic Serum.**—To treat scarlet fever patients with animal serum Moser<sup>2</sup> immunized horses with streptococci coming from the blood of such patients. After some months' treatment the horses were bled, and the serum used in the treatment of 84 patients suffering from all grades of the disease. Of these 22 were light cases, 28 grave, and 34 malignant; 16 died, 15 of which belonged to the last class. The best results were derived in cases where the serum was injected early and the doses were large; all symptoms, but especially those of intoxication, improving very quickly. Normal horse serum and Marinorek's antistreptococcic serum were tried without result. [E.L.]

**Agglutination of Streptococci.**—Meyer<sup>3</sup> has experimented with streptococci obtained from a large number of various diseases regarding their agglutinating property with antistreptococcic serum. He has made a number of important discoveries, and promises a detailed account of them shortly. In the meantime he has formulated his results as follows: 1. Streptococci may be agglutinated in the same manner as other bacteria, with their corresponding immune serums. 2. By means of this phenomenon we are able to differentiate absolutely between human streptococci occurring in anginas and pyogenic infections. Even those of the first variety may be separated into classes showing differences, depending upon the severity and variety of the disease. 3. Bactericidal serums which are to be made use of in the treatment of diseases must not be manufactured with bacteria which have been made virulent by passing them through animals, as has been the custom. [E.L.]

REVIEW OF LITERATURE

**Janet's Method in the Treatment of Urethral and Vesical Diseases.**—Spitzer<sup>4</sup> has modified Janet's method of irrigating the urethra and bladder by substituting for the catheter a Y-shaped glass cannula, the single limb of which is separated into two parts by a glass septum, each half communicating with one limb of the "Y." One is connected with the irrigator, the other serves to carry the fluid away. The fluid is easily controlled and all parts of the urethra are brought in contact with the irrigating solution. In other respects Janet's method is followed. Spitzer has experimented with a number of different solutions, but has found potassium permanganate by far the best. He uses it lukewarm in a strength of 1-3,500; to wash out the anterior urethra, a fall of 20 inches; for the posterior urethra and bladder, of 60 inches is sufficient. A

<sup>2</sup> Wiener klinische Wochenschrift, October 2, 1902.  
<sup>3</sup> Gazette Medicale de Paris, October 25, 1902.  
<sup>4</sup> Deutsche medicinische Wochenschrift, October 2, 1902.

<sup>1</sup> La Médecine Moderne, October 29, 1902.  
<sup>2</sup> Wiener klinische Wochenschrift, October 9, 1902.  
<sup>3</sup> Deutsche medicinische Wochenschrift, October 16, 1902.  
<sup>4</sup> Wiener klinische Wochenschrift, October 16, 1902.

liter is permitted to flow through, and should not take longer than five minutes to do so. Daily irrigations should be started as soon as the infection is diagnosed, and good results may be expected after from 12 to 15 irrigations, much better results than any other method will give. If after four or five irrigations no improvement is noticed, other methods are substituted. Should periurethral inflammation be present, should the irrigation give the patient much pain, or the gonorrhoea be getting visibly worse, contraindications exist; they are, however, the only contraindications against its use. It is also a useful method of treatment in chronic anterior urethritis, but always in conjunction with other agents. It is contraindicated in acute posterior urethritis if blood appears in the urine, and if it inflicts much pain. Prostatitis and epididymitis are not necessarily contraindications. Both chronic urethritis and cystitis require much longer treatment than acute anterior and posterior urethritis. [E.L.]

**Abdominal Wounds in War.**—From a study of results in the Spanish-American and Boer wars Charles Roberts<sup>1</sup> concludes that, as a rule, the conditions in a field hospital are not suitable for laparotomy, that many recover without laparotomy, that in those who die the nature of the injury is such that death must result whatever be the conditions of operation, and exploration may add fresh danger. When the conditions of operation approximate those in civil practice laparotomy should be undertaken for intraperitoneal hemorrhage endangering life, and for probable perforation of the stomach or bowel, provided that the patient is seen early. [H.M.]

**Treatment of Gangrenous Noma by Excision.**—Ranke<sup>2</sup> reports his fourth case of noma after measles, with recovery after extensive operative interference. It concerned a child of 3½ years, which on the fourth day of measles developed noma of the genitalia and rectum. The ulcers were excised, the operation going for some distance on all sides through healthy tissue. Recovery was uninterrupted and associated with but slight disfigurement. [E.L.]

**Tetanus Following Injection of Gelatin.**—The case reported by Eigenbrodt<sup>3</sup> was a girl of 19 with hemorrhage after a nasal operation. Hemophilia being suspected, 75 cc. of a 2% solution of gelatin was injected under the skin of the thorax. The next day pain was felt at the points of injection, and 48 hours later the parts became gangrenous. On the fifth day symptoms of tetanus appeared and death followed in 19 hours. Bacteriologic examination of specimens from the autopsy revealed the tetanus bacillus in different parts of the body. Examination of the remainder of the gelatin showed no bacilli, nevertheless Eigenbrodt is convinced that the gelatin was the source of the infection. [A.G.E.]

**When to Operate for Appendicitis.**—Dieulafoy<sup>4</sup> reports the case of a man of 23 with a history typical of acute appendicitis; peritonitis did not play a very important role, the behavior of the kidneys and liver pointed to gangrene of the appendix, and autointoxication. The urine contained large amounts of albumin, granular casts, leukocytes, and biliary pigment. Operation was performed on the fourth day. Behind the cecum was a small collection of fetid pus, and in it the gangrenous appendix; there was no sign of peritonitis. The patient sank gradually; on the fourth day hematemeses occurred repeatedly, and he died in a condition of coma. At the autopsy many small hemorrhages were seen distributed over the mucosa of the stomach and intestine; the peritoneum was almost normal, the heart, lungs, spleen, kidneys and liver seemed normal to the naked eye. A histologic examination of the kidneys revealed a subacute degenerative nephritis, caused most likely by a toxin eliminated by the renal secretory substance. The centrolubular liver cells were the seat of a granulofatty degeneration, the result of a subacute intoxication. As in this case so in many others, the infection and its complications are very light, but the toxin evolved at the point of infection produces the gravest complications, and in the author's opinion this intoxication is even more important than the infection. To protect against these grave complica-

tions he insists on the early operation in all cases of appendicitis. An operation in the interval is of benefit because it protects the patient against future attacks. The only rational way, however, is to operate so early that symptoms of infection and intoxication have not had time to appear. All cases operated on by the author before the third day have recovered; those operated on on the third day have also gotten well, but in some of them grave complications have arisen. If operated on later, the failures are many, due primarily to the results of infection and intoxication. [E.L.]

**Intestinal Anastomosis: Comparative Methods.**—In cases of bad obstruction unassociated with gangrene of the bowel, it is considered by Archibald MacLaren<sup>1</sup> the safer method to practise complete or partial eventration, with stripping of the intestines, according to the method suggested by Maylard, by means of one or more openings in the intestine. A fecal fistula may be allowed to form, leaving resection to a later operation. There are certain parts of the bowel in which it is better to employ the Murphy button, on account of the difficulty of accurate suturing. These are the duodenum, under certain circumstances the ileocecal regions, and the stomach; but particularly the lower sigmoid and rectum. For the purpose of uniting the bowel after resection of the upper part of the rectum, the Murphy button has especial advantages. The Connell mattress suture, with all the knots on the inside of the bowel, is also of the same type, and is, he believes, the best intestinal suture yet offered. The only possible objection is that the suture line might be infected by the contact of the suture material with the intestinal mucous membrane during the suturing and tying of knots. [F.C.H.]

**A Case of Stenosis of the Duodenum.**—Reach<sup>2</sup> reports the case of a woman who, following upon repeated attacks of cholelithiasis and localized peritonitis, developed a stenosis of the duodenum as the result of rupture into it by the calculi containing gallbladder and pericholecystitis. The symptoms of the case pointed to the existence of a carcinoma engrafted upon an old ulcer. A large mass could be felt in the epigastrium; a test-meal showed the absence of free hydrochloric acid and the presence of lactic acid; the peristaltic waves were reversed; there was melana and cachexia. For several years symptoms pointing to gastric ulcer had preceded. Gastroenterostomy was followed shortly after by death. [E.L.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### REVIEW OF LITERATURE

**Craniotomy.**—Voorhees<sup>3</sup> believes that craniotomy remains a proper procedure in certain cases, as in dealing with a monstrosity; or when the fetus is larger than the parturient canal and is dead when first seen by the physician; it may also be proper in case of a nonviable child when the mother's life is in danger and she is not in a condition to bear a cutting operation. He describes the technic of the operation and gives the statistics of the Sloane Maternity Hospital showing that since the founding of that institution, out of 11,796 obstetric cases there were 96 craniotomies with a mortality of 26. In 64 cases the mother's condition was such as to warrant no other procedure. There were at least 11 in which today there would be no hesitation in performing either a symphysiotomy or cesarean section, more probably the latter. Voorhees concludes that the operation of itself should be attended with practically no mortality in the hands of the careful operator, and that the cutting operations, especially cesarean section, should be done more frequently in proper cases, inasmuch as the maternal mortality has been reduced almost to nothing by the improvement of the technic of these operations, and inasmuch as almost every baby can be saved. [v.k.]

**Chloroform in Gynecologic Practice.**—In the University clinic of Munich the results in 500 cases of pure chloroform narcosis have been tabulated with the greatest accuracy, says

<sup>1</sup> Medical Press and Circular, September 10, 1902.

<sup>2</sup> Münchener medizinische Wochenschrift, October 28, 1902.

<sup>3</sup> Gazette heb. de Médecine et de Chirurgie, October 16, 1902.

<sup>4</sup> Bull. de l'Acad. de Med. de Paris, July 8, 1902.

<sup>1</sup> St. Paul Medical Journal, October, 1902.

<sup>2</sup> Wiener klinische Wochenschrift, September 25, 1902.

<sup>3</sup> American Journal of Obstetrics, December, 1902.

Evelt,<sup>1</sup> with the object of demonstrating how to anesthetize with the smallest amount of chloroform and the least possible danger. The longest duration of the anesthesia was 216 minutes with the use of 143 grams ( $4\frac{1}{2}$  oz.) in a radical abdominal operation. The smallest measure of chloroform used was 4 gm. (1 dram) with a narcosis of 18 minutes, for a curetment. The briefest duration was 10 minutes, for an examination. In 36 cases where there were signs of heart weakening oleum camphoræ was injected subcutaneously. In 10 cases asphyxia and collapse were observed, but no death resulted. A half-hour before administering the chloroform,  $\frac{1}{2}$  gr. of morphia was injected subcutaneously. Each patient during the entire operation was in a state of complete anesthesia. The high efficiency of chloroform as an anesthetic in laparotomy was especially noted, because the tension of the parietal peritoneum in such operations is exceedingly painful. In the necessarily high pelvic position in laparotomy and the consequent hyperemia of the brain, the patient comes very readily into a state of complete anesthesia. Evelt describes the method of administering chloroform, its action upon the patient, and the after-treatment. He also quotes the statistics of other clinics and operators, showing that chloroform is extensively and satisfactorily used by many operators in gynecologic practice. [w.k.]

#### **Puerperal Eclampsia: Treatment by Thyroid Extract.**

—H. O. Nicholson<sup>2</sup> notes that when eclampsia threatens the walls of the radial arteries are contracted, there is pronounced and permanent rise in arterial pressure, which increases as convulsions become imminent; the urine is markedly diminished, as also the urea excreted, this pointing to disturbed nitrogenous metabolism. A larger supply of iodothyronin is needed in the pregnant than nonpregnant state and the gland undergoes enlargement. When the supply becomes suddenly insufficient toxic substances, which may be intermediate or imperfectly converted products of nitrogenous metabolism, enter the blood, causing arterial contraction, especially in the kidneys. Thyroid extract favors complete metabolism and relaxes spasm of the arterioles, reestablishing secretion of urine. It is very valuable as a prophylactic. With diminished urine, edema, headache, and vomiting .3 gm. (5 grains) should be given twice daily. In suppression of urine the dose must be pushed to thyroidism, 10 or 15 grams by mouth or hypodermics of liquor thyroidei being given every hour if necessary. [H.M.]

**Management of Breech Presentation.**—Porter<sup>3</sup> estimates that breech presentation occurs once in about 50 cases of labor, and the fetal mortality is estimated at from 10% to 35%. Breech cases require careful supervision, and are usually tedious. Serious delay is likely to occur with the breech at the brim, in the pelvis, or with the delivery of the head. The first condition may become a serious matter, particularly if the membranes are ruptured, since retraction of the uterine walls may interfere with uteroplacental circulation. With the breech delayed at the superior strait, the usual teaching is to bring down one or both legs and make traction. This plan is excellent if the cervix is well dilated or easily dilatable; but if the dilation of the cervix is imperfect, requiring considerable force for its completion, it is a questionable procedure. The legs in advance may form a powerful dilator, but the maximum diameter is insufficient to prepare the soft parts for the prompt passage of the head. Greater dilation is inevitable if the thighs be allowed to remain flexed and the legs extended along the body of the child. If the breech is carried through the cervix and over the perineum, with the legs in this position, the dilation is generally sufficient to permit the ready extraction of the head. Hunter originally advised bringing down the legs in the above condition, but he later admitted the danger and advised against it, as in nearly every such case in which he brought down the legs he lost the child. When the shoulders appear the arms should be swept down over the face, and as the head enters the pelvis it should be crowded down with the hand, keeping the pelvic curve in mind. Pressure over the fundus with the other hand is a valuable aid. The proper axis in which to make traction may best be made by the bimanual method, and failure, if it comes, will be due to traction in the

wrong axis, rather than lack of sufficient flexion. Have the forceps always in readiness. If in a given case it is possible to deliver the after-coming head, it can and must be done with promptness. [w.k.]

**Causes, Symptoms, and Treatment of Muscular Insufficiency of the Nonpregnant Uterus.**—Theilhaber<sup>1</sup> has made a special study of cases of prolonged menstruation, of menorrhagia, and metrorrhagia, and concludes that in very many of the cases the condition is analogous to the hemorrhage after parturition, *i. e.*, it is due to an inability of the weakened uterine muscle to contract sufficiently. From a pathologic study of 61 uteri, and from numerous clinical observations, he distinguishes between six different types of insufficiency of the uterine muscle: 1. Hypoplasia of uterine muscle occurring in young girls; the uterus is often larger than normal, due to hyperplasia of the connective tissue; the bloodvessels are abnormally well developed. 2. Degeneration of the uterine muscle, the result of infections, of anemia, and chlorosis. 3. Myofibrosis, a sign of the approaching menopause. 4. Congested, enlarged uterus, the result of adnexal and peri-uterine disease. 5. Myomatous uterus; the profuse bleeding is caused by an increased arterial blood supply and venous stasis. 6. Subinvolved uterus. In most of these the uterus is larger and thicker than normal, its mucous membrane hyperplastic, its contractions are weak, and there is venous stasis; leukorrhœa results on account of the increased blood supply, and the connective tissue increases in quantity at the expense of the muscular tissue. During menstruation the contractions become more severe, and the bleeding becomes profuse. The treatment consists of tonics to improve the general condition of the patient, abdominal massage, intrauterine irrigations, local application of irritants to the uterine cavity, the introduction of specially devised instruments, the galvanic current, vaporization, hot and sometimes cold vaginal irrigations, and ergotin, to incite contractions; cool sitz baths, hydrastis canadensis, stypticin, and scarification glycerin tampons diminish the blood supply and lower the blood-pressure. Many cases are greatly improved by a change of climate, baths of different kinds, regulation of diet, and other similar factors. [E.L.]

**Interpretation of the Histology of the Villi from Early Intrauterine and Extrauterine Specimens: The Syncytium.**—Stahl,<sup>2</sup> from the study of eight specimens, six intra- and two extrauterine, concludes that the syncytium with its cells, both layers, is fetal in origin. It is the peripheral, muciparous stroma of the chorion or the villus as modified and added to by the ameboid activities of the nuclei (Langhans) upon their surrounding environmental tissues. There is no distinct or technical cell structure presented in the so-called Langerhans cell; there is only a characteristic nucleus present. Part of the nuclei in the syncytium become corpuscles of the blood, and this seems not an untoward ultimate function for the nuclei. Again, in a specimen, maternal blood corpuscles are seen to penetrate through, or are absorbed by, the outer layer of the syncytium and nuclei; they extend unaltered to the inner row, but not beyond. The early chorion presents externally a protoplasmic periphery, containing nuclei, the so-called Langerhans cells, forming the early or primal syncytium. To the syncytium, with its nuclei, are given as physiologic function the properties of attacking, dissolving, and assimilating its environmental tissues, to furnish nutrition to the growing ovum. The villus is a bud, a sprout of the chorion. There is a great difference in function between the decidual cell with its apparent distinct limiting membrane and the nuclear cell without such limiting membrane. The large white decidual cell is essentially a defender of maternal tissue; the syncytial nucleus, on the contrary, is a rover, a freebooter cell, which, before it consumes maternal tissue, must paralyze, hence the necessity for a free surrounding neutralizing plasma. The picture of the early villus suggests a gelatinous tissue, expansion and rapid growth, with great nuclear activity. The picture of the mature villus suggests a connective tissue, consolidation (fibrosis) and early decadence, with little nuclear activity. [w.k.]

## TREATMENT

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPLEMAN

## EDITORIAL COMMENT

**Magnesium Dioxid.**—Hatch<sup>1</sup> describes the wonderful properties of magnesium dioxid, known under the senseless and misleading trade name of biogen. According to this author, magnesium dioxid gives up an atom of oxygen when brought in contact with any substance electrochemically more positive than magnesium. He says, without supporting his statement, however, by statement or citation of experimental proof, that this liberation of oxygen takes place in the blood after the internal administration of magnesium dioxid. It is quite true, as Dr. Hatch says, that any substance that can be introduced into the blood through the ordinary channels and there liberate oxygen has a very valuable place in therapeutics. Theoretically, however, there are a number of difficult and apparently insurmountable chemico obstacles in the road of such action, and one naturally wishes other evidence of the existence of such virtues in a new compound than the mere statement that it will decolorize urine stained with methylene blue. Dr. Hatch further asserts that the underlying etiologic factor of pernicious anemia and chlorosis is a lack of oxygen in the system, and that consequently the most rational treatment is an oxygen-furnishing substance such as magnesium dioxid. We cannot bring ourselves to accept his idea of the pathogenesis of these affections. We are firmly convinced that the blood can obtain more oxygen from a lung filled with fresh air than from all the oxygen-liberating drugs in creation, and if oxygen was all that was necessary to remove the underlying process of diseases, they would never have existed.

## REVIEW OF LITERATURE

**Treatment of Tuberculous Peritonitis by Gelatinized Serum.**—Lafond-Grellety<sup>2</sup> reports the case of a woman aged 36, the victim of tuberculous peritonitis with a tendency to ascites, who was cured by the injection of gelatinized serum into the peritoneal cavity. He employed 20 cc. (5 drams) of a 5% solution of gelatin at the temperature of 98.6° F. The injection caused pain lasting about an hour, but caused no rise in temperature or cutaneous reaction. After a few days the hypogastric enlargement had entirely disappeared. However, since the hypogastrium remained tender to pressure, Lafond-Grellety made another injection under the same conditions as the first. In less than a week all painful phenomena had ceased and four months later the patient was considered cured; neither gait nor position produced the least painful sensation in the abdomen, and the general health was good. [L.F.A.]

**Clinical Experiences with Iodothyryn.**—Roos<sup>3</sup> has used iodothyryn with good results in parenchymatous goiter and cretinism of children, and also in fibrous struma, when associated with iodine locally. Cystic goiter and cretinism in adults are not improved appreciably by the remedy. He advises it in obesity and uncomplicated cases of arteriosclerosis because of favorable experimental evidence; his clinical successes have been less evident. Several cases of long standing psoriasis have improved considerably under its use. The dose of iodothyryn for adults is from 1 to 2 grams (15-30 grains) daily; for children in proportionate doses. An interval of several days should elapse after it has been administered for from five to seven days. [E.L.]

**Subconjunctival Injections of Sodium Cinnamate.**—A. K. Letzenious<sup>2</sup> obtained good results from the employment of subconjunctival injections of sodium cinnamate in various forms of keratitis, ulcers of the cornea, iritis, iridochoroiditis, iridocyclitis, scleritis and episcleritis. In all these affections the drug reduces very materially the pain which is usually

present. The effects on the lesion itself are more marked in corneal affections; alterations of the iris and choroid are less influenced by the treatment. In suppurative lesions the injections do more harm than good. Before giving the injections, the eye is first rendered aseptic and anesthetized with a cocaine solution; about .3 cc. (5 minims) of a 1% solution of chemically pure sodium cinnamate is then injected beneath the conjunctiva. These injections are but slightly painful and may be repeated every two days, or even daily, without producing any reaction, excepting a slight hyperemia. [L.F.A.]

**Turpentine in Diseases of the Urinary Tract.**—Liégeois<sup>1</sup> recalls that Oesterley employs turpentine as a diuretic in edema due to Bright's disease, as follows:

Digitalis leaves . . . . .	1 gram (15 grains)
Extract of squill . . . . .	1.4 grams (22 grains)
Turpentine . . . . .	1.4 cc. (22 minims)
Powdered licorice . . . . .	a sufficient quantity

For 50 pills. One to 10 daily.

Lépine employs terpin or turpentine bihydrate in the same condition, but in smaller dose, usually about .4 gram (6 grains). In cases of chronic pyelitis turpentine has given good results when combined with quinin in order to overcome the tendency of turpentine to upset the stomach. It may be given as follows:

Venice, Bordeaux or Canada turpentine, } of each . 0.1 gram (1½ grains)
Extract of quinin,

For one pill. Three may be taken during the principal meals.

In cases of chronic pyelitis with formation of calculi, the following may be used:

Canada balsam } of each . . . 0.1 gram (1½ grains)	
Balsam of Peru	
Calcined magnesia . . . . .	a sufficient quantity

For one pill. Three may be taken during the principal meals.

The balsam of Peru in this prescription is somewhat eupeptic in character; it increases the anticatarrhal properties of the turpentine, it prevents ammoniacal fermentation of the urine following the transformation of the cinnamic and benzoic acids which it contains into hippuric acid, and it is also said to aid in the expulsion of the calculi. Turpentine produces good results and sometimes a cure in chronic mucopurulent catarrh of the bladder in old people. Martinet administers .5 cc. (8 minims) of the spirit of turpentine daily, increasing the dose gradually. In the author's experience 10 drops of the spirit of turpentine daily has given the best results. In hematuria turpentine may be used only in those cases of chronic pyelitis in which the hemorrhage arises from the pelvis of the kidney. Under these circumstances Albert Robin employs

Ergotin . . . . .	4 grams (1 dram)
Gallic acid . . . . .	0.5 gram (7½ grains)
Syrup of turpentine . . . . .	31 grams (1 ounce)
Solution of lime-juice . . . . .	124 grams (4 ounces)

One dessertspoonful every two hours. [L.F.A.]

**Treatment of Ozena.**—Bordier and Collet<sup>2</sup> report that they have used electric currents of high frequency in the treatment of two cases of ozena, with very good results. The current was applied by means of a special electrode with which it could penetrate far into the nasal cavities. The applications were given twice a week for a period of about two minutes at each application; later they were given once every eight days. Bordier and Collet consider the application of electricity in this form one of the best and most energetic methods of treating ozena. [L.F.A.]

**Balsam of Peru in the Treatment of Bronchitis.**—Huchard<sup>3</sup> employs balsam of Peru in the treatment of chronic bronchitis, as follows:

Balsam of Peru . . . . .	0.05 gram (.8 grain)
Balsam of Tolu . . . . .	0.05 gram (.8 grain)
Venice turpentine . . . . .	0.05 gram (.8 grain)
Powdered opium . . . . .	0.02 gram (.3 grain)

For one pill. Five or six daily. [L.F.A.]

**The Turkish Bath in the Treatment of Tetanus.**—S. Zlotovsky<sup>2</sup> states that the Turkish bath is an excellent means

<sup>1</sup> Med. Examiner, 1902, 12, 569.

<sup>2</sup> La Semaine Médicale, No. 38, September, 17, 1902, p. 312.

<sup>3</sup> Münchener medicinische Wochenschrift, September 30, 19 .

<sup>1</sup> Journal des Praticiens, Vol. xvi, No. 40, 1902, p. 625.

<sup>2</sup> La Semaine Médicale, No. 38, September 17, 1902, page 312.

<sup>3</sup> Journal des Praticiens, Vol. xvi, No. 21, 1902, page 332.

of combating tetanus of traumatic origin when antitetanic serum is not obtainable. The temperature must be maintained at from 102° to 120°, night and day, and the patient must take a hot bath every three hours lasting 30 minutes. This treatment must be continued for at least 15 days. By this means the trismus and opisthotonos soon disappear and the patient recovers gradually. [L.F.A.]

**Treatment of Soft Chancre with Salicylic Acid.**—Szanto<sup>1</sup> employs the following ointment of salicylic acid in the treatment of soft chancre:

Salicylic acid . . . . . 1 gram (15 grains)  
Tincture of benzoin . . . . . 2 grams (  $\frac{1}{2}$  dram)  
Vaselin . . . . . 30 grams ( 1 ounce)

The diseased area is first washed with a solution of corrosive sublimate, then the ointment is applied on a piece of gauze, and this is covered with a dry dressing, which must be changed every two days or oftener, depending on the amount of secretion. In five cases thus treated the secretion ceased, and the wound healed very rapidly. [L.F.A.]

**The Soziodolates in the Treatment of Conjunctivitis.**  
—A. Chtchepinsky<sup>2</sup> employs the soluble salts of soziodolic acid (biiodoparaphenolsulfonic acid), especially sodium soziodolate or zinc soziodolate, in acute or chronic conjunctivitis in a 2% to 6% solution. In mild cases he confines himself to simple lavage, at first with a medicated solution, then with water; in the graver forms he begins by freeing the lids and conjunctiva from pus and the products of secretion, then he drops two or three minims of the soziodolate solution into the conjunctival sac. Usually this is done once a day, but it may be repeated morning and evening. In the majority of cases it causes a burning sensation which diminishes in five minutes, to disappear completely at the end of about 15 minutes, without causing an increase in the hyperemia or photophobia. In some cases it is not accompanied by any disagreeable sensations. Under this treatment the inflammatory phenomena quickly disappear; the purulent secretions become purely catarrhal. In Chtchepinsky's experience, zinc soziodolate is particularly efficacious against acute conjunctivitis, as well as in subacute outbreaks of chronic conjunctivitis. [L.F.A.]

**Traumatic Tetanus Treated by Baccelli's Method, Resulting in Death.**—Chaffard<sup>3</sup> reports the case of a man, aged 40, who was seized with grave tetanus as the result of getting dirt in a wound while intoxicated. Injections of carbolic acid, although practised from the beginning, according to the method of Baccelli, and associated with injections of antitetanic serum, caused no improvement. Death occurred 29 hours after onset of the symptoms. [L.F.A.]

**Mercurial Injections in the Treatment of Locomotor Ataxia.**—Leredde<sup>4</sup> believes that much benefit can be obtained by mercurial injections in locomotor ataxia, and cites one case in which this treatment resulted in marked diminution of the painful phenomena of the disease. Any mercurial preparation may be employed, but it should be given hypodermically in doses sufficient to produce almost the full physiologic effects of the drug. He states that in his opinion the failures reported from this treatment have been due to insufficient dosage. [L.F.A.]

**Sulfur as a Substitute for Iodoform.**—L. A. Kharitonov<sup>5</sup> finds that sulfur exercises a similar action to iodoform on diseased tissues, without the least danger of accident by absorption. It is also odorless and inexpensive. He first washes the wound with a 0.5% solution of potassium permanganate, then dusts it with crystallized or precipitated sulfur. In the treatment of soft chancres sulfur seems to produce a much more rapid and energetic effect than iodoform. [L.F.A.] [There is only one substitute for iodoform—another substance of the same appearance, odor, composition, and name. s.s.c.]

**Hot-air Baths in Dermatology.**—Dauban<sup>6</sup> recommends the use of hot-air baths in disturbances of cutaneous secretion, acute inflammatory dermatoses and all forms of dermatitis

induced by external causes. It has also been used successfully in the treatment of lupus and soft chancre. By this means the local circulation is stimulated, diapedesis is facilitated and phagocytosis is increased. Certain microorganisms are also destroyed by high temperatures. The local pain and itching are relieved. The baths should last from 15 to 30 minutes, care being taken that the patient is not burned by direct contact with the apparatus. [L.F.A.]

**Treatment of Nervous Diabetes.**—Malbec<sup>1</sup> directs that patients receive the usual diet for this disease. He also prescribes a daily cold douche lasting 15 to 20 seconds, followed by brisk friction of the entire body with a coarse towel. For eight consecutive days the patient should be given the following:

Antipyrin . . . . . 1 gram (15 grains)  
Sodium bicarbonate . . . . . 1.5 grams (22 grains)

For 20 cachets; one cachet before the two chief meals.

During the next eight days one of the following pills should be taken with each meal:

Extract of valerian . . . . . 0.2 gram (3 grains)  
Extract of belladonna . . . . . 0.01 gram (  $\frac{1}{4}$  grain)  
Strychnin arsenate . . . . . 0.001 gram (  $\frac{1}{81}$  grain)

[L.F.A.]

**Treatment of Epistaxis by Penghawar Djambi.**—A. Weber<sup>2</sup> reports the case of an old woman suffering from epistaxis which was rebellious to all treatment. Her physician was in the habit of tamponing the anterior and posterior nasal fossas, after having tried all other hemostatic measures. When first seen by Weber the patient was very anemic, the nares were closed with an enormous tampon of gauze, which had not stopped a continuous slow oozing of blood over the upper lip for more than 10 days. This tampon was reinforced, but as the hemorrhage was not controlled when seen the following day, the tampons were removed and the nasal fossas washed thoroughly. By the aid of a forceps a quantity of penghawar djambi about the size of a pea was introduced into the nostril to the apparent origin of the hemorrhage. The bleeding ceased instantly and did not occur again. Since this case Weber has used the drug exclusively in the treatment of epistaxis and it has never failed him. Penghawar djambi belongs to the fern family and grows in Java, Sumatra, and Borneo. The yellowish, silky hairs of the plant are used as a hemostatic. [L.F.A.]

**Treatment of Epilepsy by the Calcium Salts.**—E. Audenino and A. Bonelli<sup>3</sup> have noticed a decrease in the absorption of calcium in a certain number of epileptic patients. By reason of this they have treated the disease by various preparations of calcium. Ten patients, varying from 14 to 37 years of age, were given either lime-water, calcium bromid, calcium carbonate or lactophosphate for a certain length of time. In almost all cases this was followed by a diminution in the gravity and the frequency of the convulsive attacks; in one case the attacks disappeared entirely for a period of 40 days, and in another for 56 days. The absorption of calcium by the intestines being sometimes very insufficient, the authors treated a second series by the hypodermic injection of a 1% solution of calcium chlorid in the daily dose of from .02 to .06 gram (  $\frac{1}{2}$  to 1 grain) of the salt, or by the injection of a 1-30 solution of calcium lactophosphate in the dose of from .3 to .6 gram (5 to 10 grains) daily. Of four patients thus treated, in three the convulsions disappeared during the course of treatment. Audenino and Bonelli believe that the administration of the calcium salts distinctly reduce the number of epileptic seizures. [L.F.A.]

**FORMULAS, ORIGINAL AND SELECTED.**

**An Ointment for Painful Rheumatic Joints.**—Mau-range<sup>4</sup> recommends the following:

Methyl salicylate . . . . . 23 grams ( 6 drams)  
Guaiaacole . . . . . } of each . 5 cc. (80 minims)  
Spirit of turpentine }  
Lanolin . . . . . 15 cc. ( 4 drams)  
Vaselin . . . . . 23 grams ( 6 drams)

This should be applied rapidly to the painful joint and covered immediately with a layer of taffeta. The application may be renewed twice daily. [L.F.A.]

**Changes in the Medical Corps of the U. S. Army for the week ended January 3, 1903:**

The following named officers now at San Francisco, Cal., will proceed to their respective homes, where they are authorized to await their honorable discharge from the service on February 1, 1903: Captains Elmer S. Tenney, William E. McPherson, Francis J. Pursell, assistant surgeons United States Volunteers.

DESHON, Major GEORGE D., surgeon, United States Volunteers (captain, assistant surgeon, United States Army), is relieved from further duty in the division of the Philippines, and will proceed to San Francisco, Cal., and report by telegraph to the adjutant-general of the Army for orders.

BROWNLEE, First Lieutenant CHARLES Y., assistant surgeon, is granted leave for twenty days. So much of orders of December 20 as direct Lieutenant Charles Y. Brownlee, assistant surgeon, to sail from San Francisco, Cal., January 1, is amended so as to direct him to report to the commanding general, department of California, for transportation to the Philippine Islands on the transport to leave San Francisco, Cal., February 1, and upon arrival at Manila to report to the commanding general, division of the Philippines, for assignment to duty.

REYNOLDS, First Lieutenant CHARLES R., assistant surgeon, now at San Francisco, Cal., will proceed to Fort Washington for duty, to relieve First Lieutenant Frederick F. Russell, assistant surgeon, who will proceed to Fort Wingate for duty.

THORP, CHARLES W., contract surgeon, now at Marcellus, Mich., will proceed to Fort Grant for duty, to relieve Captain Charles E. B. Flagg, assistant surgeon, who will proceed to San Francisco, Cal., for assignment to duty with troops en route to the division of the Philippines, and upon arrival at Manila, P. I., will report for assignment to duty.

POWELL, DWIGHT C., contract surgeon, now at Logansport, Ind., will proceed to Fort Barancas for duty, to relieve Captain Thomas J. Kirkpatrick, assistant surgeon, who will proceed to San Francisco, Cal., for assignment to duty with troops en route to the division of the Philippines, and upon arrival at Manila, P. I., will report for assignment to duty.

The following changes in stations and duties of officers are ordered: Major Charles Willcox, surgeon, now at San Francisco, Cal., will proceed to Fort Totten for duty, to relieve Major Edwin F. Gardner, surgeon; Major Gardner will proceed to Fort D. A. Russell for duty, to relieve Captain William F. Lewis, assistant surgeon; Captain Lewis, upon the expiration of the leave heretofore granted him, will comply with the provisions of orders of November 24.

WELLS, Captain GEORGE M., assistant surgeon, is relieved from further duty at Fort Wadsworth, to take effect upon the expiration of his present leave, and will then proceed to Fort Bayard for duty, to relieve First Lieutenant Horace D. Bloombergh, assistant surgeon, who will proceed to San Francisco, Cal., for assignment to duty with troops en route to the division of the Philippines, and upon arrival at Manila, P. I., will report for assignment to duty.

LYSTER, First Lieutenant WILLIAM J., assistant surgeon, will proceed to Fort Wayne for duty.

Orders of November 21 are so amended as to direct Major WILLIAM H. CORBUSIER, surgeon, upon the expiration of his present leave to proceed to Fort Crook for duty, to relieve Captain Paul F. Straub, assistant surgeon, who will proceed to San Francisco, Cal., for duty to accompany troops to the Philippine Islands, where he will report for assignment to duty.

CATERMOLE, Captain CHARLES A., assistant surgeon, United States Volunteers, now at San Francisco, Cal., will proceed to his home, where he is authorized to await his honorable discharge, February 1, 1903.

BEATTY, WALTER K., contract surgeon, is granted leave to include January 31, on account of sickness.

**Changes in the Medical Corps of the U. S. Navy for the week ended January 3, 1903:**

BRISTER, J. M., assistant surgeon, detached from the Frolic and ordered to the El Cano—December 24.

WEBB, U. R., assistant surgeon, detached from the Iris and ordered to the Naval Station, Cavite, P. I.—December 24.

DUNN, H. A., assistant surgeon, detached from the Vicksburg and ordered to the Frolic—December 24.

CRAWFORD, C. A., passed assistant surgeon, detached from recruiting duty and ordered home to wait orders—December 29.

ANGENY, G. L., passed assistant surgeon, detached from the Lancaster and ordered to the Essex—December 29.

PLUMMER, R. W., assistant surgeon, detached from the Naval Hospital, Chelsea, Mass., and ordered to duty at Chattanooga, Tenn.—December 29.

FREEMAN, G. F., assistant surgeon, detached from the Essex and ordered to duty at Naval Hospital, Chelsea, Mass.—December 29.

ULSH, W. H., assistant surgeon, retired from active service by reason of disabilities incurred in the line of duty—December 19.

CURL, H. C., passed assistant surgeon, ordered to the Naval Hospital, Mare Island, Cal., for treatment—December 30.

**Changes in the Public Health and Marine-Hospital Service for the week ended January 1, 1903:**

BAILHACHE, PRESTON H., surgeon, leave of absence for seven days on account of sickness, under paragraph 179 of the regulations.

MATHEWSON, H. S., passed assistant surgeon, granted leave of absence for seven days from December 2, 1902.

GRUBBS, S. B., passed assistant surgeon, detailed to represent the service at meeting of the American Public Health Association at New Orleans, La., December 8-12—December 6, 1902. To proceed to Ensenada, Cal., for special temporary duty—December 12, 1902. To proceed to Mazatlan, Mexico, for special temporary duty—December 30, 1902.

KORN, W. A., assistant surgeon, granted leave of absence for seven days from December 25, 1902, under paragraph 181 of the regulations.

SCHERSCHESKY, J. W., assistant surgeon, to proceed to Charleston, S. C., and assume temporary command of the service during absence, on sick leave, of Acting Assistant Surgeon F. F. Sams—December 31, 1902.

ROBERTSON, H. MCG., assistant surgeon, relieved from duty at Chicago, Ill., and directed to proceed to New York, N. Y. (Stapleton), and report to medical officer in command for duty and assignment to quarters—December 30, 1902.

*Promotions.*

ACHENBACH, JOHN, to be pharmacist of the first class—December 18, 1902.

MAGUIRE, E. S., to be pharmacist of the first class—December 18, 1902.

PUBLISHED WEEKLY AT 1321 WALNUT STREET, PHILADELPHIA, BY THE AMERICAN-MEDICINE PUBLISHING COMPANY

VOL. V, No. 3.

JANUARY 17, 1903.

\$5.00 YEARLY.

The expense of tuberculosis to the people of the United States after careful estimation by Dr. Biggs, of New York, is placed at \$330,000,000. He first calculates the loss to New York City by putting a value of \$1,500 upon each life at the average age at which deaths from tuberculosis occur. This gives a total value of the lives lost annually of \$1,500,000. But this is not all, for at least nine months prior to death these patients cannot work, and the loss of service at \$1.00 a day, together with food, nursing, medicines, attendance, etc., at \$1.50 a day, results in a further loss of \$8,000,000, making a yearly loss to the municipality of \$23,000,000. For the whole country the 150,000 deaths from tuberculosis represent in the same way a loss of \$330,000,000. Dr. Biggs also says that the total expenditure in the city of New York in the care of tuberculous patients is not over \$500,000 a year, *i. e.*, not to exceed 2% of the actual loss by death, etc. "If this annual expenditure were doubled or trebled it would mean a saving of several thousand lives annually, to say nothing of the enormous saving in suffering." Further evidence of this is shown in the fact that in the last 20 years the total deaths from tuberculosis in New York have decreased instead of increased, notwithstanding that there has been an increase of 70% in the general population.

**Dr. Robin and the Crusade Against Tuberculosis.**—The New York *Tribune* of last Sunday contained an account sent by cable of a lecture delivered at the Sorbonne by Dr. Albert Robin, of Paris. The account is of course not to be absolutely relied upon, but the conclusion of the lecturer seems to have been that when tuberculosis is once established in the system it is incurable, and that medical science and philanthropy are on the wrong tack, and all that has been previously done in the crusade against tuberculosis is in vain. Robin says that the early stage of predisposition can be determined by "the excess of respiratory consumption and daily organic demineralization or loss of mineral elements of the system." In proof, 36 cases of tuberculosis are summarized, 10, he says, relapsing in six months, 10 in a year, only 5 out of 36 being saved. Then about 14% after all are admittedly cured? In his haste to be dramatic the French scientist forgets that from 25% to 33½% of all postmortems show healed tuberculosis lesions. He also forgets that perhaps as great good

is done the community by the educative influence of those who have been in sanitariums.

We have asked Professor Welch, of Baltimore, to give our readers his opinion in the matter, and he courteously replies as follows:

It is not probable that the newspaper account, to which your telegram calls my attention, of Robin's views is either complete or accurate. He is made to take the position that the modern crusade against tuberculosis is occupied exclusively with the establishment of sanatoria. This of course entirely misrepresents the matter. The establishment of sanatoria is only a part, and a relatively small part, of the prophylactic measures recognized as essential to check the spread of tuberculosis. Dr. Biggs can tell of the other measures, mainly of a preventive nature, which have already made a distinct impression upon the occurrence of tuberculosis in New York. I have no doubt that these other measures taken together outweigh in importance the foundation of sanatoria.

Furthermore Robin is made to assign to sanatoria a function which no enlightened person attributes to them. There is nothing particularly novel in pointing out, as Robin seems to have done, and as many before him have done, that sanatoria are not an agency of prime importance in checking the spread of tuberculosis in the community. More important in this respect and greatly needed in our cities are hospitals for the accommodation of poor patients in more advanced stages of tuberculosis than are suitable for treatment in a sanatorium.

I am absolutely skeptical concerning Robin's claims, as reported in the newspaper, to have discovered a method of positively recognizing a bodily state antedating but essential to infection with the tubercle bacillus. All efforts, he is made to say, should be concentrated upon the cure of this state. It is of course in the management of cases of tuberculosis recognized at the earliest possible date after the occurrence of infection that the greatest benefits of sanatoria are to be expected and have, I believe, been demonstrated. It will be interesting to hear what Dr. Trudeau and others with similar experience have to say concerning Robin's statements as to the large percentage of quick relapses following sanatorial treatment.

The really effective prophylactic measures against tuberculosis are based upon the recognition of the tubercle bacillus as the cause of the disease and upon efforts to prevent infection by removal or destruction of the various sources of infection, of which the most important is the sputum of consumptives. Of the importance of all this nothing appears in the newspaper reports of Robin's communication, but it is hardly conceivable that he fails to recognize it.

It would be a great pity if the sensational and probably misleading statements in the newspaper should check the movement to establish sanatoria and hospitals for tuberculous patients. Mr. Phipps' magnificent donation which seems to contemplate provision both for prevention and for cure of tuberculosis is sure to do an immense amount of good.

**Communicability of Tuberculosis by Milk.**—Criticism of the ground taken by Koch at the London Congress has been so widespread, and in most instances so acrid, that a careful consideration of the view held by him is really obligatory, since Koch has done too much of value to justify hasty criticism. The *Deutsche medizinische Wochenschrift*, No. 48, 1902, reprints the address by Koch before the Berlin International Congress for Tuberculosis. Koch takes up first the question of the so-called "primary intestinal tuberculosis" in children, and shows that they are by no means so frequent as is claimed by some writers. One and one-quarter years ago the Prussian "Kultusministerium" sent an order to all the Prussian universities to send all cases of primary intestinal tuberculosis which could be considered as due to the use of milk or meat from tuberculous cattle to Koch, and the same order was sent to Heller, of Kiel, who has reported 37.8% of primary intestinal tuberculosis in tuberculous children. But not a single case has been reported to him. The second point made is that if the disease were really transmitted by the products of tuberculous cattle, we should observe epidemics instead of single cases, for the milk of tuberculous cattle as well as the meat is most often consumed by a number of people. Koch calls attention to the fact that the classic case of an epidemic reported by Olliver was later corrected by Olliver himself, who found that the suspected milk had not been consumed by the young persons who had contracted tuberculosis, but by the servants in the institution, none of whom had developed symptoms. None of the single cases reported are, according to Koch's opinion, of any great value, for in not all was an autopsy made, nor were other possibilities of infection excluded. Koch concludes that the harmful effect of the products of tuberculous cattle has not yet been proved. Whether "Perlsucht" and tuberculosis of man are identical is a question not taken up in this paper.

**Medicine and the Isthmian Canal.**—In our issue of August 16 we called attention to the profession's responsibility in the construction of the Isthmian canal, and the duty of our government to see to it that a good force of medical men, hospitals, etc., should be provided for the thousands of men to be employed in this great work. We are glad to see that the thought has been taken up by the American Association for the Advancement of Science, and the following resolutions, drawn up by Professor Welch, of Baltimore, at the suggestion of General Leonard Wood, were adopted on January 2, 1903:

Inasmuch as the construction of the Isthmian canal is through a region in which without energetic sanitary control there is sure to be enormous loss of human life from preventable diseases, particularly from pernicious malaria and yellow fever, as well as great waste of energy and of money from disabilities caused by such diseases, and

Inasmuch as the measures for the restraint of these diseases, which have already achieved even their partial extermination in Cuba under American administration, require expert knowledge based upon practical familiarity with tropical diseases, experience in the application of these measures, and large authority in their administration,

*Resolved*, That the American Association for the Advancement of Science begs most respectfully and earnestly to call to the attention of the President of the United States the importance of appointing as a member of the Isthmian Canal Commis-

sion a medical man possessed of the qualifications indicated. The Association is convinced that the mere employment of such a sanitary expert by the Commission will not be likely to secure the desired results.

*Resolved*, That the permanent secretary of the Association transmit a copy of these resolutions to the President of the United States.

In General Wood's opinion the only serious problem connected with the construction of the canal is the sanitary one—malaria, yellow fever, and perhaps uncinariasis being the gravest dangers. But in the present state of medical science these diseases are wholly preventable. Our professional record in Cuba is so splendid that every physician will demand that it shall be equaled on the isthmus. Let there be a sanitary expert appointed on the Commission. If in addition to this General Wood himself should be placed at the head of the Commission, every safeguard and assurance both of administration, efficiency and hygienic security would be assured.

**The Lowering Deathrate.**—In England the death-rate has been reduced more than 11% in the last thirty years. This is shown in a table taken from *Public Health*, which gives the mortality in comparison, for five-year periods, at all ages and of infants, as follows:

Years Included.	Deaths at all Ages per 1,000 Living.	Death under One Year per 1,000 Births.
1851-1855 . . . . .	22.7	157
1856-1860 . . . . .	21.8	152
1861-1865 . . . . .	22.6	151
1865-1870 . . . . .	22.4	157
1870-1875 . . . . .	22.0	153
Average . . . . .	22.3	154
1876-1880 . . . . .	20.8	144
1881-1885 . . . . .	19.4	139
1886-1890 . . . . .	18.9	145
1891-1895 . . . . .	18.7	151
1896-1900 . . . . .	17.7	156
Average . . . . .	19.1	147

In the United States the rule holds as well in all except two cities, Baltimore and San Francisco. It is believed that the explanation of this anomaly lies in the fact that the statistics of fifteen years ago in Baltimore were inaccurate, and in San Francisco the higher rate is due to the lessened number of Chinese. The *New York Sun* is responsible for the following table:

City.	1887.	1902.
Manhattan . . . . .	26.27	19.73
Brooklyn . . . . .	22.71	18.14
Philadelphia . . . . .	22.04	17.67
Chicago . . . . .	20.21	13.88
Boston . . . . .	24.97	19.70
St. Louis . . . . .	20.71	17.72
Baltimore . . . . .	19.16	19.63
San Francisco . . . . .	18.27	19.06
Washington . . . . .	22.40	21.83
New Orleans . . . . .	25.34	21.24
Pittsburg . . . . .	22.04	19.70
Louisville . . . . .	23.30	16.02
Savannah . . . . .	23.77	15.21
Cincinnati . . . . .	19.97	18.88
Albany . . . . .	23.81	17.59
Denver . . . . .	17.10	14.30
Detroit . . . . .	18.65	13.85

Gratifying as these figures are it should not be forgotten that the mortality would be at least one-half less if the knowledge of the prevention of disease gained by medical science were realized in our social life.

**Nontaking Vaccinations.**—Dr. Eugene Stadelman, of Descubridora, Dgo., Mexico, writes:

Vaccination is compulsory in the Republic of Mexico, and each spring we receive notice to vaccinate all children who have

not been successfully vaccinated. Two years ago I vaccinated among several hundred children an American child about a year old. This attempt proved unsuccessful, as did eleven others which were made upon this child during the six months following, although I took special care to procure the best vaccine virus. The father of the child had seen considerable smallpox during his residence in this country and was very much alarmed lest the baby should contract the disease. It was due to his earnest entreaty that I sent to the United States for a fresh supply of virus. One week after the twelfth vaccination the child's body broke out in the most beautiful eruption of vaccinia; beginning on the chest it spread during one night to the arms, face, legs, feet, and hands. The eruption was pustular all over the body but was not umbilicated, and it entirely disappeared by drying and desquamation within six days after the appearance of the first pustule. The site of the vaccination became slightly edematous but did not cause much trouble. It did, however, leave a very well marked cicatrix.

Dr. George W. Sargent, of Seneca Castle, N. Y., writes that after four or five unsuccessful vaccinations by others he has recently repeated the operation four times without result upon a blacksmith 50 years of age.

Dr. C. W. Fenn, of San Diego, says that "if the statement and memory of an adult female may be relied on, mine was the eighteenth and the only successful vaccination."

**A new field of work for nurses** has been opened in New York City. It was found that the rules of the Board of Health when thoroughly executed by the physicians who visited the schools periodically resulted in keeping away a large number of pupils afflicted with epidemic disorders. Sending them home did not cure them and many fell behind their classes or did not return at all. It seemed as if the sanitary regulations or the school attendance must be sacrificed. Then a nurse suggested that two trained nurses should be assigned to school buildings in the neglected districts, and should treat in the schools all minor disorders, and visit the homes of children requiring more serious attention to instruct their mothers as to what should be done for them—how, for instance, boric acid should be used in sore eyes, and simple remedies administered for colds and other troubles. The results of this plan, it is said, have even exceeded the expectations and in a few weeks nearly all the children who were out of school on account of various disorders were back. It was also shown that one nurse who took hold of this work sympathetically could look after the children in three or four great buildings, teaching the foreign-born mothers to do most of the work without calling in physicians. The plan has worked so well that the educational authorities have decided to engage nearly a dozen trained nurses to look after some forty buildings, and the innovation promises soon to become an institution. Two considerations should be rigidly observed, first, that the nurses thus detailed shall have been thoroughly instructed in such work by practical physicians, and secondly, that the work itself should have the supervision of the visiting physicians of the schools.

**The Cry of the Cripples.**—Dr. Newton M. Shaffer in a recent number of *Charities* tells of the cripples of New York, of their sudden emergence, and of the hopes aroused by the visit of Dr. Lorenz. It was thought that

possibly 100 applications might be received at the Cornell University clinic. Instead of this within a month 2,000 patients were received, examined, classified, and entered for treatment. The sudden appearance of this army of crippled and deformed was an astonishing revelation even to those supposed to be familiar with the facts. In the entire city Dr. Shaffer estimates that nearly 8,000 such child patients were brought under observation in the various hospitals by the interest excited by Dr. Lorenz's visit, "the most of whom for various reasons were not receiving proper care or attention." Dr. Shaffer divides the cripples into four classes: 1, those allowed to go on without treatment; 2, the disappointed and those unsuccessfully treated because of imperfect dispensary treatment; 3, the relapsed patients; 4, the small class of the "floaters."

"Lorenz has gone, but the sufferers remain."

**The gifts in 1902 of the charitable**, according to the annual cyclopedia of Appleton, amounted to over \$85,000,000, but the amount that can be distributed is a little less than \$70,000,000. The precise figures given are as follows:

Colleges and educational institutions, including schools for manual training . . . . .	\$20,127,525
Church work, Sunday-schools, and Young Men's Christian Association . . . . .	7,588,220
Foreign missionary work . . . . .	263,500
Benevolent societies . . . . .	4,364,724
Hospitals, nurseries, and asylums . . . . .	26,480,958
Museums and art institutes . . . . .	6,372,422
Libraries . . . . .	2,157,000
Cooper Union . . . . .	942,440
New York Historical Society . . . . .	50,000
<b>Total . . . . .</b>	<b>\$68,346,789</b>

Of the immense amount given for educational purposes five-sixths were contributed by persons still living, while six-sevenths of the total for foreign missionary work came to the boards through bequests of deceased friends. Hospitals and kindred institutions received about half of their increase from persons still living, and half as beneficiaries under wills.

**The Drug-store Replacing the Saloon.**—The history of much of the prohibition movement shows that radical laws may change the places and the methods of selling liquors, but not the amount. It may also compel the intemperate to change the kinds of drinks and substitute for them various poisons and narcotics. In other words, the drug-store and the grocery-store replace the rum-shop, bad and impure concoctions are used for those more or less pure, and morphin, cocain, etc., are consumed instead of whisky and beer. H. P. Hynson (Am. Pharmaceutical Association) has examined the statistics of the importations of cocain and morphin, and finds that those of cocain have increased over 400% since 1898, and those of morphin and opium over 600%. The medical uses of these drugs have probably lessened. Hynson also investigated the number of customers of the drug-stores addicted to the use of these drugs and he estimates that there are five known to each pharmacist. The W. C. T. U. should work for laws making it a criminal offense to sell such things except upon a physician's prescription.

**Pseudoscientific Nonsense.**—There was recently received into one of our Philadelphia psychopathic institutions an individual who had for years made a

comfortable living by cooking up nonsensical yarns concerning nonexistent scientific discoveries for the Sunday newspapers. He could give his descriptions such an air of plausibility that the newspaper editors were as completely fooled as the readers. It is suspected that members of his secret brotherhood are today actively at work in the newspaper world. But it is scarcely credible that they have penetrated the universities and are playing there the part of solemn and erudite teachers. The *New York Times* states that "one of Harvard's science staff" is experimenting upon an untutored Indian lad of the forest, with the view of transforming him into "a person of culture and blameless morals," all without effort upon the child's part, and solely by means of the impressions on his mind made during hypnotic trance. The practicability of this miracle is said to be vouched for by a professor of Columbia University, who, we are assured, also holds that the whole world of sinners may be hypnotized past all possibility of backsliding into a state of religious fervor. Blockheads and criminals need only hypnotic suggestion to transform them into paragons of perfect intellectuality and morality. To stop all this and bring this mad professorial world back to sanity, we have need only that a whisper and a wink should be given the S. P. C. A. and the anti-divisionists. Verbum sap!

**The Phipps Institution.**—For his gift of a million dollars the medical profession will as a unit rise up and call Mr. Phipps blessed! It is, we believe, the greatest single bequest made in the almost universal crusade of civilized nations against tuberculosis. To have been the means of securing it we shall also be delighted to honor Dr. Flick. No less an authority than Dr. Biggs, of New York, has declared that more than one-half of the entire adult population acquires the disease at some time in life. That only about one-seventh die of it shows that Dr. Robin's statements as to the curability of tuberculosis are erroneous, and is a hint to us that in this case cure is demanded as much as prevention. Indeed, cure is prevention, because the sanatorium treatment has a double function, the removal of a source of infection and in this way lessening the spread of the disease, and secondly, returning a cured patient later to the community who will act as an educator in the community in the great principles of prophylaxis. The sanatorium must be looked upon as an educative institution, and this is not the least of its duties, and there is no danger that this aspect will be forgotten either by Mr. Phipps or Dr. Flick. Germany today has sanatoriums for over 20,000 patients, and such institutions are multiplying in every country. Let the good work go on!

**Making sewers of our rivers** should never have been allowed and so soon as possible should be stopped. There are other ways better and cheaper of the disposal of sewage well known to science which should be put into use. Perhaps the most striking illustration of this folly is the expenditure of \$40,000,000 or \$50,000,000 by Chicago on the drainage canal. It has been demonstrated that the disposal of sewage does not only not require the contamination of running streams, and at an enormous

expense, but that rightly utilized sewage may be made a source of profit. The recent increase of the number of cases of typhoid fever in Chicago is evidence of the egregious sanitary blunder of the drainage canal. It is true that of all the large cities of the world Chicago has the lowest deathrate, but this fact only shows how much the deathrate might be lessened if the mortality were not needlessly increased by typhoid.

**A Physician's Aspiration.**—As a Christmas card a wellknown busy physician sends to his personal friends a leaflet, signed by himself, reading as follows:

"To do without thought of winning or achievement; to serve without hope of gratitude or recognition; to accept the task and opportunity of the day and ask only strength to do it well; to complain of nothing; to live openly and self-containedly a life of moderation free from ambition—let this and these things be my daily aspiration."

What an exquisite fusion of religion and ethics! In his case love and right do not guide character, but have become character. And words never better expressed the ideal of the true physician. In these days when even our calling is becoming commercialized, when success and fame are illogically sought through the healing office, when men so often write of disease for the sake of their own selfish aims, it is helpful to know that there are doctors free from ambition.

## EDITORIAL ECHOES

**"Original Articles."**—There are some medical writers who seem to be in the habit of having two or more copies made of everything they write and submitting them at the same time to several journals, to be published under the heading of "Original Articles." Such articles are certainly original so far as the authors are concerned, but when published in several journals at the same time they cease to be original as far as the journals which publish them are concerned. Important addresses delivered on important occasions may with perfect propriety be published simultaneously in a number of journals, but papers read before medical societies and papers written for medical journals should, as a general rule, be submitted to that particular journal which the author desires to have publish his paper, and to no other. If for some special reason the author desires to have his paper appear simultaneously in another journal, the editor of the journal to which the article has been first submitted may be requested to send a galley proof to the other journal, with the request that with the article shall be printed a notice that the article is published simultaneously with, and through the courtesy of, the editor of that journal to which it was originally submitted. Our views on this subject are those of the editors of all the best medical journals, and also, we are happy to say, they are the views of the better class of medical writers, those whose contributions we are most desirous of receiving.—[*St. Paul Medical Journal.*]

**To Assist Medical Research.**—The *New York Times* makes the following announcement: A new fellowship in medicine of the annual value of \$1,200 and tenable two years has been established at Columbia University. The fellowship is to be known as the Proudfit Fellowship, in honor of the late Alexander Moncrief Proudfit, of the class of '92, who left a large bequest to the University. It is established distinctly for research work, and is to be offered to graduates of the College of Physicians and Surgeons to enable them to pursue advanced study and research in internal medicine either in this country or in Europe. Awards will be made once in four years.

## AMERICAN NEWS AND NOTES.

## GENERAL.

**Cholera in the Philippines.**—News comes from the War Department at Washington that since the appearance of the plague in the Philippine Islands, September, 1902, the total recorded number of cases was 52,536, of which 37,473, or 71%, resulted fatally.

**Army Bill.**—One of the interesting features of the measure is a proposition to muster out a Porto Rican regiment on July 1, 1903, with two months' extra pay for each officer and private. The bill also carries with it an appropriation for \$60,000 for a hospital building to be erected at Vancouver barracks.

**Vacancies for Assistant Surgeons in the Army.**—There are now 35 vacancies in the grade of assistant surgeon in the United States Army. The next examination will be held in Washington next April. After this examination these vacancies will be filled, though it is asserted that some of the vacancies are to be filled by men now passing an examination in the Philippine Islands.

**Reorganization of Army Hospital Corps.**—Secretary Root has submitted to the House Military Committee a plan for the reorganization of the hospital corps. It is proposed that the titles of hospital steward and acting hospital steward be abandoned and the titles of sergeants, first class, and sergeants be substituted. The grade of corporal is established and privates divided into two classes. It is believed that the proposed legislation will be of material benefit to the medical department.

**Precautio[n] to Bar Out Bubonic Plague.**—Surgeon-General Walter Wymann, of the Marine Hospital Service, has taken active measures to prevent the introduction of bubonic plague into the ports of the United States. An assistant surgeon of the service has been dispatched to Mazatlan and another to Ensenada, both Mexican shipping ports, the latter situated in Lower California, where the disease is said to be in epidemic form. An effort will be made to prevent the inhabitants of these cities from embarking on ships bound for ports in the United States.

**Athletics in the Army.**—Major General Bates, commanding the Department of the Lakes, has issued an order to encourage athletics and field sports among soldiers of the United States Army. A part of the order reads as follows: "In order to promote interest among enlisted men in athletic training, one day in each month will be designated as Field Day at each post in this department, and will be devoted to athletic games and exercises. At each post an officer designated by the post commander will superintend the program of exercise, which will be as interesting as possible."

**Medical Licenses in the Hawaiian Islands Illegal.**—Because of errors of those in office some 29 physicians of Hawaii, 16 of whom are from Japan, must now pass new examinations. It appears that the error occurred in allowing the board of examiners to hold office for three instead of two years, as the law provides. During their false tenure of office many licenses were granted which are now declared to be illegal. A disputed point was the admission to practise of Japanese and the requirement that they should be examined in English. The new board, it is asserted, will conduct more rigid examinations than those held heretofore.

**Meeting of the American Medical Association, New Orleans, La., May 5-8, 1903.**—For this occasion the Southern Railway has authorized a rate of one fare for the round trip from Washington and all prominent points throughout the entire South. Dates of sale will be May 1, 2, 3, and 4, tickets being good for a continuous passage in each direction, with a final limit of 10 days from the date of sale. Tickets can be extended for a longer period, however, provided they are deposited in person by the original purchaser with the special agent at New Orleans not later than May 12, 1903, and a fee of 50 cents is paid at the time of deposit, when the final limit will be extended to a date not later than May 30, 1903.

**Hospital Benefactions.**—PHILADELPHIA: In adjudicating the estate of the late Thomas Elkinton legacies were bestowed to hospitals as follows: Jefferson Hospital, \$5,000; Orthopedic Hospital, \$5,000; Polyclinic Hospital, \$5,000; University of Pennsylvania Hospital, \$5,000.—The German Hospital and the Mary J. Drexel Home will each receive the sum of \$569,883 from the estate of the late John D. Lankenau, who was formerly president of these institutions. HACKENSACK, N. J.: The late Jacob B. Berdan, of Paterson, bequeathed \$50,000 to the Hackensack Hospital. WEST CHESTER, PA.: Under the will of the late Susanna H. Thomas, of this city, the Chester County Hospital will receive \$1,000. CHAMPAIGN, ILL.: The late Mrs. Isabella D. Harwood, of this city, bequeathed \$2,000 to the Julia F. Burnham Hospital. DETROIT, MICH.: According to the will of the late Dr. George S. Elliott, a prominent dentist of Detroit, his entire estate of \$15,000 will go to the Children's Free Hospital.

## EASTERN STATES.

**Foot-and-Mouth Disease Stamped Out.**—News comes from Boston that the foot-and-mouth disease is now practically eradicated from New England. Those States in which the disease prevailed, namely, New Hampshire, Rhode Island, Maine, Massachusetts, and Vermont, are said to be entirely free from the disease.

**Compulsory Vaccination in Melrose, Mass.**—According to an announcement made by the Melrose Health Board all persons who cannot show evidence of having been vaccinated within 14 months must submit to vaccination at once or pay a fine of \$5. Ten physicians have been employed for the work and have begun a house-to-house canvass. At present there are no cases of smallpox in the city.

## NEW YORK.

**Lorenz Orthopedic Charity Hospital.**—The *New York Tribune* states that application has been made to the State Board of Charities for approval of the certificate of incorporation for the proposed Lorenz Orthopedic Charity Hospital. The object is to establish a hospital or dispensary for the free treatment of all persons afflicted with deformities, especially congenital dislocation of the hip, to be treated according to the Lorenz method.

**Street Car Sanitation.**—A sanitary expert employed by a committee of the Merchants' Association of New York City in a letter to that body enumerates the measures which he considers essential to the public health with reference to proper sanitation in street car traffic: "They are the prevention of expectoration; improvement in the existing means of ventilation by means of screens outside the transoms to exclude gusts of wind, and a device whereby the transoms may be operated from the ends of the car; the use of movable floor grating of a nonporous nature and of leather or some other smooth-faced material for seat coverings; electric lights to be placed at the sides of cars above the windows so as to furnish a proper light for reading; cuspidors of ample size to be placed in stations of the elevated railroad, and public toilet-rooms in elevated stations to be kept clean and in order."

**Sickness Among Street Cleaners of New York.**—It is stated that 40 street cleaners on an average are laid off every day on account of sickness in New York City. A physician acquainted with the circumstances states that their maladies are attributable to their duties, and a large percentage of the diseases that they contract consist of affections of the respiratory organs, tuberculosis being not infrequent. The prevalence of respiratory diseases accounts to a large degree for the using of pipes by the street cleaners, who are permitted by the authorities to smoke while at work. It is claimed that this in many cases prevents the contracting of disease. Since the street cleaners when laid off for illness receive no compensation or remuneration whatever, it is stated that the officials are endeavoring to arrange for the setting aside of the fines of the cleaners for the purpose of creating a fund for the benefit of those who are incapacitated by illness similar to the arrangement which exists in the police department of the city. The majority of those contracting the diseases are cleaners in the downtown districts, especially on the East side, the West side being comparatively free.

## PHILADELPHIA, PENNSYLVANIA, ETC.

**New Dispensary for Episcopal Hospital.**—The Board of Managers of the Protestant Episcopal Hospital at their fifteenth annual meeting decided to erect a separate dispensary building at the cost of \$75,000. A ward for contagious diseases is also to be provided for.

**Lectures on Tropical Diseases.**—A series of lectures on tropical diseases is being given by Captain Charles F. Kieffer, Surgeon United States Army, at Jefferson Medical College. This is the first series of lectures on tropical diseases which has ever been given in this country. Captain Kieffer has had a wide experience in the West Indies and in the Philippine Islands, and is therefore qualified to speak with authority on this interesting subject.

**Prospective Appropriations for Hospitals of Pennsylvania.**—An exchange states that one of the features of the present session of the Legislature will be the contest for increased appropriations for State institutions, particularly hospitals. A point is made that new members especially are anxious to secure appropriations for their home hospitals, and of the 204 members in both branches of the present Pennsylvania Legislature 163 are new. It will be remembered that the appropriations made for hospitals by the last Legislature was cut heavily by the Governor. It is now stated that instead of a deficit, as was then predicted by the executive, that the funds have accumulated in the State Treasury to more than offset the deduction which he made. The total amount appropriated to charitable institutions and hospitals by the last Legislature was \$2,282,233. The surplus now in the State Treasury would permit an addition to this class of appropriations of over 50%, and

doubtless liberal hospital appropriations will be made by the present Legislature.

**Licenses to Practise Medicine Granted.**—The State Board of Medical Examiners for Pennsylvania has granted 64 licenses to practise medicine in this State. The applicants were from the various medical colleges and universities in the State, as well as from universities in Italy, Germany, and France. Dr. Beates, president of the board, asserts that there has been a marked improvement in the quality of applicants during the past few years. This is accounted for from the fact that all candidates must now have had a preparatory education equivalent to a high school standard, and must have spent at least four years in a recognized school of medicine before applying to the State Board for examination.

**A Million Dollars to Fight Tuberculosis.**—Mr. Henry Phipps, of New York, has made a most generous offer to Philadelphia, and in fact to all persons suffering from tuberculosis, regardless of location. The generous act consists in donating \$1,000,000 to be used for the maintenance, construction, and proper equipment of buildings and pavilions in the congested portion of Philadelphia, to combat the great white plague. The institute will be made the center for the dissemination of knowledge concerning tuberculosis and its proper prevention and treatment. The donor hopes with this institution, working in correlation with others of minor pretensions and capacity, to stamp out tuberculosis. The institution will be modeled after the Pasteur Institute of Paris, and will be devoted exclusively to the investigation, study, and treatment of tuberculosis. It will consist of an administration building, provided with a Finzen light institute, an institute of hydropathy, with baths and all the modern conveniences for the proper treatment of tuberculosis. There will be a dispensary for the treatment of ambulatory cases modeled after Emile Roux's Dispensary at Lille, France. Thus the institution will be able to carry its instruction and treatment into the homes of the poor and destitute, and to inaugurate a method of education and instruction which in time it is hoped will in many cases at least prevent acquisition of the disease. Lectures will be given and conferences held on the subject of tuberculosis. Dr. Flick, of Philadelphia, a prominent specialist on tuberculous diseases, will be at the head of the institute. While it is true that the statutes of Pennsylvania prohibit the erection of hospitals in the congested districts of Philadelphia, it is confidently believed that the present Legislature will repeal this statute in the interest of the Phipps institution, which will be an entirely independent property. The buildings will cost probably between \$200,000 and \$300,000, and the endowment of \$1,000,000 more will yield an annual income of some \$40,000 for the maintenance of the institution.

#### SOUTHERN STATES.

**The American Association for the Advancement of Science,** with all the affiliated societies, which convened recently in Washington, D. C., had about 1,000 persons in attendance. Every section was abundantly supplied with papers and was well attended.

**Fear that Chinese May Carry Bubonic Plague.**—Texas State Officer George R. Tabor, as a precautionary measure to prevent the admission of bubonic plague into Texas from Mexico, has issued an order to all quarantine officers on the border that all Chinese in the State shall be kept under surveillance for 15 days.

**Rules Governing Grants Given by the Carnegie Institution.**—In applying for a grant the object of the investigation must be stated concisely, and when necessary details must be furnished. An agreement must be made to prosecute the proposed research diligently and to place in the hands of the secretary of the institution at certain specified times a report of progress made and results achieved with an itemized statement of expenditures. The results of an investigation must not be published without first offering the manuscript to the institution for publication and if they do not desire to publish four copies must be furnished to the institution by the applicant. Due acknowledgment of aid given by the Carnegie Institution must appear in such publications. In case a grant is made the recipient must agree to conform strictly to the rules relative to grants of research adopted by the Carnegie Institution November 26, 1902. According to these rules applications for grants may be made at any time. The Executive Committee will consider carefully each application and decide upon it. When a grant is made or declined the applicant will be notified promptly. A detailed account of all expenditures must be made from time to time and a complete statement submitted on completion of the investigation. All apparatus, books, and materials purchased and collections made by means of grants must be considered the property of the institution. A grant made for a specified purpose can be used for that purpose only, and if the recipient desires to change in any way the subject of his research he must make an application for a new grant. Any part of an appropriation which is not needed to complete the specified investigation must be returned to the institute. Payments of grants will be generally paid quarterly, but in special cases they may be made more frequently.

#### WESTERN STATES.

**Yellow Fever on British Ship.**—From Port Townsend we learn that the British ship "Conliebank," which lately arrived from Panama, reports the death of six members of the crew from yellow fever during the voyage. The vessel is in quarantine at Diamond Point.

**Physician's Certificate Required to Secure Coal.**—It is asserted that local coal dealers in Toledo, Ohio, will not sell coal unless a physician's certificate is presented showing that there is illness in the home of the prospective purchaser, and that coal is necessary as a safeguard for the patient.

**Cats Carry Contagion.**—The Board of Health of Rockford, Ill., have found that cats are largely responsible for the spread of contagious and infectious diseases and have therefore issued an order that all cats having their habitation in homes where scarlet fever, diphtheria, or other contagious diseases are present shall be put to death.

**Rats Show Plague Bacilli.**—It is announced that Dr. Eagan, of the British Columbia Health Board, who has been conducting an investigation in San Francisco concerning the existence of bubonic plague in that city, has reported to the British Columbia government that a number of dead rats which have been examined have shown the plague bacilli. He recommends that a strict quarantine be maintained against vessels arriving from San Francisco.

**Treatment of Pulmonary Tuberculosis in Illinois.**—The report of the State Board of Health, which has been submitted to Governor Yates, of Illinois, emphasizes the necessity for the immediate construction of city sanatoriums for the proper treatment of those afflicted with pulmonary tuberculosis. It is estimated that of the 5,000,000 inhabitants of Illinois 700,000 will die of consumption. To provoke emulation attention is called to the fact that proper care for consumptives is being inaugurated in all of the progressive States in the Union. The board also urges the election of a State Board of Medical Examiners. This would leave the Health Board free to perform sanitary work alone. The work of the Health Board is said to have greatly increased within the last few years, having now reached such a magnitude that it is practically impossible for it to carry out the work successfully under its present plan.

## FOREIGN NEWS AND NOTES

#### GENERAL.

**Miscellaneous.**—On the occasion of his Jubilee Lord Lister was created Knight of the Grand Cross of the Order of Dannebrog by the King of Denmark.—Dr. Herman Nothnagel, professor of clinical medicine and therapeutics in the University of Vienna, has been nominated a life member of the Upper House of the Austrian Parliament.—Professor Josef Nusbaum has been appointed professor of comparative anatomy at the University of Lemberg.—Professor Robert Koch, the bacteriologist, has sailed for Rhodesia, where he will study the cattle plague. He will receive \$250 a day, exclusive of expenses, and will be assisted by two physicians.

**Deaths Due to Contaminated Plague Serum.**—An exchange states that the deaths of 19 Indian natives which occurred at the village, Makowal, near Gujrat, in the Punjab, have been traced to inoculations made from a certain phial which was found to contain contaminated plague serum. In spite of a most searching investigation it has not been discovered by what means the contamination occurred, but the serum proved fatal in every case in which it was administered. It was feared that the fatality would excite great apprehension among the natives, who, under their head men, had volunteered freely for general inoculation under the system organized by Sir Charles Rivaz, but it is said they have taken the matter very philosophically, admitting its accidental nature and expressing their readiness to submit to inoculation with the new serum.

#### CONTINENTAL EUROPE.

**Berberi on French Ship.**—From Dunkirk, France, comes the news that the French ship "Mezli" arrived at Saigon, Cochinchina, infected with berberis. The second and third officers were dead on board and many of the crew had to be sent to hospitals.

**Further Progress in the Sanatorium Movement in Germany.**—The sick benefit society, which includes the district of Berlin, has sent a circular to the employers of wage earners calling their attention to the new sanatorium at Beelitz, and urging them to inform their workmen and workwomen that free accommodations are offered to all working people suffering from chronic affections such as neurasthenia, anemia, gastric disorders, bronchial catarrh, rheumatism, gout, debility after acute disease, etc., in case their affection offers the prospect of a cure after a four to six weeks' course at the sana-

torium. It is especially urged on wage earners still at work, but feeling the inroads of a chronic affection, who might be completely reestablished by a course at the sanatorium. During the absence of the breadwinner at the sanatorium a weekly sum will be paid to his family. Employers are asked to use their influence to have their employes take advantage of the offer.—[*Journal American Medical Association.*]

**German Society for School Hygiene.**—The sanatorium treatment of tuberculosis in Germany is for the benefit of adults. Children have not been regarded hitherto, while France has accommodations for 1,200 in its seashore children's sanatoriums. In the November meeting of the German Society for School Hygiene, Baginsky pointed out that scrofulous and tuberculous children should be classified as follows: (1) Those with inflamed glands, eruptions, and catarrhal inflammations; (2) those with actual but not open tuberculous lesions of bones, glands, or joints; (3) with open lesions of this kind, and (4) those with pulmonary tuberculosis. The anemic children of the first group require merely to be placed in a more favorable environment. Those with pulmonary lesions should be placed in a sanatorium for lung diseases, but the others are best treated in a seashore sanatorium. Experience teaches, he states, that bone and joint tuberculous lesions frequently heal without the necessity for an operation under the influence of the sea air. Other speakers mentioned that the climate of France was more favorable for the purpose than that of Germany, and Orth urged the erection of a seashore sanatorium at Naples or at the Madeiras. A committee was appointed to discuss ways and means.—[*Journal American Medical Association.*]

### OBITUARIES.

**Bushrod W. James**, of Philadelphia, January 6, aged 66. He was graduated from the Homeopathic Medical College, Philadelphia, in 1857, and was well known as an eye and ear specialist. He was one of the committee which aided in forming the International Convention of Homeopathic Physicians, held in 1876. He was an active member of the American Institute of Homeopathy, one time president of the Pennsylvania State Medical Society, and for seventeen years surgical editor of the *American Observer*. He was also a member of the American Association for the Advancement of Science and of the American Public Health Association.

**Colin McPhail**, of Summerside, Prince Edward Island, December 3, aged 40. He was graduated from the Trinity Medical College, Toronto, in 1892, and also took a postgraduate course in Edinburgh. He was vice-president of the Canadian Medical Association for that province and was also an active member of the Maritime Medical Association.

**Archibald Y. Scott**, of Toronto, January 3, aged 41. He was graduated from the Trinity Medical College in 1887. He held the position of professor of botany and chemistry in the Ontario College of Pharmacy, Toronto, since 1891.

**Dennis J. Loughlin**, of Philadelphia, December 27, aged 55. He was graduated from the Jefferson Medical College in 1881. He was appraiser of drugs at this port and was a member of the Pennsylvania State Legislature.

**A. C. McDonnell**, of Montreal, January 2, aged 74. He was graduated from the medical department of McGill University in 1852. He served for over 20 years on the consulting staff of the Hotel Dieu Hospital.

**James C. Lawrence**, of Columbus, Ohio, December 23, aged 43. He was graduated from the Columbus (Ohio) Medical School in 1889. He was twice president of the Columbus Academy of Medicine.

**C. W. Hopkins**, medical superintendent of the Maternity Hospital, Montreal, died recently in that city. He was graduated from the medical department of McGill University in 1902.

**R. Herbert Clement**, of San Francisco, Cal., December 23, aged 32. He was graduated from the Hahnemann Medical College of the Pacific, San Francisco, in 1893.

**William H. Fox**, in Ashland, Va., December 31, aged 80. He was graduated from the medical department of the University of Pennsylvania in 1849.

**Albert W. Atwater**, of St. Regis Falls, N. Y., January 6, aged 41. He was graduated from the University of Vermont Medical College in 1885.

**William R. Grove**, of Columbia, Pa., January 3, aged 65. He was graduated from the University of Maryland School of Medicine in 1895.

**William T. Hughes**, of Bedford, Pa., at Philadelphia, December 21. He was graduated from the University of Pennsylvania in 1873.

**Charles S. Hoover**, of Ottawa, Ill., January 6. He was graduated from the University of Maryland School of Medicine in 1884.

**R. S. Wallis**, of Rockdale, Tex., January 6. He was graduated from the Jefferson Medical College, Philadelphia, in 1860.

**John W. Hignutt**, of Denton, Md., January 12, aged 73. He was a graduate of the Jefferson Medical College, Philadelphia.

**Rush Winslow**, of Appleton, Wis., December 27, aged 59. He was graduated from the Rush Medical College in 1866.

## CLINICAL NOTES AND CORRESPONDENCE

[Communications are invited for this Department. The Editor is not responsible for the views advanced by any contributor.]

### SOME QUEER THINGS IN MEDICAL JOURNALS.

BY

D. H. GALLOWAY, M.D., PH.G.,  
of Chicago.

Medical writers often make curious and sometimes startling statements. Some of these are doubtless due to typographic errors on the part of the printer, but many of them show internal evidence of being built on a complete misapprehension on the part of the writer of the facts in the case.

O. Stansberg, M.D., of Chico, California, in *American Medicine*, August 17, 1901, page 244, says, under the title of "Hydrogen Dioxid in the Removal of Powder Stains:" "I was induced to try this by the wellknown bleaching action of hydrogen dioxid." The doctor obtained results in the removal of powder stains by the use of this agent, and he evidently believes that his results were due to the bleaching action of the dioxid on the gunpowder. The black color of gunpowder is due to the presence of finely powdered charcoal, and of course this color cannot be removed by any agent which does not enter into combination with it, and at the temperature of the experiment the carbon would of course not be burned by the oxygen of the dioxid. The good results reported in this case were doubtless due to the mechanical removal of the grains of gunpowder by the bubbles of gas which were liberated in contact with or under them by the action of the blood on the dioxid.

Dr. Cutler, in an article in the *Journal of the American Medical Association* for May 26, 1900, speaks of "The Morphology of Water and Morphology of Air." These expressions should mean the form and structure of water and air respectively. Water is a liquid, and a liquid may be defined as a substance having no form of its own, but assuming the form of the vessel in which it is contained, but having a definite surface. Air is a gas, and a gas has no form of its own, but takes the form of the vessel in which it is confined, which it fills completely. It seems to me unjustifiable to speak of water or air as having form or structure.

In the *International Textbook of Surgery*, Vol. i, page 456, a writer speaks of the evaporation of vapor. Evaporation is the change of a liquid into a vapor, therefore it is hardly correct to use such an expression.

Spencer Cleveland heads an article "The Action of Neutral Alkaline Salts and Water." The chemic reaction of liquids is either acid or alkaline, and is determined by the property of changing litmus and other vegetable colors red or blue respectively. If the substance has no effect upon litmus, it is said to be neutral, therefore it is difficult to see how a salt can be at one and the same time neutral and alkaline. A medical advertisement states that the use "of our preparation increased the number of red corpuscles in a certain case from 3,000,000 to 4,000,000 per cc." It is a common mistake to speak of centimeters when the writer means millimeters, and is doubtless due to unfamiliarity with the metric system.

Dr. James Moores Ball in an article in the *Tri-State Medical Journal* of October, 1898, speaks of sterilizing a slippery-elm tent in alcohol containing 1 to 4,000 bichlorid solution. He fails to tell us how much of the 1 to 4,000 bichlorid solution his alcohol contains. It is inferred, however, that the alcohol itself holds in solution one part of bichlorid to 4,000 of the alcohol.

Even such a book as "Gray's Anatomy" speaks of "coronary arteries being the size of a crow's quill." I wonder how many students of "Gray's Anatomy" have ever seen a crow's quill? A famous textbook on surgery (though I have lost the reference) speaks of something as being the size of the quill of a Canada goose.

An advertiser offers thermometers with certified lens front, *alum case*, at \$5.00 per dozen. Alum would make an aseptic case for thermometers perhaps, but its brittleness would preclude its offering much protection to the thermometer. He means aluminum of course, but does not say so.

A writer in the *Medical Bulletin* of Philadelphia says that

iodoform has therapeutic qualities of a high order, and gives as a reason for his belief that it has successfully "held its ground against so many less odorless and more esthetic rivals."

In the *Journal of the American Medical Association*, October 22, 1898, there is a quotation from the *Klin. Therap. Woch.* The subject is heart epilepsy, and in it the writer is made to say that no attacks have occurred for three months, during which time he administered *two grams of bromin and five grams nitroglycerin tablets twice a day*. The dose of bromin, if ever administered internally, would surely not be greater than 100 mg., yet this writer is said to have given 2,000 mg. twice a day. The maximum dose of nitroglycerin is probably a milligram or less, but according to the *Journal*, this writer gave a tablet containing 5,000 mg. twice a day for three months.

Dr. Leo Ettinger, in the *Medical Record* for October 16, 1897, gives a prescription in which he calls for 1 cc. of morphin sulfate, .02 cc. of atropin sulfate, .5 cc. of chloral, and 30 cc. of water. A cubic centimeter of a solid is likely to be a very indefinite quantity. Dr. Mellish speaks of a dose of eucain as being  $\frac{1}{2}$  to 2 grains per kilo. I believe it is not good form to express a fact partly in one and partly in another system of weights.

In the *Philadelphia Medical Journal* of July 1, 1899, Dr. Smilie uses the term *compound oxygen* in the title of an article on anesthesia. Oxygen is at the present time believed to be an element, and it is certainly contrary to all rules of chemical nomenclature to speak of an element as compound. Chemically speaking there could be no more flagrant violation of proper use of words than to speak of *compound oxygen*. This same writer speaks further on of the oxid of carbon in the blood being a deadly poison. He does not indicate which oxid he refers to; carbon dioxid being one of the constituents of exhaled air and not particularly poisonous, I presume he refers to carbon monoxid. In the *Philadelphia Medical Journal*, December 2, 1899, there is a note from Dr. Buehler on a "Home Remedy for Leg Ulcer." If his communication is to be of any value to the readers he should tell them what he really uses, as there is no *black oxid* of lead. There are three oxids of lead, yellow, or litharge,  $PbO$ ; puce colored,  $PbO_2$ ; and red,  $Pb_3O_4$ ; then as oxid of lead and camphor do not make a paste, one would like to know what was used in the paste besides the things he mentions.

In reading one meets thousands of statements which are not verifiable by previous knowledge nor by ordinary experiment, and when a writer is so inaccurate in things we happen to know, we are likely to give but little credence to the statements about things we do not know. Medical lecturers are woefully derelict in their statement of facts, and newspaper writers wretchedly so, but we have a right to expect better things in scientific publications.

## THE TECHNIC OF VACCINATION.

BY

MYRON METZENBAUM, B.S., M.D.,

of Cleveland, Ohio.

1. Cleanse a wide area on the arm with pledgets of cotton moistened with alcohol. Change the pledgets until the cotton is no longer soiled when through rubbing.

2. Break off the ends of the capillary lymph tube and eject the drop of vaccine lymph on to the arm.

3. Then with the sterile scarifier or needle scarify through the transparent or translucent lymph so lightly as not to draw blood, and making a checker-board pattern from  $\frac{1}{4}$  to  $\frac{1}{2}$  inch square. Then with the side of the scarifier or needle the lymph may be further rubbed over the scarified area.

By this method of scarifying through the lymph the vaccine is carried by the scarifier under the skin and, in a manner, introduced hypodermically. Then apply a large shield, which better removed after the second day so as not to constrict the circulation and cause a local edema; and then apply a clean dry dressing, which remains on until after the scab comes away. If the arm becomes inflamed support it at day time and elevate it on a pillow at night. A 20% mercuric ointment or 5% ichthyol ointment may be gently rubbed over the inflamed area and

applied over the pustule daily and protected with a dressing. Unguentum hydrargyri and ichthyol are both readily absorbable antiseptics and soon allay the inflammation.

## BUBONIC PLAGUE IN CALIFORNIA.

To the Editor of *American Medicine*:—I note that in the number of *American Medicine* for December 27, 1902, page 997, there appears under the caption "No Bubonic Plague in San Francisco" an item based upon an alleged interview in the *San Francisco Call* with Surgeon A. H. Glennan of this service now at San Francisco, California, in which Surgeon Glennan is made to say that plague does not now, and never has prevailed in San Francisco, and that the bacillus of the disease which existed there was that of chicken cholera.

I would invite your attention to the fact that under date of December 14, 1902, Surgeon Glennan telegraphed the Bureau that the statement attributed to him by the *Call* was false. An authoritative denial was published in the *Sacramento (California) Bee* of December 16, 1902.

WALTER WYMAN,  
Surgeon-General Marine-Hospital Service.

## "AUTHOR'S" CRITICISM OF THE W. C. T. U.

BY

JOHN MADDEN, M.D.,

of Milwaukee, Wis.

To the Editor of *American Medicine*:—In your issue of November 22, "Author's" criticism of the action of Mrs. Hunt as a representative of the W. C. T. U. seems to me not entirely just to Mrs. Hunt. I have had considerable correspondence with her, and she has consulted me a number of times in regard to scientific facts about alcohol as those facts are known to the medical profession, and I have been asked to read some of the "Physiologies" seeking her endorsement before being offered to the public. At all times she has shown a sanity and reasonableness quite above criticism, always expressing a desire to keep abreast with the profession in its experimental work with alcohol. Of course, no one will deny that when competent medical opinion conflicts or is in doubt, Mrs. Hunt always takes the position least favorable to alcohol. Surely no one can blame her for this. She does not occupy the position of a judge of technical scientific points. She is, instead, devoting her life to lessening the terribly destructive effects of alcohol. No one will deny the vastness nor the importance of this field of philanthropic labor. Now, while no physician or physiologist can conscientiously support her the moment she steps outside of scientific fact, surely no one can justly criticize her for refusing to put the alcohol question in its least unfavorable (to pro-alcohol interests) light. According to "Author's" own confession, I think he was wrong. I think it is wrong to teach any pupil in any department of our schools that "alcohol is sometimes a food and sometimes a poison," thereby creating the impression that its food value is equal to or outweighs its destructiveness as a poison, when as a matter of fact there are at least a thousand cases of poisoning resulting from the ingestion of alcohol, for every case in which it is judiciously used as a food. Moreover, children are incapable of understanding the technicalities of this question of what constitutes a food, and to what extent and under what conditions alcohol may be regarded as such. Nor is the profession by any means of one opinion in the matter. Some of the ablest and most conscientious of our physiologists and physicians have repudiated alcohol as a food altogether, and on very rational grounds. Would our schools, therefore, be justified in either teaching the unqualified statement that "alcohol is sometimes a food and sometimes a poison," or going into the technicalities of the scientific discussion? After all, are we not very near the truth when we teach, without qualification, that alcohol is a poison, and ought not this to be taught in the public schools?

Moreover, we believe that the "stimulant" value of alcohol has been conclusively shown to be non-existent. That alcohol is not a stimulant is supported by an overwhelming weight of testimony, and any book which should teach our children that alcohol is a stimulant must necessarily disseminate error.

## ORIGINAL ARTICLES

DRAINAGE IN CHRONIC INTESTINAL CATARRH :  
ITS IMPORTANCE AND TECHNIC.<sup>1</sup>

BY

NORMAN BRIDGE, M.D.,  
of Los Angeles, Cal.

Chronic intestinal catarrh, as we meet it in practice and as we generally understand it, is usually restricted to the colon. That catarrh of the small intestine occurs there can be little doubt, for catarrh probably is a disorder which attacks at some time or other every mucous membrane of the body; but the symptoms and signs that we can identify as belonging to chronic catarrh of the bowels nearly all point to the region below the ileo-cecal valve.

This disease, the most common of the chronic affections, produces quite a variety of symptoms, and is responsible for many collateral and widely variant disorders of other organs and systems of organs. These include debility, discomfort, pain in the abdomen, colicky symptoms, alternations of constipation and diarrhea, bloody passages, hemorrhoids, tenesmus, insomnia, mental apathy and incapacity, and actual melancholia. It occasionally destroys life indirectly by lowering vitality and making the body a victim to some intercurrent disease. It occurs at nearly all ages and to both sexes. Infants have it (as shown by repeated mucous discharges) as well as adults.

Numerous influences conspire to produce it, prominent among them being indigestion in the stomach and small intestine, irritating things in the colon, chiefly irritating ill-conditioned feces, general debility, and perhaps poisons accidentally acquired. It is also often produced, as it is usually perpetuated, by failure of frequent, regular, and complete evacuation of fecal matter from the colon itself. Lack of efficient drainage from the colon is a prolific source of mischief in this as well as other directions. Decomposing retained fecal matter, or matter unchanged and that merely acts as a foreign body, is capable of keeping up a catarrh almost indefinitely. Some degree of constipation, involving a part or all of the colon, is a much more common condition than is usually supposed, and it is responsible for many more catarrhal symptoms than we have been ready to believe. Many people in fair health, who suppose they have sufficient alvine evacuations daily, are carrying almost constantly in the colon above the sigmoid flexure a large amount of feces that do various kinds and degrees of mischief, including the production of chronic catarrh and ptosis of the transverse colon. This condition is demonstrable in many people by the use of a large enema immediately after a supposedly complete evacuation, proving that the colon was by no means emptied. Nor is it surprising that such should be the case when we consider the numerous sacculations of the colon, its great distensibility, and the several flexures at differing angles along its course, as well as the nervous and muscular sluggishness that the colon itself frequently shows. But it is surprising, however, when we consider the anatomy and physiologic of the colon and the artificial lives we all live, that catarrhs and constipation are not more frequent.

If these postulates are correct, then regular complete and harmless evacuations are more useful than any other measure in the prevention or treatment of chronic catarrh of the colon. This measure assists more than any other the normal physiologic forces of the parts involved, and these forces, when unimpeded, always tend to prevent catarrh and to cure it when it exists. Many of us in treating this disease seem to have forgotten that there is an innate physiologic power in the colon that tends to

keep the functions normal, and is capable of doing this if it has a fair chance. As a result we have prescribed various astringent drugs, which are not real intestinal antiseptics, and also other supposed panaceas or specifics, and then wondered why the disease did not disappear and why a permanent cure was not effected.

It ought to be a cardinal doctrine for this affection that no other treatment is in order until the aforesaid regular, free and harmless evacuations are provided for; in other words, until free drainage is instituted, and not even then if these measures are sufficient. That they often are sufficient has been frequently proved. The modern scientific treatment of disease aims in general to brush away the causes and to remove the obstacles to recovery so far as possible, and there is not the slightest reason why this rule should not be followed with catarrh of the intestines. It is always safe, conservative and wise, and does not bar or prejudice any other useful treatment that may be found necessary afterward.

When constipation is manifest, whether there are symptoms of catarrh or not, the measures for relief are usually restricted to so-called laxative drugs, to suppositories and enemas, and occasionally to massage and mental efforts to induce regularity of habits. These measures are all more or less efficacious when used with caution, regularity and faithfulness. Many of the foods used are laxative because indigestible; most of the laxative drugs are used without system, according to the inclination of the patient from day to day, and are usually prompted by symptoms of biliousness and taken commonly in cathartic doses rather than such as might act as a tonic to the intestinal mucous membrane. The suppositories, enemas and other measures are subject to similar drawbacks. In spite of all this the measures have done vastly more good than harm, only much less good than some of them are capable of doing if used in the right way.

No routine treatment of catarrh of the colon is worthy of the widest confidence, although perfect and daily drainage as a principle of treatment is of the greatest consequence. Each case should be pondered by itself and a treatment adopted in accordance with its needs, but the principle of drainage ought to be insisted on in every case. It should be insisted on so strenuously that it is worth while to catalog the indications that point to the need of better drainage, some of the obstacles to its accomplishment and the basal facts in the technic that belongs to it.

In general there is need for better drainage when it is known that there is liable to be accumulated fecal matter anywhere in the large intestine. Various signs point to this condition. To bring away considerable masses of fecal matter from the colon by an enema or by a quick saline cathartic after the patient has supposed the colon to have been emptied is proof positive; and one experience of this sort proves the possibility of the frequent existence of the trouble, especially in the presence of other symptoms.

The finding of scybala, especially after the passage of softened material, is evidence of the retention of fecal matter in some intestinal pocket longer than is good for a catarrh; and scybala mixed with mucus is a positive demonstration of this fact. The colon is a reservoir for the storage of fecal matter for an indeterminate time when in health; but when in the condition of chronic catarrh no such material should remain long enough to become hardened, and the hardening process begins very promptly in and near the region of catarrh. If the retention occurs just above the seat of the disease it is nearly as bad as though within it, for so situated the hard masses probably interfere with the return circulation from points below. Colicky pains, whether slight or severe, are usually in the colon; they nearly always signify difficulty in moving fecal matter forward, and as unmistakably indicate the necessity of some measure of assistance. Intestinal flatulence, especially the discharge

<sup>1</sup> Presented to the Association of American Physicians at Washington, D. C., May 1, 1902.

of fetid gas, always means the same thing. In case of either colicky pains or fetid flatulence an enema is nearly always followed by a prompt discharge of fecal matter, with prompt relief of all the symptoms.

General discomfort in the abdomen or in the back, tenderness at some localized point in the abdomen, and rectal tenesmus, all suggest lack of drainage from some point in or above the sigmoid, and these symptoms should never be permitted to last long without testing with an enema or a laxative. Insomnia, mental heaviness, or irritability, nervous discomfort in the lower extremities, and inability to keep the legs still, often point to the need of a free evacuation of the colon—the symptoms disappearing the moment this end is accomplished. Diarrhea may continue for days, and disappear as soon as the whole of the colon is evacuated daily and without irritation.

Obstacles to the practical accomplishment of free drainage are numerous. First is to know the right thing to do; to understand the sequence in which the different measures that are sometimes useful should be tried; the appreciation of some of the anatomic and physiologic difficulties is not always easy, and the lack of constancy on the part of the average patient in carrying out the best measures is the worst obstacle of all.

Enteroptosis is one of the anatomic obstacles. It exaggerates the splenic and hepatic flexures and makes it difficult for the contents to pass them. More than the usually expended peristaltic force is required to empty the colon, and the power of the intestine in this direction is usually reduced. Then there is at times great muscular apathy in the intestinal wall. When this or the ptosis exists we have a positive obstacle. This is most apparent at the flexures, of which there are several—the hepatic, the splenic, one at the lower end of the descending colon, where the gut curves forward into the false pelvis, and several flexures of and about the sigmoid proper. These last differ in different people—as the sigmoid differs in length, position and curves.

The tetanic rigidity of the colon often found in regions of this tube in chronic catarrh, and the pathology of which is so far a mystery, often impedes the movement of the contents downward, as it causes pain in the process. This state of rigidity often continues for hours and even days. Probably its most common location is the descending colon and sigmoid. It fluctuates from moment to moment, and does not always relax completely to let fecal matter pass, but often forces it through its narrowed lumen in small particles, with acute pain. This fact can be demonstrated easily in a positive case on palpation by any one, even by the patient himself, if he has rather thin abdominal walls.

The vertical posture of the body for two-thirds of the time of our lives hinders the easy evacuation of the colon. Not walking on all-fours we are at a disadvantage as compared with the lower animals. Our habitual posture increases the enteroptosis, and so tends to increase any stretching of the transverse colon and also any irritation at the splenic flexure, provoking countless cases of catarrh. It also frequently increases the obstacles of the lower flexures and the rectum.

The means to accomplish drainage should be employed regularly, not fitfully, nor merely when the patient feels like it. If laxative medicines are used—and there is no objection to them, even as a beginning treatment—they should be taken, not in cathartic, but laxative doses, and daily or twice a day, as may seem best; never to produce griping, aching, or tenesmus. No unyielding rule can be made for the selection of the right drug, since patients have so many personal idiosyncrasies. The salines agree best with some, the vegetable laxatives with others. Of the latter, cascara, rhubarb, senna, and aloes are the best. They are usually taken in too large doses. Two weeks' trial with any one of them is probably a sufficient test. The oils sometimes act best of all. Olive oil (in large, regular doses)

is the most rational for a constant laxative, although castor-oil agrees with some patients perfectly; while a large daily dose of pure vaselin (2 or 3 drams) is sometimes a most successful medicine. Of the salines, probably the best are magnesium sulfate, sodium sulfate, and sodium phosphate. Coarse food and indigestible substances seem to be beneficial for some constipated patients; they induce daily dejections without harm, but they are a poor resort for the patient with intestinal catarrh. Moreover, with the debilitated patient, and especially in rectal constipation, they are liable to induce abscesses. The psychic method of securing (or trying to) a daily evacuation by going to stool regularly and trying is rarely successful in chronic catarrh of the colon. It is a good measure for people in health who have sluggish bowels; it may prevent catarrh, hemorrhoids, and ischiorectal abscesses, and is much to be commended for this purpose, and in proportion to the few people who practise it regularly, it is often successful. For catarrhal cases some artificial aid is usually necessary; even in those with diarrhea there are often hard fecal masses retained in some pockets or sacculations, and the retention of which aggravates the diarrhea. In many such cases there is a marked irritability of the rectum and sigmoid, compelling the prompt evacuation of every particle of substance the moment it enters them, while just above are often retained hard masses that help to continue the diarrhea. In all such cases there should be secured occasionally a free evacuation of the entire colon, either by castor-oil or a normal salt solution enema. Sometimes the great irritability of the rectum makes it extremely difficult to use the enema successfully; and sometimes the tetanic rigidity of the upper sigmoid and descending colon offers a serious obstacle to the inflow of water, pain and tenesmus occurring unless the current is very slow.

For the purpose of drainage in chronic catarrh no other measure is so generally useful as enemas properly and regularly taken, and managed rationally, and especially when aided by the use of posture to secure evacuation. The enema should be used daily or twice a day, as seems necessary. No harm will ever come to the intestine if the water is warm enough, is introduced slowly to avoid colicky peristalsis, and never pushed to the point of causing pain by distention; especially is this true if the normal salt solution is used. The enema should be taken with the body horizontal, and preferably on the left side at beginning. As soon as the fluid reaches the splenic flexure it is liable to cause more discomfort and tenesmus as it rises into the transverse colon. This is a sign to the patient to turn upon his back, which usually relieves these feelings and allows the enema to flow painlessly clear to the end of the cecum. Next to the completely horizontal posture, the preferable one for taking the enema is that with the body bent far forward while seated on the closet.

The best enema for daily use is plain water or normal salt solution (a heaping teaspoonful of salt to a quart).<sup>1</sup> This latter never irritates the intestine; indeed, it is so soothing to the mucous membrane that sometimes the enema is long retained and discharged in repeated small portions, without inconvenience to the patient. In such cases either pure water or a stronger salt solution may be used.

The normal salt solution has an excellent effect on the catarrhal surfaces; it washes away mucus and comforts the irritated spots. The best temperature of the enema for the average patient is 100° to 105° F. A few vigorous patients find good effect from cold or cool injections, and doubtless these often do provoke quick action; but most patients with catarrh are reduced in vitality, and the warm enemas are better for them. A fountain

<sup>1</sup> The latest investigations seem to show that the true normal salt solution contains nearly, if not quite, 9 parts of common salt, instead of 8, to 1,000 of water. This requires 155 grains to a quart, which is about a heaping teaspoonful.

syringe should always be used, and if possible, at least a quart of water should be introduced into the bowel for an adult patient, and no effort should be made to retain it for any length of time. There is a lay theory abroad that an enema must, in order to be effective, be retained several hours before being expelled, and any patient is liable to have heard of it and be misled by it unless warned by the physician. Patients sometimes suffer for hours in the foolish attempt to retain large quantities of water in the colon, and then complain that they cannot take enemas without pain. The theory is, of course, as senseless as that other one that an enema habit may be formed which will be calamitous.

Sometimes in taking an enema a little fecal matter in the rectum will cause an extreme degree of tenesmus after a few ounces of water have been introduced; then it is best to stop and expel this, when the intestine may accept a quart or more (introduced slowly) without special discomfort, and a free movement from the upper regions of the colon be induced. Attempts to take the enema in the sitting posture or with a rapid flow may cause similar tenesmus and make it quite impossible to fill the colon to the splenic flexure.

The usual posture of the body, and the normal and abnormal anatomic conditions, often make the colon difficult to empty thoroughly, even with the aid of an enema. The enema is sometimes retained, causing occasional colicky pains, and similar discomfort is produced or increased by attempts to expel the accumulation.

Posture of the body as a factor in the action of the intestine, and especially in the evacuation of it, is not enough studied or enough taken advantage of.

One of the most remarkable effects of posture is shown, I think, when the body is thrown forward at stool so that the anterior wall of the abdomen is nearly horizontal. This maneuver conduces to a freer and prompter evacuation in health; it lessens the colicky pains with which a catarrhal colon is evacuated, and facilitates the process; it tends to prevent an annoyance that often occurs in these cases, consisting in retention of a portion of an enema, which may be expelled in small instalments at successive sittings afterward, and often with more or less discomfort of a colicky character.

The explanation of some of the effects referred to is easy to see. The forward position allows the sagging transverse colon to come back to or toward its normal position, and its flexures (the hepatic and splenic) to be somewhat relieved of strain, so that the contents may pass more easily. By this posture the lower forward curve of the descending colon, the upward curve (when there is one) of the sigmoid, and the rectum, with the short side of its curve forward—all have the force of gravity in their favor in efforts to evacuate, and can the more easily unkink their flexures and so lessen colicky pains and obstruction. Colicky pains are prone to occur most at the flexures and sharpest turns of the intestine, and at the points of tetanic rigidity, where, of course, most peristaltic force is required. Experiences of this kind tend to prove that the erect or sitting posture is a physical disadvantage in efforts to evacuate the colon and rectum, and that the contention is correct that the animals that walk on all-fours, the bodies of which are always horizontal, have distinct physical advantages over us in the ease with which their functions are performed.

The dorsal decubitus ought to relieve the difficulties of the transverse colon and its flexures, and doubtless does, but it is a gravity obstacle to the lower descending colon and the rectum, and is of incomparably less value than the forward position as an aid to drainage.

Sometimes a patient is annoyed for hours by flatulence that shows itself by the discharge of a bubble of gas, usually fetid, every few minutes, and with no inclination for a movement of the bowels. Then by sitting at

stool with the body bent forward an evacuation is secured within a few minutes. This occurs even after he has been straining at stool in the erect posture with only discomfort and no evacuation or inclination to one.

The repeated discharge of fetid gas or any considerable quantity of odorless gas should lead to prompt efforts for an evacuation; that is to say, the presence of gas shows that usually the large intestine is more or less loaded with fecal matter that should be gotten rid of, and which the intestine is not harboring or storing in the physiologic way. The normal way is without development of malodorous gas in any quantity.

Occasionally a patient has slight colicky pains in efforts to evacuate fecal matter or an enema that has just been taken, and these pains may be attended by a sense of nausea or faintness. The colic, the nausea and faintness all are reduced or abolished by the extreme forward position of the body. One patient has repeatedly demonstrated this proposition by bending his body forward when it has happened that the colic or the other sensations have occurred at stool, and with the result that the disagreeable feelings have promptly ceased and the evacuation as promptly ensued. He has learned that this maneuver will relieve him of distress, and help the bowel to evacuate itself.

In most cases of catarrh when there is any degree of enteroptosis some benefit may be derived from a firm bandage worn about the lower abdomen. It lessens and represses the deformity to a slight degree, and so far facilitates drainage as well as better circulation in the intestine, and hence improves the tendency to recover. Probably there is some dragging down of the transverse colon as well as of the stomach in most of these cases.

The wearing of an abdominal bandage has been rather fashionable in certain quarters, usually on the theory that it prevents cold-taking, diarrhea and other diseases of the abdomen. As probably in the majority of cases the bandage is worn rather snug, it is likely that it has done more good by lessening the splanchnoptosis than in any other way. The tendency on the part of the wearer of a bandage to draw it rather firmly during the time of his daily vertical activities doubtless grows out of a sense of comfort from the support, and this latter is probably due to a relief from the pull downward of the organs.

The best form of bandage is one made of elastic material and to fit firmly about the lower part of the abdomen. Perineal straps are usually required by thin people to keep the apparatus from sliding up out of place. Any good effect from the bandage depends on its being kept in the right position and making steady and firm pressure. If it exerts its chief force on the upper part of the abdomen it is worse than useless, for then it aggravates the splanchnoptosis, with all its misfortunes.

## DIPHTHERIA ANTITOXIN IN THE INFECTIOUS OR BACTERIAL BRONCHOPNEUMONIA OF CHILDHOOD.<sup>1</sup>

BY

JOSEPH O'MALLEY, A.C., M.D.,  
of Philadelphia.

Visiting Physician to St. Agnes' Hospital.

Bronchopneumonia, which is also called catarrhal pneumonia, lobular pneumonia and capillary bronchitis, is an inflammation of the terminal bronchus and the air vesicles that make up a pulmonary lobule, and may occur independently of preceding bacterial infection, as from direct irritation by smoke and noxious vapors or aspiration of food and gases. In such cases it may be associated with or arise by extension from inflammatory processes in the upper air passages; it may be caused by

<sup>1</sup> Read before the Southern Branch of the Philadelphia County Medical Society, March 27, 1902.

chloroform and less often by ether administered for surgical anesthesia in the presence of artificial light, through combustion. It may arise from purely local infection by agents recognized and unrecognized, and probably not specific; it may occur through extension from bronchitis of any origin, but it is usually met as a complication or sequel of one of the infectious diseases, especially those of childhood. Even when it is the only prominent manifestation of the existence of infection, as, for example, in influenza or tuberculosis, it is to be regarded as a secondary infection. It is usually associated with or follows measles, scarlet fever, smallpox, whoopingcough, influenza, tuberculosis, erysipelas, dysentery, meningitis and typhoid fever.

Bacterial bronchopneumonia, with which we have most to do, is a morbid process affecting the terminal bronchioles, the pulmonary vesicles and the pulmonary lobules in scattered areas. It occurs secondarily to some preceding morbid process of bacterial origin. Apart from the tubercle bacillus the organisms most frequently found in bronchopneumonia are *Micrococcus lanceolatus*, *Streptococcus pyogenes*, *Staphylococcus aureus* and *albus* and *Bacillus pneumoniae* of Friedländer. In cases occurring in diphtheria *B. diphtheriae* (Klebs-Löffler) is frequently found, and in influenza, *B. influenzae* (Pfeiffer) and other organisms have been reported. It is rare for pure cultures of any of the organisms mentioned to be found except in the case of the pneumococcus, which is associated most frequently with the pseudolobar type of the disease. The streptococcus is the most common in the lobular type. Mixed infection is the rule. Wright and Mallory have described a capsular bacillus found by them in the lungs of a man who three weeks after diphtheria died with a severe bronchopneumonia. Carmichael says there are four clinical types of infantile pneumonia recognized: (1) Complete consolidation of lobar distribution without signs of bronchial catarrh; (2) with no signs of consolidation, bronchial catarrh being generally distributed over one or frequently over both lungs; (3) with bronchial catarrh and large areas of incomplete consolidation of lobular distribution; (4) with bronchial catarrh and larger areas of incomplete consolidation of distribution. The differentiation of the last three types depends to a greater or less extent upon the degree of consolidation accompanying. The acute pneumonia of infancy and early childhood is a bronchial pneumonia in the majority of cases. Bacteriology demonstrates that it cannot be considered a specific disease in the sense that it is due to any special organism, for similar if not identical pathologic changes are produced in the lung tissues by various organisms. The reason why the same infection that produces a catarrhal pneumonia in infants should produce a fibrinous pneumonia in adults or in children over 5 years is explained by the fact that the alveoli of the lung are not fully developed until about the fifth year.

Catarrhal pneumonia is essentially a pneumonia of infancy, and the types commonly met are but two—the lobular and the pseudolobular. In the lobular type the dissemination of the morbid process and the distinctly lobular involvement of the alveoli can be readily demonstrated. In the pseudolobular the extent of the affected areas gives a resemblance to the consolidation of croupous or lobar pneumonia.

Tuberculous bronchopneumonia is the most common and most fatal form; next in frequency is the infectious bronchopneumonia, associated with the diseases of childhood which, according to distinguished pediatric authors, causes more deaths in children than do the fevers themselves. It is well known that when a culture in broth, of pathogenic bacteria, say the diphtheria bacillus, is passed through a Chamberland filter, the germless filtrate will be found to hold in solution a powerful poison; this poison or toxin can be precipitated and it gives the reaction of an albuminoid substance, but its chemie composition is not yet fully known. If normal

serum from the blood of an animal is mixed with this toxin the serum will not lessen its virulence. The serum of an animal rendered proof against diphtheria, if added in sufficient quantity, will neutralize the toxin derived from the diphtheria bacillus, thus proving the existence of a new substance in solution which is called an antitoxin.

In nearly all diseases caused by bacteria the toxin given off by the bacterium is the immediate source of the group of symptoms called the disease. This toxin tends to destroy cell-nuclei everywhere, and if unchecked will cause death. There are various theories advanced to explain the process of cure in such diseases. One theory is, that the toxin in the circulation excites the body cells to produce a neutralizing antitoxin which counteracts it somewhat as an alkali mitigates the action of an acid. In some diseases, like pneumonia and diphtheria, this antitoxin passes out of the blood in a short time and a person may, therefore, be attacked repeatedly by these diseases. In other cases, as typhoid fever, the antitoxin remains in the blood for years and prevents the recurrence of these diseases—such a person is said to be immune against a certain disease.

G. Sims Woodhead<sup>1</sup> theorizes as follows as to the causation of immunity:

Many of the pathogenic organisms act under very special conditions and upon very complex proteid substances. The results vary greatly, but disintegration of these proteids is never carried so far as in the ordinary processes of decomposition of dead organic matter, animal or vegetable. Consequently substances are formed characteristic of the earlier stages of breakdown viz., enzymes, toxins and toxalbumins, albumoses, ptomaines and similar substances, rather than the simpler nitrogenous or carbon-holding substances of more advanced disintegration—water, carbon dioxid, ammonia, nitrates, nitrites, etc. In disease processes we have the results of the action of the products of the earlier stages of decomposition of proteid matter, at which exceedingly complex substances are formed, rather than of the later stages, when decomposition is more fully carried out. By a process of hydrolysis, anthrax and diphtheria bacilli and their products convert crude albuminous material into substances nearly allied to albumoses. Hankin and Cartwright Wood maintain that these albumoses, when injected into an animal, exert a protective action against the specific disease with which it is associated. The enzymes or ferments which appear to precede or to be formed along with the albumoses have in most instances a much greater lethal activity, but they appear to exert a comparatively slight protective effect, although when injected with sufficient care they give rise to modifications in the protoplasm of the cells, which are thus rendered more resistant to the action of toxins. The albumoses appear to have a similar power of bringing about a modification of the cell, which enables it to resist the attacks of the toxin without at the same time exerting the powerful toxic influence which the enzymes exhibit. This production of albumoses or some similar substance in disease is therefore of vital importance in the production of immunity. A number of enzymes which in many respects resemble the toxins formed by disease-producing organisms have been described—amylase, invertin; enzymes which split up glucosids, cellulose, urea, and fat; enzymes which have the power of peptonizing albuminous substances and converting them into peptones, albumoses and similar proteid derivatives; chromogenetic enzymes which have the power of producing coloring matter, etc. These enzymes may remain and do their work in the cell, hydrolyzing the cell substance, or they may become separable functions and do their work outside the cell. It has been argued that the so-called antitoxin present in the blood-serum of a patient recovering from an attack of diphtheria or tetanus is simply the accumulation of such a separated or separable function which can act on the toxin outside instead of within the cell. Upon this the theory of the antitoxin treatment of these diseases, e. g., tetanus and diphtheria, may be said to depend. The toxins are exceedingly complex substances, and although they are frequently spoken of as specific poisons, it must be remembered that they are probably combinations of non-specific substances with perhaps a single specific poison (enzyme plus globulin, etc.). In diphtheria and tetanus toxins, for example, there are certain common substances by the action of which fever, general symptoms or local swelling may be set up, but in addition to these there is in tetanus toxin a specific substance which exerts a selective action on certain nerve cells, inducing the special and characteristic symptoms by which tetanus may be distinguished from almost any other disease. In diphtheria toxin, too, along with the substances that produce general effects are those which pick out portions of the nervous system, and combining with these, or acting upon them, give rise to the paralytic symptoms so often developed during or

<sup>1</sup>Allchin's Manual of Medicine, Vol. i, pp. 30, 31, 32.

after an attack of diphtheria. Now it is evident that in the treatment of disease by antitoxin it is necessary not only to antagonize the specific, but also the general actions of these poisons. It is possible to imagine that substances which only exert a specific effect may be produced along with others which attack the general poisons. The specific action is, however, always the more difficult to obtain. It is possible that by the use of a general antitoxic substance a patient might be helped to tide over the effects of the action of the specific toxic substance, and the possibility must be recognized that an antitoxin for diphtheria, for instance, might be of such a character that it would enable a patient to recover, still leaving unaffected the specific action on the nervous system. This, however, is not probable.

Within the past two years a number of instances in which antidiphtheric serum has been employed with success in other infectious diseases than diphtheria have been noted. How or why antidiphtheric serum acts in these mixed bacterial conditions we do not understand, but that it does act, and promptly, too, has again and again been demonstrated by numerous observers, some of whom have thought that by its entrance into the body it produces a leukocytosis which in turn produces an antitoxin; some think it acts as a stimulant to the protective powers of the body. There is immunization or partial immunization which may be called indirect, as when vaccine immunizes wholly or in part against variola, or when erysipelas counteracts the poison of infectious pneumonia, as has been noted in some instances, and which certainly happened in the cases of bronchopneumonia occurring in my own practice in which antidiphtheric serum was used in the treatment. It is well known that the use of a serum containing an antitoxin is not confined to the treatment of diphtheria. Animals have been rendered proof against diseases caused by various species of streptococcus, and their serum used to prevent or to cure analogous diseases in man. Dr. Weisbecker has experimented with serum from patients recovering from measles, with which he injected others in the incubation stage. He considers the results quite satisfactory, as the course of the disease was much modified and patients with measles and pneumonia were cured. The serum treatment of smallpox has been shown to be rational and efficient, but as a preventive it is not likely to supplant vaccination.

Antidiphtheric serum has been employed in the treatment of malignant scarlet fever and Dr. Alcide Treille has used it in malarial fever. M. Fourrier used it in the treatment of a young child who showed an angina during the course of grave scarlet fever. The case was almost hopeless at the moment treatment began, but from the first injection the coma into which the child had sunk disappeared and subsequent injections led to a rapid recovery. Since then M. Fourrier has employed this treatment in similar cases with most successful results and he recommends it in all grave cases of scarlatina. Serum prepared on the principle that governs the production of diphtheria antitoxin has proved successful in a number of instances of bronchopneumonia of tuberculous origin. The work done by Prof. Maragliano, of Genoa, and the results of the use of tuberculin are well known. Although it has proved a failure as a curative agent, it does lead to a formation of antitoxin, but it is not known that sufficient antitoxin to prove curative can be produced by the use of safe doses. Very recently the successful work of Prof. Talamon, of the Buchat Hospital in Vienna, in lobar pneumonia, has attracted worldwide attention. Dr. Montgomery Paton, of Australia, claims that antidiphtheric serum is a specific for sepsis and other secondary conditions which have a streptococcal causation. He also claims that antidiphtheric serum is a specific for simple inflammation, trauma, etc., whether such inflammation is regarded as being a distinct entity or only an attenuated sepsis. He holds that diphtheria antitoxin has no parallel in medicine as an absorbent of inflammatory tissue, and that it has considerable influence on the coagulability of the blood. It has great power in some depressed conditions, probably due to septic conditions

acquired or to autotoxemia. It has been found by Carrier, that while diphtheria antitoxin given hypodermically is a specific for the poison of the Klebs-Löffler bacillus and weak for the septic organisms, when given by the mouth it is specific for the staphylococcus and streptococcus and weak for the Klebs-Löffler bacillus. Dr. Paton reports its successful use in erysipelas, peritonitis, appendicitis, acute rheumatic polyarthritis, puerperal infection, secondary infection, tuberculosis, traumatism, bronchopneumonia (he does not say whether secondary or not), in abscess, suppuration, etc., wherever the staphylococcus or streptococcus is to be found.

The cases of bronchopneumonia in which I used antidiphtheric serum occurred at various times during the past two years and were all secondary pneumonias of bacterial origin, complicating the various infectious diseases and exanthems of childhood.

CASE I.—James B., aged 2½, had been ill with influenza. I saw him November 22, 1900, and found him profoundly prostrated; nasal alae dilating, respirations 70 to 75, pulse 170, temperature 105°. Physical examination gave the harsh breath sounds and subcrepitation of bronchopneumonia. As the child's condition was extremely critical, 3,000 units of antidiphtheric serum were injected into the cellular tissues of the groin; this was done within 16 hours of the onset of pneumonia. Eight hours later the reaction was marked, temperature had dropped to 103°, the pulse-rate from 170 to 104, respirations from 70 to 35; the defervescence continued and the child made an uninterrupted recovery. The bacteriologic examination of the culture made from the child's throat was negative as to the Klebs-Löffler bacilli.

CASE II.—I saw N. B., aged 2, on March 4, 1901, at 1.30 a.m. Temperature was 103°, fauces negative, respirations 50, pulse 142. Later in the day, about 10 a.m., temperature was 104.4°, respirations 75, pulse 150; physical examination showed catarrhal bronchopneumonia. The child's condition became extremely grave, temperature continued to rise to 105° with increasing pulse and respirations. One thousand units of antidiphtheric serum were used about the sixteenth hour of the pneumonia; nine hours later an extraordinary improvement in the child's condition was noticed. Defervescence occurred by lysis and the child made an uninterrupted recovery.

CASE III.—Baby R., aged 7 months, had bronchopneumonia as a sequel to measles. Physical examination revealed bronchial breathing, and at intervals over both lungs subcrepitant rales were heard in scattered areas, temperature was 105°. The autotoxemia was so profound that a persistent clonic muscle tremor was present. The little patient was unable to suckle and was gravely ill. Two thousand units of antidiphtheric serum were injected into the cellular tissue of the left groin at 4.30 p.m. of the day I saw him. Defervescence began 8½ hours thereafter, convulsive tremors ceased and the paramyoclonus disappeared. Pulse dropped to 136, temperature to 101.4°, and the baby began to nurse. Two thousand units of antidiphtheric serum were again injected and defervescence continued by lysis until the normal was reached, about the third day thereafter. Patient made an uninterrupted recovery.

The fever reaction in all of these cases occurred by lysis within 8 to 10 hours after the use of the serum. I believe it was not a coincidence but occurred in each case within the length of time stated. All the children were unusually ill. At the time of first using the serum, November, 1900, I was unaware of the observations of Fourrier and Weisbecker, but was led to use the antidiphtheric serum because of the proximity of a case of diphtheria; thinking the bronchopneumonia in my little patient was of bacillary origin, perhaps due to Klebs-Löffler bacilli. The astonishing result obtained encouraged me to try the antidiphtheric serum in bronchopneumonias complicating the exanthems. Since that time I have used the serum repeatedly in like conditions with uniformly satisfactory results. I have also used it in scarlet fever in which the anginal symptoms were pronounced, and I obtained a rapid amelioration of this symptom, and, in short, of all the distressing symptoms.

I believe we have in antidiphtheric serum a most valuable therapeutic agent for a class of cases otherwise beyond ordinary therapeutic aid; particularly in those cases of bronchopneumonia which so often cause a fatal complication in the bacterial diseases of childhood, such as measles, influenza, whoopingcough and scarlet fever.

## THE ETIOLOGY OF ENDOCARDITIS, WITH ESPECIAL REFERENCE TO BACTERIAL AGENCIES.\*

BY

SANFORD BLUM, A.B., M.D.,

of San Francisco, Cal.

Chief of Clinic for Diseases of Children, Medical Department of the University of California.

## HISTORICAL SKETCH.

Raymond Vieussens (1648-1716) ascertained the anatomical structure of the heart and learned some symptoms of heart disease. He even made an accurate diagnosis in a case of stenosis. Later, Lancisi (1654-1720) published two books in which he discussed heart disease. He mentioned hypertrophy and dilation of the heart and the connection of dyspnea with cardiac disease.

Albertini (1672-1733) introduced palpation—the first means employed in the physical examination of the heart. He differentiated between disease of the right and left sides of the heart. Morgagni (1661-1771) noted the far greater frequency with which the left side was attacked.

Senac (1693-1770) systematized the existing knowledge of heart disease. He recognized pericarditis and endocarditis as separate affections. Inflammation of the endocardium he placed among the most prominent causes of valvular changes.

*Percussion.*—Auenbrugger's method of physical examination was first applied to the heart by Corvisart.

Kreisig ascertained the inflammatory origin of pathologic alterations of the endocardium and traced to this source thickening, ulceration, perforation, and aneurysm. He recognized rheumatism and scarlet fever as diseases complicated by endocarditis. Bouillard (1796) emphasized the coincidence of endocarditis with articular rheumatism.

Laennec and Skoda studied and taught the application of auscultation as a diagnostic method. In his book, "Perkussion und Auskultation," Skoda designated the normal heart sounds "tones," the abnormal sounds "murmurs" (geräusche), a classification which is still adhered to. He defined the gross pathologic lesions of endocarditis and deduced the various symptoms each would cause. He verified his conclusions by postmortem examinations. To him is due the credit of having explained the various cardiac murmurs and their import in differentiating the various cardiac lesions.

*Microscopic Researches.*—The first reports of microscopic observations in cases of endocarditis come from Rokitansky<sup>1</sup> (1855). He described certain fine granular masses observed in endocarditic deposits, but did not determine their nature. About the same time Virchow made a similar observation. But Winge and Heiberg were the first to give definite information in this line of investigation. Winge's<sup>2</sup> case occurred in a man who, as the result of an abscess on the foot, developed septicemia and died. His heart after death presented evidences of malignant endocarditis, and in the diseased portion of the endocardium the microscope revealed chains of elements which were evidently of a foreign nature. Heiberg's case occurred in a puerperal woman. Dying under septic exhibitions a few days after confinement, bodies similar to those described in Winge's case were found in the ulcerated

heart valves. These organisms, which from their occurrence in chains as well as from their resistance to chemical reagents, were evidently of a bacillary nature—and in fact were probably streptococci—Winge and Heiberg believed they were leptothrix chains. But the finely discriminating eye of Virchow, to whom preparations from both patients were submitted, detected essential differences in structure, and in a postscript to Heiberg's<sup>3</sup> report he calls attention to these differences, and cautions against classifying these entities as leptothrix.

In 1873 Eberth<sup>4</sup> designated two cases as of a diphtheric nature. He arrived at this conclusion by studying the morphologic characteristics of the discovered bacilli and by observing their reaction to the various stains. With bacilli obtained from his second patient he caused a diphtheric process on the cornea of a rabbit. Wedel (1873), Burkhart and Eisenlohr (1874), Meyer (1875), Eichhorst (1876), Gaber, Birsch Hirschfeld, and others reported cases of bacterial endocarditis. In 1878 Klebs published 27 cases in which he had found bacteria. The same year Köster advanced a theory as to the connection or continuity of ulcerative and verrucose endocarditis. He advanced the theory, based on the researches of Weigert, Eberth and others, that the primary pathologic alteration caused by bacteria in the endocardium was a necrobiosis. Consequently the inflammatory phenomena were to be regarded as a reactionary process leading to thickening, shortening of the valve segments, and to the formation of verrucosities. He differentiated further two etiologic varieties of verrucosities, real excrescences or growths, and deposits (auflagerungen). He stated that in all patients with ulcerative endocarditis who were examined soon after death it was only exceptionally that micrococci could not be found, and he announced his belief that in all cases of acute ulcerative endocarditis micrococci had been present in the initial stages.

In 1881 Litten, from the reports of other investigators and from his own observations, felt justified in attributing all cases of endocarditis to parasitic agencies. Like Klebs, he divided endocarditis into two classes—septic and rheumatic.

A definite variety of bacillus in endocarditic lesions was first positively recognized in 1885 by Philippeaux, who obtained cultures of streptococci and staphylococci from material derived from endocarditic deposits.

In 1886 Netter and Weichselbaum identified the pneumococcus and *Bacillus coli*. Heller's discovery of tubercle bacilli in five cases of endocarditis negated Rokitansky's theory that the existence of pulmonary tuberculosis or endocarditis in an individual precluded in that individual the possibility of development of the other—that, in other words, pulmonary tuberculosis and endocarditis could not exist together.

Weichselbaum's review (1889) of the bacteria found in endocarditis embraced the following varieties: Staphylococcus, streptococcus, *Diplococcus pneumoniae*, *Bacillus endocarditidis griseus*, micrococcus, *Micrococcus endocarditidis rugatus*, and *Bacillus endocarditidis capsulatus*. He made plain his opinion that endocarditis was due only to bacteria, and could be caused by many forms.

In addition to the varieties mentioned, typhus (Viti) and diphtheria cases have been described. Gonococci have been recognized in pathologic endocarditic tissues by Leyden (1893), Michaelis, Thayer, and many others. Thayer succeeded in finding gonococci antemortem in the blood of a patient suffering from gonorrhoeal endocarditis. Influenza bacilli have recently been reported, and Leyden has described a fine diplococcus which he believed to be rheumatic.

*Experimental Endocarditis.*—The first experiments directly connected with endocarditis were performed by Winge and Heiberg. Portions of the embolic masses derived from their cases (Winge, 1869, Heiberg, 1872) were introduced into the bodies of rabbits

\* Thesis submitted to degree committee, University of California, for degree M.S., April 15, 1902. Degree conferred May 14, 1902.

—in some cases subcutaneously, in others intraperitoneally. In none of these animals did an endocarditis develop, although micrococci had been demonstrated in the diseased tissues from both patients. The failure to obtain positive results in these experiments may be explained by the fact that in the endocardiums of the animals experimented upon no *locus minoris resistentie* existed, a condition which later experiments have proved to be prerequisite for the success of such experiments. Conheim supplied a method of obtaining this condition. In lecturing to his students he suggested, in order to produce artificially valvular lesions for the purpose of studying their results, the introduction of a sound into the left carotid artery and the puncturing of the aortic valves. This action would produce mechanically an aortic insufficiency (regurgitation) accompanied by a diastolic murmur. In the later series of experiments on bacterial endocarditis this method of causing a defect in the cardiac endothelium has been adopted quite generally. In my own experiments I employed a fine, blunt cannula with a closely-fitting trochar. By this device I avoided wounding the parts traversed before reaching the valves, and by temporarily ligating the carotid about the cannula the loss of blood was minimized, and so the necessity for hurry, with consequent ill-success of the operation, was obviated. Prudden modified Conheim's operation by the use of chemicals to cause a valvular lesion, and obtained positive results.

To Rosenbach is due the credit of producing, experimentally, the first cases of bacterial endocarditis. He introduced bacilli into the circulation of rabbits recently operated upon by Conheim's method, and succeeded in this manner in causing bacterial endocarditis. His researches resulted in positive experimental cases of streptococcus and staphylococcus endocarditis.

Pursuing similar lines Wyssokowitsch and Orth, in 1886, verified Rosenbach's results by repeating his experiments, and added to the list of cases produced experimentally those caused by *Bacillus endocarditidis* of Nicolaier. This list was further increased by Fraenkel, who experimentally caused pneumococcus endocarditis.

*Original Investigations.*—Such was the position reached by investigators of the etiology of endocarditis when in 1897 I began a study of the subject. My first experiments were performed while working in Leyden's clinic at the Charité (Berlin). There I repeated, in cooperation with Michaelis, the experiments of Rosenbach, Wyssokowitsch and Fraenkel; and succeeded in obtaining positive cases of bacterial endocarditis with streptococci, staphylococci and pneumococci. The macroscopic lesions in these cases appeared as verrucosities, varying from a pinhead to a pea in size. Microscopically they were shown to consist of organized tissue masses, in the interior and in the deeper portions of which, colonies of the specific bacteria employed were plainly discernible. The nature of the bacteria was further checked by differential staining methods and by culture.

As before mentioned, tubercle bacilli in the diseased endocardium had been repeatedly described. Still there were those who claimed that their presence was purely accidental, and who maintained that the tubercle bacillus could not cause endocarditis. In this series of experiments the tubercle bacillus also gave positive results. In one rabbit, which died six weeks after having been operated upon in the usual method and which had been inoculated with tubercle bacilli immediately after the operation, excrescences the size of a pinhead were found postmortem at the points where the aortic valves had been punctured. Both macroscopically and microscopically these nodules presented the characteristics of tubercles. Furthermore, I succeeded in staining and demonstrating (Verein für innere Medizin, Berlin) considerable numbers of tubercle bacilli in sections made through such a tubercle. In 1898 I published this work

with Michaelis, under the title "Zur experimentelle Erzeugung von Endocarditis Tuberculosa."<sup>5</sup>

My next successful case was with the typhoid bacillus. This case has not been published, but is mentioned by Lee and Weis in their inaugural dissertations for the doctor's degree at the University of Berlin. Several efforts were made to obtain positive cases of typhoid endocarditis, but we were successful only in the one here reported. These experiments were performed on rabbits, and in general the typhoid bacillus is not specifically pathogenic for rabbits. In the successful case the rabbit was inoculated with a culture which had been passed through several rabbits previously and which had, presumably, acquired a specific virulence. The nature of the bacilli in the large colonies found in this case was verified by their decolorizing in the section when treated by the Gram method of staining, as well as by cultures and the demonstration of flagellums in the culture bacilli.

Emmet Holt,<sup>6</sup> commenting on the exceedingly rare occurrence of acute endocarditis in infancy and early childhood, says that in reports of autopsies of over 1,000 children less than 3 years of age not a single case is to be found. My next case occurred in an infant 2½ months old, and on account of the clinical and scientific importance of this case I shall quote it at some length.

The case was as follows:

Julius Rieger, 2½ months old, entered the hospital October 8, 1898. He was the ninth child, full term, easy delivery (third child was stillborn, seventh was premature). Nourished at breast one month, then artificially. He was always very strong. Appetite was always good, never had vomiting; bowels were always regular, but a rash has been present since October 1. It covers the entire body; appeared first in red spots, later vesicles formed, which broke. Three days ago there appeared on the back of the left hand a swelling which has now almost disappeared. Since last night there is swelling of the backs of both feet. Vesicles and ulcerations of the corners of the mouth have been present three days. The child has been extremely restless and feverish the past week. Father luetic, mother healthy.

*Physical Examination.*—The child is 60 cm. in height, weighs 4,970 gm. and is of average development. On the face, back and limbs is noticed a widespread papular syphilid. Lips are crusted. Coryza is present and rhagades are seen at the angles of the mouth. Examination of the heart discloses nothing abnormal; examination of the lungs is also negative. The abdomen is distended; liver is exceedingly large. The spleen also is enlarged and is palpable two fingers breadth below the ribs. Examination of the blood shows 3,700,000 erythrocytes, some poikilocytes, hyperleukocytosis, and quite a number of normoblasts and marrow cells. In the stained preparations rod-shaped bacilli are recognized. Urine is concentrated and contains albumin.

October 11, 1898: On the abdomen, which was rubbed yesterday with 0.25 ungt. cinereanum, there is a vesicular elevation of the epidermis. Fever and anorexia are present.

October 12-13: Passages are slightly dyspeptic. There is no fever.

October 14: A stool having the odor of decayed proteids. Exanthema is decidedly faded. There are pronounced snuffles and eczema of the ear.

October 15: Stools continue dyspeptic. There is slight edema of the back. The nasal mucous membrane discharged a considerable amount of yellow pus, which did not show any specific bacillus microscopically.

October 16: Cultures of the nasal discharge show pseudodiphtheria bacilli and indefinite cocci. The rhinitis interferes with feeding.

October 17: The dermatitis caused by the inunction is healed. The points of former exanthema are desquamating; the epidermis of the palms of the hand is being cast off in large flakes.

October 18: The rhagades of the mouth bleed frequently; coryza continues; the total amount of nourishment taken has diminished; the stools have become slimy.

October 19: There is decided loss of weight. Temperature 39.4°C. Meteorism is present. Examination of the stools and of lungs affords no important disclosures. A suspicious snoring respiration is present.

October 20: There is high fever, 39.4°C.; retraction of the head, and the face is extremely pale. Abdomen is meteoric and distended. On the right great toe is a well-filled, bloody vesicle, which has appeared suddenly and has a diameter of 1 cm. On the second toe a smaller similar vesicle. A loud, rough, systolic murmur is plainly audible over the heart. Pulse is strong. Voice is hoarse. Diarrhea is present.

October 21: Death occurred at 9.30 a.m.

From October 8 to October 18 the illness was unaccompanied by any particular elevation of temperature. From the latter date till death, high fever was present constantly.

The autopsy showed lobular pneumonia, chronic intestinal catarrh, hepatic interstitial lues.

The pericardial sac contained a dark-yellow fluid. The heart was of normal size; in the right ventricle was a very small blood-clot: the ventricle was fairly capacious. Left ventricle was empty; the walls were of ordinary thickness. The aortic valves were normal; the mitral valves are somewhat thickened at their margins, and easily detachable blood-clots adhere to them. On the superior surface of both segments of the mitral valve near their free borders are several miliary nodules.

The liver is very large—weight 320 gm. Surface is smooth; the cut surface is very hard and shows a fatty appearance. Fatty degeneration in parts of the tissue. Here and there on the cut surface are gray miliary nodules.

From the heart's blood obtained 1½ hours postmortem, pure cultures of pyocyanus bacilli were obtained. Mice and guinea-pigs inoculated with 24 hour cultures so obtained died of pyocyanus septicemia in from 18 to 29 hours, according to the amount of the culture injected subcutaneously. The amount employed in these experiments varied from 0.5 cm. to 1.0 cm. In the miliary verrucosities described on the mitral valve and in the tissues of the valve were found colonies of bacilli identical with those propagated in cultures from the heart's blood.

Finally, with the cultures obtained from this case I caused, experimentally, a pyocyanus endocarditis in a rabbit. This experiment was performed in the usual manner, viz., the aortic valves were perforated by puncturing with a probe through the carotid artery. The vessel having then been ligated and the wound closed, a portion of the culture was injected, under aseptic conditions, into a vein of the ear.

This case, which came under my observation while I was in the Children's Hospital, in Graz, is unique in that it is the only case of positive bacillary endocarditis reported in an infant, as well as the single known case of pyocyanus endocarditis in which a mixed infection did not exist. It is to be noted that in this case *Bacillus pyocyanus* was demonstrated in blood taken antemortem.

This case was followed in the hospital by a pyocyanus epidemic, in the course of which several children died. The epidemic was studied and reported by Professor Theodore Escherich.

Recently Fritz Mayer has caused experimental endocarditis with bacilli obtained from the tonsils of patients afflicted with rheumatism, and which he believes to be the bacillus of rheumatism.

The intimate relationship existing between rheumatism and endocarditis has long been recognized. Primarily regarded as a complication, endocarditis is now received as a manifestation of rheumatism, and in these cases a bacillus is assumed as the cause of both. Should this prove to be the case the proportionally greater frequency of endocarditis in cases of rheumatism in childhood could be easily explained by the lesser power of resistance of the endocardial structures—as of the structures in general—at this age. The complication of the acute infectious diseases by endocarditis may likewise be explained by ascribing to these diseases a bacterial pathology.

*Summary.*—From what has preceded, together with clinical observation, certain deductions seem proper:

1. Bacterial agencies are active in the causation of endocarditis.

2. The presence of bacteria in the circulation is not alone a sufficient cause; but a predisposition—a *locus minoris resistentie*—must exist in order for them to secure a foothold. (Experiments of inoculation in which the endocardium is not wounded give negative results.)

3. Not all bacteria are capable of causing an endocarditis, but in general those which are pathogenic for the individual may cause endocarditis (under proper conditions). However, under certain circumstances, as in my typhoid case, a bacillus ordinarily nonpathogenic may acquire a specific virulence. And again, as in the pyocyanus case, the lowered vitality of the individual (in pyocyanus case child had hereditary visceral lues) may afford opportunity for an ordinarily nonpathogenic germ to secure a lodgment.

4. There are other causes of endocarditis beside bacteria. From the time when the theory of a parasitic origin of endocarditis was first tentatively advanced

there has been a gradual strengthening of this opinion, until now it is enthusiastically maintained that bacteria are responsible for all cases of endocarditis. This view may be immediately confuted, since certain atheromatous conditions may directly cause the lesions characteristic of endocarditis, without the necessity of any further agency. Furthermore, cases of congenital and infantile endocarditis cannot all be placed in this category, although in some of these such influence may probably operate. This department of the subject—congenital and infantile endocarditis—merits more attention than it has heretofore received. Finally, there are cases of known mechanical and chemical origin. Such are due to traumatism, rupture of the valves or chordæ tendinæ, cases associated with systemic disturbances, such as occur in goiter, diabetes and chronic alcoholism.

Endocarditis may then be classified with reference to its etiology as follows:

1. Congenital and infantile endocarditis may be due to defective development, to reparative processes as suggested by Parrot and to other causes (unknown).

2. Endocarditis due to known bacterial agencies, *e. g.*, streptococcus, staphylococcus, tubercle bacilli, pyocyanus bacillus.

3. Endocarditis of probable bacterial origin, associated with definite diseases presumably of a bacterial nature but of which the bacterial agents are still undiscovered, *e. g.*, rheumatism, chorea, syphilis, exanthems, etc.

4. Endocarditis due to mechanical or chemical insults, *e. g.*, blows, strains, noxious excretory products in the blood, alcohol, atheroma.

### THERAPY OF OTITIS MEDIA SUPPURATIVA CHRONICA.<sup>1</sup>

BY

LEE WALLACE DEAN, M.S., M.D.,

of Iowa City, Iowa.

Professor of Otolaryngology and Rhinology, University of Iowa; Ophthalmic Surgeon, Iowa College for the Blind; Assistant Ophthalmic Surgeon, University Hospital.

Owing to the diversity of opinion as to the advisability of using various substances in the treatment of chronic suppurative otitis media, and because of the difference of opinion as to the results obtained by the use

<sup>1</sup>Read before the Iowa State Medical Association, June 20 to 23, 1902.

of the various drugs, one ought not, in presenting this subject, to confine himself to those treatments and operations which he himself has found to be best. The medicamentarium of most of us is too limited to allow of the expression of a positive opinion as to the actions of all drugs. Rather, one ought to present the different treatments as given by the leading otologists of today. This seems very easy to do, but when one examines carefully the literature of various authors he finds it quite difficult to reconcile their opinions as to the results to be derived by the various treatments and operations.

At the 1902 meeting of the Western Ophthalmologic and Oto-Laryngologic Association there was held a symposium on this subject and those of us who had the pleasure of being present were convinced that the treatment of this disease was far from being a fixed one. Various authorities said they had secured from a certain treatment of this disease favorable results varying from 15% to 100%. A certain method was thought to be the very best by some and of no use by others.

Examination of the literature of today gives similar results. For instance, many authorities recommend diluted hydrogen dioxid as the best cleansing agent and disinfectant for the middle ear, while Dench<sup>1</sup> says it is no better than any other antiseptic solution for cleansing the ear, and is often deleterious; because it may cause trouble by pressure if the fluid enters the antrum of the mastoid. Randall<sup>2</sup> says, "Even the fundamental facts of aural surgery have not yet been grasped by otological practitioners, and as a result of their observations they entirely disagree."

An explanation of these differences of opinion may readily be found. Chronic suppurative otitis media includes a large number of different conditions. The middle ear is not composed simply of the tympanic cavity, but it includes the eustachian tube, tympanic cavity, and the antrum of the mastoid and the mastoid cells, and those cells may frequently pervade the whole temporal bone from the zygoma to the sella turcica and may invade the occipital bone behind and below.<sup>3</sup> We may have an involvement of only one of these different parts or even of only a part of one, as when we have suppuration limited to the lower part of the tympanic cavity, or two or more of the cavities may be involved. The part which is affected may have a number of pathologic conditions.

There may be simply an increased secretion on the part of normal sized glands. In other cases one might have this same condition and in addition a little pocket, formed by fibrous bands in the upper part of the middle ear, and in this pocket the secretions may have collected and become impacted so that there would be present a constant additional irritant to the mucous membrane of the ear, or the mucous membrane may be edematous and thickened with or without infiltration and the formation of fibrous tissue. Then we may have polyps, small or large, interfering with the escape of the secretion. There may be an ulcerated mucous membrane with or without a superficial or deep necrosis of the bone. One would be very foolish to suppose that a given medicine or treatment would be beneficial, or produce a cure in all these conditions. The treatment is influenced by the quality and quantity of the secretion, by the secondary changes in the external meatus, position, and size of the perforation of the drum, and the general health of the individual.<sup>4</sup>

The climatic condition of one's location, or the class of patients one has to deal with, or the prevalence of certain epidemics, might produce a series of cases which would possess some one of these characteristic conditions more than another, and as a result one might naturally conclude that the best treatment for chronic otorrhea would be the treatment which he found to be the most beneficial in his cases. Politzer gives us a nice explanation of why we might be in favor of one medicine in the

treatment of this disease when he says<sup>5</sup> that in many cases one drug will not produce any effect in chronic suppurative otitis media, while for some unexplained reason another will act very successfully.

As to the different antiseptics which are used in the middle ear, Dench very nicely sounds the keynote of the whole affair when he says<sup>6</sup> that in syringing the ear we may use either bichlorid of mercury solution, a saturate solution of boric acid, or a 2% solution of carbolic acid, or any other convenient solution.

There has been such a great difference of opinion among otologists as to the practical treatment of otorrhea that Allport<sup>7</sup> divides ear specialists into three classes: (1) The ultra conservatists, who still possess an abiding faith in syringing, inflation, drugs, etc.; (2) the conservatists, who try the above treatment for several months, and failing in this, resort to more radical measures; (3) the radicals, who as soon as chronicity is established proceed to open the mastoid and tympanum.

Those of the first class are gradually going over to the second class, in which we find men like the late Dr. Gruber, Politzer and Urbantisch. Among the radicals we find some of the very best men of today, as Stache, Schwartz, Holmes, Yansen and Dench.

The treatment of chronic suppurative otitis media should be divided into two classes, medicinal and operative.

Medicinal treatment has for its function the cleansing and disinfection of the middle ear, the removal of excessive secretions by astringent action, and the removal of hypertrophies by caustic action. It would be impossible to name all of the drugs that have been used for these purposes.

Politzer<sup>8</sup> says that most important in the treatment of chronic otorrhea is a thorough cleansing of the secretion, for if it remains in the middle ear it will result in the ulceration of the mucous membrane and bone. In cleansing the middle ear one must use other means beside medication and syringing through the external meatus. Secretion can be removed by politzerization, the use of Siegel's speculum, by catheterization, and by syringing through the eustachian tube.

MacCuen Smith<sup>9</sup> says that in irrigating the tympanic cavity the solution should be made to pass through the eustachian tube into the nasal pharynx by directing the patient to open and close the mouth several times and to make repeated efforts to swallow.

Aitken<sup>10</sup> mentions a very good method of applying drugs to and cleansing the middle ear. He takes a probe having at its end two spiral teeth, and wraps cotton around the end so as to form a swab which will fill the external meatus. This he uses as a piston forcing the fluids into and then out of the accessory cavities. One is often surprised to see how large an amount of debris can be removed by such a simple measure after all that can be has been removed by syringing.

Hovell<sup>11</sup> recommends the use of the tympanic syringe to syringe out the middle ear through the perforations in the drum.

For cleansing the middle ear we may use sterilized warm water, containing 1% of sodium chlorid, which will help dissolve the pus.<sup>12</sup> If there is any disagreeable odor we may add carbolic acid, 1%. After syringing the ear once or twice, some cotton on the end of a probe should be used to remove all debris possible, until a nice, clean, bright red surface is obtained.

The use of digestive ferments for removing dried and impacted pus has gained some prominence. Papain, which will dissolve dead tissue and false membranes, and which will not attack living tissue, has been used for this purpose. Johnson, of Edinburgh<sup>13</sup> reported that papain possessed remarkable efficiency for the removal of debris from the middle ear. Hovell<sup>14</sup> says that a solution of pepsin and papain not only removes the debris, but will also dissolve cicatricial tissue, filaments and

bands. Munger<sup>15</sup> reports good results from the use of enzymes for dissolving the foreign material. Chambers<sup>16</sup> also reports good results in otorrhea from the use of other proteolytic enzymes, in connection with the cleansing of the tympanic cavity. In cleansing the middle ear a large opening should be made in the drum if the perforation is small.

The disinfectants, both liquids and powders, which have been used in this disease, are almost numberless.

Among the liquids we have<sup>17</sup> carbolic acid 1%, corrosive sublimate 1/200%, resorcin 4%, salicylic acid .5%, formalin<sup>18</sup> .5%, iodoform emulsion, hydrogen peroxid and camphoroxol. Of powders, Politzer<sup>19</sup> recommends first boric acid; second, iodoform; third, iodol. Bishop<sup>20</sup> recommends aristol as one of the best powders to be used in the middle ear.

Carbolic acid, 1% solution is especially indicated when we wish to combine a disinfectant with a deodorizer<sup>21</sup>. If the odor is very disagreeable one may use 1/200% solution of mercuric chlorid. In such cases, however, one should be very careful that the solution does not run down the throat.

Boric acid, while not a strong disinfectant, has been shown to possess a very efficient therapeutic action in chronic otorrhea. Hovell<sup>22</sup> says practical experience has proved that the best results are obtained by the use of boric acid solution and boric acid powder. Formalin, in addition to its disinfectant and deodorant action, is said to possess the special property of preventing the growth of granulations and to aid in the healing of ulcerated surfaces.<sup>23</sup>

Iodoform emulsion is one of the very best substances for use in this disease, especially when there is a tuberculous history. It is one of the disinfectants which can be kept in contact with the surfaces of the tympanic cavity for a long time. In using iodoform emulsion it is my practice to cleanse the ear with one of the disinfecting solutions, dry thoroughly, and then with the patient's head turned upon one side, pour into the external meatus the iodoform emulsion until it is nearly filled. Then I take a cotton swab which just about fills the external meatus and, by applying pressure, force the emulsion down into the tympanic cavity and sometimes through the eustachian tube into the throat. Owing to the viscosity of the emulsion, by blocking up the external meatus with a little cotton, the medicament may be held in contact with the walls of the tympanic cavity for 24 hours. Patients do not complain of the odor of the emulsion when used in this way, and it has given me very nice results, especially in those cases in which there was more or less necrosis in the middle ear and the patient objected to the radical operation.

With the exception of Dench, hydrogen dioxid has received almost universal recommendation by the authorities. It is a good disinfectant because of the readiness with which it penetrates into the crevices and corners of the middle ear, dissolving out the mucus and pus. It is used in a strength from 6% to 10%. It is very efficient when there is a simple hypertrophy of the mucous membrane, no stricture of the eustachian tube, and no necrotic bone. When there is much pus impacted in the middle ear I frequently use the ordinary hydrogen dioxid undiluted, applying it directly to the mucous membrane by means of a swab.

Since 1899, when Stetter<sup>24</sup> reported for the first time the use of camphoroxol in chronic suppuration of the middle ear, it has been much used. Beck,<sup>25</sup> of Berlin, states it should be a 33½% solution of alcohol, containing 1% of camphor and 3% hydrogen dioxid. He further says that it has just twice the disinfecting action of hydrogen dioxid, a 5% solution in water having a well marked disinfecting action. Stetter says that both camphoroxol and menthoxol are superior deodorizing disinfectants. Pond<sup>26</sup> recommends the use of camphoroxol in otorrhea. North<sup>27</sup> says that he has secured very good results from the use of the same drug. Dr. Hotz<sup>28</sup>

reports success from its use in otorrhea. He uses it undiluted on a swab and applies it directly to the parts of the tympanic cavity. He then gives the patient equal parts of camphoroxol and water to drop into the ear every morning and evening. In addition to this treatment, when possible he uses the intratympanic catheter to irrigate the tympanic cavity with boric acid solution through the eustachian tube. He reports cases in which he was sure the mastoid operation would have to be performed in which cure ensued upon injecting equal parts of camphoroxol and water into the tympanic cavity. He reports this treatment as resulting in a permanent cure in cases in which the classic symptoms of mastoiditis were present. He states camphoroxol had no effect upon granulations, and reports three cases in which operations were positively indicated and which a cure was brought about by the use of camphoroxol.

Phelan<sup>29</sup> says it is nonirritating and stable, and that while some patients have no pain with an undiluted solution, others suffer great pain from a 10% solution. He believes that many cases seeming to demand operation may be cured by its use.

It has the advantage that it combines with the disinfecting, cleansing and deodorizing action of hydrogen dioxid the astringent action of alcohol. Hydrogen dioxid exerts a disinfecting action, which lasts only from three to ten minutes, but as the parts come in contact with the camphor a disinfecting action is exerted which continues for some time afterward. The camphor also acts as a sedative. It has proved so satisfactory in my practice that it has replaced almost entirely hydrogen dioxid.

Of the astringents which are used in chronic otorrhea we have, among others, a weak solution of silver nitrate, varying from .25% to 2% solution; zinc sulfate, 2%; copper sulfate, .5%.<sup>30</sup> Hovell<sup>31</sup> says the use of astringents is far less efficacious than boric acid solution. Politzer<sup>32</sup> recommends the use of alcohol as an astringent, especially if there is a hypertrophied condition of the mucous membrane, or if small polyps are present. He says one ought to begin with a diluted solution and work up to the concentrated. Knapp<sup>33</sup> recommends the use of zinc sulfo-carbolate, 1 or 2 parts to 50 parts alcohol and 50 parts water. When a large perforation exists and also in cases of otorrhea with only a scanty discharge, Urbantschitsch<sup>34</sup> recommends the employment of gelatin bougies containing such astringents as acetate of lead, tannin, copper sulfate and zinc sulfate. He also uses thin plates which can be cut into small strips and passed through the perforation into the tympanic cavity.

As a caustic, solutions of silver nitrate and chromic acid are used. Silver nitrate may be used in solutions varying from 5% to 25%, dropped into the ear or applied by means of a swab. Before using either silver nitrate solution or chromic acid a few drops of 5% solution of cocain should be dropped into the external meatus. After the use of silver nitrate, sodium chlorid ought to be dropped into the tympanic cavity. The use of silver nitrate is commonly indicated with perforations and granulations in the middle ear and in the superficial necrosis of the temporal bone. If one can see the polyps it is better to cauterize them with caustic acids and the actual cautery. In using either of these two things one must be careful and not cauterize too much, or there may be a reaction, resulting in an inflammation that may even threaten the patient's life.

In applying powders to the tympanic cavity and the meatus the tympanum is cleansed very carefully by syringing and inflating by Politzer's method and then carefully dried. The powder is blown into the ear by means of an insufflator. The powder should only be used by the physician and only when he is seeing the patient every day.

Dench<sup>35</sup> says under no condition should a patient be supplied with powder to blow into the ear. Even when

the perforation is very large it is possible for the preparation to dry in a firm crust after absorbing the discharge, and this crust, becoming closely attached, constitutes a barrier to the free exit of the secretion. Even when applied by a physician the patient should be directed to syringe the ear immediately when there is pain or giddiness. This trouble may be avoided by just barely covering the membrane with the powder.

In using any one, two or three of the remedies mentioned we must always remember when the patient does not do well to change to some other drug, because in many cases when one medicine will not produce the desired result another will be very efficient. In carrying out any treatment it is advisable to make frequent examinations of the discharge with the microscope to see if there is any diminution in the number of microbes.<sup>36</sup> Dench<sup>37</sup> recommends when other things have failed, the application of a little piece of paper to the drum-head, as recommended by Blake. The paper moistened in mercuric chlorid 1 to 1,000 is pressed down on the membrane so as to occlude the opening. The stimulation which this foreign body produces is frequently sufficient to affect a complete closure of the opening in the drum-head, while its protective action produces retrograde changes in the congested lining of the middle ear.

The so-called dry treatment, the use of a piece of gauze for drainage in the external meatus, materially aids in the treatment by removing from the middle ear deleterious secretions as soon as formed, and by itself is frequently sufficient to cure the disease.

Politzer<sup>38</sup> recommends the dry treatment if there is a constant discharge from the middle ear, but holds that it is contraindicated in cholesteatoma, granulations, caries in the temporal bone and when the mucous membrane is sensitive. McBride<sup>39</sup> says that it can be rarely attempted with any probability of success, but occasionally it succeeds when other remedies fail. Bishop<sup>40</sup> warns us against it if the middle ear is at all sensitive. MacCuen Smith<sup>41</sup> advises its use when cases do not progress favorably, but holds that it is contraindicated when the perforations are small.

Ballanger<sup>42</sup> divides suppuration of the middle ear into four classes: (1) Suppuration of the middle ear proper; (2) suppuration in the attic; (3) suppuration involving the attic and antrum; (4) suppuration involving the tympanum, attic, antrum, antrum and mastoid cells.

He advises dry treatment in the first class of cases only.

The dry treatment in my hands has not been very efficacious when used alone, but has been very successful when used in connection with medical treatment in those cases in which there was an abundant discharge from the middle ear.

Of the greatest importance is the constitutional treatment. Hovell<sup>43</sup> says anemia, scrofula and syphilitic conditions should be treated by internal medication. Politzer<sup>44</sup> says the internal administration of tonics and alteratives and the placing of weak children out of doors will aid greatly in securing beneficial results by increased nourishment of the parts in the middle ear. Thiosinamin has recently come into extensive use in connection with all diseases of the middle ear. While this drug has been used mostly for otitis media catarrhalis sicca, it has also been used extensively in chronic otorrhea when fibrous tissue has been formed. There is a great difference of opinion as to the value of the drug in this connection. Professor Hebra<sup>45</sup> recommended its use in opacities of the cornea. Liebreich<sup>46</sup> is not impressed with the remedy because of the uncertainty of its therapeutic action. Shoemaker<sup>47</sup> says injections of thiosinamin have a decided effect upon corneal opacities. Upson<sup>48</sup> states that its value is due to the fact that it increases the number of leukocytes and causes the absorption of morbid tissue and scars. He claims that it is useful in removing fibrous tissue in any part of the

body. Beck<sup>49</sup> reports that it will improve tinnitus, and he also recommends<sup>50</sup> its use in all cases in which absorption of fibrous tissue is advisable. He reports two cases of chronic suppurative otitis media in which secretion was almost controlled and in which there was considerable tinnitus, resulting from fibrous bands formed during the active process. He secured a fair improvement from the use of thiosinamin. Dr. Suker<sup>51</sup> says it is especially good when there is a small perforation. The drug is probably best given as recommended by Beck,<sup>52</sup> in 1 grain doses three times a day, gradually increasing to a dose of 3 grains three times a day. Suker<sup>53</sup> recommends 3 grain doses three times a day at the start. In using the drug one must always remember its contraindications. It should never be used without consultation with the family physician if there are any abdominal organs which are being held in position by scar tissue as the result of an operation, or if there are any tuberculous nodules in the lungs, the microbes being hemmed in by fibrous tissue, the most serious results might be produced by its administration.

Alderton<sup>54</sup> recommends for chronic otorrhea atropin in small repeated doses, and pilocarpin in doses of 1/12 grain twice a day. They are never to be given together.

If patients are healed by any of the above treatments, cotton should be kept in the ear during cold and damp weather, the feet should be kept warm and dry, and they should not expose themselves any more than possible to prevent a return of the trouble.<sup>55</sup>

In addition to the systemic treatment all causative agents must be removed, such as adenoids, spurs, deviations of the septum and the various forms of nasal pharyngitis and strictures of the eustachian tube.<sup>56</sup>

As operative procedures we have, first, the removal of polyps; second, ossiculectomy; third, curetting; fourth, the radical operation.

Polyps may be removed either with the snare or ring knife. Before removing a polyp with a snare, a 10% solution of cocain should be dropped into the middle ear. With a little care the polyp with its pedicle may be removed entire. Care should be taken with very large polyps not to tear away a plate of bone which may form the wall of the cochlea or semicircular canal, or the roof of the tympanic cavity. The smaller polyps may be removed more readily by means of the ring knife. After the removal of the polyp its base should be cauterized with silver nitrate or chromic acid. With me this operation has been a very unsatisfactory procedure, even when the bases of the polyp have been cauterized. I have had frequent recurrences. It is now my custom always to investigate with a probe so soon as the polyp has been removed, and if an extensive periostitis or necrosis of the bone is found to recommend the radical operation.

Indications for ossiculectomy and the results secured vary much with different authorities.

Politzer<sup>57</sup> gives the following indications for ossiculectomy: (1) When caries of the temporal bone is present; (2) when there is an interference with the free discharge of pus; (3) when cholesteatoma is present; (4) perforations in the membrana Schrapnelli; (5) when there are granulations in the upper part of the tympanic cavity. Buck<sup>58</sup> says if impacted pus and other substances cannot be removed from the tympanic cavity by other means, perform ossiculectomy. Dench<sup>59</sup> recommends it when necrosis of any of the parts of the middle ear can be discovered. Ballanger<sup>60</sup> says it should be performed when the suppuration is confined to the attic and the antrum as it converts the attic and the middle ear into one cavity. Pierce<sup>61</sup> says that he has had 100% good results from the operation. Holmes<sup>62</sup> has had 98% good results. Randall<sup>63</sup> has never secured a good result from ossiculectomy. However, he does not believe in the operation, and only carries it out as a last resort. He maintains that if the discharge cannot be stopped by removing the debris and getting good drainage from the

middle ear, that it cannot be done by ossiculectomy, and the results of his operations seem to indicate that such is the case. In one of his articles, however,<sup>64</sup> he says: "Those upper portions of the tympanic cavity which are with difficulty seen or reached from the external ear have great pathologic importance, for when drainage fails here, there is no soft membrane to give in a safe direction an easy exit to the pent up secretion. In this condition the removal of the drum-head and ossicles is advised when they seem to be obstructive in this suppurative condition." Ludwig<sup>65</sup> reports 42 cures in 75 cases operated upon by ossiculectomy and curetment. Grunert<sup>66</sup> cites 13 cures in 28 operations. Dench<sup>67</sup> reports 47 cures in 81 cases. In 19 cases operated upon, I have had 14 good results. Ossiculectomy should certainly be performed whenever we find one of the small bones has a necrotic area.

Quite frequently the long process of the hammer is necrotic. If this is the only necrosed bone in the middle ear, its removal may stop the process. If the necrosis is limited to one bone, as it is quite frequently in the case of the long process of the hammer, and if the tympanic cavity does not contain hypertrophied mucous membrane or granulations, curetment is not advisable. If these things are present, however, curetment followed by the use of silver nitrate is a very good procedure.

The most satisfactory treatment for chronic suppurative otitis media is the radical operation. The danger of the operation is very small. In the hands of the skilled surgeon it should be hardly more than double the scarce-measurable dangers of etherization, and unless extensive lesion is found there should be practically no scarring.<sup>68</sup> A thorough knowledge of the anatomy of the region is absolutely essential for the performance of this operation. Dr. Randall told me that he had never had a case of facial paralysis from the radical operation. Healing results in from one to four weeks, and mortality from the mastoid operation varies largely from extraneous causes, few, if any, deaths being ascribable to the intervention. Before performing the radical operation one ought to examine the fundi to see that there is no choked disc indicating involvement of the brain or its meninges and the other symptoms of trouble at the base of the brain should be looked after.

Leutert<sup>69</sup> recommends the lumbar puncture in order to tell whether the chronic suppuration has extended into the cranial cavity or not. The puncture should be made between the fourth and fifth cervical vertebrae. Pierce<sup>70</sup> recommends treatment two months and then if the discharge continues performing the radical operation. Politzer<sup>71</sup> recommends the radical operation if extensive caries of the temporal bone is present. In all cases when one can find an extensive necrotic area in the wall of the middle ear, and in all cases in which the discharge will not be stopped by ordinary treatment the radical operation should be resorted to. When mastoiditis is present it is indicated. One is even justified in performing this operation when extensive necrosis is suspected. Certainly if the general surgeon is justified in exploring the peritoneal cavity, the otologist is justified in exploring the mastoid cells. The mastoid operation is the only means by which we can secure thorough drainage from the antrum of the mastoid.

Randall<sup>72</sup> says that the tympanic antrum is involved in almost every suppuration, and before the suppuration can be stopped it must be drained. It is the only procedure by which we can remove a large amount of dead bone from the middle ear.

Certainly there have been more deaths as the result of not operating than from the result of unnecessary operations.

I can safely say that it is a procedure which has given me by far the best results with the least loss of time to those suffering from a bad form of chronic suppurative otitis media. I do not believe it wise to treat the majority of our patients for two months before

operating. I believe that if there are large polyps or caries of the temporal bone, or if there is long-standing suppuration in the attic accompanied by cholesteatoma, that we ought immediately to relieve the patient from danger of serious consequences by doing the radical operation. I have never performed a radical operation which was not perfectly satisfactory to the patient. The importance of urging the radical operation when there is a persistent discharge cannot be overestimated. The nearness of the middle ear to the brain and the lateral sinus make it imperative that this suppurative process be removed.

I could enumerate a large number of cases in which valuable lives have been lost simply because the suppurative process was allowed to exist in this most dangerous locality.

Germs may pass through the oval or round window into the internal ear and then directly into the cranial cavity through the ductus endolymphaticus, or they may be carried either by the blood or lymph into the brain and produce an abscess or meningitis.

To recapitulate: When a patient presents himself with this trouble in the middle ear it is best to make as good a visual examination as possible. One ought to try investigation with a probe. If the ear is sensitive a little chloroform should be administered, in order that a complete examination may be made. If on making this examination one finds that there is a necrotic area in the middle ear, shown by a roughness of the bone, an ability to pass the probe into the antrum of the mastoid, or by the irritation of the facial nerve, an immediate radical operation should be advised.

If one finds a roughness of the long process of the hammer, its extraction is recommended. If there is a roughness of any of the other small bones of the middle ear with a hypertrophied condition of the mucous membrane, or if cholesteatomatous masses can be discovered, ossiculectomy, followed by the use of silver nitrate, is recommended. The presence of polyps indicates their removal, the cauterizing of their bases, and the use of astringents. The absence of polypoid growths or necrosis would indicate a cleansing of the middle ear, disinfection and the use of mild astringents.

If in any of these cases the discharge does not disappear, the radical operation ought to be strongly insisted upon.

In many cases, when there is simply a collection of dead cells and pus in the middle ear acting as an irritant, the simple cleansing of the ear will be sufficient to cause the trouble to disappear. In other cases, when we have a hypertrophied condition of the mucous membrane, one or two weeks' treatment may be sufficient to stop the discharge. In the majority of cases, however, the discharge will not disappear, or if it does, it will return whenever the patient is exposed to the cold.

THE LORENZ OPERATION, WITH REPORT OF A CASE.

BY  
 JAMES K. YOUNG, M.D.,  
 of Philadelphia.

Professor of Orthopedic Surgery in the Philadelphia Polyclinic, etc.

The following successful operation for congenital dislocation of the hip illustrates the technic employed by Professor Lorenz in his so-called "bloodless" operation:

T. B., aged 5 years, male, suffering from double congenital dislocation of the hips, was referred to me by Dr. Frank V. Cantwell, of Trenton, N. J.

There was nothing in the prenatal history to account for the deformity, but the mother states that the labor was accelerated by the attending midwife, and to this haste attributes the deformity.

On examination the dislocations were found to be upward and backward, the top of the trochanter being on the right side, two inches above Nelaton's line, and in the left 1½ inches above.

The trochanters were prominent; the lordosis was excessive, showing an obtuse angle at the junction of the sacrum with the lumbar vertebra.

Traction of the limbs reduced the deformity slightly, but the heads of the femurs could not be placed in their normal positions. The child walked with a sideward rolling movement, a form of locomotion expressed by the term "waddle."<sup>1</sup>

**The Preliminary Treatment.**—For 10 days before the operation the patient was placed in the recumbent position and traction weights of 6 pounds were attached to each leg. This stretched the powerful muscles about the hip-joint and rendered the reduction less difficult.

**The Operation.**—The operation consisted of five distinct parts, which must be employed in the order given:

1. Hyperabduction and tearing of the adductors. The pelvis was fixed by an assistant, the limb was forcibly abducted and the adductor muscles were separated from their attachments to the pelvis by manual pressure.

2. Hyperflexion.—The patient in the prone position, the lower extremity was slowly and forcibly flexed until the foot touched the ear, in a similar manner to the method employed in stretching the sciatic nerve.

3. Hyperextension.—The patient lying upon the opposite side the lower extremity was forcibly extended, the knee being bent.

<sup>1</sup>The child was admitted to St. Francis' Hospital, Trenton, N. J., and with the assistance of Dr. Frank V. Cantwell, the attending surgeon, Dr. Howard Reed of Philadelphia, and the resident staff, the reduction was successfully accomplished by the writer in the presence of a large number of local physicians.

4. Traction.—The patient lying in the prone position, forcible traction was made upon the extremity by means of a skein of yarn fastened about the ankle, the pelvis being fixed by the hand of an assistant.

5. Reduction.—The reduction of the head of the femur into the acetabulum was accomplished by placing a triangular wooden block beneath the trochanter, the patient lying in the prone position, and strongly abducting the thigh. After the head of the femur was reduced, the anterior part of the capsule was enlarged by hyperabduction of the thigh together with rotation.<sup>1</sup>

**The Dressing.**—The limbs were held in a hyperabducted position with the knees flexed by means of a heavy plaster-of-paris dressing. They were first encased in stockinet drawers, cotton batting and muslin rollers, the perineum being entirely covered in by figure-of-eight turns. A movable strip of muslin was inserted within the stockinet drawers with a free end extending above and below for the purpose of massage and cleanliness. From 12 to 15 plaster-of-paris bandages were applied, completely covering the muslin rollers. A large fenestrum was removed from the perineal region, and the dressing trimmed over the popliteal spaces.

The dressing will remain on for six months. The reduction of the dislocation in the right limb was much more difficult than in the left, and more forcible traction had to be employed.<sup>2</sup>

**After-treatment.**—After the removal of this cast the after-treatment will extend over a period of 18 months. Passive and active movements of the hips will be used, the limbs being gradually brought forward into the frontal plane.

The patient will be supported upon a stool, and an apparatus to make compression of the hips will be applied. The patient walks with the limbs in an abducted position throughout almost the entire period.

A CONTRIBUTION TO PERNICIOUS ANEMIA.

BY

O. E. LADEMANN, M.D.,  
 of St. Louis, Mo.

Clinical Assistant, Medical Department of the Washington University, St. Louis, Mo.

As early as 1821 Andral described pernicious anemia. He was followed by such writers as Coombe (1823), Marshall Hall (1837), Piorry (1840), and others, but Addison (1843) unquestionably deserves the credit for having first accurately described the disease. He called it "idiopathic anemia." To Biemer (1868) we owe a revival of interest in the subject.

Biemer,<sup>1</sup> in his article on anemias, classified as "essential anemia" all those conditions which lead to a progressive destruction of red blood-cells (poikilocytosis, etc.) associated with a disturbance on the part of the nervous system uninfluenced by medicaments and finally terminating fatally without discovering any accountable pathologic lesion in the various organs.

It was demonstrated later that such intestinal parasites as *Bothriocephalus latus* (Botkin, Dehio, Hoffmann, Müller, Natason, Askanazy, Reyher, Runeberg, Jawein, Schapiro, Lichtenheim, and others) and the *Ankylostoma duodenale* (Hirsch, Daniels, Bäumlner, Wucherer, Griesinger, Bilharz, Bowen, Lichtenstern, and others) often produce the clinical as well as the hematologic picture of a primary pernicious anemia, and after the expulsion of the parasite the individual made a speedy recovery.

Becker<sup>2</sup> reports a case in which two *Tenia mediocanellata* produced the same picture as idiopathic pernicious anemia. Fenwick,<sup>3</sup> in 1877, called the attention of the medical profession by publishing four cases of so-called idiopathic pernicious anemia associated with gastrointestinal symptoms, which ended fatally. In each case he was able to demonstrate microscopically an atrophy of the glands and mucous membrane of the stomach. Subsequently analogous or similar changes found in the stomach were reported by Haberschon, Ponfick, Schumann, Nothnagel, Nolan, Brabazon, and others. Fenwick, from his findings, gave as the etio-

<sup>1</sup>As a test that the reduction had been accomplished, the knee-joints could not be extended beyond a right angle.

<sup>2</sup>The anatomic conditions present, the thorough reduction and the age of the child, promise a favorable functional and anatomic result in this case.

logic factor of pernicious anemia an atrophy of the parenchymous structure of the stomach followed by a subsequent inanition. In a later publication he modified his theory.

Later the toxin theory was established, this being based upon the fact that owing to the absence of the gastric juices, ptomains were formed in the alimentary tract which became absorbed, causing a hemolysis (McPhedran,<sup>4</sup> Osler and Henry,<sup>5</sup> Hunter,<sup>6</sup> Fenwick,<sup>7</sup> Kinikut<sup>8</sup>).

Rosenheim<sup>9</sup> (1888) published two fatal cases of severe anemia associated with marked gastrointestinal disturbance, in which the necropsy showed as the only accountable pathologic lesion an atrophied condition of the glands and mucous membrane of the stomach.

Eisenlohr<sup>10</sup> published a case of severe fatal anemia with secondary anemic degeneration of the spinal cord, in which the patient had never manifested any gastrointestinal symptoms, though free HCl and pepsin were absent. The necropsy revealed an atrophy of the glandular structure, the submucosa and mucosa muscularis of the stomach.

Wiltschur<sup>11</sup> (1883) published a similar case with a fatal ending, though in his case there was no secondary changes in the cord as noted by the foregoing authors. In this case, however, the gastrointestinal symptoms were very pronounced, manifested in frequent vomiting and diarrhea.

Grawitz,<sup>12</sup> in his discussion on the etiology of primary pernicious anemia, gives as the causation an atrophy of the glands and mucous membrane of the stomach and intestines, giving rise to an insufficient assimilation and the formation and absorption of ptomains in the small intestines followed by hemolysis. In the same discussion Hausmann found in 22 cases of idiopathic anemia no other accountable lesion than the gastrointestinal changes already enumerated, and therefore looks upon "anadenia" (Ewald) as being the etiologic factor.

Jacob,<sup>13</sup> on the other hand, expresses a different opinion from those of the authors thus far quoted, giving as the cause of pernicious anemia some unknown virus, and regarding the alimentary changes as secondary. Ewald, however, regards the changes in the digestive tract as primary. Strümpell<sup>14</sup> sees no connection between pernicious anemia and the changes in the gastrointestinal tract.

Cabot,<sup>15</sup> in a series of eight autopsies in pernicious anemia, did not find atrophy of the gastric tubules in any case.

Hunter,<sup>16</sup> in looking through the literature on the subject, collected 273 cases (83%) of pernicious anemia in which gastrointestinal symptoms had been manifested, and regarded the destruction of the corpuscular elements as being directly due to the absorption of a bacterial poison produced by the swallowed bacteria, as in caries of the teeth, etc.

According to Senator,<sup>17</sup> the atrophic changes found in the stomach are not sufficient to produce such severe anemia. He calls attention to the fact that after the complete extirpation of the stomach, changes do not occur as in pernicious anemia. In regard to changes in the intestines, he says "many cases come to the autopsy table with a chronic enteritis, showing an atrophied condition of the glands without ever having shown any signs of anemia during life."

Strauss,<sup>18</sup> from a series of experiments on absorption and metabolism, concludes that the changes in the stomach are secondary. Faber and Bloch<sup>19</sup> state positively that the gastric changes are not the cause of pernicious anemia. Dana<sup>20</sup> believes that pernicious anemia, while a disease of hemolysis, is primarily one of hematogenesis. He gives little consideration to the ptomain theory. Schumann<sup>21</sup> discusses it as a toxemia. Bain<sup>22</sup> regards primary pernicious anemia as a primary blood destruction taking place in the portal area as the result of some toxic agent, but speaks little of the changes found in the alimentary tract.

Adami<sup>23</sup> considers pernicious anemia to be the result of a subinfection, as he terms it, through the gastrointestinal tract. Ransom<sup>24</sup> concludes that the hemolysis is due to the absorption of a hemolytic poison from the intestinal canal.

During my service as interne in Professor Nothnagel's clinic I had the opportunity of seeing two cases of pernicious anemia brought to the autopsy table, and in each case there was atrophy of the glands, mucosa, and submucosa of the stomach and small intestines. During life each patient presented marked gastrointestinal symptoms, such as vomiting, etc. A test-breakfast (Boas-Ewald) in each case showed free HCl and pepsin ferment absent. Lactic acid was not present.

From the superficial amount of literature given, it will be readily seen that the pathologic changes found in pernicious anemia are by no means agreed upon, though the consensus of opinion is toward an "achylia gastrica" (Einhorn) as the existing lesion. It is still more unsettled as to whether the hemolysis is due to the absorption of some toxic material in the alimentary tract, or whether it is a primary hematogenesis.

To me the formation and absorption of some toxic agent in the alimentary tract seems most plausible, and upon this assumption I base my therapy, which consists of daily irrigations of the intestinal tract. The improvement will be seen from the following case:

Mrs. K., aged 32, an American, has no children. Her family history is good. She was operated upon three years ago for a narrow cervical canal, otherwise she never had any ailment until the present trouble.

In July, 1900, she became quite nervous and easily excited. This she attributed to a neighbor, who caused her considerable worry. During the month of August she had an attack of diarrhea associated with colicky pains in the abdomen, of such a persistent nature and causing such exhaustion that medical assistance was sought. After being under treatment for some days the diarrhea ceased and the pains in the abdomen disappeared. The patient now had good health for some time, save that she was nervous and excitable at times. Later she was troubled frequently with attacks of diarrhea associated with pains in abdomen, lasting for a period of three to four days, but not until the following year (1901) did the patient notice any marked changes in herself. From this time on she noticed a gradual weakness, that she became easily fatigued upon the slightest exertion, and had frequent attacks of palpitation, vertigo, shortness of breath, etc. The pallor, weakness, and anemic symptoms, such as headache, palpitation, etc., gradually increased, the patient still being troubled with her bowels periodically. Gastric symptoms, as vomiting, etc., were not manifested. In November, 1901, the patient's condition necessitated her confinement to bed, and medical attendance was required. In spite of the fact that arsenic and the different iron preparations were given, the patient still continued to grow gradually weaker and weaker. In March, 1902, she was sent to the hospital and came under my care.

Examination showed a middle-aged, comparatively well-nourished woman. She complains of extreme exhaustion, anemic symptoms (sleeplessness, palpitation, etc.), distressing cough, loss of appetite, diarrhea and cramping pains in the abdomen. Her pallor is extreme and of a waxy character. The conjunctivas, lips, and the mucous membrane of the mouth are almost bloodless. The scleras present a slightly subicteric appearance. There is a moderate general edema. Panniculus adiposus is moderately well developed. Muscles of the extremities are somewhat flabby. Over the entire body dark brown pigmented spots are seen, most marked on the back of the hands and forearms. They are irregular in shape and vary in size from a pin's head to a pea, some are slightly larger (probably an arsenic melanosis). The osseous system presents nothing striking. The long bones are straight, with no thickening of the epiphyses. Pressure on the long bones gives rise to pain.

Examination of the arterial system shows the radial artery soft, somewhat narrow, and its course straight. Pulse wave is small, and the volume poor. The pulse itself is equal and rhythmic, with rate of 110, and tension R. 95 (tonometer). Respirations are costoabdominal, rather rapid and superficial, with a rate of 26. Temperature is 101°.

The head is mesocephalic, symmetric, and presents no peculiarities. The eyes have medium pupils and react promptly to light and accommodation. Sympathetic reaction is also prompt. Movements of the eyeballs are unimpaired.

Ophthalmic examination without mydriasis reveals the fundi and optic discs very pale, arteries threadlike, veins tortuous and pale. Retina about papillas for a distance of two papilla diameters is hazy. Retinal hemorrhages cannot be found.

The conjunctiva of the eyeball and eyelids is exceedingly pale. Arterial pulsation is easily produced by pressure on the eyeball.

The tongue with the exception of a superficial glossitis shows nothing characteristic. The mucous membrane of the mouth, excepting an extreme pallor, shows nothing striking. Pharynx is extremely pale.

The carotids pulsate slightly. The external jugular shows a negative centrifugal venous pulse. Over the veins of the neck a continuous bruit is heard (Nonnensausen). The thyroid and the cervical glands of the neck are not enlarged.

The thorax is well formed, proportionate and symmetrical. Pressure on the sternum causes pain (Mosler's symptom). Inspection shows the apex beat in the fifth intercostal space within the left mammary line. Palpation of the lungs is negative. Percussion over the lungs gives a loud, deep resonant note. The border of the lungs is posteriorly four fingers' breadth below the angle of the scapula anteriorly, right lung (mamillary line) fifth intercostal space, left lung (parasternal line) third intercostal space. The margins were freely movable. On auscultation, sharpened inspiratory and prolonged expiratory murmurs were heard. Both dry and moist rales were audible over both lungs excepting in the apices, where nothing abnormal was detected.

The apex beat of the heart is not sharply circumscribed in the fifth intercostal space within the left mammary line. Palpation gives a feeble impulse. On percussion there is an apparent dilation to the right. The dullness extends to the middle of the sternum, due to a retraction of the lungs. The dullness to the left corresponds to the apex beat. In the upper boundary there is a relative dullness at the third rib, and an absolute dullness in the third intercostal space. Over the entire cardiac area and for some distance beyond, on auscultation, a loud blowing systolic murmur is heard (hemic) being loudest over the base. Besides this murmur, over the base of the heart, a continuous murmur is heard, transmitted downward from the veins of the neck. The second pulmonic sound is rather loud but not accentuated, being due to a retraction of the lungs.

Traube's space is tympanitic in all portions. The abdomen is quite prominent and distended with gas. Palpation is negative. Percussion gives a high tympanitic note. The spleen is enlarged two fingers' breadth below the free border of the ribs. The liver also extends two fingers' breadth below the free border of the ribs.

Examination of the nervous system shows the cranial nerves intact. The reflexes (biceps, triceps, forearm, patellar, ankle, etc.) are normal. No disturbance in coordination. Sensations, heat and cold, tactile and of pain are normal. Patient complains at times of tingling and numbness in finger tips and toes.

The bladder and rectum show no disturbance excepting diarrhoea, which is independent of a central affection.

An examination of secretions and excretions was carried out as follows: Ewald-Boas' test-meal showed the motility of the stomach to be good. Free HCl was absent, and the expressed contents did not have any effect on litmus paper. Lactic acid was not present. Examination of the stools showed the presence of considerable mucus, many crystals of fatty acid, a few plant cells and muscle fibers. A repeated search for parasite eggs was made but they were never found. The urine obtained by means of catheter was of a light yellow color, varying in amount from 1,200-1,500 cc. A slight trace of nuclealbumin and serum-albumin was present. Sugar, acetone, diacetic acid, peptone, etc., were absent. Indican was considerably increased. Sediment showed a few form elements.

A blood examination made March 10, 1902, was as follows: Reds, 732,000 (Thoma-Zeiss); whites, 2,320 (Thoma-Zeiss-Türk modification); hemoglobin, 20% (Fleischl-Miescher modification with control); color index, 1.5. The stained specimen showed a high degree of poikilocytosis with many macrocytes and microcytes. Megaloblasts, normoblasts, and poikiloblasts were seen throughout the field. The hemoglobin of each individual blood-cell was increased. A percentage estimation of the different leukocytes was not made, as it is of little diagnostic value in pernicious anemia.

A complete discussion of the case would require too much space, therefore the essential changes only will be given:

March 15.—Edema is gradually disappearing, cough is greatly improved, and the urine contains no albumin.

March 21.—Blood examination shows: Reds, 1,592,000 (Thoma-Zeiss); hemoglobin 30% (Fleischl-Miescher); color index, .9.

March 30.—Reds, 2,236,000 (Thoma-Zeiss); whites, first count, 2,120; whites, second count, 1,980 (Thoma-Zeiss-Türk modification); hemoglobin, 50% (Fleischl-Miescher with control); color index, 1.1.

Stained specimen still showed a moderate poikilocytosis. Nucleated red cells were not present.

April 5.—Reds, 2,790,000 (Thoma-Zeiss); whites, 2,500 (Thoma-Zeiss-Türk modification); hemoglobin, 50% (Fleischl-Miescher).

Stained specimen showed a formation of rouleaux. Excepting the leukopenia and the relative increase in the lymphocytes, nothing striking was seen.

April 11.—Reds, 3,644,000; whites, first count, 2,800; whites, second count, 3,120; hemoglobin, 70% (Fleischl-Miescher).

Stained specimen had quite a normal appearance, save the extreme leukopenia. Patient was permitted to leave bed for one hour daily and attempt to walk. This was the first time in five months that the patient was able to be about.

April 20.—Reds, 3,452,000 (Thoma-Zeiss); whites, 2,420; hemoglobin, 55%.

The drop in the hemoglobin was due to the patient being out of bed each day, as will be shown in the next hemoglobin examination. Patient was not allowed to leave bed.

April 25.—Hemoglobin, 70% (Fleischl-Miescher). Patient was permitted to leave bed again and sit in the open air daily.

April 30.—Reds, 3,088,000; whites, 2,400; hemoglobin, 65%. Stained specimen had a similar appearance to the one of April 11.

Patient was again ordered to bed. Her appetite began to diminish; this had been good during the entire time since the beginning of the irrigations. Though her bowels gave more or less trouble during the entire treatment, it was never severe, but now she began to have increased discharges and quite severe cramps in the abdomen.

May 3.—Her face became suddenly edematous; there was likewise slight edema of the extremities, which disappeared the following day. Numerous red (urticaria) spots appeared over the entire body, disappearing the following day. This was a toxic erythema and the edema an "acute essential hydrops," which no doubt was due to the absorption (probably increased absorption) of some toxic agent in the alimentary canal.

May 4.—Reds, 2,800,000; whites, 2,900; hemoglobin, 55%.

This last examination was made at 12 o'clock. The patient felt considerably better than on the previous day, as the cramping pain was very much diminished, and the discharges less frequent. When I left the hospital the patient was in good spirits. Without warning death suddenly occurred under symptoms of asphyxia at 4.30 p.m., May 4.

Stained specimen showed a slighter tendency to the formation of rouleaux. Poikilocytes or nucleated reds were not present. A white blood-corpusele was seen in every fourth or fifth field ( $\frac{1}{2}$  oil immersion Zeiss).

The percentage estimation of leukocytes is: Polymorphous, 53%; small mononuclear, 35%; large mononuclear, 7%; transitional cells, 2%; eosinophiles, 3%.

The therapy had consisted of daily lavage of the stomach with 1,000 to 2,000 cc. of water and high enemas of 1,000 cc. The diet consisted chiefly of milk, eggs, and milk preparations. Fowler's solution was administered from March 10 to March 30, gradually increasing to 15 drops, t.i.d., after which time it was discontinued.

The improvement during this time was as follows: The erythrocytes increased to 1,504,000; the hemoglobin 30%. Fowler's solution was discontinued from March 30 to April 5. The improvement during this time was an increase of 554,000 in the red blood-corpuseles; the hemoglobin remained stationary. From April 5 Fowler's solution was again given in increasing doses up to 25 drops until the time of death. The improvement between April 5 (the count being at that time 2,790,000 red corpuseles and 50% hemoglobin) and April 11 was quite astonishing, there being an increase of 854,000 erythrocytes and 20% hemoglobin. Between April 11 and April 20 there was a decrease of 192,000 erythrocytes and a considerable decrease of hemoglobin (15%). As before stated, this was due to the patient being up, as the hemoglobin again reached 70% April 25. The red blood-corpuseles between April 20 and April 30 decreased 334,000 and the hemoglobin 5% since April 25.

This decrease was probably due to the fact that the patient was again permitted to leave her bed every second day from April 25 to April 30, after which time she was confined to bed.

Between April 30 and May 4 there was both a decrease in the number of red corpuseles and hemoglobin, the former decreasing 288,000 and the latter 10%, when death suddenly occurred. This decrease was probably due to an increased formation and absorption of toxins as the patient a day previous (May 3) presented a toxic erythema and a sudden slight edema of the face and extremities, the edema of extremities disappearing the following day. This edema in my opinion was also due to the toxins affecting the blood-vessel walls, allowing a slight transudation of serum (acute essential hydrops) from the fact that it appeared and disappeared so rapidly. The gastrointestinal symptoms were likewise in favor of an increased absorption of toxins, as on the day previous to death vomiting and purging increased and the cramps in the abdomen were

very severe. The next day the vomiting disappeared, stools were less frequent in number, and cramping pain also disappeared.

The improvement in my case was undoubtedly due to the flushing of the gastrointestinal tract rather than to the administered arsenic.

*Autopsy* was performed 17 hours after death. The general appearance was that of a medium sized woman with fairly well developed muscles and subcutaneous fat. The skin and visible mucous membranes were anemic. Numerous bronze colored spots about the size of a pea were distributed over the body, mainly over the upper extremities. An examination of the cranial cavity showed that the dura and pia were of normal color and thickness and free from adhesions and hemorrhages. Convolutions and sulci were normal. Incisions into the brain substance showed it was anemic. A very small amount of clear fluid was found in the ventricles. There were no other pathologic changes found.

An incision was made from the thyroid gland to the symphysis pubis. Diaphragm was situated at the level of the sixth intercostal space. In the pelvic cavity was found 8 cc. of a clear yellowish fluid. The intestines were pale and free from adhesions.

The lungs were not completely relaxed and slight adhesions of the pleura were found about the third intercostal space on both sides. There was no fluid in the chest cavity. On incision into the lungs a slight edema was found. The lower lobes showed signs of a slight bronchitis, otherwise nothing abnormal was found. A thorough search for thrombi or emboli was made to account for the sudden death, but the result was negative.

The pericardial sac contained a small amount of clear fluid. The sac was free from adhesions. Size was approximately normal. Muscular tissue of the heart presented the signs of a slight fatty degeneration. The various orifices and valves presented nothing abnormal.

The adipose capsule of the kidneys was quite large. Both kidneys were somewhat increased in size. The fibrous capsule was removed easily and the surface was smooth. On incision into the kidneys the cortex was found to be somewhat wider than normal. The parenchyma showed signs of a fatty degeneration; the pelvis was not enlarged. The suprarenal capsules were devoid of any pathologic changes.

The spleen was considerably enlarged. On its surface were seen several small fibromas. The capsule was normal. The consistency of the spleen approached the normal. Its color was a bluish red. Trabeculas and pulp were apparently normal.

The lower border of the liver extended one finger's breadth below the free margin of the ribs. Its consistency was somewhat soft. The surface, with the exception of a few small fibromas, was smooth. The cut surface was smooth and presented a grayish, yellowish-red color (fatty degeneration).

The uterus, ovaries and tubes were normal.

The stomach was about normal in size. Upon opening it the mucous membrane was found to be smooth, thin, and almost lusterless, showing small recent mucous and submucous hemorrhages, located chiefly in the greater curvature and near the pylorus. The muscularis was atrophied. The general appearance of the duodenum was similar to that of the stomach. With the exception of a slight atrophy of the mucosa in the remaining small intestine, no pathologic changes were found. The large intestine presented its normal appearance. No pathologic changes were found in the pancreas.

*Microscopic Examination.*—Section of the lungs showed edema and a slight bronchitis. The specimen of the heart showed less fatty degeneration than was expected from the macroscopic appearance. The sections of the kidneys showed a decided fatty degeneration with very slight inflammatory changes in the parenchyma. The spleen specimen, with the exception of a few fibromas, as mentioned in the macroscopic examination, showed no pathologic changes. Section of the liver presented the picture of a slight fatty degeneration. The sections of the stomach showed atrophic changes in the mucosa, submucosa, muscularis and the glands, with small recent mucous and submucous hemorrhages. In the specimens of the duodenum similar atrophic changes of the mucosa, submucosa, and muscularis were found. Brunner's glands were atrophic and slightly degenerated. The various organs were examined microscopically, but only those which presented macroscopic changes have been reported.

Eichhorst<sup>25</sup> in his "Lehrbuch" mentions that Sandy reports several recoveries, and Meyer is favorably impressed with irrigation of the stomach in cases of severe anemia with gastric symptoms. Perutz<sup>26</sup> reported a case of pernicious anemia in which daily lavage and high enemas had been instituted and speedy recovery followed. Grawitz also reports favorable cases of severe anemia with gastric disturbances in which lavage of the stomach had been practised. The recovery, however, is not a permanent one, for so soon as the flushing is discontinued new toxins will form and become absorbed as

the pathologic lesion remains uninfluenced by the irrigation.

Though many recoveries and marked improvement have been reported from the use of arsenic in large doses (Suckling, Abrams, Osler, White, Warfringe, Fussell, Henry, and others), I am convinced that this medication in my case was not the essential therapeutic agent. I have seen some slight improvement from its administration but never a recovery, and it is questionable in even those cases if the improvement was due to the arsenic. Cabot<sup>27</sup> thinks that many of the improvements in the symptoms attributed to the use of arsenic are actually the result of a tendency that the disease itself shows to remissions.

Tyler and Cooper<sup>28</sup> report a case of pernicious anemia showing the good effects of the above mentioned medication. Though the hematologic picture in the foregoing case corresponded to one of primary anemia, it was nothing more than a severe secondary anemia due to the previous hemorrhage of the bowels which occurred several days before the first blood count was made. The fact that the patient was able to leave the hospital in less than one month from the date of admission would also point to an error in the diagnosis. The gastrointestinal symptoms manifested in Tyler's and Cooper's case are easily explained, being due to a chronic alcoholic gastroenteritis.

It has been shown repeatedly that the hematologic picture is not an absolute pathognomonic sign of pernicious anemia, as cases are on record showing that secondary anemias have corresponded with that of primary and also the reverse, and has often led to errors in the diagnosis. The rapid recovery in Tyler's and Cooper's case was probably due to the rest rather than to the arsenic.

I do not wish it to be inferred that I am of the same opinion as Dr. Deaver,<sup>29</sup> who regards the entire science of hematology as a "waste of time," for laboratory experience has shown differently; nor would I be interpreted as not believing in the administration of arsenic in pernicious anemia; on the contrary, it should always be given. No doubt it has its effect if the cause of the formation and absorption of the toxins in the alimentary tract be removed, but that arsenic approaches a specific in pernicious anemia is certainly untrue, and in those cases in which it acted as such there was evidently an error in the diagnosis.

Ziemssen recommended the transfusion of blood, and reports a few favorable cases, but not sufficient to warrant its continuance. The intestinal antiseptics, as recommended by Hunter, may be tried, but in my opinion deserve little consideration.

In conclusion, I thank my colleagues, Dr. Fischer for his kindness in examining the fundi, and Drs. Vogt and Hirschi in assisting and giving their valuable opinion at the autopsy and for examining the specimens microscopically.

## SPECIAL ARTICLES

### A COMPARISON BETWEEN FOREIGN AND AMERICAN SURGERY.

BY

NICHOLAS SENN, M.D.,  
of Chicago.

The average physician seldom sees more than the hospitals of his own country. It is a great privilege and a rich experience to have an opportunity to visit the hospitals of four continents in succession, and to study their facilities, scope of work, and methods pursued in the treatment and care of the sick. Such an unusual opportunity presented itself to me on my recent mission to St. Petersburg and long journey to the Orient. This trip was not one purely of pleasure or recreation. It included many hardships, as the journey through Asia and Egypt was made in midsummer, when the heat was greatest and the pestiferous insects most numerous and in best fighting condition. After the adjournment of the Seventh Conference of the International Red Cross the main object of my tour was to familiarize myself with the present surgical methods in the different hospitals of the countries through which I traveled. My observations were made in France, Germany, Russia, Turkey, Syria, Palestine, Egypt, Austria, England, Sweden, and America, and have been briefly described in the pages of this journal. I found everywhere satisfactory proof that our profession is a truly international one, bound together without regard to color, religion, or politics by a strong tie of a common desire to advance science and benefit humanity. I have become more convinced than ever that this bond of union is stronger in the medical than any other of the learned professions. The desire and genuine willingness to learn and to instruct are more pronounced among medical men than any other class. I also became satisfied that modern progress in medicine and surgery has no geographic limits. The medical men throughout the entire civilized world are all engaged in doing their share toward the advancement of science, and make their contributions according to surroundings, opportunities and facilities for work. It is not difficult to accomplish great results in a well-equipped institution with adequate financial resources. I admired particularly the scientific work in some of the small laboratories in the distant Orient, where many investigations of far-reaching value have been made under the greatest difficulties. It is work of this kind that is entitled to full recognition. The progress of medicine has penetrated the most remote countries that have any claim on civilization. The dawn of the light of original thought and research is visible everywhere, and is rapidly forcing out of existence routine practice. The science of medicine is rapidly retracing its steps from whence it came. The newest and best in medicine in Asia and Africa comes from Europe, more especially from Germany. The missionary physicians have been the pioneers in disseminating modern medicine throughout the distant East, and in establishing outposts for scientific research. In many of the small laboratories of the missionary hospitals, original work is being done which would be creditable to larger and better equipped institutions. The spirit of awakening has taken a firm foothold upon the soil of Asia and the Dark Continent, and will soon

bring about changes in the care of the sick and in the prevention of disease that will be a source of gratification to those who called it into existence. The universities and hospitals of Russia would compare favorably with those of any other country. The medical profession of England enjoys the respect of the government and the public, and is exceptionally well qualified to cope most successfully with the prevention and treatment of disease. The lethargy in medical matters which prevailed in France for a considerable length of time has disappeared and has given place to an energetic and enthusiastic search for the unknown in the science of medicine. Germany and Austria have done more for the advancement of scientific medicine during the last half century than all of the other European countries combined. Germany is today the Mecca to which medical students and practitioners make pilgrimages from all parts of the world for the purpose of obtaining the material for a firm foundation upon which to build the superstructure of rational medicine. Surgery in all of these countries has attained a high degree of perfection. Some of the hospitals, more especially those supported by the different governments, are palaces for the sick, and are supplied with all conceivable means and appliances for asepsis.

It is a great privilege to serve the sick in such an institution, as more than one-half of the battle with disease and accidents is fought by the well trained nurses and the staff of assistants with long service and large experience. It is in less favored hospitals that the surgeon assumes greater responsibilities, and it is the results he records that are within reach of the general practitioner and which represent the achievements of the mass of the profession. All of the European physicians are well-educated men, as the entrance to their medical education is well guarded, for medical colleges are gradually recognizing the importance of an adequate preliminary education as an essential requirement for the successful study and training of the medical student, but the change from a medium to the highest standard is slower than the present conditions demand. On the other hand, I believe we can claim, without fear of contradiction, that our students apply themselves more closely to their studies than those of any of the European schools, and that more of the mass of our profession keep pace with medical progress after graduation than the physicians abroad. The keen competition and the inborn activeness and desire to succeed that characterize the average American physician make him a diligent student and a tireless practitioner. There is no country in the world where so many medical journals are read as in America, and where postgraduate education is more keenly appreciated. Our active, well-attended, numerous medical societies, local and national, keep up the scientific interest of the rank and file of our profession, and are the most important agents in stimulating and furthering postgraduate education.

The vast clinical material of the large European hospitals is utilized to greater advantage than the clinical material here. Autopsies are more frequently made and with greater thoroughness. All hospitals of any size issue an annual report in which will be found a concise retrospect of the medical and surgical work for the year. These publications are valuable literary contributions and are eagerly looked for and liberally quoted by authors. Politics and church influence do not cripple hospital management as much in Europe as in America. The university professors are sure of their hospital appointment until their retiring age reminds them of the limitation of their career as teachers. The esteem and respect for medical men abroad is much keener than here and they occupy a higher position in the social world and political circles. From a practical standpoint the American doctor compares well with his colleagues abroad. His natural aptitude, his education and training harmonize in making him self-reliant and in making the best use of his knowledge at the bedside. The American doctor is impartial in the selection of his reading material. He has no national prejudices. He absorbs knowledge from all available sources. All new innovations and discoveries are given a prompt and fair trial. Many of our physicians and surgeons make frequent visits abroad and return with new ideas which enlarge their knowledge of disease and open new fields for their practice and surgical activity. It is safe to make the

statement that the gigantic progress in American medicine and surgery which has been made during the last quarter of a century is due largely to what our students and practitioners have borrowed in Europe and the seed thus introduced has found here a fertile soil and has yielded fruit a hundredfold. From a medical and surgical standpoint no country is independent, and we have reached a stage in the growth of medical science which brings us up nearly to the same level with any of the foreign countries. We have every reason to look with a justifiable pride on the part America has taken in the rapid development of modern surgery. The teachings of Lister were eagerly grasped and promptly applied in practice. Some of the countries on the continent were slow in adopting the new views, America never hesitated. From what I have seen on three continents I can say without hesitation that the aseptic precautions which are in use by our surgeons are applied as thoroughly here as anywhere else. The average American surgeon is resourceful. He may not have the same broad preliminary and professional education as his European colleagues, but he is quick and determined in the selection and use of appropriate therapeutic resources. The American surgeon is eminently practical. He is peculiarly well fitted for emergency work. He performs the most difficult task with the simplest means and appliances. American ingenuity, recognized the world over, is well represented in the medical profession. A visit to Europe, Asia, and Africa, with a view of ascertaining the present status of surgery in different countries, awakens a new interest in the science and art of medicine as they exist in our own country. On my return from Europe I remained two days in New York for the purpose of visiting a few of the most prominent hospitals to obtain the necessary material upon which I could base a practical comparison between foreign and American surgery.

Midsummer is not a good time to see surgical New York, as most of the prominent surgeons are enjoying their much-needed rest and recreation at that time. I was fortunate to find a few of the men I was anxious to see at home and at work.

New York has four medical schools, all of them in excellent repute. Among these the College of Physicians and Surgeons is the one that is entitled to first place, by virtue of age and the elaborate facilities it can extend to its students in its theoretic and practical courses. Most of the clinical teaching of this college is conducted in the

#### ROOSEVELT HOSPITAL.

The Roosevelt is one of the best, if not the best, private hospitals in New York. The name of this institution commemorates the philanthropy of a grand-uncle of our present Chief Executive, who donated \$1,400,000 for the erection and maintenance of the hospital. The pride of this hospital is the W. J. Syms operating-room, built at an expense of \$250,000, the gift of the man whose name it bears, and which was opened for clinical teaching in 1892. It is the most costly and probably the most perfect operating theater in the world. The construction of the interior of the room, as well as everything within it, are such as to adapt them for perfect aseptic work. The teacher of clinical surgery who visits this part of the hospital, and who has been less fortunate in his surroundings, is perfectly amazed at the conveniences which are at the disposal of his more favored colleagues here. In the amphitheater the large college clinics are held. Professors Weir and Bull give each one clinic a week. Drs. Brewer and Blake give each three clinics to small classes of 20 every week. The students of this college have every opportunity to acquire the necessary surgical skill that a large material and effective teaching can offer. In a small side room, equally well equipped, the more serious operations, and operations upon private patients, are performed. Another room is devoted to septic cases, and in it will be found every possible convenience for antiseptics. The McLean operating-room is another very luxurious part of the hospital, and is used exclusively for gynecologic operations. The students attend this clinic in small sections. Two anesthesia rooms are within easy reach of the main operating-room. The hospital has 250 beds. Two rooms, with two beds each, near the main operating theater, are reserved for patients who

have undergone a serious operation, and there they remain until they recover from its immediate effects, when they are assigned to the wards where they belong. The disinfection-room and two rooms for the preparation of the dressing material are all that money and skill could make them. The hospital is well supplied with trained female nurses. The training-school connected with it has 60 pupils. The nurses are not overworked, as is the case in many other hospitals. The wards, with 36 beds, are attended to by five nurses. The course of study and training for the nurses is three years. During this time they are given an opportunity to perfect themselves in the nursing of a great variety of patients. Eight internes are employed for the surgical side alone, perhaps more internes to the number of patients than in most hospitals. The outdoor department is very large, and two automobile ambulances are seldom at rest. Ether is the anesthetic in general use.

*Weir's Method of Hand Disinfection.*—This method is virtually the one relied upon by all of the surgeons connected with the Roosevelt Hospital, and might well be termed the Roosevelt method. It is as follows:

Thorough scrubbing of hands with flowing, warm, sterile water and potash soap. About a tablespoonful of small crystals of sodium carbonate are then placed in the palm of one hand, to which is added about one-third as much of chlorid of lime. The hands are thoroughly rubbed with this mixture for some length of time, when they are rubbed dry with a sterile towel and are then rinsed in sterile water. Professor Weir places much stress on the penetrating power of chlorin gas, which reaches microbes in the appendages of the skin and in the layers of the epidermis inaccessible to many of the antiseptic solutions.

The finger-nails receive proper attention in the mechanical treatment of the hands. After the chlorid disinfection sublimate solution is used in the usual way as an additional safeguard. Alcohol is occasionally used, but is not considered essential in completing the hand disinfection.

Professor Weir has proved the reliability of this method of hand disinfection by numerous bacteriologic examinations, which invariably demonstrated the absolute sterility of the surface thus treated. Weir only makes use of rubber gloves in aseptic cases when he has to operate upon joints and the abdomen. Dr. Brewer uses gloves in all of his operations. Catgut, silk, silkwormgut, and horsehair are used for suture material. For buried sutures catgut is usually employed.

*Roosevelt Method of Catgut Sterilization.*—Immerse in juniper oil for 4 days; immerse in sulfuric ether for 14 days; immerse in benzine for 14 days. Boil in alcohol for half an hour to an hour, according to the size of the catgut. Keep in alcohol ready for use.

The iron-stained silkwormgut is a favorite material for superficial sutures.

The anesthetic is administered in the anesthesia-room by one of the internes. Two internes and two trained nurses assist the operator. The patient is prepared the evening before the operation and the final disinfection is made after the patient is fully under the influence of the anesthetic.

Professor Weir has had a long and varied surgical experience. He entered the regular army in 1861, soon after his graduation, and did most creditable service during the Civil war. He is well remembered by his army colleagues. During his recent all-around-the-world trip he visited the Philippine Islands. Here he found many of his old army friends, who did all in their power to make that part of his journey pleasant and profitable. Weir's name is intimately associated with the surgical literature of America. He has been an earnest student, a successful surgeon, an impressive teacher, and a prolific writer. He finds it difficult to cut loose from his professional work, as this brings to him more satisfaction than idle recreation. During my stay in New York he came to the city for a few days from his vacation to perform a number of operations on private patients.

The patient operated upon the day of my visit to the hospital was a very interesting one.

The man was about 50, and the subject of a somewhat obscure affection involving the floor of the mouth and the submental and submaxillary regions. A number of weeks ago while taking outdoor exercise in the country he suddenly experienced a sensation near the base and lower surface of the tongue as though some sharp foreign substance had entered the tissues. A violent inflammation followed, which involved the submental and submaxillary regions. This in-

flammation terminated in the formation of an acute abscess. The swelling subsided only in part after the abscess was incised and a fistulous opening remained. A hard mass remained and resisted all treatment. A positive differential diagnosis between an inflammatory affection and malignant disease could not be made. Under ether anesthesia a horseshoe-shaped incision was made along the lower border of the inferior maxilla. The flap was reflected as far as the hyoid bone. At this stage of the operation a piece of the indurated tissue was excised and the pathologist of the hospital, who was present, made a frozen section and examined it under the microscope. This examination demonstrated the inflammatory nature of the affection. By a careful and somewhat difficult dissection all of the infected glands and indurated tissues were thoroughly excised. A large rent in the mucous membrane of the floor of the mouth was made. A Penrose drain was inserted into one angle of the wound and the external incision closed with fine iron-dyed silk wormgut sutures. The oval wound was tamponed with a strip of iodoform gauze saturated with compound tincture of benzoin. An external absorbent dressing finished the operation.

The Penrose drain is a most excellent one for capillary drainage. It consists of a tube of very fine soft rubber loosely filled with absorbent gauze.

Weir has made a very fine collection of appendicitis specimens. The specimens are fastened on one side of a narrow strip of white cardboard, and on the other side is a drawing and the legend. The specimens are preserved in cylindrical glasses containing a formalin solution. It is hoped that this valuable collection of pathologic specimens will be utilized for the benefit of the general profession in illustrating the pathologic condition of this as yet somewhat obscure disease.

Dr. Brewer is one of the attending surgeons to Roosevelt Hospital, and also clinical instructor in the College of Physicians and Surgeons. He is a young surgeon full of promise, in fact, as Professor Weir informed me, "one of the coming men." During Weir's absence he does most of the operative work. It was a source of pleasure and profit to me to witness a few of his operations.

CASE I.—*Left inguinal hernia, radical, by Bassini's method.* Left inguinal hernia of many years' standing, for which truss was worn for a long time. Patient was a man of 30, otherwise in excellent health. Ether anesthesia was employed. Final disinfection was done before operation. Hand disinfection by Weir's method. Incision was made over entire length of inguinal canal. Partial isolation of sac, when it was grasped with two dissecting forceps, between which it was opened with scissors. Omental part of hernial contents adherent to the sac. The omentum was separated, tied with catgut, and amputated at a safe distance below the ligature. After complete isolation of the sac it was transfixed at the neck with needle covered with catgut and tied and cut off below the ligatures. The cord and accompanying vessels were now isolated and lifted out of the canal with a folded strip of iodoform gauze. The inguinal canal was closed with chromicized catgut sutures, the material always employed in performing this part of Bassini's typical operation. Next the fascia of the external oblique muscle was sutured over the cord with a continuous suture of ordinary catgut sterilized by the Roosevelt method. Iron-dyed silk wormgut interrupted suture was employed for the skin. The dressing was sterile loose gauze and absorbent sterile cotton held in place by strips of adhesive plaster and an abdominal bandage with two perineal straps. It is routine practice here to drain such wounds with a folded piece of sterile gutta serena tissue. The wound is frequently doused with warm physiologic solution of sodium chlorid.

CASE II.—*Fistula following operation for acute appendicitis; laparotomy; suturing of cecal perforation.* The patient, a young man, was operated upon by Dr. Brewer two months ago for acute appendicitis. The wound healed by primary intention, but a small fistula remained which failed to heal. There was a very scanty seropurulent discharge at times. It was supposed that this fistula was caused and was maintained by an infected silk ligature. The fistulous opening was enlarged by incising the scar tissue in both directions. The fistula led into the abdominal cavity and the incision had to be enlarged. The great omentum and cecum came into view and in following the fistulous tract a minute perforation in the cecum was found where the appendix was ligated at the first operation. The perforation was thoroughly disinfected with hydrogen dioxide and was closed with a continuous Lembert suture of very fine catgut. The external incision was sutured with two tiers of buried catgut sutures and superficial iron-dyed silk wormgut sutures. A gutta serena strip drain was placed in the lower angle of the wound. Dry hygroscopic sterile dressing was applied.

#### NEW YORK HOSPITAL.

This is probably the most elaborate and best equipped private hospital in New York. It is well endowed and it is said that it takes more money to take care of a patient in this

than in any other hospital. The number of patients corresponds with that of the Roosevelt. A new wing with 50 beds is for private patients and has a separate staff of internes and nursing force. The rooms are luxuriously furnished. Some of them have a bath-room and closet conveniences. The ward patients pay \$2 a day, while the private rooms command from \$30 to \$75 per week. A small but beautiful separate operating-room is connected with this department of the hospital. It is in this room that Dr. Charles McBurney performs most of his operations. The training-school of this hospital is attended by 80 pupils, who are required to take a course of three years before they are permitted to apply for final examination. The lectures are given by members of the attending staff. The general operating-room seats 75 students. No fee is charged for clinical instruction. Students from all of the four medical schools take advantage of the excellent clinical teaching given here by the large staff of attending physicians and surgeons. The students of the Cornell Medical School take private courses, for which they pay a small fee. The surgical staff includes the well-known names of L. A. Stimson, Francis W. Murray, A. B. Johnson, Frank Hartley, and P. R. Bolton. These men keep up the high standard of clinical surgery of this, one of the best known of the New York hospitals. Ether is the anesthetic of choice. The catgut is sterilized by Saul's method. Sulfate of ammonium catgut after a fair trial has been abandoned, as it was found too brittle in tying the ligatures and sutures. Silk and iron-dyed silk wormgut are used for superficial sutures. Hand disinfection with chlorid of lime is in general use.

Rubber gloves and caps are worn constantly by operators and assistants. Two internes and two trained female nurses assist the operator. A third interne administers the anesthetic. I was fortunate enough to find Dr. Alexander B. Johnson at work. He is professor of surgery in the Cornell Medical College, and one of the most careful and skilful operators in New York. On the day of my visit he had to deal with two very rare cases.

CASE I.—*Ulcer of stomach; laparotomy.* The patient was a young man, who was admitted into the hospital for hemorrhage from the stomach. The general condition of the patient was fair. No special distress after eating and no vomiting, excepting during the bleeding attacks. On two occasions he vomited a large quantity of blood, and decomposed blood passed per rectum. A median incision was made. The stomach was unusual in size and appearance. The pylorus was incised transversely. Near the pylorus and the small curvature of the stomach two bleeding points were found in the course of a vein of considerable size. Visceral incision was enlarged and mucous membrane of the stomach freely everted for inspection. The remaining part of the interior surface of the stomach was inspected through a bivalve rectal speculum and with the aid of reflected light, but no additional lesions could be discovered. Hemorrhage from the two bleeding points was arrested with two purse-string sutures of catgut.

Visceral incision closed with continuous catgut suture for mucosa and mattress catgut Lembert sutures. In closing the external incision, catgut was used for the peritoneum, muscular layer, fascia, and iron-dyed silk wormgut and fine silk for the skin. Gutta serena strip drainage was employed, the drain to be removed in 48 hours. A small, dry dressing for the external wound, held in place with strips of adhesive plaster, and abdominal bandage. Although no distinct ulceration could be discovered, there must have been minute erosions that caused the venous hemorrhage, and the treatment resorted to undoubtedly succeeded in preventing recurring attacks.

CASE II.—*Late fever complicating appendicitis; operation, exploratory laparotomy.* A young man was operated upon by Dr. Johnson four weeks ago for gangrenous appendicitis. Early operation. Appendix was removed, and the wound healed by primary intention. No untoward symptoms until a few days ago a high temperature developed which ranged between 104° to 105° F. Other general symptoms confirmed the suspicion of the existence of a retrocolic, hepatic, or subphrenic abscess. Liver was enlarged. No palpable swelling in the ileocecal region. Ether anesthesia was employed. Incision was made four inches in length below and parallel with the right costal arch. Liver was found enlarged, but no indications of the existence of an abscess within, above, or beneath it. The incision was enlarged sufficiently for the insertion of the hand which was employed in making the necessary intra-abdominal palpation for the detection of a suppurating focus, but nothing was found that could explain the remote post-operative fever. The abdominal incision was closed with buried and superficial sutures in the usual manner. The operator came to the conclusion that in all probability the remote septic complication was the result of a thrombo-phle-

bitis, which had its origin at or near the primary seat of infection.

BELLEVUE HOSPITAL.

This is the wellknown, large, general charity hospital of New York. It is an old institution, but improvements have been made from time to time so that it serves its present purpose well. Its present capacity is 1,000 beds. The emergency department is the largest of any hospital in New York. Four ambulances are in use all the time, and 18 horses are always in readiness for this service. The automobile ambulances have been abandoned, as not infrequently something would go wrong when speed was most required. The attending staff is made up largely of members of the faculties of the four medical colleges. It is the great center of clinical teaching for students and practitioners. Surgical clinics are given daily in the two large operating-rooms. The training-school for female nurses is attended by 80 pupils, and the school for male nurses by 90. The course of training is three years. Forty-five internes assist the attending staff in taking care of the vast clinical material. It is estimated that 24,000 patients enter this hospital every year. The morgue is one of the finest in the country. The mortality in this hospital is for obvious reasons very high, as many accident cases are brought to its doors with patients in a dying condition. The number of postmortem examinations made annually sums up into many thousands. The morgue is a great school for the study of gross pathology. The surgical practice in this hospital is not uniform, as many of the operators pursue methods of their own. Dr. Gill Wylie is one of the attending gynecologists. His aseptic precautions are very simple, and yet efficient. He scrubs his hands with warm water and ethereal solution of soap, cleanses the finger-nails thoroughly, and then resorts to chemical disinfection by immersion for a few minutes in a solution of bichlorid 1 : 8,000 to which three parts of tartaric acid are added. He performs his operations in a small room connected with his ward. On the day of my visit he was absent from the city, and his patients were in charge of his assistant, Dr. Lee. An Alexander operation was performed for retroversion of the uterus with skill that would have done credit to his clinical teacher. The delirium tremens ward and detention wing are well worth a prolonged visit, as they contain an abundance of the most valuable clinical material, interesting and profitable alike to the alienist and general practitioner.

This completes a description of my surgical observations during the last four months, and I return to my private practice and college work fully satisfied that from a surgical standpoint America compares well with any of the foreign countries I had an opportunity to visit. In conclusion, I desire to thank all of my colleagues, near and far, for the many courtesies extended to me on my long and highly-interesting and profitable journey.

NEW YORK, August 29.

**The Pathological Society of Philadelphia** will hold a symposium on snake venom at the meeting on January 22. The speakers will be S. Weir Mitchell, Flexner, Naguchi, Kin-youn, and MacFarland. Dr. Welch, of Johns Hopkins, will open the discussion. The medical profession is invited to be present.

**Contemplated Improvements to St. Agnes' Hospital, Philadelphia.**—It is announced that improvements costing about \$200,000 will be made to this hospital in the near future. The proposed improvements will consist of the erection of several new buildings, among which will be a new wing on the south side of the central building similar to that on the north side. To this extension will be added a separate stone structure for patients who must be isolated, and another building for a children's ward. It is also proposed to erect a nurses' home and an operating-room.

**Mortality in Boston.**—According to the vital statistics published by the Boston Health Department for the year ended December 31, 1902, an encouraging decrease of the mortality in all contagious diseases with the exception of smallpox is noted. The total number of deaths was 10,972, as against 11,300 for 1901, and the deathrate per 1,000 inhabitants was 18.70, as against 19.70 for the previous year. The number of deaths of children under 5 years of age was 3,375, as compared with 3,469 in 1901, the percentage to total mortality being 30.76 last year as against 30.69 the year before. The deathrate for 1902 was the lowest since 1865, the highest being 30.43, in 1872, when the city was scourged with smallpox.

9. A Study of Sir James Paget in his Writings. HELEN C. PUTNAM.

1.—See *American Medicine*, Vol. III, No. 24, p. 990.

2.—**Progressive Idiopathic Atrophy of the Skin.**—Ravogli reports the clinical history and microscopic findings in the case in connection with a study of the literature of the subject. In this case the atrophy resulted from a syphilitic gumma at the junction of the pons and medulla pressing on the origin of the seventh and eighth nerves just at the point which is the center of the vasomotor nerves. The process was of a chronic inflammatory nature of trophoneurotic origin, causing a sclerotic condition. The connective tissue fascicles were hypertrophied, reminding one of keloid. The elastic fibers were much diminished, and the whole of the corium seemed to be made up by abundant enlarged collagenous fibers. In some places the papillas had disappeared; in others they were enlarged. The nervous ramifications were compressed. Disturbance of the trophic nerves causes hyperemia and stasis. The anomalous hypernutrition causes hypertrophy and the collagenous condition, and pressure from this atrophy of the elastic fibers, nerveterminals, glands, hair follicles, etc. [H.M.]

3.—**Lupus Erythematosus and Tuberculosis.**—Anthony discusses the opinion of other authors as to the etiology of skin affection, and concludes that discoid lupus erythematosus is a granuloma which has no relation whatever to tuberculosis, but which may be accompanied by a general eruption; that tuberculosis may produce symptomatic lupus erythematosus, usually with disseminate, atypical plaques; that what may be shown by statistics regarding the relation of lupus erythematosus to tuberculosis depends on what is understood as evidence of tuberculosis, and also what is included in lupus erythematosus. [H.M.]

### Boston Medical and Surgical Journal.

January 8, 1903. [Vol. CXLVIII, No. 2.]

1. The Malignancy of Joint Tuberculosis. Illustrated by a Series of 47 Cases. CHARLES F. PAINTER.
2. The Importance of Increased Hospital Accommodations for the Treatment of Measles. JOHN H. MCCOLLOM.
3. An Experimental and Practical Demonstration of the Value of Downes' Electrothermic Angiotribe. JOHN W. KEEFE.
4. Plague Serum in Three Cases. W. J. CALVERT.
5. The General Treatment of Tuberculous Bone and Joint Diseases. JOEL E. GOLDTHWAIT.

1.—**The Malignancy of Joint Tuberculosis.**—After treating 139 cases of Pott's disease, 180 of hip disease, and a lesser number in the smaller joints in the orthopedic department of the Carney Hospital, Painter's conclusions are: Tuberculous disease tends to recur after apparent cure in a considerable proportion of cases. This recurrence is usually a local one. Metastases are not common. Trauma is frequently associated with the recurrence. Indirect trauma is probably the exciting cause of the recurrences, especially where partial ankylosis or deformity exists. Patients who have suffered from bone and joint tuberculosis should be cautioned that they are not well when symptoms have ceased and that reasonable care must be exercised to avoid recrudescences. Deformity and shortening should be corrected so far and as accurately as possible to lessen the chance of recrudescence. Mechanical treatment, especially fixation, should be used in the acute conditions in childhood.

Exploratory interference, where discretion is used, with a view to removal of isolated foci, is *advisable* in many cases in children, and is to be *urged* in the majority of the recrudescences, if seen early. Recognition of the fact that patients with hip disease, Pott's disease and tumor albus have tuberculosis just as much as if they had phthisis, and should be treated accordingly, must be insisted upon. The number of recurring cases was 47 and the location of the disease as follows: Pott's disease, 16; hip disease, 17; knee, 10; ilium, 1; ankle, 2; shoulder, 1. Twenty-nine of the patients were males, 18 females; abscess occurred in 33 cases. Average age at time of exacerbation, 28; average duration of quiescence, 12½ years. [A.B.C.]

**2.—Hospital Accommodations for Measles.**—McCollom calls attention to the need of hospital accommodation, especially for adults in boarding houses, believing that many lives might be saved and much suffering prevented. Early diagnosis by Koplik's sign and prompt isolation is the only way in which the disease can be diminished. In hospitals, 2,000 cubic feet should be allowed for each patient ill with the measles, and patients should be carefully kept in separate pavilions from those with scarlet fever. Those suffering from both diphtheria and measles should be specially isolated. He gives statistics of the relative prevalence of measles and scarlet fever in the army and navy, and of the mortality from the same in large cities, showing that measles is much the more fatal. [H.M.]

**3.—The Value of Downes' Electrothermic Angiotribe.**—Keefe experimented with this instrument on four dogs, doing in each case a resection of the intestine. In one instance he simply clamped the intestine in two places and the intervening mesentery allowing a current of 60 amperes to flow for 50 seconds. The four-inch piece of intervening intestine was resected, the now cut ends being sealed by the clamping and cautery action, a lateral anastomosis with the Murphy button was done. The dog died and necropsy showed the ends had sloughed, extravasation setting up a peritonitis. The same experiment was performed on another dog, except an end-to-end anastomosis with the Murphy button was done. The result was peritonitis and death. In two other instances end-to-end anastomosis by sutures was done, leaving the gut ends sealed as before. But in each case the ends sloughed into the lumen of the bowel and the dog made a good recovery. The author reports the use of the instrument in eleven celiotomies for various gynecologic troubles and no unfavorable results whatever followed. Its advantages are: Rapidity of operation. Asepsis and cleanliness during the operation; no soiling with blood, pus or feces, as one may meet with in the removal of a pus tube, appendix or portion of intestine by other methods. Hemostasis without the aid of a ligature. No secondary hemorrhage from the slipping of ligatures, or the subsequent infection of the same. Less pain subsequent to operation, as the tissues are not puckered and constricted by ligatures. The manner of using the instruments is very simple, and one should try this method before passing judgment thereon. [A.B.C.]

**4.—Plague Serum.**—Calvert reports one case in which Yersin's serum, and two in which Kitasato's serum was used. One of the latter recovered, and he believes the serum was of value, and if larger quantities had been used in the other cases, more favorable results might have been obtained. [H.M.]

**5.—The General Treatment of Tuberculous Bone and Joint Disease.**—Goldthwait says during the past few years there has been a growing tendency in the profession to recognize that while surgical tuberculosis is in the beginning a local process, it is distinctly a debilitating disease which may easily result in its developing elsewhere, and that in the treatment every effort should be made to improve the patient's nutrition and increase the resisting power. Out-of-door life should be insisted upon almost as much as with pulmonary tuberculosis. Forced diet is needed and the best possible hygiene both at home and when at work should be had. These features are not for a few months, but should be observed by the patient during the remainder of his life. [A.B.C.]

- 3. Adhesive Plaster Strapping for Sprains: the Indications for Its Use. FINLEY R. COOK.
- 4. Inguino-Superficial Hernia (Kuester). ALEXIS V. MOSCHCOWITZ.
- 5. Remarks on Bacteriology and Serum Treatment of Puerperal Septicæmia, with an Illustrative Case. CHARLES S. WHITE.

**1.—Routine Treatment in New York Hospitals.**—Loomis gives a synopsis of the treatment of typhoid fever, pneumonia, articular rheumatism, and pleurisy with effusion, showing a fairly unchangeable method in each institution, the result of many years' experience. The details of treatment in the various hospitals differ distinctly, however results compare favorably. The typhoid mortality is only 10%. In treatment opinion differs only in four particulars: whether the diet shall be exclusively milk or not; when and how it shall be modified at the end of the disease; what temperature indicates the giving of the Braudt bath; and whether it shall be given in every case. In acute articular rheumatism the author believes too early change from a milk diet and too early getting up are the most important causes of relapse. [H.M.]

**2.—Extrauterine Pregnancy.**—Boldt, after seeing 258 cases in his own practice and consultation since November, 1879, gives the causes of tubal gestation as contortion of the tube; the presence of small neoplasms or mucous polypi within the tube, or neoplasms in the wall of the tube; pathologic changes in the fecundated ovum may also prevent it from migrating into the uterine cavity. Probably the most frequent cause is inflammatory conditions of the tube which prevent tubal peristalsis. He classifies its various forms according to the seat of the conception product. The placenta forms at the site where the ovum is imbedded, the maternal bloodvessels coming from those of the tube. The changes which take place in the wall of the tube consist in an hypertrophy of the muscular structure and an increase of connective tissue, with a thinning of the wall near the site of the ovum caused by its pressure, and the consequent atrophy of the muscle. Usually the death of the embryo within the tube takes place during the first two months after the faulty conception. Yet a few instances are on record in which the development went on to, or nearly to, full term, and a living child was delivered by means of abdominal section. The most frequent termination of tubal gestation is tubal abortion and not, as is believed by many physicians, a tubal rupture. Were the latter the case, the deathrate in tubal gestation would be greatly increased. In tubal abortion and *gradual* tubal rupture the symptoms are very similar, and the treatment may be similar. But usually rupture is diagnosed by the suddenness of the attack, and the excruciating pain followed by more or less pronounced syncope. It is very difficult at times to make a differential diagnosis between subacute pyosalpinx, especially of gonorrhœal origin, and tubal pregnancy, but inasmuch as either condition requires surgical intervention to bring about a well being of the patient, he does not see the necessity of making a preliminary vaginal section or puncture. Boldt discusses two methods of treatment, conservative and surgical. If tubal abortion is in progress, and it is evident that the blood has clotted, the conservative treatment is permissible but the patient must be kept in absolute rest and under constant surveillance, and if the tumor does not increase in size and becomes firmer in texture, the treatment may be continued to ultimate recovery, which usually occurs in from four to six weeks. But the moment there is found to be an increase in size of the tumor or there is a sudden attack of pain, operation is necessary. If the history and symptoms show that the patient has had a complete tubal abortion, objectively determined by the absence of a thickened fallopian tube, such as we would find were the embryo still within the tube, and if she has recovered from the shock thereof, a similar conservative course is permissible. A hematocœle will then form, readily recognized by the examining finger, and its increasing firmness and diminution in size would indicate that its absorption is progressing satisfactorily. He has observed 23 cases in this condition who went on to complete recovery. But when surgical intervention is necessary, as it is in a large proportion of cases, Boldt advises abdominal rather than vaginal section. [W.K.]

**3.—Adhesive Plaster Strapping for Sprains.**—Cook says that Virgil P. Gibney, who contributed an article in 1893

and again in 1895 on this subject, was the first to bring it prominently before the profession. Gibney, however, asserts that Edward Cotterell, of London, was the first to use adhesive plaster for this purpose. Cook asserts that strapping has been found of value in a great variety of articular and periarticular affections. It is indicated when we have relaxation of tissues, following acute or subacute inflammatory disturbance, of a rheumatic, specific, gonorrhoeal, tuberculous, or traumatic character. A relaxation of veins leads to a passive venous stasis, with exudation into joints, bursas, tendon sheaths, and neighboring cellular tissue. There is swelling, tenderness, pain, and impairment of joint function. There may be redness and increased local heat, and in chronic affections a cellular hyperplasia, leading to a connective tissue thickening of the normal structures within and without the joints, and the formation of adhesions. Adhesive plaster strapping meets in a measure all these conditions. It affords support, protection, induces counter irritation, fomentation, supports relaxed tissues and bloodvessels, and is an excellent form of massage. [A.B.C.]

**4.—Inguino-superficial Hernia.**—Moschowitz reports the case on account of the rarity of the condition. The patient was a man of 28. Since he could remember the left testicle had never occupied its normal place in the scrotum, but beginning with adolescence he had noticed a small ovoid tumor in the left inguinal region, which he properly regarded as the missing testicle. At about 20 the testicle began gradually to descend, but never passed into the scrotum. The effort at gradual descent caused pain which was only relieved by a truss applied, contrary to directions, below the testicle. The truss was worn until the present attack, which was precipitated by an attempt to walk upstairs. Pain was great. Operation showed that the testicle and hernial contents had passed up at an angle between the overlying structures and the aponeurosis of the external oblique. The author has been able to find but 16 other cases in the literature, including the 14 collected by Goebel. [A.B.C.]

**5.—Serum Treatment of Puerperal Septicemia.**—White reports a case of recovery in which other treatment failed. He calls especial attention to the diminished pulse-rate following serum injection. Fall in temperature and improvement in mental symptoms were also attributable to it. As we are unable to differentiate the various forms of streptococcic intoxication, we are justified in using serum in all sepsis due to this organism. Alarming symptoms following its use rarely occur. [H.M.]

### New York Medical Journal.

4. The Diagnostic Value of Abdominal Rigidity. JOSEPH A. BLAKE.
5. Morphine Habituation and its Treatment by Hyoscin Hydrobromid. S. ORMOND GOLDAN.
6. Bronchial Tuberculosis. ALBERT ABRAMS.
7. The Successful Treatment of Pulmonary Tuberculosis, Mechanical and Medicinal. DAVID WARK.
8. The Physician and the Pharmacopela. M. I. WILBERT.

**1.—The "Lorenz hip depresser" and "Lorenz spica"** are described by Jaeger. The depresser is a simple apparatus to assist in the application of fixation bandages to the hip-joint itself or to the entire lower extremity. With it faulty positions and contractions may be corrected and then held in the corrected position firmly and evenly while the bandage is being applied. It may be fastened to any sufficiently projecting table top. Its three main parts are: (a) The hip rest; (b) foot and knee rests for the sound leg, which can be fastened to either side of (c) the extension foot rest for the diseased leg. Traction with this apparatus is stronger than can be applied by hand, and is kept up evenly until the end of the dressing. The lower extremity can be put up in the plaster bandage in the position of (relative) abduction, without obliging the patient later to walk with the limb held strongly out from the body. This is accomplished in that the traction on the diseased leg and the simultaneous pushing up of the healthy leg cause tilting of the pelvis. The Lorenz spica extends from above the crest of the ilium to the knee. The salient feature of this plaster spica is the painstaking modeling out of crests and

spines of the ilia into the spica, thus insuring absolute fixation of femur and pelvis. [C.A.O.]

**2.—Ovarian Fibroma.**—Royster reports a case in a woman of 55 in which the diagnosis of fibroma of the uterus had been made. The menopause came at the age of 50, but three years later the flow recurred, lasting 10 days or more. At the time of operation it was not so excessive, and appeared only at irregular intervals. She complained of pain in the left side and around the umbilicus, and of a burning sensation in the chest. Urination was difficult and frequent, but her general condition was good. Examination revealed a very hard, smooth, somewhat movable tumor about the size of a large orange in the posterior culdesac. At the time of operation a small quantity of ascitic fluid was present; the uterus was normal. There were no adhesions, and the tumor was easily removed. A complete pathologic report is given. [C.A.O.]

**3.—**See *American Medicine*, Vol. IV, No. 21, p. 804.

**4.—Abdominal rigidity**, according to Blake, is a constant symptom in all irritations and inflammations of the peritoneum and is therefore a valuable sign in the diagnosis of the presence of foreign materials in the peritoneal cavity even before inflammation has ensued. It is a fairly accurate index to the severity and extent of a peritoneal implication, and is, therefore, valuable in observing the course and estimating the severity of a peritonitis. Three cases are reported to show that rigidity in abdominal hemorrhage is well marked and that it appears coincidentally with the escape of blood into the peritoneal cavity. Two cases are reported in which rigidity occurred immediately after rupture of the intestine and another after the escape of urine into the peritoneal cavity. Rigidity is always present in peritonitis, except in the chronic cases, such as tuberculous peritonitis and cases of advanced general peritonitis in which it may be absent or not accentuated. Rigidity is absent in the catarrhal forms of appendicitis but as soon as the inflammation extends to the peritoneum it appears and increases directly with the amount of peritoneum involved. A case illustrating this is reported. When an abscess forms and becomes walled off by adhesions, the rigidity diminishes in extent as the peritonitis becomes localized, and finally disappears in many cases if the abscess becomes quiescent. Rigidity is not present in intestinal obstruction unless peritonitis is present from ulceration or gangrene of the bowel. Rigidity is of great value as a sign indicative of perforation in typhoid fever. It is manifest as soon as local peritonitis results from implication of the peritoneum by the ulcerative process, and is marked as soon as perforation occurs. Blake believes that absence of rigidity in a case of supposed perforation is a contraindication to operation. Rigidity may be present in the upper part of the abdomen in inflammations of the pleura, the peritoneum being normal. [C.A.O.]

**5.—Morphine Habituation.**—The treatment advocated by Goldan consists in the frequent hypodermic administration of hyoscin hydrobromid, beginning first with a very small dose,  $\frac{1}{100}$  to  $\frac{2}{100}$  gr., to determine idiosyncrasy; the dose of  $\frac{2}{100}$  to  $\frac{1}{100}$  gr. is repeated hourly, or frequently enough to keep the patient under its influence. After two days he endeavors to defer the repetition of the dose to every two or three hours until the third or fourth day, when, depending upon the case, the time for administration may be extended to from three to six hours, and on subsequent days an occasional dose may be given. During this period a nurse must be in constant attendance. Attention must be given to the respiration and heart, the room should be darkened, absolute quiet enjoined, food by the stomach discontinued and nutrient enemata substituted. The author reports success in each case, the extreme in quantities representing  $\frac{1}{2}$  gr. a day for about seven months, for an actual sciatica, to 30 grs. daily for nine years for no definite purpose. [C.A.O.]

**6.—Bronchial Tuberculosis.**—Abrams has collected 25 cases of tuberculosis of the tracheobronchial glands without involvement of the lungs, occurring in adults. The following points in the diagnosis of this condition are emphasized: A history of cough, which is spasmodic in character, and almost suggests the brazen metallic cough of aortic aneurysm; the presence of tubercle bacilli in the sputum; dyspnea, which is out of all proportion to the signs obtained by physical exami-

nation of the lungs; dulness anteriorly and posteriorly, corresponding to the bifurcation of the trachea; the evidence of comparative good health, notwithstanding the long duration of symptoms; and finally the negative results of pulmonary disease, as determined by physical examination and the demonstration of enlarged bronchial glands by skiascopy. It has not been the experience of the author that tuberculous adenitis of the bronchial glands is always secondary to some focus in the lungs. The treatment comprises nutrition, air, sunshine, and a hygienic environment. Codliver-oil is lauded. Syrup of the iodid of iron in continuous and increasing doses seems to exert some specific influence in this disease. The writer has employed with good results *sapo viridis*, one dram, rubbed in daily in different portions of the body after the manner of mercurial inunctions. [C.A.O.]

**7.—Pulmonary Tuberculosis.**—Wark advocates suitable mechanical treatment in conjunction with the tonic and sanitary means now commonly employed in the treatment of this condition. The restricted respiration and defective blood circulation may be largely corrected by active and passive movements prescribed for and applied to the patient, by which the thorax can be expanded, the elasticity of its walls increased and all the muscles of respiration invigorated. Attention must also be given to the complete reduction of tissue debris to those forms that promote complete elimination. Remedies competent to improve the invalid's capacity to digest and assimilate fats occurring in food, and what is, if possible, of much greater importance, that will restore the ability to develop fatty matters from carbohydrates and other food elements. [C.A.O.]

**8.—The Physician and the Pharmacopeia.**—Wilbert notes the gradual decrease of interest in the pharmacopeia on the part of physicians and the corresponding increase in the number of proprietary or patented preparations, ostensibly intended for the exclusive use of the medical profession. He urges more concerted action on the part of physicians to aid in furthering scientific and ethical advances. The necessity of unifying the more potent medicaments is mentioned and a plea made that this innovation be introduced into the coming edition of the "United States Pharmacopeia." [C.A.O.]

### Medical News.

January 10, 1903. [Vol. 82, No. 2.]

1. Boiling as a Method of Sterilizing Catheters. C. B. NANCREDE and W. H. HUTCHINGS.
2. *Veratrum Viride* as an Antitoxic. A. B. ISHAM.
3. The More Frequent Diseases of the Joints: Their Etiology and Treatment, with Report of Cases. JOSEPH H. STOLPER.
4. Intermenstrual Pain. JENNIE G. DRENNAN.

**1.—Boiling as a Method of Sterilizing Catheters.**—The present paper by Nancrede and Hutchings is really the complement of a paper previously published (*Medical News*, November 23, 1901). Their final conclusions after extensive study and many experiments are that these experiments incontestably prove that caloric can be successfully employed for all varieties of catheters with the exception of the soft French instrument, provided all air is expelled from the interior. This essential having been secured, although in a great majority of cases five minutes immersion in water which is actually boiling will suffice, ten minutes of actual ebullition should be employed, especially for the smaller calibered instruments. A previous cleansing with warm soap-suds is desirable although not essential, reducing as it does the time of exposure requisite to sterilize the instruments. The employment of a saturated solution of ammonium sulfate is desirable for English catheters but is not essential and detracts from the simplicity of the method. [A.B.C.]

**2.—*Veratrum Viride* as an Antitoxic.**—Isham believes that in grave sepsis it is one of the most potent remedies. Since the last report 27 cases have been successfully treated and he now presents 9 cases in which it was given subcutaneously. Twenty drops of Norwood's tincture is the initial hypodermic dose for an adult followed by 10 more in a half hour, when the first falls short of emesis. No supporting means or modifying agents have been thought necessary during its use. Isham injects it without dilution, though it leaves considerable soreness, lasting a day or two. Profound toxemia demands prompt emesis. These injections should be given in convulsions, high

temperature with delirium, acute hysteric paroxysms, colic from passage of calculi, gastralgia, etc. It relieves spasmodic constriction and quiets pain as well as morphin. It reduces temperature and by dehydration carries waste products out of the tissues, and equalizes the circulation. He discusses the action of its alkaloids and jervic acid. Through the latter it may claim to be a true cholagog. Blood-pressure falls from depletion of the vessels, not vasomotor paralysis. The outpouring of fluid appears to be due to stimulation of the secretory glands, not to mere transudation. The bile vomited is always green, showing change from active gastric secretion. An increased flow from the kidneys appears in 24 hours and lasts several days. [H.M.]

**3.—The More Frequent Diseases of the Joints and their Treatment.**—Stolper says no matter how far the disease of the joints may have progressed we should expect relief and positive curative effects if the proper treatment is adopted; we can have no general plan for the treatment of such diseases, but the aspirating needle and microscope give a valuable uniform plan for diagnosis. Diseases of the joints being due to many causes, the systemic conditions, family and personal history of the patient becomes of the utmost importance. His method of treatment is modified from Phelps', but superior to Phelps' method in the following points: (a) Carbolic acid, if used in drop doses only, does not have the desired effect; in large doses it causes sloughing of the parts, while bichlorid, if not allowed to be absorbed, accomplishes its purpose and can be used in any quantity; (b) the 1 to 2,000 solution is strong enough for germicidal purposes; (c) the use of alcohol hardens the tissues and prevents the absorption of the mercury, which is washed out with sterilized water. He urges the advisability and necessity of operations on tuberculous joints. [A.B.C.]

**4.—Intermenstrual Pain.**—Drennan discusses the existence of intermenstrual pain and its cause, and apparently considers that when it occurs it is connected with ovulation and the discharge of the unimpregnated ovum. It is a pain of a colicky nature, and is due to excessive muscular contractions of the fallopian tube. [W.K.]

### Philadelphia Medical Journal.

January 10, 1903. [Vol. XI, No. 2.]

1. What Can Be Done to Lessen the Mortality of Carcinoma Uteri? E. E. MONTGOMERY.
2. The Parasyphilitic Affections: The Curability of Tabes and General Paralysis by Intense Mercurial Treatment. DR. LEREDDE.
3. Remarks on the Treatment of the Visceral Ptoses. J. MADISON TAYLOR.
4. On the Practical Results of Actinotherapy. WILLIAM S. GOTTHEIL.
5. Treatment of Malignant Growths with the X-rays. WILLIAM S. NEWCOMB.
6. Urine Segregation, Its Importance and Methods: A New Segregator. ANDREW J. DOWNES.

**1.—Lessening the Mortality of Carcinoma of the Uterus.**—Montgomery lays stress upon two factors in lessening the mortality of cancer of the uterus, prevention and the early recognition of the disease. The cases of uterine cancer in the nulliparous and unmarried bears so small a proportion to the entire number of cases of this disease as almost to prove the rule that carcinoma is the result of previous traumatism. In view of this, much can be done in the way of prevention by the early repair of lacerations of the cervix before cicatricial changes occur. Next to prevention, the most important is the early recognition of the disease. In no condition is it more important that the physician should be upon the alert for the danger signals, for upon its early recognition will depend in the utmost degree the issues of life, and the assurance of success or failure. The tripod of symptoms upon which the diagnosis is based are pain, hemorrhage and discharge. It must be borne in mind that these symptoms are found in other conditions and are not regular in their occurrence in carcinoma. The mortality can also be lessened by early operation in healthy tissue and, with the exercise of precautions, to prevent the reimplantation of the disease. [F.C.H.]

**2.—The Parasyphilitic Affections.**—After having cured a case of tabes with mercurial treatment, after thorough researches upon the parasyphilitic affections and cases of recovery from tabes and general paralysis, Leredde is absolutely convinced that in syphilitic patients these diseases are not only syphilitic

in origin, but can also be cured by mercurial treatment if the mercury be pushed to very high doses. The published cases of recovery from tabes and general paralysis upon mercurial treatment cannot be doubted after a study of the question. The unsuccessful cases, though numerous, are due to incorrect treatment and to the existence of the irremediable degenerations produced by these conditions as in all other affections of the nervous system. It is an important fact that tabes or general paralysis developing in a syphilitic patient is not only syphilitic in origin but is also syphilitic in nature. [F.C.H.]

**3.—Treatment of the Visceral Poses.**—According to Taylor the only point regarding visceral poses which has not been sufficiently discussed is the possibility of repair and the methods by which this may be attained without surgical interference. His experience in the treatment of visceral poses has been chiefly among neurasthenics and persons troubled with obesity or excessive abdominal enlargements. Regulated exercises are not only entirely suitable for people well on in years, but among these the largest degree of relief is obtained from many vague disorders and painful states which had otherwise escaped relief. When these can be attributed to disturbance of circulation of the abdominal organs, not only are the viscera replaced if out of their normal position, but their functional activities if impaired are conspicuously restored. Those cases exhibiting evidences of sclerosis have obtained gratifying and surprising results. [F.C.H.]

**4.—The Practical Results of Actinotherapy.**—Gottheil gives a brief review of the literature of actinotherapy; omitting all considerations as to the nature and effect of the ultra-violet light rays and the means of employing them, confining himself exclusively to the publications dealing with therapeutic indications and results. The following diseases are considered: Lupus vulgaris and tuberculosis cutis in its various forms; lupus erythematosus; alopecia areata; carcinoma, epithelioma and rodent ulcer; acne and rosacea; nevus; eczema; keloid; and ulcers. [F.C.H.]

**5.—Treatment of Malignant Growths with the Röntgen Rays.**—Newcomet believes that the results obtained from the Röntgen ray treatment of malignant growths give us a hope that in the future we will have a method to relieve these sufferers and perhaps cure a certain percentage. Several cases of secondary recurrence of cancer of the breast are detailed, in which the treatment resulted very favorably. In some of these cases the treatment was apparently unfavorable, but closer observations showed that when the treatment was not employed the disease advanced with more rapidity. [F.C.H.]

**6.—Urine Segregation.**—Downes details the importance of urine segregation and the methods employed for this purpose, and details the value of his instrument, which was called the "Separate Urines Siphon." It was an improvement on the Harris instrument, simpler in construction, required no suction apparatus and introduced a new feature—siphonage alone for obtaining the urine from the divided bladder. A shorter instrument is used in the male bladder than in the bladder of the female. [F.C.H.]

## CLINICAL MEDICINE

DAVID RIESMAN

A. O. J. KELLY

### REVIEW OF LITERATURE

The relation of phthisis to factory and workshop conditions formed the subject of an interesting and important discussion at the recent meeting of the British Medical Association. Niven<sup>1</sup> points out the frequency of pulmonary tuberculosis in workpeople, and discusses in detail the social factors and the influence of alcoholism and of occupation in its development. With a view to diminish the frequency of tuberculosis in workpeople, he recommends: (1) Compulsory notification of all cases of tuberculosis, so that every operative may be instructed in the precautions needed to protect his fellow workmen; voluntary notification is almost equally useful in the poorer parts of the city; (2) all spitting in workshops should be prohibited. This is easier to state than to effect, but

with a great effort it may be managed. The first thing is to bring home to masters and operatives the vital necessity of the measure. Men required to spit should carry a pocket spittoon; (3) increased efforts should be made to secure so far as possible systematic wet sweeping daily in workrooms. The dry sweeping usually practised is likely to do much harm if spitting goes on. It would be an additional safeguard if the rooms were dredged with a disinfectant, as in the case of wool-sorters, under the special regulations; (4) attention to ventilation and lighting. As regards the lighting of workrooms, it is essential that there should be sufficient light by which to cleanse the workrooms in all parts, though more than this would be beneficial. If lighting must be artificial, it should be by electricity, or if gas is used it should be regarded as essential to use intensified lights by which complete combustion can be effected, with reflecting shades and tubes connected so as to carry off the wastegases and aid ventilation. [A.O.J.K.]

**Examination of the Pancreas in Diabetes Mellitus.**—Weichselbaum and Stangl<sup>1</sup> report 32 cases of diabetes, in all of which they made studies of the pancreas with especial reference to the islands of Langerhans. They found the pancreas diseased in all the cases, but the changes affecting the islands of Langerhans were especially marked and constant. These alterations concerned the number, size, and structure of the islands. There was diminution of their size and number in all the cases, but in addition they were affected by one or more of three special changes: simple atrophy of the epithelium, vacuolation and liquefaction of the epithelium, and sclerosis of the islands; occasionally hemorrhage and calcareous infiltration were also present. All of these changes, however, led to diminution of size and ultimate destruction. The alterations in the parenchyma of the pancreas were neither constant nor ever sufficiently marked to be considered of primary importance. The lesions included atrophy of the tubules, proliferation of the central acini, increase in the amount of interstitial connective tissue, interstitial pancreatitis both acute and chronic, fat necrosis, lipomatosis, cirrhosis of the pancreas, and atheroma of its arteries. Their results correspond very closely with those of other recent observations. The authors believe that the parenchymatous alterations and those in the islands of Langerhans are entirely independent of each other. While they are not positive in the statement that the changes in the islands of Langerhans cause diabetes, still they believe that the evidence gathered of late by themselves and others is in favor of the existence of such a causal relation. In addition to pathologic changes mentioned above they base their opinion on the facts that the alterations in the islands of Langerhans have never been observed in other diseases; that cases in which pancreatic disease exists without change in the islands of Langerhans are nondiabetic; that the Langerhans changes are constant in diabetes, the alterations in the rest of the pancreas are not; and that inasmuch as the two parts of the pancreas are so different in their development and structure it is likely that they also vary in their function. [E.L.]

**Transmission of Human Tuberculosis to Cattle.**—Johannes Fibiger and C. O. Jensen<sup>2</sup> report the results of their experiments on inoculations of cattle with bacilli from human beings affected with localized tuberculosis, with the object of ascertaining whether the organisms from these local lesions, *e. g.*, chronic intestinal tuberculosis, behave differently from the ordinary human tubercle bacilli, and whether, through their greater virulence for cattle, it is possible to detect their bovine origin. Inoculations of calves from three cases of tuberculosis of children showed the bacilli to be so virulent as to warrant the conclusion that the cases were all due to infection from cattle. Taking all their cases together they found the greatest variation in the virulence of bacilli for calves—from complete avirulence to virulence of the highest degree. This suggests the thought that possibly the virulence of tubercle bacilli for cattle is gradually weakened by retention in the human organism. [C.S.D.]

**On Sugar as a Food.**—L. M. Cowley<sup>3</sup> presents a review of recent contributions on the value of sugar as a food, and finds that in most cases it fills a true physiologic need, and is

<sup>1</sup> Wiener klin. Woch., September 18, 1902.

<sup>2</sup> Berliner klinische Wochenschrift, September 22, 1902.

<sup>3</sup> Revista de Medicina y Cirurgia, September 10, 1902.

<sup>1</sup> British Medical Journal, September 13, 1902.

naturally sought for in such fruits and plants as contain it. It has been demonstrated to be a most economic ration, owing to the ease with which it is assimilated and to the relatively large amount of energy which it affords. It has been shown by Lucke, of Strasburg, and others to possess marked antiseptic properties, and because of this virtue is employed as a topical dressing. [C.S.D.]

#### Intestinal Secretion and the Action of Drugs Thereon.

—Edkins<sup>1</sup> states that he was unable to demonstrate experimentally the existence of an intestinal secretion, and that he was unable to find in the work of others any convincing evidence of the existence of such secretion. He is disposed to think that the actions of cathartics is due to (1) removal or destruction of the intestinal epithelium; (2) diffusion of some part of the drugs into the lymph spaces, thus allowing them to affect the nerve endings, and so cause an increase of peristaltic movements; (3) escape of lymph into the lumen of the gut, causing a watery state of the contents, though this is probably of much less importance than the exalted peristaltic action. It is not in the least necessary to call in the aid of a secretion heightened by the action of drugs. Normally there is practically no evidence of the existence of such a secretion. [A.O.J.K.]

**The Classification of Cirrhosis of the Liver.**—As stated by Arthur R. Edwards<sup>2</sup> a classification of hepatic cirrhosis may be made upon an etiologic, pathologic or clinical basis. Schematism and over refinement are often observed in the classifications made, yet it is difficult to formulate a division to include all varieties without some contradictions, either pathologic or symptomatic. Accurate theoretic and pathologic differentiation is important with reference to the therapy, as in syphilitic cirrhosis, in malaria, gout, diabetes, dyspepsia, lead poisoning or other kindred causes, and again in the atrophic cirrhosis, in the relief of which surgery now plays a constantly increasing role. [F.C.H.]

**Diaphragmitis.**—Rohrer<sup>3</sup> calls attention to the pathologic findings in cases of inflammation of the diaphragm complicating pneumonia. He believes it to be a common complication of pneumonia and says that in most of those cases in which it is not found it will be observed that the specimen was obtained from a part of the diaphragm remote from the inflamed lung. Extension of the inflammatory process from the pneumonic lung to the diaphragm takes place in two or three ways—(a) by direct extension; (b) by the lymphatics; (c) by the blood vascular system. He says that to inflammation of the diaphragm is due in large part the "pleuritic stitch pain," also the pain in the abdomen often complained of, especially by children. When the patient lies on the affected side the pain is diminished because there is less motion of the chest-wall and diaphragm in that position. The dyspnea of frequency, always present in pneumonia, is due in large part to the patient's efforts to restrict the movements of the diaphragm. The condition is principally a myositis, and may be mild or intense, in keeping with the grade and extent of the pneumonic condition. It is of bacterial origin, the usual microorganism being the pneumococcus. [C.A.O.]

#### Bacteriologic Research in Six New Cases of Noma.—A.

Trambusti<sup>4</sup> concludes from these cases and from the experience of Comba, Longa, and others that the bacillus isolated by him and described in *Il Policlinico*, January, 1902, is not the specific cause of this disease, and that noma is not to be regarded as a specific malady but as a form of gangrene which may be determined by a variety of microorganisms in association with the species commonly found in the body cavities communicating with the exterior. [C.S.D.]

**Tetanus and Vaccination.**—McFarland,<sup>5</sup> as a result of an analytic study of 95 cases of this rare complication, concludes: 1. Tetanus is not a frequent complication of vaccination. 2. The number of cases observed during 1901 was out of all proportion to what had been observed heretofore. 3. The cases are chiefly American, and occur scattered throughout the eastern United States and Canada. 4. The cases have nothing to do with

atmospheric or telluric conditions. 5. A small number occurred after the use of various viruses. 6. An overwhelming proportion occurred after the use of a certain virus. 7. The tetanus organism is in the virus in small numbers, being derived from the manure and hay. 8. Occasionally through carelessness or accident the number of bacilli becomes greater than usual, and may lead to the epidemic occurrence of tetanus. 9. The future avoidance of the complication is to be sought for in greater care in the preparation of the vaccine virus. [A.O.J.K.]

**The Toxicity of Methyl Alcohol.**—Reed Hunt, associate professor of pharmacology in Johns Hopkins University, Baltimore, Maryland,<sup>1</sup> was led by the reported cases of poisoning from methyl alcohol used as an ingredient in medicine, or in flavoring agents, such as essence of Jamaica ginger, peppermint, etc., to review carefully the symptoms of acute and chronic poisoning from this substance. In acute poisoning with methyl alcohol the state of coma is deferred, but the duration of the intoxication is prolonged. There is a marked falling of bodily temperature, and hemorrhages from the abdominal tract occur. Convulsions of a rhythmic or choreiform character occur, and sometimes persist for a day or two, being followed by loss of sensation and of reflex movement. Convulsive movements of the eyes are characteristic, and often constitute nystagmus of a pronounced type. There is usually dilation of the pupil. Methyl alcohol is capable of injuring the eye to a far greater extent, and also in smaller doses, than is ethyl alcohol. In cases of chronic methyl alcohol poisoning, the ganglion cells of the retina showed degeneration changes. The interesting and highly important discovery has been made that methyl alcohol is partially oxidized in the body, and that its administration leads to the formation within the body of a markedly poisonous acid (formic). Even when small quantities of methyl alcohol are administered, quantities too small even to cause narcosis, formic acid is still found in the urine. This shows how difficult it is for the body to completely oxidize methyl alcohol. The tendency to attribute the poisonous qualities of methyl alcohol to impurities appears to be without good reason, as it has been found that even in crude commercial preparations of wood alcohol impurities are not present in sufficient quantity to cause death. In this connection Kuhnt and others have decided that the blindness and death in the cases which they have studied could never have been caused by any of the impurities or by all combined, but that they are due to the methyl alcohol alone. [C.S.D.]

**Carcinoma.**—In discussing the causation of carcinoma, Reyburn<sup>2</sup> says that it is probably always local in its early stages, and that its origin is due to an injury or local irritation of the part affected. He believes that it is a disease of senility or decay of the tissues, or at least occurs at the time when the retrograde metamorphosis of the tissues is taking place. It is comparatively rare in hot climates, and especially where the diet of the inhabitants is composed chiefly of rice or other starchy foods. The disease is very prevalent at the present time where animal food is largely consumed; the number of cases of carcinoma has been found to increase in proportion to the increase in the consumption of nitrogenous or animal foods. The writer says that the theory of Dr. Gaylord, that carcinoma is caused by a protozoon or animal microorganism, seems to be disproved by later investigations, and that the probability is that carcinoma is simply erring epithelium which has taken an abnormal growth and development. [C.A.O.]

**A case of hemophilia** in a woman with symptoms of defective circulation in the legs and threatened gangrene of the toes, and the occurrence of death with cerebral symptoms, is reported by Arkwright.<sup>3</sup> [A.O.J.K.]

**Typhoid Fever and Tuberculosis.**—Péhn<sup>4</sup> cites two cases to show the successive development of these two diseases as opposed to the former view that there is an antagonism between them. The first was a robust man of 34, who had a severe and long-continued attack of typhoid fever. Six weeks after its onset the signs of pulmonary tuberculosis appeared and later

<sup>4</sup> Lyon Médical, November 2, 1902.

large numbers of tubercle bacilli were found in the sputum. The second case was a woman of 24, who, while in a hospital, developed pulmonary tuberculosis and typhoid fever intercurrently. The first patient is still living and engaged in hard labor; the second died within four months. [A.G.E.]

**The Movements and Innervation of the Stomach.**—May,<sup>1</sup> as a result of experimental investigations, concludes that the vagus controls both motor and inhibitory fibers of the stomach musculature, and that the influence of these fibers is definite and easily demonstrated. On the contrary, it is believed that the splanchnic nerves have no direct influence, either motor or inhibitory, on the muscular wall of the stomach. [A.O.J.K.]

**The Clinical Value of Ehrlich's Dimethylamidobenzaldehyde Reaction.**—Kozickowsky,<sup>2</sup> by a large number of experiments and tests, determined the clinical significance of Ehrlich's dimethylamidobenzaldehyde reaction. To obtain this test a tube is filled one-third full of urine and 10 drops of the dimethylamidobenzaldehyde solution added. If the reaction be positive, the color of the urine will turn red. The author uses a scale of colors to determine the intensity of the reaction by comparison. This scale is marked with the following tints: cognac color, rose color, light and dark red. A pathologic condition is indicated only when one of the two last colors are present. The test-tube should be allowed to stand for one minute before determining the presence of the reaction. Kozickowsky tested 1,000 specimens of urine, and concluded that the pathologic reaction occurs in the severe constitutional diseases. It is not a specific test for any one disease, nor does it occur in all severe diseases. It is of clinical significance, however, because it may indicate the development of a complication or a severe stage of a disease. This reaction, with the aid of the clinical symptoms, should be an indicator of the degree of intoxication, and its disappearance for several days in succession indicates a lessening in the severity of the disease. The author determined that fever alone could not produce this reaction. [W.E.R.]

**Fatal Ulcerative Streptococcus Colitis; Blood-casts of the Colon.**—Beck<sup>3</sup> reports that a male patient of 34 had suffered at the age of 16 for three weeks from an acute attack of dysentery, and at the age of 22 from typhoid fever and pneumonia, after which he enjoyed remarkably good health. In the present attack he suffered from periodic attacks of diarrhea lasting two days and occurring at intervals of about one week. After four of these attacks he was free for several weeks when the diarrhea returned, the disease again being characterized by periods of intermission, but in each successive attack the symptoms became more pronounced, and there was rapidly progressing emaciation and corresponding weakness. During these attacks he had never observed blood in the stools. Eight days before admission he was seized with intense abdominal pains, and began to have frequent evacuations of the bowels—15 to 20 movements daily. The patient passed two casts of the intestine measuring 13 cm. and 42 cm. (5 inches and 13 inches) respectively. The patient died in collapse and necropsy showed the large intestine to be the seat of numerous ulcers. Spreads made and observed microscopically showed numerous colon bacilli and streptococci. [A.B.C.]

**An instance of temporary reminiscence of a long-forgotten language during the delirium of bronchopneumonia** is reported by Freeborn.<sup>4</sup> [A.O.J.K.]

**Experimental Examinations Concerning the Nature of the Circulatory Disturbances in Collapse During Acute Infectious Diseases.**—The teaching concerning the cause of circulatory weakness in collapse during acute infections has been, until lately, that it depends upon a paresis of the vasomotor center of the medulla. Pässler and Rolly's<sup>5</sup> denial of this is based upon a series of experiments with dogs infected with diphtheria toxin in whom the disturbance was claimed to have been due to cardiac paresis. To decide this question they are using an entirely new method of experimentation.

The working capacity of the heart in rabbits was tested by measuring the blood-pressure of infected animals before and during collapse, in the carotid artery and in the auricle, the demands on cardiac power being increased at the same time by abdominal massage and compression of the aorta. The reflex irritability of the vasomotors was noted through the faradic stream. They used diphtheria toxin and pneumococcus cultures for experimentation, and after producing intoxication with them, it was seen that the vascular disturbance always began as a vasomotor paresis. The heart muscle acted so well through it all that even after the beginning of the arterial palsy the blood-pressure remained the same. Cardiac weakness appeared only after the carotid pressure sank secondary to complete vasomotor paresis, and this is more due to a deficiency of the blood-supply to the heart muscle, due to the vascular paresis, as proved by the fact that if sufficient blood is given to the heart by aortic compression and greater distention of the bloodvessels the cardiac weakness disappeared for the time. The pneumococcal infection did not injure the heart muscle, but the diphtheria-heart showed a diminished resisting power in asphyxia, the direct result of the diphtheria poison. [E.L.]

**Leukocytosis in Pneumonia.**—Lambert and Daley<sup>1</sup> report their observations of leukocytosis in 87 cases of acute lobar pneumonia, varying in degree of severity and extent of lung involvement. They found that there was no ratio existing between the amount of leukocytosis and the height of the temperature. When two or more lobes were involved the count was higher than when only one lobe was affected, though the severity of the infection influenced the count more than the extent of pulmonary exudate. A persistent low count, *i. e.*, below 7,000, indicates a fatal prognosis. Of 21 fatal cases the count varied from 10,600 to 56,000, averaging 32,778. In some cases the count began with 13,000 to 14,000, and fell rapidly to 2,600 on the day of death. In others, just before death the count rapidly rose to from 20,000 to 23,000. In 21 cases with protracted resolution, the counts varied from 8,000 to 63,000, averaging 21,851. Of 40 uncomplicated, moderately severe, and very severe cases the count averaged 22,268. In the mild cases with high temperature the average count was 15,577, with low temperature the average count was 12,669. Extension of the process is often followed by an increase in leukocytosis. When there is an extension of the process and resolution of previous consolidation the count rises. In one case, complicated by a serous effusion, the count rose from 19,600 to 25,400. In six cases in which empyema complicated pneumonia there was a sudden rise in the count to about double the count on the previous day. They conclude that variation in the count points to (1) an extension of exudate, (2) sudden resolution, (3) both of these, (4) or to a sudden development of a purulent infection superimposed upon a preexisting pneumonia. [J.H.W.R.]

**Contribution to the Study of Cyclic Vomiting in Children.**—F. Valagussa<sup>2</sup> is of the opinion that recurrent vomiting occurs in children inheriting a uric diathesis, that it is a sign of abnormal metabolism and may be absolutely separate from any affection of the gastrointestinal apparatus. The disease is not a morbid entity but a complex syndrome of which vomiting is the principal symptom. The pathogenesis of the recurrent attacks holds the relation of an acid intoxication of the organism, which we designate uricacidemia, and the recurrent vomiting may be considered as the equivalent of gouty attacks in children of arthritic heredity. [C.S.D.]

**Pneumococcal Meningitis: Recovery with Persistence of Slight Brachial Paralysis.**—This case is reported by Archard and Grenet.<sup>3</sup> The patient was a man of 58, with symptoms including intense pain in the head, back and legs, chills, fever, sweating, etc. Spinal puncture was performed six times, cultures from the fluid removed at one of them showing the characteristic diplococcus. Hytologic examination of the fluid obtained at various punctures showed the following: Only polymorphonuclear cells; lymphocytes, 81%; polymorphonuclears, 19%; some endothelial cells; polymorphonuclears, 55.6%; lymphocytes, 44.6%; polymorphonuclears, 92.7; lympho-

cytes, 7.3%; complete disappearance of polymorphonuclears, a few lymphocytes present; entire absence of cellular elements. Cytoscopy of the fluid gave the following for the six specimens: -0.55, -0.41, -0.38, -0.56, -0.50. The oscillations of the leukocytes followed more or less closely the irregular fever, the great polymorphonuclear increase noted as occurring in the fourth sample being coincident with a marked recrudescence of fever. The favorable termination of the case was perhaps due to the comparatively low virulence of the organisms, inoculation into a mouse not causing its death. [A.G.E.]

**Hairballs and Other Concretions in the Stomach.**—Fenwick<sup>1</sup> discusses hairballs and other concretions in the stomach, pointing out that hairballs are much more common in young women than in other persons, and that while they may be present without noteworthy symptoms they usually occasion more or less gastric disorder. Vegetable tumors are much less common than hairballs, and consist usually of fruit skins, fruit stones and stalks, or the fibrous roots of certain medicinal plants. Gastroliths usually occur in men about middle age, who from a morbid desire for alcohol in any form have been in the habit of drinking varnish, polish, or any other resinous fluid containing it. Most cases have been mistaken for carcinoma of the stomach (on account of the common palpable tumor), but the diagnosis is usually possible by attention to the age and sex of the patient, the duration of the complaint, and the physical characters of the tumor which, in the case of the hairball, is crescentic or globular in form smooth, hard, painless, and so freely movable that it can be pushed upward beneath the left costal arch. Furthermore, the outlines of the tumor cannot be distinguished from those of the stomach, HCl is usually present in the vomit, and it is impossible to insert a tube more than two inches into the stomach. In most cases the appropriate treatment is operative. [A.O.J.K.]

**The Causes and Treatment of Angina Pectoris and Allied Conditions.**—Breuer<sup>2</sup> agrees with the schools of French clinicians, who consider true angina pectoris with its violent retrosternal radiating pain, its feeling of cardiac oppression, and impending death, a consequence of the sudden anemia of the heart muscle. The coronary arteries or the aorta in their neighborhood are sclerosed; they supply sufficient blood to the heart in a period of rest, but when bodily exertion or increased arterial pressure call for more blood they cannot supply sufficient and the anemia thus produced causes the stenocardial conditions. The cardiac weakness, which was formerly considered the cause of the attack, is only a result of the anemia and is proportional to it. The diagnosis of true angina from pseudoangina is usually easy. In the former disease the attacks are usually, if not always, due to heightened muscular efforts; in the latter, of which there are four subvarieties (hysterical, reflex gastric, neuritic, and toxic), they are spontaneous, or brought on by mental emotion. He considers the treatment of angina from the standpoint of its attacks and their prevention. The best drugs for the former are morphin, amyl nitrite, and nitroglycerin, for the latter erythronitrol, nitroglycerin, the iodids, but especially does he praise theobromin, which was first recommended by Askanazy in 1895, and which is considered by him one of the most beneficent therapeutic discoveries of the age. It is best given in the form of diuretin in daily doses of from 40 to 50 grs., which then must be gradually reduced until the minimal dose preventing the attack is found. It, like the nitrites, prevents the attack only while being taken, but it can be used for weeks without the slightest unpleasantness. The author publishes a number of observations in which theobromin or one of its derivatives was used, and in all of them—and they included not only true coronary angina, but also such allied states as aortic, aneurysmal and nicotinic stenocardia, and several cases of gastric and abdominal cramps, some of which came to autopsy later proving themselves to have been arteriosclerosis of the abdominal aorta and its branches—was the number of attacks markedly diminished. He discusses the differential diagnosis of these various states, intermittent dysperistalsis due to intestinal anemia, intermittent claudication, etc., tracing their connection

to angina pectoris and other sclerotic conditions. The action of theobromin diminishes the pathologic reflex irritability of the arteriosclerotic bloodvessels, preventing the onset of spasms, just as do the slower acting nitrites. It also probably diminishes blood-pressure. He also advises the drug in cases of headache, in which the origin is probably arterial. [E.L.]

**A case of membranous gastritis** terminating in recovery of the patient (with a review of the literature) is reported by Grünbaum.<sup>1</sup> [A.O.J.K.]

**Actinomycosis in America.**—After summarizing previous contributions to the subject W. J. Ewing<sup>2</sup> gives an account of six cases noted by himself. About 100 cases of this disease have occurred widely spread throughout the United States. Though the affection is not confined to either sex or to any special age or occupation, it occurred in 36% of the cases in persons handling cattle or grain. The clinical characteristics vary with the part of the body attacked; abscesses are formed and when facial the pain is often mistaken for toothache and teeth are extracted without relief. Bronchial cases simulate pulmonary tuberculosis and abdominal cases appendicitis. Diagnosis is uncertain without demonstration of the ray-fungus, which occurs in the contents of the abscess. The spread of the disease is sluggish by infection of contiguous tissue or by metastasis, the blood current acting as carrier. Treatment with injections of cynamyl, muriate of cocain, zinc chlorid, and silver nitrate, respectively, has resulted favorably in some cases. Many cases have been treated surgically by excision, incision, and curetage. Recovery followed with great difficulty and only after repeated operation, except when potassium iodid was used in connection with operative treatment, in which case the action of the drug brings about a solution of the cellular infiltration around the abscess and the discharge of the ray-fungus in imitation of nature's own method of healing. [C.S.D.]

**Pancreatic Lithiasis.**—Kinnicutt<sup>3</sup> reports a case of pancreatic lithiasis, the calculi having been recovered from the stools, and reviews the literature (6 cases). Of the symptoms described by different writers, nausea, vomiting, and diarrhea, cannot be regarded as characteristic. The pain does not differ in kind or location from that of cholelithiasis, although in one case the location of the pain along the left costal arch was possibly suggestive. The presence of an unusual number of undigested striated muscle fibers in the stools cannot be regarded as positively diagnostic. An abnormal amount of fat in the feces is by no means a constant or even frequent symptom of pancreatic disease. The presence or absence of jaundice is not of diagnostic importance. The decisive evidence of pancreatic lithiasis is the recovery of the characteristic concretions in the stools. With the exception of the concretions in the stools the symptoms mentioned may fail to furnish evidence of pancreatic lithiasis, but their various combinations may be suggestive. Thus, attacks of epigastric colic of obscure nature, with or without jaundice, associated with a large number of muscle fibers in the stools, accompanied or followed by glycosuria, should be regarded as a reasonable basis for a diagnosis of pancreatic lithiasis. Müller's investigations indicate that a greatly diminished splitting up of the ingested fat *per se* positively indicates the absence of pancreatic juice in the intestinal digestion. In this case, therefore, in the absence of cachexia or other signs of a neoplasm of the pancreas or of neighboring organs which would occlude the ducts by pressure, a pancreatic lithiasis should be suspected. [A.O.J.K.]

**Tropical or Amebic Abscess of the Liver and Its Relationship to Amebic Dysentery.**—Rogers<sup>4</sup> states that the ameba is constantly found in an active condition in the wall of tropical abscesses of the liver, although frequently absent from the pus in its cavity. The ameba is the only organism constantly found in such abscesses. Staphylococci and other pyogenic bacteria are absent from the pus in a great majority of cases when the abscess is first opened. In cases in which a complete record is available there is either a history of dysentery, or lesions of this disease are found postmortem in over 90% of the cases, and it cannot be certainly excluded in the

<sup>1</sup> British Medical Journal, 1902, ii, 1096.

<sup>2</sup> Münchener medicinische Wochenschrift, September 30 and October 7 and 14, 1902.

<sup>3</sup> Lancet, ii, 283, 1902.

<sup>4</sup> Johns Hopkins Hospital Bulletin, November, 1902.

<sup>5</sup> American Journal of the Medical Sciences, cxxiv, 948, 1902.

<sup>6</sup> British Medical Journal, ii, 844, 1902.

remainder. The dysentery precedes the liver abscess or lesions in the large bowel of an antecedent date are found postmortem in 95% of the cases. The form of bowel disease associated with the large tropical or amebic abscess of the liver is amebic dysentery. Severe sloughing forms of catarrhal dysentery may be associated with small multiple pyemic abscesses, which is a totally distinct condition from tropical or amebic abscess, and is very rarely recognized during life. Quinin solutions rapidly destroy the ameba, and may be used with advantage in washing out liver abscesses after they have been opened. They are also worthy of a trial as injections after aspiration of the pus as a possible curative measure, especially in such cases as are free from the ordinary pyogenic organisms. [A.O.J.K.]

## GENERAL SURGERY

MARTIN B. TINKER

A. B. CRAIG

C. A. ORR

### EDITORIAL COMMENT

**Antiseptic and Aseptic Surgery.**—Since the days when Pasteur first showed that germs cause wound supuration and Lister devised his carbolic acid method of destroying bacteria, so many other methods of accomplishing the same end have been devised, that to enumerate them would be an almost endless task. While the number of chemicals and the methods of using them are so numerous, no efficient bactericide has yet been found which does not also affect delicate tissues to some extent. This was first laid down as a principle by Lister in his own words as follows: "An antiseptic is injurious to the cellular elements of the body as well as to microbes. The art of the surgeon lies, therefore, in employing it in a sufficient but not excessive dose." The knowledge of this injurious effect on the tissues led to the introduction of the methods of aseptic surgery. By means of boiling and the use of autoclaves we are now able to prepare germ-free dressings and instruments without the use of antiseptics. Gloves, masks and elaborate operating-room outfits have added still further to the complex possibilities of preparation but in the hands of certain operators have resulted in increased safety to the patient. Some like Schleich have gone so far as to entirely discard the use of antiseptics, even in the preparation of the hands and the skin of the patient and this method when thoroughly carried out has given good results. Bacteriologic examination, however, shows that without the use of antiseptics, germs are always present and perfect healing is due to the vitality of the parts. At present the majority of conservative surgeons who claim to practise aseptic surgery have continued to make use of antiseptics to some extent, believing that there is less danger from injury to tissues with suitable solutions than from bacteria. While the introduction of aseptic methods gives excellent results without any wound reaction it is certain that except in the hands of those thoroughly trained by long experience with careful men, the method is far less safe than the antiseptic method. A point which is frequently forgotten is that no matter how careful the preparation of the operator and the patient, both must keep clean after being once prepared. Of late the tendency seems for the pendulum to swing back in favor of the more liberal use of antiseptics than formerly, though extreme measures such as the use of the spray, originally recommended by Lister, are not being reintroduced. As would be natural to expect, a number of papers which have recently appeared in the Lister jubilee number of the *British Medical Journal* especially emphasize the advantages of the antiseptic method as compared with aseptic methods. So eminent a surgeon as Lucas-Championniere, of Hotel Dieu, Paris, makes the statement that he has always exactly followed the original Lister method and he believes that accidents are always the penalty of infidelity to this well established principle. While few have adhered to the original method, we

believe that those who have done so are not as far from the position of the average conservative surgeon of the present day as those, like Schleich, who have gone to extremes in aseptic methods, and so far as the safety of the patient is concerned, this middle ground will in the future no doubt be the one generally adopted.

### REVIEW OF LITERATURE

**Adhesive Perigastritis Secondary to Gastric Ulcer.**—Duplant<sup>1</sup> speaks of the symptomatology and treatment of these lesions and reports several cases. Two types of perigastritis are observed, the first and most frequent corresponding to ulcers on the small curvature and anterior surface of the stomach. In this type, the left lobe of the liver, the parietal peritoneum under the left false ribs and the omentum may be adherent to the stomach. Consequently pain is felt on the left side and is increased by pressure under the left false ribs. A slight induration or even a tumor may be felt in the left epigastric region. The second type corresponds to pyloric ulcers. Subjective symptoms are not marked unless there is pyloric stenosis. Perigastritis rarely induces vomiting unless there is stenosis. Treatment is surgical intervention and Duplant believes that gastroenterostomy should be added to freeing of adhesions, whether there be pyloric stenosis or not. [A.G.E.]

**Congenital Hydronephrosis.**—Acker<sup>2</sup> reports two cases. The condition was due to congenital malformation of the urinary canal. In the cases described the cause was found in the bladder near the opening of the ureter or the verumontanum. Both cases were operated upon, death ensuing in one case in three hours and in the other in eight hours. [J.H.W.R.]

**Aseptic Method of Lister in the Present and in the Future.**—Lucas-Championniere<sup>3</sup> gives great praise to Lister and says he gave a scientific basis to surgery. He made it rest on established truths. He did away with that uncertainty in which the greatest surgeons up to that time had left it, and inspired by the ideas of Pasteur concerning the infinitely little and on fermentations, he conceived the idea that the infinitely little and its germs of all kinds everywhere strove against any efforts of the organism toward repair. His first practical attempt consisted in withdrawing a compound fracture from the action of these germs. He recognized that without cutting off the access of air he was able to transform this compound fracture into a center in which the process of repair was identical with that occurring at the center of the simple fracture. He could at will withdraw it from these complications of wounds which, he maintained, were all of a septic nature. To free the wound from germs was sufficient. He removed those which had collected in it, he prevented the introduction of new ones at the time of dressing and their access during the interval between the dressing and the final cicatrization of the wound, and thus proved to the world the practicability of his ideas concerning the aseptic treatment of wounds. [A.B.C.]

**Malignant Disease of the Gallbladder.**—Mayo<sup>4</sup> states that of 405 operations on the gallbladder and biliary passages, for all causes, 20 were for malignant disease. He then discusses the etiologic relationship between gallstone disease and cancer of the gallbladder, concluding from the following facts that gallstones are the most important etiologic factor: 1. Gallstones are almost constantly present in primary malignant disease of the gallbladder and rarely in secondary. 2. The relative proportion of gallstone and malignant disease of the gallbladder in women and men is practically identical. 3. The pathologic lesions found are best explained by this theory. 4. The similarity in age frequency. If the proportion be only 1 in 20 it certainly aids in deciding that the early removal of active gallstones is sound surgery. The diagnosis is considered, attention being called to the fact that a cystic gallbladder of long standing or an adherent bladder shrunken upon a mass of stones may give rise to a hard tumor simulating malignant disease. Four cases are reported, cholecystectomy being followed by recurrence in three. One of the latter was a partial hepatec-

<sup>1</sup> *yon Médical*, December 14, 1902.

<sup>2</sup> *Washington Medical Annals*, November, 1902, p. 330.

<sup>3</sup> *British Medical Journal*, December 13, 1902.

<sup>4</sup> *Northwestern Lancet*, December 15, 1902.

omy. Mayo states that all cases in which the liver or the glands in the fissure of the liver are secondarily involved are followed by early recurrence. [A.G.E.]

**Surgical Treatment of Chronic Nephritis.**—Lepine<sup>1</sup> discusses the surgical measures useful in chronic nephritis and reviews the literature on the subject. Certain cases reported by Harrison, Israel, Edebohls and others, had led to the hope that by irritating the periphery of the kidney, thus relieving congestion and stimulating the formation of new bloodvessels, an amelioration in the process of chronic nephritis might be accomplished. Lepine believes in the cases of displaced kidney in which the ureter is twisted, and in consequence a nephritis has developed, that fixation of the kidney is justifiable. Clinical experience has demonstrated in certain cases the usefulness of this operation, which has been followed by a disappearance of the nephritic pain and the bloody urine, symptoms which have resisted previously all medical treatment. After decortication in cases of Bright's disease, the urine is first diminished and then increased, but without presenting any change in composition during the following weeks. To determine the effect of operative procedures on venous stasis he performed experiments on dogs, artificially producing venous stasis, then later decapsulating the kidney. There was no appreciable increase in the amount of urine after the last operation. In the case of painful unilateral congestion which has resisted all medical measures, or a case of anuria following a "poussée congestive," operation is indicated. He believes it is possible by decapsulation to favorably affect the functional activity of the secreting cells of the kidney, but the operation is a serious one and is particularly grave when done upon a patient more or less enfeebled, and who is perhaps threatened with uremia. Operation upon simple Bright's disease cannot be advised. [J.H.W.R.]

**Acute Hemorrhagic Pancreatitis.**—The case described by Lando<sup>2</sup> was that of a middle-aged man who died 31 hours after the onset of acute epigastric pain and vomiting. Autopsy showed areas of fat necrosis in the abdominal wall and omentum, but the changes in the pancreas were different from those of previously reported cases. Lando compares them as follows: (1) Instead of an infiltration of red blood-cells, there were only the remains of their disintegration; (2) instead of normal areas interspersed between the necrotic ones, there could not be found in any portion perfectly normal acini; (3) instead of small-celled infiltration being marked, it was seen in only a few scattered areas; (4) instead of a marked increase throughout of the connective tissue, there was only a slight increase in the region of the tail of the organ. [A.G.E.]

**Traumatic Stricture of the Esophagus.**—Borden<sup>3</sup> reports the case, which was operated upon by Abbe's method. The patient, a man, while insane had swallowed a solution of iye, which resulted in the development of a stricture of the esophagus. An unsuccessful attempt was made to dilate the stricture by retrograde dilation, and later Abbe's method was successfully employed. This consisted in passing from above downward through an opening in the neck into the stomach a filiform sound, to which was attached a silk thread. The sound was brought through the previously made opening in the stomach and traction with a sawing motion was made with the silk thread until it was possible to pass a stomach tube. The operation was successful, both wounds healing rapidly. [J.H.W.R.]

**Plugging with Iodoform Gauze in Operations Performed in Cavities of the Body.**—Von Bergmann<sup>4</sup> describes the method in three operations in which the pharyngeo-oral cavity has to be opened, viz., resection of the upper jaw, operations on the tongue, and total extirpation of the larynx. In each of these operations he packs the wound with iodoform gauze, and the results show rare infection, even though the area of operation is in close contact with the secretions from the mouth. Up to the year 1900 he had performed 47 total and 23 partial resections of the upper jaw. Of the 47 resections, 7 patients died—4 of broncho pneumonia, 1 of collapse, 1 of pul-

monary embolism, and 1 of erysipelas. Of the 23 partial resections, 1 patient died of pneumonia. Infection occurred in one case, that of erysipelas. In extirpation of the tongue, or of large pieces of the tongue for carcinoma, he invariably carries out Langenbeck's method. The wound which remains in the floor of the oral cavity and in the lateral wall of the pharynx is tightly plugged with iodoform gauze as is the wound in extirpation of the upper jaw, the method for which he describes in detail. He has performed 159 of these operations, 131 of the patients recovering and 28 dying. Of the deaths, 16 occurred in the course of a few hours following the operation or during the first two days, shock being responsible for them. In the remaining 14 deaths, 9 were caused by aspiration pneumonia, thus showing infection of the wound in a very small percentage of the cases. He has performed 46 operations on the larynx, 20 for total extirpations and 28 one-sided operations or excision of small segments. Of the 20 total operations, 6 patients died soon after the operation, not one of cellulitis of the throat, but all of aspiration pneumonia. Up to 1890 he had performed 11 total extirpations with 5 deaths. After that he never performed the operation without shutting off the mouth and throat cavity from the trachea, and in 9 subsequent operations there was but 1 death. [A.B.C.]

**Tuberculous Rheumatism: Essential Hydrocele of Tuberculous Origin.**—By essential hydrocele Rome<sup>1</sup> means that form which is without granulations or classic tuberculous lesions and with integrity of the testicle and epididymus. He reports the case of a man of 60, who at the age of 14 had synovitis of the right knee, this being followed by three other attacks, the last at the age of 60. The man also had double orchitis at the age of 16. At the age of 57 a right hydrocele appeared, this and the knee being operated on three years later. The tunica vaginalis was thickened but showed no classic tuberculous lesion. The testicle and epididymus were normal. Animals inoculated with the fluid developed tuberculosis. [A.G.E.]

**Chronic Pancreatitis.**—Hardin<sup>2</sup> reports the case, which occurred in a woman of 49, who had previously had both breasts removed for cancer. The symptoms came on acutely and consisted of severe pain in the epigastrium lasting for four hours, which was followed by a sense of fulness and discomfort in the region of the stomach, associated with frequent eructations of gas. Attacks of pain recurred every third day, while during the interval the stomach symptom persisted. There were present some rise of temperature, jaundice, nausea, constipation, and neurasthenic symptoms. The examination was practically negative, except for slight tenderness and resistance to deep pressure in the epigastrium. An operation was performed, but as the pancreas was found enlarged and nodular the presence of a cancer was suspected, and nothing was done except to open and drain the gallbladder. A small piece of the pancreas was removed for examination, which showed chronic pancreatitis but no cancer. The patient recovered entirely. He divides the causes of chronic pancreatitis into (1) obstruction of the pancreatic duct by calculus in the duct, a gallstone in the common bile duct, or a gallstone in the diverticulum of Vater; (2) infection by microorganisms; (3) toxic substances in the blood. He discusses the symptoms, diagnosis, prognosis, and treatment of this disease, which was first described in 1896 by Riedel, though not until recently has its true significance been recognized. The treatment is purely surgical. [J.H.W.R.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### REVIEW OF LITERATURE

**Early Rupture of Tubal Pregnancy.**—The rupture of a tubal pregnancy in a young woman seven days after missing one menstrual period is reported by Banga.<sup>3</sup> Symptoms were those of internal hemorrhage, and operation 38 hours after the onset revealed a small, ragged perforation of the left tube near

<sup>1</sup> La Semaine Médicale, December 3, 1902, p. 397.

<sup>2</sup> St. Paul Medical Journal, January, 1903.

<sup>3</sup> Washington Medical Annals, November, 1902, p. 375.

<sup>4</sup> British Medical Journal, December 13, 1902.

<sup>1</sup> Gazette heb. de Médecine et de Chirurgie, November 20, 1902.

<sup>2</sup> Washington Medical Annals, November, 1902, p. 357.

<sup>3</sup> Chicago Medical Recorder, December 15, 1902.

the uterus, in which an artery was still bleeding. No adhesions were present, the peritoneum being smooth to the edge of the perforation. There was no bloody discharge from the uterus before, nor had there been up to two weeks after the rupture. [A.G.E.]

**Quadruple Pregnancy.**—Baudouin<sup>1</sup> reports an interesting case that occurred in the service of Dr. Mataranga, of Paris. A woman of 33, twice married, had borne seven children, five by the first and two by the second marriage. The eighth pregnancy was quadruple, there being two placentas. The membranes of the first ruptured about 24 hours before the other. The first contained three female fetuses, two of them being united from the umbilicus to the clavicles, forming a sternopage. The other was normal, and is still living. The second pouch contained a male fetus that was dead. Baudouin calls special attention to the fact that this was a quadruple pregnancy from two ovums, one of which produced three fetuses of the same sex. This placenta contained ridges, dividing it into distinct compartments. [A.G.E.]

**Invagination of Uterus Due to Ventral Fixation.**—Holland and Robinson<sup>2</sup> report a case of invagination of the uterus that occurred in a woman of 26 who, in 1898, had been treated for posterior displacement by ventral fixation. Normal labor was followed by invagination of the uterus and death. Examination showed that a space in the fundus of the uterus three inches square had atrophied as the result of the peritoneal band produced by operation, this being only about one-eighth the thickness of the adjacent uterine wall. [A.G.E.]

**Spontaneous Rupture of the Uterus During Labor.**—Lafourcade<sup>3</sup> describes a case of uterine rupture that occurred during the presence of the attending physician and very shortly after an examination had been made. The patient was a woman of 42, in her fifth pregnancy. The preceding deliveries were spontaneous. The uterine tear was 18 cm. long, two-thirds on the left side of the organ and one-third transversely above the isthmus. The fetus and placenta passed into the peritoneal cavity. Laparotomy and supravaginal hysterectomy were followed by recovery of the patient. The uterus showed no abnormality except a slight interstitial myositis. [A.G.E.]

## TREATMENT

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPLEMAN

## EDITORIAL COMMENT

**The Increase of Drug Habits Becoming a National Menace.**—In the *American Journal of Pharmacy* for November, 1902, is the report by Mr. Hynson, chairman of the committee appointed by the American Pharmaceutical Association to investigate the question of the acquirement of the drug habit. This report, while it is written from the standpoint of the pharmacist, reveals a state of affairs so truly appalling that it merits the consideration of every physician, indeed of every person interested in the welfare of society. As perhaps the most accurate means of determining the question of the increase in the drug habit in the last few years, the committee gives the statistics concerning the importation of two plants most commonly employed for this purpose, namely, opium and cocain. Since 1898 the population of the United States has increased 10 percent; the amount of opium imported, however, has increased to the startling extent of 500 percent, and this despite the fact that it is less frequently used by the physicians than in years past. The importation of opium for 1902 amounts to the astounding sum of 712,000 pounds; and this is exclusive of more than a ton of morphin. This increase in the importation of opium is paralleled in the case of cocain, the quantity of that alkaloid brought into the country in the year covered by the report being three times as large as the importation

of 1898. As the committee points out it is impossible that there should have been any such enormous increase in the legitimate demand for the drug. Indeed, it would seem probable that the administration by physicians, certainly of opium and probably also of cocain, has diminished rather than increased, and it is thus safe to conclude that practically all of this supernormal demand is by drug "fiends." From responses to letters addressed to a number of pharmacists and physicians in various cities and towns in the East, the committee concludes that in the eastern portion of the United States out of every 1,000 inhabitants about 3 are addicted to the use of some drug other than alcohol. The condition of affairs among certain classes is almost inconceivable; thus one of the correspondents whose business is in the Tenderloin district of New York is personally acquainted with 200 opium habitues, while the police officers assert that cocain adulterated with acetanilid is peddled from door to door as an ordinary necessity of life. Such a condition of affairs is so threatening to the very existence of society that its causes cannot be too thoroughly investigated in order to discover a proper remedy. The committee believes, and we think justly so, that a great part of the responsibility for this horrible state of affairs rests upon the drug dealers, both retailers and wholesalers. When a customer returns to a drug store week after week to purchase large quantities of morphin or cocain, or a jobber sells cocain in large quantities at frequent intervals to a retailer, the dealer must know that the consumer is using the drug for improper purposes and certainly has, as the committee claims, a right to refuse to supply it; nay more, he is morally obliged to do so. To quote the words of Mr. Hynson: "The excuse so often made—'If I don't sell it to him, some one else will'—is as cowardly as it is specious." It would seem that the only way to prevent these immoral sales is by legislative enactment, and the two professions of pharmacy and medicine should unite for this purpose.

## REVIEW OF LITERATURE

**Lactose and Magnesia.**—Huchard<sup>1</sup> recommends the following as an antacid and as a laxative:

Lactose . . . . . 39 grams (10 drams)  
Calcined magnesia . . . . . 62 grams ( 2 ounces)

One dessertspoonful to one tablespoonful daily in a half glass of water. [L.F.A.]

**Treatment of Uterine Hemorrhages.**—A. Martinet<sup>2</sup> employs hypodermic injection of the following in uterine hemorrhages:

Bonjean ergotin . . . . . 2 grams (31 grains)  
Glycerin . . . . . 10 cc. ( 2½ drams)  
Distilled water . . . . . 10 cc. ( 2½ drams)

From 1 to 10 cc. (15 to 150 minims) of this solution may be injected in 24 hours, depending upon the amount and persistence of the hemorrhage. [L.F.A.]

**Anesthesin.**—Paraamidobenzoic acid ethylester or anesthesin is a white powder, odorless and tasteless, fugaciously irritating to mucous membranes, soluble in ether, alcohol, fatty and ethereal oils; slightly soluble in hot water, not at all in cold water. It is not poisonous in even larger doses than 2 grams (30 grains). It belongs to the orthoform group of anesthetics and is considered the best of these by Spiess.<sup>3</sup> He contrasts the use of the two groups and concludes that we cannot do without either. For operative purposes the cocain group is a necessity; for the after-treatment, orthoform. Spiess uses anesthesin in all minor injuries, in painful surgical dressings, in painful affections of the skin or mucous membrane when the diseased nerve endings can be reached by the agent. In whooping cough and acute coryza he considers it almost a specific. [E.L.]

**Treatment of Chronic Diarrhea with Insufficiency of the Gastric Juice.**—Soupault<sup>4</sup> states that in certain cases of

<sup>1</sup> Gazette Medicale de Paris, November 22, 1902.

<sup>2</sup> Chicago Medical Recorder, December 15, 1902.

<sup>3</sup> Gazette Medicale de Paris, December 13, 1902.

<sup>1</sup> Journal des Praticiens, Vol. xvi, No. 22, 1902, p. 350.

<sup>2</sup> Bulletin Général de Thérapeutique, Vol. cxliv, No. 13, 1902, p. 507.

<sup>3</sup> Münchener medizinische Wochenschrift, September 30, 1902.

<sup>4</sup> Bulletin Général de Thérapeutique, Vol. cxliv, No. 9, 1902, p. 351.

diarrhea, due to deficiency in the gastric digestion, a rapid amelioration and even complete cure may be obtained by the administration of hydrochloric acid, as follows:

- Hydrochloric acid . . . . . 6 to 8 grams (1½ to 2 drams)
- Syrup of lemon . . . . . 150 grams (5 ounces)
- Distilled water . . . . . 1 liter (1 quart)

A large glass of this should be drunk during each meal. Patients may drink it pure or diluted with an equal amount of water. [L.F.A.]

**Strophanthus and Camphor in the Treatment of Acute Myocarditis.**—Lemoine<sup>1</sup> prefers strophanthus in the treatment of acute myocarditis when it is necessary to support a failing heart. He usually prescribes it in the following way:

- Extract of strophanthus . . . . . .005 gram (½ grain)
- Extract of triticum { enough
- Syrup of acacia { to make } . 1 pill

One pill morning and evening. Sometimes three pills may be taken, rarely four, and this number should not be exceeded. In cases of collapse, strophanthus must be associated with a rapidly diffusible stimulant. Under these circumstances 16 to 30 minims of ether may be injected subcutaneously, or the following prescription may be used:

- Camphor . . . . . .05 gram (7½ grains)
- Ether
- Distilled water } of each . . . . . 4 grams (1 dram)

Fifteen to 45 minims of this solution may be injected subcutaneously in 24 hours. [L.F.A.] [Camphor solution, 1:10, in oil or ether, is the best cardiac stimulant now at our command. A syringeful (say 20 minims) may be given hypodermically and repeated as needed. s.s.c.]

**Treatment of Chronic Diarrhea.**—Lyon<sup>2</sup> directs attention to a proper diet in chronic diarrhea, to the gastric and intestinal medication, and to the treatment of the general condition of the patient. When there is lenteric diarrhea the food must be as easily digestible as possible; in cases in which there is a deficiency in the secretion of pepsin the food should consist of pure milk and of starchy vegetables prepared with milk. If there is hypopepsia accompanied with dilation and active fermentation it is first necessary to perform lavage of the stomach several times with boiled water in order that the milk will be tolerated. In cases of hypopepsia, without dilation and with decreased gastric secretion, kephyr is preferred to milk because it stimulates secretion and increases the acidity of the gastric juice. The gastric treatment comprises measures which will stimulate the remaining healthy glands of the mucous membrane of the stomach and which will combat fermentation. The first indication may be met by the administration of 2 grams (30 grains) of sodium phosphate in a half glass of hot water or hot vichy water before breakfast, or the following prescription may be used:

- Sodium chlorate . . . . . 10 grams (2½ drams)
- Syrup of belladonna . . . . . 30 grams (1 ounce)
- Distilled water . . . . . 120 grams (4 ounces)

One dessertspoonful before meals.

Small doses of sodium bicarbonate may also be given before meals. Massage of the stomach has given good results; it acts as a tonic to the muscles of the stomach, decreases stasis which is a persistent cause of fermentation, and aids in the propulsion of food through the alimentary canal. [L.F.A.]

**Treatment of Rheumatic Endocarditis.**—Huchard<sup>3</sup> reviews the treatment of rheumatic endocarditis and concludes that from the beginning of an attack of acute articular rheumatism, when the endocarditis in its very first stage is unrecognized and without waiting for the appearance of inflammatory endocarditis, sodium salicylate should be given promptly in doses varying from 4 to 8 grams (1 to 2 drams) for adults, and from 3 to 5 drams (45 to 75 grains) for children. By this means he believes that the development of rheumatic endocarditis and the later lesions of the valvular orifices may be prevented. When the endocarditis has already begun and is of recent origin, the employment of the iodids and mineral waters may result in a definite cure. Chronic endocarditis, of one or two

years' standing, should receive the usual treatment for valvular disease of the heart. Careful attention to the diet is imperative. Digitalis and quirin may be used as indicated. [L.F.A.]

**The Toxic Varieties of the Family Rhus.**—Schwalbe<sup>1</sup> has made microscopic examinations of members belonging to the rhus family, and reports that the oil which is the active poisonous principle of the plant is contained in canals throughout the entire plant, the roots, stems, leaves, etc., being traversed by them. Straight and curved hairs are connected with these canals, and in them the oil is seen as yellow globules and in clumps. The hairs are found on the under surface of the leaves; the stems are surrounded by them. As remedies for the poison he advises repeated applications of a ¼-1% solution of potassium carbonate or weak solution of ammonia. [E.L.]

**Treatment of Alopecia.**—Gastou<sup>2</sup> favors the following treatment of alopecia: 1. Diseased areas should be isolated and circumscribed by epilation; to facilitate cure the parts should be stimulated. Infectious zones, dental lesions (Jacquet), and organic or visceral disturbances should be sought and treated. If the alopecia is limited, or if there are multiple areas, epilation should be practised around each. 2. The treatment consists of daily frictions with a pledget of cotton dipped in

- Carbolic acid . . . . . 4 grams (1 dram)
- Acetic acid . . . . . 50 drops
- Glycerin } of each . . . . . 60 cc. (2 ounces)
- Alcohol }

The area is then covered with

- Salol . . . . . 1 gram (15 grains)
- Vaselin . . . . . 19 grams (5 drams)

Wash the hairy skin with Van Swieten's solution.

3. When the alopecia persists alternate Van Swieten's solution with one of the following stimulating lotions:

- Chloral . . . . . 1 gram (15 grains)
- Camphorated alcohol . . . . . 180 cc. (6 ounces)
- Spirit of turpentine . . . . . 15 cc. (4 drams)

or,

- Chloral . . . . . 1 gram (15 grains)
- Corrosive sublimate . . . . . .2 gram (3 grains)
- Spirit of turpentine . . . . . 15 cc. (4 drams)
- Compound spirit of turpentine . . . . . 30 cc. (1 ounce)
- Camphorated alcohol . . . . . 150 cc. (5 ounces)

In case of dry seborrhea the following may be applied on and around the diseased areas:

- Sublimed sulfur . . . . . 3 grams (45 grains)
- Balsam of Peru . . . . . 15 grams (4 drams)
- Vaselin . . . . . 15 grams (4 drams)

In case of oily seborrhea:

- Salicylic acid } of each . . . . . 1 gram (15 grains)
- Turpeth }
- Styrax ointment . . . . . 10 grams (2.5 drams)
- Balsam of Peru . . . . . 31 grams (1 ounce)
- Vaselin . . . . . 19 grams (5 drams)

Every six or eight days the surface may be rubbed with a cotton tampon dipped lightly in

- Carbolic acid . . . . . 8 grams (2 drams)
- Glycerin or alcohol . . . . . 15 drops

This should be wiped off immediately afterward and the application should be made only by the physician and never when there is redness, oozing or vesication. [L.F.A.]

**FORMULAS, ORIGINAL AND SELECTED.**

**Hypodermic Injection for Syphilis.—**

- Mercury biniodid . . . . . 0.4 gram (7 gr.)
- Potassium iodid . . . . . 0.5 gram (8 gr.)
- Sodium phosphate . . . . . 1 gram (15 gr.)
- Normal saline solution, sufficient to make . . . . . 50 cc. (1½ oz.)

One cubic centimeter of this solution contains one centigram of biniodid of mercury. [H.C.W.]

**For Exophthalmic Goiter.—**

- Desiccated adrenal substance . . . . . .3 gram (5 grs.)
- Desiccated thymus substance . . . . . .3 gram (5 grs.)

Mix. Make a compressed tablet, which is to be allowed to dissolve slowly in the mouth; or encapsulate dry and give with water. This dose is to be given twice daily at first and increased according to effect. [s.s.c.]

**Changes in the Medical Corps of the U. S. Army** for the week ended January 10, 1903:

ARWINE, JAMES T., contract surgeon, is granted leave for twenty days.  
 BAKER, CHARLES L., contract surgeon, is granted leave for one month.  
 RUSSELL, First Lieutenant FREDERICK F., assistant surgeon, leave granted September 29 is extended fourteen days.  
 ADAIR, GEORGE F., contract surgeon, will proceed to Fort Morgan for temporary duty, relieving Captain Henry Page, assistant surgeon, who will thereupon return to his proper station, Fort Monroe.  
 WALL, FRANCIS M., contract surgeon, is granted leave for one month with permission to apply for an extension of one month.  
 ROUSSEAU, ZOTIQUE, contract surgeon, now at Watervliet Arsenal, N. Y., will report to the commanding officer of that arsenal for duty.  
 THOMPSON, LOUIS A., contract surgeon, is relieved from duty at Fort Thomas and will proceed to his home, Dayton, O., for annulment of contract.  
 O'BRIEN, PATRICK, hospital steward, now at San Francisco, Cal., will report at Fort Miley for duty at that post.

TEMPLE, OSCAR F., hospital steward, now at San Francisco, Cal., having relinquished the unexpired portion of furlough granted him from the division of the Philippines, is relieved from duty at Fort McDowell, and will be sent to Fort Ethan Allen, to relieve Hospital Steward William Lyon. Steward Lyon will proceed to Manila, P. I., for assignment to duty.

The following changes in the stations and duties of officers are ordered: First Lieutenant John J. Kelly, assistant surgeon, is relieved from duty at Fort Porter, and will proceed to Jackson Barracks for duty to relieve Captain Henry C. Fisher, assistant surgeon. Captain Fisher will proceed to Baltimore, Md., and assume the duties of attending surgeon and examiner of the recruits in that city.

BURFORD, OLIVER H., contract surgeon, will proceed to Jackson Barracks and report to Captain Henry C. Fisher, assistant surgeon, for duty.

HUBBARD, WILLIAM H., hospital steward, is relieved from further duty at Benicia Barracks, and will proceed to Manila, P. I., for assignment to duty.

BROWN, Colonel JUSTUS M., assistant surgeon, leave granted September 16, is extended to and include February 13.

VOSE, First Lieutenant WILLIAM E., assistant surgeon, is relieved from further duty at Columbia Arsenal, Columbia, Tenn., and will proceed to Fort Logan H. Roots.

VAN DEUSEN, First Lieutenant JAMES W., assistant surgeon, leave granted November 29 is extended one month.

LYSTER, First Lieutenant WILLIAM J. L., assistant surgeon, now at Fort McDowell, will report to the commanding officer of that post for duty.

CHAMBERLAIN, GEORGE E., contract surgeon, is granted leave for one month.

BENTLEY, CARLE E., contract surgeon, will upon being relieved from duty at Fort Logan H. Roots, proceed to his home for annulment of contract. Leave for one month is granted Contract Surgeon Carle E. Bentley.

BJORCK, NELS J., hospital steward, Manila, P. I., is relieved from further duty in the division of the Philippines and will proceed to San Francisco, Cal., and report to the commanding general department of California.

**Changes in the Medical Corps of the U. S. Navy** for the week ended January 10, 1903:

BIGERT, E. S., medical director, retired, detached from the Naval Recruiting Station, New York, and to continue duty at Marine Recruiting Station, New York—January 3.

WOOLVERTON, T., medical inspector, retired, ordered to the Naval Recruiting Station, New York—January 3.

HOLLOWAY, J. H., assistant surgeon, commissioned assistant surgeon from September 26, 1902—January 3.

GUTHRIE, J. A., passed assistant surgeon, detached from the Yorktown and ordered to the Vicksburg—January 5.

OHNSORCK, K., assistant surgeon, detached from the Vicksburg and ordered to the Yorktown—January 5.

PECK, A. E., assistant surgeon, detached from the Annapolis and ordered to the Naval Station, Cavite, P. I.—January 5.

WEBB, U. R., assistant surgeon, detached from the Naval Station, Cavite, P. I., and ordered to the Annapolis—January 5.

STEPHENSON, B. F., medical inspector, retired from active service on account of disabilities incurred in the line of duty January 3, 1903, and to continue on duty at Naval Hospital, Portsmouth, N. H.—January 7.

DICKSON, S. H., medical inspector, detached from the Iowa and ordered to the Newark as fleet surgeon of the South Atlantic Station—January 7.

HAAS, H. H., passed assistant surgeon, detached from the Montgomery and ordered to the Prairie—January 8.

PAGE, J. E., passed assistant surgeon, detached from the Newark and ordered to the Montgomery—January 8.

**Changes in the Public Health and Marine-Hospital Service** for the week ended January 8, 1903:

BAILHACHE, PRESTON H., surgeon, granted leave of absence on account of sickness for thirty days from January 6—January 8, 1903.

CARTER, H. R., surgeon, leave of absence for three days from January 5, 1903, under paragraph 179 of the regulations.

GREENE, J. B., passed assistant surgeon, relieved from duty at New York (Stapleton)—December 31, 1902.

GRUBBS, S. B., passed assistant surgeon, to proceed to Guaymas, Mexico, for special temporary duty—January 8, 1903.

PARKER, H. B., assistant surgeon, to report to chairman of board of examiners at Washington, D. C., January 12, 1903, to determine his fitness for promotion to the grade of passed assistant surgeon—January 5, 1903.

VON EZDORF, R. H., assistant surgeon, to report to chairman of board of examiners at Washington, D. C., January 12, 1903, to determine his fitness for promotion to the grade of passed assistant surgeon—January 5, 1903.

ANDERSON, J. F., assistant surgeon, to report to chairman of board of examiners at Washington, D. C., January 12, 1903, to determine his fitness for promotion to the grade of passed assistant surgeon—January 5, 1903.

ROBINSON, D. E., assistant surgeon, relieved from duty at Seattle, Washington, and special temporary duty at Port Townsend Quarantine and assigned to duty at Port Townsend Quarantine—December 31, 1902.

KEYES, J. M., acting assistant surgeon, granted leave of absence for thirty days from January 5—December 24, 1902.

SEMS, F. F., acting assistant surgeon, granted leave of absence, on account of sickness, for thirty days from January 1, 1903—January 5, 1903.

BROWN, F. L., pharmacist, granted leave of absence for ten days from December 25—December 27, 1902.

SCHLAAR, W. F., pharmacist, relieved from duty at Washington, D. C., and directed to proceed to Boston (Chelsea), Mass., and report to medical officer in command for duty and assignment to quarters—January 6, 1903.

## Resignation.

KEYES, J. M., acting assistant surgeon, resigned to take effect February 3, 1903.

PUBLISHED WEEKLY AT 1521 WALNUT STREET, PHILADELPHIA, BY THE AMERICAN-MEDICINE PUBLISHING COMPANY

VOL. V, No. 4.

JANUARY 24, 1903.

\$5.00 YEARLY.

National gratitude to medical scientists is a duty which every physician should lose no opportunity of encouraging. We are indeed naturally prone to be glad if the popular feeling toward us is not one of hatred, and if it is only one of indifference—not a medical name appears in the so-called Hall of Fame—we pass on in wonder if the world will ever know or care for its greatest benefactors. Any one of a half dozen medical discoveries made by American medical men are as valuable to humanity as those commemorated in any monument or hall of fame. A bill has been introduced in the Senate and House at Washington providing for a pension of \$4,000 a year for the widow of Dr. Reed. It is not necessary to tell members of the profession, and especially the readers of *American Medicine*, of Dr. Reed's services. There can be but one opinion, that they have been such as to call for national recognition. That the amount of the proposed pension is by no means large when all the circumstances are considered will be admitted. We beg every physician to use all his influence, direct and indirect, with his senator and representative at Washington, to secure the passage of the Act, and to prevent any cutting down of the amount of the pension. There are a thousand other methods of preventing waste of the public funds that might well be instituted. Ingratitude for unselfish scientific medical discovery is one of the most deplorable and most expensive of our national sins.

The shortening of college courses as related to preparation for the study of medicine is a subject of very present interest to American educators. In this connection recognition has undoubtedly been taken of a fact referred to some years ago by President Gilman in his discussion of university problems, viz., that the distinctive college has been disprized by the modern high school. Any rearrangement of requirements for collegiate degrees or for entrance into professional studies must take account of the fact that our best secondary schools are to a large extent meeting "the old idea of a liberal education intermediate between that of the preparatory school and that of the professional or technical school." Graduates of the highest institutions of this country and Europe now fill instructor's chairs in the secondary schools of our great cities and they have been quick to seize upon every foot of ground abandoned or

neglected by the colleges until the latter in their zeal to attain university rank find themselves overlapping at each end of their course. There have arisen in many communities great city colleges, sometimes so-called, as in New York and in Baltimore; sometimes, as in Philadelphia, still retaining the name of high school. There has been very naturally an extension of good teaching and modern methods from the universities into the secondary schools and the proposition to shorten the college course is but an attempt to readjust curriculums to a new order of things. The important point to be considered after all is that the student shall have formed habits of attention, memory, discrimination, classification, and judgment, and such habits having been formed the college need not hesitate to shorten the way leading to higher and professional studies.

**Surgery in Remote Country Districts.**—In the city, with numerous hospitals, surgical assistants, trained nurses, and all the armamentarium which the modern hospital affords we are prone to assume that only with such conveniences can clean surgery be done; in fact, that no surgery is being done save in well appointed places. That the facilities which hospitals and trained assistants afford give us the desirable condition no one will, of course, gainsay; but that they are absolutely essential to aseptic surgery will be disputed, and correctly, by many country doctors. We forget that many parts of our country are far removed from any of the conveniences deemed necessary for successful surgical work. What shall the country physician do, called as he often is, into remote districts to find a patient desperately ill from an affliction demanding surgical interference? Distance, time, poverty, and prejudice on the part of the patient dispel all thoughts of a hospital. Illustrative of the difficulties met and the success achieved, a few words quoted from a Southern practitioner of known veracity may not prove amiss. He says:

"In modern surgery the first step in any operation is, of course, asepsis. With abundance of trained assistants and a small brigade of nurses, in a well appointed hospital it is a simple matter to be clean. But in the country, in a small farmhouse or cabin, with only surface water and kitchen utensils on the one hand, and rags, dirt, cobwebs, and a desperately ill patient on the other, what would our city surgeon and his trained assistants do? One would be safe in saying he would

be more confused and less able to apply his presumably more extensive knowledge than his country brother, who has never had the pleasure of hospital facilities nor trained help, but has invariably had to depend on such facilities as his own ingenuity could devise, and with the help of those who, perhaps, have never before seen an operation. But even under these adverse circumstances we can do clean and successful surgery, and it is being done daily by the bright, active, country doctors, and many lives are being saved."

Concerning his method of preparation and adaptation of means to an end we quote further, as follows:

"By carefully scrubbing the floor and walls with soap and water, then a strong carbolic or corrosive solution, with all furniture removed and windows open, it is possible to convert a dirty room into a place in which clean surgery can be done. Boil the necessary sheets, towels, basins, instruments, cotton, gauze, and suture and ligature material. Water previously boiled is poured while hot into clean jugs or pitchers and allowed to cool. The hands are sterilized in the usual way, and the operating table, improvised by placing a door, shutter or wide board on barrels, chairs or benches, is covered with boiled wet sheets. Small tables, benches or chairs are likewise covered and serve as a place for instruments, dressings, etc. The patient is shaved and scrubbed in the usual way, placed upon the operating table and the field of operation surrounded by boiled, though wet, towels or sheets. The instruments, dressings, ligature and suture material are covered by sterile towels. The entire time necessary for such preparation should not exceed two hours, and in very urgent cases, and with intelligent though untrained assistance may be done in half this time. Under these apparently adverse circumstances the writer has repeatedly opened up the shoulder, knee and ankle joints, the skull cavity, and the abdomen without a single instance of infection."

When we remember that such practical and successful work is being done, especially in the sparsely settled portions of country, by scores of bright, careful and energetic men, it should divest us of some of our preconceived ideas about the absolute necessity for hospital facilities in doing successful aseptic surgical work. Hospital conveniences are necessary for the refinements of surgery; but for practical, urgent, and life-saving surgery their necessity has not yet become absolute. The country doctor yet plays an important role in surgical work, and it is not probable that this will become less in the future. It is often quoted of the elder Gross that he always felt like taking off his hat in the presence of the country doctor—the broadest, most resourceful and most useful of medical men.

**The Plague at San Francisco.**—At a conference of health officers of many States, held at Washington this week under the presidency of Surgeon-General Wyman, the chief topic of discussion was the danger of the spread of bubonic plague throughout the United States because of the action of the State Board of Health of California and the city government of San Francisco. The whole profession and country have stood aghast at the shame and ignominy whereby the existence of plague at San Francisco has been concealed and denied. Dr. Glennon, sent to San Francisco by the Surgeon-General to investigate and report upon the facts, telegraphs that 93 cases of the disease have occurred in the city—6 in whites, 4 in Japanese, and 83 in Chinese. Of 22 dead rats found in Chinatown, 11 were infected. The following was part of a resolution passed by the conference:

"The gravity of the situation is greatly increased by the gross neglect of official duty by the State Board of Health of

California and the obstructive influence of the recent Governor of California, by the failure of the city government of San Francisco to support its city Board of Health, and by the obstacles opposed to the operations of the United States Public Health Service."

It is incomprehensible that the professional conscience and the mere self-interest of the American people should so long have permitted this criminal selfishness of a few blind and stupid people in California. Let there be a speedy end of the disgrace. If Surgeon-General Wyman has not the power, it should be supplied by the President of the United States. "The public safety is the supreme law."

**Eponymic Terms in Medical Literature.**—The *Spectator* has recently published some interesting communications on the need of some word to express the ever-increasing class of terms derived from surnames, *e. g.*, boycott, macadam, mackintosh, gerrymander, and an ample list of "long-tailed words in -osity and -ation" has been proposed by correspondents to supply the apparent deficiency. It is curious that no one has referred to the word *eponym*, already in our standard dictionaries, and having the exact significance desired. Man has ever sought to embalm the memory of important persons, places or things by the use of eponyms. Cities, mountains, temples, fountains, glaciers, and marine abysses all bear tribute to geographic or geologic notables. With botanists, flowers and fruits, from St. Maw's clover and timothy grass to the baldwin and shaddock have served to grace the memory of the lovers of plants. Zoologists have followed suit with Steller's rhytina and a veritable Noah's ark of other creatures whose enumeration would serve as the index of a naturalist's directory. The mineralogist is particularly prone to the use of cognomial appellations, while astronomers, chemists and electricians have given us "anthroponomatic" terms which have become so familiar as to lose the dignity of capitalization; watts, ohms, and amperes are words familiar to school boys, while faradism and galvanism crowd elbows with mesmerism, eddyism and other terms suggestive of the charlatan. The history of anatomy, physiology, pathology, and therapeutics shows every advance in knowledge to be marked by "onomataneric" terms of inestimable value to the student of medical progress, every niche in the bodily temple being occupied by the shadowy suggestion of the fathers of medicine from Fabricius and Vater to Paget and Langerhans. So far as the memory of the average medical student is concerned, the terms eustachian valve, Pacini's corpuscles or the island of Reil serve as well to fix his anatomic acquisitions as would a more strictly scientific terminology, and thus far the language of medicine offers no greater difficulties to the novice than that of the other sciences, and the attempt on the part of certain writers to eliminate altogether from medical writing the so-called aneronomatic terms is not at all likely to meet with success.

**Teaching the Humanities Minus the Spirit of Humanity.**—During the centuries in which the arts

and sciences lay dormant the teaching of the classics was essential to the perpetuation of the ideals and culture of Greek and Latin civilization. Latin was particularly necessary as the universal language of educated men, and through the study of the classics the lamp was kept burning in the temple of wisdom. So long as Latin served as a means for conveying a familiarity with the highest human ideals and attainments, so long as it was the accepted language of historic record and employed in the teaching of the learned professions, so long as it had to do with human nature, interests or affairs, did it as a factor in education exert humanizing influences. Gradually, however, the methods characteristic of scientific research have been adopted in the teaching of languages, and the student of Latin and Greek no longer acquires the old-fashioned familiarity with classic writers, but spends the bulk of his time in the elucidation of syntactic obscurities, a drill of undoubted value, but not because it gives any peculiar insight into human interests or affairs. The crowding of the curriculum in preparatory schools and colleges, together with other factors, has gradually brought about the fact that that Latin and Greek which affords no familiarity with classic ideals and writers represent the humanities with humanity left out. For centuries it was necessary to read Greek to get at the beautiful truths of the New Testament, but the King James version has brought the spirit of Christianity to millions and in the same way the best that classic civilization had to offer is available through translations. Latin having therefore to a very considerable extent shifted its place and purpose in education is, like Greek, rapidly giving way to studies which, if they do not hold up classic standards, do serve to bring the student into closer touch with the spirit of modern civilization. If Latin can be so taught as to make Horace and Virgil as familiar as Scott and Tennyson then we could wish every professional man a classical training. If a Latin course means but a feast of grammatical dry bones, then let the student get at more humanizing food without loss of time. There is little force in the utilitarian plea that the classics as now taught are of practical use to the physician in the understanding of medical terminology; all that he needs in this way can be secured by the perusal of books such as Goodell's "Greek in English," or even the good old "Scholar's Companion."

If the classics are to hold their own as studies preparatory to medicine they must rest their claims solely on humanistic grounds, they must stand for the good, the true, and the beautiful, as science and modern languages can place a stronger plea on the ground of practical utility.

**Abandonment of Latin by Medical Writers.**—The constant perusal of medical literature shows clearly that so far as an intelligent use of medical terminology goes the student of medicine needs Latin no more than he needs Arabic. To be sure, some medical writers are pleased to lard their sentences with occasional Latin phrases, but a collection of these suffices to show how few and hackneyed they are, and how little force and elegance they lend to medical writings. Most authors

are satisfied to garnish their pages with bits of such Latinity as *ante mortem, contagium vivum, habitus phthisicus, in articulo mortis, in utero, in vitro, loco dolenti, materies morbi, per os, per primam, post abortum, prime viæ* (we no longer meet with *secundæ viæ*), and *primum movens*. Others, particularly the authors of English textbooks and contributors to English journals, are fond of quoting, either in the body of the text or as chapter captions, selected aphorisms such as Galen's "*Dolor dolentibus inutile est,*" Hippocrates' "*Spasmos febris accedans solvit,*" Leibnitz's "*Natura non agit saltatim;*" that of Harvey, "*Omne vivum ex ovo,*" often occurs in Virchow's paraphrase "*Omne cellula e cellula,*" while Borelli's "*Qui bene diagnoseit bene curat,*" seems to be a favorite. None of the expressions ordinarily used would suffer in force if rendered in English, and the writers would avoid all suggestion of pedantry. We recall a former teacher whose frequent use of the expression gained him the nickname of "*pari passu*" without greatly adding to his dignity. Modern medical terminology and nomenclature augments so rapidly and presents such a hodge-podge of derivatives that only the lexicographer concerns himself with etymologic significance—to others the terms are but symbols. The advertising pages of medical journals are replete with the proprietary names of new remedies, built on the "*unecda biscuit plan,*" while eponymic terms mark the progress of medical discovery at every stage. In none of these is Latin in the least helpful.

**The Profits of a Prophetess.**—Mrs. Eddy, as is well known, disbelieves in the materiality of the world, and consequently in the material existence of the money of the world. It is strange therefore to find her so shrewd and careful to gather wealth, nonexistent and immaterial as it is. How much she has made by the sale of immaterial souvenir spoons we do not know, but every believer we understand has been made to buy one or two. How much she has made by the sale of her immaterial photographs one can also not estimate, nor from all the other skilfully devised methods of securing the immaterial dollars of her immaterial adherents. For three weeks' instruction her pupils have been required to give her 300 nonexistent dollars, but we do not know the number of spiritual pupils she has taught. Of one source of income, however, we can make some more definite estimate. One of the late editions of her immaterial book was numbered 220. The number is immaterial. As it is sold at an absurdly high price, high at least for other material people, the net profits on each copy cannot be much less than \$2.00. If each edition was only 1,000 copies the profits of going into the Eddyite kind of book-business have been nearly half a million of spiritual dollars! And yet Americans are said to be cunning in money matters! Mrs. Eddy has surely demonstrated that they are the most gullible of all people. African savages could not be humbugged so easily.

**Ophthalmic-Oscillatory Ophthalmology for Inter-Ocular Diseases.**—There lies before us a circular, noteworthy because of a number of qualities, the

linguistic and scientific being the chief. As to the last we have this statement:

"The master minds in the field of Ophthalmology, both in Europe and this country, have worked upon the theory that to stimulate the interocular circulation, rebuild the capillaries which become inactive in the interstitial tissues of the nerve papillas of the retina, nutrition would become active and the retina would again respond to the action of light."

It required 20 years for the "gentleman of high medical standing" to devise a couple of little glass cups placed over the eyes whereby the eyes are drawn outward when a vacuum (and no hyphen between those two *u*'s, nor any diereses over them!) is created, etc., and the oscillation causes a regular vibration of the optic nerve. Among other "inter-ocular diseases" we are assured that "cortical opacity of the lens are most successfully treated." Also the other inter-ocular diseases, "glaucoma, choroiditis, retinitis, atrophy"—these also "can be cured." "No one discovery since Holtzholm gave the ophthalmoscope to the medical world has ophthalmology received so valuable a discovery." U. S. Senator Money is said to endorse "this wonderful machine," and several doctors are mentioned as having been cured by it of inter-ocular diseases. Money can do wonders of course, but we fear it is powerless to change the truths of ophthalmology and of English grammar. Poor Ophthalmology! and the fame of Holtzholm! and the unprotected patients who are exhilarated!

The coinage of new words and new degrees continues to amaze the poor lexicographer. He can hardly keep step with the advance guard of scientific workers, but he cannot come within sight or sound, at least of understanding, of those of the cranks. It is a strange delusion of the ignorant that by the use of ill-formed, unnecessary, nonunderstandable, and highfalutin words they can make people still more ignorant than themselves believe that something great and novel and mysterious is going on or to be bought. Circulars lie before us as we write of a strange institution which promises to teach its students "mentology" for \$50. The "first section" of "mentalopathy" will be taught, "including all laboratory expenses," for another \$50, and the "second section" for a third \$50. "Psycho-theology" requires another \$50, and so on. For degrees and diplomas in all the departments, \$300 is asked. These degrees and diplomas are, in mentalopathy, "Men. B," and "Men. D." "Log." is that for "Logic;" in Mentalology, M.Ph.D.; in "psycho-theology," P.T.D.; in "ethics," that of E.D. When was the original degree of D.F. conferred?

Invention and physiology are often intimately related and interdependent, a fact that may be overlooked, and that is illustrated by the labor and ingenuity expended in trying to shorten the work of nerve and hand in telegraphing. An operator who sends 15,000 words in 8 hours, makes about 180,000 depressions and relaxations of the key. The nerve impulses are by no means limited to these 360,000 distinct movements as one who has studied physiology at once understands. The result is telegraphers' paralysis, and many devices

to prevent it. The dot and dash, each with its separate double movement, have not been shortened or mechanized until recently. The "autoplex" is said to reduce the number of depressions of the key to about one-third the number required without it. "Mississippi" by the old way required 31 depressions, which by the autoplex are reduced to 12. The method by which this is brought about is by means of a lever, which if thrown to the right makes dots mechanically until thrown to the left, when it makes dashes. It is said that an operator learns to use it expertly within a week.

**The Pride in Old Age.**—In the thirty-eighth annual report of the Home for Aged and Infirm Colored People of Philadelphia there is an account of one of the inmates, Mary McDonald, who "if so," must be over 131 years of age. The only proof of the "if so" is that the woman remembers persons living and events taking place in 1777 and 1778. We have entire sympathy for the cause of the care of the aged and infirm, but this must not be allowed to influence the statistics of centenarians. It is very doubtful if anybody has ever lived 131 years, and when the sole proof of such a claim is the memory of events transpiring and persons living over 100 years ago, there is no dependence whatever to be placed upon the report. Psychologists know how readily the mind transforms the record of things told by others into memory of things experienced by self. All who have carefully attended to their subtle mental processes have probably detected the unconscious method of the mind whereby "what elders have said becomes what I have seen." This habit may become almost the single prop of self-esteem in old age.

**The etiology and cure of cancer** is made perfectly clear by the following communication to the president of a medical school:

Dec 31—1902 (Happy new year)  
—, N. Y. — R. F. D.

Dear Sir:—I see by the N Y Herald you dont know what causes a cancer or its cure. I think I can explain it so you can understand, as it is quite necessary doctors should know how to cure every part of the human system is why I write this, though our lives are all done "from before the foundation of the earth." First a vein is bursted by some cause, bruise or pressure, and then the blood is decomposed (killed) in that spot, and other blood like bees in a hive goes to see what is the matter and while trying to heal the spot become poisoned by the dead blood and so the cancer grows like a boil and poisons the whole body and life ceases. Now to cure it is to bind on a poultice of clay, that kills the bachali of all skin dissesas even to leprocy or small pox, It draws the swelling all down so a core can be taken out. Tea made of Chinese night soil can poison a person when made of scroffula, leprosy or any other dissesas though doctors preachers undertakers and lawyers get a job Please answer

**Medical Diplomas Fraudulently Obtained.**—Professor James B. Angell, president of the University of Michigan, is credited with the following statement in his annual report. "We have for some years had reason to suspect that diplomas, especially our medical diplomas, had occasionally been fraudulently obtained. It happens, of course, that now and then a diploma is either lost in the transportation of baggage or destroyed by fire. For some years we issued a duplicate diploma on the simple request by letter of the holder of the original. Of late years we have required the applicant to send us an affidavit, swearing to the loss of the diploma and to the circumstances of the loss. We write the word 'duplicate' in red ink on the new diploma. It has been found even these precautions do not furnish an absolute safeguard against fraud."

## BOOK REVIEWS

**Practical Diagnosis: The Use of Symptoms and Signs in the Diagnosis of Disease.**—By HOBART AMORY HARE, M.D., B.Sc. Lea Brothers & Co., Philadelphia and New York.

Hare's Practical Diagnosis needs no introduction to the profession. It should be stated, however, that the fourth edition has been exhausted and the fifth edition, much amplified, thoroughly revised and up to date, has appeared. The author's plan of discussion and elucidation is one which will appeal to the student and busy practitioner. The book is divided into chapters, as follows: Feet and Legs, Hemiplegia, The Eye, The Blood, The Thorax and its Viscera, etc. Under each of these is discussed all the pathologic conditions which are likely to affect that particular part of the body. Thus necessary information, so far as diagnosis is concerned, may be had without exhaustive and perplexing research. To quote the author's own words: "The present edition differs materially from its predecessors in the fact that its scope has been broadened to include not only the symptoms, discussed in the manner just described, but also the physical signs and clinical tests which experience has proved reliable." It will be seen, therefore, that the work is not only revised, but that it is amplified advantageously. It contains 236 illustrations and 25 colored plates, is written after the author's usual clearness, and is issued synchronously with the ninth edition of his Textbook of Practical Therapeutics, to which it is a companion volume.

**The International Textbook of Surgery.**—By American and British Authors. Edited by J. COLLINS WARREN and A. PEARCE GOULD. W. B. Saunders & Co., Philadelphia.

To surgeons it need hardly be recalled that the first edition of this splendid and exhaustive work, consisting of two volumes, one devoted to General Surgery and the other to Regional Surgery, was issued but two years ago. The work deservedly attracted wide and favorable attention, coming as it did from men in both England and America who have achieved an eminence which commands authority. Further commentary is unnecessary, except to state that the editors, conscious of the rapid progress made in surgery, particularly in military surgery, determined to bring the work up to the very latest findings. To this end, therefore, the chapters pertaining to military and naval surgery have been thoroughly revised and rewritten; likewise the chapters having to do with the lymphatic system; the surgery of the kidneys, the surgery of the spleen, etc. The whole work has been carefully revised, not only by the individual and special authors, but by the editors as well. In the present edition the volume on General Surgery has 461 illustrations and nine full-page colored plates, and the volume devoted to Regional Surgery has 499 illustrations and eight full-page colored plates. This valuable contribution to surgical literature and science should have a place in the library of every one engaged in surgical work.

**Cellular Toxins or the Chemical Factors in the Causation of Disease.**—By VICTOR C. VAUGHAN, M.D., LL.D., and FREDERICK G. NOVY. Lea Brothers & Company. Octavo; pp. 495. Cloth, \$3.00 net.

The first edition of this work appeared 14 years ago under the title "Ptomaines and Leukomains, or Putrefaction and Physiological Alkaloids." The advance in knowledge regarding the synthetic substances produced by microorganisms has been such as to render the title of former editions inappropriate. Moreover, the text has been for the most part rewritten and several new chapters added, making the work an authoritative treatise, including all advances made in the knowledge of the subject down to the close of the year 1901. The chapter on the Specific Precipitins and that on Lysins are particularly valuable and alone worth the price of the book to all practitioners who wish to obtain a clear comprehension of specific serums, of agglutination and of hemolytic and bacteriolytic phenomena. We know of no other work in English in which is to be found a more thorough presentation of the sub-

ject of Food Poisoning than that presented in Chapter X, under which, adopting the terminology of Husemann, the authors include the poisoning from mussels (mytilotoxism), that from fish (ichthyotoxism), that from the flesh of diseased animals (kreatotoxism), that from cheese (tyrotoxism), that from milk (galactotoxism), and that from vegetable foods infected with molds and bacteria (sitotoxism), including lathyrism and maldism. The latter term refers to what is ordinarily known as pellagra, a disease prevalent in Southern Europe, and which becomes in certain localities a national calamity, 56,000 cases having occurred in Lombardy alone in a single year. The authors offer no positive information concerning the poisonous substance which causes this disease, but a recent discovery is that the poison is inherent in the spores of the common green mold *Penicillium glaucum*. The chapters on the examination of Poisonous Foods, on Methods of Extracting Ptomaines, on the Importance of Bacterial Products to the Toxicologist and on the Chemistry of Ptomaines and Leukomains are perhaps of greater interest to the physiologic chemist than to the general practitioner; but the final chapter, on Autogenous Diseases, though brief, is suggestive as to the absorption of poisonous excretory proteids by the intestinal walls, especially in infants, as to the action of certain secretions and excretions on tissues with which they have no normal relation, as, for example, that of normal bile on the pancreas. Here also is discussed the subject of diseases due to abnormality in those organs whose function is to prevent the passage of certain substances into the general circulation, as that of the thyroid in preventing that form of mucinemia known as myxedema.

**The Work of the Digestive Glands.**—Lectures by Professor J. P. PAWLOW, Director of the Physiologic Department of the Institute for Experimental Medicine. Translated into English by W. H. THOMPSON, M.D., Dublin. (Sole authorized English translation.) Philadelphia: J. B. Lippincott Company, 1902. Price, \$2.00.

This book is an English translation of the work first published in the Russian language in 1897. It also includes the later work of Pawlow on the physiology of the bile, succus entericus, and salivary secretion. This, with more recent notes by the author, brings the work up to date. The book consists of nine lectures detailing the results of experiments by Pawlow and his associates regarding the excitation of the digestive glands, their action, interrelation, etc. The work of Lecture IX, dealing with the physiology of the bile and the succus entericus, was done five years later than the preceding. This last chapter also considers the pathology and experimental therapeutics of digestion. The methods of experimentation are given and their accuracy discussed. This is a valuable book; one that merits careful reading by the practising physician as well as by the experimental physiologist. The efficient translation makes the book very readable.

**A Treatise on the Diseases of the Eye, Nose, Throat, and Ear: For Students and Practitioners.**—By Various authors. Edited by WILLIAM CAMPBELL POSEY, A.B., M.D., and JONATHAN WRIGHT, M.D. Lea Brothers & Company, 1902.

This massive volume of over 1,200 large octavo pages is the joint product of 27 well-known authors, and it is safe to assume that no important thought in the three specialties is omitted. The rational arrangement and general uniformity of conciseness, thoroughness, practicality, and simplicity of language, as well as the absence of overlapping, bear witness to the efficient editorial supervision. The contributors are eminently practical and progressive practitioners and an international aspect is given to the work by the inclusion of several writers from Great Britain and Canada. In the main, a conservative attitude has been maintained and the needs of the general practitioner rather than the ultra-specialist and theorist have been kept in mind. Worthy of especial mention are the chapters The Eye in Relation to General Health, The Histologic Pathology of Diseases of the Nose and Throat, and Purulent Inflammation of the Middle Ear. The sections on Diseases of the Eye occupies 666 pages, that on Nose and Throat 384 pages,

and on Diseases of the Ear 124 pages. The work is well printed on good paper and is profusely illustrated with 650 engravings and 35 plates in colors and monochromes, not all of which are noteworthy for excellence. A comprehensive index is included. The only really adverse criticism to be made is the questionable taste of the publishers in producing such an unnecessarily large and unwieldy volume by combining under one cover complete treatises on specialties that are now commonly disassociated in colleges, clinics, societies, periodicals, and practice. Literary productions on the ear, nose, and throat may be combined with good reason and the interrelation of the subjects is plainly evident, but works on the eye should be published separately, notwithstanding commercial reasons for combination.

**The Elements of Bacteriologic Technic.**—A Laboratory Guide for the Medical, Dental, and Technical Student. By J. W. H. EYRE, M.D. W. B. Saunders & Co., Philadelphia and London, 1902.

We have only words of commendation for this book. When one refers to it for a certain technic, he finds it stated concisely and clearly, and not hidden in a mass of uncertain and antiquated instructions. The illustrations are numerous and instructive. It is difficult to select chapters of special merit, but those on staining methods, experimental inoculation of animals, and bacteriologic analyses are models of conciseness and definite information. The terminology of Chester has been adopted throughout. We can recommend this book to students as one that supplements the usually scanty details of technic that are given in larger and more imposing works of this class. The typography and binding are all that could be desired.

**Little Masterpieces of Science.**—Edited by GEORGE ILES. Doubleday, Page & Co., New York.

These six little volumes, admirably selected and edited, are made up of essays by the best writers in six divisions of scientific work—the skies and earth, invention and discovery, natural history, exploration, health and healing, and mental science. The medical volume contains articles on the history of the Discovery of Anesthesia, by Sir James Paget; Jenner and Pasteur, by Sir J. R. Bennett; Pasteur and His Work, by Geddes and Thomson; Tuberculosis and its Prevention, by Dr. Prudden; Malaria and Mosquitos, by Dr. Sternberg; the Art of Prolonging Life, by Dr. Robson Roose; Natural Life and Death, by Dr. B. W. Richardson; Care of the Eyes, by Buel P. Colton; and The Progress of Medicine in the Nineteenth Century, by Dr. Billings.

**How to Succeed in the Practice of Medicine.**—By JOSEPH McDOWELL MATTHEWS, M.D., LL.D. John P. Morton & Co., Louisville, Ky.

This little volume of over 200 pages contains a great fund of practical hints and suggestions from one who speaks from the standpoint of experience and authority. Some idea of the scope of subjects considered may be had from a mere mention of the themes discussed. They are: Requirements for entering the medical profession; location; marriage; ethics; the first year; specialties in medicine; the business side of it; the young versus the old doctor; the country versus the city doctor; art in medicine; some rare types you will meet; lights and shadows. Every young man beginning the practice of medicine should read this book carefully, for it is not only entertaining but it furnishes suggestions, warnings and directions too valuable to be missed. Every physician, young and old, should read especially the chapter devoted to "The Business Side of It;" and many a layman would find both pleasure and profit in perusing its pages. Doctor Matthews has rendered a distinct service to the profession and credit to himself in producing this book.

**Regional and Minor Surgery.**—By GEORGE GRAY VAN SCHAICK, M.D. The International Journal of Surgery Company, New York, N. Y.

It is soon apparent to him who begins the general practice of medicine that one of the branches grossly neglected during his course of instruction is so-called minor surgery; and it is

this very work which the general practitioner will be called upon to perform. The little volume written by Dr. Van Schaick on this subject is well adapted to the needs of the busy general practitioner. The author has wisely avoided the subjects of a technical nature and has confined himself to the ordinary but scientific treatment of such subjects as are usually grouped under the head of the title. The work is a grouping of discussions under headings such as The Hips, The Nose, The Hand and Fingers, etc., etc., and under each heading are discussed the various surgical affections to which the member is liable, together with the proper treatment of the same. The work is well written, profusely illustrated, and merits a place in our surgical literature.

#### BOOKS RECEIVED.

[Prompt acknowledgment of books received will be made in this column, and from time to time critical reviews will be made of those of interest to our readers.]

**Botany and Pharmacognosy.**—By HENRY KRAEMER, Ph.B., Ph.D., Professor of Botany and Pharmacognosy, and Director of the Microscopical Laboratory in the Philadelphia College of Pharmacy. Illustrated with plates from original drawings by the author. Printer, Edward Stern & Co., Inc., Philadelphia.

**Therapeutics of Dry Hot Air.**—By CLARENCE EDWARD SKINNER, M.D., LL.D., New Haven, Conn., Professor of Thermo-therapy in the New York School of Physical Therapeutics, Editor of the Department of Thermo-therapy in the Journal of Advanced Therapeutics, Physician in Charge of the Newhope Hot Air Sanitarium, New Haven, Conn., Member of the American Medical Association, American Electro Therapeutic Association, American Röntgen Ray Society, American Association for the Advancement of Science, Yale Medical Alumni Association, etc. 200 pages, substantially bound in cloth. Price \$2.00. A. L. Chatterton & Co., New York.

**System of Physiologic Therapeutics:** A practical exposition of the methods, other than drug-giving, useful in the prevention of disease and in the treatment of the sick.—Edited by SOLOMON SOLIS COHEN, A.M., M.D., Senior Assistant Professor of Clinical Medicine in Jefferson Medical College, Physician to the Jefferson Medical College Hospital, and to the Philadelphia, Jewish, and Rush Hospitals, etc. Vol. V. Prophylaxis—Personal Hygiene—Civic Hygiene—Care of the Sick.—By JOSEPH MCFARLAND, M.D., Professor of Pathology, Medico-Chirurgical College, Philadelphia; HENRY LEFFMANN, M.D., Professor of Chemistry in the Woman's Medical College, Philadelphia; ALBERT ABRAMS, M.D. (University of Heidelberg), formerly Professor of Pathology, Cooper Medical College, San Francisco; and W. WAYNE BAYCOCK, M.D., Lecturer on Pathology and Bacteriology, Medico-Chirurgical College, Philadelphia. Illustrated. P. Blakiston's Son & Co., Philadelphia, 1903.

**Progressive Medicine, Vol. IV, December, 1902:** A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences.—Edited by HOBART AMORY HARE, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Octavo, handsomely bound in cloth, 412 pages, 54 illustrations. Per volume, \$2.50, by express prepaid. Per annum, in four cloth-bound volumes, \$10.00. Lea Brothers & Co., Philadelphia and New York.

**Surgical Anatomy and Operative Surgery:** For Students and Practitioners.—By JOHN J. MCGRATH, M.D., Professor of Surgical Anatomy and Operative Surgery at the New York Post-Graduate Medical School, Visiting Surgeon to the Harlem Hospital and Assistant Visiting Surgeon to the Columbus Hospital, New York. Illustrated with 27 illustrations, including colors and half-tones. Royal octavo, extra cloth, \$4.00 net, sheep or half Russia, \$5.00 net. F. A. Davis Company, Philadelphia.

**Book on the Physician Himself and Things that Concern His Reputation and Success.**—By D. W. CATHELL, M.D. The Twentieth Century edition, being the eleventh edition, revised and enlarged by the Author and his Son, WILLIAM T. CATHELL, A.M., M.D. Pages, 411, royal octavo, extra cloth, \$2.00 net. F. A. Davis Company, Philadelphia.

**A Pocket Textbook of Anatomy.**—By WM. H. ROCKWELL, JR., M.D., Assistant Demonstrator of Anatomy, College of Physicians, Columbia University, New York. In one 12mo volume of 600 pages, with 70 illustrations. Lea's Series of Pocket Textbooks. Edited by BERN B. GALLAUDET, M.D. Cloth, \$2.25 net; limp leather, \$2.75 net. Lea Brothers & Co., Philadelphia and New York.

**Saunders' Medical Hand-Atlases: Atlas and Epitome of Diseases of the Mouth, Pharynx, and Nose.**—By DR. L. GRUNWALD, of Munich. From the second revised and enlarged German edition. Edited, with additions, by JAMES E. NEWCOMB, M.D., Instructor in Laryngology, Cornell University Medical School; Attending Laryngologist to the Roosevelt Hospital, Out-Patient Department. With 102 illustrations on 42 colored lithographic plates, 41 text-cuts, and 219 pages of text. Cloth, \$3.00 net. W. B. Saunders & Co., Philadelphia and London, 1903.

**Saunders' Medical Hand-Atlases: Atlas and Epitome of Human Histology and Microscopic Anatomy.**—By Privatdocent DR. J. SOBOTTA, of Wurzburg. Edited, with additions, by G. CARL HUBER, M.D., Junior Professor of Anatomy and Histology, and Director of the Histological Laboratory, University of Michigan, Ann Arbor. With 214 colored figures on 80 plates, 68 text-illustrations, and 218 pages of text. Cloth, \$4.50 net. W. B. Saunders & Co., Philadelphia and London, 1903.

**Materia Medica and Pharmacology.**—By DAVID M. R. CULBERTII, Ph.G., M.D., Professor of Botany, Materia Medica, and Pharmacognosy in the Maryland College of Pharmacy; Professor of Materia Medica and Pharmacognosy in the University of Maryland Medical and Dental Schools. Third edition, enlarged and thoroughly revised, with 473 illustrations. Lea Brothers & Co., Philadelphia and New York, 1902.

## AMERICAN NEWS AND NOTES.

## GENERAL.

**Bubonic Plague Conference.**—The National Convention of Delegates from the various State Boards of Health called to consider the danger threatened by the possible introduction of the bubonic plague into the United States assembled in Washington, D. C., January 19. This convention was called by the Surgeon-General of the Marine-Hospital Service, and was demanded by the State Boards of Health of Connecticut, Colorado, Texas, Louisiana, Minnesota, Maryland, Illinois, New York, and Pennsylvania. Representatives of 19 State Boards of Health were present at the conference. Resolutions were unanimously adopted declaring that the present danger to California and to the United States lies primarily in the persistence, during nearly three years, of a definite nidus of plague infection in that part of San Francisco known as Chinatown; that the gravity of this circumstance has been greatly increased by the gross neglect of official duty by the State Board of Health of California and the obstructive influence of the recent Governor of California, by the failure of the city government of San Francisco to support its city Board of Health, and by the obstacles opposed to the operations of the United States Public Health Service.

**Miscellaneous.**—Dr. Nelson H. Henry has been reappointed adjutant-general of New York.—At a recent meeting of the trustees of the Columbia University, Dr. L. E. La Fetra was appointed instructor in diseases of children and chief of clinic in that department at the College of Physicians and Surgeons. BALTIMORE, MD.: Dr. Leonard K. Hirschberg has been appointed director of the laboratory of hygiene at the College of Physicians and Surgeons of this city. NEW YORK CITY: On January 1, Dr. Emily Dunning began a two years' term as resident physician and ambulance surgeon at Gouverneur Hospital. She is the first regular woman interne appointed to any hospital maintained by the city.—Dr. Myron P. Denton and Dr. George M. Creevy have been appointed to Bellevue, and Dr. Samuel J. Kopetzky to Harlem hospitals as expert anesthetists. CHICAGO, ILL.: Professor G. N. Stewart, of Cleveland, Ohio, has been elected head of the department of physiology in the University of Chicago, taking the place left vacant by the resignation of Dr. Jacques Loeb.—Dr. Robert F. Weir has retired from the presidency of the New York Academy of Medicine and Dr. Andrew H. Smith has been installed as his successor.—Announcement has been made that Dr. George T. Stewart, formerly superintendent of Bellevue, has been appointed superintendent of the four contagious disease hospitals under the control of the Board of Health.

**Plague in Mexico.**—It is asserted that 107 deaths have occurred from plague in Mazatlan since January 1 and that new cases are being reported constantly. The 14 cases with 13 deaths which have occurred at Ensenada are believed to be due to infection brought by persons arriving from Mazatlan, although this fact has not been proved. It is now stated that the disease has spread to Toporico, having been carried by a white man who admitted he was from Mazatlan and who said he had little trouble in getting through the quarantine lines. It is rumored that the disease has been discovered in a number of the small interior towns in Sonora. The Guaymas quarantine against ships from Topolobampo, Mazatlan, and even San Francisco is being rigidly maintained. A late report states that the people of Topolobampo are dying like sheep and the survivors are leaving the stricken city as fast as possible, many going at night in skiffs. It is feared these departures will spread the disease. The appearance of plague at Mazatlan and Ensenada could readily be explained by the following facts given in the Public Health Reports: "Mazatlan has about 30,000 inhabitants and is the point where most Chinamen land who desire to enter the United States illegally from the south. They reship at San Francisco from the trans-Pacific steamer to the coastwise Pacific mail and land at Mazatlan, where they take the 'Curacao' to Ensenada and there await their chance to get across the border. The vessel makes a round trip a month between San Francisco and several Mexican ports."

**Dr. Reed's Services to Humanity.**—Entirely out of the class to which belong so many private pension bills is one soon to be submitted to Congress in behalf of the widow of Walter Reed, major and surgeon, United States Army. His services to humanity and to his country were very great, for it was due to his energy, intelligence, and courage that the relation between mosquitos and yellow fever was established in Cuba, and not only that island freed—forever, if the measures the efficacy of which he demonstrated are not neglected—from a disease that had devastated it for 200 years, but our Gulf and South Atlantic States relieved of a danger that constantly threatened them, and had often inflicted enormous losses of life and property upon their citizens. Dr. Reed did not, like one of his associates, die of the disease from which he saved others, but he took the chance of doing so without hesitation, despite the fact that, because of a heart affection, he had not for some years past been able to secure insurance upon his life. Certainly the country owes him a debt of gratitude, and a pension that would put his wife and daughter beyond want would be a

fitting expression of that feeling. As has been well said, so important was the result of Dr. Reed's work that if this alone were the outcome of our war with Spain, its cost in blood and treasure would have been measurably repaid. Enough popular interest in the pension bill should be shown to insure its passage, and not much effort should be needed when it is found so easy to put on the rolls so many names that cannot pass the far from too searching scrutiny of the Pension Bureau.—[*New York Times.*]

**Hospital Benefactions.**—PHILADELPHIA: The will of the late Dr. Bushrod James devises \$55,000, several pieces of real estate in the city, and several lots at Island Beach, N. J., to the city of Philadelphia, for the purpose of establishing a free hospital in Philadelphia for the treatment of diseases of the eye and ear. The will directs that the proposed hospital be called the Washington James Eye and Ear Institute, and that the \$55,000 be invested as an endowment fund, the income to be used for its maintenance.—The University of Pennsylvania Hospital has received a gift of \$10,000 for the endowment of two free beds from a woman who wishes her name withheld.—According to the will of the late Henry C. Cochran the following bequests will become effective on the death of his widow: The Pennsylvania Hospital will receive \$10,000, \$5,000 of which is to be used for improving the conditions of the insane; the Presbyterian Hospital will receive \$5,000; the University of Pennsylvania Hospital, \$5,000; the Philadelphia Polyclinic, the Gynecean Hospital, and the Medico-Chirurgical Hospital, each \$1,000; the Philadelphia Dispensary and the Northern Dispensary, each \$500.—The late James Wilson bequeathed \$1,000 to the Presbyterian Hospital. BUFFALO, N. Y.: The late W. C. Mills, of this city, bequeathed \$10,000 to the Buffalo General Hospital. NEW YORK CITY: According to the will of the late Isaac T. Carpenter, upon the death of his sister the following institutions will each receive \$1,000: The Woman's Hospital, New York Society for the Relief of Ruptured and Crippled, German Hospital and Dispensary, New York Eye and Ear Infirmary, Mount Sinai Hospital, New York Infirmary for Women and Children, New York Homeopathic Infirmary for Women in the City of New York, Home for Incurables, and the Nursery and Children's Hospital.

## EASTERN STATES.

**Distribution of Vaccine Lymph.**—The report of the Massachusetts State Board of Agriculture regarding the production of vaccine lymph at the State Agricultural College for free distribution, which is now under consideration in the House, states that a part of the veterinary department of the college could be used in the production of vaccine, their being stables, laboratories, and apparatus available for the purpose, but that it would be necessary to erect an additional building for stabling and laboratory purposes. It is estimated that such a building would cost about \$9,000, and the apparatus necessary for its equipment about \$2,500 more. It is suggested that an annual appropriation of \$3,000 be made to cover salaries and incidental expenses. The board believes the plan is practicable; that the work can be done at a minimum cost; and that the location of the college is a distinct advantage in the distribution of lymph.

## NEW YORK.

**The McKinley Memorial Hospital** for Diseases of the Digestive Organs, of New York City, has applied to the State Board of Charities for permission to incorporate. It is intended to treat diseases of the digestive organs and to establish a laboratory for original investigation.

The recommendations in Governor Odell's message pertaining to medical matters were as follows:

Separate buildings for superintendents and medical staffs at Poughkeepsie, Utica, Buffalo, Binghamton, Rochester, and Gowanda (\$225,000); home for nurses, Kings Park (\$51,000).

Tuberculosis hospitals at six institutions (\$90,000).

Transfer of inmates of Bedford Reformatory to reformatories for women at Hudson and Albion; its conversion into a hospital for insane (\$150,000).

Prohibition of use of Elmira Reformatory by the United States Government.

Removal of State Industrial School (Rochester).

Amendment of child labor law so as to make effective the statutes regarding the employment of children.

Amendment of tenement-house law.

## PHILADELPHIA, PENNSYLVANIA, ETC.

**Health Certificates for Teachers.**—A resolution has been passed by the Board of Education of Philadelphia which will require students entering the Normal School to present a certificate of good health. The idea is to prevent those entering and graduating from the school who are unable to act in the capacity of teachers. This plan has been followed successfully in Chicago and Denver.

**The Chair of Obstetrics, Woman's Medical College of Pennsylvania.**—Professor Anna E. Broomall last spring resigned the chair of obstetrics in the Woman's Medical College of Pennsylvania, but consented to remain in the college for one year only. Her connection with this department will therefore terminate with the close of the present session. The faculty will consider the subject of nominating a successor at a very early date, probably during the present month.

## SOUTHERN STATES.

**Study of Criminals.**—The House Judiciary Committee has reported favorably on the bill establishing a laboratory for the study of the criminal, pauper, and defective classes in connection with the Department of Justice. The bill provides that there shall be established in the Department of Justice a laboratory for the study of the abnormal classes. Such work will include not only laboratory investigations, but also the collection of jurisprudential, sociologic and pathologic data, especially as found in institutions for the criminal, pauper and defective classes and as may be observed in hospitals, schools, and other institutions, also investigation of anarchistic criminals, mob influence and like phenomena. The causes of social evils are especially to be sought out, with a view to lessening or preventing them. These results and those of similar work are to be collected and published from time to time. There is to be a director of the laboratory at an annual salary of \$3,500. Specialists to assist him are to be employed in investigations, and such other help as may be necessary to carry on the work. An appropriation of \$20,000 is made in the bill, one-half of which is to be immediately available. When the legislative, executive, and judicial appropriation bill passed the House no provision was made for continuing the work of a specialist in criminology and cognate subjects in the Bureau of Education, Mr. Harris, chief of the bureau, it is understood, having recommended that no appropriation be made. The work has heretofore been done by Mr. Arthur Macdonald, who has published a number of monographs and books on the criminal and defective classes.

## WESTERN STATES.

**"Wisconsin Medical Journal."**—The first number of this journal, which is edited by Dr. Arthur J. Patek, of Milwaukee, appeared this month with an exceptionally high grade of contributors. The publication will be issued monthly, the subscription being placed at \$2.00 per year.

**Barbers Aspire to be "Doctors."**—The *Chicago Tribune* is authority for the statement that the "tonorial artist" of Chicago aspires to be a "doctor of medicine." A bill is prepared which the Legislature of Illinois will be asked to pass. It requires that all shops and implements be kept clean and sanitary, and that the barbers be versed in medical knowledge. It also requires the examination of all applicants after they have served three years' time with a licensed barber. The bill further provides for a board of five commissioners and ten inspectors.

## FOREIGN NEWS AND NOTES

## GREAT BRITAIN.

**Editorship of the "Practitioner."**—It is announced that Malcolm Morris, who has retired from the editorship of the *Practitioner* after eight years' incumbency, will be succeeded by W. Cecil Bosanquet.

**Decreased Birthrate in London.**—According to the statistics for 1902 the birthrate for London reached the lowest figures since registration began, the rate being only 29 per 1,000 inhabitants. The deathrate is given as 17.1 per 1,000, the lowest since 1840; the marriage rate was 17.6 per 1,000.

## CONTINENTAL EUROPE.

**Hospital for Lepers in Paris.**—The authorities of Paris propose to erect a hospital for lepers in that city and an appropriation of 25,000 francs has been asked for this purpose. In the city of Paris there have been reported 19 cases of leprosy, and it is asserted that the physicians of Paris have less concern in regard to the contagiousness of leprosy *per se* than for the strong predilection which lepers have for tuberculosis.

## OBITUARIES.

**Oliver Wendell Weeks**, past surgeon-general of the Grand Army of the Republic, died in Marlon, Ohio, January 13, aged 62. He was graduated from the Cincinnati College of Medicine and Surgery in 1865. He was president of the Board of the United States Pension Examining Surgeons during Presidents Harrison, McKinley, Roosevelt, and part of President Cleveland's administrations. He was a member of the American Medical Association, Ohio State Medical Society, and president of the Marion County Medical Society. He was an ex-member of the board to examine applicants for the West Point Military Academy and the Annapolis Naval Academy from the Eighth and Thirteenth Congressional Districts.

**Frederick J. Bancroft**, of Denver, died in San Diego, Cal., January 17, aged 68. He was graduated from the medical department of the University of Buffalo in 1861. He served as a surgeon with the Union forces during the Civil war, and was chief surgeon of the Colorado and Southern Railway and Colorado Midland Railway Companies. He was

an occasional contributor to medical literature, his works being mostly upon effects of climate upon certain diseases.

**El H. Coover**, a prominent physician of Harrisburg, Pa., died January 13. He was graduated from the Jefferson Medical College, Philadelphia in 1850. He was a member of the American Medical Association, Pennsylvania State Medical Society, Dauphin County Medical Society, and was a Founder and first president of the Harrisburg Academy of Medicine.

**E. Edwin Spencer**, of Cambridge, Mass., January 19, aged 69. He was graduated from the Cincinnati Eclectic College in 1856, and from the Worcester Medical College in 1859. He was city physician of Cambridge until 1891, when he was appointed a member of the Board of Health, and afterward became its chairman.

**Anson S. Fraser**, of Sarnia, Ont., December 31, aged 56. He was graduated from the medical department of Queen's University in 1869. He was for nine years examiner in physiology for the Ontario Medical Council and was largely instrumental in the establishment of the Sarnia General Hospital in 1896.

**Mareus A. Bogie**, in Kansas City, January 4, aged 62. He was graduated from the Long Island College Hospital, Brooklyn, in 1864. He was chief surgeon to the Kansas City Belt Railway and a member of the International Association of Railway Surgeons.

**James N. West**, of Toccoa, Georgia, January 11. He was graduated from the Jefferson Medical College, Philadelphia, in 1891. He was a member of the Georgia State Medical Association and was medical examiner for a number of life insurance companies.

**Irving S. Vallandigham**, in Middletown, Del., December 30, aged 62. He was graduated from the University of Maryland in 1862. He served as an assistant surgeon in the Confederate Army and was a member of the American Medical Association.

**Henry Van Ostrand**, in Yankton, S. D., December 26, aged 84. He was graduated from the Geneva (N. Y.) Medical College in 1843. During the latter part of the Civil war he served as assistant surgeon to the First Michigan Engineers and Mechanics.

**Robert E. Williams**, an assistant surgeon in the United States Volunteers, died at the United States General Hospital, Presidio, of San Francisco, December 30, aged 58. He was graduated at the University of Georgetown, Washington, D. C., in 1870.

**Henry H. Howland**, in Denver, Colo., December 27, aged 53. He was graduated from the medical department of the New York University in 1873. He was a member of the American Medical Association and was well known as a laryngologist.

**George T. Motter**, of Taneytown, Md., died in Westminster, Md., January 16, aged 61. He was graduated from the medical department of the University of Nashville in 1864. During the Civil war he was a surgeon in the Federal Army.

**Ralph Brooks**, in Hampton, Va., January 4, aged 27. He was graduated from the University of Pennsylvania in 1897, and at the time of his death was first assistant physician at the National Soldiers' Home, Hampton, Va.

**John Allard Jeancon**, of Newport, Ky., January 13. He was graduated from the Royal College of Surgeons, London, Eng., in 1854. During the Civil war he served as surgeon of the Thirty-second Indiana Volunteer Infantry.

**Susan R. Pray**, of Brooklyn, N. Y., January 13, aged 45. She was graduated from the Woman's Medical College of the New York Infirmary, New York City, in 1882. She was a member of the Health Board for thirteen years.

**Charles Edmond Chase**, in Woburn, Mass., December 26, aged 53. He was graduated from the University of Vermont, Burlington, in 1873. He was a prominent member of the Massachusetts Medical Society.

**H. B. Tingley**, a well-known physician of Borough of Queens, New York City, was killed by a train at Rockaway Beach, January 14, aged 45. He was graduated from the Baltimore Medical School in 1889.

**John B. Amiss**, of Harrisonburg, Va., January 4, aged 68. He was graduated from the New York University in 1858, and was a member of the National Association of Railway Surgeons.

**Robert H. Goldsmith**, a well-known physician of Baltimore, Md., died January 14, aged 70. He was graduated from the University of Maryland School of Medicine in 1852.

**Charles A. Osborne**, in Owosso, Mich., January 2, aged 70. He was a graduate of the Buffalo Medical College and served as surgeon during the Civil war.

**L. A. Burgess**, of New Iberia, La., January 15, aged 72. He was graduated from the medical department of the Tulane University, New Orleans, in 1856.

**George W. Howard**, a retired physician of Vicksburg, Miss., January 12, aged 68. He was graduated from the Medical College of Virginia in 1863.

**William H. Hildreth**, a retired physician of Newton, Mass., died January 15, aged about 65. He was a graduate of the Dartmouth Medical College.

**William G. Cole**, in Van Wert, Ohio, January 1. He was graduated from the New York University in 1843, and served as a surgeon in the Civil war.

- T. L. Webb**, in Cookeville, Tenn., December 24, aged 50. He was graduated from the Georgia College of Eclectic Medicine and Surgery in 1889.
- W. W. Watkins**, in Carthage, Mo., January 2, aged 75. He was graduated from the College of Physicians and Surgeons, Keokuk, Iowa, in 1882.
- William C. Gallagher**, in New York City, January 5, aged 40. He was graduated from the Bellevue Hospital Medical College, New York, in 1886.
- Ernest W. Bradley**, at Grass Valley, Cal., December 28, aged 48. He was graduated from the Hahnemann Medical College, Chicago, in 1879.
- William H. Haviland**, in Columbus, Ohio, December 30, aged 38. He was graduated from the Starling Medical College, Columbus, in 1889.
- Charles H. Black**, in Turtle Creek, Pa., January 2, aged 53. He was graduated from the Jefferson Medical College, Philadelphia, in 1875.
- Charles W. Hedges**, in Newkirk, Okla., December 21, aged 26. He was graduated from the Vanderbilt University, Nashville, Tenn., in 1901.
- Ralph G. Morgan**, in Indianapolis, Ind., January 1, aged 29. He was graduated from the Medical College of Indiana, Indianapolis, in 1898.
- John E. Palmquist**, in Holdrege, Neb., December 21, aged 32. He was graduated from the University of Minnesota, Minneapolis, in 1896.
- William Lindsay**, in Strathroy, Ont., December 9, aged 59. He was graduated from the medical department of Victoria University in 1869.
- Nesbitt F. Jordan**, in Bloomington, Ill., December 28, aged 45. He was graduated from the Medical College of Ohio, Cincinnati, in 1884.
- William S. White**, in Lexington, Va., December 20, aged 59. He was graduated from the University of Virginia, Charlottesville, in 1875.
- Schuyler F. Shidler**, near Sheridan, Mo., January 3. He was graduated from the College of Physicians and Surgeons, Chicago, 1888.
- Ephraim W. Gantt**, in Lockport, N. Y., January 5, aged 72. He was a graduate of the College of Physicians and Surgeons, New York.
- Allen G. Berry**, in Ashland, Ky., December 30, aged 43. He was graduated from the Kentucky School of Medicine, Louisville, in 1886.
- J. Henry Rider**, in Cape Girardeau, Mo., December 23, aged 61. He was graduated from the Missouri Medical College, St. Louis, in 1870.
- Jacob L. Heller**, of Philadelphia, January 12, aged 36. He was graduated from the Jefferson Medical College, Philadelphia, in 1892.
- James Beahan**, in Rochester, N. Y., January 3, aged 80. He was graduated from the Jefferson Medical College, Philadelphia, in 1852.
- William H. Middleton**, in Camden Point, Mo., December 25. He was graduated from the Washington University, St. Louis, in 1866.
- Robert G. Petway**, in Nashville, Tenn., December 24, aged 68. He was graduated from the Nashville (Tenn.) Medical College in 1855.
- William Bevier**, in Waterloo, Ind., December 29, aged 80. He was graduated from the Eclectic Medical Institute, Cincinnati, in 1852.
- Louis Charette**, in Glens Falls, N. Y., December 26, aged 87. He was graduated from the Albany (N. Y.) Medical College in 1852.
- James T. Scott**, in Paynesville, Mo., December 28, aged 70. He was graduated from the Missouri Medical College, St. Louis, in 1854.
- James DeWolf**, near Baraboo, Wis., January 5, aged 60. He was graduated from the Harvard University Medical School in 1866.
- William L. Demmon**, in Clarkston, Mich., December 28, aged 30. He was graduated from the Detroit College of Medicine in 1894.
- William E. Brownell**, in New Bedford, Mass., December 27, aged 45. He was graduated from the New York University in 1879.
- William J. Deane**, at Kingston, N. Y., December 31, aged 36. He was graduated from the University of Buffalo, N. Y., in 1895.
- Waldo E. Clark**, at Saginaw, Mich., December 19, aged 45. He was graduated from the Detroit College of Medicine in 1887.
- L. E. Towne**, in Broadhead, Wis., January 6, aged 76. He was graduated from the Rush Medical College, Chicago, in 1868.
- William A. Looney**, in Vienna, Ill., January 5, aged 74. He was graduated from the Rush Medical College, Chicago, in 1868.
- Daniel P. Buckey**, at Flemington, W. Va., December 29. He was graduated from the Baltimore Medical College in 1894.
- H. Van Gerhart**, in San Diego, Cal., December 28, aged 29. He was a graduate of the Missouri Medical College, St. Louis.
- J. J. Arendale**, in Waller, Tex., January 5. He was graduated from the University of Tennessee, Nashville, in 1894.
- William R. Freeman**, in Bellbuckle, Tenn., January 1. He was graduated from the University of Nashville in 1871.
- George W. Harding**, in Ahmednagar, India, January 13. He was a graduate of the Rush Medical College, Chicago.
- James McCullough**, of Watertown, N. Y., January 13, aged 48.
- J. W. Summers**, of Cameron, S. C., December 28, aged 65.
- James H. Lowe**, in Atlanta, Ga., January 21, aged 82.
- John Stevens**, in Bangor, Me., December 21, aged 67.
- Arthur J. Padron**, in New Orleans, December 30.

CLINICAL NOTES AND CORRESPONDENCE

[Communications are invited for this Department. The Editor is not responsible for the views advanced by any contributor.]

HYDROGEN DIOXID IN MERCURIAL STOMATITIS.

BY

ALBERT H. FRIDENBERG, M.D.,

of New York City.

The tendency to mercurial stomatitis depends so much upon individual predisposition, that, given teeth that are defective, or even artificially sound, plus the indication for vigorous mercurial treatment, one can by no means be assured, no matter how minutely one has instructed the patient in the care of his mouth or impressed upon him the importance of certain prophylactic measures, that this justly dreaded complication can always be prevented. Even when the customary injunctions are faithfully adhered to, cases of mercurial stomatitis are not infrequent, often very severe, and notoriously rebellious to treatment. The evils of "salivation" must not be underestimated. The patient suffers intensely, often being deprived of rest, sleep, and the ability to masticate and to swallow food for many days in succession. Pain, insomnia and insufficient nutrition combine to sap rapidly the vital forces and thus become potent factors for evil, especially when added to the natural inroads of the specific disease in question. The plight of such a subject presents a composite picture of misery, physical and mental, not readily forgotten when once witnessed, owing not only to the actual suffering entailed, but equally because of the overwhelming depression of spirits so frequently attendant upon the revelation of the presence of an infection, the loathsome, treacherous, protracted and uncertain nature of which is but too well appreciated by the intelligent class. In fact, by some authorities, the baneful effects of salivation, when severe, are represented as second only in importance to the destructiveness of the original disease itself.

In an emergency of this kind, recently, I exhausted the list of remedies usually suggested, to no avail, when, finally, I had recourse to the use of hydrogen dioxide locally, and with such unexpectedly gratifying results that I am impelled to put this memorandum on record, with no apologies, even in view of the comparative triteness of the subject.

The case was that of an anemic and highly nervous young married woman, infected by her husband, and in the early secondary stage. Her face and body were so thickly sown with the typical maculopapular eruption that she was hardly recognizable. The pharynx and tonsils were affected. Her hair was falling out copiously; she had violent cephalalgia and acute nocturnal osteocopic pains. Her mental and physical distress was extreme and bordered on hysteria. Energetic mercurial treatment was therefore imperative. After ten inunctions in as many days, and in spite of the usual prophylaxis of the buccal cavity, stomatitis set in and rapidly assumed a severe form. The tongue was swollen, flabby, indented; the gums were tender, softened, reddened, and receded from the roots of the loosened teeth; the edematous pillars of the fauces made of each act of deglutition an agonizing effort; the dribbling of viscid saliva and the fetid breath added to her wretchedness. The inferior maxilla and the cervical region were everywhere exquisitely sensitive to the touch. The usual remedies proved inefficient. Neither potassium permanganate, silver nitrate, tincture of galls, rhatany, nor even the once popular mercuric chlorid in weak solution availed. Internally atropin and duboisin were administered. They appeared, for a time, partially to control the flow of saliva, but they did not alter the local condition nor give relief. The patient was exhausted by loss of sleep and of sustenance and by constant pain, and was rapidly getting into a desperate condition. She whimpered for relief. It occurred to me to try hydrogen dioxide, which I advised as a mouth-wash, diluted, one part in three of water, every half hour. The result was most gratifying, the patient experiencing, within 24 hours, a measure of relief not previously obtained with all the other remedies combined, faithfully employed for five days. In two days she was comfortable, and thereafter recovery was rapid and complete.

Those of us who are familiar with this undesirable complication and with the difficulties attending its management, will appreciate the boon of a remedy, which, while free from the objectionable features of others much favored heretofore, seems to act with promptness and precision.

## INSUSCEPTIBILITY TO VACCINATION.

BY

WM. C. WOODWARD, M.D.,  
of Washington, D. C.

To the Editor of *American Medicine*:—Apropos of certain recent very positive statements to the effect that insusceptibility to vaccination does not exist, you inquire, "What is the greatest number of nontaking vaccinations known to any of our readers?" I personally have been vaccinated so frequently that I cannot recall the exact number of times. I think I can safely say, however, that it was somewhere between 15 and 30. These vaccinations covered a period extending from childhood to the present time. They have been done with numerous varieties of vaccine matter, including in childhood humanized virus. The operations have been performed by local practising physicians, inspectors of the Health Department, on one or two occasions by medical officers of the Marine-Hospital Service, once by a representative of a propagator of vaccine lymph, and once by a physician directly connected with the propagations of such lymph. Not one of these vaccinations has been successful. I have frequently come into contact with smallpox in the wards of the smallpox hospital and elsewhere, and have as yet felt no ill effects from such contact.

I have made it a practice to be vaccinated practically after each exposure to infection, and notwithstanding the above facts will continue such practice.

THE FABLE OF THE SICK DOCTOR.<sup>1</sup>

(With apologies to Mr. Ade.)

The Doctor who never had any Time to take his own Medicine or consider his own Symptoms, Got Sick suddenly like a Mere Patient.

They rushed him to the Hospital in the Ambulance, put him to bed, took his Temperature, and decided on an Operation because he had a New-Fangled Ailment.

But the Doctor had no enthusiasm about his Case. He Felt Sick.

The Surgeon came around with that Brisk, Professional Air that is part of the Business, and patted him on the Back and Patronized him with sundry Jollies. But the Doctor had his Private Opinion that it was No Joke.

The Nurses, who are Good Girls but human, said in their hearts: "Here is a chance to get on the Right Side of the Doctor, so he will call us Ministering Angels." And their Assiduity fairly rustled. But the Doctor was an Old Bachelor who sometimes said "Damn" when he felt like it. And certain restraints are necessary in the Presence of Ministering Angels.

The Doctor had a Hobby on germs when he was well. He could tell you the Difference between Bacilli who were Second Cousins removed, and those who did not Go in the same circles of Society, and in Latin words long enough to cross the page and Lap Over. But when they began scrubbing him with solutions and doing him up in Antiseptics and Oiled Silk, and Regretting that they couldn't put him in the Sterilizing Kettle before the Operation to make him perfectly Aseptic, the only reason he did not Quit the Place was that the Power had Given Out.

The Doctor could give you Hard Facts for an article on the beneficence of Modern Abdominal Surgery, which is the euphonious for Free-Hand Carving, but when the Surgeon was ready he was as Well SCARED as a man can be and keep up Cheerful Appearances. Long training in the Lugubrious Business had made Cheerful Appearances second nature with him.

When he Returned to Earth he wished he had continued in the Air Ship. He felt like a Premature Baby in an Incubator. If he'd been the First Heir he couldn't have attracted more Attention when he made his first Noise. Between feeling his pulse and fanning him, hot-water Bottles and Ice packs, basins at Intervals and alcohol sponges Frequently, tender solicitude and Fluttering Anxiety, he was the Whole Thing.

<sup>1</sup>A contribution from a lay friend, representing the layman's point of view.

The Doctor knew, Professionally and from Text Books, of the Baleful Effects of Alcohol, and he could be jocund with the fruitful grape on Provocation. When he began to feel of his Symptoms and his Head, and to Diagnose his Case from Force of Habit, he admitted that it was a Double Distilled Sulphuric-and-Brimstone, Alcoholic "JAG" (in the vernacular). Which is to say that he was Coming Out of the Ether. And he was Sicker than a Dog, and Sorry for himself.

But the Surgeon declared the Operation was Successful.

Then all the Doctor's Friends Mourned.

"For," they said, "That Settles It—the Man will Die."

A hospital is a Training school for Meekness of Spirit. When a man who has always walked in Authority and Commanded in Power gets into a little white bed with a big surgeon over him and half a dozen nurses to represent the Tyranny of Petticoats, he needs to be a brave and discreet man or he'll get called a Crank.

There are two kinds of patients in a hospital—patients and Cranks. A patient is a Sick Person who takes his Medicine. A Crank is a Person who requires a Firm Hand and the Head Nurse.

When the Attending Physician said, "Don't give him That"—"See that he takes This"—and the nurse wrote it down in her book and it became that Cast Iron, Rigid and Unimpeachable Legislation "The Doctor's Orders"—the Sick doctor smiled in a sick fashion and remembered all the Cast Iron and Unimpeachable "Doctor's Orders" for which he had been responsible.

Beside, a man who has been House-boating on the Styx and on liquid diet will put up with most anything when he Gets Back to Terra Firma.

As a Doctor, wise men had hung upon his words, and what he said invariably proceeded. As a patient, he was not supposed to have any common sense or to use his own brain for purposes of personal cerebration; when it was time to sleep the light was put out; when it was time to wake the nurse sloshed Soapsuds in his eyes and towed him into a knowledge of the hour of the morning when the night nurse "Did Up her work for the day." When he desired sustenance the ministering Angels turned Deaf ears to him; when it was Time for anything they poured it Down his throat. When he entreated for a Smoke he learned that the Ladies objected to Tobacco, and the Attending Physician declared that he would have a chance to Smoke Hereafter. But the Attending Physician had smoked his own After Dinner Cigar and could afford to be facetious.

In the course of time he became a Grateful Patient. Every Case eventually becomes a Grateful Patient, for the Good Name of the Institution. The others die. Gratitude is the first Stage of Convalescence. He listened for the rustle of petticoats down the corridor and the jingle of safety-pins hung in a string to the band of a starched linen apron. He listened to the ceaseless footsteps of Ministering Angels who work 25 hours a day with no pay for overtime. And he learned more about the cheerful Humanities and the brotherhood of man and the sisterhood of woman than he had ever read in the Christian Poets or the Heathen Philosophers, and if there had been but One Ministering Angel it would have been Fatal. As it was, he thought up Extenuating Circumstances for Mr. Roberts, of Utah.

But about the time he arrived at a realizing sense that life was a Bed of Roses and that he Owned the Greenhouse, the thermometer suddenly Dropped and he Felt a Chill. There was a New Patient in the next Room, and he heard the Tender Solicitude rustle through the wainscoting. And they came and Turned him out of the Place and hung a New Chart on the footboard, and they said: "We are Glad to get Rid of you. For you are no longer an Interesting Case. You are Well."

Now, as a Medical Man, he had hitherto taken a very complacent view of the Profession. But Thirty Days in Solitary Confinement had given him time to Think. A new Relation of things Percolated through his inner consciousness with the comfort of Being Taken Care Of, and he said in himself: "Go to! Half the patients would Die were it not for the Nurses."

Moral: A Doctor can learn a heap about his own Business if he tries being a Patient.

M. A. W.

## INFLUENCE OF NEPHRECTOMY UPON ABSORPTION.\*

BY

S. J. MELTZER, M.D., AND W. SALANT, B.S., M.D.,  
of New York City.(A preliminary communication from the Rockefeller Institute for  
Medical Research.)

Our study of the effects of subminimum doses of strychnin upon nephrectomized rabbits brought to light the fact that these animals can gradually receive a good deal more than the fatal dose without manifesting any reaction. In discussing this remarkable result we mentioned among other explanations the possibility that in nephrectomized animals absorption from subcutaneous tissue is perhaps impaired. This latter suggestion, although in conformity with the view prevailing among pathologists, is as yet only a surmise; so far as we know this question was not yet made a subject of a systematic experimental study. The reason for the assumption that absorption is impaired after nephrectomy is found in the well known pathologic fact of the appearance of edema and ascites in the course of some diseases of the kidneys. All theories on the formation of edema seem to agree that it is due to an increased transudation of serous fluid from the blood into the lymph spaces and that the plethoric condition of the blood, which is brought about by the diminished excretion of water by the diseased kidneys, is at least one of the causes of the increased transudation. With these premises in view it seems obvious that the entire removal of the kidneys surely ought to lead to plethora and an increased transudation and therefore also to a decrease in absorption from the lymph spaces.

However, in the many nephrectomies we have performed on rabbits and guineapigs we have never observed edema following this operation; nor have other experimentors recorded an increase in transudation after the removal of the kidneys. We have therefore decided to subject the question as to the behavior of absorption after nephrectomy to an experimental test.

We shall report here only our essential results, and those very briefly. The experiments were made on rabbits by introducing salt solutions through a fine opening into the peritoneal cavity and removing it very carefully again after varying intervals. There was a normal control rabbit for each nephrectomized animal. Lumbar nephrectomy was practised and care taken not to injure the peritoneum.

The first series of experiments was made with a solution of 0.8% sodium chlorid, it being considered approximately isotonic with the serum of the rabbit.

The result was a surprise. Not only was the absorption in the nephrectomized rabbits not less than in the normal, but it was distinctly better. In five experiments the average absorption for the normal was about 20 cc. per kilo to 22 cc. for the nephrectomized animal. The differences were still more striking when the percentages of the injected volume were compared: 43% for the normal to 65% for the nephrectomized rabbit.

These results, which seem to show that nephrectomy rather favors absorption, directed our attention to a factor which has been hitherto neglected in the considerations of the effects of nephrectomy; it is the increased osmotic pressure of the blood. As the urine has usually a higher osmotic pressure than the blood, it seems quite obvious that after nephrectomy the osmotic pressure of the blood ought to be increased. If this be correct, then a solution of 0.8% sodium chlorid, which is about isotonic with the blood of normal rabbits, is probably hypotonic with the blood of the nephrectomized ones; hence the better absorption in the latter animals.

In our next experiments we have carried out several series with solutions of sodium chlorid of 1%, 1.2%, 1.5% and 2% concentrations. We shall not give particulars. It will suffice to state that, for instance, in the series with solutions of 1.2%, the average of seven experiments for the normal amounted only to 0.5 cc. per kilo against 12 cc. per kilo for the nephrectomized rabbits, or 0.6% for the normal against 25% of the injected volume in the nephrectomized animals. That means that the absorption of a solution of 1.2% sodium chlorid was in nephrectomized animals at least 24 times as good as that which took place in normal ones. With solutions of 1.5% sodium chlorid there was in three out of four normal animals a negative absorption, that is, more fluid was recovered than injected; while in nephrectomized animal there was in each case still a considerable positive absorption. Only in the series with 2% solutions was there one case also among the nephrectomized animals in which more was recovered than introduced.

Our experiments demonstrate clearly that after nephrectomy absorption is considerably improved. They clear up the mysteries why no edema was observed after nephrectomy in animals or in pathologic cases of acute anuria in human beings lasting some times five to six days. The first effect of complete anuria is not an increase of the normal transudation but an increase of the power of absorption of the blood.

A full report will appear soon in the *Journal of Medical Research*.

The experiments were carried out in the pathologic laboratory of the College of Physicians and Surgeons, New York. We wish to acknowledge our indebtedness to Professor Prudden, the director of the laboratory.

SECONDARY CARCINOMA OF THE LIVER, WITH  
REPORT OF A CASE IN WHICH THE LIVER  
WEIGHED 15,110 GMS. (33½ LBS.)\*

BY

HENRY A. CHRISTIAN, A.M., M.D.,  
of Boston, Mass.

Instructor in Pathology, Harvard University; Second Assistant Visiting Pathologist, the Boston City Hospital.

[From the Pathological Laboratory of the Boston City Hospital.]

Among 1,650 consecutive postmortem examinations recorded in the Pathological Laboratory of the Boston City Hospital, 60, or 3.63%, showed carcinoma affecting some organ of the body. Of these 1,650 cases, 362 patients were under 20, so that the percent of carcinomatous involvement for adult patients was 4.65%. Again this total of 1,650 cases includes 268 from the South Department, where only the acute infectious diseases, as scarlet fever and diphtheria, are treated. Deducting these there remain 1,382 cases, of which 4.34% were carcinomatous.

The liver was involved in 25, or 41.66% of the 60 cases of carcinoma. This represents 1.51% of the total number of autopsies, or 1.94% of those over 20. Of these 25 cases, the carcinoma was primary in the liver in 5, and secondary either by direct extension or by metastasis in 20. The percentage of liver involvement in this series of cases is apparently a small one.

In 4,200 autopsies at Guy's Hospital, reported by White,<sup>1</sup> 126, or 3%, showed carcinoma of the liver, and this corresponds with the figure given by Leichtenstern,<sup>2</sup> who in 6,019 autopsies found carcinoma of the liver in 174, or 2.89%.

In 311 cases of carcinoma at the Zurich medical clinic, reported by Siegrist,<sup>3</sup> the liver showed involvement clinically in 45 cases, and this by postmortem examination was corrected to 77 cases, or 24.7% of the total.

\* Presented at the meeting of the American Physiological Society, December 31, 1902, Washington, D. C.

\* Contributed to Vol. XIII of the Medical and Surgical Reports of the Boston City Hospital.

An analysis of the 20 cases of secondary carcinoma of the liver shows 11 males and 9 females. The ages ranged from 28 to 70, as follows :

28 years.....	1 case.
3) to 40 ".....	2 cases.
40 to 50 ".....	3 " "
50 to 60 ".....	7 " "
60 to 70 ".....	7 " "

The duration of the disease, owing to the very indefinite character of the early symptoms, is difficult to estimate. When determinable it was in most cases from 3 to 8 months, and in some much less. In only one case was one year with certainty exceeded, and possibly in another in which there was a history of gallstone attacks during a period of 8 years. Jaundice was present in one-half of the cases, and ascites in one-third. In only 4 cases did the spleen exceed the average normal weight of 171 gms. as given by Orth, and in these cases the enlargement was explainable as the result of a concomitant acute infectious process, to which in one case was added a malarial splenitis.

In the 20 cases, the primary growth was in the stomach in 5, pancreas 4, large intestine and gallbladder, each 3, rectum 2, esophagus, breast, and prostate, each 1.

The picture presented by the liver in the different cases varied both as to the extent and character of the involvement. In 13 cases the liver surface was nodular, the nodules varying in size from 3 mm. to 6 cm., or even larger. Umbilication of the nodules was often present. The cut surfaces of the livers were thickly studded with carcinoma nodules, generally whitish in color, but frequently mottled by bile staining or foci of hemorrhage. The liver tissue between the nodules appeared normal or showed evidence of compression. In none was there more than a slight increase of connective tissue in the liver substance. In all of these cases all parts of the liver seemed to share equally in the diseased condition. In 4 cases the liver showed only a few nodules. In one of these there was a single nodule in the right lobe, in another one in the left lobe; a third showed two nodules, and a fourth a few. In 2 cases the liver was involved by extension in the immediate vicinity of a primary growth in the gallbladder, besides showing a few scattered metastases.

One case differed from all the others in having an almost perfectly smooth surface, and a very extensive diffuse growth in the liver tissue, with only here and there the formation of small discrete nodules. The involvement was more marked toward the periphery of the liver than at the center, and in places assumed an indefinite wedge-shaped distribution. The liver weighed 3,400 gms.

The structure of the liver growths was that of the primary, in most cases adenomatous in type. The size of the liver showed great variation. When the involvement was slight the liver showed little change, but even in cases with extensive and apparently equal involvement there was great variation in size. About half showed considerable enlargement. In no case was there marked atrophy.

The weights were :

1,000 to 1,500 gms.....	5 cases.
1,500 to 2,000 ".....	5 " "
2,000 to 2,500 ".....	2 " "
3,000 to 4,000 ".....	3 " "
5,000 and over.....	4 " "
Weight not given.....	1 case.

In one of the cases the liver weighed 8,100 gms., while another reached the enormous weight of 15,110

gms. The amount of abdominal space encroached upon by the liver in the former case is well shown in the accompanying photograph (Plate 1). The latter case, besides the enormous size presents other points of interest, and is here given in detail.

*Clinical History.*—G. W., aged 62, a bookbinder by trade, was born in Grisons, Switzerland. His family history presents no points of interest. His father, mother, and a sister lived to an old age, dying without any signs of a malignant growth.

*Present History.*—The patient came to America in 1868. In 1873 he had smallpox. With this exception there has been no previous illness. He has always been temperate in his habits, and denies venereal disease. Since he was about 30, he has drunk occasionally a small amount of beer and smoked in moderation.

*Present Illness.*—The present illness dates definitely from September, 1898. Prior to that period the patient seems to have had no symptoms, at least none suggesting the need of medical attention. At that time his physician was consulted for loss of

Plate 1.

strength, dyspnea on exertion and swelling of the abdomen. Just how rapidly these symptoms had developed is not known. His physician, Dr. Clement, states that, when seen in September, 1898, his liver extended far below the umbilicus on the right side, and well down to its level on the left side. The surface of this mass felt smooth, except near the mid line, where there was an area about 5 cm. in diameter, which was distinctly elevated.

The patient was ordered to take a vacation, and while away from Boston was very sick with vomiting, headache, and dizziness. At this time he was in bed for almost six months, and then was able to be up, occasionally working for a day. In May, 1900, he became confined to the house, his feet began to swell, and his abdomen continued to enlarge. He steadily lost weight, and became jaundiced. The size of the abdomen and the degree of jaundice has varied from time to time.

Until about August, 1900, constipation had existed, though relieved readily. On several occasions, about this time, small amounts of blood were passed by the rectum. This was at the time attributed to obstruction of the portal circulation.

On November 24, 1900, he was admitted to the service of Dr.

Sears, at the Boston City Hospital, for observation. A physical examination on this date shows a poorly developed, emaciated, slightly icteric man. His radial arteries are atheromatous, his pulse regular. The upper limit of the heart is at the second interspace; the right border at the level of third rib, 5.6 cm. to the right of the median line; the left border at the level of the fifth rib, 13.2 cm. to the left of the median line. The apex of the heart is not made out. Its action is regular and no murmurs are present.

Lungs are of good resonance, except on the right side, below the mid scapular region, where there is an area of dulness. A few moist rales are present chiefly in the bases.

The liver flatness begins at the fourth rib, and extends downward to a point 2.5 cm. below the umbilicus. A large part of the abdomen is occupied by an easily palpable tumor mass, whose lower edge can be felt 5 cm. below the umbilicus. This edge is irregular and blunt. Beginning at the mid line it can be traced to the right in an outward and slightly downward direction for 5 cm., but from here it dips more perpendicularly toward the pelvis. From the mid point toward the left, it can be traced outward and slightly upward to its intersection with the left mammillary line, where it again dips downward and outward toward the pelvis (Plate 2). The surface of the tumor

August, 1900. Slight amount of blood per rectum.  
 November, 1900. Emaciated, icteric, liver border as in photograph.  
 May, 1901. Very weak, emaciated, ascites, marked hydrops of legs.

August, 1901. Death. Known duration 35 months.  
*Postmortem Examination, August 20, 1901.*—B. C. H., U.01.24.—Body of a gracefully built, emaciated man 166 cm. long. Rigor mortis present. Slight yellowish tinge to the skin. Marked edema of legs, the skin of which is tense and shiny. Abdomen is immensely distended, and at the umbilicus measures 111 cm. in circumference. The lower border of the ribs flares out at a wide angle to contain the immense tumor within.

The abdominal wall is very tense and very thin. Through it the nodulation of the tumor is distinctly visible. On opening the abdominal cavity a considerable amount of fluid escapes under pressure. The abdomen contains several thousand cubic centimeters of clear fluid. The entire upper and middle portions of the cavity are occupied by a greatly enlarged nodular liver. The point of insertion in the liver of the round and falciform ligaments is displaced to a point 11.5 cm. to the left of the median line. The distance between the tip of the ensiform cartilage and the lower border of the liver is 25 cm. From the tip of the right ninth rib to the lower border of the liver is 22 cm., from the tip of the left ninth rib to the lower border is 20 cm. From the costal margin to the insertion in the liver of the round ligament is 13 cm. The liver is entirely free from adhesions, and is held in place only by the normal ligaments. The diaphragm reaches to the third rib on the right side, to the fourth space on the left side.

The stomach lies behind the tumor mass, about in the normal position, and shows no nodules or other abnormality. Just below the border of the liver a portion of the transverse colon appears. Below this the space is occupied by coils of small intestine. Duodenum, jejunum, ileum, and colon are normal.

Pancreas is normal.

Mesenteric lymph nodes are not enlarged. A few of the retroperitoneal lymph nodes in the region of the pancreas are slightly enlarged, white, and firm.

The spleen is crowded into the left upper quadrant of the abdomen, is firmly adherent to the diaphragm, and is not enlarged.

The kidneys occupy a normal position. On section they are pale and firm. The capsule is slightly adherent, tearing away a small amount kidney substance on removal. Adrenals are normal.

The right lung is firmly adherent everywhere to the parietes. It is greatly compressed and the lower half is entirely atelectatic. The upper half is air-containing, but very edematous.

The left lung is free from adhesions, air-containing, and very edematous. On the surface of the lower lobe are numerous whitish and reddish areas 2 to 3 mm. in diameter, composed of many short, delicate, filiform projections.

The heart is normal.

The aorta shows a few small patches of sclerosis.

In the rectum the mass described below can be palpated, but does not occupy a great portion of the pelvis, and there are no evidences of its having caused any obstruction.

Bladder and prostate are normal.

The liver (weight, 15,110 gms., 33.31 pounds avoirdupois) measures 38 cm. in greatest length from right to left border, 39 cm. in greatest length from superior to inferior border, and 19 cm. in greatest anteroposterior diameter. It is coarsely nodular. (Plate 3.) The nodules vary in diameter from 2 cm. to 8 or more cm., and project above the general surface from .5 to 3 or 4 cm. With the exception of these coarse nodules the surface of the liver is smooth and glistening, and there are no evidences of adhesions except along the lines of attachment of the normal ligaments of the liver. The general surface of the liver is dark red to pale red or pink in color. It is mottled with numerous small and fairly large, almost white areas, and a smaller number of somewhat similar, but bluish-black areas. Many of the larger nodules are mottled in color, dark red, brown, bluish-black and white. None of the nodules shows umbilication, but on palpation some suggest fluctuation, as if the central portions were much softened. The superior surface to the right of the falciform ligament is almost smooth in contradistinction to the coarsely lobulated appearance of the other parts of the liver, and is mottled with many small whitish and greenish areas, none of which measures more than 5 cm.

On section (Plate 4) the liver shows large and medium-sized, rounded areas of a dark red color. About some of these there appears to be an indefinite connective tissue capsule, but many are in direct contact with liver tissue. Between these masses the liver is yellowish-gray and appears fairly normal. There are some areas of liver tissue as large as 5 by 7 cm. None of the nodules seen in section shows evidence of central softening.

The gallbladder is normal, free from adhesions, lies in a deep groove between nodular projections of the liver, and is dark green in color. Bile ducts are normal.

Plate 2.

thus bounded is hard, with several smooth mounds and ridges that are easily seen. Some of these have an elastic feel as though of fluid under tension.

The abdomen is tense and protuberant. Below the tumor edge there is tympany, except in the extreme flanks. The girth at a point 10 cm. above the umbilicus is 105 cm.

BLOOD COUNTS.

November 8, 1901:	
Red blood globules.....	3,704,000
Leukocytes.....	8,000
Hemoglobin.....	75%
Differential count of 200 leukocytes:	
Polymorphonuclear neutrophils.....	45.5%
Small mononuclears.....	31.5%
Large mononuclears and transitionals.....	9.5%
Eosinophiles.....	13.5%
November 24:	
Red blood globules.....	3,952,000
Leukocytes.....	9,800
Hemoglobin.....	50%
Differential count of 333 leukocytes:	
Polymorphonuclear neutrophils.....	50.8%
Large and small mononuclears.....	38.7%
Eosinophiles.....	10.5%

Three days after admission the patient returned to his home.

During all this time the patient's appetite remained good. He had a light general diet, with much milk. Occasionally there was distress after eating. Pain was never a prominent symptom, and often was entirely absent. Accumulation of fluid gave no trouble until the last few months of life, and then was most in evidence in the legs, which were frequently tapped, with much relief. Often as much as three quarts of fluid escaped during twelve hours. The abdomen during this time contained fluid, probably as much as it could accommodate. During this period his symptoms were such as could be explained by the mechanical pressure of an enormously enlarged liver on neighboring organs, combined with an increasing exhaustion. He died August 19, 1901.

*Clinical Summary.*—Previous history negative.

September, 1898. Loss of strength, dyspnea on exertion, swelling of the abdomen, liver border below the umbilicus.

May, 1900. Confined to house, feet begin to swell, abdomen continues to enlarge.

The portion of the inferior vena cava attached to the liver is normal.

In the rectum, situated approximately 7 cm. above the internal sphincter ani muscle, there is a slightly nodular, soft, brownish-black excrescence which projects 1 cm. into the lumen

Plate 3.

of the rectum. The base of this is formed by a hard, indurated mass, whose maximum diameter is 3 cm. There is no evidence of ulceration of mucosa in this region. In the areola and connective tissue between the rectum and the sacrum is a hard, indurated mass, 10 cm. long, 3 cm. broad, and nowhere more than 1 cm. thick. This follows up behind the rectum, but is nowhere attached to it except at the site of the above-described excrescence. This excrescence is situated 2.5 cm. above the lower limit of this indurated mass.

[ ] Section through the middle of the nodule in the rectum shows an outer irregular border of purplish-black gradually shading into grayish-white in the center. This tissue is soft. Beneath this the tissue is hard, in places is glistening white, in others reddish with a few narrow bands of glistening white.

*Anatomic Diagnosis.*—Adenocarcinoma of the rectum, invasion of postrectal tissues, metastases in postperitoneal lymph nodes and in liver, compression and atelectasis of right lung, slight chronic diffuse nephritis, anasarca, hydroperitoneum.

*Microscopic Examination.*—In sections through the primary nodule in the rectum the surface is covered by mucous membrane. The outer one-third of this is necrotic, and shows no nuclear stain. The deeper parts stain fairly well. Much of the epithelium lining the glands has desquamated. That remaining intact is of the type normal to the rectum. In some places the mucosa is sharply limited, and the bases of the glands lie in a supporting framework of fibrous and elastic connective tissue, beneath which there is a well-formed muscularis mucosae layer. In other places there is no such line of demarcation, and the glands pass directly into the deeper tissues. All evidences of the other layers of the intestine—submucosa, muscularis and serosa—have disappeared. In place of these there is an adenomatous growth, subdivided by numerous connective tissue trabeculae, and this constitutes the entire thickness of the rectum at this point.

Where the normal glands of the rectum pass into the underlying tumor, the structure is that of fairly regular tubular glands, separated by narrow bands of loose connective tissue. This represents the simplest form of the growth. The greater part of the rectal growth and the metastases in the lymph nodes (postrectal and post-pancreatic) and liver are of a greater complexity.

In the latter the intertubular stroma is greatly reduced, often being represented by a single strand of connective tissue or a slight meshwork in which a small blood vessel is supported. The tubules have elongated and subdivided. The lumen in places is dilated, and filled with desquamated cells or red blood globules; in others it is narrowed, or has entirely disappeared by coalescence of the two layers. The result of such changes is the formation of large cellular areas separated by broad dense connective tissue trabeculae. In the cellular areas there is a very small amount of loose connective tissue in which the cells are grouped into gland spaces. Everywhere this adenomatous structure is present, though often obscured by desquamation of cells or approximation of two layers of lining epithelium; it is very evident where hemorrhage has taken place into the lumina and distended them into definite spaces lined by epithelium.

The epithelial cells of the tumor are columnar. Their height

varies, but in a given field they are of quite uniform size. They have oval vesicular nuclei, with fine chromatin granules. Most of them show one or two coarser chromatin granules, though irregular in contour, suggesting nucleoli. The nuclei are situated distally or in the mid zone of the cell rather than at its basal end. Mitotic figures are not numerous. The cytoplasm is homogeneous. Nowhere are there goblet cells. The epithelial cells form a layer, in places one cell deep, in others several cells deep. The desquamated cells are round and their nuclei are often shrunken and stain intensely. In many places the epithelial layer has separated from the basal membrane. The stroma of the tumor consists almost entirely of fibrous tissue, but in the coarser trabeculae there are numerous elastic fibers without any apparent relation to bloodvessels, beside those in the walls of the bloodvessels.

The postperitoneal lymph nodes show metastases of the same character as the primary growth in the rectum. In some nodes this almost completely replaces lymphoid tissue; in others it is present as very small nodules.

In the liver the growth is similar, though here there has been very extensive hemorrhage into the nodules. In most of these areas the red blood globules are discrete and remarkably well preserved. The liver tissue about these nodules is compressed, and the liver cells much atrophied. Radiating out between the liver lobules are broad bands of connective tissue, often containing new-formed bile ducts. There is a slight intralobular connective tissue increase, and in places small groups of separated atrophied liver cells are enclosed in the connective tissue trabeculae. There is very little evidence of necrotic changes in these liver nodules.

The villous processes described on the pleural surface of the lung are composed of loose vascular connective tissue. The other organs present no noteworthy lesions.

The greatest interest in this case lies in the enormous size of the liver. That secondary carcinoma produces the largest livers is generally conceded, and numerous cases have been reported in which the liver attained great size. Thus there are a number of cases with weights between

Plate 4.

8,000 and 10,000 gms. (18 to 22 pounds avoirdupois). Gordon<sup>4</sup> describes one of 24 pounds and Axel-Key<sup>5</sup> one of 25 pounds. Gould and Pyle<sup>6</sup> ascribe to Kraus a case in which the liver weighed 25 pounds and to Gooch one

weighing 28 pounds. We have found one case exceeding ours in weight. This is one reported by Powell.<sup>7</sup> He says, speaking of the size of the liver: "At a medium its ordinary weight may be estimated at about 3 pounds or somewhat more; but the variations of its weight and relative bulk are in many cases of disease most striking. I have seen a liver weighing a little short of 40 pounds." However the nature of the process in these last three cases is not stated.

A second point of interest in this case is its long duration, more than 35 months. Most writers state that a duration of one year is unusual, and those cases lasting two years are very exceptional. Leichtenstern<sup>2</sup> in 19 cases, collected from the Tübingen clinic and statistics of Frerichs and Murchison, finds an average duration of 20 weeks. In 25 cases, from Biermer's clinic, the average is 17 weeks. In<sup>3</sup> 13 of our cases, in which the approximate duration could be estimated, the average is 25 weeks.

It is in just such a case as the one we have reported that a long duration might be expected. The primary growth was in the rectum and offered no obstruction to the lumen of the intestine. Hence interference with the digestive functions was reduced to a minimum. With a good appetite and no intestinal obstruction, nutrition was maintained, and in this case the symptoms seemed to depend on the mechanical obstruction of the enlarged liver. On the other hand, the larger number of cases follow a primary growth in the upper gastroenteric tract, where there is greater possibility of hindrance to metabolism and the downward course might be expected to be more rapid. Again with the longer duration there was greater chance for liver enlargement. It is of interest to note in this connection that the second largest liver in our series also occurred in a case in which the primary growth was low down in the gastroenteric tract, but here unfortunately the patient was admitted in a moribund condition and no history was obtainable.

In conclusion we wish to express our thanks to Dr. Clement and to the clinical and pathologic staffs of the Boston City Hospital for data and assistance.

THROUGH-AND-THROUGH INTESTINAL SUTURE, WITH REPORT OF ADDITIONAL CASES.<sup>1</sup>

BY

F. GREGORY CONNELL, M.D.,

of Leadville, Colo.

Surgeon to St. Vincent's Hospital; formerly Adjunct Professor of Surgery, College of Physicians and Surgeons, Chicago (Medical Department University of Illinois).

In reviewing the literature of intestinal surgery, we find that the suture has passed through the following phases or progressive steps: 1. The suture including all coats, with the knot on the serosa, in the peritoneal cavity. 2. The suture including the peritoneum only. 3. The suture including the peritoneum and the muscularis. 4. The suture including the peritoneum and the muscularis, and penetrating but not perforating the submucosa. 5. The suture including all coats, with the knot on the mucosa, in the lumen. At the present time the question appears to be, whether to perforate or not to perforate all coats of the bowel wall.

That this was the trend of thought at the end of the nineteenth century is unmistakably evidenced by the following quotations:

N. Senn: "Any surgeon who hastily transfixes the bowel with a needle from 30 to 40 times in applying the Lembert suture is liable to perforate the whole thickness of the bowel once or more, and the puncture may become the seat of a perforation and the direct cause of a fatal peritonitis."

O. H. Allis: "The rule that the serous coat must only be pierced is no longer entertained; and the operator will act wisely if he penetrates the thickness of the intestinal wall."

Edw. Martin: "In regard to all intestinal sutures, it seems clear that the dread of penetrating the mucosa is one of the legacies left from preantiseptic days. The peritoneum will stand a great deal of insult if it is not soiled, and it will stand some soiling, if it is not insulted; but the combination is deadly. If there be infection carried by the thread traversing the mucous membrane there are few records to prove it. If the sutures are properly applied, some of them are almost certain to penetrate some part of the mucous membrane."

C. N. Dowd: "Can we put our sutures through the entire intestinal wall in order to gain this firm support? This seems to me to be the most important question concerning intestinal sutures at the present time, and the answer should be yes."

While the through-and-through suture was brought to the attention of the profession by Maunsell, and emphasized by Wiggin, who was the first to repeat the method of Maunsell in America, he was not a pioneer in this particular phase of intestinal suturing, being antedated by Bishop in 1885, and by Vesein in 1871. (Not to mention the old and obsolete methods, such as the "Glovers" and similar ones which were utilized before the Lembert principle of seroserous apposition had been advanced.)

Bishop described and employed a perforating suture in his so-called "continuous-interrupted" stitch, which like all others of this variety, not excluding Maunsell's and its many modifications, presents a weak spot which necessitates secondary or retaining stitches. Vesein utilized a suture that passed through all the layers of the intestinal wall, but was secured by merely a double twist of the ends instead of by their being tied in a knot.

The through-and-through suture knotted on the outside, on the serosa, without retaining stitches, was presented in September, 1892, by M. E. Connell with experiments which seemed to be entirely satisfactory. (This method differed from the older methods of perforating stitches, knotted on the serosa, in that the seroserous apposition and a diaphragm take the place of the attempt to unite the histologic elements, layer for layer, of the older methods.)

In the literature three cases are found in which this method has been employed upon the human being, and with perfect recovery of the patients. But despite this favorable outcome, both experimentally upon the lower animals and in actual experience upon the human being, it is acknowledged by the majority of authorities that the safest place for the knot in perforating stitches is within the lumen of the bowel.

It may be regarded as axiomatic that the ideal location for the knot of an intentional perforating stitch is outside of the peritoneal cavity in the lumen of the intestine; the term intentional is here used advisedly. It must necessarily follow that in an unintentional perforating suture the knot ought to be similarly located, *i. e.*, in the lumen.

If these two statements are true (and it has been shown that the great majority of intentional non-perforating sutures are in reality unintentional perforating sutures, owing to the comparative sizes of the needle and the submucosa) then the desirable situation for the knot, in practically all intestinal sutures, is *in the lumen of the gut*.

In the comparatively primitive methods of Bishop and Vesein an attempt is made to place the knot upon the mucosa. In the former the knot is tied in the line of union and then pushed into the lumen, a very unsafe procedure, and one which necessitates the introduction

<sup>1</sup> Read before the Mississippi Valley Medical Association, October, 1902.

of retaining or reinforcing stitches, and the principle of which is to be found resurrected by Dowd in the *Annals of Surgery* for July, 1902. In the latter (Vesey) the attempt is made, but as a result the security of the union rests upon a double twist of the threads instead of a firm and secure knot.

The method of Maunsell is an improvement upon the earlier attempts, in that all of the stitches at the site of the enterorrhaphy are securely knotted in the lumen. In order to do this a complicated invagination is necessary, and as a result a longitudinal incision at the convex border must be closed with sutures that include but a part of the entire wall, and are tied upon the serosa. This method of Maunsell's has been used quite extensively, and with almost uniform success. (In 1899, 29 cases were collected from the literature.) As is usual with successful procedures, it has been modified by many investigators, notably Cheatle, Hartigan, Ullman, and Wiggin. Cheatle and Hartigan, each independently of the other, placed the second incision closer to the line of union; in fact, making it continuous with the circular incision at the convex border, in this manner doing away with the objectionable invagination. Cheatle afterward suggested that this longitudinal incision be closed transversely to the long axis of the bowel, *a la* Heinecke-Mikulicz, and so reduce the danger of stenosis. Ullman, after invaginating as does Maunsell, instead of suturing the cut ends, inserted a hollow cylinder of carrot and tied a circular ligature around the carrot and the two invaginated ends. The invagination was then reduced and the second incision closed with Lembert sutures.

Each of these methods are modifications, as claimed by their originators (improvement or not), in which the principle of the original method is retained and utilized. The essential and characteristic feature of the Maunsell operation is a complete line of through-and-through stitches knotted in the lumen at the site of the enterorrhaphy, and at a more or less distant point an incision by means of which it was possible to so place the stitches, and then the closure of this second incision by means of Lembert sutures. In December, 1898, Dr. Fredk. Holme Wiggin, of New York, presented what was termed a modification of the Maunsell method, in which all but the last few stitches of the enterorrhaphy are closed with perforating stitches, such as Maunsell recommended, through-and-through circular stitches tied in the lumen directly over the seam of the union. As it was deemed impossible to place the knots of these last few stitches in the lumen securely without resorting to the second incision, the operation was concluded by utilizing Lembert sutures for this final part of the procedure.

This method will be found to differ radically from that of Maunsell in that the line of union is but *partially* united by perforating stitches. The completeness, thoroughness and security, at the site of the union, for which Maunsell was willing to go through the difficult and complicated procedure of invagination, followed by the closure of the second incision, are entirely disregarded in the Wiggin "modification." It was evidently in an effort to do away with just such weak spots that Maunsell devised his operation. Had it been considered advisable to introduce through-and-through sutures but a part of the way around the circumference of the bowel, it is not likely that he would have made his second incision and invagination. The fundamental principle of the Maunsell method is perforating sutures tied in the lumen throughout the entire line of union. Any method which does not conform with the fundamental principle can hardly be consistently classed as a modification.

Oscar H. Allis, in 1902, strongly advocated the suturing of the entire thickness of the gut wall in intestinal anastomosis. His method is similar to that of Dr. Wiggin in that the last few stitches are inserted from the serous aspect of the bowel and are consequently knotted

on the outside of the bowel wall. But it is strikingly different in that these last few stitches, or the last stitch, are not Lembert, but instead deliberately include all the different layers of the intestinal wall, and are then knotted upon the serosa, the same as M. E. Connell advocated in 1892.

The perforating suture has been employed, not only in simple enterorrhaphy as we have seen, but also with the use of artificial aids in suturing. Such a suture was used with the bone plate and is today employed with the Murphy button. In both of these methods and their many modifications the through-and-through suture is tied upon the serosa; thus at first sight appearing to be contrary to the axiom regarding the location of the knot in stitches of this character, but on second thought this marked difference will be found between such sutures when employed alone and when with a foreign body. In the latter instance, the knot, while on the peritoneal surface, is shut off from the general cavity by the serous apposition external to the knot caused by the areas of the serosa brought together by the foreign bodies, while in the former instance the knot is in the free peritoneal cavity and not excluded by any adhesions of serosa external to it. In Breitenbach's suture a similar condition is found, the knot on the serosa, but the direction of the stitch places the knot toward the cut margins and thus it is excluded, more or less completely, from the free peritoneal cavity by apposed serosa.

A very pertinent question at this time might be put thus: Why should we employ a through-and-through suture in preference to a suture that aims to penetrate but a portion of the entire thickness of the intestinal wall?

Since the days of Lembert it has been handed down as an iron-clad rule that any stitch involving the serosa must not include the mucosa. But that this rule was being constantly broken, either consciously or unconsciously, no one can doubt, for as early as 1887 Senn says "Any surgeon who hastily transfixes the bowel with a needle from 30 to 40 times in applying the Lembert suture is liable to perforate the whole thickness of its wall once or more, and the puncture may become the seat of a perforation and the direct cause of a fatal peritonitis."

This rule of Lembert is to be found in force and emphasized as late as 1891 by Halsted, of Baltimore, in his article which calls attention to the clinical importance of the submucous layer of the intestinal wall.

The fact that the submucosa is strong and resisting, and capable of securely holding a stitch when once inserted, and that the other layers are of little value in this respect, is of the utmost importance in intestinal surgery, the credit of which adds another to the many laurels of that great teacher and surgeon, Samuel D. Gross.

Although the work of Gross upon this point is so complete and perfect that nothing has been added to it up to the present time, and it was completed and published in 1843, it did not attract any attention until Halsted in 1891 presented his work, which was, in effect, a repetition of that done long before by Gross. For some reason, possibly because the profession was not prepared for such an advance at that early date, the work of Halsted was proclaimed as an epoch-making event; while the previous work of Gross, similar as far as this important point is concerned, and which emphasized this particular phase of the intestinal suture, has been disregarded, or rather lost sight of, only to reappear at this later date with greater brilliancy.

The works of Gross and Halsted as regards the submucosa differ in this one particular. Gross says "it is the membrane *through* which the surgeon should always carry his needle in sewing up wounds of the intestines."

He evidently realized the comparative thinness of this layer; Halsted, on the other hand, failing to consider the comparative sizes of this layer and the ordinary

intestinal needle, states that the suture must "penetrate but not perforate" the submucous layer. I have shown<sup>1</sup> that the usual intestinal needle is approximately six times as large in diameter as the thickness of the inelastic human submucosa, rendering such a procedure as "penetration without perforation" an impossibility, at least practically impossible, for the surgeon of average training and manual dexterity. In order to emphasize the point I take the liberty of paraphrasing a few lines written by the immortal Abraham Lincoln:

Some surgeons may claim to split the submucosa all of the time, and all surgeons may claim to split the submucosa some of the time, but all surgeons can not claim to split the submucosa all of the time.

With this splitting of the submucosa out of the question, we must choose between two evils: the danger of not including the submucosa, with yielding as a result, on the one hand, and the real, or hypothetical, danger of perforating into the lumen, with "capilarity" as a result, on the other. To do away effectually with both of these dangers, the through-and-through suture, knotted in the lumen, is recommended.

*Through-and-through* to prevent the possibility of not including the submucosa, and thus absolutely excluding the yielding of stitches. This element of danger (yielding), according to Rosenthal, is the cause of the peritonitis in 50% of the cases which terminate fatally, and in speaking of which Edward Martin says: "Cases of fatal peritonitis are not due to penetration of the mucous coat, but to failure to include the submucosa."

*Knotted in the lumen* in order to diminish, if not exclude, the danger of leakage. In a suture that penetrates all the layers of the intestinal wall, with the knot on the serosa, the probability of leakage occurring is considerably greater than is this same danger when the knot is situated upon the mucosa within the bowel. Cluinski states that in all cases of union, by suture alone, in which leakage occurred, the seat of the leakage was at the site of the knot. Had the knot been within the lumen this leakage would, in all probability, not have taken place, for under such circumstances the knot, as well as the entire suture, would have been excluded from the peritoneal cavity; or, as Dr. Ferguson expressed it, "The possibility of leakage is minimized, as all coats of the bowel are included in its grasp. The mucosa is friable and the knot sinks in to the submucosa. All the knots being on the internal surface of the bowel, it takes but little seroserous lymph to seal up the peritoneal surface, and any drainage that takes place along the suture from the mucosa toward the peritoneum will at once be returned by capillary attraction to the inside of the bowel again."

The two advantages, (1) less danger of yielding or tearing; (2) less danger of leakage, even though yielding or tearing does not occur, while constituting the chief and foremost reasons for utilizing the perforating suture, are not the only advantages to be derived from its use. Among others of no inconsiderable importance may be mentioned (3) smaller diaphragm; (4) diminished adhesions; (5) less danger of necrosis; (6) no foreign body; (7) decrease in time.

3. *Smaller Diaphragm*.—In every method of suture which adheres to the Lembert principle, *i. e.*, seroserous apposition, a diaphragm, large or small, will invariably be formed, the size of which depends upon the method of union employed and the care with which the technic has been carried out. In a method requiring two or more rows of sutures the lumen will, of necessity, be encroached upon to a greater extent than it will if but one row of sutures is employed.

Dowd in his recent article credits Ballance and Edwards with saying that the Maunsell reinforced by the Lembert suture gives practically no diaphragm. This is directly opposite to the result of my experiments,

and also contrary to the statements made by these same gentlemen in the *Med. Chir. Trans.*, 1896, in which they say that while performing autopsies after the Maunsell operation the circular line of union was often located only with the greatest difficulty, owing to the fact that there was visible practically no diaphragm, while the location of the longitudinal incision, which was closed with Lembert's, was plainly visible and marked by a prominent ridge.

In the *Annals of Surgery*, June, 1902, Martin, of Philadelphia, cites an experiment as follows: "In one dog subjected to an end-to-end suture by the Connell suture and lower down to a similar procedure by the O'Hara forceps, some hard feces which passed through the upper line of junction lodged in the lower and produced an obstruction." This possible source of failure and danger is spoken of by Senn, in the following terms: "If in applying the Czerny-Lembert suture, more than a few lines of the margin of the bowel is inverted between the two rows of sutures there is great danger of causing primary traumatic stenosis by the projecting circular ring in the lumen of the bowel."

Murphy has shown that a broad serous approximation is not necessary, that a line of approximation is as good as half an inch; therefore, it is not advisable to include too large a portion of the gut wall in the bite of the stitch, the smaller the bite the smaller the diaphragm will be. Dr. Bartlett says: "The lumen in my five-day specimen was far too narrow, a result of the peritoneal sutures being placed too far from the free end of the gut, and of too much tissue being inverted in consequence. The remedy for this is apparent."

4. *Diminished Adhesions*.—The knot and free ends upon the serosa are prolific causes of the formation of adhesions, which are followed by their characteristic disagreeable, if not dangerous, symptoms. Adhesions are caused by raw (denuded of endothelium) surfaces or foreign bodies. By placing the knot and ends within the lumen, outside of the peritoneal cavity, the chances that these objectionable adhesions will be formed are materially decreased. To show that the importance of these adhesions is not exaggerated we refer to Halsted, who says: "The success of any form of intestinal suture is inversely proportionate to the extent of adhesions which result from the employment of the particular method."

5. *Less Danger of Necrosis*.—The possibility of the inverted margins of the cut ends being shut off from their blood supply and in consequence becoming gangrenous, has been pointed out by many, especially by Maunsell and by Senn, the former stating: "A double line of sutures should never be applied in intestinal surgery, it obstructs the circulation too much, and interferes with firm plastic peritonitis, and in some cases causing gangrene of the inverted portion of the gut." And the latter in the statement, "That the second row of sutures in the Czerny-Lembert has often been the cause of gangrene of the inverted margin of the bowel would not be difficult to prove by many postmortem records."

By utilizing but one row of sutures this danger of necrosis of the inverted margins of the cut ends can be eliminated.

6. *No Foreign Bodies*.—A perforating suture will invariably pass away into the lumen of the canal and be eliminated with the feces. A Lembert suture will become encysted, remaining as a foreign body, or slowly work its way through the intestinal wall into the canal and then away with the fecal current. If the Lembert suture does escape into the alimentary canal it will occupy a much longer time in doing so than will the stitch that includes the whole thickness of the intestinal wall.

Dr. Bartlett<sup>1</sup> presented a specimen in which all of the interrupted sutures but one had passed away within the

<sup>1</sup> Journal American Medical Association, October 12, 1901.

<sup>1</sup> Medical Bulletin Washington University, April, 1902.

first 16 days. In the writer's experiments in a 21 day specimen the continuous suture was found in the lumen, entirely free from the site of the union. We have found that a through-and-through suture will invariably pass away, and much sooner than will the Lembert suture.

In the perforating suture, with the knot placed on the mucous membrane, there is no burrowing of this bulky part of the stitch through the tissues to induce an irritation which may extend beyond the safety line.

The final outcome after the employment of this stitch is a clean adhesion of the serosa, leaving a union in which there is no foreign body of any description, not even a buried suture.

7. *Decrease in Time.*—By using but one row of stitches instead of two or more, the time of the operation is materially decreased. As is likewise done by the employment of the square, or what has been termed the "side-knot" stitch instead of the circular or "top-knot" stitch of Maunsell, as it decreases by one-half the number of knots to be tied.

Fig. A.

The technic of introducing and tying the last stitch will occupy but a minute after a little practice. Regarding this technic we take the liberty to quote from DeForrest Willard, who, in speaking of this method, says: "and was struck with its simplicity and with the rapidity of the operation." And from Alex. Hugh Ferguson: "The technic of the operation can be readily picked up by once performing the operation upon the dog or cadaver." And I might add—even upon the finger of a glove.

In speaking of the tying of the last knot in this method, Dr. Wiggin in a recent article says: "It would appear to be necessary, after separating the united tissues by passing the needle from the outside of the bowel into the lumen between them, to bring them into close approximation again by means of a Lembert suture, otherwise leakage of the intestinal contents might occur at this point."

This is, as stated in the above quotation, merely an appearance. The use of the words "united tissues" might be misleading, as no union exists at this time; the two walls are merely held in serous apposition by means of the stitches already inserted, and the needle is simply allowed to pass between them. No such leakage has occurred in a very extensive experience upon dogs, dating from October, 1898, when it was first accomplished by me, nor has leakage at this or any other point been noted in any of the cases in which this method has been employed upon the human being.

Upon a careful examination of the bowel walls at this point it is found that the cut ends are inverted, forming a diaphragm, with perfect serous apposition (see Fig. 4). Here, then, is found all that is essential for the establishment of a rapid and firm union, *i. e.*, seroserous apposition and at the same time all that is necessary to prevent leakage, *i. e.*, the diaphragm with the valve-like action. This diaphragm, which acts like a valve, is of the greatest value in preventing leakage, possibly of even more importance than serous apposition. Pressure from within the lumen will cause the two inverted ends which constitute the diaphragm to be forced more closely together. It is this fact, the same in principle as

is the prevention of the regurgitation of urine from the bladder into the ureter, that will and does prevent leakage of the intestinal contents after enterorrhaphy. The greater the force from within, the sutures not yielding, the closer will the opposite cut ends be held together, and the smaller will be the likelihood of the contents escaping.

Leakage is practically excluded, and none the less so, at the point where the needle was passed and the knot tied than at any other place; for the serous apposition at this point was interfered with but for a moment, and that moment before any attempt at histologic repair had been made by nature. As soon as the knot slips back into the lumen the same serous apposition and diaphragm obtains as before.

It is well known that in each and every suturing of the bowel regardless of the method employed, contamination of the serosa is unavoidable, but this is readily counteracted by flushing the area of suture with normal salt solution or the glycozone, which has been so highly recommended. Supposing, then, that some infective material, small in amount as it must be, is carried to the serosa in tying the knot, this, from the viewpoint of Edw. Martin, may be regarded as but a very little additional soiling to that already brought there in performing the enterorrhaphy proper, and no "insult" to the peritoneum.

In speaking of the square or side-knot stitch and the method of tying the last knot, thereby allowing all stitches to be through-and-through, Dr. Wiggin in the same article says: "These changes in detail are, in the writer's opinion, of no practical import."

The square or side-knot stitch should not be disregarded as it is a great improvement over the circular or top-knot stitch of Maunsell, and makes the use of a secondary or retaining stitch unnecessary, which is considered by most all to be essential when the latter is employed.

With the circular or top-knot stitch the two inverted cut ends lie within the circle formed by the suture

Fig. 1.—Mesenteric stitch.

thread (see Fig. A-2). Unequal pressure upon these ends as they lie within the suture may cause them to assume the relative positions seen in Fig. A-3-4, and with an aggravation of this unequal pressure, as might be caused by gaseous distention, or a mass of fecal matter, an exaggeration of the condition will result which may cause an

eversion instead of an inversion of one cut end (see Fig. A-5). Thus giving rise to a seromucous instead of a seroerous apposition, with great danger of peritonitis or the formation of a fecal fistula as an outcome. Such an occurrence, as the ends slipping by one another, is an absolute impossibility when the square or side-knot stitch is employed (see Fig. A-1). Another reason for using this form of stitch in preference to the circular is that by so doing the number of knots to be tied is reduced one-half and the time of the operation materially decreased. The location of the knot in these two varieties of stitches, while similar in being within the lumen, are different in that in the circular it is situated directly over the line of union, while in the square it is to be found at one side of the seam, out of the way. Regarding this particular form of stitch Bartlett may be quoted as follows: "I had a leak at the mesenteric insertion in an end-to-end anastomosis where the union depended upon peritoneal sutures. This is not likely to occur (and in my experience did not) when the first suture is a square one, through-and-through, as in the Connell method."

If it is, as had been said, "of no practical import" to make the last one or two stitches through-and-through and knotted in the lumen, why not leave three or four, or four or five to be closed with Lembert's? Or, as a matter of convenience, why not exclude the perforating suture entirely and utilize Lembert's throughout the entire union, if it is a matter of "no practical import?" But is it not a fact that the through-and-through suture is better and safer than any stitch that aims to include but a portion of the intestinal wall? That the Lembert suture is not satisfactory is shown by many operators, who have substituted a perforating stitch for it. As a chain is no stronger than its weakest link, we find an enterorrhaphy in which the last stitches are Lembert's no stronger than the Lembert stitch.

To sum up concisely we may, therefore, state in the form of a syllogism: If 12 Lembert sutures are bad, and 10 perforating and 2 Lembert's are better, then 12 perforating sutures are best.

As to the technic, I will describe briefly, and with the aid of drawings, the more important points of the procedure.

The method of tying the final knot within the lumen upon the mucosa, and the square or side-knot stitch;

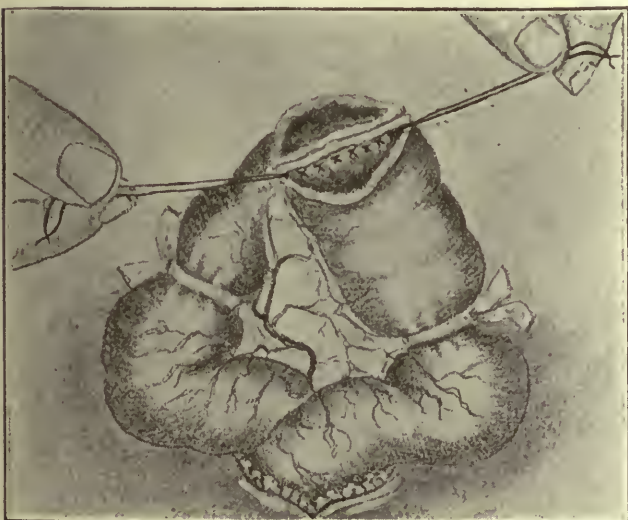

Fig. 2.—First third sutured end stitches used as guy threads.

these two details are probably the only, or at least the most important, innovations. As stated on previous occasions, either the interrupted or the continuous suture may be employed, the choice depending upon the

teaching or the experience that the operator has had. This method may be applied equally well in circular enterorrhaphy, lateral anastomosis, pylorotomy, pyloroplasty, gastroenterostomy, and in incised wounds of intestine or stomach. In fact, under any conditions when the ordinary sutures may be employed.

In using the interrupted suture, the first stitch should be taken at the mesenteric attachment. (See Fig. 1.) This stitch is of the greatest importance, on account of the separation of the serous covering of the bowel at this point, and great care should be exercised in securing a perfect serous approximation at this

Fig. 3.—Last stitch in last third.

point. In order to do this in the most satisfactory manner, a stitch should be introduced as follows: The needle is made to enter the bowel wall of one cut end from the lumen, perforate all coats and pass through the serosa of one side of the triangular space formed by the separation of the serous coats; then on over and through the serosa of the opposite cut end, at the same relative point, side of the triangular space, then on through the wall into the lumen. This completes one-half of the stitch, and is made with one movement of the needle.

The needle is next reversed, and at a distance of about  $\frac{1}{2}$  inch (3 mm.) is made to repeat the steps in the opposite direction, *i. e.*, entering the mucosa of the second cut end, passing through all coats of the bowel wall, including the serosa of the triangular space, and then through the serosa of the triangular space of the first cut end, on through the wall into its lumen where the needle end and the free end of the suture are tied in a knot on the mucosa. This stitch, which acts similar to a brad, absolutely secures a perfect serous approximation at this point, which is considered by all to be the most difficult portion of an enterorrhaphy. Dr. Bartlett says: "I had a leak at the mesenteric insertion in an end-to-end anastomosis where the union depended upon peritoneal sutures. This is not likely to occur (and did not in my experience) when the first suture is a square one 'through-and-through' as in the Connell method."

The remainder of the union is closed by stitches exactly similar to this first stitch. The cut ends are held in proper position by any convenient means, such as the Lee holder, the Allis tenaculum forceps, or suspending loops of thread; but the best method in my experience is the plan of introducing a stitch, such as are the other stitches, at a conveniently distant point, and leaving the ends of this stitch long, to be held by an assistant while the intervening stitches are being inserted. (See Fig. 2.) This method has the advantage of consuming no additional time, for when the union is completed up to this stitch and the long ends are of no farther use, they are cut away leaving the stitch itself in place. This method, which I described in 1901, has been adopted by Dr. Wiggin in the description of his method published in 1902.

With the ends thus held in proper position, the introduction of the stitches is a very simple matter, merely one passage of the needle through all coats of both cut ends and then at a

Fig. 4.

distance of about  $\frac{1}{8}$  inch (3 mm.) the same process in the opposite direction, and finally, the tying of the knot upon the mucosa at one side of the seam. (See Fig. 2.)

This is repeated till all but a small portion of the union is completed. Owing to the fact that it is impossible to place this last portion of the cut ends in the same relative position that we placed the first part, *i. e.*, seroserous apposition, it is therefore necessary, in order to introduce the same variety of suture, to proceed somewhat differently.

In order to place the last stitch and knot in exactly the same relative position as the first ones we proceed in this manner:

The needle enters the gut wall from the lumen, passes through all coats and emerges from the serosa of one side. It is then made to cross over to the opposite wound margin, and entering the serosa, passes through all the coats into the lumen of this side. The needle is then turned upon itself and made to retrace its steps at about  $\frac{1}{8}$  inch (3 mm.) distant, passing from

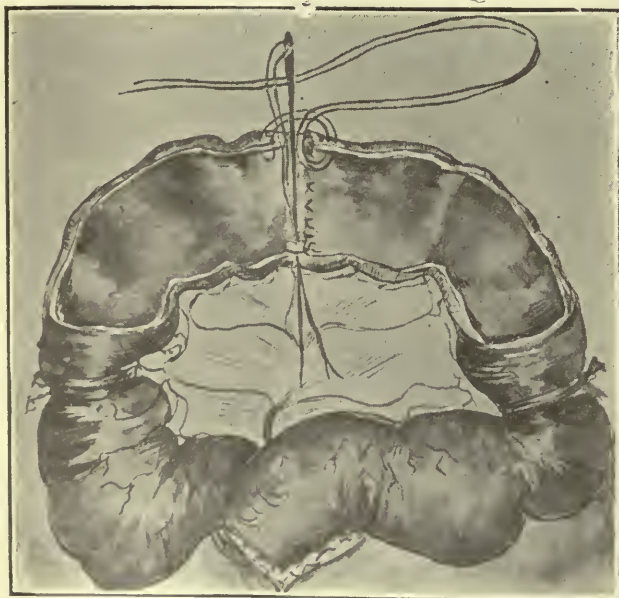

Fig. 5.

the lumen through all coats, emerging from the serosa; then over to the opposite side and entering through the serosa, and finally ending in the lumen of the cut end at which it began.

Now the two ends of the thread which are to make the knot are side by side, emerging from the mucosa into the lumen, and then extending from the ununited part of the enterorrhaphy out of the body. (See Fig. 3.) The needle in introducing this stitch has passed through the cut ends in exactly the same order as it did when inserting the stitches in the earlier part of the operation when the cut ends were held in seroserous apposition, *i. e.*, mucosa, submucosa, muscularis, and serosa, then immediately on into the other cut end through the serosa, muscularis, submucosa, and the mucosa, and then this order repeated in the opposite direction  $\frac{1}{8}$  inch (3 mm.) away.

The needle and the free end of the suture now hang side

Fig. 6.

by side from the mucosa, and in order that they be tied in a firm knot proceed as follows:

At a point in the line of union, about opposite this last and still untied stitch, a threaded needle is inserted, eye first, between two of the previously inserted and tied stitches. The needle is passed between the apposed serous surfaces into the lumen. (See Fig. 4.)

By passing the needle still farther onward it is made to present at the location of the last stitch, where the ends of the suture still protrude, and where the surfaces are not united. By slightly withdrawing the threaded needle a loop is formed with its thread, into this loop are placed the two free ends of the last stitch, which is to be tied. (See Fig. 5.) By withdrawing the

Fig. 7.

needle and in its loop the stitch ends, these ends will be made to present upon the peritoneal aspect of the bowel on the opposite side between two of the previously inserted and tied stitches, *i. e.*, at the point where the threaded needle was inserted. Slight traction upon these ends will cause the remaining portion of the line of union to become inverted, and seroserous approximation will obtain entirely around the site of suture. (See Fig. 6.) Upon greater traction the bowel will become flattened, bringing the mucous membrane upon which the last knot is to be located into intimate relationship with the line of suture at the point where the free ends protrude. (See

Fig. 7.) The knot is tied with the bowel in this flattened position, thus avoiding the occurrence of any slack. While still retain-

Fig. 8.

ing the tension and the flattened position the ends of the knot are cut off short, so preventing any long free ends in the lumen.

Upon allowing the bowel to assume its normal contour, that of a cylinder, the knot will slip between the already tied stitches into the lumen, and as it is attached to the mucosa of the opposite pole of the diameter of the gut it goes with that portion of the bowel wall. (See Fig. 8.)

By this procedure we complete an enterorrhaphy with all knots on the mucosa, but without the secondary incision of Maunsell.

As to the deaths:

- No. 4 died of shock on the day of the operation.
- No. 9 died on the eighth day, and at the autopsy the site of the operation was perfect.
- No. 11 died one-half hour after leaving the table; was in extremis at the time of the operation.
- No. 19 died of shock 12 hours after the operation.
- No. 25 died one hour after leaving the table; was in extremis at the time of the operation.
- No. 32 died one hour after leaving the table; was in extremis at the time of the operation.
- No. 33 died on the third day after the operation; liver, pancreas, and kidney injured by the bullet.
- No. 34 died on the third day after the operation; at autopsy the line of suture was found intact.
- No. 35 died three hours after the operation.
- No. 39 died on the third day after the operation, with suppression of urine.
- No. 48 died on the fifth day after the operation, and at autopsy the line of suture was found intact.
- No. 50 died 62 hours after the operation, of shock. At the autopsy the anastomosis was found to be in perfect condition.
- No. 51 died on the fourth day after the operation. At the autopsy one of the anastomoses was found in perfect condition, the other to be at fault. "This is possibly explained by the

extreme attenuation of the bowel wall, due to the original infection" (tuberculosis).

No. 52 died two days after the operation; at the autopsy the anastomosis was found to be in perfect condition.

No. 55 died of shock 36 hours after the operation.

No. 57 died in collapse the fifth day after operation. "Autopsy revealed a sloughing of bowel at the side of the Murphy button, complete ring having been removed by button. The stomach and duodenum, closed by Connell stitch, was found united."

No. 58 died five days after operation from an undiscovered wound of the kidney. Autopsy showed wounds in bowel united throughout.

No. 59 died three weeks after operation. Autopsy revealed complete union, no evidence of leakage.

No. 62 died soon after the operation; peritonitis existed at the time of operating.

No. 63 died soon after the operation; general peritonitis marked at time of operation.

No. 64 died 48 hours after the operation, of shock. "There were no signs of leakage discovered at the autopsy."

#### CONCLUSIONS.

1. The suture that aims to include but a portion of the bowel wall is dangerous: (a) because it is liable to fail to include any of the submucosa, in consequence leaving a weak stitch; (b) because if including any of the submucosa it is almost certain to penetrate the coat, leaving a stitch open to the dangers of capillarity.

2. By utilizing a through-and-through suture the danger of yielding is excluded.

3. By employing a suture that is knotted in the lumen the danger of capillarity is diminished.

4. It is acknowledged that the most appropriate place for the knot when all coats are perforated is in the lumen of the bowel.

5. It is undeniable that when the submucosa has been perforated accidentally the knot ought to be placed inside.

6. It is also undeniable that many so-called Lembert stitches perforate the submucous coat, and thus convert an intentional nonperforating into an unintentional perforating suture.

7. Undeniable, too, that owing to the extreme tenuity of the submucous coat ( $\frac{1}{8}$  of the thickness of the needle which is to "penetrate but not perforate" it) we are utterly unable to differentiate between a perforating and non-perforating Lembert stitch.

8. The logical conclusion is that the ideal location for the last and all knots in an enterorrhaphy is outside of the peritoneal cavity, in the lumen of the bowel.

9. As a chain is no stronger than its weakest link it is of practical import that the last one or two stitches be also perforating and knotted in the lumen.

10. The diaphragm by its valve-like action is of great value in the prevention of leakage.

11. The tying of the knot, according to the method described above, does not interfere with the establishment of firm union or tend to leakage.

12. The side-knot, or "square" stitch, in rendering a retaining suture unnecessary is superior to the top-knot or "circular" stitch.

## TRANSMISSIBILITY OF PLAGUE.<sup>1</sup>

BY

W. J. CALVERT, M.D.,

of St. Louis, Mo.

Lecturer on Tropical Diseases in the Medical Department of Washington University, St. Louis, Mo.

Although two thousand years old and discussed by every writer on plague, this subject is not only interesting and instructive, but of especial importance at the present time. Our growing intercourse with plague-infested districts, our knowledge that plague may thrive in any climate during any season of the year, and recent work relating to this disease, must ever give the subject a prominent place in our public discussions.

<sup>1</sup>Read before the St. Louis Medical Society of Missouri, November 8, 1902.

The discovery of *Bacillus pestis bubonice* by Kitasato and Yersin, in 1894, opened to us a new field which in time must disclose the long hidden secrets of this disease. *Bacillus pestis*, at or below the body temperature, grows luxuriantly on ordinary culture media and maintains its virulence for an indefinite time. Its viability has been much discussed, and the results of numerous workers have greatly varied. Naturally, varying degrees of vitality must, in part, explain this seeming inconsistency. Its viability, naturally, varies with surrounding conditions. On culture media, protected from harmful influences, the organism may live for months, even years. Deprived of these luxuries its life is shortened, but even here may be protracted for a surprisingly long time.

Rappaport saturated silk threads, cotton goods and paper with healthy cultures and subjected the organism to various harmful influences. He found that the organism lived 19 days in the sunlight and 23 days in darkness at ordinary room temperature, 22 days in the desiccator, 11 days in the thermostat, 1 hour at a temperature of 60° C., and 15 minutes at 89° C. The German Commission found virulent organisms in sputum after 10 days; Abel, in sterile water, after 20; Hankin, in various cereals, after 13; Jokote, in buried plague cadavers, after 30, and on dried linen, kept at 16° C., Abel found living organisms after 30 days. In dried, pulverized organs of animals dead of plague, living organisms have been found after 48 days.

While in Manila I performed a series of experiments to determine the viability of *Bacillus pestis*. Sterile slips of writing paper were inoculated by immersion in a 48-hour culture suspended in salt solution. The slips were then placed in sterile test-tubes in a thermostat at 32° C. to 34° C. For each examination five slips were used. They were transferred from the sterile tubes to bouillon for 48 hours, from which pure cultures of the plague bacillus were obtained by plating. When the experiment was undertaken it was my intention to inoculate monkeys and rats with each recovered culture, but unfortunately, when needed, animals could not be bought. At the end of 12 days five slips were positive, 17 days three, 28 days four, 34 days two, 39 days none, and 44 days one. One animal was inoculated with a culture recovered after 17 days in the thermostat. A typical fatal case of plague developed, from which the organism was recovered at autopsy.

Kitasato found that the organism was killed after 4 hours' exposure to direct sunlight, and the German Commission after 2 hours'. I prepared slips of paper as above described and exposed them on a brick pavement to direct sunlight. At intervals of 15 minutes two slips were examined as above. All of the slips were positive up to and including 2 hours and 45 minutes; after this the bacilli were dead. An animal inoculated with cultures recovered after 2 hours and 45 minutes, developed a fatal attack of plague.

To disinfectants the organism seems most susceptible; weak solutions of the several poisons kill the bacilli in a remarkably short time. On media, cultures maintain their virulence for many months. Full virulence has been noted after 15 months. Frequently I have found four months' old cultures as virulent as when young. Even in a dried state virulence is long maintained. I obtained a most virulent culture from paper slips after 17 days in a thermostat, and from dried organs cultures have remained virulent after 48 days.

The long life and maintenance of virulency under unfavorable conditions are most important, and may explain the origin of successive epidemics, especially when a previous epidemic is long continued by occasional cases. If the organism can live 44 days on dry paper and 48 days in dry organs, how much longer may it live in more favorable media to be found in all of the Oriental cities? These findings suffice to explain the transmission of plague to foreign ports.

Lymphatic glands harbor the first organisms entering the body. Here they multiply and later gain access to all parts of the body. The blood may be infected from the second day of disease until death. In one case I found bacilli in the blood for a period of 45 days. After septicemia develops, bacilli may be found in saliva, urine, feces, etc. Owing to multiple submucous hemorrhages in the stomach, vomitus may be laden with bacilli. Through these means clothing, furniture, etc., in the sick-room may become infected, and the infection carried to neighboring localities. Convalescents in whom septicemia continues many days are especially dangerous, as the individual may go to neighboring districts or to foreign lands.

History shows the susceptibility of domestic animals. As early as First Samuel, chapters V and VI, plague among the Philistines and the pollution of the fields by dead mice are mentioned. Many observers mention the high mortality and migration of rats and mice. Swine, cattle, and horses are susceptible, as are many wild animals.

Recent observations have given to insects an important role in the transmission of diseases. In "De regimine pestilentico," published in 1498, the first mention of the role of flies in plague is made. Since this time numerous observers have mentioned the importance of insects in spreading plague, but few have given definite information. Yersin found bacilli in dead flies in his laboratory in Hong Kong. Nuttall<sup>1</sup> found that flies contracted fatal attacks of plague, so could carry infection. This observation is of especial importance, as it shows flies may infect foodstuffs. Nuttall also made a series of experiments on numerous insects. He found that the bacilli could live five days in the stomach of bed bugs, but failed to produce the disease in animals bitten by infected bugs. After feeding on plague-infected cadavers, especially rats, ants may carry infection. If after biting, infected insects are mashed, the bite may serve as a portal of entry for the liberated bacilli. Numerous instances of blebs containing bacilli have followed the bites of insects. Fleas are also susceptible to plague, and undoubtedly carry infection from rat to rat, but considerable doubt exists as to the possibility of fleas infesting rats, using man as a host. Simond noted that persons handling rats recently dead of plague, frequently contracted the disease, while those removing the animals some hours after death were not affected. He thinks the fleas had left the latter, and naturally concluded that in the former fleas carried the infection. Mosquitos do not play an important role in this disease.

Raw material and fabrics may be infected by sputum, etc. In Kobe, Kitasato found bacilli in goods from Bombay. Employees working with this material contracted the disease.

All nationalities are susceptible to plague. The apparent racial immunity is due to some artificial protection arising from national characteristics. Of these, dress which best protects the individual, personal and domestic cleanliness, are most important.

Owing to many almost insurmountable difficulties definite information regarding portals of entry for plague is not at hand. Experimentation on animals has shown that an introduction of bacilli into the tissues is sufficient to produce plague. The number of bacilli so introduced seems to be of minor importance. This fact indicates that a few bacilli lodged in a small, even microscopic, wound may produce plague. The location of primary buboes is of considerable importance in this connection. In adults, 69% of primary buboes are femoral and inguinal, 22% axillary, and 9% cervical. The large percentage of inguinal and femoral buboes, especially among unshod races, would indicate the infection of small sores in the most exposed regions, namely, the legs and feet; while from less exposed parts we find a

smaller percentage of primary buboes. Additional evidence for this source of infection may be found in the location of primary buboes in children. Here we find inguinal and femoral buboes in 19% of all cases; axillary 32%, and cervical 49%. It is well known that whenever possible a child will put anything in its mouth and is inclined to play on the floor or ground where the hands are more liable to infection than are the feet. From abrasions in the mouth infection is carried to the cervical glands. In some cases infection may occur through the lungs, especially pneumonic cases.

Much discussion has failed to decide the possibility of contracting plague through the digestive tract. Animals have been fed infected material with and without contracting plague. Some observers think that in positive cases infection is received through the nose or through abrasions in the mouth, thence to the cervical glands. Other observers have found primary mesenteric buboes after feeding infected blood. I inoculated ordinary gelatin capsules with virulent plague cultures, then sealed the capsules with celloidin. The sealed capsules were then forced into the stomachs of monkeys. By this method the mouth and esophagus were protected from the organism. Plague was not produced, nor were the animals at all sick. Control animals subcutaneously inoculated with bacilli from the same tube from which the capsules were prepared died within the usual time. Capsules taken from the same box from which the capsules to be inoculated were obtained were readily soluble in the mouth and in plain water. These observations warrant the conclusion that in rare instances plague may be contracted through the alimentary tract, but in feeding experiments infection more often occurs through small abrasions in the buccal mucous membrane.

Infection through the genitals, although rare, has been noted. The following case of a Filipino boy is interesting: Two days after sexual intercourse a urethral discharge was noted. The patient reported to his family physician, who diagnosed gonorrhea and prescribed the usual treatment. Two days later the patient developed a right inguinal bubo with high fever and unconsciousness. When first seen by an inspector plague was suspected, so the patient was removed to the hospital, where he died soon after admission. An autopsy was made immediately. From the urethra an abundant pearly white discharge was found, which on examination showed polynuclear leukocytes, spermatozoa, and a pure culture of *Bacillus pestis*. The organism was identified in culture and by animal inoculation. This discharge had existed two days. Autopsy revealed typical lesions of plague. The inguinal bubo indicates infection from the external genitals. The time element shows that infection occurred about the time of copulation. All attempts to find the woman were futile. The importance of this case is the probable source of infection and the presence of plague bacilli in the semen. I have found several illac primary buboes in women. Here the infection most probably came from the vagina. Previously a case in which bacilli were found in the blood for 45 days was noted. In these cases a few bacilli might gain access to the semen to find new soil in the vagina. This evidence is circumstantial but strong.

Direct transmission plays a minor role in the spreading of plague. Excretions, hemorrhages from the nose and lungs, vomitus, fluid from pustules and carbuncles, pus from buboes and old plague sores, sputum from plague pneumonia, edema of the lungs and ulcerated tonsils contains bacilli in varying numbers and may serve as a medium of direct transmission. As patients die during the height of disease, plague cadavers are infected and a source of danger. Bites of infected insects and animals are worthy of note. While in Hong Kong, Dr. Bell told me of a Chinese street sprinkler who found a sick rat in a hydrant. While trying to kill the animal the Chinaman was bitten on the left thumb. Several days later he developed a fatal case of plague with a left

<sup>1</sup> Johns Hopkins Hospital Reports, Vol. viii, Nos. 1, 2, 1899.

axillary primary bubo. The relatively small number of cases of plague occurring among attendants in plague hospitals and workers on plague demonstrate the minor role of direct transmission.

In indirect transmission the viability and virulence of the organism are of prime importance. Infected material, foodstuffs, convalescent patients, etc., have already been mentioned. Air and water rarely, if ever, carry infection, except in pneumonic cases. In infected cities certain houses become, so to speak, endemic plague centers in which case after case develops in spite of thorough disinfection.

In conclusion, it may be said that the plague organism is long lived; is carried by raw materials, insects, etc., gains access to the system through superficial abrasions, wounds, and the pulmonary tract and that a relatively small number of organisms may cause the disease.

## KARYOKINESIS IN MALIGNANT TUMORS.<sup>1</sup>

BY

FREDERICK G. CANNEY, M.D.,  
of San Francisco, Cal.

The law of genetic cellular continuity was first clearly outlined by Virchow, and has now become one of the fundamental data of biology. The cell can have no other possible origin than by the division of a preexisting cell of the same kind. By cell division the hereditary substance is split off from the parent body. Cell division is one of the central facts of development and inheritance. The mechanism of cell division, as considered at the present time, consists in a division of both the nucleus and protoplasm. Remak originally taught that cell division proceeds from the center and extends to the periphery, that it begins with a division of the nucleolus, is continued by simple constriction and division of the nucleus, and is completed by the division of the cell body and membrane.

This simple explanation was accepted as sufficient for many years. Later observations demonstrated that cell division was by no means so simple a process. In 1873 Schneider asserted that cell division was a complicated process, involving changes in both nucleus and protoplasm. He was followed by Fol, Strasberger, van Beneden, Flemming, and others. For the nuclear changes present Sleicher gave the name karyokinesis in 1878. In 1879 Flemming asserted that cell division occurred in two ways: First, by direct division; second, by indirect division, and in 1882 he proposed the terms mitosis (indirect or karyokinetic cell division) and amitosis (direct or akinetic cell division). Modern research has indicated that amitosis or direct division is of infrequent occurrence compared with mitosis or indirect cell division. In considering briefly the subject of mitosis, we have first to consider the cytosome, which is the purely cytoplasmic part of the cell, that is, all exterior to the nucleus except those bodies which are known as archosomes. The cytosome, therefore, contains such constituents as cell wall, metaplastic granules and secretions, various rays, spindles and fibers. The karyosome or nucleus comprises the following parts: Nuclear wall, chromosomes, and their constituents, linin, and what are known as nucleoli. It includes all bodies, which when the cell is at rest, reside within the nuclear wall. The archosome, which is the centrosome or centriole, as named by Boveri, with its spheres (the somosphere and centrosphere), is the third element around which important changes occur in mitosis.

The constituents of the nucleus may be divided into three parts, chromatin, linin and nuclear wall. The nuclear wall is undoubtedly only a condensation of the linin network, so we have really to deal only with the chromatin and linin or chromatic and achromatic sub-

stance. The chromatin is important inasmuch as it undergoes certain interesting changes during the phases presently to be briefly described. The process of mitosis involves three contemporaneous series of events which affect the nucleus, centrosome and the cytoplasm of the cell respectively. For purposes of convenience, it is customary to divide the successive phases into four parts. These phases are not, however, separated in any way in nature, but merge imperceptibly one into the other. These phases are prophase, metaphase, anaphase, telophase. First I would say a few words as to the changes occurring during the prophase. As the cell prepares for division, the most noticeable event occurs in the nuclear material. The chromatin, which is the darkly staining material of the chromosomes, arranges itself in more or less convoluted thread, known as the spirem. Sometimes this is a single thread, and sometimes it is divided into a definite number of segments, called the segmented spirem. However, it finally breaks up into a definite number of distinct bodies, known as chromosomes. The chromosomes are not distinctly homogeneous as they first appear, but on closer investigation are seen to be made up of granules like beads, which Dr. Eisen has named

Section I.—Showing chromosomes, not yet split—spirem stage.

chromioles. The chromioles are grouped into certain aggregations which he has called chromomeres. The chromomeres seem to be presided over by one or more rounded, well defined bodies formed in the nucleus either free or attached to the chromosomes, known as the chromoplast or nucleolus. It has been thought to have a function in directing the complicated changes of the chromosomes, just as the centrosome governs the formation of the spindle outside the nucleus.

The staining power of the chromatin now reaches a maximum. As a rule the nuclear membrane fades away, and the chromosomes lie free in the cytoplasm. Every species of animal or plant is supposed to have a definite number of chromosomes, which regularly recur in the division of the cell.

Meanwhile contemporaneous changes are going on outside the nucleus in the formation of a structure known as the amphiaster, formed under the influence of the centrosomes. The structure consists of a fibrous spindle, at either pole of which is a star or aster, formed of rays radiating into the surrounding cytoplasm, the appearance resembling the iron fillings in the field of a magnet. The center of each aster is occupied by a minute body, known as the centrosome or centriole. As the amphiaster forms, the chromosomes group themselves in a plane passing through the equator of the spindle, and this has been designated as the equatorial plate. The

<sup>1</sup> Presented before the San Francisco Microscopic Society.

amphiaser is supposed to form under the influence of the centrosome, which divides into two halves, an aster being developed around each centrosome, while a spindle stretches between them. It is usually considered that this process occurs outside the nucleus, and as the nuclear membrane fades away, some of the astral rays grow into the nucleus, become attached to the chromosomes, and finally pull them into position in the equator

Section II.—Showing chromosomes split and segmented.

of the spindle. It is claimed by some that the amphiaser forms inside the nucleus, but I think the consensus of opinion holds to the other view. The entire structure resulting from the preceding changes is known as the karyokinetic or mitotic figure. It may be described as consisting of two parts, first, the chromatic figure, formed by the deeply staining chromosomes, or the chromosomic process, and the achromatic figure, consisting of a spindle and asters, or the radiosomic process.

The metaphase forms the initial phase of actual division. Each chromosome now splits lengthwise into two halves exactly alike, which diverge to opposite poles of the spindle, and here each group of daughter

Section III.—Showing chromosomes in groups forming seven daughter nuclei.

chromosomes finally gives rise to a daughter nucleus. Certain variations arise in some cases, but the cardinal fact invariably obtains, viz., that the chromatic network is converted into a thread, which, whether continuous or segmented, splits lengthwise into two exactly equivalent halves. The splitting of the chromosomes, discovered by Flemming in 1880, is the most important operation of cell division, and by it the daughter nuclei receive

exactly equal portions of chromatin or hereditary substance.

During the anaphase the chromosomes, which have split lengthwise and are arranged in definite groups, diverge to opposite poles of the spindle, where they become centralized into a mass near the pole of the aster. As they diverge the two groups of daughter chromosomes are connected by a bundle of achromatic fibers stretching across the interval between them, known as the interzonal fibers.

In the telophase or final phase of mitosis the entire cell divides into two, in a plane passing through the equator of the spindle, each of the daughter cells receiving a group of chromosomes, half the spindle and one of the asters with its centrosome. Meanwhile, a daughter nucleus is reconstructed in each cell from the group of chromosomes it contains.

The slides presented are taken from a rapidly-growing spindle-cell sarcoma of the thigh. The tissue was cut into small cubes and placed immediately in bichromate-acetic fixative solution. The sections were cut four

Section IV.—Showing clump of ten young cells breaking through the cytoplasmic membrane.

micromillimeters thick and stained with hematoxylin and eosin.

The sections show some departures from the typical process of karyokinesis, as described above. The first section shows a cell about 70 micromillimeters in diameter undergoing mitosis. It is surrounded by the spindle-cells of the tissue, being separated from them by a cellular interval. The chromosomes stain intensely and are arranged in a segmented spirem. The cell membrane has faded away and the chromosomes lie free in the cytoplasm.

Section II shows a mitotic cell also, about 70 micromillimeters in diameter, in which the chromosomes have split and segmented and are lying free in the cytoplasm. Many of the chromosomes have a V shape, others are semicircular, or oval, or single points.

Section III shows the chromosomes arranged in definite clumps (there being seven in number within the old cell wall); the cell outlines of the daughter cells are perfectly distinct from the neighboring cells.

Section IV shows the next step in development, a group of cells, ten in number, lying in a shell, representing the old cytoplasmic membrane. The chromosomes stain darkly, indicating recent mitosis. The old cytoplasmic membrane is intact, except in two places where the cells are breaking through. The next step consists in an ingrowing of connective tissue between the daughter cells, and we have the picture

present in any part of the tissue that has not undergone recent mitosis.

It seems to me that the tissue shows certain departures in an unbroken chain. While there are many mitotic figures that indicate that only two daughter nuclei are formed, the four sections presented indicate in an unbroken chain a mitosis in which there are many daughter cells formed in the plane of the section. As a cell is not a flat structure, but a circular mass of protoplasm, it seems evident that if all the serial sections of the cell could be presented there would be at least 50 daughter cells formed from the fragmentation of a single nucleus.

The spindles that were present in this tissue presented certain departures from the ordinary. While in many cases the equatorial plate showed the normal arrangement with the rays converging to the two poles, probably the most common form consisted in a branching or Y-shaped arrangement, and in some few cases a double Y.

The most natural question as to Figures I, II and III is whether they are examples of karyorrhesis, and therefore an evidence of degeneration, or whether they are examples of a pathologic mitosis, tending to the production of multiple daughter cells.

The drawings were made by me with as great accuracy in detail as was possible. The lenses used were a 3 mm. apochromatic Zeiss, with compens. ocular 18, using an oil immersion achromatic substage condenser.

## X-RAYS IN SURGICAL DIAGNOSIS.<sup>1</sup>

BY

ARTHUR T. McCORMACK, M.A., M.D.,  
of Bowling Green, Ky.

Member of the Warren County Medical Society, Kentucky State Medical Association, American Medical Association, Surgeon-General Kentucky State Guard, etc.

The discovery of rays of light which penetrate substances ordinarily opaque, termed by the discoverer, Professor Conrad Röntgen, x-rays, probably marks an era in medical and surgical diagnostics. It may be classed with the discovery of the microscope, the clinical thermometer, the stethoscope and the hypodermic syringe as one of the great mechanic agencies upon which scientific, as distinguished from empirical medicine, is based. In all cases in which it is of any value at all as a diagnostic aid it is probably the most valuable we have, as it is the most definite in the information, given to the trained eye, of any instrument at our command. While it is possible, owing to the initial cost of the apparatus, the cost of maintenance, and the technical and electrical difficulties in the management of even the most improved machine, that x-ray machines may never become so universally employed as some of the cheaper instruments we now have, *e. g.*, the stethoscope or thermometer, yet I venture the prediction that within a few years no medical or surgical diagnosis in any but the plainest cases will be considered definite or complete without a report from a reputable, competent radiographer. It will doubtless be difficult for physicians not familiar with the x-rays to understand the dependence upon them by every one accustomed to their use. Of course we are but at the threshold of our knowledge of this agency, but even now Williams is able to make a positive diagnosis of the beginning of tuberculosis long enough before physical signs can be found to make the difference between success and failure in the treatment of this most common and most dreaded disease, while Leonard has taught us not only to make an absolute positive or negative diagnosis of renal or ureteral stone, but at the same time to locate it so definitely that the danger of the surgical procedures necessary to its re-

moval is reduced to a minimum. The methods of these masters of our art are placed freely at the command of all medical men, and it is only he who will not, who fails to avail himself of their assistance.

First, it may be better to give brief attention to the machinery and technic necessary for the production of x-rays of sufficient brilliancy to produce satisfactory results. I have used both the coil and static machine, and while I freely admit that excellent results may be obtained from either, I feel confident that to any other than the x-ray specialist or one who employs an operator, that the well-built static machine of 10 or more revolving plates equipped with a first-class motor of sufficient power to get a very rapid revolution of the plates will be more satisfactory than any other form of apparatus. In country districts, where neither water nor electric power can be obtained, no static machine will be found satisfactory unless a small gasoline or steam engine is purchased with them. It is very tiresome to turn even the lightest machine by hand-power, and the light thus generated is an uneven one at best. The only troublesome thing one must do with a static machine is to keep several bowls of perfectly dried calcic chlorid in the case, and in very warm wet weather—during dog-days, for instance—these bowls must be set in the stove and baked for some time, until perfectly dry. Sometimes during the summer this must be repeated as often as every second or third week, but ordinarily once every month will do until the house begins to be warmed by artificial heat, when the bowls may be left alone until summer again. Much of this trouble, and it sounds worse than it is in practice, may be avoided by having glass plates six or eight inches thick under the legs of the machine.

In practice the question frequently arises as to whether the examination should be with the fluoroscope or whether a radiograph should be made. It seems to me that no x-ray examination, especially in surgery, is complete unless the fluoroscopic examination is especially thorough. In all cases when a permanent record is desirable, as in operative cases, or in cases in which one is observing newgrowths of sufficient density to show on a plate, it is well to make two or more pictures at such angles as will best show the deviation from the normal. Each plate should be definitely identified and the distance of the plate from the tube noted as well as their position relative both to one another and to the object radiographed. In medicolegal cases this is of especial importance, and the time seems almost at hand when the evidence in many personal injury cases will be considered incomplete without the testimony of a radiographer.

In considering the x-ray in surgery proper, we more easily understand our object by considering it (1) in bone surgery and (2) in surgery of the soft parts. We may for further convenience divide (1) bone surgery into (a) fractures and dislocations, (b) newgrowths involving bone, (c) diseases of the bones other than newgrowths, and (d) the detection of foreign bodies contained within bones or bony cavities; and (2) surgery of the soft parts into (a) the detection of foreign bodies in the soft parts, (b) newgrowths, (c) affections of the organs within the chest other than newgrowths, and (d) renal, ureteral, vesical, and hepatic calculi.

### 1. BONE SURGERY.

(a) *Fractures and Dislocations.*—The mistakes made by our profession in the treatment of this particular class of afflicted persons are more prominent than in any other branch of our art. Röntgen's discovery revolutionizes at once our methods of diagnosis and treatment, and makes both so accurate and so safe that diagnosis in all cases in which it is available is certain, and the prognosis and treatment are laid before us as an open book. Of course, many fractures and dislocations may be detected and treated almost perfectly without the aid of the x-ray (but we cannot safely tell which these are with-

<sup>1</sup> Read before the Kentucky State Medical Association, Paducah, May 9, 1902.

out their use), and I feel confident that if two radiographs could be taken, or even if sketches of the position of the fragments could be made from a fluoroscopic examination, and this could be repeated after as complete reduction as possible, the physician would know almost perfectly the amount of displacement that probably would result. This could be shown and explained to the patient, and the necessity, should it exist, for wiring the fragments together could be made plain. Fluoroscopic examination should be repeated frequently and each observation should be carefully recorded. Many linear fractures without displacement can be recognized only from a radiograph. Every user of the x-rays must be surprised especially at the frequency of fracture of small bones of the hand and foot in cases formerly treated as sprains, and they are of particular value in fractures complicated with dislocations when one or the other injuries are frequently overlooked by ordinary examinations. Most fractures in which there is great danger of permanent deformity are easily recognizable from a simple fluoroscopic examination, and the method necessary for relief lies before one.

(b) *Newgrowths Involving Bone.*—In such conditions the value of the x-rays is apparent. It is well to remember that exostoses following fractures simulate newgrowths and that the growths are nearly always a little more extensive than they appear, owing to the comparative softness of the edges of the growth. Frequently the entire area of the growth shows only as a dark spot on the negative, due to the rarefaction of the bone and the lower density of the tumor. Radiographs should always be made in suspected malignancy.

(c) *Diseases of Bones Other than Newgrowths.*—In simple periostitis the edges of the bone appear roughened. The bone should be examined around its whole circumference very closely. In tuberculous infection of the joints the infusion is apparent and is always darker when purulent than when serotic, and the affected bone areas are roughened and less dense. In poliomyelitis of the long bones the borders of the canal are roughened. Of course the distinction between various bone lesions, whether tuberculous, syphilitic, malignant or simple, must be cleared up by the physical examination and history of the patient.

(d) *The Detection of Foreign Bodies Contained Within Bones or Bony Cavities.*—Foreign bodies may be detected when they are driven into the bones or bony cavities when they are more dense to the rays than the bones or when they are much less dense than the bones, but only in the latter case if they are of considerable size. Of particular interest is the localization of particles of glass, stone or metal in the eye, or of similar substances or of bullets in the brain or pelvis.

## 2. SURGERY OF THE SOFT PARTS.

(a) *Foreign Bodies in the Soft Parts.*—Such bodies are more readily located. This method is particularly useful in the removal of pins, needles and small pieces of metal from the hands or feet. Every practitioner knows the annoyance and difficulty of finding such small objects. Instead of making radiographs in perpendicular planes as is ordinarily recommended, I have found it much easier to locate the foreign body with the fluoroscope after thoroughly cleansing the nearest adjacent skin surface. After this I take a sharp scalpel of sufficient breadth and make a puncture to the end of the needle or broadest part of any other foreign body and then introducing a very small but strong pair of forceps through the puncture, remove the offending matter. This procedure is extremely simple and is not a matter of as many minutes as it takes to describe it. A similar procedure may be followed when sufficiently dense foreign bodies are in the nose, larynx, trachea or esophagus. In these cases an assistant is necessary, who should introduce the proper forceps to reach the foreign body so as not to injure the soft parts. The light necessary for

this part of the procedure may be gotten from a candle. Then the operator, watching the introduction of the forceps with the fluoroscope should guide the jaws so they grasp the edge of the object and then gently yet firmly extract it. Modifications of this method will suggest themselves for foreign bodies in other parts.

(b) *Newgrowths.*—The size and depth of many newgrowths of soft parts may be marked out very definitely with the x-rays. Particularly important, as modifying the character of operations, is the location of growths of some size in the neck as to whether they extend behind the clavicle and into the thorax. Several tubes of varying degrees of resistance should be used in such cases. Even large abdominal tumors cannot usually be made out but the displacement of the diaphragm is always noticeable. Aneurysms may also be considered under this head for convenience: they are usually very dark and their pulsations easily noted.

(c) *Affections of the Organs Within the Chest Other Than Newgrowths.*—No examination of the chest may be considered complete without the aid and confirmation of the fluoroscope. Many examinations of normal as well as abnormal chests are necessary for one to appreciate this fact. Surgically we are chiefly interested in empyemas, pleurisy with effusion, gangrene of the lung and tuberculosis. Dr. Williams, in his extraordinarily complete work on this subject, has shown that in all affections of the lungs the diaphragm on the affected side has a relatively lessened range of motion as compared with the sound side. Darkened areas in the lungs indicate disease of the lung substance while cavities and emphysema are shown by clear bright spots, or in the latter disease over all of both lungs. Pleuritic effusions are readily noted by the displacement of lung and often also of the heart. In empyema the resistance to the light is much greater and the area filled with pus is almost or quite black. Gangrene of the lung is similar in appearance to pneumonia but the area is usually larger and darker. Displacement or enlargement of the heart may be readily noted and given its proper significance.

(d) *Renal, Ureteral, Vesical, and Hepatic Calculi.*—Leonard has taught us how to make a positive diagnosis of renal, or ureteral calculus by making a radiograph with a low tube—so low in fact that anything in the abdomen of greater density than the soft parts will be shown. He expresses perfect confidence in his negative as well as positive diagnosis, and his wide experience and perfect success make him our Nestor in this department. We cannot yet as certainly find stones in the bladder or the gallbladder, but this is purely a question of technic and may be solved satisfactorily any day. It is important in all cases when ureteral or renal stones are located to operate as soon as possible, not only for relief to the condition but also because the stone may move and not be readily found.

Thus briefly have I outlined the present status of the x-ray in surgical diagnosis. Truly we may say we are but in the infancy of this most wonderful art. Every day is bringing newer uses for the x-ray in all branches of medicine. No conservative expert will claim that everything in medicine is settled by its use or that any agency we now have at our command should be discarded. It makes a most—may we not say the most—valuable addition to our diagnostic armamentarium and its very value makes it more important that we should the more frequently examine the sputum and the blood, that we should all the better ground ourselves in the use of the stethoscope and microscope, that we should collect and keep more careful histories and case notes, and above all that we be better, broader, more careful and more painstaking physicians.

A memorial hospital, to honor the memory of the late Rev. Richard S. Storrs, the eminent Brooklyn preacher, and to bear his name, will be erected by friends in Foochow, China.

## SPECIAL ARTICLES

## WIDENER MEMORIAL INDUSTRIAL TRAINING SCHOOL FOR CRIPPLED CHILDREN.

BY  
DE FOREST WILLARD, M.D.,  
of Philadelphia.

Clinical Professor Orthopedic Surgery, University of Pennsylvania.

The Widener Memorial Industrial Training School for Crippled Children, now under process of erection through the broadminded liberality of Mr. P. A. B. Widener, is in memory of his wife and son. It has for its object the special training and equipment for the struggle in life of a class of individuals seriously handicapped in the race. Thirty-two acres situated on the Old York Road, but within the city limits, has been purchased for the purpose and the buildings are already partially completed. The grounds are studded with magnificent old trees and the location is most healthful. The buildings being erected (designed by Mr. H. Trumbauer) are of the Colonial style of architecture and consist of a central convalescent department, an educational department and an industrial department, together with cottages and administration building; also heat, light and power house, machine shop, disinfecting and incinerating plants, isolation cottage, etc. All the appliances are of the most sanitary, helpful and useful character. The cost of grounds and buildings will approximate \$1,000,000, which together with an endowment fund of \$2,000,000, will make the total investment \$3,000,000.

important of helpers in the restoration and continuance of health, outdoor occupations will be favored for both boys and girls, and the 32 acres of ground will be utilized in floriculture, agriculture, the care of stock, dairy products, poultry, etc., all these industries being taught by the best methods. Girls will be taught all branches of cooking, housekeeping, etc., together with sewing, millinery, dressmaking, mending, and the more delicate needle decorative arts. Boys will be instructed in machine work, the manufacture of braces, shoes and clothing, printing, engraving, silver marking and various like trades.

The place will be emphatically a school and not a hospital, but convalescents and cured patients will be received from any hospital. In case of relapse the patient will be returned to the hospital for further treatment. During the convalescent stage, patients will be under the constant supervision of a physician, while at the same time their education will be advanced to a greater or less degree, as strength of brain and body will permit. When possible, children will be taken early in life, and will not be graduated until they have attained some means of partial or entire support. As the work is along new lines which have not been attempted to any extent in this country, and only very moderately in Sweden and Finland, the adaptation of mental and physical powers will require careful study in order to raise the individual in the moral as well as the physical scale.

Among the plans suggested for elevation of the standards, as soon as the boy or girl has developed a certain amount of proficiency it is proposed that he or she shall be paid wages and shall pay board, thus developing a sense of responsibility and self-respect. Economical habits will be fostered,

The Widener Memorial Home for Crippled Children.

The school is intended to individualize the physical disabilities of each patient and to give to that individual a thorough practical training in the occupation for which he or she may be best fitted, physically and mentally. With the serious crippling of muscular force so constantly found in this class, great discrimination will be necessary in deciding upon the most suitable trade or occupation. Each one will be studied with the view of bringing out the qualities best fitted to secure self-support, thus raising the individual from a condition of dependency to one of self-dependence, and not only relieving the State from a burden, but also making a good citizen.

The institution is to be put upon the broadest possible basis, without discrimination of race, creed, or color, the intention being to avoid as far as possible the errors of institution life and to follow the best conditions of family home training. The sexes will work, study and play together, but in their house life will be placed in separated small cottages, in numbers of twenty, under the direct influence of a housemother, where the normal conditions of home will be approximated as closely as possible. Individual rooms will be assigned to older scholars.

The primary object will be to train the hands or feet or body for some useful occupation, while at the same time a moderate brain education will be enforced. Any child showing decided brain power will receive higher education at already existing institutions in the city. The whole training will be eminently practical. As sunshine and fresh air are the most

while regularity and method will be secured by an accurate keeping of yearly personal accounts. The establishment of a penny savings bank, etc., will stimulate the desire to earn and to accumulate.

A gymnasium especially arranged for the development of weakened portions of the body, and sunny winter playrooms and porches will be provided, also smooth asphalted outdoor exercising grounds, etc. Each building is supplied with elevators, and each cottage will have a homelike evening sitting-room, with books, games, etc. The auditorium will be used not only for secular and religious purposes, but also for the teaching of music, both vocal and instrumental.

As the work develops it is also expected that the necessity will arise for a boarding-house for graduates, where plain but healthful and clean accommodations can be secured at a price graded consistently to the earning powers of the individual. These handicapped workmen and workwomen will thus be placed conveniently to the region of supply and demand, and can continue their home life in close daily contact with the center of graduate instruction.

From the above outline it will be seen that the work of this school is, briefly, to supplement the work of the hospitals; to strengthen and physically renew the weak ones, and then to educate them into habits of industry, order, cleanliness, self-respect and self-reliance; to apply such mental, moral and religious training as will render them true, honorable, useful and self-sustaining members of the community.

8. Gastrojejunostomy with the McGraw Elastic Ligature, for the Relief of Gastropostosis. H. O. WALKER.
9. The Mortality Following Operations for Pus in the Pelvis. HUNTER ROBB.

1.—See *American Medicine*, Vol. III, No. 24, p. 991.2.—See *American Medicine*, Vol. III, No. 24, p. 990.3, 4, 5.—See *American Medicine*, Vol. III, No. 25, p. 1056.

6.—**Syphilis of the Larynx.**—This is fortunately rare. But one instance of primary lesion has been observed. When the disease is hereditary it occurs in the early months of life or about adolescence, in the former showing secondary, in the latter tertiary lesions. Absence of pain when not attempting to swallow is most characteristic. When a gumma ulcerates the process begins at the center and there is some pain, especially on swallowing. When ulceration occurs near a cartilage perichondritis follows and a sequestrum is frequently formed, which gives rise to a permanent discharge either into the larynx or outside of the neck. Ultimately stenosis takes place. Sometimes the larynx is entirely obliterated, requiring a cannula to be worn permanently. Robertson gives a table showing the main differences between syphilis, carcinoma, and tubercle in this location. The usual systemic treatment is indicated. Patients will often take large doses of iodids who will not tolerate smaller ones. It is well to begin with 20 grains. The ulcer should be cleansed, cauterized with iodine crystals in creosote (saturated solution) or painted with lunar caustic or burned with the galvanocautery. The object of treatment is to prevent stenosis. [H.M.]

7.—**Wax Models of Skin Diseases.**—Wallis shows cuts of models of some rare manifestations. It is the truest means of illustrating the morphologic conditions. [H.M.]

8.—See *American Medicine*, Vol. IV, No. 18, p. 688.

9.—**Mortality in Pelvic Operations.**—Robb believes the mortality following operation for suppurative disease can be kept under 5%. The deathrate is influenced by the virulence of the organism, the individual resistance, the time and manner of carrying out the operative technic. The *Streptococcus pyogenes* is most to be feared. Abdominal drainage is seldom necessary, as the germs are generally dead. It is needed when it is impossible to remove the suppurative structures and when perforation of the bowel is feared. Irrigation with salt solution removes the pus and promotes absorption of inflammatory products. The elevated position with the abdomen filled with salt solution tends to prevent intestines and omentum from adhering to the incised surfaces. Should symptoms of infection occur there is then sufficient time to reopen the abdomen and wash out the infective material. Operations for pus in tubes and ovaries are not, as a rule, attended by more dangers than others. [H.M.]

## Boston Medical and Surgical Journal.

January 15, 1903. [Vol. CXLVIII, No. 3.]

1. A Synopsis of Ten Weeks' Service on the Boston Floating Hospital. ROBERT W. HASTINGS.
2. A Case of Retinal Hemorrhage in a Patient of Seventy-three; Treatment by the Faradic Current: Complete Recovery. HASKET DERBY.
3. Vesical Appearances in Renal Suppuration. EDGAR GARCEAU.
4. The Treatment of Hay-fever. LORENZO B. LOCKARD.
5. Poisoning of the Underwood Family by Wood Alcohol. E. G. HOITT.
6. Wood Alcohol Poisoning. S. W. ABBOTT.

1.—**The Boston Floating Hospital.**—Hastings gives a brief history of the hospital and describes the work at present carried on. Experience has led to the conclusion that fresh, clean milk is better than pasteurized food. Milk containing less

than 10,000 bacteria per cc. was obtained and the milk sugar solutions used in modifying it were sterilized by boiling for 30 minutes. No preparations were heated beyond 100° F., and that at the feeding time. Mothers were instructed in the art of pasteurizing, however, as milk generally has millions of germs to each cc. Peptonized foods showed an increase in bacteria, and a tendency not to hold together, consequently fresh extract of pancreatin and sodium bicarbonate were used, the cream (12%) peptonized and sterile sugar solution added afterward. Whey for sick babies should be made with essence of pepsin and whole, not skimmed milk. Babies with gastrointestinal troubles were usually put first on rice water made from flaked rice. If there was vomiting, albumin water was used. In exhaustion, panopeton or beef juice was given. Two wards were supplied with air with a humidity of 50% and a temperature of 72° F. by means of an ice machine, steam pipes, and a powerful fan. To prevent infection from diarrhea, flies were kept away, dejecta destroyed, and cyanid of mercury used for the hands. Hypodermoclysis was found valuable for stimulation. It can readily be given by a nurse. The stomach and nasal tube was used when food was refused. Enteroclysis was performed 700 times during the season. [H.M.]

2.—**Retinal Hemorrhage: Treatment by Faradic Current.**—Derby reports that a woman of 73, whom he had treated for a number of years, suddenly experienced great impairment of vision in the right eye. Vision was less than one-tenth. Dilatation of the pupil and ophthalmoscopic examination showed numerous retinal hemorrhages, the largest being extensive and in the macular region. She was given 10-minute treatments three times a week for about seven months with the faradic current, together with small doses of potassium iodid internally. The small hemorrhages cleared up before any apparent impression was made upon the large macular hemorrhage, which also finally entirely disappeared, leaving but an indistinct haziness. Vision to the extent of eight-tenths returned—slightly better than before the hemorrhage. The author hopes other members of the profession will try this method of treatment and determine conclusively whether it possesses actual value. Attention is called to the relief from pain following an application of the faradic current. [A.B.C.]

3.—**Vesical Appearance in Renal Suppuration.**—Garceau calls attention to the usually accepted statement that a pouting and inflammatory appearance of the ureteral orifice occurs on the side corresponding to an inflammatory or suppurating kidney. That this is generally true cannot be questioned but that it cannot be relied upon without corroborating evidence is illustrated by a case he reports in which after prolonged renal disease and vesical irritation a cystoscopic examination revealed an ulcerated and inflammatory condition of the left ureteral orifice while all other evidence went to show that the diseased kidney was the right. Daily irrigations with boric acid solution greatly relieved the vesical irritation and a subsequent cystoscopic examination showed both ureteral orifices normal although disease of the right kidney, apparently a stone, plainly exists. The patient refuses to permit a skiagraph and the exact renal condition can only be surmised by a long history of pus in the urine, repeated attacks of renal colic, enlargement of the right kidney and apparent absence of tuberculosis. [A.N.C.]

4.—**Treatment of Hay-fever.**—When Lockard finds no abnormality in the nose he lightly cauterizes both turbinates to obtund sensibility. Abnormalities should be corrected early to allow time for complete recuperation before the hay-fever season. He outlines a treatment for the elimination of uric acid and the correction of existing neuroses. In all cases he gives nitromuriatic acid (not the dilute), 3 to 5 drops after meals and at bedtime. If it causes diarrhea, the acid phosphates or lemonade can be substituted temporarily. Sodium bicarbonate results in immediate aggravation of all symptoms, counteract by acids, and alleviation ensues. Adrenalin chlorid is more efficacious than cocain. Its use should be followed by an oily spray, especially before going into the open air. Atropin may be needed for the hydrorrhea, and may be combined with morphin and caffeine. When the acid treatment

fails, suprarenal gland, 5 grains, 3 to 5 times daily, may be tried. A cold douche or ice-bags to the spine will sometimes cut short the accompanying asthma. Nothing, however, is as useful as *dracontii* with belladonna, chloroform, and *althea*. [H.M.]

**6.—Wood Alcohol Poisoning.**—Deaths from this are on the increase, and Abbott advocates legislation requiring all retail packages of wood alcohol to be labeled as poison, sold only by registered pharmacists, and then only when a record of sale is made. The patent medicine trust will probably oppose such legislation. [H.M.]

**Correction.**—The abstract which appeared in *American Medicine*, January 3, 1903, p. 27, of the paper by Taylor and Waterman, "Landry's Paralysis," contained the statement that a fatal termination of the disease is not uncommon which is explained at necropsy. It should have read *unexplained* at necropsy.

### Medical Record.

[January 17, 1903. Vol. 63, No. 3.]

1. Some Questions in Heredity. A. ALEXANDER SMITH.
2. Methods of Quarantine Against Yellow Fever Adopted in Havana, Cuba, During the Year 1901. W. C. GORGAS.
3. The Surgical Treatment of Puerperal Eclampsia and the Prevention of Convulsions. DOUGLAS H. STEWART.
4. Hypertrophy of the Lymphoid Ring of the Pharynx and Its Surgical Treatment. H. HOYLE BUTTS.
5. A Case of Sepsis, Following an Attack of Osteomyelitis from a Slight Cause. SAMUEL KOHN.

**1.—Heredity.**—Smith limits himself to that phase of heredity which has a bearing on clinical work. The most we can say about pulmonary tuberculosis is that lessened resistance may be inherited. Congenital tuberculosis is rare. The disease in the newborn can usually be traced to infection in utero. Gland, joint or bone disease, when the parents have been free from tuberculosis and a grandparent affected, presents a puzzling question. Is spontaneous recovery due to inherited tolerance? Certain diseases often develop at corresponding periods in parent and offspring through several generations. Gout is believed to be hereditary, and due to errors in eating and drinking through several generations. It often appears through inheritance in individuals whose own habits of life are correct. The older children may escape and the younger develop the disease, because the immediate ancestor acquired habits after the birth of the former such as to lead to disease in the latter. Rheumatism, or a tendency to it, is inherited. If infectious, only a vulnerability could be transmitted. Cancer seems to be inherited many times. In some families there is a distinct tendency to bronchial asthma, cardiac disease, arteriosclerosis, and hemophilia. All recognize the neuropathic constitution as transmissible. Mental derangement more than any other disease is inherited. Alcoholism is probably due to inherited deficiency in mental control. We call inherited tolerance to disease vitality. Racial susceptibility has long been noted. [H.M.]

**2.—Quarantine Against Yellow Fever.**—The quarantine regulations at Havana in 1901 were modified in accordance with the view that mosquitos and not fomites were the carriers of infection. Gorgas reviews the measures taken to kill the mosquitos and prevent their infection in the city itself, and describes those to prevent the disease carried in from the surrounding country. No question was raised about merchandise. The authorities wished merely to keep out those sick with yellow fever and keep others who had contracted it from developing it in the city. A medical inspector was employed in each infected town to notify Havana by telegraph of any non-immune going into that city. There were also inspectors on all trains from infected towns who reported all nonimmunes. The latter were visited once daily at their residences for five or six days after arrival and the temperature taken. A few sharp punishments for evasion effected general compliance with the regulations. Out of 1,250 nonimmunes, 27 developed the fever. Traffic and passenger travel was not interfered with. The temptation is great, if the necessity is sufficient, for a non-immune to try to avoid the present quarantine regulations of the United States. The relief to commerce under the Havana system would be enormous. [H.M.]

**3.—Puerperal Eclampsia.**—Stewart maintains that puer-

peral eclampsia has two causes: one intrarenal, due to diseased kidneys, and the other extrarenal, due to pressure upon renal veins, inferior vena cava, or ureters; and he defines it as a "neurosis caused by the action of poisonous blood upon the nerve centers." He emphasizes the point that albuminuria before the seventh month usually indicates postpartum danger, and in the last two months trouble before or during labor. In diet have the patient avoid meat. Impacted feces sometimes cause albuminuria, and when this condition is relieved even by stretching the sphincter muscle if necessary, the albuminuria is relieved and normal labor follows. It may also result from an obstructed urethra, and diminish when that is remedied. That venesection is curative in eclampsia Stewart says even its opponents admit, since in 15 recorded cases in which blood-letting was the sole treatment after convulsions had actually taken place there was only one death; but he believes that it is preventive also, and that inasmuch as we are dealing with a poisonous blood whose poisons would escape if possible, the simplest plan is to make a safety opening in the circulation. If forbidding meat and freeing rectum and urethra does not lessen albumin, we should draw off four ounces of blood. Follow that with a leech on alternate days. This is a working minimum. Bleed till the blood tension comes down, and albumin, swollen feet, headache and disturbances of sleep will be relieved. In one case small bleedings, begun on October 5, 1902, with albumin 50% by bulk, lessened the amount to 5% by October 10, 46 ounces having been taken in all. Every symptom had improved. Watery loss can be made up by rectal irrigation. Frequent small bloodletting is not depressing; on the contrary, it removes a depressing poison and the patient becomes less anemic. Stewart says that with diet, fresh air, exercise, frequent small venesections, a free urethra and rectal irrigations, we may eliminate the causes, and puerperal eclampsia need occur only in neglected cases. [W.K.]

**4.—Hypertrophy of the Lymphoid Ring of the Pharynx and Its Surgical Treatment.**—Butts first considers hypertrophy of the lymphoid structure in the vault of the pharynx, the so-called "adenoids of the vault." The wellknown signs are enumerated—mouth breathing, snoring at night, difficulty in respiration, pigeon breast, cough and frequent colds, lack of proper development, etc. The treatment is, of course, removal, and this should be done, except in very rare instances, under a general anesthetic. Hypertrophy of the faucial tonsils, of course, demands removal, and this should be done under a general anesthetic and with a tonsillotome. While the preceding conditions arise in infancy and early childhood, hypertrophy of the lymphoid tissue at the base of the tongue is rarely seen until adult life. Contact of this mass with the epiglottis causes irritation and is responsible for the symptoms, the most pronounced of which are the sensation of a fulness, a foreign body or "lump" in the throat, and a cough, especially marked at night. The galvanocautery preceded by cocanization is the best plan of removal. It should be repeated after a week until the mass is removed. [A.B.C.]

**5.—Sepsis Following Osteomyelitis from a Trivial Injury.**—Kohn reports the case. A young woman took a ride on a scenic railway and another on a carousel. During the rides, especially the former, she gripped strongly the supports to maintain her equilibrium. Following this there was pain in the right wrist. Inflammation, pain, swelling, tenderness, prostration, high fever, and endocardial murmur supervened. All the symptoms of a profound sepsis were combated by every known remedy for five weeks, when the patient died. The osteomyelitis of the ulna, apparently resulting from the sprain, was operated upon without general relief, no pus being found. A necropsy showed in all the internal organs the evidences of general sepsis and the diagnosis was osteomyelitis of ulna; staphylococemia; acute endocarditis of aortic valve, with perforation into right auricle; acute endocarditis of right auricle. Point of primary invasion not demonstrable. [A.B.C.]

### New York Medical Journal.

January 10, 1903. [VOL. LXXVII, No. 2.]

1. Colorado Climate and Eastern Patients. W. A. CAMPBELL.
2. The Repair of Lacerations of the Pelvic Floor. JAMES HAWLEY BURTENSHAW.

3. The Origin of Chorioepithelioma of the Uterus. SAMUEL WYLLIS BANDLER.
4. Some Tonsil Affections. RICHARD B. FAULKNER.
5. Report of a Case of Tetanus Following Vaccination. WILLIS S. COOKE.
6. Thoughts on Fetal Intracranial Hemorrhage. DOUGLAS H. STEWART.
7. Note on the Salt Starvation Principle in Epilepsy Treatment by Bromids. L. PIERCE CLARK.

1.—**Colorado Climate.**—Campbell discusses the natural and acquired advantages of Colorado as a health resort and gives some points in the care and treatment of pulmonary patients in general. He says many patients are sent to this climate who have not been informed as to their true condition or who have been promised a cure in a very short time; such patients are, therefore, very hard to treat. He maintains that more active efforts should be made to get patients to Colorado in the earlier stages of tuberculosis, when a much larger number are cured. He believes being out of doors is the essential factor in the treatment of tuberculosis. The exercise, especially of a new arrival, should be strictly under the control of a physician. Sleeping on open porches is most advantageous. Pure air, good food, and a moderate amount of exercise are important factors. The complications must be met by therapeutic agents, but the treatment of the disease is more or less symptomatic. [C.A.O.]

2.—See *American Medicine*, Vol. IV, No. 17, p. 649.

3.—**Chorioepithelioma of the Uterus.**—Bandler says that we have in chorioepitheliomas a reproduction of the same constituent elements as are found in normal placentation, and are observed in benign and malignant cases of hydatid mole, and that these cells exert the same influence and effect on the maternal tissues as do the fetal cells in a normal uninterrupted pregnancy. They invade, as do the normal trophoblast cells, the maternal decidua and destroy it, and infiltrate and erode the walls of vessels. They invade and infiltrate deeply, too, the uterine wall. Their invasion of the maternal vessels and capillaries gives them, from their earliest existence as malignant cells, the opportunity of invading the maternal circulation, with a resulting early formation of metastases. Chorioepithelioma, occurring generally after abortion or hydatid mole, is certainly the cause, rather than the result, of the abortion. It represents a more advanced stage than that of hydatid mole, but both of these conditions, in a basic way, follow the normal processes in their course and growth. The only difference is the power of unlimited growth possessed by the chorionic cells in these pathologic conditions. The difference in the resistance offered by the patient points to a constitutional element, the lack of some normal secretion, as an important factor in the etiology of chorioepithelioma. [C.A.O.]

4.—**Tonsillar Affections.**—Faulkner calls attention to the absorptive power and phagocytic function of the tonsils, and states that every case of tonsillar affection demands thorough antiseptics, greater care in the preservation of lymphoid structure, more conservative surgical, and decidedly more comprehensive and detailed medical treatment of the nares. [C.A.O.]

5.—**A case of tetanus following vaccination** is reported by Cooke in a child of 4. The vaccine was of the glycerinated variety on an ivory or celluloid point, encased in paraffin. Precautions as to cleanliness were observed, and the scarification done at a point on the right leg about three inches below the knee, over the outer head of the soleus. A typical vaccine pustule followed, and the child was sent to the country. In about one month the child began to show symptoms of tetanus, later both trismus and opisthotonos occurred. In all [1,600 units of antitoxin were injected. Potassium bromid, chloral and whisky were also given. Recovery followed. Cooke believes that the wound became infected with the germ of tetanus while the child was at play in the country. [C.A.O.]

6.—**Fetal Intracranial Hemorrhage.**—Stewart believes that this accident arises from unequal squeezing; that is, a lack of countercompression on the vertex simultaneously with heavy urging pains acting on the body. This causes increased tension in the intracranial vessels, and happens under certain conditions and at a definite stage of labor, the forceps in the majority of cases being applied too late or not at all. A heavy pressure on the body in a dry labor before overlapping, especially if there is constriction of the veins of the neck by an

encircling cord, is a fairly certain cause of cerebral engorgement. Theoretically he advises the Kemp irrigator and the normal salt solution at 115° F. Derivatives are called for, and this method works well in older children. [C.A.O.]

7.—**The salt starvation principle in epilepsy treatment by bromids** is urged by Clark. Experiments have shown that bromin can replace chlorin in the body tissues; therefore by sodium chlorid starvation and the continual administration of the bromids we get an organic bromid compound acceptably fulfilling the physiologic role of chlorin and at the same time acting as a therapeutic agent of sedation in epilepsy. Under this method much smaller doses are necessary to control epileptic seizures. It is especially recommended in those acute idiopathic cases which require such large doses of bromids given in the ordinary manner that fatal intoxication is imminent; in those in which even unusually high dosage bromid is of little value; in those totally intractable to the bromid salt, and finally, in all chronic cases where a long continued sedation is necessary to hold in partial check the severity and frequency of epileptic attacks. The dietary should be especially arranged for palatableness and consist of cereals, milk, and vegetables. Sodium bromid should be given in the patient's food in place of table salt, as it is nearest like it in point of taste. Clark says that the results he has obtained from hypo-chlorization diet and the bromid treatment of epilepsy are the absence of "bromism," gastric irritation, constipation, and the mental hebetude common in the older forms of bromid sedation. [C.A.O.]

1. The Etiology, Pathology and Symptomatology of Acute Suppuration of the Middle Ear. EDWARD BRADFORD DENCH.
2. Complications of Acute Middle-Ear Suppuration. JAMES B. CLEMENS.
3. The Treatment of Acute Suppuration of the Middle Ear. WENDELL C. PHILLIPS.
4. The Etiology, Pathology and Symptomatology of Chronic Purulent Otitis Media. M. D. LEDERMAN.
5. Complications of Chronic Suppuration of the Middle Ear. ROBERT LEWIS, JR.
6. The Treatment of Chronic Suppuration of the Middle Ear. JAMES F. MCKERNON.

1.—**Etiology, Pathology and Symptomatology of Acute Suppurative Otitis Media.**—Dench says the predisposing cause of acute suppurative otitis media is any condition which conduces to a chronic congestion of the upper air tract and the tympanum, *i. e.*, any obstruction to nasal respiration. Among the many causes thus acting are chronic hypertrophic rhinitis, acute rhinitis, acute inflammation of the nasopharyngeal space, adenoid vegetations, and diseases such as chronic heart, chronic nephritis, anemia, diabetes, etc., all tending to lower the general vitality. In any of these conditions if we have the direct cause, *viz.*, pathogenic germs gaining access to the middle ear, either by way of a ruptured drum, or through the eustachian tube, suppurative otitis media is the result. The condition often occurs also as a complication of the acute infectious diseases—measles, diphtheria and scarlet fever. In the pathology we notice that a *purulent* inflammation almost always involves the upper part of the tympanic cavity, whereas a *catarrhal* inflammation involves, as a rule, the lower part, but a catarrhal process may easily become so pronounced as to rupture the drum, and may of course extend into a suppurative process. Among the pronounced symptoms of acute suppurative otitis media are stuffiness in the ear followed by pain which may become very severe, impairment of hearing, vertigo, vomiting, rise of temperature, which in children may suddenly reach 105° F. or 106° F. A sudden rise in the temperature of a child suffering with one of the exanthems should at once arouse suspicion of acute otitis media. [A.B.C.]

2.—**Complications of Acute Suppurative Otitis Media.**—Clemens says an otitis externa may be one of the complications leading to violent inflammation of the lining of the osseous canal, closure of the canal, and extension to the auricle. Mastoid disease is a frequent and dangerous complication, not infrequently leading to meningitis, thrombosis of the sigmoid sinus with consequent pyemia, abscess of the brain. Wide extension of inflammation in the neck and toward the vertex may occur. Other complications mentioned are caries of the

neighboring osseous structures; facial paralysis, indicating involvement of the fallopian canal; cervical adenitis; retro-pharyngeal abscess. A localized meningitis occurs in almost every case of acute suppurative otitis media in young persons. In conclusion he states that in all obscure diseases of children repeated and careful examinations of the ear should never be neglected, for the work of Ponfick, who made 100 autopsies upon infants dying of various acute and chronic diseases, wherein the majority of the cases middle-ear inflammation was not suspected, showed it present in all but nine. Ponfick believes the tympanum acts as an incubator and generator, promoting toxic symptoms in localized infective diseases. Pomroy, of Boston, has verified this observation. [A.B.C.]

**3.—Treatment of Acute Suppurative Otitis Media.**—Phillips believes that in acute middle-ear suppuration early and free drainage is of the utmost importance; patients should remain in bed until acute symptoms have passed; free purgation, preferably by calomel, should be had; microscopic examinations of pus should be made; local treatment should consist of cleanliness and free drainage; proper internal medication is indicated; prolonged attempts to abort suppuration of the mastoid cells are condemned; early operative interference in mastoid suppuration prevents more serious complications and gives far better hearing results; uncomplicated cases of acute suppuration of the middle ear, when properly treated, always recover in from two days to three weeks; the responsibility for preventive treatment must be largely assumed by the family practitioner. He should fully appreciate the importance of preventive treatment when caring for grip, the exanthems, or other infectious intranasal conditions, and also, the early and complete removal of diseased adenoid tissue. [A.B.C.]

**4.—Complications of Chronic Suppurative Otitis Media.**—Lewis considers the structures involved in the complications under three heads: those which relate to the parts primarily involved; those which involve still other auditory structures, as the petrous bone, auditory nerve, etc., and those involving structures not related to audition. Classed under the last are pachymeningitis, leptomeningitis, intracranial abscess, extradural and intradural; thrombosis of the sigmoid sinus with a probable pyemia, and diffuse metastatic abscesses with synovitis, gastroenteritis, hepatitis, etc. In this country 4,000 patients with brain-abscess of otitic origin, one in every 19,000 of population, annually die, while, according to Körner, the deathrate in Prussia from otitic brain-abscess is about three for each 20,000 of population. According to Pitt, the number of brain-abscesses which occur from otitic disease is 30% of the whole number. Barr estimates it as high as 50% of the whole number of abscesses of various origin. Pitt estimates that 5% of all cases of meningitis and two-thirds of all cases of sinus-phlebitis are of otitic origin. In brain-abscess the cavity is connected in 92% of the cases with the suppurating ear by a fistulous tract. In 95% of the cases there are multiple abscesses. In 6.6% of the cases the abscess lies within the brain and is separated from the source of the disease by normal brain tissue. [A.B.C.]

**5.—Treatment of Chronic Suppurative Otitis Media.**—McKernon considers only two methods—the dry, and the irrigation or wet treatment. The first prime requisite is cleanliness of the auditory canal and adjacent parts, find the opening in the ear-drum and enlarge it if necessary; determine at the first whether there is caries of the ossicles, and if so remove them. The essential features of the dry method, carried out under aseptic precautions, are: A fine powder is insufflated over the drum surface as well as the canal walls; zeroform, nosophen, boric acid, acetanilid, aristol and iodol have all been used with good results; after this, a small wick of gauze iodoform, borated or plain sterilized, is passed up and, if possible, into the perforation, and the canal is loosely filled to the meatus. The essential features in the irrigation treatment, now almost universally used, consist in syringing the ear with one of the following solutions: Bichlorid of mercury 1:4,000 to 1:8,000; boric acid, 20 grains to the ounce of boiled water; carbolic acid, 1% to 2%; a weak solution of formalin and a solution of potassium permanganate; normal saline solution or warm sterilized

water. If granulations are present they should be cocainized and removed by chemicals. The proper treatment of the many complications is given. [A.B.C.]

### Philadelphia Medical Journal.

January 17, 1903. [Vol. XI, No. 3.]

1. The Anatomopathologic Characteristic of Syphilis. J. RENAULT.
2. Two Cases of Perforation in Typhoid Fever, in One of Which An Operation was Performed. JAMES HENDRIE LLOYD and THOMAS LUTHER COLEY.
3. Two Erroneous Surgical Decisions in Intestinal Perforation from Typhoid Fever. JOHN B. ROBERTS.
4. A New Method of Hemoalkalimetry and a New Hemoalkalimeter. ARTHUR DARE.

**1.—The Anatomopathologic Characteristic of Syphilis.**—Renaut believes that syphilis, like tuberculosis and glanders, is caused by a living pathogenic agent. Consequently there is no reason to seek a lesion which essentially characterizes the disease, any more than in tuberculosis or glanders, as is the case, however, in diseases which are truly neoplastic. On the other hand, it is necessary to make out the general import of the lesions of syphilis. After much research he concludes that gummas have no anatomic individuality, that they are even less constant in structure than tuberculous granulations, which are certainly rarely alike; and there is no typical tumor characteristic of syphilis. He details at length arguments to prove that syphilis is an infectious disease, all the stages of which are characterized by an attack on the bloodvessels, affecting the intima of the arteries particularly. [F.C.H.]

**2.—Perforation in Typhoid Fever.**—Lloyd and Coley reports two cases of typhoid fever which presented examples of the difficulties of definitely determining the onset of perforation in the course of enteric fever. One patient was a butcher of 52. At autopsy a perforation one-eighth of an inch in diameter was found nine inches from the ileocecal valve. The other patient was a laborer of 36, upon whom an operation was performed about 12 hours subsequent to the time of suspected perforation. Four large perforations were found, and the abdominal cavity was filled with fecal accumulations. The perforations were closed, the abdomen thoroughly washed with normal salt solution, which was also used intravenously during the operation. Death ensued in 24 hours. [F.C.H.]

**3.—Two Erroneous Surgical Decisions in Intestinal Perforation from Typhoid Fever.**—Roberts details two cases in which a failure was made to diagnose perforation. After a study of cases of perforation in typhoid fever, he concludes as follows: The occurrence of pain and the increased rate of pulse and respiration are probably the most valuable early diagnostic symptoms of perforation; the count of leukocytes seems to have little value, unless it be hereafter proved that a count of the polymorphonuclear leukocytes has diagnostic significance; and a sudden fall in temperature is not a necessary accompaniment of perforation. [F.C.H.]

**4.—A New Method of Hemoalkalimetry and a New Hemoalkalimeter.**—Dare submits for consideration a new method of hemoalkalimetry, and describes an instrument devised expressly for this purpose. The reader is referred to the original article, as it does not well lend itself to valuable abstract. [F.C.H.]

### CLINICAL MEDICINE

DAVID RIESMAN

A. O. J. KELLY

#### REVIEW OF LITERATURE

**Abdominal Pain in Enteric Fever.**—Allyn<sup>1</sup> enumerates the various conditions which may give rise to abdominal pain in enteric fever, and says the abdominal causes, such as distended bladder, menstruation, abortion, and labor have nothing to do with the specific fever proper. The important causes are intestinal colic and distention of the bowel with gas; enterocolitis; deep ulceration, so that the serosa is involved; phlebitis of an abdominal vein; coincident appendicitis; ileus; peritonitis without rupture; cholecystitis and liver abscess; hemorrhage and perforation. Concerning a complicating appen-

<sup>1</sup> Medicine, November, 1902.

dicitis, he says McCrae and Mitchell report a case which was operated on and ended in recovery. There was no evidence that the appendicitis was due to a typhoid process. The only organisms obtained from the appendix were the bacillus subtilis and saprophytes. Fitz found that perforation was in the appendix in 3% of 167 cases; and one of Gairdner's 47 cases had a perforation in the appendix. Perforation of the appendix alone occurred in 3 of the 112 operative cases collected by Finney. In the 20 cases of perforation at the Johns Hopkins Hospital perforation of the appendix was found in 2, and Cushing reports another in a group of 9, which makes perforation of the appendix occur in 9.6% of cases showing perforation. [A.B.C.]

**Diseases of the Kidneys.**—Singer<sup>1</sup> reviews the literature and reports his observations upon the various symptoms seen in disease of the kidneys. He found soldiers, especially cavalrymen and others subject to great exertion, are prone to have hématuria which is caused by the rupture of the renal capillaries and disappears when the latter become healed. Hematuria after exertion may be the first symptom of developing nephritis. Such a hemorrhage has been given as a diagnostic symptom of stone and the patient operated on only to find that the hemorrhage was the result of a latent nephritis. Hence patients with hemorrhage from the kidneys should be watched for some time before resorting to a surgical operation. Singer believes that latent renal tuberculosis is frequently mistaken for nephralgia and treated as such. Many cases of obscure renal pain are tuberculous in origin. The author considers renal tuberculosis not a fatal condition and reports cases which had been positively diagnosed as tuberculosis and yet made a spontaneous recovery. A case of temporary albuminuria is reported in which the patient, with a chronically enlarged spleen, showed albumin only when lying on the left side. This was due to pressure on the renal veins. Temporary albuminuria may occur after exertion, as seen in students at military academies. Statistics are given which show that from 15% to 96% of foreign soldiers present albumin in their urine after a march. No symptoms of disease were ever seen to follow this form of albuminuria. Transitory albuminuria is seen in persons with healthy kidneys, but who may suffer either from a dilated stomach, pelvic tumors or enteritis. Febrile albuminuria is not due to fever, as was once thought, but is caused by the presence of microorganisms and their toxins. Nephritis may occur as a complication in acute infections, and of the latter scarlet fever and influenza are the most frequent. The prognosis of this form of nephritis is varied. Its most favorable course is its disappearance with the disease, or it may become chronic. It may change from a permanent to an intermittent albuminuria. Occasionally there remains a minimum amount of albumin with no influence on the general health. The cyclical albuminuria of adolescence occurs in young people of a neurotic temperament who are otherwise healthy. Constitutional anomalies during the developmental stage causes cyclical albuminuria. The prognosis of this form is most favorable. [W.E.R.]

**Modern Sewage Disposal.**—After biologic treatment sewage should be utilized for maintaining vegetation, but instead the final effluent is discharged into the nearest water-course, its main effect being to spread disease by means of oysters and other shellfish. It has a manurial value and its failure as a fertilizer, R. Caldwell<sup>2</sup> believes, has been due to its application to too small an area, the land becoming waterlogged. The typhoid bacilli, not destroyed completely by the biologic treatment in filter beds, die out rapidly in unsterilized cultivated soils. [H.M.]

**Pulmonary Gangrene.**—W. Ophülo<sup>3</sup> reports on five cases of pulmonary gangrene, from which he concludes that: 1. The disease is probably always due to mixed infection with pyogenic cocci and other bacteria of a more saprophytic nature. 2. Quite frequently the latter belong to the class of actinomycetes (including in this class all branching bacteria, like tubercle bacilli, diphtheria bacilli, etc.), and they may be more or less acid-proof. 3. The gangrenous process is always accompanied

by pneumonic processes, which in the more chronic cases usually appear in the form of a chronic catarrhal pneumonia with carnification. [C.S.D.]

**Bovine and Human Tuberculosis.**—Wolff<sup>1</sup> reviews the literature and reports his results in inoculating a calf with a culture of tubercle bacillus obtained from a case of human intestinal tuberculosis. The animal before inoculation was perfectly healthy. After injection two tuberculous reactions were obtained and all the typical symptoms of bovine tuberculosis developed. The calf died in 83 days, and the postmortem examination revealed large and small caseating tumors at the seat of inoculation and tuberculous foci in nearly all of the internal organs. Microscopically the tubercles presented structures very similar to those found in human tuberculosis. The tubercles at the seat of infection were calcified and caseated, while those in the more distant regions of the body were newly developed. This proved that the disease began from the area of inoculation and then spread throughout the body, and not from an accidental infection in some other part of the body. Wolff concludes that bovine tuberculosis is transmissible to the human body and *vice versa*. He believes the bovine tubercle bacillus is more virulent than the human variety, and advises that all milk should be thoroughly inspected to prevent the spread of tuberculosis. [W.E.R.]

**Asylums for the Insane.**—These should, C. Vintras<sup>2</sup> thinks, be gradually converted into sanatoriums. By giving a freer hand to those at the head personal initiative should be encouraged. Too much care cannot be taken in the selection of those continually with the mentally afflicted. Those active in mind rather than body make the best attendants. Active mental occupation as well as recreation should be provided for the patients. Prizes should be offered and attempts made to reopen their minds as one opens the mind of a child. [H.M.]

**Echinococcosis Cured by Injections of Sublimite.**—The use of injections of corrosive sublimate in the treatment of echinococcus cysts and spoken of as the Baccelli method appears to be meeting with success among Continental physicians. Three cases are reported, one of which, that of S. Cona<sup>3</sup> is particularly interesting; what at first appeared to be a case of pulmonary tuberculosis was finally diagnosed from shreds, etc., ejected in the course of severe attacks, to be an echinococcus cyst of the superior lobe of the right lung. This, like the cases of echinococcus cysts of the liver reported by Carlo Berruti and by E. de Magistris, was treated and cured by emptying the cyst by aspiration and then injecting 20 cc. of a 1% solution of corrosive sublimate. A bibliography of reports on the successful use of this method is given by Cona. [C.S.D.]

**Hemorrhage in Enteric Fever.**—Curtin<sup>4</sup> calls attention to the rarity of hemorrhage in children with enteric fever, and discusses the etiology, pathology, diagnosis, and treatment of this complication. Dangerous conditions when associated with hemorrhage are: Renal disease, organic heart disease, hemophilia, tympanitic distention of the abdomen, obstinate diarrhea, and vomiting. He advocates the usual medicinal treatment and gives favorable mention to ergot and suprarenal extract, especially if in cases in which the hemorrhage is an oozing from the mucous membrane. The author states that since the application of cold to the body surface was introduced in treatment the number of hemorrhagic cases has considerably increased, according to hospital records that furnish the data. This is attributed to congestion of the internal viscera, and consequent increased vessel-tension, caused by the wellknown fact that application of cold to the body surface causes the blood to seek the internal organs. [A.B.C.]

**The Relation of the Thymus Gland to Marasmus.**—Stokes, Rührhah, and Rohrer,<sup>5</sup> from a careful study of the question, conclude that atrophy of the thymus gland is always found in cases of infantile atrophy; that the condition of the thymus gland is an index of the general nutrition in infants; and that the state of nutrition of infants may be estimated by a microscopic examination of the thymus at autopsy. [A.O.J.K.]

**Transposition of the Viscera.**—Arnell<sup>1</sup> reports five cases of congenital transposition and one case of acquired transposition of the viscera, and discusses the theories advanced to account for the conditions. [A.O.J.K.]

**Pulmonary Edema and Fibrinous Bronchitis Following Thoracentesis.**—A woman of 43 was tapped by Magenau<sup>2</sup> for a left-sided pleural effusion. Within a few hours a violent cough started, and she expectorated a great deal of thin sputum. Cardiac oppression and sensations as of impending death were present. These symptoms lasted several days. In the sputum were noticed a number of fibrinous bronchial casts. Gradual recovery resulted. Cases of edema of the lungs combined with fibrinous bronchitis after a thoracentesis are very rarely seen. The fibrinous bronchitis is believed to be inflammatory, and the pulmonary edema has usually been ascribed to an osmosis through the walls of the pulmonary vessels, the result of trophic injuries from long continued pressure of the exudate, the whole being assisted by cardiac complications. Magenau believes the whole process is inflammatory instead of more or less mechanical, and considers the fibrinous bronchitis a more intense stage of inflammation than the simple edema. [E.L.]

**Atonic Motor Insufficiency and Dilatation of the Stomach.**—Saundby,<sup>3</sup> from a careful study of the question, states that atonic dilatation of the stomach is a common condition; that it occurs about twice as often in women as in men, and most frequently between the ages of 20 and 50 years; that it is ten times more common than dilatation from obstruction, which generally occurs after 30 years of age. It is caused by neurasthenia or by any prolonged debilitating illness which may set up neurasthenia. There are no characteristic symptoms and no correspondence between the amount of dilatation and the severity of the symptoms. The diagnosis in the great majority of cases can be made by distending the stomach with CO<sub>2</sub> evolved from 120 grains of sodium bicarbonate and 90 grains of tartaric or citric acid. The prognosis does not depend upon the extent of the dilatation, but rather upon the duration of the symptoms, the general health of the patient, and the effect of treatment. The treatment must be mainly that of neurasthenia, supplemented by the use of such drugs and diet as may be indicated by complications, such as gastritis. Gastroenterostomy often fails to relieve these cases. [A.O.J.K.]

**Congenital Acholous Chronic Icterus.**—Widal and Ravant<sup>4</sup> report the case. The symptoms, occurring in a man of 29, had existed for years. The liver and spleen are at times increased slightly in size, returning to almost their normal size after an exacerbation of the symptoms. The pulse was slow, and the plantar, patellar and pharyngeal reflexes were abolished, the achilles and cremasteric reflexes lessened. These seemed to be the only symptoms resulting from this long biliary intoxication. The general health was perfect, and there was no dyspeptic symptom. Five cases presenting symptoms in common with the one described were cited from the literature. In certain cases it may be due to a congenital deficiency of the hepatic cells, calling forth an increase in bile formation by "Diabete biliare," which ends perhaps by awakening a susceptibility in the biliary passages to infection. [J.H.W.R.]

**Cerebral Syphilis of Vaccinal Origin with Acute Basilar Meningitis.**—Porot<sup>5</sup> gives in detail the history of this case, the patient being a man of 23. He presented the typical symptoms of syphilitic basilar meningitis, the diagnosis of syphilis being corroborated by the presence on the body of numerous pigmented, cicatricial syphilides. There was no history of venereal disease, but the patient stated that the scars came from a series of ulcerations that followed vaccination five months before when he entered the army. The physician who vaccinated him and his comrades used the same lancet for all and charged it with vaccine from a plate. The symptoms and history and appearance of the man are thought to fully justify diagnosis of vaccinal syphilis. The patient rapidly improved under mercurial treatment. [A.G.E.]

**The Treatment of Pleurisy with Effusion.**—Delafield<sup>1</sup> advocates the treatment of pleurisy with effusion by aspiration alone, and not by medicine, and he tabulates the results of his treatment of 200 patients in support of the soundness of his contention. The fluid taken from the chest was bloody in 25 cases, turbid in 18 cases, and clear serum in the remainder. Of the 200 patients, 182 left the hospital entirely cured; 6 left the hospital within 10 days after the aspiration and probably recovered; 6 left the hospital at periods of from 17 to 36 days after the aspiration, the pleurisy was better but the results were uncertain; and 6 left the hospital at the end of from 24 to 38 days not at all improved. In more than one-half of the cases the duration of the pleurisy before aspiration was from 10 to 30 days. The length of time that elapsed from the aspiration to the entire cure of the patient was as follows: Within one week 64 cases, within two weeks 138 cases, within three weeks 158 cases, within four weeks 179 cases, and within six weeks 179 cases. The aspiration was done once in 142 cases, twice in 45 cases, three times in 9 cases, and four times in 4 cases. In private practice the results are better than in the hospital. In the fortunate cases, within 24 hours after one aspiration there is no more fluid and no more pleurisy. In a large number of cases the pleurisy is cured within a week, and no patient ought to be sick more than two weeks. [A.O.J.K.]

**Barlow's Disease.**—Hutinel<sup>2</sup> reports three new cases in infants from 11 months to 2½ years of age, fed on sterilized milk and prepared farinaceous food. They suffered violent pain and functional weakness of the legs. The treatment, consisting of fresh milk, lemon juice, and meat juice, resulted in the rapid disappearance of the symptoms. Ausset<sup>3</sup> observed a case of Barlow's disease in an infant 11 months of age, fed on boiled cows' milk and soups. He concludes that sterilized milk and prepared farinaceous foods are not the only food capable of causing Barlow's disease. He believes that this disease is only a complication of rickets—a sort of "septicemic hemorrhagique" of intestinal origin. Marfan<sup>4</sup> reports three cases of Barlow's disease, and concludes that sterilized milk is not the only cause of this disease. [J.H.W.R.]

**The Action of Chalybeate Mineral Waters in Chlorosis and Anemia.**—Wybauw<sup>5</sup> has made a careful study of this question, and gives notes of 15 cases of anemia and chlorosis, some slight, others profound. He reaches the following conclusions: (1) Carbonated iron waters (type of spa) have a certain therapeutic action in doses that would be inefficacious if the iron contained was given in a pharmaceutical preparation; (2) this efficacy is probably due to the fact the iron is held in solution in a very unstable form; (3) the effect of the waters is persistent—in patients who remain too short a time at the springs to be cured it is noted that good results are afterward obtained from preparations of iron hitherto not efficacious; (4) these waters cause constipation in but few cases, on the contrary the constipation due to anemia frequently disappears under their use; (5) external methods of treatment, as hydrotherapy, carbonic acid baths, etc., have a favorable action in raising the state of nutrition, but used alone will not cure anemia. [A.G.E.]

**Gastrointestinal Disturbances in Arteriosclerosis.**—Neusser<sup>4</sup> discusses those diseases of the heart and arteries in which the circulatory symptoms are pushed into the background, the symptoms of which the patient complains pointing to a disease of the gastrointestinal tract, and often leading to such diagnoses as gastric ulcer, catarrh, dilatation, splachnoptosis, etc. He reports a case of aortic regurgitation and atheroma of the aorta which for five years had been treated as chronic gastritis, the patient getting worse and worse; another which, because of slight jaundice and other symptoms, had been called cholelithiasis. The patient died suddenly, and the autopsy showed aortic insufficiency and stenosis of the coronary arteries, but no gallstones. Sclerosis of the abdominal aorta or any of its branches may produce the same symptoms, and mistakes in diagnosis have been made a number of times. He mentions the case of a woman who, on account of paroxysmal

<sup>1</sup> American Journal of the Medical Sciences, 1902, ii, 885.

<sup>4</sup> Wiener klin. Woch., September 18, 1902.

pain and constipation over a period of four years, had been thought to be suffering from chronic obstruction. An operation did not produce any improvement, and the autopsy revealed an occlusion of the mesenteric arteries as the result of sclerosis. The pain in such cases is explained on the theory of the pain of intermittent claudication: an insufficient amount of blood being supplied to the intestines by the sclerosed branch. [E.L.]

**Rheumatic Myocarditis.**—Fisher<sup>1</sup> reports two cases in which alterations of the myocardium were attributed to the rheumatic poison. In the first case, fatal cardiac failure associated with well marked signs of rheumatism occurred, and at the necropsy the cause of the cardiac failure was found to be fatty degeneration of the heart which, it is believed, may fairly be attributed to the rheumatism. In the second case the appearance clinically was that of chronic disease of the mitral valve, but after death the heart was found to be greatly dilated, and the mitral valve, though thickened, presented no lesion that could account for death. Fibroid disease and fatty degeneration of the myocardium, however, were present, and these, it is believed, were probably produced by the rheumatism. [A.O.J.K.]

**Prevention of Diphtheria Infection.**—A. Griffith<sup>2</sup> believes that while prophylactic doses of antitoxin are very useful in preventing the development of diphtheria in persons exposed to infection, they do not diminish the risk to others associating with them. The only way to prevent the disease spreading is to keep away from those who have been exposed, and who have bacilli in their throats, whether clinically ill or not. In mixtures of Behring's serum and sterile broth, one to eight, cultures multiply freely. It is difficult to think that the small amount injected can affect bacilli directly. It simply renders the recipient immune. Patients nursed at home seem to lose their infectiousness sooner than others, because they are truly isolated, and yet complete isolation and antiseptics locally applied often produce no effect. The ideal method is to swab all contacts and isolate them until free of bacilli. On account of the work involved, this is often impossible and the best we can do is to exclude them from school for a certain time. [H.M.]

**Increased Weight of Infants Immediately Preceding Death.**—Audebert<sup>3</sup> considers at length the pathogenesis of the increase in weight of some infants during the days immediately preceding death, and cites cases as examples. In one the increase was 350 gm. (11½ oz.) in five days; in another 400 gm. (13½ oz.) in 10 days; in still another 200 gm. (6½ oz.) in 20 hours. Experiments with ingesta and excreta lead to the conclusion that in certain morbid conditions, as tuberculosis and bronchopneumonia, the excreta, particularly the products of respiratory action, are considerably diminished. This will result in increase of weight even though alimentation be below the mean. Another important cause is visceral hyperplasia, evidenced mainly in bronchopneumonia. [A.G.E.]

**Thermic Fever.**—Lewis and Packard<sup>4</sup> give the details of the treatment of 92 cases of thermic fever treated at the Pennsylvania Hospital in the summer of 1901. The total mortality was 14.4% (13 cases), but no patient with a temperature less than 106° F. on admission died, and no patient with a temperature over 111° F. recovered. Convulsions, usually severe, were present in 14 cases. The treatment of the (32) mild cases (100° to 102° F.) consisted of rest in a cool portion of the ward, the application of an ice-cap, the administration of the aromatic spirit of ammonia, or alcohol, or strychnin, and occasionally a cool bath. The treatment of the (22) severe cases consisted of the administration of stimulants, as they were required by the state of the pulse, the application of an ice-cap, and either a cold bath or, in the more obstinate cases, the employment of rubbing with ice until the temperature approached the normal. In addition to the foregoing some of the extremely severe cases were subjected to bleeding (8 to 10 ounces), hypodermoclysis, and intravenous transfusion of normal saline solution—with good results. Abstracts of some of the case histories are given.

A valuable review of the study and treatment of heatstroke at the Pennsylvania Hospital and elsewhere is given by Spellissy in the same journal, page 485. [A.O.J.K.]

**Fallacies of the Copper Reduction Test for Sugar.**—F. D. Boyd<sup>1</sup> deals with substances apart from glucose and which may have no pathologic significance and yet will produce copper reduction. Glycuronic compounds are found in apparent health; after administration of drugs of the aromatic series; in infectious conditions such as typhoid, general sepsis, tonsillitis, etc. A urine containing these compounds will, however, not undergo fermentation with yeast. HCl and orcin or phloroglucin produces a brilliant red passing to reddish-blue, followed by a blue-green precipitate, which alcohol dissolves, giving a greenish-blue color. Urine containing glycuronic acid is levorotatory. Kreatinin produces a green color. Uric acid, unless present in excessive amount, does not cause any appreciable reduction. Alkaptonuria is of importance only from its liability to be mistaken for glycosuria. It may occur in constipation with decomposition of tyrosin in the intestine. Pyrocatechin causes a green color, hydrochinon a deep brown. No reduction of copper is likely to occur, except in the presence of glucose, if the observation be carried out at a temperature below the boiling point. The urine and copper solution should be boiled separately, the test-tubes then removed from the flame, and after 30 seconds poured together, and no reduction will occur from the less active bodies. [H.M.]

**Hemophilia and Life Insurance.**—Whitridge<sup>2</sup> gives in detail the history of a hemophilic, a man who died at the age of 25 from exsanguination. He stated that from a life insurance standpoint, hemophilia is not an important disease. The mortality records of the Maryland Life Insurance Company, which has been in existence for 37 years, show no death diagnosed as due to hemophilia, and only one in the purpuric class—purpura hæmorrhagica. The importance to medical examiners of anemia, as a sequel of hemophilia and of other diseases, is emphasized. [A.G.E.]

**Hidden Aortic Aneurysm.**—Schroetter,<sup>3</sup> while making a routine physical examination of a patient with an abscess of the nasal septum, had his attention drawn to a peculiar dilation, thickening and tortuosity of both carotid arteries. The patient did not complain of any symptoms pointing to the circulatory system, and an examination of the heart and arteries revealed no lesions. A Röntgen picture of the thorax showed a large aneurysm at the beginning of the descending aorta. No symptoms nor signs such as we would be likely to expect to find in the early stages of aneurysm were present. The only additional factor was found on examination of the larynx; the left vocal cord was slightly less mobile than the right, but this was only discovered after the recognition of the aneurysm. [E.L.]

**Gigantism.**—Meige<sup>4</sup> claims that gigantism and akromegaly are closely related to each other, and probably have a common etiology. Both conditions exhibit, besides enlargement of the skeleton, a great similarity in other symptoms, such as sexual torpor or impotence, muscular asthenia, polyuria, ocular defects, etc. In recent years autopsies have been performed on giants, and have disclosed frequently lesions of the pituitary body, which lesions are usually regarded as having an etiologic relation to akromegaly. Gigantism is a condition which develops during youth and adolescence, while akromegaly is a disease of adult life. Both conditions are due to an excess of the osteogenetic function. If the abnormal process occurs during youth, while the epiphyses of the bones are still in a cartilaginous state, the increase in size takes place in the length of the bones and gigantism results. But if this same abnormal process acts after the epiphyses have become ossified, the growth occurs in the breadth and thickness of the bones, producing the physical features of akromegaly. The identity of the two conditions is also supported by the facts that giants frequently develop signs of akromegaly in adult life, and that the two diseases may coexist if the pathologic process is brought into play at the time of adolescence. C. A. ORR

## EDITORIAL COMMENT

**The Surgery of Tuberculous Cavities of the Lung.**

—A reviewer in the *Centralblatt für Chirurgie*, December 20, 1902, speaks of the recent article by Willard<sup>1</sup> as a very thorough piece of work in lung surgery, giving the results of a large personal experience and experimentation on animals with a rich collection of references to the literature arranged in tabular form. We believe the reader of Willard's article will find it worthy of this flattering commendation. In the chairman's address before the section on Surgery and Anatomy of the American Medical Association is collected in concise form nearly all of our present information about the surgery of tuberculous cavities in the apex of the lung, together with the results of extensive experimentation. Willard is led to believe from his studies that with improvement in operative technic pneumonotomy will become a practical operation which will be specially helpful in the early period of cavity formation. He recognizes, however, the very important fact that many of these cases are successfully treated by hygienic and general methods and for this reason it is frequently very difficult to obtain the consent of the patients to operation. Advanced cases are not well suited for operation, for there is usually streptococcus infection and the cavities are frequently multiple. Operation may be employed in such cases, however, as palliative to cough, hemoptysis and sepsis. Abscess of the lower lobes of the lung following pneumonia or pleurisy, whether tuberculous or not, should be treated by incision and drainage at any stage. Willard believes that in the future tuberculous foci will be eradicated in the same way as tuberculosis of the joints and other tissues is now successfully removed. One of the great difficulties which stands in the way of the realization of this prediction is difficulty in diagnosis. The most careful physical examination, even if accompanied by use of the x-rays, frequently fails to accurately locate the focus of disease and until this can be done operation cannot be safely undertaken. Whitacre's recent thorough studies of autopsy material at the Cincinnati Hospital also show the frequency with which multiple abscesses are met which would preclude successful operation in the majority of such cases. However, if the diagnosis can be successfully made there seems to be no reason why Willard's sanguine predictions should not be fulfilled. He finds experimentally that the most important step in successful operation is the production of firm adhesions between the parietal and visceral pleura. This prevents the danger of pneumothorax during the operation and permits the safe excision of tuberculous foci. Willard was able to bring about such adhesions by suture of a rectangular area to the chest wall through the intercostal spaces. In this way he was able to cut out a piece of lung, the remaining portion of lung retaining its function. To avoid possible danger of pneumothorax during operation he advises that a Fell-O'Dwyer artificial respiration apparatus with a jar of oxygen be at hand during operation. While the number of patients that will be saved by intervention, such as Willard recommends, is no doubt small, it is only by such careful study of the conditions for operation that the field for intervention would be further extended and future advances will be made.

## REVIEW OF LITERATURE

**Excision of the Esophagus for Carcinoma.**—Faure<sup>2</sup> reports operative removal of carcinoma of the esophagus 11 cm. in length, involving that portion just above the level of the

bifurcation of the trachea. Resection of the ribs near the vertebral insertion was necessary. The operation, he states, was not specially difficult, but the patient died the day following without evidence of hemorrhage, shock, or pulmonary complications to account for death. [M.B.T.]

**Acute Mastoiditis and the Question of Trephining.**—Bliss<sup>1</sup> states the wonder is that infection is not more frequently carried to the cranial cavity from an acute infection of the mastoid, since the anatomic relationship is very intimate. In all instances the roof of the middle ear cavity is very thin, and in some instances a bony roof does not exist; the petrosquamous sutures never close in some instances, and the mastoid vein empties into the lateral sinus. A number of cases illustrating the danger and variation in symptoms of acute mastoiditis are reported. Unfortunately the question of when to operate can not be answered dogmatically; these indications for operation are given by the author: First, steady, persistent pain over the mastoid process at the region of the antrum—more important still if it extend along the lateral sinus toward the base of the skull; second, edema; third, the patient's temperature, a steeplelike rise and fall especially indicating danger. The other symptoms, as vertigo, nausea, vomiting, double vision, mental dulness, etc., may be present. Early treatment of acute otitis media often prevents mastoiditis; its onset should be treated by douching the external auditory canal with a very warm boracic solution, and the application of dry heat. [A.B.C.]

**Intestinal Occlusion Complicating Intrapertitoneal Hematocele.**—G. Jacquet<sup>2</sup> reports nine observations of this complication of hematocele, and draws the following conclusions: Intestinal occlusion is a possible complication of hematocele. Whenever the physician is confronted with the phenomena of intestinal occlusion, he must think of the possibility of a hematocele; when the latter affection is recognized, he should remember the accidents which it may cause in the intestinal tract. Obstruction may result from three causes: 1. Compression of the intestine by a fetal mass or a lithopedion. 2. Compression rapidly following an enormous extravasation of blood. 3. Slow obstruction by the formation of cicatricial bands resulting from the organization of a clot or from the inflammatory reaction of peritonitis. Surgical intervention is absolutely indicated. The incision should be made through the abdominal wall, in order to liberate the intestine whenever the symptoms indicate the inclusion of a portion of the intestine in the walls of the pouch. [L.F.A.]

**Paracentesis of the Tympanic Membrane in the Treatment of Acute Otitis.**—Grunert<sup>3</sup> disagrees with Piffil, who says that in acute otitis media the drum should never be perforated, or if possible, should be prevented from rupturing, as this delays improvement, and makes the prognosis more unfavorable. He agrees with him that cases in which perforation does not occur, or paracentesis does not have to be done, heal quicker than others, but insists that paracentesis is necessary in cases meeting Schwartz's indications, and that if they are disregarded until complications arise, the prognosis will certainly be very grave unless spontaneous rupture occurs rapidly. Piffil's statement that he had to perform paracentesis only 10 times in 482 cases of acute middle-ear disease, is insufficient, as he does not inform us how often the tympanic membrane ruptured spontaneously. [E.L.]

**Separation of Urine by Compression of the Ureteral Orifices.**—Rochet and Pellanda<sup>4</sup> claim that any method of partitioning the bladder is faulty and not reliable. Their instrument is based on the constancy of the anatomic relations of the trigone of the bladder. The instrument consists of two parts, a tunneled metal portion resembling a lithotrite, and a thin rubber tube carried in one compartment of the metal tube. The instrument is introduced into the bladder and the blades separated, which results in exposure of the rubber tube. Air is then forced into this tube which balloons and compresses the ureteral orifice of the side to which it is applied and stops the flow of urine. The secretion of the opposite side passes out through the tunneled portion of the instrument. A separate

<sup>1</sup> International Clinics, Vol. III, Twelfth Series.<sup>2</sup> Journal of the American Medical Association, 1902, Vol. xxxix, p. 665.<sup>3</sup> La Semaine Médicale, 1902, Vol. xxii, p. 423.<sup>4</sup> Lyon Médical, Vol. xciv, No. 41, p. 511, 1902.<sup>5</sup> Münchener medizinische Wochenschrift, October 28, 1902.<sup>6</sup> Gazette heb. de Médecine et de Chirurgie, December 14, 1902.

instrument is required for each ureter. Very satisfactory results are obtained. Detailed cases will soon be published. [A.G.E.]

**Perforating Gastric Ulcer ; Celiotomy ; Recovery.**—Barnet and Turner<sup>1</sup> report the case of a woman of 34 who had suffered for some time from attacks of indigestion. She was suddenly taken with violent pain in the abdomen, nausea and collapse. Pain was relieved by morphin, but recurred and was accompanied by uncontrollable vomiting. The physical signs of beginning peritonitis were present. The patient was removed to the hospital, a distance of 1½ miles, and prepared for immediate operation. On opening the abdomen perforated ulcer in the stomach was found, from which gastric contents were pouring. The ulcer was closed with three Lembert sutures, the peritoneal cavity was flushed with sterile water and the abdomen closed. Uneventful recovery followed. [M.B.T.]

**Congenital Cystic Kidney with Pararenal Hematoma in a Syphilitic.**—Fels<sup>2</sup> reports the case of a sailor, whose illness began as acute gastroenteritis, which was shortly followed by pain in the region of the kidney and spleen where a large, hard, round mass could be detected; it extended upward to the diaphragm and was not tender. The urine was normal in amount and contained small quantities of albumin and sugar, but no organic sediment. The patient was markedly anemic and cachectic, but a blood examination showed nothing but a parallel running diminution of red blood-corpuscles and hemoglobin. The leukocytes were slightly increased. Regarding the diagnosis no decision was reached. The following conditions were considered possible: Tumor of kidney; tumor of spleen as a result of an atypical leukemia; splenic tumor as a result of chronic malaria. The autopsy revealed a very extensive, encapsulated, pararenal hematoma of the left kidney; partial deficiency of left kidney with parenchymatous nephritis of remaining portions, and cystic degeneration of capsule. Congenital cystic kidney in right side, syphilitic splenitis, hepatitis, and aortitis. A careful microscopic description of spleen, kidneys, and liver is given, which brands the case as unique in pathology. He refers to a number of cases described by others and which bear some similarity to his. [E.L.]

**Pneumococcus Arthritis with General Infection.**—Siredey<sup>3</sup> reports the case of a girl of 14 who developed suppurative arthritis of a metacarpophalangeal joint during the course of a right-sided pneumonia. She was taken with intense abdominal pain for which the abdomen was explored, but the cause of the trouble was not found. The patient died on the fifth day after entrance to the hospital, and the necropsy showed no peritoneal lesion to account for the abdominal pain, but a diaphragmatic pleurisy on the same side as the pneumonia. The pneumococcus was grown from the blood in this case. [M.B.T.]

**Separation of the Urine from the Two Kidneys.**—Luys<sup>4</sup> describes his perfected instrument, the original having two faults. One was that the rubber partition was too long, causing pain; the other was that of a possible mixture of the urines which could be avoided only by pressing the bladder wall against the instrument by means of a finger introduced into the rectum. These objections have been overcome. The instrument consists essentially of two metallic catheters grooved on their inner surfaces to hold an intermediate metallic tube that contains a chain covered by a thin rubber hood. The three parts are united and passed into the bladder. Tightening the chain causes it to subtend the curve of the instrument like the cord of an arc, thus drawing up with it the rubber which forms a partition. The claims made for the instrument are simplicity, efficacy, and ease of manipulation. [A.G.E.]

**Acute Osteomyelitis During Childhood.**—Gonser<sup>5</sup> makes an extensive report of 32 cases of osteomyelitis, the greater number of which he had been able to reexamine at different periods after operation. The following are his conclusions: 60% are males, 40% females; 69% occur during the

first decade, 31% during the second. The greater number occur during the winter months; bacteriologic examinations were made in 15 cases; in 10 of these the bacterium present was *Staphylococcus pyogenes aureus*; other bacteria found were *Staphylococcus pyogenes albus*, streptococcus, typhoid bacillus, and diplococcus lanceolatus. As exciting causes in his cases he enumerates furuncles, traumatism without external lesions, skin wounds, varicella, pneumonia, angina, typhoid fever, and empyema. In four instances a recurrence was noted. The amount of shortening was very slight in nearly all the cases, not sufficient to produce any discomfort. [E.L.]

**Operation for Chronic Gastric Ulcer.**—Mansell Moullin<sup>1</sup> believes that when ulcer of the stomach has become chronic it is hardly ever cured in the full sense of the term. The older the ulcer becomes the less the chance of healing and the greater the liability to complications. Moullin has operated in 13 cases of this kind, not counting perforations. In many of the patients the loss of blood had been extreme. In six transfusion was performed on the table or immediately afterward. Two patients in desperate condition died. The others recovered without bad symptoms. He believes that if the two patients who died had been operated upon before so much blood was lost they would have probably recovered, and if ulcers of the stomach were operated upon as soon as recognized, before they have become chronic, there would be fewer deaths from hematemesis, perforations, and such later troubles as pyloric stenosis, hour-glass contraction, pain and dyspepsia from adhesions, perigastric and subphrenic abscesses, and dilation of the stomach would become far more rare than at present. [M.B.T.]

**A Case of Artificial Anus with Peculiar Etiology and Rare Localization.**—Speiser<sup>2</sup> relates the case of a woman in whom recurrence of a vaginal carcinoma occurred in the inguinal and pelvic lymph glands. One of the inguinal glands on the left side suppurred, requiring incision; other smaller abscesses existed in the neighborhood of the left obturator foramen. The latter opened into the rectum and also burrowed forward into the inguinal wound, thus producing an artificial anus, which beginning at the upper part of the rectum, passed beneath the horizontal portion of the pubic bone, through the obturator foramen, and terminated in the inguinal abscess. [E.L.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### REVIEW OF LITERATURE

**A Case of Uterine Rupture Intrapartum Cured Without Operation.**—Mendel<sup>3</sup> reports the case of a multipara whose uterus during the birth of the seventh child (partly decomposed) was torn from cervix to fundus. A coil of intestine prolapsed and came in contact with the dirty bed clothes; the putrid placenta was removed from among coils of intestine. The intestines were cleansed and replaced, the uterus and vagina tamponed with iodoform gauze and ice applied locally. The woman did not present a single bad symptom after the shock; the gauze was removed on the sixth day, and she left her bed on the fourteenth day. She was delivered of a living child several times after successfully. [E.L.]

**Operative Treatment for Puerperal Pyemia.**—Sippel<sup>4</sup> wishes to correct his earlier opinion that puerperal pyemia, with rare exceptions, ends fatally. Not a small number of patients recover spontaneously. These are those in which there are no disturbing symptoms during the first few days of the puerperium, in which the uterus has shown good involution, and in which early chills are not virulent and the general condition is negative. In such cases the thrombic mass shows no tendency to spread and the chills soon cease. In other cases the long continued and repeated chills are followed by high fever and complicated by alarming appearances. The involu-

<sup>3</sup> Deutsche medizinische Wochenschrift, November 6, 1902.

<sup>4</sup> Centralblatt für Gynäkologie, December 13, 1902.

tion of the uterus is checked; in the ligaments thickened veins can be felt and albuminuria sets in. This indicates a virulent thrombus and without relief must soon cause death. When the abdomen is opened the surgeon can judge by inspection whether the resection of a vein will suffice, or whether the walls of the uterus being engorged its removal is necessary. During the operation it is recommended to irrigate the infected region with normal warm saline solution. This irrigation preserves the epithelium of the peritoneum completely, so that its natural protective power against infection remains unimpaired. Sippel expresses his faith that Trendelenburg's hope will be realized that not only the chronic but also the acute form of puerperal pyemia can be successfully combated through properly timed operative treatment. [w.k.]

**Spasmodic Contraction of the Os as an Obstruction to Delivery.**—Durlacher<sup>1</sup> reports what he considers an unusual case in which delivery was prevented by a spasmodic closing of the os during the labor pains. Between the pains the os seemed soft and distensible, but at each pain there occurred a ringformed spasmodic closure. Hence the use of forceps became necessary, and gentle traction could be employed only during the intervals between the pains, yet in 20 minutes the living child was delivered. This condition seemed entirely different from a rigid os, and the writer thinks would eventually result in rupture of the lower uterine segment without instrumental delivery. Mechanical aid appears to be the only effective therapy in such instances. [w.k.]

**An Apparatus for the Application of Local Cold in the Genital Tract.**—Stroynowski<sup>1</sup> describes an apparatus which he has devised to supersede the icebag for the relief of pain in the pelvic organs. It consists of two lead tubes which open into a metallic knob flattened on two sides. One tube is for the inflow and the other for the outflow of the icewater, and both are covered with rubber to protect the vagina from the cold, while the knob is adjusted to the painful or inflamed organ, thus relieving pain or reducing inflammation. The writer says it is not to be denied that this instrument could be used in the beginning of tubal pregnancy to produce tubal abortion. By this simple local process the patient would escape the danger of an operation. [w.k.]

**A Case of Primary Carcinoma of the Tube.**—According to Graefe,<sup>2</sup> Orthmann reported the first sure case of primary tubal carcinoma, in 1888. Subsequently Zangemeister published a table of 52 cases, but in 14 years few more have been added to this list. In comparison with ovarian and uterine cancer the tubal is exceedingly rare. Graefe adds another to the list. When he first saw the patient he found an enlarged retroflexed uterus, a sausage-like tubal tumor the size of an orange, and a small mucous polyp hanging from the external os. The diagnosis was hydrosalpinx and pyosalpinx, and because of the blood-colored watery discharge the possibility of a tubal cancer was recognized. For this reason celiotomy was advised, but refused. Hydrastis was employed and a large Meyer's ring introduced, under which treatment the discharge ceased and the patient's general condition was much improved. When Graefe saw her two years later, for three months she had been suffering a yellowish discharge and severe abdominal pains. The tubal tumor seemed unchanged, the uterus was smaller, and just below it was a movable tumor the size of a child's head. She now consented to an operation and a right-sided, intraligamentous ovarian cyst was removed, also the left-sided tubal sac. Her convalescence was undisturbed, and eight months after operation she was in good condition. The tubal sac was opened and emptied of a pure serous fluid, and situated on its thin walls a tumor the size of a chestnut was found, which the microscope showed to be a papillary carcinoma. This case is an evidence of the long time that a carcinoma may remain in a tube in a benign form. The writer suggests two causes for its slow growth—the pressure of the Meyer's ring upon the tubal sac and the complete closure of the uterine ostium of the tube with the cessation of the usual discharge. At the time of the operation there were nowhere any signs of metastasis. [w.k.]

**Atrophy of the Uterine Mucosa.**—R. Volk<sup>1</sup> reports the case of a woman suffering from what was variously diagnosed as a sixth-month pregnancy and as tumor but which proved to be the latter. At operation a myoma was found situated upon the anterior wall of the uterus which was removed and the patient recovered. The interesting feature of the case was the complete atrophy of the mucous membrane of the uterus. The development of an intramural myoma generally causes hyperemia of the mucosa which bleeds very freely. The opposite was the result in this instance. As the patient had had scarlatina in childhood and her menses had been very irregular and very slight, only continuing one day, Volk was in doubt whether to ascribe the atrophy to the scarlatina or to the presence of the myoma. [w.k.]

**Hemorrhage During the Later Months of Pregnancy and Early Stages of Labor.**—Jardine<sup>2</sup> states that the marginal variety of placenta prævia in which only a small portion is below Bandl's ring and bleeding is not great occurs more frequently than is supposed. Palliative measures to stop hemorrhage should be tried if the fetus is not viable. Rest, opiates, and laxatives are indicated. If the fetus is viable and the hemorrhage severe, the cervix and vagina should be plugged. When the cervix is sufficiently dilated a leg should be brought down and gentle traction continued. In these cases the head should never be dragged through the undilated os; a torn cervix with placenta prævia is sure to cause excessive hemorrhage, with probable death. When the os is fully dilated, delivery should be effected at once by version or forceps, stripping off the placenta so far as one can reach before turning. After delivery the placenta should be removed at once. Ergotin should be administered and the uterus grasped between one hand in the posterior fornix and the other on the abdomen. In accidental hemorrhage the plug may be used with safety if uterine contractions are fairly strong; if there are no contractions the danger of converting an external into an internal hemorrhage is great. If postpartum hemorrhage continues after trial of the usual remedies, Jardine recommends injection of suprarenal extract into the uterus, or using a plug wrung out of it. [H.M.]

**Vaginal Cesarean Section.**—Bumm<sup>3</sup> describes 13 cases of this operation with one death which occurred three hours after the operation in case of eclamptic coma. The eight cases which came to the hospital in an aseptic condition recovered without fever. Fever occurred in four cases, one after removal of a fetid cancer, two were cases of eclampsia and one of nephritis. While at first cervical carcinoma was the most frequent cause for vaginal cesarean section, Bumm thinks it should now be used in many cases of eclampsia, he having been brought by a year's experience of different methods to the opinion that in cases of eclampsia delivery should follow the first attack and that the vaginal method is simpler and less dangerous than the classic cesarean section, and in his opinion is much more certain and exact than the use of the metallic dilators now in vogue. In one case this method was used on account of severe hemorrhage from a deep-seated placenta. He deems it advisable also when a torpid uterus reacts very badly, or not at all, in response to any irritant or stimulant such as manipulation or introduction of instruments so liable to cause infection. He advises early operation so as to preserve the fetus intact and uninjured. [w.k.]

**Primiparas Under 16 Years.**—Palotai,<sup>3</sup> from a review of the literature on this subject and the statistics of 24 cases, reaches the following conclusions regarding the labor and delivery of primiparas under 16 years of age: The course of pregnancy is normal, rarely interrupted by abortion; more frequently by premature delivery; the labor is of short duration and mild in character; the necessity for surgical interference is not to be feared; the prognosis in regard to injuries of the birth canal during delivery is very good; the puerperium does not differ from the normal, and there is the best prognosis for the child. He believes that nature takes care when conception becomes possible that the consequences usually run their course without special hindrance. [w.k.]

## TREATMENT

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPLEMAN

To *Editor of American Medicine*:—I have used the vapor of carbolic acid in the treatment of pulmonary tuberculosis of the lung in a way that I have never seen in print. I use a lamp that burns kerosene and has a chimney about 2½ inches long. Just above the top of the chimney is a small metal basin which will hold about 1 ounce. Light your lamp at bedtime. Fill the basin with carbolic acid and you have a treatment that works while you sleep. The kerosene and acid will last till morning. The acid does not boil but gently fumes. It is not unpleasant to the taste and smell. Cough is relieved; the breathing is fuller and freer; the general condition soon begins to improve. A man aged 29 is now using it with marked improvement in every respect. He is compelled to sleep in same room with his wife and three children. I believe it is a great help to them also as a preventive. I have never seen any bad effects from its use. I used it with my children when they had whooping-cough. It did good.

C. C. HUBBARD, M.D.,  
Worthville, N. C.

[We publish the above without endorsement or condemnation. The method is not new, and while decidedly useful in whooping-cough, needs more care than the letter of our correspondent would imply. In pulmonary tuberculosis it ranks among the number of more or less useful palliatives and has no curative value.]

## REVIEW OF LITERATURE

**Kephyr.**—Henry Duprat<sup>1</sup> has made a complete study of kephyr and recommends it as a substitute for milk in cases in which no other food can be taken. Kephyr is an acidulated beverage made from cow's milk or from goat's milk by a process of special fermentation with irregular yellowish grains composed of yeast fungi and bacteria. There are three varieties of kephyr, depending on the degree of fermentation. Kephyr No. 1, obtained after 24 hours, has a slight laxative action; it contains 0.6% of alcohol; No. 2 is fermented for two days; it has the disadvantage of sometimes causing diarrhea and must then be replaced by kephyr No. 3, which is slightly constipating and contains about 0.9% of alcohol. Kephyr No. 2 is employed ordinarily. It should be given in small doses at first, half a glass the first day, increased gradually until two or three quarts are taken in 24 hours. It is employed in cases of general feebleness, muscular and nervous asthenia, severe gastroenteritis of children, in gastric cancer and dyspepsia due to deficient secretion of hydrochloric acid and in various intestinal disorders. It should be swallowed slowly in order to avoid the too sudden formation of carbonic acid in the stomach. [L.F.A.]

**Diuretic Value of Agurin.**—DeBuck<sup>2</sup> reports his trials of agurin, which is the double salt of theobromin and sodium acetate. It has the advantage over the older theobromin preparations that it is less likely to disturb the stomach. He asserts for it that it not only increases the quantity of urine but that it also favors the elimination of solids, and that acetyl radical by oxidation in the system renders the organic exchanges more active. In cases of diminution of urine from fever or from weakness the drug is very helpful. He also found it useful in dropsy of cardiac origin, especially when combined with heart tonics, as digitalis. In cases, however, in which there is degeneration of the renal epithelium the drug has little power. It is best given in solution, in peppermint water for example, in doses of 0.25 to 0.5 gm. (4 to 8 grs.) daily. [H.C.W.]

**Cigar Ashes in Insect Bites.**<sup>3</sup>—It has been advised to use cigar ashes in the treatment of insect bites in the place of ammonia, which is not always at hand. The ashes are moistened with water and placed on the bitten area. The potassium carbonate found in the ash is believed to counteract the acid which is secreted by the insect and deposited in the wound. [W.E.R.]

**Canceroin in the Treatment of Cancer.**—R. Dalla Vedova<sup>1</sup> reviews a paper by Adamkiewicz entitled "New Successes of Canceroin in Cancer of the Tongue, the Larynx, the Esophagus, the Stomach, and the Breast," and then proceeds to relate the subsequent history of two of the cases as reported by Eiselberg and by Kohn, one of which was operated upon, the other dying of cancerous degeneration. Testimony as to canceroin is cited from Poten and Schultz-Schultzenotein, and the conclusion is reached that there has been an excessive and precipitate enthusiasm for an agent which is entirely without value in the cure of cancer. [C.S.D.]

**Treatment of Painful Reflex Anuria by Epidural Injections of Cocain.**—Bergouignan<sup>2</sup> reports the case of a woman suffering from locomotor ataxia, who presented the following urinary symptoms: Night and day she complained of a frequent desire to urinate, coincident with severe painful crises localized in the lower part of the abdomen, and comparable to a sensation of torsion or constriction. During these crises there was a very painful emission of a few drops of urine. Not more than eight ounces of urine was passed in 24 hours. There was no history of locomotor ataxia in her family. Her illness began four years previously by disturbances in gait, soon followed by girdle and vesical pains with vomiting. The urinary symptoms continued without interruption since the beginning of the disease, and combined with the gastric crises rendered existence intolerable. No treatment which she had received lessened the vesical pains or increased the amount of urine voided. The injection of 15 minims of a 2% solution of cocain into the spinal canal was followed by immediate relief; the pain decreased gradually and disappeared in 10 minutes. In the evening the patient had a desire to urinate, but was unable to do so. The following morning, however, she urinated abundantly without pain. The next morning the vesical pains returned, although very slightly, and disappeared during the afternoon. Because of a slight return of her symptoms, a second injection of 20 minims of a 2% solution of cocain was given three days after the first. During the days following, micturition became more and more easy, the patient passing about two quarts daily. Nine days after the last injection she was discharged cured. Six months later the vesical crises returned. An injection of 15 minims of the same solution was followed by complete relief. Bergouignan employed this treatment in many such cases with excellent results. [L.F.A.]

**A Prophylactic Against Nephritis in Scarlet Fever.**—Tobeitz<sup>4</sup> advises turpentine oil in scarlet fever to prevent the development of nephritis. This complication is seen in 5% of all cases of scarlet fever, but after this treatment it was found in only three out of 136 cases. Tobeitz prescribes 12-25 drops of this oil in a day. [W.E.R.]

**Ichthyol in Tuberculosis.**—Williams<sup>5</sup> reports favorably on the use of ichthyol in tuberculosis. He quotes the statement of Zuelzer that it lessens the nitrogenous elimination and increases the body weight. He has employed it in 600 cases, and believes it the most useful drug we have in the treatment of this disease. It has a great advantage over creasote in that it does not disturb the stomach; indeed, it seems rather to improve the condition of the digestive tract. After its use the cough becomes easier and expectoration thinner. He believes it has a valuable action as an expectorant. He employed it with favorable results in tuberculous ulcers and caries of bone. He first cures as thoroughly as possible and packs with gauze saturated with pure ichthyol. Recently he has employed a suspension of ichthyol with orthoform, with very favorable results. In laryngeal tuberculosis he employs a 10% spray. Ichthyol is preferably administered in capsules, beginning with .6 cc. (10 minims), and increasing up to 2 or 2.5 cc. (30 or 40 minims) three times a day. Its greatest drawback is its unpleasant taste, which sometimes persists for a long time. Recently he has employed a tasteless preparation known as ichthoform, with equally good results. [H.C.W.]

**Changes in the Medical Corps of the U. S. Army for the week ended January 17, 1903:**

HOFF, Lieutenant-colonel JOHN VAN R., deputy surgeon-general, leave granted for seven days is extended twenty-three days.

CAMPBELL, GEORGE F., hospital steward, is relieved from further duty at the Army and Navy General Hospital, Hot Springs, Ark., and will proceed to Fort D. A. Russell to relieve Hospital Steward Henry Bunker. Steward Bunker will proceed to Manila, P. I., for assignment to duty.

AYER, IRA, contract surgeon, is granted leave for two months to begin and end in Manila, and with permission to visit Japan.

BLOOMBERG, First Lieutenant HORACE D., assistant surgeon, is granted leave for one month to take effect upon his being relieved from duty at the U. S. General Hospital, Fort Bayard.

HESS, First Lieutenant LOUIS T., assistant surgeon, will proceed to Legaspi, Albay, for duty.

ADAIR, Lieutenant-colonel GEORGE W., deputy surgeon-general, will proceed to Zamboanga, Island of Mindanao, reporting to the commanding general, department of Mindanao, for assignment to duty as chief surgeon of that department.

CORBUSIER, HAROLD D., contract surgeon, is granted leave for ten days, from about January 31.

KIRKPATRICK, Captain THOMAS J., assistant surgeon, is granted leave for one month, to take effect upon his relief from duty at Fort Barrancas.

MAXWELL, SAMUEL A., contract surgeon, is relieved from duty at Fort Grant and will proceed to San Francisco, Cal., and report for transportation to the Philippine Islands, where he will report for assignment to duty.

DAYWALT, GEORGE W., contract surgeon, now in Washington, D. C., will proceed to Fort Schuyler for duty, to relieve First Lieutenant Theodore C. Lyster, assistant surgeon, who will proceed to West Point, N. Y., and report to the superintendent of the U. S. Military Academy for duty.

WOOD, HALSEY L., contract surgeon, is relieved from further duty on the transport Warren, and will proceed to Vancouver Barracks for duty.

TURRILL, Lieutenant-colonel HENRY S., deputy surgeon-general, now in temporary charge of the medical supply depot in New York City, will assume permanent charge of that depot.

The following-named officers, now at San Francisco, Cal., will proceed to their respective homes, where they are authorized to await their honorable discharge, February 1, 1903: Majors Robert Burns, Frederic A. Washburn, Jr., R. H. Zauer, Frederic Hadra, Abram L. Haines, H. A. Grube, surgeons, U. S. Volunteers; Captains Fred M. Barney, W. Turner Wooton, Herman J. Schlageter, Thomas K. Mullins, John Gilbert, Clark I. Wertensbaker, Herbert Gunn, Gerry S. Driver, Edwin M. Trook, James F. Presnell, Harry A. Littlefield, Charles G. Elcher, T. C. Longino, William T. Tanner, Frederic A. W. Conn, Leonard K. Graves, Edward A. Romig, James B. Pascoe, Francis J. Bailey, assistant surgeons, U. S. Volunteers.

So much of orders of December 5 as relate to the discharge of Captain Perceval S. Rossiter, assistant surgeon, U. S. Volunteers, is amended so as to honorably discharge Captain Rossiter January 14, 1903, upon tender of his resignation.

The following-named contract surgeons are relieved from duty in the department of California, and will report for transportation to the Philippine Islands, where they will report for assignment to duty: William G. Gregory, Alwin M. Guitard, John F. Leeper, James R. Mount.

HALL, HENRY M., contract surgeon, now at Cedartown, is relieved from further duty as transport surgeon on the transport McClellan, and upon the expiration of his present leave will proceed to the Philippine Islands for duty.

**Changes in the Medical Corps of the U. S. Navy for the week ended January 17, 1903:**

HAAS, H. H., passed assistant surgeon, ordered home via Prairie—January 9.

PAGE, J. E., passed assistant surgeon, detached from the Newark and ordered to the Montgomery—January 9.

BENTON, F. L., passed assistant surgeon, detached from duty with recruiting party, ordered to Washington, for assignment with battalion of marines, leaving for the Philippines—January 10.

TAYLOR, R. L., KEENE, W. P., MCCORD, D. P., and JANNEY, W. H., appointed acting assistant surgeons for three years' service—January 10.

CRAWFORD, C. A., passed assistant surgeon, resignation accepted to take effect January 12, 1903—January 12.

CHAPMAN, R. B., JUDD, H. W., MILLER, J. T., and CAMPBELL, R. A., appointed acting assistant surgeons for three years' service—January 12.

MCCORD, D. P., acting assistant surgeon, ordered to Lansing, Mich. for duty with recruiting party—January 12.

TAYLOR, R. L., acting assistant surgeon, ordered to Ogden, Utah, for duty with recruiting party—January 12.

BUCHER, W. H., passed assistant surgeon, detached from Naval Hospital, Norfolk, Va., and ordered to the Naval Hospital, Pensacola, Fla.—January 13.

GORDON, F. T., pharmacist, ordered to the Naval Dispensary, Washington, D. C., for duty—January 14.

LEDBETTER, R. E., assistant surgeon, detached from the Illinois and ordered to the Newark—January 14.

**Changes in the Public Health and Marine-Hospital Service for the week ended January 15, 1903:**

WHITE, J. H., assistant surgeon-general, to proceed to Brunswick, Ga., for special temporary duty—January 13, 1903.

CARTER, H. R., surgeon, leave of absence for three days under paragraph 179 of the regulations amended so that it shall be for two days only.

GUITERAS, G. M., passed assistant surgeon, to report to chairman of board of examiners at Washington, D. C., January 15, 1903, for examination to determine his fitness for promotion to the grade of surgeon—January 13, 1903.

OAKLEY, J. H., passed assistant surgeon, granted leave of absence for two days from January 21—January 13, 1903.

LAVINDER, C. H., passed assistant surgeon, granted leave of absence for one month from January 23—January 13, 1903.

DUKE, B. F., acting assistant surgeon, granted leave of absence for ten days from January 4—January 7, 1903.

WALKLEY, W. S., acting assistant surgeon, granted leave of absence for five days from January 13—January 16, 1903.

PUBLISHED WEEKLY AT 1321 WALNUT STREET, PHILADELPHIA, BY THE AMERICAN-MEDICINE PUBLISHING COMPANY

VOL. V, No. 5.

JANUARY 31, 1903.

\$5.00 YEARLY.

The increased mortality from pneumonia has often been alluded to in our columns, but we fear the fact has not arrested the attention either of the public or of the profession as it should. In the latest issue of the Bulletin of the Chicago Health Department are figures that are really startling. Our crusade against pulmonary tuberculosis seems almost a mockery if the death-rate from pneumonia rises while that from tuberculosis falls. In the last two years the deaths from pneumonia have been one-eighth of all, one-third more than from pulmonary tuberculosis, and 46% more than from all other contagious and infectious diseases combined. During the first 17 days of January, 1903, more than one-fifth of all deaths were due to pneumonia. The deaths from tuberculosis in Chicago in 1860 were 25.28 per 10,000 (276 deaths in 109,206 population). In 1900 they were 15.30 per 10,000 (2,599 deaths in 1,698,575 population), a decrease of nearly 40% (39.1) of tuberculosis mortality in the 40 years. From pneumonia the 48 deaths in 1860 represent a rate of 4.40 per 10,000 of the population; in 1900 the 3,389 deaths represent a rate of 19.95 per 10,000, an increase of more than 350% (353.4) of pneumonia mortality. The whole country shows a decrease of 20.7% of deaths from tuberculosis and an increase of 7.4% of deaths from pneumonia during the 40 years.

**Ignoring the New Until the Quacks Force it Upon Our Attention.**—An eminently sound and conscientious practitioner tried in vain for 20 years or more to arouse the profession to a sense of the value of massage and mechanical therapeutics in the treatment of certain diseases. At last he gave up in despair. It was not just then fashionable. Editors would not accept his articles, and the lazy-minded, the exploiters of the popular opinion, beguiled themselves with the old-fashioned sneer at the “hobbies of hobby-riders”—and the world went on in its blind way. Then came the osteopaths and the biceps-worshippers of the cheap magazines, and what the profession would not listen to from its own members was, willy nilly, forced upon the attention by the quack. It is true that other regulars and scientists prior to the quack knew all and far more than he of the value of massage, but like so much other knowledge, it was not realized in daily practise by the leaders and by the masses of the profes-

sion. It required the compulsion of ignorant popular enthusiasm to make us actually treat our patients by these methods and to put into use the partial veritable truth turned into an untruth by the extremism and indiscrimination of the charlatan. But why need we carry out, generation after generation, this stupid belittling and ignoring of the new truth? There are many such illustrations as the one we have cited, of our strange indifference to methods of treatment, 10, 20, or 30 years after demonstration has been made of their efficacy and value. Let us keep our minds open and flexible!

**The county jail, says *Charities*,** at least in New Jersey, “as a school for crime is a great success. As a place for punishment, it is an absolute failure. As a part of the State’s correctional program, it is a lamentable farce.” In only one jail of the State is employment afforded. In the entire State, except eight “probation officers,” there are no public reformatory influences for girls and women. Continual recommitment, of course, plunges the poor creatures into deeper degradation. “Feeble-minded girls come again and again to the almshouse to give birth to feeble-minded children.” “The prosecutor of Middlesex characterizes its jail as notoriously insecure, filled with filth, vermin, and disease-germs.” The enforced idleness (the inmates are not even required to wash themselves), the mixture of young and old offenders, etc., add to the horror of this medieval barbarism persisting in supposed civilization. To make reform impossible the larger the number of prisoners the greater the profits of the 21 sheriffs of the State, who make each year a clear profit from board of prisoners amounting from \$30,000 to \$60,000.

**The Henry Phipps Institute for the Study, Treatment, and Prevention of Tuberculosis.**—Dr. Lawrence F. Flick has at our request kindly furnished us with an epitome of the plans of the institution, from which we learn that it is to be devoted exclusively to the work of exterminating tuberculosis. Prevention will be the ultimate object of all that is done in the institution, which will be planned and operated with this aim foremost in mind. The institute will consist of pavilions with a capacity of 100 beds, well equipped laboratories, facilities for hydrotherapeutic and prototherapeutic work, and of such other accessories as may be

necessary. There will be a dispensary wherein treatment and aid will be given to the consumptive poor who are unable to stop work or who cannot gain admission to some institution. The pavilions will be built with balconies and a roof garden so that patients may be kept in the open air as much as possible, and the wards and balconies will be so constructed that every bed can be run out on a balcony. The beds will be used exclusively for patients in advanced stages of the disease, the object being to take them out of their homes and thus prevent the spread of the disease. The house patients will furnish the clinical material for scientific research in the laboratories and in the various departments. Facilities will be given for testing all new methods of treatment having a scientific basis. The dispensary work will be modeled upon the Emile Roux dispensary, at Lille, under the management of Dr. A. Calmette. Patients will be treated both at the dispensary and, when too far advanced to come to the dispensary, at their homes. Medicine and food will be supplied them when necessary, as also disinfectants, spit-cups, and paper napkins. They will be taught the use of these things, and they will be kept under supervision so as to carry out proper preventive measures. Printed instructions will be furnished in order to prevent the spread of the disease and an effort will be made to enforce the rules which are laid down. A literary bureau will be established through which information about the work in tuberculosis throughout the American Continent will be gathered, and from which information may be sent out to all who desire it. An effort to stimulate activity in the crusade against tuberculosis will be made through this bureau, and aid will be extended in efforts at organization wherever such aid is called for. If the growth of the work will justify it a magazine will be published devoted to the cause. The holding of conferences and congresses upon the subject of tuberculosis for the purpose of stimulating thought and action will be encouraged and patronized. The staff of the institute will be gradually formed as necessity arises and will be composed of young men who desire to devote themselves to the study and prevention of tuberculosis. With a view of bringing clinical and laboratory work as closely together as possible only men will be appointed to the staff who are trained in both clinical and laboratory work. As ultimately equipped the staff will consist of four clinical chiefs—a surgical chief, a laryngological chief, a dermatological chief, and a neurological chief—each of these with the requisite assistants. The four clinical chiefs will preside over the wards and the dispensary, and the others will have charge of special work and will be given opportunity for special study. The plan here briefly outlined may have to be modified by practical experience, but gives in a general way what is contemplated. A temporary place will be secured and work will be inaugurated in this temporary home during the time that the permanent establishment will be planned and erected. It is expected that this time will be about one year.

**The King's Sanatorium for Consumptives.**—King Edward, it will be remembered, offered three

prizes for the best essays upon and plans for a sanatorium for tuberculous patients. The prizes were \$2,500, \$1,000 and \$500. The first was awarded by the advisory committee to Dr. Arthur Latham with the assistance of the architect, Mr. A. William West. Dr. Latham's paper is an admirable extension of his own motto: "Give him air; he'll straight be well."

Dr. Latham is only in his thirty-fifth year, and besides carrying on a practice at Brook street is an assistant physician at St. George's Hospital and at the Brompton Hospital for Consumption. He is the son of Dr. Latham, professor of medicine at Cambridge. To Hermann Brehmer Dr. Latham gives the honor of having founded the system now to be developed. According to Dr. Latham the essential principles to be observed are a life spent in the open air under conditions which give immunity from tuberculosis; complete freedom from any debilitating circumstances which may lead to an exacerbation of the disease; methodical hill-climbing as an exercise in certain cases; an abundant dietary, in which milk, fatty food and vegetables occupy an important place; constant and unremitting medical supervision. Dust is to be avoided, infected material to be destroyed, a pure atmosphere secured, and indoor amusements and life rigorously discouraged.

Billiards, cards, etc., should be forbidden. In the early stages of the disease pulmonary rest is to be secured by bodily rest, but this must not be allowed to drift into laziness, nor must the other extreme of over-exertion be allowed. Each bedroom, in Dr. Latham's plan, is to be 10 feet high, 12 feet broad and 14 feet deep. Immediately opposite the door is a square projection 7 feet long by 4 feet deep, enclosed by windows looking east, west and south, and any or all of these may be open according to the direction of the wind, so that the patient may lie at ease in fresh air without a draft. If it costs too much to give each room its own three-sided projection, two may be combined, but each room in that case would lose one of its three aspects. The first prize essay, it is understood, was regarded as containing the most practicable plans; the second was approved because it provided for a recreation-room at the top of the building, which in summer could be turned into a roof garden; the third was noteworthy by reason of the comfortable design and appointments of the patients' rooms.

A combination of the three plans should provide a model sanatorium, and as the results of the experiment are to be carefully observed by scientific men, the model may, in course of time, be followed in the erection of similar institutions elsewhere.

**Pneumonia a Contagious Disease.**—We wonder if the fact that patients and their friends ignore the contagiousness of pneumonia is often due to professional negligence. An exaggerated conception of the contagiousness of tuberculosis is held by the lay world, but pneumonia is, of course, far more contagious. And patients and profession alike have not realized the new fact that the mortality of pneumonia is in some cities and parts of the country higher than that of tuberculosis. Dr. Reynolds, of Chicago, returns to this les-

son and emphasizes the necessity of the following measures :

Pneumonia is a highly contagious disease, the cause of which is a microorganism in the sputa of those suffering from the malady, and contracted by inhaling this germ. Therefore, the same care should be taken to collect and destroy the sputa that is taken in pulmonary tuberculosis, or in diphtheria or influenza.

During the illness the greatest pains should be taken to prevent soiling bed-clothing, carpets or furniture with the sputa, and after the illness the patient's room should be thoroughly cleansed and ventilated.

The fact that the disease is most prevalent in the winter season, when people are most crowded together and live much of the time in badly ventilated apartments, makes obvious the necessity of thorough ventilation of houses, offices, factories, theaters, churches, passenger cars and other public places, in order that the air which must be breathed may be kept clean and free from infectious matter.

Laymen should be taught not to be afraid of a patient who has pneumonia, influenza or tuberculosis, but to be afraid of lack of cleanliness about him during his illness, of failure to enforce prophylactic measures and of close, badly-ventilated apartments during the season when these diseases most prevail.

Since pneumonia is most fatal at the extremes of life—the young and the aged—special care should be taken to guard children and old persons against exposure to the infection of those already suffering with the disease and against cold, privation and exposure to the weather, which are potent, predisposing causes.

#### The Coal Famine and Increased Mortality.—

From all parts of the country come reports of the increase of sickness and death due to the scarcity and expensiveness of coal. The hospitals in eastern cities are overfilled because patients are unable to get coal at home, and are thus forced into the hospitals. In Chicago the condition is summarized by the Department of Health as follows :

Fully 10%, or nearly 200,000 residents of Chicago, are today suffering from ailments of a grave character caused by privation and exposure resulting from the coal famine. Already these ailments are reflected in the enormous increase of deaths among those at the extremes of life—the young and the aged, in both of whom the powers of vital resistance are at the lowest. Since the first of the year there has been an increase of nearly 20% (19.2) in the number of deaths among those under 5 years of age over the number in the corresponding period of last year, when this deathrate was about normal. Among those over 60 years of age the increase is much greater—24% last week over the week previous, and 36.7% over the normal rate of the corresponding period of 1902.

This excess of increased deathrate among the aged is caused chiefly by the effects of cold and exposure in hastening to a fatal termination many of the chronic diseases, the sufferers from which under ordinary conditions might have survived for many years.

When at last it shall be legally determined who is responsible for this crime against the community, against its very health and life, the punishment should be mercilessly meted out.

**What is Osteopathy?**—This question is asked by the editor of an osteopathic journal in order to answer it himself. In doing so he finds that it is in part the bloodless operation for hip-joint disease, and that the Lorenz method was done by Still long before Lorenz thought of it, and done much better than Lorenz ever did it, much

quicker, without plaster casts, etc. It is also the method of doing away with ametropia and the need of glasses by giving "a proper blood-supply," etc. Osteopathy, in a word, is a "non-drug and non-operative school of medicine and surgery." But later the editor assures that the microbe theory is "unreasonable and insufficient" because microbes "thrive and grow best only after osteopathic causes have weakened cell-life and the resistance of the tissues." There is but one conclusion to be drawn from this lucid illucidity—that osteopathy both cures and causes (or causes and cures, we are not sure which) the "disturbance in the nutrition of cell-life" which constitutes disease. This remarkable use or misuse of language, however, is the natural product of the mental state which devised the word osteopathy and its more strange definition, as "the mechanical removal of disease causes by manipulative treatment." We had already such words as the following with well-understood meanings and etymologically derived :

*Hydrotherapy* : The treatment of disease by means of water.

*Homeopathy* : The treatment of disease by drugs that produce like symptoms.

*Allopathy* : The treatment of disease by drugs that produce opposite symptoms.

It goes without saying that *osteopathy* can mean only the treatment of disease by bones, *i. e.*, by the application or administration of bones. Such being the case it follows that not Still but Samson was the founder of osteopathy, as osteopathically and accurately set forth in Judges xv, 15, 16, 17.

**The adoration of the biceps** is the newest and most successful of the modern physiologic idolatries. If one will examine the things for sale at a popular and cheap news stand, he will only begin to realize the extent of the new cult. Then let him buy a dozen copies of the cheap magazines, and sit down to a careful statistical tabulation of the "ads" and the amount of money spent by the biceps worshipers; it will soon be evident that Mother Mary Mason Baker Glover Patterson Eddy has a rival to be reckoned with, and a rival who does not believe that muscles are immaterial. Systems and sects of the muscles, indeed, have their own distinct magazines, and hundreds of typewriters are at work sending copies of "form-letters" to far away adherents who devotedly believe in the individual treatment of their particular case. From a letter lying or lying (we are not certain as to the orthographic form of the word) before us, we extract the following excerpt. It was addressed to a highly educated physician by a man without education, physiological or medical :

"I will give you an appetite and a strong stomach to take care of it; a digestive system that will fill your veins with rich blood; a strong heart that will regulate circulation and improve assimilation; a pair of lungs that will purify your blood; a liver that will work as nature designed it should; a set of nerves that will keep you up to the standard of physical and mental energy."

All this is to be supplied in half-a-dozen lessons "by mail, \$10.00 in advance." It is not very bad, this new form of religion. It is surely superior to the elder

worship of the navel by the ancients and orientals. Discriminating patients, however, are wearying of it, and turn with relief to the new specialists in genuine medicine, who are rapidly establishing themselves in practice; and who, being trained in physiology and pathology, adapt physical exercises to the always peculiar needs and diseases of the individual patient. The form-letter of the typewriter is not the best way to practise medicine.

**Drug adulteration** is a peculiarly infamous bit of scoundrelism of which both the medical and pharmaceutical professions should make an end. Whatever may have been the ultimate motives and whoever may be blame-worthy, the recent examinations of 373 samples of one drug obtained from different stores in New York City, of which 315 were found adulterated, reveal a condition of the drug trade that is startling. Is it possible, one is compelled to ask, that but a small percentage of all drugs are pure? If so "therapeutic nihilism" has an unexpected and most sufficient ground for being. How many of the "failures of the patients to react," how many deaths, have been due to the odious adulteration scamps? Again appears the great need of a united and organized profession which would have mind and power to blacklist and thus kill out the dishonest dealers or manufacturers who traffic in human disease and death. If it is easy for a health board to test and demonstrate the adulterated drug after it has been bought from the retailer, it is just as easy for the pharmacist to do so with his own drugs before he sells them. There are many honest druggists who do so, and from whom no impure articles can be obtained. It is our duty as medical men to support them and to aid them in their struggle against the negligent and the criminal who are the common enemies of both the well and of the sick.

**The Crime of Encouraging the Professional Beggar.**—A few years ago there was unearthed in a European city a manufactory of cripples. For years children had been maimed in every diabolic way that would not bring death, in order to produce the most ghastly objects possible, to be used for the purpose of exciting the pity of the criminal almsgiver. The police in our cities are, to-day, expert in not seeing the professional beggar, and if forced to "run him in" they allow him to return at once. It is only by carrying out the laws against mendicancy that foolish selfish people can be taught the folly of their selfishness, and can be shown how the Society for Organizing Charity can bring relief to the deserving poor. Only thus also can the society expose such atrocities as that of Charles Berkowitz, who has often been in the police courts of New York for 20 years. This man had accumulated a beggars' fortune. According to his own story told the magistrate he was brought to this country from Russia by his parents when he was 13 years old, and was sent out by them on the streets to beg. He said that his parents told him to look at the sun, as this would give his eyes the appearance of being blind. Constant looking at the sun, so he declared, had made him totally blind.

## EDITORIAL ECHOES

**Another Politician's Blunder.**—It is very clear, also, that if Governor Odell had not made his raid upon the State prisons and hospitals, but had left them in the excellent condition in which they had been placed by preceding legislatures and governors, his reelection would not have been doubtful for a moment. His bill repealing former laws which have been the work of experts and disinterested men and women, who were moved by the single desire and purpose to improve the lot of the most unfortunate class in the community, stirred into personal opposition to him an influential class, mostly of his own party. These persons assumed that the object he had in view was to make political spoils of the offices and minor places in these institutions. When he paraded a long list of accusations of extravagance and inefficiency against the boards of managers of these institutions as a reason for abolishing the system, it was found that every charge in the list was either destitute of foundation or was applicable to a state of things long antecedent to the system which he was attacking. These proceedings made him an object of suspicion.—[*N. Y. Evening Post.*]

**Vapor and Verbiage.**—Some student of morbid psychology should set himself the task of making an exposition of the present American mania for haziness of thought and emotion, concealed under an equally nebulous verbosity. So frightful in extent and passion is this furious intoxication that its bombast and nonsense should not allow us to forget that the drunken orgy must be well paid for. There are thousands of people and hundreds of books and periodicals devoted to the awful art of self-deception by means of diseased introspection and self-consciousness, coupled with an amazing pouring forth of meaningless, grammarless, and magniloquent words. It is also startling to notice how such rubbish is finding its way into periodicals whose editors at last find themselves incapable of longer resistance. Take as an instance several articles in a recent number of the *Medicolegal Journal*. One comes upon whole pages in reading which he wonders if the crazy phantasmagoria of fantastic images and words could have any meaning even to the writers. Philologists will also notice that there is the same soaring away from accepted custom and law in the use of words, as there is in every other department of thought. *Illapse, mesmerizee, menticulture, erythismic, curtained* (of an actor called before the curtain), *spiritualization of the physical*, and hundreds of such terms, the seeming products of hashish dreams, or of the katzenjammer that follows them, meet us in these strange writings. We ask in all seriousness if much of this is not in reality the result of cocaineomania or some other form of drug-drunkenness. Some minds do not act in this way. An article in the latest issue of the *Review of Reviews* on "The New Thought," or "The New Metaphysical Movement," tells us about "circles of silent unity," "mental science temples," "divine scientists," etc. But in all this jargon of the wild-eyed we find that antimedicine and antiscience is, as they would write, "the energizing principle." Mr. Tyner says that "their one aim and teaching is healing—not simply the curing of physical disorders, but that larger gospel of health that includes the comforting of the afflicted and the binding up of the broken-hearted." One of these "mesmerizees," who signs himself Dr., and who describes his doings with his patients, says "by the method of subliminal presentation" he "elevates himself above the plane of the material and the transient and becomes insensible to accusation and insult, immune to the toxin of resentment." The fact is beyond disputing as regards either himself or thousands of other "new physicians" and "new metaphysicians."—[*Cleveland Medical Journal.*]

## AMERICAN NEWS AND NOTES.

## GENERAL.

**Yellow Fever.**—It is asserted that yellow fever has made its annual appearance at Vera Cruz, Mexico. Five deaths, including two Germans, have been reported, and there are a number of cases under treatment.

**Charter for Tuberculosis Congress.**—It is announced that a charter covering a period of 20 years has been granted the American Congress of Tuberculosis. The object of the organization is to study the best methods for the treating of tuberculosis and all pulmonary diseases.

**Disease Among School Children.**—According to Dr. Kingsman, the medical member of the school board in Washington, D. C., fully 50% of the children attending schools in the southwestern section of the city are sick with either measles, whoopingcough, or chicken-pox. The doctor states that although the trouble has continued now for some time the disease has heretofore been confined to the younger pupils, but now the students in the high schools are affected to some extent. The advisability of establishing a quarantine to protect the community from children so affected is being considered.

**Drink in the Army.**—The Secretary of War has transmitted to Congress the reports of post commanders and other army officers on the effects of closing the canteen. [See *American Medicine*, Vol. IV, No. 23, p. 880.] In accordance with these reports the Adjutant-General makes the following recommendation: "The restoration of the exchange as it existed prior to the passage of the act of February 2, 1901, prohibiting the sale of beer, is desired and urged by the great majority of officers and men, and by none more than those of pronounced temperance views. Numerous reports confirm the views long held by this office that the old exchange contributed to sobriety, health and contentment of the men. The increase of desertions and of trials for infractions of discipline is, by those best informed, attributed to the abolition of the former privileges of the exchange."

**Hospital Benefactions.**—PHILADELPHIA: The Presbyterian Hospital has received a gift of \$30,000 for the erection of a maternity house from an unknown friend.—Under the will of the late Moses Reinhard an estate of \$46,000 is bequeathed to the Northern Trust Company as trustee to pay certain annuities and use the balance of the income to establish a room in the Home for Aged and Infirm Israelites of the Jewish Hospital, to be known as the "Michael and Martha Reinhard Room." If this gift shall be accepted, \$15,000 will be paid upon expiration of annuities. If not accepted, the income is to go to the Federation of Jewish Charities and the hospital will receive \$10,000. Among other bequests, subject to annuities, are the Jewish Foster Home, \$10,000; Jewish Maternity Association, for a free bed, \$3,000.—The late Hannah W. Gadsden, of Philadelphia, bequeathed \$5,000 to the Episcopal Hospital. COLUMBIA, PA.: The heirs of the late Henry Houston, of this city, have given \$5,000 to the Columbia Hospital for the endowment of a bed to be known as the "Henry H. Houston Memorial." ALBANY, N. Y.: The late William J. Weaver bequeathed \$5,000 each to Albany Hospital, Child's Hospital, Home for Aged Men, St. Peter's Hospital, and \$2,000 each to Home for the Friendless and the Homeopathic Hospital. GLOUCESTER, MASS.: Under the will of the late George R. Bradford, of this city, the Addison Gilbert Hospital receives \$10,000 for the purpose of maintaining a free bed for indigent persons.

**Miscellaneous.**—PHILADELPHIA: Dr. Simon Flexner, professor of pathology at the University of Pennsylvania, has received a grant from the Carnegie Institution, and his assistant, Dr. Noguchi, has been appointed the first research assistant.—W. B. Saunders & Company, of Philadelphia, have opened offices in New York City, placing them in charge of Dr. Reed B. Granger, for many years connected with the *New York Medical Journal*, and another representative who is thoroughly familiar with the methods of the Philadelphia house.—EPISCOPAL HOSPITAL: On account of the resignation of Dr. D. D. Stewart there is a vacancy on the medical staff of this hospital.—COLLEGE OF PHYSICIANS AND SURGEONS: Andrew Carnegie has offered \$50,000 for the maintenance of a library, conditioned upon the college raising \$50,000 more. Of this second \$50,000 F. W. Vanderbilt has given \$10,000, and Clement A. Griscom \$5,000. CHICAGO: Dr. Frank Billings has been elected president of the Cook County Hospital staff, and Dr. L. Blake Baldwin has been appointed secretary.—Dr. George W. Webster has been elected president of the Illinois State Board of Health.—Dr. W. B. Wherry, associate in bacteriology at the University of Chicago, has been appointed bacteriologist in the government laboratories at Manila, P. I. BALTIMORE, MD.: The position of surgeon-in-chief of the Presbyterian Eye, Ear, and Throat Charity Hospital, which was creditably filled by Dr. Julian J. Chisolm, who retired voluntarily in 1899, has been filled by Dr. Harlan. The management of the hospital is conducted by a board of three physicians appointed annually. Dr. Francis M. Chisolm, a son of Dr. Julian J. Chisolm, is a member of this board.

## EASTERN STATES.

**The Convalescents' Home** at Wellesley, Mass., was recently destroyed by fire, resulting in a loss of \$25,000. At the time there were about 50 patients, all children, in the building, but every one was removed to a place of safety. The home was connected with the Children's Hospital, Boston, and was one of the largest buildings in town.

## NEW YORK.

**State Registration of Nurses.**—A bill providing for such registration has been introduced in the New York Legislature. The majority of the physicians in the State have petitioned for its passage, because of the increasing number of untrained and incompetent nurses who pass as graduates.

**Examinations for Bacteriologist and Laboratory Assistant.**—The Municipal Civil Service Commission, of New York City, will hold examinations February 5, 6, to fill the positions of bacteriologist and laboratory assistant in the Department of Water Supply, Gas, and Electricity and in the Department of Health.

**Instruction in Mental Diseases.**—A course in the methods of instruction in mental diseases has been established at the Pathologic Institute of the New York Hospitals for the Insane, on Ward's Island. The course of instruction is to be continued for several months. Assistant physicians of the hospitals will take part. Several of the State hospitals will each send two physicians in order that as many as possible of the young physicians of the State who have direct charge of the insane may profit by such course of instruction. The latest methods of examining patients, arriving at diagnoses, keeping records, etc., will be carefully taught.

**Changes at Bellevue Hospital.**—At Bellevue Hospital, in common with the principles in many other hospitals, the custom has been to send out the youngest of the residents in point of service on the ambulance and when calls come in. This has been discontinued, and hereafter only residents having had at least six months' service in the hospital will be permitted to act as ambulance surgeons. Some change has been made in regard to the examination and the admission of patients. The building for the insane at Bellevue is now in charge of three skilled alienists. These physicians will not only receive and care for patients but they also perform the duties formerly exercised by the State Medical Examiners, this latter position having been abolished. The change is thought to be a great improvement over the past method.

## PHILADELPHIA, PENNSYLVANIA, ETC.

**Pennsylvania State Asylum for Criminal Insane.**—A bill introduced into the Legislature provides for the appointment of a commission to select a site for a State Asylum for the criminal insane.

**Amendment to Bill Respecting Bequests to Charitable Institutions.**—A bill recently introduced into the Pennsylvania Legislature amends the act relative to bequests given to charitable institutions by eliminating the portion that makes such bequests made less than two months before death invalid.

**Typhoid Fever and Smallpox.**—Typhoid fever has reached an epidemic stage in Philadelphia and smallpox is on the increase. There were 323 cases of typhoid reported for the week ended January 17, as against 217 cases for the week previous. The statement is made that about 2,000 cases are now under treatment in the city. Smallpox has also increased, there being 35 new cases reported for the week ended January 17, as compared with 33 the week before. Throughout Pennsylvania an increase is noted in all diseases resulting from cold, and this is especially true of smallpox, which is well known as a cold weather disease. The statement is made that cases have increased in numbers and virulence to a degree entirely disproportionate to the increase at the same season last year, such increase being due to a very great extent to the present lack of fuel. A vigorous effort is being made to have Legislature reestablish the emergency fund to enable the Board of Health to cope with smallpox and other epidemics which may occur in the State.

**Appropriations Asked for by Various State Institutions.**—The amounts asked for the year 1903 from the State Legislature by the various public institutions of Pennsylvania reach a total of \$5,201,601.40, while the total amount recommended by the committee on appropriations for the same period is \$3,638,554.66. It will be observed that a large reduction has been made in the sum asked for by most of the public institutions. By far the greatest number of institutions seeking aid are hospitals, and it is confidently hoped by those in charge of such institutions that liberal sums will be granted for their maintenance, as in many instances in the past various hospitals in the State have been seriously crippled for want of proper funds. The total sum asked for by the various institutions for the year 1904 reaches a total of \$5,113,130.13, while the total sum recommended by the committee on appropriations for the same period is \$3,656,083.39. In addition, it is recommended that \$2,000,000 be appropriated for the expense of the indigent

insane for the two years; \$500,000 for a State institution for epilepsy; and \$50,000 for an institution at the Western Penitentiary for the convict insane.

**Temporary Home for Phipps Institute.**—Temporary quarters for the Phipps Institute for the Prevention of Tuberculosis have been secured by Dr. Lawrence F. Flick at 238 Pine street, Philadelphia. It is understood that these quarters are secured for one year, with the privilege of extending the lease for five years, or of purchasing the property if it is deemed wise. While the quarters are by no means so pretentious as the institute when equipped will afford, yet it is considered that they are sufficient for present needs. It is believed that the temporary quarters will be in working operation within two weeks. According to the *Philadelphia Ledger*, two bills have been introduced into the Legislature for the repeal or modification of the act prohibiting the establishment of new hospitals of any kind in built-up portions of cities. The Senate bill which repeals the present act has already passed that body and has been reported to the House with a favorable recommendation by the Judiciary General Committee. The House bill, which empowers boards of health to grant permission for the establishment of new hospitals in cities, has passed its first reading.

#### SOUTHERN STATES.

**An epidemic of measles** is reported to be raging in Baltimore. For the week ended January 24 there were 314 new cases reported, with 11 deaths.

**The Eye, Ear, Nose, and Throat Hospital**, of New Orleans, La., recently purchased a property in the central part of the city which they will hold as a site for the erection, on some future occasion, of a five or six-story building for hospital purposes. A central location for the contemplated hospital was desired as it would thus be more accessible to the poor and also near the other hospitals and medical schools.

**Quarantine Stations Purchased.**—It is asserted that the United States Treasury Department has purchased for Florida the State's quarantine stations at Pensacola, Charlotte Harbor, Fernandina, Miami and Mayport, at a cost of \$32,000. This sale was in obedience to a joint resolution of the Florida Legislature of 1901, after an appraisal. The Federal Government took over the quarantine system in July, 1901, and has been operating it since.

#### WESTERN STATES.

**The Western Ophthalmologic and Otolaryngologic Association** will hold its next regular meeting at Indianapolis, Ind., April 9, 10, 11, 1903. An interesting program will be rendered.

**Women Urge Pure Food War.**—It is reported that 1,400 women in Indiana have signed a petition asking the Legislature to appropriate money for a laboratory and for the appointment of chemists who will examine all food to find if it is adulterated.

**The Illinois State Medical Society** will hold its annual meeting in Chicago, April 29, 30, and May 1, 2, 1903, instead of May 19, 20, 21, as previously announced. This change has been made in order to anticipate the earlier meeting of the American Medical Association at New Orleans.

**Health of Chicago.**—According to the bulletin of the Chicago Health Department for the week ended January 10, fully 10%, or nearly 200,000 residents of the city, are suffering from ailments of a grave character caused by privation and exposure resulting from the coal famine. Already these ailments are reflected in the enormous increase of deaths among those at the extremes of life—the young and the aged, in both of whom the powers of vital resistance are at the lowest. Since the first of the year there has been an increase of 19.2% in the number of deaths among those under 5 over the number in the corresponding period of last year, when this deathrate was about normal. Among those over 60 the increase is much greater—24% last week over the week previous, and 36.7% over the normal rate of the corresponding period of 1902. This excess of increased deathrate among the aged is caused chiefly by the effects of cold and exposure in hastening to a fatal termination many of the chronic diseases, the sufferers from which, under ordinary conditions, might have survived for many years. "Street car colds" are, in the experience of every physician in general practice, increasing with frightful rapidity. Pneumonia and bronchitis, as direct results, are endemic in every part of the city. Since the first of the year there has been a 22% increase in the deaths from these two diseases, and as compared with the first 10 days of 1902, the increase is a little more than 41%. The great increase of scarlet fever deaths during the past week—16, as compared with 5 during the week before—is due to kidney complications, favored by exposure to cold and following what seemed to be light attacks of the disease. There have been 20 deaths from whoopingcough during the last fortnight, the highest number ever recorded for any similar period. Six cases of smallpox were sent to the isolation hospital during the week. None of the victims had ever been properly vaccinated, although two had old, faint, imperfect marks, said to be from vaccinations in early childhood.

#### CANADA.

**St. Michael's Hospital, Toronto.**—Two lots adjoining the hospital property on the north side have been purchased, and the houses occupying them will be remodeled and used as a maternity ward. The space in the hospital at present occupied by this ward will be used to extend the surgical department. Later it is proposed to erect a building connecting the new maternity ward and the hospital proper.

## FOREIGN NEWS AND NOTES

#### GENERAL.

**Quarantine Against San Francisco.**—The Government of Ecuador announced that all ports of that republic will be closed to steamers arriving from San Francisco owing to the fear of the importation of bubonic plague.

#### GREAT BRITAIN.

**Insurance for Appendicitis.**—The London *Daily Mail* states that the prevalence of appendicitis has suggested to one of the prominent firms at Lloyds that the public might desire to insure against it. For a premium of five shillings the insured, if he has to undergo an operation for appendicitis, will receive his direct expenses paid up to £200, and in the event of his death, under or from the operation, the total sum of £200 will be paid. It is stated that many people are taking advantage of the opportunity afforded to secure insurance.

#### CONTINENTAL EUROPE.

**Serum for Pneumonia.**—According to an exchange Professor Tizzoni, of the Bologna University, has announced to the Royal Academy of Sciences the discovery of a serum to combat pneumonia.

**Increase of Nurses in Germany.**—At the annual meeting of the Nurses' Branch of the German Red Cross Society it was stated that in the 18 years from 1882 to 1900, the number of male nurses had increased from 5,478 to 11,868, and that of female nurses from 17,661 to 38,937.

**Prizes for Essay on Ichthyism.**—The St. Petersburg Academy of Sciences have offered two prizes, one amounting to \$2,575, and the other to \$515, for the best papers elaborating protective measures against poisoning by fish toxins. The contest is to be international and the papers may be written in English, German, French, Latin, or Russian, but must be received by the Russian Minister of Agriculture not later than October 1, 1903.

**Medical Men in Politics.**—It is a noteworthy fact that medical men play a much more important political role in continental countries than in either England or the United States. Such an illustrious example as Virchow illustrates this. In the French republic there are fully 40 or 50 deputies who are physicians, and the Minister of the Interior, Dr. Combes, is a medical man. The president of the Swiss Confederation, Deucher, is also a physician and is about to begin his third term of office.—[*Journal American Medical Association.*]

**Health of Berlin.**—According to the Public Health Reports, during the week ended December 6 the deathrate of Berlin amounted to 15.5 per 1,000 of inhabitants, which was somewhat higher than the corresponding week of last year, when the rate was 15.2 per 1,000. A decided increase is noted in the rate for the following week ended December 13, when it was higher than it had been since the beginning of June, amounting to 17 per 1,000. This increase is ascribed to the more frequent occurrence during the week of acute intestinal and acute respiratory diseases; tuberculosis was responsible for 87 deaths as against 75 of the foregoing week. The almost general and considerable increase in the mortality led to an investigation, which proved that two-thirds of the large German towns had less favorable sanitary conditions than Berlin.

#### OBITUARIES.

**Max Schede**, at Bonn, December 31, aged 59. During the Franco-German war, 1870-71, he was one of the physicians who occupied a prominent place on the medical staff of the German army, and on the conclusion of that war he was appointed director of the surgical section of the Berlin Municipal Hospital in the Friedrichshain. Upon the establishment of the New Hamburg Hospital Dr. Schede was appointed organizer of the surgical section of that institution. He was instrumental in bringing about the use of mercuric chlorid as an antiseptic in the practice of surgery. He was for some years head of the surgical section of the General Hospital of Hamburg. Later he was appointed ordinary professor of surgery at the University of Bonn, and had the title of Privy Councillor of Medicine conferred upon him. He was a skilful operator, and was the inventor and perfecter of many surgical and orthopedic modes of treatment. His writings were

numerous, but consisted chiefly of contributions to the various prominent periodicals of medical science. He helped found *Das Centralblatt für Chirurgie* in 1874 and was its editor until 1880.

**Henri Varnier**, a leading obstetrician of France, died recently, aged 43. He contributed largely to medical literature. Besides numerous papers on continuous irrigation in puerperal fever, gangrenous cystitis in the course of retroflexion of the gravid uterus, vaginal urethrocele complicated by calculi, etc., he collaborated with Pinard and Champetier de Ribes in the production of an atlas of obstetric morbid anatomy, and with Farabocufin an Introduction to the Study of Midwifery. He was also the author of a treatise on the mechanism of delivery and the technic of obstetric operations, and of a fine work, illustrated with numerous plates, on everyday midwifery, which appeared in 1900. He was one of the editors of the *Annales de Gynécologie* and of the *Revue d'Obstétrique et de Pédiatrie*. He took a prominent part in the revival of symphysectomy in France.

**J. M. B. Ward**, of Chester, Pa., January 22. He was quarantine physician at the Marcus Hook Station and was killed by falling through the hatchway of the steamer "Exeuntia," which was on its way to Philadelphia and had stopped for the usual inspection. He was a member of the Delaware County Medical Society and of the J. M. Da Costa Medical Society of Philadelphia, and was surgeon of the Sixth Regiment, National Guard of Pennsylvania, ranking as lieutenant.

**Photinos Panas**, professor of ophthalmology in the University of Paris, died recently, aged 70. In 1873 he published a book on strabismus and ocular paralyses, and he was also the author of works on affections of the lacrimal apparatus, inflammatory diseases of the internal membranes of the eye, retinitis, and the pathologic anatomy of the eye. In 1879 he was elected a member of the Académie de Médecine, and was at one time its president.

**Rush Winslow**, of Appleton, Wis., January 3, aged 59. He was graduated from the Rush Medical College, Chicago, in 1860 and from the Bellevue Hospital Medical College, N. Y., in 1871. He was mayor of Appleton from 1887 to 1892. He was largely instrumental in establishing the St. Elizabeth's Hospital and was on the staff of house physicians.

**Margaret Stanton**, in Syracuse, N. Y., January 22, aged 58. She was graduated from the College of Medicine, Syracuse University, in 1876. She was formerly president of the Onondago County Medical Society and was the only woman who ever held this office. She was a member of the staff of St. Joseph's Hospital and was the first woman to receive appointment as a city physician.

**Joseph Edwin Clark**, of Brooklyn, N. Y., January 22, aged 80. He was graduated from the College of Physicians and Surgeons, New York, in 1849. He had been a visiting physician of St. Peter's Hospital since 1875. He was a member of the Kings County Medical Society and Physicians' Mutual Aid Association.

**Edward T. Dickerman**, of Chicago, died in Springfield, Ill., January 23, aged 35. He was graduated from the Northwestern University Medical School in 1890 and was an assistant surgeon for eighteen months in the General Hospital at Vienna.

**Alexander Scott**, of Forest, Ont., January 21, aged 62. He was graduated from the Detroit Medical College in 1871 and from the University of Toronto in 1872. He served for three years as medical health officer for Forest.

**Charles Palmer**, at Ipswich, Mass., January 11, aged 78. He was graduated from the Jefferson Medical College, Philadelphia, in 1848. He was a member of McClellan's surgical staff during the Civil war.

**Burdette A. Terrett**, in Natchitoches, La., January 23. He was graduated from the medical department of the Tulane University, New Orleans, in 1900. He was a founder of *American Medicine*.

**Lucian H. Shepherd**, of Oswego, N. Y., January 25, aged 37. He was graduated from the College of Medicine, Syracuse University, Syracuse, N. Y., in 1895.

**Hawkins Stone**, at Garrisonville, Va., January 21, aged 87. He was graduated from the medical department of the University of Virginia, Charlottesville, in 1837.

**Arthur Beavis**, at Mapimi, Durango, Mex. He was at one time pastor of the Unitarian Church and had practised medicine in Denver and Aspen, Colo.

**Charles H. Haessler**, at Pottsville, Pa., January 23, aged 73. He was graduated from the College of Physicians and Surgeons, New York, in 1853.

**George T. Motter**, of Taneytown, Md., January 17. He was graduated from the medical department of the University of Nashville, in 1864.

**John Lord**, in Biddeford, Me., January 21. He was graduated from the Medical School of Maine at Bowdoin College, Brunswick, Me., in 1866.

**W. S. McKay**, of Port Arthur, Ont., January 10. He was physician in charge of the hospital at Superior Lumber Company's camp.

**J. G. DeVeaux**, of Wheeling, W. Va., died near Panama Park, January 23.

**Christopher Kiersted**, of Jersey City, N. J., January 25, aged 81.

**Henry W. Day**, of Belleville, Ont., January 10, aged 72.

## SOCIETY REPORTS

### THE PLAGUE CONFERENCE.

Held at Washington, D. C., January 19, 1903.

[Specially reported for *American Medicine*.]

The Plague Conference, called by Surgeon-General Wyman, under the law of 1902, at the request of twenty State Boards of Health, met in the U. S. Marine-Hospital building, at Washington, on January 19. The following States were represented: MAINE, by Dr. C. D. Smith; VERMONT, by Dr. H. D. Holton; CONNECTICUT, by Dr. C. A. Lindsley; RHODE ISLAND, by Dr. G. T. Swarts; NEW YORK, by Dr. Daniel Lewis; NEW JERSEY, by Dr. Henry Mitchell; PENNSYLVANIA, by Dr. Benjamin Lee; DELAWARE, by Drs. A. Lowber and C. W. Cooper; MARYLAND, by Dr. J. S. Fulton; DISTRICT OF COLUMBIA, by Dr. W. C. Woodward; VIRGINIA, by Dr. Paulus Irving; NORTH CAROLINA, by Dr. R. H. Lewis; SOUTH CAROLINA, by Dr. T. C. Simmons; LOUISIANA, by Dr. Arthur Nolte; TENNESSEE, by Dr. J. A. Allbright; INDIANA, by Dr. J. N. Hurty; MINNESOTA, by Dr. H. M. Bracken; INDIAN TERRITORY, by Dr. M. B. Thompson; COLORADO, by Dr. H. R. Bull; IOWA, by Dr. J. L. Kennedy; CALIFORNIA, by Dr. Mathew Gardner.

A preliminary meeting was held at the New Willard on the evening of the eighteenth. Dr. Mathew Gardner, the delegate from California, introduced himself as having been temporarily appointed by Governor Pardee a member of the State Board of Health to represent the State at the Conference. Dr. Gardner described himself as surgeon-in-chief to the Southern Pacific Railroad, unfamiliar with and unconcerned in the plague controversy, unacquainted with and not responsible for the other members of the State Board of Health, but charged with the verbal assurances of the Governor of California and of the commercial bodies of San Francisco that the existence of plague is recognized, and that all interests will combine in its eradication.

General Wyman read the report of Surgeon Glennan upon the inspection of California towns outside of San Francisco. No evidences of plague were discovered in these inspections. Dr. Wyman reported upon his personal visit to San Francisco in December, including his inspection of Chinatown, and said that he had the personal assurance of Mayor Schmitz, of San Francisco, that all opposition to the view that plague exists is now at an end. Dr. Glennan reported 50% of dead rats and 1.1% of living rats examined infected with plague. Referring to the outbreak in Mexico, Dr. Wyman gave the view of the U. S. Consul at Vera Cruz, that plague might have reached Mazatlan in a ship from the Orient, and said that Chinamen from the Orient transshipped at San Francisco might have carried plague to Mexico.

Dr. Woodward, of District of Columbia, asked how much plague is now present in San Francisco, and whether it is true that vessels are clearing from the port of San Francisco with clean bills of health? In reply to these questions the Surgeon-General said that there is "not much" plague in San Francisco.

Dr. Fulton, of Maryland, discredited Surgeon Glennan's report on the ground that the inspections were imperfect in method and because the California inspector who accompanied Surgeon Glennan was a surgeon to the Southern Pacific, who had been identified continuously since May, 1900, with the combination to deny and to conceal plague. Dr. Fulton read the annual message of the Mayor of San Francisco delivered on January 12 and reiterating the Mayor's denial that plague exists in California. Attention was called to the reorganization of the City Board of Health of San Francisco on January 9 into accord with the Mayor's views and to the fact that Drs. Ruggles and Coffee of the California State Board of Health are Southern Pacific Railroad surgeons. Evidence was offered that the Mexican outbreak is traceable to San Francisco. Mazatlan has no trade with the Orient, but has constant coastwise trade with San Francisco. The steamer "Curacao," whose San Francisco wharf overhangs a Chinatown sewer, probably carried plague to Mazatlan.

Dr. Gardner, of California, defended the inspections of Surgeon Glennan, and asserted his own fitness to be appointed by Governor Gage as associate in the work of Dr. Glennan.

Dr. Lee, of Pennsylvania, inquired if it were possible that an American State tolerated a large foreign population so entirely exempt from all responsibility to the laws of the city and State as Dr. Gardner had shown the Mongolians to be.

Dr. Smith, of Maine, remarked upon the indefiniteness of the information from California and upon the absence of a plan to discover and to deal with cases of plague. Remarks on these points were also made by Drs. Lindsley, of Connecticut, and Mitchell, of New Jersey.

At the appointed meeting on the 19th, Surgeon-General Wyman was in the chair. Dr. Swarts, of Rhode Island, was elected secretary. The earlier proceedings were similar to those of the previous evening. Dr. Woodward, of District of Columbia, presented a chart of the reported plague mortality of California for the years 1900, 1901, and 1902, showing a steady and strong rise since its discovery in March, 1900. Dr. Nolte, of Louisiana, inquired if the steamer "Curacao" cleared from San Francisco for ports in Mexico with a clean bill of health. The following resolution was passed:

WHEREAS, This Conference believes without a shadow of division of opinion that plague exists and has existed in San Francisco, the representative from California, Dr. Gardner, is requested to present to this Conference, within as short a time as possible, definite signed assurances from the Governor of the State and the Mayor of San Francisco which will bind the City Board of Health and the State Board of Health, so far as the Governor and the Mayor can control these officers, to assume each their several and joint responsibilities in the suppression of plague, to pursue them to the utmost in harmony with each other and in full cooperation with the U. S. Public Health and Marine-Hospital Service.

With the information furnished by Surgeon-General Wyman and by Assistant Surgeon-General Joseph White in hand the Conference took a recess. The delegates immediately went into caucus to prepare resolutions. The following resolutions were adopted:

## I.

The presence of plague in California is established beyond debate by:

1. The investigations of Kellogg, of the San Francisco Board of Health; Rykogel, for the California State Board of Health, and Kinnynn for the United States Marine-Hospital Service.
2. By the later investigations of Pillsbury for the State Board of Health, and by those of J. White, M. White, Flint, Currie, Carmichael, Blue, and Glennan for the United States Marine-Hospital Service.
3. By the findings of Flexner, Barker, and Novy, composing a special committee acting under Federal authority.
4. By the findings of independent and disinterested investigators supplied with materials from autopsies done at San Francisco, and working in San Francisco, Chicago, Boston, New York, Washington, Baltimore, Philadelphia, and Ann Arbor.
5. By the occurrence of a case of human plague in Ann Arbor due to an accident in the manufacture of Haffkine's prophylactic fluid with a culture of plague bacillus obtained in California.
6. By the autopsy records of 90 cases of plague now in the possession of the United States Marine-Hospital Service and of the San Francisco Board of Health, and published in part in the *Occidental Medical Times*, of San Francisco.

## II.

The presence of plague in any community where proper restrictions are not taken to prevent its spread is an injury to the best interests of that community. Such injury is in any case avoidable by the proper cooperation of all interests involved, commercial, professional, and governmental. The Conference regards the habitual publication of the actual facts relative to infectious disease and preventive procedures as the surest route to popular confidence, and as one of the means best adapted to minimize the injury liable to result from the presence of such diseases.

## III.

The present danger to California, and to the United States lies primarily in the persistence, during nearly three years, of a definite nidus of plague infection in the part of San Francisco known as Chinatown; but the gravity of this circumstance is greatly increased by the gross neglect of official duty by the State Board of Health of California and the obstructive influence of the recent Governor of California; by the failure of the city government of San Francisco to support its City Board of Health, and by the obstacles opposed to the operations of the United States Public Health Service.

## IV.

The Conference will consider the safety of the country sufficiently assured as soon as satisfied that a competent City Board of Health of San Francisco and a competent State Board of Health, in cooperation with the United States Public Health Service, will proceed under definite, harmonious and effective laws and ordinances; that they are provided with ample funds; and that they are jointly and severally in the free exercise of their lawful powers.

## V.

The Conference expresses its conviction that the United States Public Health Service has deserved well of the State of California, and of the country, and that it would go far toward the restoration of popular confidence if the United States public health officials were admitted to the same relations with the State Board of Health as have been steadily maintained with the Board of Health of San Francisco.

## VI.

The praise of this Conference and the gratitude of the city of San Francisco are due to Drs. John M. Williamson, Vincent R. Buckley, W. B. Lewitt, Rudolph W. Baum, Louis Bazet, and W. R. McCarthy of the City Board of Health of San Francisco. These men have the unreserved confidence of the executive health officers of the country.

A resolution was proposed informing the Hon. Elihu Root, Secretary of War, that in the opinion of the Conference the presence of plague is a consideration of weight against the maintenance of a U. S. Transport Station at San Francisco, and that the danger is largely augmented by the gross misconduct of the State Board of Health and the hostile attitude of Mayor Schmitz and the public press of San Francisco. This resolution was opposed by Drs. Lewis, of New York, and Simmons, of South Carolina. A substitute was offered by Dr. Woodward, of District of Columbia, restating the same opinion in general terms, but without any personal or official reference or allusion. This passed by a vote of 8 to 7. Its reconsideration was moved and carried.

At the afternoon session the first resolution of the morning session was reconsidered and rescinded on the representation of the delegate from California that it was physically impossible to obtain the assurances asked for in a short time.

The resolutions prepared by the delegates in caucus and printed above were all passed. The resolution concerning the U. S. Transport Station at San Francisco was again brought up, and after some discussion was indefinitely postponed. Dr. Bracken, of Minnesota, introduced a resolution requesting

the U. S. Public Health Service to institute a State border inspection of railroad trains. This resolution was lost.

A copy of the official report of Health Officer Fagan, of British Columbia, on the plague at San Francisco was read. This report noted the recent appearance of the tonsillar and pneumonic forms of plague and the infection of rats in San Francisco.

A letter from Dr. Eduardo Liceaga, president of the Superior Board of Health of the Republic of Mexico, was read, asserting the moral conviction of the Mexican authorities that the plague infection of Mexico had originated in San Francisco, and protesting against the dishonest conduct of the State Board of Health of California. The secretary was instructed to make a suitable reply to the communication of the Superior Board of Health of the Mexican Republic, enclosing the resolutions passed by the Conference.

The delegate from Maryland asked the Surgeon-General why vessels are allowed to leave the port of San Francisco with clean bills of health. The Surgeon-General replied that he did not know that it was true that vessels leaving San Francisco carry clean bills of health, but if it were true the responsibility lay with the consuls of foreign governments stationed at that port. Dr. Nolte, of Louisiana, inquired if Dr. Wyman's answer to Dr. Fulton's question was also a reply to his own (Dr. Nolte's) inquiry at the morning session. Dr. Wyman replied in the affirmative.

Dr. Gardner, of California, asked the Surgeon-General if the U. S. Public Health and Marine-Hospital Service would assume full control of the campaign against plague, California and San Francisco furnishing the necessary funds and subordinate officers. The Surgeon-General replied that upon request of the Governor of California and the Mayor of San Francisco, with the consent of the Secretary of the U. S. Treasury Department, he would accept this proposition.

The Conference requested the Surgeon-General to furnish a full report upon the plague in California at the next meeting of the National Conference in June.

Telegram to Dr. Gardner from Governor Pardee.

SACRAMENTO, CAL., January 22.

DR. M. GARDNER,

Ebbitt House, Washington, D. C.

Your dispatch of January 21st received and have consulted San Francisco authorities. State and city officials are in perfect agreement with the conclusions reached. There should be thorough cooperation between United States and State in dealing with situation. State officials stand ready to do everything the law will permit and which may be found necessary to secure cooperation. Legislature will undoubtedly make adequate appropriation bill for \$100,000. Already in both houses. State authorities will expend appropriation under advice and direction of Public Health and Marine-Hospital. State officers guarantee to do everything within power which the Federal representatives consider necessary and to do it in a way which Federal officials advise. Our laws do not permit State officials to turn over to Federal representative, but practically the same result will be reached by course above proposed. Officials of California realize thing to be done is to take most effective means to reassure everybody and they are willing and glad to be guided by Public Health and Marine-Hospital authorities in the adoption of means to secure this end.

GEORGE C. PARDEE.

(Copy telephoned)

Telegram from Mr. Herrin to Dr. Gardner, dated January 22.

Your telegram 21st. Governor Pardee and Mayor Schmitz will cooperate in every reasonable way permitted by law, but law does not permit money of State or city and county to be expended except by its own officials, and they must therefore retain control of work, which can be done, however, in accordance with instructions of the Federal authorities.

WILLIAM F. HERRIN.

**Hospital for Prisoners.**—The *Times-Democrat* announces that a hospital is to be erected for State prisoners in the Florida penitentiary. This institution with nearly 1,000 prisoners has heretofore been without any place where sick convicts might be cared for. Plans have just been completed for the erection of a hospital for convicts at Ocala at a cost of \$8,000.

**Does "Ill" Mean "Sick"?**—There are signs of an existing propensity to constrain the partial withdrawal of the word "sick" from the American language in favor of the word "ill." Newspapers in their head-lines and elsewhere speak nowadays of "a very ill man." It used to be "a very sick man." Why the change? "An ill wind" is a satisfactory use of language, but "an ill man" grates on the ear, and sounds like an attempt to improve on a usage that had no perceptible defect. They say this new whim is a euphemism imported from England. A correspondent of a Boston paper discusses and disapproves it, protesting not only against the use of the unwarrantable adverb "illy," but against "the growing use of the word 'ill' in place of the homely word 'sick.'" This Boston protestant, quoting Webster, finds that Shakespeare with hardly an exception uses "ill" to mean mental, moral, or impersonal disorders. "Ill at ease," "ill-advised," "ill-bred," "ill fares," are all fit and familiar uses of a good and industrious little word that has plenty of legitimate work of its own to do, without being constrained to figure as a feeble substitute for "sick." ## CLINICAL NOTES AND CORRESPONDENCE

[Communications are invited for this Department. The Editor is not responsible for the views advanced by any contributor.]

## SUBCUTANEOUS INJECTION OF SOLIDIFYING OILS TO CORRECT A SADDLE-BACK NOSE.

BY

JOSEPH A. M. SMURL, M.D.,  
of Philadelphia.

Considerable has been written in recent medical literature pertaining to the introduction under the skin of solidifying oils to correct anatomic irregularities, but thus far, in my personal researches, I have failed to find any illustrative evidence of the work accomplished. With due respect to Corning, Gersuny, and von Angerer, and the methods employed by these celebrated men, I experimented with injections of paraffin over four years ago, and after many discouraging failures, due to the imperfection of the syringe employed, for I tried to make the ordinary hypodermic syringe do the work, I began to perfect a syringe which meets the requirements admirably. This syringe is modeled after Dr. Janet's, made entirely of metal, about three inches long, and has a capacity of about three drams, with a caliber equal to that of the ordinary syringe. My needles are made about the size of the antitoxin syringe needle, but have an elongated point, which facilitates the distributing power. In

many cases, a glass syringe, when subjected to sufficient heat to melt the paraffin, breaks, hampering the operator to no small degree. The metal syringe overcomes this annoyance and works beautifully.

Among the many patients that I have operated on, in only one case was there the slightest evidence of a complication, then it was only a slight ecchymosis, which disappeared in 48 hours without any special attention. Great care must be exercised so as not to introduce the needle into a vein, as serious results might occur. I have discarded employing a local anesthetic before introducing the injection, an objectionable feature being the distention due to the anesthetic, this disguising in a measure the field of operation. I now find that the hot solution modifies the pain to a more or less extent. Considerable attention is devoted to the preparing of the paraffin; it is mixed with red vaselin in the proportion of one of vaselin to three of paraffin; it is then subjected to an intense heat. After boiling the solution for at least one hour, I allow it to cool, and then place it in an antiseptic container, the ordinary jar with a screw top answering the purpose very well. The paraffin can be shaved into fine bits—it saves time in introducing the preparation into the syringe. The surface to be operated on must be antiseptically prepared. The syringe, which is filled with the wax, is heated slowly over a spirit lamp, and when liquefied is introduced under the skin very cautiously, and with the left

hand molded into the desired position. The accompanying illustrations represent the most aggravated type of saddle-back nose. In this case, one operation was not sufficient to overcome the deformity. It required three injections at an intermission of about three weeks' duration, for I found that the skin would not stretch sufficiently at the first sitting to allow me to complete the work. The patient was instructed to massage the nose gently every day, and consequently when she presented herself for a subsequent operation the skin was quite relaxed. Fig. 1 shows that the nose, before operating, was not only depressed, but the end was pronouncedly tilted. The operation also obliterated this deformity, giving to the patient a good profile.

There is a diversity of opinion as to whether the paraffin undergoes a gradual chemic change leaving a mass of new tissue, or whether it becomes embedded in an accretion of fibrous tissue.

My experience in 10 cases in which paraffin was introduced into the cellular tissue of the arm, purely for experimental purposes, was that it became thoroughly encapsulated by fibrous tissue, with no chemic change taking place whatever.

## THE CONTROL OF MOUTH-BREATHING AT NIGHT.

BY

STEWART W. TUFTS, M.D.,  
of Pittsburg, Pa.

Assistant Surgeon to Passavant Hospital.

Having had much difficulty in getting patients to use the ordinary methods for obtaining the control of mouth-breathing at night, I was led to seek a simpler plan which would be more popular. I believe that the most simple method which can be devised is to stick a piece of silk isinglass courtplaster, about  $\frac{3}{4}$  by  $1\frac{1}{2}$  inches, across the closed lips. For a person with a moustache or beard it will adhere strongly enough to the edges of the lips. The patient will suit this idea to his case. The plan is a little alarming to some, but when assured that it can be very quickly removed and that it does not irritate the lips, they accept it enthusiastically, and although there is much joking about it, I find this method as popular as headgears were objectionable. During the last five years I have made mouth-breathing a subject of careful observation, and I find that at least 90% of my patients with acute and chronic diseases of the respiratory tract are mouth-breathers at night. This proportion may seem large, but it is a fact of common observation that most persons who snore deny it, and so it requires careful consideration to arrive at the truth. Some of my patients will strongly insist that they breathe properly until they are watched while asleep. In some of these I have had the best results; 90% of the patients observed had sufficient room in the nose to breathe correctly during the day, but in some of them, of course, nose and throat treatment was required to complete the cure of mouth-breathing at night. The necessity for the correction of this habit is illustrated in the treatment of hypertrophic rhinitis, in which in attempting to increase the nasal caliber after a certain point the function of the nose is interfered with and the patient still breathes wrongly at night. At this point the correction of the habit by plaster will improve vasomotor control of the circulation of the nose and complete the result. The first requirement for a normal nose is that it be used constantly, the blood supply being such that if the nose is not used, the mucous membrane congests and gradually thickens from hypernutrition. As an experiment I used the courtplaster so that I would be able to answer any objections to it, and discovering myself a victim of the habit, I continued its use two weeks. At the end of this time I ceased to clear my throat, my voice improved in power and quality, and I could sing one note higher than ever before.

After carefully investigating the breathing of 19 entire families, comprising a total of 84 persons, I found that 70% of them breathed through the mouth at night. This proportion also harmonizes with my general observations. The necessity for the correction of the habit is made very clear by the facts that

air inspired through the nose receives from 20° to 40° of heat, and becomes at least two-thirds saturated with moisture, and that the nose is a most effective germ filter. The mouth has none of these functions, and when it is used in breathing the lungs must receive a large number of germs and suffer damage from the unmodified air. The importance of this subject is further emphasized by the fact that according to the census of 1900, 40% of the total number of deaths between the ages of 20 and 50 years were due to diseases of the respiratory tract. The increase of six years to the average of human life in the last 20 years has resulted mainly from improvements aimed at purification of the atmosphere, but the air of our houses and cities is still far from ideal. Now, in consideration of the immense mortality from lung diseases, how great is the necessity for using such a good air filter as the nose. Yet 70% of people fail to use it at night, and we as physicians have overlooked its importance in our treatment of the sick. From these facts it appears that the correction of mouth-breathing is one of the most important measures of preventive medicine, and it seems to me also one of the most efficient measures of physiologic therapeutics. My general results in the treatment of respiratory diseases are better now than before the use of my method, and my patients who used to have a laryngitis or bronchitis follow acute rhinitis are now enabled to avoid such sequels; I have more control of asthma and hay-fever. One severe asthmatic in spite of the fact that she refused to have her nose, which was in very bad condition, treated, was relieved through controlling her breathing; in another case of years' duration cure was effected by the same means; the nose, pharynx, and larynx improve more rapidly, and the voice gains in quality and strength. In tuberculosis I believe that the avoidance of mouth-breathing lessens the tendency to a mixed infection, bronchitis, colds and cough, and increases the oxygenating power of the lungs. The application of this idea is of large value to singers and speakers, who should be observed while asleep to make sure of their proper breathing. Many of my patients when they take a cold use the plaster to make sure of correct breathing, because they are enabled to avoid laryngitis or bronchitis, and have found that their colds are of shorter duration. If the nose is too much occluded at bedtime the use of sprays, cold sponging of the face and shoulders, or the use of a few gymnastic exercises which equalize the circulation are of value. In investigating mouth-breathers do not give credence to a denial, but direct the patient to observe carefully the condition of the nose, throat, and mouth upon awakening, or as a final test let him be observed while asleep. The difficulty in getting the truth is the main reason why this subject is so often overlooked. Many physicians give the subject no attention whatever, unless the case is one of enlarged tonsils or adenoids. To obtain a clear realization of the bad results of this habit let the reader keep his nostrils plugged for a day, and no further demonstration will be required. This group of facts should show the great absurdity of treating patients with pulmonary tuberculosis, pneumonia, diphtheria, bronchitis, asthma, influenza, and laryngitis, and allowing the inspiration of a germ-laden, cold, dry atmosphere through the mouth, when the nose is ready, after possibly some slight adjustments, to filter, warm, and moisten the air.

### ACCESSORY THYROID TUMORS SITUATED AT THE BASE OF THE TONGUE.

BY

J. E. SUMMERS, JR., M.D.,  
of Omaha, Neb.

To the Editor of *American Medicine*:—In a paper bearing the above title, Dr. Randolph Winslow, of Baltimore (*American Medicine*, December 13, 1902), reports an interesting case in which he operated successfully upon the patient. In discussing the literature of the subject the doctor evidently unintentionally overlooked the fact that it is to an American surgeon, Bernays, of St. Louis, that we owe our accurate knowledge of the subject. In the October, 1888, number of the *St. Louis Medical*

and *Surgical Journal* Bernays reported a case. He was the first man to operate upon and discuss in an intelligent manner struma at the base of the tongue. Bernays' reference to the historic work of His, bearing upon the thyroglossal tract and its relations to the growth of struma, was the first bright ray to clear up the dark subject. R. Wolf, of Hamburg, did not report his case until April, 1889, and it was published some months later. The recognition of the nature of the cases referred to by Butlin, seen prior to Bernays' report, followed naturally; and in consequence today many cases are matters of record. In a paper read by me at Minneapolis, Minn., December, 1900, before the Western Surgical and Gynecological Association, in which I tried to classify a tumor removed from the base of the tongue as an endothelioma, my microscopic findings seeming to differentiate this tumor from a struma; it developed in the discussion that several members had operated upon but failed to report their cases of struma of the base of the tongue. So far as I know the literature of the subject no case of this character has ever been reported in the male, but Dr. C. H. Mayo, of Rochester, Minn., in the discussion of my paper reported one occurring in a boy of 15. It seems to me that Bernays' paper never received the recognition it deserved.

### A CASE OF INTESTINAL OBSTRUCTION DUE TO IMPACTION WITH LUMBRICIDS; OPERATION; DEATH.

BY

W. O. BULLOCK, JR., M.D.,  
of Lexington, Ky.

The following case of intestinal obstruction is interesting on account of the unusual nature and severity of its exciting cause:

Wm. B., white, aged 6, was sent to the Good Samaritan Hospital, July 16, 1902, by Dr. Baucome, of Spears, Ky., with a diagnosis of intestinal obstruction, due to worms. The child was taken sick a week before, had passed 10 or 12 worms, and the parents consequently administered an anthelmintic. As this did not relieve the symptoms, the little patient was plied with all the domestic remedies at hand, including purgatives and medicines to settle the stomach. After four or five days of unsuccessful effort, the parents sent for a physician, who, after endeavoring to relieve the condition by high enemas, advised that surgical relief be instituted immediately. This, however, was postponed till the following evening when the child was brought to the hospital. At the time of admission the patient's condition was one of extreme emaciation. The abdomen was flat and a sausage-shaped mass could easily be made out in the right iliac region. Temperature 98°, pulse 132-140, and weak. This, coupled with a history of persistent vomiting and absolute constipation, led me to a diagnosis of intestinal obstruction, due probably to intussusception. The patient was placed on the operating table at 7.25 p.m. under ether. Upon making a vertical incision in the outer border of the right rectus, the deep epigastric vessels were encountered and these were tied at both ends of the wound. A finger was introduced and immediately met the distended gut beneath the incision. It proved to be the colic end of the ileum, distended to the size of the ascending colon for a distance of about eight inches, and packed solidly with lumbricoid worms; for eight or ten inches more the bowel was filled with worms, but not to the same extent, the mass tapering to a point a few inches higher up. The walls of the bowel were so attenuated that the individual worms could be distinguished readily. The bowel was bluish and the serosa, which was beginning to lose its glistening appearance, was torn several times in consequence of efforts to work the mass of worms to and through a longitudinal slit made near the ileocecal junction. After removing the mass the color of the bowel improved, and the opening was closed by three rows of Lembert sutures superimposed. The mesentery at the site of the obstruction was greatly thickened and edematous. The abdominal incision was closed by through-and-through silk worm-gut sutures. The duration of the operation was 45 minutes. The patient left the table in bad condition, pulse between 150-160, and was given strychnia and normal saline solution hypodermically. He rallied somewhat during the night, but sank again and died at 8.30 a.m., July 17, of shock and exhaustion, 12 hours after operation.

The number of worms removed at operation was 92, and 2 more were passed by the bowel before the child died. The worms were not coiled or knotted, but lay for the most part parallel with each other except at the lower end, where they were somewhat tangled.

## ORIGINAL ARTICLES

## A NOTE ON THE ANATOMY OF THE PERIRENAL FATTY TISSUE.

BY

W. W. KEEN, M.D.,  
of Philadelphia.

Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia.

In the many operations which I have done upon the kidney, I have invariably recognized an anatomic disposition of the perirenal fat which I do not find described in any of the textbooks on anatomy or surgery. The recognition of it facilitates very greatly the finding of the kidney and hence I call attention to it.

There are two distinct layers of fatty tissue surrounding the kidney: First, that which should be called the transversalis layer of fat and, secondly, the proper perinephric fat or fatty envelope surrounding the kidney itself. In operating on the kidney, so soon as the fat bulges through the incision, if it is carefully cut or torn through, gradually deepening the incision or tear, a distinct interval between these two layers will be found, which is recognized by a layer of connective tissue, similar to that which is found, for example, between the internal oblique and transversalis muscles. The second layer of fat then presents itself. If this is incised or torn through and drawn into the wound, the opening thus made in it becomes a sort of infundibulum or funnel-shaped opening, at the bottom of which the kidney is invariably found. Occasionally the first layer of fat does not extend so far posteriorly as the second layer, but commonly, so far as the operating surgeon is concerned, they lie superposed.

At my request, Dr. A. B. Craig, one of my assistants, has made two dissections of the parts and describes them as follows:

I find the two fatty layers of which you speak. The external layer is less thick than the internal and is continuous with the transversalis fascia. This fascia in passing posteriorly becomes thin, cellular, and reticular and the fat is embedded in its meshes. After passing through this layer there is a distinct interval before we come upon the thick fatty capsule of the kidney proper, which latter completely envelops the kidney and is more or less adherent to the true capsule. The fatty capsule has a more or less distinct fibrous covering, which is continuous below with the reticular tissue which passes down with the ureter and surrounds the bladder, rectum, etc., while it is continuous above with the attenuated reticular structure which intervenes between the peritoneum and the caudad surface of the diaphragm, and is continuous across from one kidney to the other.

It appears to me that this structure is morphologically continuous with that fatty-reticular layer between the transversalis fascia and the peritoneum, often fairly marked in the region of the inguinal rings, and denominated 'peritoneal fat,' and which, therefore, in the region of the kidney would be postperitoneal.

I have consulted over a score of anatomies, general surgeries, and special surgeries on the kidney. None of these alludes to the two fatty layers with the exception of DaCosta's Modern Surgery, and this allusion is due to information given to Prof. DaCosta by myself and which he also confirmed some years ago by some careful dissections made at my suggestion. He, however, simply alludes to the existence of these two layers, but does not describe them.

**Work of the State Board of Health in Massachusetts.**—Since the work of investigating reported adulteration of foods, drugs, examination of water supplies, and sewage systems was given to the State Board of Health in 1883, 138,310 samples have been examined and 1,647 complaints entered. The cost of collection, analyses, etc., has been reduced from \$2.26 per sample in 1883 to \$1.12 in 1902. The total expense for the year just ended was \$11,700.23 and the fees paid amounted to \$2,617.98. In its work with reference to water supplies, drainage, sewage, etc., the board has expended \$33,999.44 out of an appropriation of \$34,000. The work will continue.

## TWELVE CASES OF MALIGNANT DISEASE TREATED BY THE RÖNTGEN RAYS.

BY

HENRY PERKINS MOSELEY, M.D.,  
of New York City.

Radiographer to the Presbyterian Hospital, New York City.

The following cases occurred in patients treated at the Presbyterian Hospital during the last year. Several patients are also either still under treatment or sufficient time has not elapsed since their discharge to warrant drawing any conclusions from them. In all this work the attending physicians and surgeons of the hospital have shown great kindness and courtesy and my thanks are due them for their uniform sympathy and for their many helpful suggestions in regard to the therapeutic use of the Röntgen rays.

The apparatus used consists of a ten-plate Waite and Bartlett static machine and a 50 cm. coil made by the Heinze Electric Co., of Boston, used with the Heinze liquid interrupter. The hospital supply of 110 volts direct current is used to run the motor for the static machine and is also used directly into the interrupter for the coil, for which no rheostat nor transformer is required. The areas treated have been usually at a distance of 15 to 30 cm. measured to the target of the tube. The surrounding tissues have been protected by lead foil. The time of exposure has been 5 to 10 minutes on alternate days. Occasionally more or less frequent exposures have been given, according to the case. When the coil was used a current of 1½ to 2 amperes was passed in the primary. Tubes of various makers have been tried and the most satisfactory results have been obtained with those tubes which give out a large number of rays which are not highly penetrating. It seems that the tubes of high vacuum cause dermatitis more readily than those of a low vacuum, but the curative effects do not seem to be so good with them in spite of the fact of their being able to influence so actively the healthy skin.

## I.—EPITHELIOMA.

**CASE I.**—Epithelioma of the lip. The patient, Michael C., a laborer, aged 50, was born in Ireland.

**Family History.**—There is no cancer and no tuberculosis in the family. His father died in a famine in Ireland and his mother died of fever.

**Previous History.**—When 26 he had pleurisy for 6 months and has had two attacks since, the last 15 years ago. He denies all venereal disease. He was formerly a hard drinker, but now uses only one pint of beer a day. He has smoked constantly a short clay pipe, which stuck to his lip but which, he says, did not get hot.

**Present Illness.**—Six years ago he "pulled skin off his lip" by its sticking to the pipe. It bled quite a little. He kept smoking and the area gradually increased in size. It has never healed and has bled considerably. Various ointments and applications have been used. He tried smoking on the other side of the mouth, but the area did not heal. Scabs would form and fall off about twice a week. He noticed no swelling in the neck. He absolutely refused any cutting operation, so that it was impossible to get a section for the pathologist. Dr. George T. Jackson, of this city, said, however, that there was no doubt of the diagnosis.

**Physical Examination.**—March 7, 1902: To the left of the middle of the lower lip there is an ulcer about ½ inch by ¼ inch. It is very slightly indurated around the edges; there are slight scabs on its surface; and it bleeds easily. There is no enlargement of the cervical glands.

**Treatment** was begun March 7, 1902. To excite the tubes the coil usually was used, occasionally the static machine. The tubes used were of very low vacuum placed at a distance of 30 cm. for the first few treatments, but soon this distance was diminished to 15 cm. The time of exposure was 5 to 10 minutes. In all, 19 treatments were given, about 3 a week, but the patient was of necessity irregular in presenting himself owing to his occupation. On May 24, 1902, the last treatment was given, the ulcer being healed. August 31 a letter from the patient said there had been no return. October 7 the patient was seen and there had been no return. It is perfectly healed, only a very slight thickening being left. There is no glandular involvement. The patient still smokes constantly, but on the other side of his mouth.

The patient reacted most satisfactorily to treatment. Seven months have elapsed since the last treatment and

there is no evidence of return. No burning was produced. The growth was superficial and there was no glandular involvement, but it had proved resistant to other methods of treatment.

CASE II.—Epithelioma of the lip. Charles McH., Irish, aged 80.

*Family History.*—His father had a cancer of the lip removed by operation without recurrence and died years later of senility.

*Personal History.*—For 65 years the patient has smoked a short-stemmed pipe. Since the middle of March, 1902, he has noticed a slight induration at the middle of the lower lip which has never healed. It scabs over. The scabs fall off and it bleeds, being a source of great annoyance.

*Physical Examination.*—August 28, 1902: There is a small indurated area at the middle of the lower lip about  $\frac{1}{2}$  inch in diameter covered with a scab, which, being removed, causes bleeding. There is no enlargement of the cervical glands. The clinical appearance is typical of epithelioma.

Dr. A. J. McCosh advised against operation on account of the patient's age and infirmity. Treatment was begun August 28, 1902. The coil was used to excite tubes of very low vacuum placed 8 to 15 cm. from the area treated. The treatments were given irregularly at first, but between August 28 and September 30, 17 exposures of 10 minutes each were made. As no effect seemed to be produced the treatments were then given more frequently, 13 exposures being made between October 1 and October 18, at the end of which time the area had markedly increased in size, being *twice as large* as when first seen. The patient was advised to discontinue treatment temporarily on October 27. On November 17, when next seen, there was a marked improvement, the area having diminished in size to its original dimensions. Four treatments were given on alternate days and the patient disappeared, being confined to the house with a severe bronchitis (?). On December 17 he again presented himself, showing to my astonishment a lip absolutely healed, with healthy mucous membrane in place of the ulcerating area and a disappearance of all induration. Up to this time the number of treatments had been 36. He is still having weekly exposures.

The improvement and final healing after rest and cessation of the treatment was *remarkable*. There is in certain cases a cumulative effect of the rays, their influence continuing after the treatment is stopped.

CASE III.—Epithelioma of face. Mrs. N., a widow of 80, was born in Ireland.

*History.*—Four years ago she noticed on the left side of her face, opposite the ala of the nose, a slight small lump. This was cauterized and treated with ointments but ulcerated and did not disappear. For the past three years the eyelid has been pulled down by the ulcerated area. Lumps have gradually grown and ulcers formed.

*Physical Examination.*—May 1, 1902: There is a large superficial ulcer 1 inch in diameter below and involving the left lower eyelid. It discharges pus and blood and causes much pain and annoyance day and night. There is marked ectropion of the left lower lid.

*Treatment* was begun May 1, 1902. The static machine or coil was used to excite a very low vacuum tube. At first, treatment was on alternate days for five minutes at a 20 cm. distance, but the patient's skin was very sensitive, becoming quite red so that two treatments a week has been as frequent as the skin would warrant, and with slight rests the treatment has been continued at these intervals. On September 20 there was only one small ulcer about  $\frac{1}{4}$  inch in diameter left. There was absolute freedom from pain and the new skin is healthy. November 11: Condition is the same as on September 20; the scabs over ulcers are very small. January 1, 1903: In spite of persistent treatment, it has been impossible to cause healing in the small areas (as noted below); the freedom from pain continues; the new skin is healthy.

The peculiarities of this case were the marked sensitiveness of the skin, and the almost immediate relief of the pain and rapid diminution in the discharge. The patient is still under treatment and now presents an area corresponding to the original ulcer filled in with healthy skin. In the midst of this area is a spot about the size of one-half the diameter of a lead pencil which seems to be filling in very slowly from the edges, and a small similar area on the right cheek near the nose. The patient is extremely grateful for the relief afforded by the absence of pain and discharge.

## II.—CARCINOMA.

CASE IV.—Carcinoma of jaw. Service of Dr. A. J. McCosh. Mr. C., aged 62, was born in the United States and has been a missionary.

*History.*—About six months ago the patient had a small ulcer at the inner side of the left cheek, caused by the irritation of a sharp tooth. This persisted and increased.

*Physical Examination.*—April 28, 1902: At the angle of the left lower jaw there is a swelling about the size of a hen's egg. It is red, adherent to the skin and underlying bone with a discharging sinus at its summit, from which comes a thin yellow exudate. Just above the angle of the mouth is a reddened nodule which is broken down and from which exudes a thick yellow discharge. On the inner side of the left cheek are a few reddened round hard nodules. On April 29, 1902, Dr. McCosh tied the left external carotid artery to cut off in part the blood supply to the tumor. The wound healed by primary union. On May 3, 1902, the Röntgen ray treatment was begun. The static machine or the coil was used to excite a low vacuum tube placed 20 cm. from the patient. The exposures were 5 to 10 minutes. Eight treatments were given on alternate days without any apparent effect. By May 16 the swelling in the left jaw had increased perceptibly in size in spite of the exposure to Röntgen ray. The patient left the hospital and died some time during the summer.

The case was most unsatisfactory for Röntgen ray treatment, as the growth had extended so far and was so badly ulcerating. The patient was failing perceptibly from day to day, and the treatment did not seem to have any effect on the local condition whatever.

CASE V.—Carcinoma of breast. The patient was Mrs. R., a widow of 49.

*History.*—This patient was referred by Dr. A. J. McCosh as having an inoperable tumor. Two years ago she first noticed a swelling in her left breast. She had no operation but had taken a course of treatment by subcutaneous injection in Boston.

*Physical examination* showed a large nodular heavy bluish mass in the lower part of the left breast including the axilla. There was no edema of the arm. The patient's general condition was fair.

*Treatment* was begun July 17, 1902. High and medium vacuum tubes were used, excited by the coil or static machine. Exposure was for 5 or 10 minutes at a distance of 25 cm. Seven treatments were given and the patient went to the country for two weeks. On her return July 28, 1902, she looked bad, the mass had grown and was ulcerating. The ulceration progressed rapidly and she soon became too weak to have further treatments. She gradually emaciated and died October 2, 1902.

This was a most discouraging case from the outset. She had neglected the disease so long that it was too late for any treatment to have results. The rapidity of the growth and its malignant nature were evident from the very first and it is another case in which the treatment did not seem to have any effect whatever.

CASE VI.—Recurrent carcinoma of breast. Service of Dr. Ellsworth Eliot, Jr. Louisa G., aged 52, was born in Danish West Indies, is a widow and colored.

*Previous History.*—In November, 1901, the patient was operated on by Dr. Eliot for a scirrhous carcinoma of the left breast of one year's duration. At this time the breast and pectoral muscles were removed and the axilla cleaned out.

*Present Illness.*—Ever since the operation the patient has suffered almost constant pain in the wound and shooting down the arm. About March, 1902, she noticed a little lump starting to grow in the region of the scar. This increased in size and has broken down, leaving an ulcer.

*Physical Examination.*—April 15, 1902: There were numerous nodules along the line of the scar, at no point being adherent to the chest wall but evidently in the skin. On April 18, 1902, Dr. C. A. McWilliams excised the scar and surrounding tissue leaving a denuded area about eight inches in diameter. This was partly closed by freeing the skin and drawing it together, the remaining areas being filled in by skin grafts done at the time of operation. In about half the area the grafts were successful. On June 25, 1902, the note is: "Wound slowly granulating over. In the granulating area are a number of small elevated patches about the size of a pea, with eroded surfaces. Below the wound in the skin is an area about two inches by three inches consisting of similar nodules." (Attention is called to this area as reference is made to it later.) July 9: On discharge from the hospital wound is in the condition of last note.

*Treatment* was begun May 28, 1902, six weeks after the operation, and was kept up regularly until September 22, 1902. The static machine or coil was used to excite very low vacuum tubes placed 20 cm. from the patient. The exposures were ten minutes, on alternate days. There was no burning produced. The patient's color prevented any change being noticed visibly, but she complained of no irritability and no sense of heat except

once. By June 9, 1902, she had improved—the discharge was less over the granulating area, which was smaller. On June 30 there was slight recurrence at the lower part of the wound. This is the same as noted in the hospital notes of June 25. July 28, the granulating area was nearly healed. Place of recurrence was much better, it was not soft; there was no discharge, no puffiness. All these conditions existed until July 11. On August 11 she complained of a slight burning sensation over the wound. Treatment was continued, however, and no bad effects were noticed. She did not complain of the burning again, and three days later said it was absent. August 27: She complained of pain, and yesterday a mass of glands was noticed above left clavicle. August 29: Nodules were noticed in the right breast. September 20: Area skin grafted has broken out at outer side and also at inner side. October 13: She was seen in the Presbyterian Hospital dispensary; she coughs a good deal and has much dyspnea. This patient was last heard of as being too weak to come to the dispensary for treatment, and it is presumed she has succumbed to the metastases.

At first this case seemed very promising. The patient presented herself regularly, and at one time the treatment seemed to be doing her good, but the recurrence later appeared in the areas of skin grafted, and metastases appeared elsewhere. The area, however, below the scar did not seem to take part in the recurrence. This condition has been noticed that vigorous treatment on one portion of the body prevents, or apparently retards a recurrence here, but has no effect on metastasis elsewhere. The fact that the patient complained of no irritability of the skin, and that there was no evidence of dermatitis raises an interesting question whether the pigment in a negro's skin might not act as a preventive to a Röntgen ray dermatitis.

CASE VII.—Recurrent carcinoma of breast. Mrs. C., an English widow of 65. This patient was referred by Dr. A. J. McCosh.

*History.*—In February, 1894, she had an amputation of the left breast at a private hospital in this city. In 1900, the first time since the operation that anything abnormal was noticed, there was seen a slight discharge from the axillary scar. In June, 1901, small spots were noticed on the scar, and the arm began to swell. The scar, shoulder and arm gradually became very painful.

*Physical Examination.*—April 10, 1902: The woman is large and well nourished, and weighs 160 pounds. The left shoulder, arm and forearm are greatly swollen, somewhat edematous and tender. Over the scar of the removed breast, and also scattered over the front of the left chest and over the left scapular region, posteriorly, are many reddened hard, infiltrated spots,  $\frac{1}{2}$  inch to 1 inch in diameter.

*Treatment* was begun on the same day. Both the static machine and coil were used to excite medium and high tubes placed at a 25 cm. distance from the area treated, the exposure being 5 to 10 minutes on alternate days. Both front and back were treated, usually alternately, but depending somewhat on the patient's desire for relief of pain. April 21, 1902, there was no change in swelling, but there was less pain. June 23: Swelling has diminished; recurrent spots are smaller, and much less painful; swelling at upper part of arm is less. Beginning June 23, the patient had daily treatment until July 4, skipping two days. The skin became quite red, and treatment was omitted until July 11, when it was found that the redness had all gone from the front. The back, however, is still red, otherwise condition is the same as on June 23. The patient wished to go to London to visit her family, and was instructed to keep up the Röntgen ray treatment there, but failed to do so.

My note of October 27, 1902, on her return, is for about 10 days after the last treatment, July 11, 1902; patient says she was badly burned on the front of the chest and over the back. Large blisters formed, but the inflammation was controlled by wet dressings, and it was three weeks before the skin was normal. At present the swelling over the chest and shoulder is markedly diminished. Nearly half of the elevated tender spots of recurrence have disappeared entirely or have left merely a small lightly pigmented area. The edema in the arm and forearm remains about the same, and is very troublesome. The pain has returned since the treatment has been stopped. Her general health is fairly good, but she does not look quite so well as in the spring before she went abroad.

The case presents interesting features. Great relief has been afforded to what was regarded as an inoperable hopeless case by her physicians, the patient herself, and her friends. The relief of pain has been most striking from the very first, and the diminution of the swelling after the vigorous treatment she received just before she went abroad is marked.

The improvement in this case, as in many, seems to have continued some time after the treatment was

stopped. The fact that it was about four or five days after the last treatment that the burn was first noticed is in accord with the observations of others, and impresses the necessity of the greatest care in the prevention of any burn, and the imperative necessity of absolutely stopping all treatment on the appearance of the slightest erythematous blush. In this particular case large areas were exposed to the treatment because of the wide distribution of the disease. During the treatment in the spring the patient's general condition improved considerably. Treatment three times a week was resumed on her return from England, with an immediate marked relief of the pain. This relief lasted about 36 hours from the time of the treatment, but after some weeks her general condition became so poor that further treatment by this method was deemed inadvisable.

CASE VIII.—Carcinoma of inguinal glands. Service of Dr. A. J. McCosh and Dr. F. Tilden Brown. Mrs. S., a widow of 68.

*History.*—The patient has had five children, all normal labors. A small sore was removed from the right labium 2½ years ago at the Woman's Hospital. It was said to be an epithelioma.

*Present Illness.*—Nine months ago a small lump was noticed in the right groin, gradually increasing in size, and recently a small area discharging pus appeared at the outer part of the swelling.

*Physical Examination.*—June 23, 1902: In the right groin was seen a hard mass half the size of an egg. It was slightly tender, overlying skin reddened, and a small discharging sinus at the outer portion. Skin was adherent, swelling was not movable on the deeper parts. No other enlargement of the superficial glands was made out.

*Treatment* was begun on June 25, 1902, and continued on alternate days and daily until September 3, 1902. High, low and medium tubes were used, both the static machine and coil being employed to excite them. The distance of the tube from the patient was about 30 cm., the time 5 to 10 minutes.

Slight erythema was produced, but no curative effect whatever could be noticed, not even a diminution in the amount of discharge, and the patient becoming markedly weaker was discharged from the hospital to return to her home in the country.

CASE IX.—Carcinoma of inguinal glands. Service of Dr. A. J. McCosh. The patient was Mr. M., a Canadian, aged 43.

*History.*—Family and personal history are negative for venereal disease or neoplasm. January, 1901, a circumcision was performed in Ottawa for a small lump on prepuce, the pathologic report being epithelioma. At this time the right inguinal glands were dissected out. Recurrence took place and a second operation was done in June, 1901, at Ottawa. The swelling in right inguinal region again appeared, and a third operation was performed in Paris in the fall of 1901. In the middle of January, 1902, the patient noticed a return of the swelling in the right groin, and on admission, on February 8, 1902, in the old scar was an enlarged hard mass of glands. Those in the left inguinal region were palpable, but not enlarged. Dr. McCosh removed the mass, which involved the ramus of the pubis and Poupart's ligament, and was adherent to the iliac and femoral veins, but "it was impossible to go wide enough of the growth to be sure of removing it entire." The wound was granulating well when patient was discharged in March, 1902. Dr. J. S. Thacher's pathologic report was carcinoma. On March 24, 1902, Dr. S. S. Graber, the patient's family physician, referred him to me for treatment. The patient had noticed swelling and a sense of discomfort in the wound.

*Examination* showed the scars of a 4-inch incision, parallel to and over the right Poupart's ligament with a vertical one descending from its center about 3 inches long. At the junction of these two scars, which was markedly depressed, was a mass feeling like an irregular collection of small glands. It was firm—not fluctuating, and slightly tender. The left inguinal glands were distinctly palpable and enlarged.

*Treatment.*—With the idea of inhibiting the growth of the mass the Röntgen rays were applied. The tube usually employed was of a medium high vacuum, excited by the coil. The distance of the target from the patient was 20 cm. The area treated was about 6 inches by 4 inches. The length of the exposure was 5 or 10 minutes, depending somewhat on the character of the rays given by the different tubes used. At first the exposures were on alternate days. From April 2 to April 20 they were given daily, then until May 3 they were omitted, as the skin became a little red. From that date until May 23 the exposures were daily. He was seen last June 9, 1902.

The improvement began soon after the treatment was instituted. The mass grew smaller and the sense of discomfort disappeared, the patient's general condition improved and he gained weight. On June 9 the mass in the scar had entirely gone and the glands in the left groin could not be palpated. He reacted very well to treatment and with the exception of a very

slight redness at one time the only disturbance to the skin seemed to be a marked pigmentation. There was no burning. On November 2, 1902, a letter from the patient's home in Canada says there is no evidence of a recurrence in the scar. He is still taking regular Röntgen ray treatment. The result in this case was most satisfactory. After his first operation recurrence was noticed nine months later. After the second four months later. After the third four months later. The last operation could not be made sufficiently radical to remove the whole growth, but the Röntgen ray treatment certainly has seemed to inhibit its growth up to the present time at least and it is now nine months since the last operation.

A striking feature of this case was the disappearance of the left inguinal glandular enlargement while the treatment was being applied to the right groin.

### III.—SARCOMA.

CASE X.—Sarcoma of pharynx. Service of Dr. A. J. McCosh. The patient, Mrs. S., aged about 40, was born in the United States.

*History.*—For one year she has suffered from increasing difficulty in respiration and deglutition. A mass has formed in the back of mouth and nose so she cannot breathe through the nose. A section of the tumor removed at Roosevelt Hospital and examined microscopically was pronounced sarcoma. The patient was referred to me by Dr. J. C. Sharpe and admitted to the service of Dr. A. J. McCosh.

*Physical Examination.*—May 21, 1902: She is emaciated and cachectic. The palate is pressed forward and downward by a smooth, firm, rounded mass underlying the mucous membrane. It is the size of an apple and causes great difficulty in deglutition and slight difficulty in respiration. There is a firm swelling below the left angle of the jaw, which is diffuse in outline and evidently involves the overlying superficial glands, which latter are otherwise not involved.

This patient had 8 treatments of 5 minutes each with a very high vacuum tube excited by the coil at a distance from the neck of 25 cm. without any apparent relief in her symptoms and without any effect on the growth whatever. The condition when she was admitted seemed hopeless, but it was thought that treatment might at least offer relief for her oppressed breathing and pain, but even this was not accomplished. The patient rapidly became worse and died of exhaustion on June 13, 1902.

CASE XI.—Sarcoma of buttock. Service of Dr. A. J. McCosh. The patient, Miss A., aged 30, was born in the United States.

*History.*—In December, 1897, a swelling the size of a hen's egg, which the patient had noticed about 6 months, was excised with the entire gluteus maximus in which it was imbedded. The pathologic report was myxosarcoma. The growth returned two years later, and in January, 1900, the tumor was the size of an orange. This with the muscles of buttock was removed. The right side of the posterior surface of the sacrum at this time was chiseled away as far as the posterior foramina from the coccyx to the lower lumbar vertebrae. During both operations a gelatinous material escaped on incision of the tumor. In August, 1901, the patient noticed a painful lump the size of a hen's egg in the old scar, which was very tender.

*Physical examination,* November 21, 1901, showed "in the right sacroiliac region extending down on to the buttock, occupying site of former operation, a tense semielastic tumor the size of a child's head, which seems to extend to adjacent parts." On November 23, 1901, Dr. McCosh removed a large amount of this mass under chloroform. "It could be felt inside the pelvis passing through the great sciatic notch and its extent was such as to make its complete removal hopeless." On leaving the hospital there was a clean granulating area 4 inches by 1 inch. Patient's general condition was good. Pathologic report, myxosarcoma. Between December 1, 1901, and January 1, 1902, the date of her discharge, the patient had injections of Coley's erysipelas serum at intervals of from two to four days. She was readmitted January 13, 1902, the wound having increased in size to about 2 inches by 6 inches and part of the tumor tissue with sloughing surface having appeared in the wound.

On January 29 it is noted that patient has been receiving from miiij-nvj of erysipelas toxin every two or three days, followed by fever and nausea, but with little apparent effect on the growth of the tumor. February 10: The patient has been daily exposed to the Röntgen rays, but there is little evident result on the tumor, which grows so fast that large pieces are cut away at each dressing. Area of wound is 4 inches by 3 inches.

*Treatment.*—From January 30 to February 21 she was given daily treatments with only two omissions, one on March 7 and one on March 12. The tube was placed so that the target was from 8 cm. to 12 cm. from the surface of the tumor. The first two exposures were of 10 minutes, the remainder 15 minutes. A tube of high vacuum was used and was excited by the static machine except for one exposure in which a small 8-inch coil was used. February 12: The discharge is much less and not purulent; surface is drier; parts have been cut away without injury. February 14, 1902: Much cut away under inflamed area; growth seems to have been stopped; discharge is still serous. February 21: Skin is scaly, red; discharge has markedly increased lately; skin is beginning to burn. March

9: Use of the Röntgen rays has been discontinued the past two weeks, but area of wound or growth of tumor has increased but little during this time. May 19: Burn has entirely healed; wound is 5 inches by 6 inches; its granulations grow rapidly and contain mucous cysts; patient is losing strength.

She died May 24, 1902, of exhaustion. No autopsy was allowed.

The Röntgen ray treatment in this case was advisedly very vigorous on account of the evident malignancy of the growth. The time of exposure was long and frequently repeated and the distance of the tube from the patient was very short. It was one of the early cases, but these conditions were carried out with the idea of possible burning and it seemed necessary to give very heroic treatment to have any effect. It was the opinion of those who watched the case that the treatment for a time hindered the growth of the tumor. The discharge diminished and the patient's general condition improved, but this was only temporary and the treatment was abandoned as being unable to prevent the growth. The burning of the skin amounted to a rather marked dermatitis. There was no sloughing or ulceration, but rather large blisters formed. It is interesting to note that the burn was caused by a rather high tube generated by a static machine. A small 8-inch coil was used only once.

CASE XII.—Sarcoma of temporal region. Mrs. H., a widow of 64, was born in Ireland, and is a domestic.

*History.*—About 1880 the late Dr. Henry Noyes, of this city, removed several small tumors from the margin of the left eye and orbit. There was a chain of them at the lower margin of the eyelid and at the outer corner. One was the size of a hen's egg. In July, 1883, the whole left side of the face swelled and became purple. She was then operated on at Bellevue Hospital, where an extensive operation was done by Dr. Lewis A. Stimson, part of the zygomatic arch being removed and leaving a deep depression over the left temporal and zygomatic area, which has gradually filled up in part, leaving only a slight depression. The records at Bellevue show that the growth was a sarcoma. She was in that hospital six weeks and made a good recovery. She did not have erysipelas.

When the patient was about 30 years old her physician told her she had a uterine tumor. Her menses had ceased, but she soon began to flow excessively, and for one year passed several large lumps, "like liver," by vagina. Then her menses ceased, and have never reappeared. She has never had children nor miscarriages. Her husband died of tuberculosis. History is otherwise negative.

Until the present illness her condition since the operation has been good. She has never had headache nor any disturbance of vision. At times she has had a peculiar sensation of water in her head. Hearing has been slightly diminished on both sides.

*Present Illness.*—Three months ago she noticed a slight swelling behind the left ear, then on the left temple. The swelling increased slowly, but became so marked that her friends noticed it. She has not noticed any glandular enlargement in the neck.

*Physical Examination.*—June 11, 1902: The patient is a healthy woman, well nourished and slightly anemic. The left zygomatic region is occupied by a diffuse, firm swelling, extending from just posterior to the outer margin of the orbit to behind the ear; from above—about 7.50 cm. above the line of the zygoma to about 5 cm. below this line. Surface is smooth, not hot, red nor tender, raised at the summit about 2 cm. above the level of the surrounding tissue. There is no interference with the motion of the jaw and no pain, but a sense of discomfort. There is no glandular enlargement.

*Treatment* was begun June 11, 1902, when an exposure of five minutes was given with a low vacuum tube, the distance being 15 cm. between the target and the surface of the swelling, the static machine being used. Two days later the patient returned, saying the sense of discomfort was less and that the swelling was smaller. June 13, 14 and 15 patient was treated, the time being increased to 10 minutes and the coil being used, the current passing in the primary being 2 amperes. On June 18 the swelling had nearly disappeared. On June 20 and 23 patient had treatment, and my note on the latter date is "the swelling has entirely disappeared" after seven treatments. There were a few treatments immediately following, and the patient was discharged to return for observation. She was seen on July 3, July 12, and August 2, 1902. After July 12 there was a roughness of the skin, following a slight erythema, but this entirely disappeared. On August 2 there was a marked depression above the site of the zygoma, as there had been according to the patient's statement previous to the appearance of the swelling. All evidence of the latter had entirely gone. There was an entire absence of the feeling of discomfort, the patient had gained weight and her color was better. The patient went west to take a household position. She was an intelligent

woman, understood thoroughly the nature of the disease, and promised to let me know of any return. Nothing has been heard from her, so the condition is supposed to be the same as when she was last seen.

The question arises what was the nature of the growth? The absence of pain, tenderness, heat, and redness seems to negative a cellulitis, of which there was not the slightest evidence. There was no history pointing to an embolus or thrombus giving rise to a localized obstruction to the venous return. The swelling had appeared very gradually, having taken three months to reach the size described. In view of the previous history of sarcoma, although nearly 20 years ago the diagnosis of sarcoma recurring at the original site seemed the only one warranted, and the fact that it responded so quickly to the treatment is in keeping with the reports of cases of other observers. If it was not a recurrence of the former sarcoma I do not know what it could have been.

SUMMARY.

The cases may be classified thus :

Case I.	Epithelioma of lip.....	Cured.
Case II.	Epithelioma of lip.....	Cured?
Case XII.	Sarcoma temporal region (recurrent).....	Cured.
Case IX.	Carcinoma of lingual region (recurrent).....	Cured?
Case III.	Epithelioma of face.....	Much improved.
Case VII.	Carcinoma of breast.....	Much relieved.
Case VI.	Carcinoma of breast.....	Not improved.
Case X.	Sarcoma of pharynx.....	Died.
Case XI.	Sarcoma of buttock.....	Died.
Case V.	Carcinoma of breast.....	Died.
Case VIII.	Carcinoma of lingual region.....	Died.
Case IV.	Carcinoma of jaw.....	Died.

From the histories it will be seen that of the five cases which had a fatal termination, all were severe and in the last stages of the disease.

Case VIII—carcinoma of the inguinal region—offered possibilities of relief in view of the satisfactory result obtained in Case IX, which was similar, but the others were recognized as practically offering no hope for improvement. The patients cured have been so reported, with the feeling that there may be recurrence, for it is often years before malignant disease makes itself evident elsewhere. In the first five cases in the above table the results have been most satisfactory, even leaving out of consideration the question of absolute cure, which can be settled only by time and further careful observations.

From these and other cases the following conclusions have been drawn :

1. The small superficial cases of malignant disease seem to be most susceptible to this method of treatment.
2. The relief of pain is a very prominent feature of the Röntgen ray treatment, and is often noticed after the first exposure. In cases which have not progressed too far, it is almost possible to promise the anesthetic effect.
3. It is impossible to determine from our present knowledge without trial what cases will be favorably influenced by treatment, but patients should be warned not to be too hopeful.
4. The danger of burning is a real one. Patients should appreciate the possibility of it before treatment is started, although with precautions it may be avoided. In hospital work when the operator is doing much Röntgen ray work, the greatest precaution should be exercised in the care of his own face and hands. The apparatus should be arranged so that all changes in the tube necessary to be made while it is running can be accomplished by switches or mechanical devices so placed that the operator can control them at a distance of 12 or 15 feet from the tube.

**Food Experiments.**—The Department of Agriculture, under the direction of Dr. H. W. Wiley, Chief of the Bureau, will conduct additional experiments relative to the value of certain foods. Infants and persons in bad health are to be used by the department as subjects for the tests. The object is to feed the foods stated to be good for infants and children to selected individuals from the foundling hospitals and asylums, and watch their temperature, growth, and weight carefully. Statements of the condition of the infants and children fed will be taken and recorded and reports made thereon.

SOME NOTES ON POLLACCI'S NEW METHOD OF DETECTING ALBUMIN IN THE URINE.

BY

GORDON LINDSAY, B.S., PH.G.,

AND

WILLIAM J. GIES, PH.D.,

of New York City.

College of Physicists and Surgeons, New York City.

Methods for detecting "albumen" in the urine have accumulated so rapidly in recent years that it is frequently a difficult matter to decide which is best adapted for special clinical purposes. The delicacy of the methods alluded to is so variable and the number of possible fallacies connected with the use of each so numerous, that the difficulties of selection are made all the greater. Then, too, in the use of the various methods, not a little confusion results from the fact that many of the tests show the presence of such amounts of proteid as are of no clinical importance—such, for example, as are contained in the normal urinary mucus.

We have recently investigated the utility of Pollacci's new method for the detection of albumin in urine. The original description appeared not long ago in the *Schweizerische Wochenschrift für Chemie und Pharmacie* (1901, xl, p. 168). We have not had access to the original paper but several abstracts<sup>1</sup> agree in giving the following facts regarding the method :

Pollacci has made a modified Spiegler reagent with the composition indicated below :

- |    |  |                               |
|----|--|-------------------------------|
| A. | 1 gram tartaric acid                           | } dissolved in 100 cc. water. |
|    | 5 " mercuric chlorid                           |                               |
|    | 10 " sodium chlorid                            |                               |
| B. | Solution A + 5 cc. formaldehyd (40% solution). |                               |

In applying this solution (B) for the detection of albumin, Pollacci uses 2 cc. of his reagent and cautiously adds 3-5 cc. of the urine, as in Heller's test, care being taken to stratify the solutions and to prevent their admixture.

"Should a white zone appear at the line of contact of the two fluids the urine contains pathologic albumin. If this ring or zone appears slowly, after about 10 to 15 minutes, it indicates the presence of only normal quantities of albumin." Pollacci established the limits of sensitiveness of the various albumin reagents now in use, compared with his own, with the following results :

Heat, with acetic or nitric acid .....	1 in 75,000
Heller's reagent.....	1 " 78,000
Potassium ferrocyanid and acetic acid.....	1 " 100,000
Joties' reagent.....	1 " 150,000
Roberts' " .....	1 " 400,000
Sulfosalicylic acid.....	1 " 300,000
Spiegler's reagent.....	1 " 365,000
Pollacci's " .....	1 " 370,000

It did not appear probable to us that this method would show only the presence of albumin. We were inclined to believe that other proteids would be indicated by it. This belief was fully warranted.

We find, as Pollacci states, that the reagent shows the presence of mere traces of albumin, although it does not appear to be so delicate as Pollacci's figures would indicate. But we have also observed that the reagent precipitates minute amounts of other proteids also, such as globulins, proteoses, mucoids, mucus proteids and even gelatins. The test has no differential value, therefore, and the reagent must be regarded as a general proteid precipitant rather than an albumin detector.

We are also unable to agree with Pollacci that the proteid normally present in the urine reacts with his reagent only after a lapse of 10 or 15 minutes. Deductions drawn from the observed breadth of the "zone" and from the lapse of time until the ring appears are not reliable. We have tested numerous samples of urine from individuals apparently in perfect health and in each instance, in less time in this connection than that speci-

<sup>1</sup> Chemist and Druggist, 1902, lx, p. 82; Therapeutic Monthly, 1902, II, p. 223; Merck's Report, 1902, xl, p. 256, also 257.

fied by Pollacci we obtained the white ring at the point of junction of reagent and urine. That these urines were normal in this respect was not merely assumed from the evident good health of the individuals excreting them, but shown experimentally by the fact that none of them gave positive reactions in Heller's test.

We have not attempted to determine, in this connection, the responsiveness of alkaloids and other remedial agents commonly detectable in the urine and frequently affecting the "albumen" tests. The presence of mercury in the acid reagent makes it probable, however, that other substances, nonproteid in character, readily respond to the reagent.

#### SUMMARY OF CONCLUSIONS.

1. Pollacci's reagent readily precipitates various proteids—simple, compound and albuminoid.
2. The test is too delicate for ordinary clinical purposes, since the normally occurring urinary proteids are precipitated by the reagent.
3. Various nonproteid substances occurring in the urine in health and disease are probably also precipitated by the reagent.
4. The latter possesses little or no advantage over Spiegler's fluid.

### TUBERCULOUS PERITONITIS.

BY

A. E. HALSTEAD, M.D.,  
of Chicago.

Professor of Surgery, Chicago Polyclinic; Assistant Professor of Clinical Surgery, Rush Medical College; Attending Surgeon to the Cook County Hospital and Chicago Baptist Hospital; Consulting Surgeon to the Illinois Eye and Ear Infirmary.

Abdominal surgery during the past few years has so greatly enlarged our knowledge of tuberculous peritonitis that we no longer regard it as a rare pathologic condition, but as one encountered frequently and often undetected before the abdomen is opened.

The way of entrance of the tubercle bacillus into the peritoneal cavity is frequently hard to determine. It was formerly thought that the peritoneum was often the only structure involved. We now know that this is rarely so, and that primary uncomplicated peritoneal tuberculosis is uncommon. Seck's statistics in 2,500 autopsies show 25% to be primary, while Borschke found in 226 postmortem examinations only two in which the disease could be said to involve the peritoneum alone. Munsterman, in 46 cases of tuberculosis of the peritoneum examined postmortem, found only one primary case. The lungs and pleura are often the primary seat of the disease, and from them the peritoneum becomes infected by direct extension of the disease. The bronchial glands in children, particularly those at the bifurcation of the trachea, have been shown by Merkel to be the starting point of the infection.

Burdon-Sanderson, Sturgis, and Carr (cited by Abbe, *Medical News*, 1896), in order to determine the origin of tuberculosis in children, reviewed the findings in several hundred autopsies, and concluded that about one-third died of some form of tuberculosis. Out of 120 autopsies, in two-thirds the thoracic glands were shown to be the point of entrance, while the mesenterics were primarily affected in one-sixth. Nothnagel and Teleky are of the opinion that the disease has for its primary site the lungs and pleura in by far the greater number of cases. The intestinal tract is at times the primary seat of the disease. Pribram, of 165 cases examined, attributed 87 to intestinal, 65 to pulmonary, 8 to tubal and uterine, and 5 to osseous tuberculosis. In 107 autopsies, in which death resulted from peritoneal tuberculosis, Phillips (*Centralblatt für klin. Chir.*, 1890) found the intestine the seat of tuberculous disease in 80, or 74% of all the cases. In 44 cases infection of the peritoneum was the direct result of disease of the mesenteric or retroperitoneal glands.

Borschke, on the contrary, in his 226 cases failed to find one case of a primary isolated lesion of the intestine from which the disease had spread, although in 140 there was a primary disease of the lungs associated with an advanced tuberculous disease of the intestine.

The female genital organs, especially the fallopian tubes, may be the starting point of the disease. That infection may reach the abdominal cavity through the tubes, even in children, is shown by Vierordt's case, in which, in a girl of 6½ years, tuberculous peritonitis was preceded by a purulent vaginal discharge in which tubercle bacilli had been demonstrated. The relative frequency of infection through the tubes is still a subject of dispute. The proportion given by the various writers varies greatly. Taking all available statistics, the cases in which the tubes are involved comprises about 25% to 30% of the patients affected. It must be remembered, however, that the disease of the tubes may be secondary to peritoneal tuberculosis, instead of being the starting point. Bone or joint tuberculosis, particularly when of the hip, is often the primary source of infection of the peritoneum. The inguinal lymphatics may also become infected, from these the iliac glands, and later the peritoneum become involved. The male genital organs also occasionally furnish the starting point of a tuberculosis which eventually invades the peritoneum. Mass has found the disease to reach the peritoneum through the umbilicus in young children.

From a clinical standpoint, tuberculous peritonitis may be considered under two heads: 1. Cases of tuberculous ascites in which the exudation of serous, or sero-sanguineous fluid is the predominant feature. The exudation is preceded or accompanied by the eruption of miliary nodules involving more or less of the peritoneal surface. 2. Cases in which tumor formation is the distinctive feature.

The diagnosis in the first class of cases can be made only when all other possible causes of ascities are excluded. There are, however, some points relative to the occurrence of tuberculous ascities which should receive careful consideration:

*The history*, frequently of some antecedent tuberculous lesion, especially of the lungs, intestine, or genital organs.

*The age of the patient*, tuberculous peritonitis occurring most frequently between the ages of 20 and 40. However, it may occur at any age, being relatively frequent in children in whom it is often associated with intestinal disease.

*Sex*.—Statistics go to show that this disease is more common in women than in men. Landler and Nothnagel found that 90% of the cases reported were in women. König collected 131 cases, of which 120 were in females, and 11 in males. The cases of Osler, Bouldland, Häne, and Maurange, taken together, give 60 males and 131 females. The autopsy records show, on the contrary, a greater proportion of males; of Nothnagel's personal cases, 101 out of 164 were in males. At the Boston City Hospital, 14 cases represented 8 males and 6 females. In spite of these postmortem records, it is probable that the disease is more common in females than in males. One reason for the difference in the figures quoted is that women are more frequently operated upon for abdominal diseases, and therefore a larger proportion are cured than among men, who are not so often treated by abdominal section.

*Temperature*.—Osler calls attention to the fact that the temperature in this form of peritoneal tuberculosis is frequently subnormal, varying from 95.5° to 97°. At times it may be normal, or slightly above normal, though this is not the rule.

*Pigmentation*, especially of the face, is occasionally noted in peritoneal tuberculosis. This may occur when the adrenals are not affected, as in a case reported by Osler.

*Onset of the Disease*.—This may vary between those

cases in which the onset is exceedingly acute, resembling suppurative peritonitis or acute intestinal obstruction, and those in which the process is extremely latent, in which a gradually increasing exudation is for a long time the only symptom. In many cases the recognition of the disease is accidental, there being no distinctive symptoms to point to its true nature. Emaciation, loss of appetite, and diarrhea are symptoms which vary with the acuteness of the disease, being more pronounced when the onset is rapid and the exudation great.

The relative frequency of the ascitic form of tuberculous peritonitis is shown by cases observed by Biat (cited by Osler). Of the 81 cases analyzed by him, in 13 there was extensive ascites. A moderate amount of fluid, however, is often observed in all forms of the disease.

The differential diagnosis of the ascitic form of tuberculous peritonitis from other varieties of chronic peritonitis is at times extremely difficult. When the disease is of rapid development it may be confounded with acute peritonitis of gonococcal or pneumococcal origin. In these cases, puncture and bacteriologic examination of the fluid withdrawn is the only means of differentiating. The greatest difficulty lies in distinguishing between tuberculous peritonitis and chronic peritonitis of other kinds, as, for instance, chronic rheumatic peritonitis. Here, only exploration will clear up the diagnosis.

There may also be, as in the cases reported by Owens, Sutherland, and Henoch, a traumatic peritonitis that offers considerable difficulty in differentiating from tuberculous peritonitis.

With chronic hypertrophic cirrhosis of the liver there may be associated a chronic inflammatory condition of the peritoneum which may simulate tuberculous peritonitis.

Lastly, the so-called "foreign body" peritonitis, particularly that occasioned by the presence of scolices in the peritoneal cavity, may be mistaken for tuberculosis of this membrane.

The presence of tubercle bacilli can only rarely be demonstrated in the tuberculous ascitic fluid found. Inoculation of the guinea pig does not always yield positive results. In the other forms of peritonitis just mentioned, which are likely to be confounded with tuberculous peritonitis, bacteriologic examination of the fluid is of great value in determining the cause.

Tumor formations the result of tuberculous peritonitis, although quite common, present great difficulty in the way of diagnosis. These tumors may originate in four different ways:

1. Tumors composed of rolls of omentum are the result of an extremely chronic inflammatory process which chiefly affects the omentum. These tumors are ridge-like in form, usually lying transversely across the upper part of the abdomen. In one of my cases the tumor was caused by the great omentum being rolled laterally on itself, forming a tumor occupying the median portion of the abdomen from just below the ensiform to a point near the pubic symphysis. They are seldom associated with any considerable amount of exudate.

The diagnosis of this form of tumor is frequently difficult and at times it has been mistaken for carcinoma. The history of the patient, especially if there should be a predisposition to tuberculosis, or the appearance of other tuberculous lesions, the most frequent of which is tuberculous pleurisy, should guide us in making our diagnosis. The presence of an area giving resonant percussion notes just above the mass, in cases in which the omentum is rolled from below upward upon itself, is of value in differentiating these tumors from tumors of the liver, for which they are often mistaken.

2. Abdominal tumors produced by sacculated exudations are the most common, as well as the ones that present the greatest difficulty in diagnosis. The fluid found in these cavities may be either serofibrinous or purulent, representing different stages of the same disease. Again, the tumor may be regular in outline when

it is entirely fluid, or irregular and nodular when composed in part of cakes of lymph or omentum. These tumors may be found anywhere, but usually occupy the middle zone of the abdomen, where they have many times been regarded as tumors of the ovaries, either cystic or solid. There is no way of distinguishing positively between the sacculated effusions of tuberculous peritonitis and cystic tumors of the abdomen. We should consider carefully the history, particularly as to tuberculous disease in the family, or as to old tuberculous lesions. Abdominal pain and irregularity of the bowels are more common than in ovarian disease. The onset is generally gradual, and the general health remains fair for some time. In some cases there is early loss of appetite, emaciation and diarrhea, associated with an irregular temperature. The physical signs are exceptionally deceptive, and in some cases are identical with those of cystic ovarian disease. When the exudate is small, the outline is not nearly so distinct as in ovarian tumors, while the form and position may change at any time, owing to the alteration in position of the intestinal coils that go to form the walls of the tumor. Irregularities in the periphery of the tumor, due to tuberculous nodules and cheesy masses, are of great value in determining the nature of these tumors. Pain on pressure is also greater than in ovarian cysts or other abdominal tumors. Bimanual palpation is of value in determining the outline and consistency of these tumors and by this means we may also be able to detect roughening of the peritoneal surfaces and small masses which would otherwise escape notice. The conditions of other organs should receive close attention, especially the pleura, lungs, and genital organs.

3. Tumors formed from matting together of coils of intestines may simulate either solid or cystic abdominal growths. They may be fixed or freely movable and may occupy any part of the abdominal cavity. Mistakes in diagnosis, although they occur, are not nearly so common as in sacculated exudations. In making a diagnosis we have the history of rapid emaciation, irregularity of the bowels and irregular temperature. Physical examination of the abdomen shows irregular areas of dulness and tympany, with more or less nodular or irregular tumors. At times there is free abdominal fluid.

4. Enlarged mesenteric, or retroperitoneal glands, may closely simulate other solid abdominal tumors, particularly retroperitoneal sarcoma. This form of tuberculosis is much less common than those above mentioned. These enlargements may vary in size from that of a walnut to masses larger than a child's head. Usually they can easily be palpated, but occasionally the presence of free abdominal fluid or excessive tympanites may prevent their recognition. The nodular character and number of these tumors, together with the presence of free fluid in the abdominal cavity and the history, are usually sufficient to make a diagnosis. Irregular tympanitic areas and persistent diarrhea, with rapid emaciation, are frequently associated with this form of the disease.

We know that recovery from tuberculous peritonitis without treatment is possible. Just what proportion of cases end in spontaneous recovery is difficult to state, because of the uncertainty of the diagnosis and the fact that its whole course may be latent; and further, the patient may recover without having known definitely that the disease existed.

Foullard collected 82 cases from the older literature, of which 20 ended in recovery. Some of these patients remained in good health from 10 to 17 years. The diagnosis was, however, based upon clinical evidence alone, and not supported by any bacteriologic examination. We are justified, therefore, in questioning the accuracy of the diagnosis in some of these cases.

At the present time, knowing that such good results

may be expected after laparotomy, most of the profession are agreed that the majority of these patients should be subjected to operative treatment. The usual method of procedure in the ascitic form of the disease is simply to open the abdomen by median incision, evacuate the fluid and drain. Some irrigate the abdominal cavity with a mild antiseptic solution, while others apply antiseptics in concentrated form directly to the diseased surface. Rendu employs a solution of camphor naphthol, which he brushes over the affected surface. This solution is claimed by M. Perrier to be distinctly antagonistic to the tubercle bacillus. Direct medication applied to the miliary tubercles, of iodoform, either dry or in the form of an emulsion, has been employed by many surgeons. It is questionable whether direct medication adds to the chances of cure after laparotomy. Statistics show that most of the cases in which cure has taken place have been of the acute miliary variety and that the treatment followed was simply incision and drainage.

The effect of laparotomy upon tuberculous peritonitis has received considerable attention during the last few years. The value of operative treatment can no longer be questioned. The proportion of cures it affords, however, is a matter of doubt and one of great interest. Many of the reports are open to criticism because of the short time the cases had been watched at the time they were reported. In one instance a recovery was reported 14 days after the operation; in another, 26 days. We agree with Winckle that freedom from symptoms for at least five years should alone constitute grounds upon which to report a cure.

The percentage of cures after laparotomy for tuberculous peritonitis varies from 25% to 85% in the cases reported up to the present time. Kummel collected 30 cases, beginning with the first operated on by Spencer Wells in 1862. In these there were 25 cures of from 9 months' to 25 years' duration. Koenig collected 131 cases, of which 75% were greatly benefited and 25% cured. Aldibert reviewed 308 cases, with 69.8% cured. The largest number of operated cases (358) has been collected by Roersch. Of these 250, or 70%, were permanently cured by laparotomy.

Up to the present time over 1,500 cases of peritoneal tuberculosis treated by laparotomy have been recorded. From these reports it is evident that the prognosis depends largely upon the anatomic form that the disease assumes. In the exudative or ascitic form, the prognosis is by far the most favorable, and can be conservatively stated as giving from 40% to 50% of definitive cures. The adhesive form gives a more unfavorable prognosis in that at most only 25% recover. In the ulcerating, caseating variety, the benefit of laparotomy is questionable.

The source of infection, *i. e.*, the location of the primary lesion, also influences the prognosis. In primary tubal tuberculosis, or in cases in which any of the accessible glands are primarily affected, the removal of the offending organ will render the prognosis more favorable. In primary lung tuberculosis it goes without saying that the prognosis as regards a permanent cure must always be dark.

Of the various hypotheses advanced to explain the manner of healing of peritoneal tuberculosis after laparotomy, we may mention: (1) The action of the anesthetic; (2) psychic influences; (3) operative trauma; (4) removal of ascitic fluid depriving the tubercle bacilli of nourishment; (5) increased absorption of the peritoneum; (6) removal of ascitic fluid containing ptomaines; (7) inflammatory reaction following entrance of air; (8) destruction of tubercle bacilli by septic inflammatory reaction following opening of the abdomen.

The way in which healing takes place in tuberculous peritonitis has been studied both from postmortem examination of partially healed tuberculous lesions and from cases in which a second operation has been performed. In 1895 Jordan studied 15 cases, in 4 of

which postmortem examination was made some time after the abdomen had been opened. In 11 the tissue examined had been secured at a second operation. He concluded that healing took place as a result of an active tissue proliferation by which the essential elements of the tubercle were compressed and destroyed. Pichini, Bumm, and Osler found connective tissue displacing the cellular elements of the tubercle, beginning first in the periphery and later extending to the center of the nodule. Riva found connective tissue substituted for the tubercle, but maintained that the proliferation began in the center, and not in the periphery of the nodule. He also asserts that the formation of connective tissue was subsequent to a degeneration of the central cells of the tubercle.

In two cases in which the patients were subjected to a second laparotomy Mazzoni found the tubercles surrounded by a zone of inflammatory exudate, the result of an increased vascularization of the parts following the operation. In the center of the tubercle vacuolation and degeneration of the epithelioid cells was observed. In other parts where the healing process was more advanced connective tissue had taken the place of these central cells.

Gatti (*Arch. f. klin. Chir.*, 1895), after an extended series of experiments on animals, concludes that the tuberculous lesions found in the peritoneum healed, not by proliferation of connective tissue, the result of an active inflammatory reaction, but as the result of hydropic degeneration first affecting the protoplasm and then the nuclei of the epithelioid cells. These cells are subsequently absorbed, along with which the bacilli and round-cells gradually disappear, leaving only the pre-existing connective tissue stroma with its vessels.

Gatti considers that as a result of simple laparotomy there follows a serous exudation in the peritoneal cavity which exerts an unfavorable influence on tubercle bacilli, destroying them or so affecting their vitality that they subsequently die and are absorbed.

The question of the danger of laparotomy in tuberculous peritonitis is of interest. Many authors hold that to open the abdomen in this disease is devoid of danger, *i. e.*, there is no mortality from the operation. This is generally true, but to demonstrate that outside of the risks incident to all operations, particularly the danger from general anesthesia, there may be a fatal termination due to the operation *per se*, we offer in evidence our first case reported. It is generally conceded that when the peritoneum is beset with tubercles its resistance against ordinary pus microorganisms is increased. Very few of these patients have died from septic peritonitis following laparotomy. In our case the fatal termination was due probably to a toxemia of some kind, the source of the toxic substance likely being the tubercles, or other products of tuberculous infection, which had undergone changes as a result of the trauma to which the peritoneum had been subjected.

Case II is reported to further support the evidence already at hand that extensive tuberculous peritonitis may entirely disappear after laparotomy.

CASE I.—Miss D., aged 19, had, up to two weeks before, been well. At that time she noticed that her abdomen was larger than usual. This rapidly increased and was associated with indefinite abdominal pain and obstinate constipation. There was some dysuria and a decided diminution in the quantity of urine. On examination the abdomen was found considerably distended and there was free fluid in the abdominal cavity. The thorax, liver, and pelvic organs were negative. There was no definite abdominal tumor, and the general appearance was fairly good. The skin was decidedly pigmented, so that it had a bronzed appearance, which suggested Addison's disease. The scleras were icteric. There was a slight, puriform vaginal discharge which, on examination, showed no tubercle bacilli nor gonococci. At the end of a week she was operated upon.

A second examination before operation showed an area of dullness extending from a point half way between the ensiform cartilage and the umbilicus and pubis. This area was wider in the mesogastrium than above and below, measuring at its widest part about four inches. On palpation there could be

felt a distinct tumor mass, spindle-shaped in outline and giving the sensation of fluctuation. This was freely movable laterally, but appeared attached above and below. On each side of this dull area was a tympanic area on percussion, until the area of free abdominal fluid was reached. A diagnosis of abdominal tuberculosis was made by excluding other forms of ascites. There was no history of tuberculosis in the family.

**Operation.**—The abdomen was opened by a median incision, and a large quantity of straw-colored fluid escaped. The intestine was firmly adherent in many places, and was closely studded throughout its entire extent with small miliary tubercles. The bursa omentalis was rolled upon itself, and in its lumen was fluid. The lower end of the omental tube was attached to the anterior abdominal wall close to the pubis. No attempt was made to separate the adherent coils of intestines. The fluid was evacuated as completely as possible and then drained.

The patient's condition during the first 24 hours following the operation was not materially changed; her temperature was normal, pulse rapid, and mind clear. At the end of the first 24 hours she was suddenly attacked with severe epistaxis, which was controlled by plugging the nares. Within a few hours hemorrhages began from all the mucous membranes. At the same time large purpuric spots appeared on the chest and the extremities, increasing in size and number until the entire surface of the body was covered. Intramuscular hematoma also developed. The temperature rose to 100° F., the pulse gradually became imperceptible, and she died in coma 36 hours after the operation.

The postmortem examination was made by Dr. Futterer, a half hour after death. General abdominal tuberculosis of the ascitic variety was found, with slightly enlarged mesenteric glands and firm adhesions matting together the whole mass of intestines. No foci were found in the lungs or pleura. There was no old tuberculous disease of the tubes. The intestinal mucous membrane was not examined.

Cultures from the peritoneal cavity were sterile; there was no pus infection of the peritoneum.

The points of interest in this case are: 1. The insidious onset of the disease. 2. The persistence of subnormal temperature. 3. Extreme pigmentation of the skin without Addison's disease. 4. The presence of a tumor in the median line of the abdomen extending from above the umbilicus to the pubis; and the tumor being formed by the great omentum becoming rolled upon itself and filled with fluid. 5. The termination of the case—death occurring 36 hours after the operation with signs of hemorrhagic diathesis. This was probably due to toxemia of some sort, the toxic substances probably being liberated as a result of the changes which occurred consequent upon operation.

**CASE II.**—B. B. is a young woman who was operated on for what was thought to be suppurative peritonitis following rupture of the appendix. Her illness began suddenly with a chill and severe abdominal pain which in the course of a few hours became localized in the region of the appendix. The temperature was high, ranging above 103° F. from the first. The abdomen soon became greatly distended, with marked rigidity of the abdominal muscles.

**Operation.**—The abdomen was opened through an incision along the outer border of the right rectus muscle on the third day after the onset of the disease. The peritoneal cavity contained a large quantity of turbid fluid, the walls of the appendix and cecum were greatly thickened, but no rupture occurred. The entire peritoneum was thickly studded with tubercles and dense adhesions, binding together the intestinal coils. The mesenteric glands were enlarged, some reaching the size of an English walnut. The appendix was removed, the cavity irrigated with salt solution and drained by tubular and gauze drainage.

The patient made a very slow recovery, leaving her bed at the end of three months. As soon as she was able to travel she was sent to Colorado. She remained there for two years and completely regained her health. At the time she left her bed she weighed about 85 pounds. When she returned to this city after an absence of two years she had gained 55 pounds.

As a result of the operation she had a ventral hernia for which she was operated on in the summer of 1899, three years after the first operation. The abdominal cavity was again opened and careful inspection showed that scarcely a sign of the former extensive tuberculous disease existed; all the tubercles had disappeared, the peritoneum was everywhere normal in appearance. Intestinal coils were nowhere adherent. The mesenteric glands had mostly resumed a normal appearance. There were a few calcareous deposits, surrounded by a wall of white fibrous tissue, seen here and there in the mesentery. Several of these deposits with surrounding fibrous tissue were excised and submitted to microscopic examination. No tubercle bacilli were found.

Since that time the patient has resided in this city and has been examined a number of times. There are no signs of tuberculous disease in any part of the body.

The interesting features of this case are:

1. The acute character of the disease, simulating closely acute appendicitis and the beginning of suppurative peritonitis at the time of operation.

2. Extensive abdominal tuberculosis, a part of which must have existed previous to the onset of the symptoms, although the patient was apparently in perfect health.

3. The complete recovery from the disease, as evidenced by return of health and disappearance of all tuberculous lesions of the peritoneum.

## CHRONIC BILATERAL PAROTIDITIS AMONG THE INSANE, WITH A DETAILED ACCOUNT OF FIVE CASES.

BY

DOUGLAS SYMMERS, M.D.,

of Philadelphia.

The literature of the parotid gland, so far as it concerns chronic parotiditis as a clinical entity, is exceedingly scant. Osler<sup>1</sup> refers to the affection in the following terms: "Chronic parotitis, a condition in which the glands are enlarged, rarely painful, may follow inflammation of the throat, or mumps. Salivation may be present. It may be due to lead or mercury. It occurs also in chronic Bright's disease and syphilis." The same distinguished author<sup>2</sup> reports a case of "chronic symmetrical enlargement of the salivary and lacrimal glands" in a negro girl, aged 11, who died later of pulmonary tuberculosis, and refers to the fact that Mikulicz<sup>3</sup> described a similar condition in 1892 as a form of chronic disease previously unrecognized and, further, that Kümmerl<sup>4</sup> reported a number of such cases and added three from the literature. Five of these patients presented chronic enlargement of the lacrimal, lingual and submaxillary and parotid glands. One involved all the salivary glands, particularly the right parotid, and another involved the parotids and submaxillaries, both cases following influenza. Still another was in a man of 47, who presented swelling of both parotids of several years' duration. This latter case, so far as I have been able to learn, is the first which appears in the literature of chronic bilateral parotitis pure and simple. To this I purpose to add five similar instances which were found among 800 insane patients in the Philadelphia Hospital—an incidence of .6%.

Delafeld and Prudden, in that chapter of their work on "Pathological Anatomy and Histology" which deals with the pathology of the parotid gland, dismiss the subject of chronic parotitis with the statement that "chronic inflammation, leading to the formation of dense interstitial tissue, sometimes occurs in the salivary glands. This may occur by itself or follow an acute inflammation." The pathologic histology of the following cases is doubtless allied to that of the chronic interstitial mammitis which Allot<sup>5</sup> describes in connection with pulmonary tuberculosis, and of which I hope to publish a case in the near future. This view is strengthened by the fact that the postmortem examination of the lacrimal glands in the case described by Dr. Osler revealed the substitution of fibrous tissue.

**CASE I.**—G. P., a German butcher, aged 41. Past history unknown.

**General Appearance.**—The patient is a weakened, gnome-like individual, 5 feet 1½ inches in height, weighing 102 pounds. He is frail and distorted in stature, of muddy complexion, and his facial expression is almost frog-like, the eyes protruding and either cheek being reinforced by a large ovoid tumor.

**Head.**—Taken as a whole the head approaches the shape of a square. The occiput is flattened and the hinder part of the vertex dips slightly inward and arises anteriorly only to turn abruptly at the upper forehead and recede rapidly downward and forward toward the frontal eminences which are noticeably large. The mastoid process of the temporal bone and the osseous surfaces in the immediate vicinity are very prominent. The ears are decidedly larger than normal and stand out unduly. The lobules are flattened and are joined on both sides by a thin bridge of tissue to the tremendously enlarged parotids. Starting slightly above the tragus on both sides and extending below the lobule and well into the neck anteriorly and into the region of the glenoid cavity behind, is an oval or egg-shaped mass. This mass is peculiarly soft and elastic to the touch and freely movable over a large area. Taken between the thumb and forefinger and rolled it imparts very much the same sensation as that which is received when the female mammary gland is similarly treated, except that the lobulations do not feel so large. The masses are symmetric in every respect, each being about three inches long, an inch in depth at its thickest part and  $1\frac{1}{2}$  inches from behind forward, the overlying skin is soft and downy, entirely bereft of hair and uniformly and deeply suffused with brownish-red pigmentation. In front and above each mass the malar arises boldly, so that a deep furrow is created which runs downward and inward from a point immediately beneath the junction of the ear and scalp and is lost in the region below the angle of the mouth. This effect is plainly shown in the accompanying photograph. The chin is somewhat pointed and sparsely dotted with stubby hairs. The mouth is loose and broad. The lower lip is negroid in type. There is nothing peculiar about the nose except a

Case I.—Taken for this article by Dr. G. E. Pfahler.

marked septal deviation toward the left and an hypertrophic rhinitis. The eyeballs bulge considerably. There is no visible enlargement of the lacrimal glands and no ptosis. The right pupil is larger than the left and oval in outline, its long axis being directed from without downward and inward. The reaction to light, to accommodation and to cutaneous irritation is normal. The hard palate is broad and distinctly dome-shaped. The teeth are imperfectly formed, irregularly distributed and veneered with tartar. There are no signs of salivation nor of xerostoma. The tongue is broad, flabby, moist and clean.

**Neck.**—The neck is rather short and thin. The sternocleidomastoids are brought into strong relief. The clavicles are prominent. The pons adami is well defined. The submaxillary, thyroid and lingual glands are not visibly enlarged.

**Chest.**—The chest is frightfully distorted. The right shoulder is elevated far above the level of its fellow. The anterior chest on the right side is flattened. On the left side, commencing at a point below the inferior angle of the scapula and external to the midscapular line, is a deep valley, irregularly S-shaped, which extends upward and inward and is lost below the axilla. The right scapular region bulges considerably, and there is a marked curvature of the spine in this direction. Expansion is only fair. Breathing is mostly abdominal. Deep inspiration is accompanied by a fibrillary tremor involving the superficial muscular structures of the left epigastrium and lower precordium. The nipples are small and normally placed. At the left apex the percussion note is impaired, particularly during respiratory percussion. The note at the right apex is hyper-resonant and approaches tympany in the neighborhood of the right axilla. The breath sounds are universally rough, particularly in the right axilla. No rales are heard. The apex beat is neither visible nor palpable, auscultation reveals no murmurs, the heart's action is slow, and the muscular element seems good.

**Abdomen.**—The belly is scaphoid, the skin loose and rough.

The liver is displaced downward, is easily palpable, and percussion reveals dulness three fingers' breadth below the costal arch in the mammillary line. The spleen is not palpable. Percussion under the costal arch below the region of the spleen does not disclose any change of note during the act of respiration, the note remaining constantly tympanitic during both inspiration and expiration. The genitalia are normal, no scars being visible.

**Limbs.**—The lower limbs present no abnormality. The gait is loose and shuffling. Knee-jerks are normal. No Babinski, no ankle clonus. Station is good. No edema.

**Urine.**—pale amber, S. G. 1.012, acid, flocculent sediment, no sugar, no albumin.

**Sputum.**—No tubercle bacilli found.

CASE II.—T. S., aged 67, mulatto, hostler, American.

**Family History.**—Negative.

**Personal History.**—(Abstracted from hospital records.) Left-sided facial paralysis in 1878. In June, 1894, patient is said to have suffered "an attack of hemiplegia," after which he displayed evidences of mental deterioration. Drank and smoked to excess. Habits irregular and erratic. Probable specific infection.

**General Appearance.**—The patient is an elderly mulatto of athletic proportions. A well-marked ptosis of the left lid, together with the position of the head, which is inclined toward the left shoulder, lends a peculiar inquiring expression to the face.

**Head.**—The head is well formed, with the exception of the forehead, which retreats rather too rapidly. The vessels of the temporal region are tortuous and hard. The ears, compared with the size of the head, are small and stand out prominently. The lobules are flattened, and communicate with a mass in either parotid region through the medium of a thin span of skin. The right ear exhibits a small tubercle on the upper helix. As the patient lies in bed, a decided prominence is observed on the right side in the region of the parotid gland. A similarly formed, but smaller and less conspicuous enlargement is seen at a corresponding point on the opposite side. The mass on the right is irregularly ovoid in shape, soft and elastic, freely movable, painless to manipulation, and its consistency is unaffected by movements of mastication. The skin over the mass is unattached. The enlargement commences a little below the roof of the zygoma anteriorly and extends downward in the direction of and into the neck for a distance of about  $1\frac{1}{2}$  inches below the angle of the mandible. Behind it extends above the lobule of the ear and into the region of the glenoid cavity. As the patient occupies the recumbent posture this mass tends to fall backward upon itself and to assume more prominent proportions. On the left side the mass, while smaller in size, corresponds to its fellow, except that it appears to be more conspicuous when the patient is in the standing posture when, indeed, with the head erect, both masses are nearly symmetric. The tongue is broad at the base and tapers finely at its free extremity. It is fissured, tremulous, thinly coated, and protrudes with marked deviation to the right. The palate is highly placed and narrow. The cornea is surrounded by a distinct ring of fatty degeneration, and the conjunctiva displays isolated patches of the same character. The pupils are tightly contracted, equal in size and regular in outline. They respond but sluggishly to the stimulation of light and to the influence of accommodation. There is distinct ptosis of the left lid. There is no nystagmus, and the movements of the eyeball are apparently unrestricted. The lacrimal gland is not enlarged.

**Neck.**—No enlargement of the submaxillary, lingual or thyroid glands is visible. The carotids throb unduly.

**Chest.**—The chest is full and splendidly formed. Expansion is normal. The mammary glands are normally placed but decidedly enlarged. They are freely movable and firm in consistency, the lobulations are palpable and each nipple is surrounded by an area of dark brown pigmentation the size of a half dollar. Manipulation is not productive of pain. The apex beat is diffuse, the aortic second sound is sharply accentuated, but no murmurs are heard. The lungs are apparently healthy.

**Abdomen.**—No abnormality detected. Spleen not palpable.

**Extremities.**—The gait is ataxic. Knee-jerks totally absent. Station only fair. Pulse rather irregular, 90 to the minute and incompressible. The artery is extensively beaded by atheromatous deposits. The legs display a number of symmetrically distributed scars, most probably specific.

**Speech.**—Slow, interrupted, stumbling.

**Urine.**—Dirty amber, S. G. 1.030, acid, flocculent sediment, no sugar, no albumin, no casts, amorphous urates, pus cells and epithelia, cylinders and bacteria.

CASE III.—L. D., aged 58, white, cigarmaker, Cuban.

**Family History.**—Negative.

**Personal History.**—(From hospital records.) Patient has had gonorrhoea, gastrodynia, influenza, rheumatic arthritis, quinsy, and malaria. There is also a history of smallpox (probably syphilis). Was salivated on one occasion. The patient was a soldier in Cuba, and was frequently wounded about the head. He was addicted to the excessive use of alcohol and tobacco, masturbated until the twenty-fourth year and indulged freely in venereal excesses.

**General Appearance.**—The patient is an elderly male, whose face, scalp and neck are strikingly swarthy. There is an extensive almost universal dilation of the superficial veins,

more especially those of the abdomen, which form a veritable network. The skin is lax and rough, and the subcutaneous tissues wasted. The surface is extremely hairy. The hands and eyelids are involved in choreiform movements.

**Head.**—The head is well developed. There is no noticeable deformity of the ears with the exception of flattening of the lobules and partial obliteration of the antitragus on both sides. In front of, behind and below the ear on either side is a mass, oval in shape as the patient lies in bed, and conforming somewhat to the general outline of a square as the patient assumes the upright posture. Each mass is about 2½ inches from above downward and an inch anteroposteriorly. It is thickest at its center, which is below the tragus, and fades gently away into the tissues of the neck below the angle of the jaw. It arises below the zygoma in front and below the glenoid fossa behind. Both masses are freely movable, painless, rather soft to the touch, and over them the skin is easily and independently movable. The palate is high and narrow, and noticeably deep in the region of the anterior palatine fossa. The tongue is thinly coated and tremulous. There is some pouching in the region of the lingual gland. The patient attempted to bite when an effort was made to explore this region with the finger. In the corresponding region behind the chin, however, no enlargement could be felt.

**Neck.**—There is no detectable enlargement of the thyroid or submaxillary glands.

**Chest.**—The clavicles, lower ribs, and xiphoid cartilage are prominent, the latter turning abruptly and pointing directly outward. At the apices expansion is delinquent and abbreviated, the percussion note is impaired to the extent of dullness and auscultation reveals bronchial breathing, but no rales. The apex beat of the heart is displaced downward and to the left, the aortic second sound is accentuated, but no murmurs are audible.

**Abdomen.**—The abdominal walls are thickly beset by dilated veins. Liver dullness extends three fingers' breadth below the costal arch. The spleen is not palpable. Respiratory percussion below the costal arch in the splenic area discloses no change of note.

**Extremities.**—The gait is awkward. Knee-jerks somewhat exaggerated, no Babinski, no clonus. The legs are dotted over by a number of scars, probably a legacy from syphilis. No edema. The radials are atheromatous.

**Urine.**—Amber, 1,020, acid, no sediment. Trace of albumin with heat and the nitromagnesium test. No sugar. Numerous hyaline casts, a few granular casts and some studded with urates, epithelial and white blood cells, and moss-like clumps of urates.

**CASE IV.**—L. S., aged 60, negro, American. Family and personal history unobtainable.

**General Appearance.**—An adult negro, well nourished, fairly well developed and of muscular proportions.

**Head.**—The head is small in proportion to the body. The nucha is thick and full and the forehead is decidedly sloping, the combined effect being to produce a pointed occiput. The upper scalp is bald. The ears are very small, highly placed and lie close to the scalp. The helix is almost entirely obliterated and the triangular fossa exists in the form of a deep, gently curving depression which slopes downward and inward to be lost as it approaches the most prominent part of the antihelix. The lower lobe is ill-shaped, flattened and is continuous with a bulging mass which occupies the parotid region on both sides. It is most noticeable in the recumbent posture. It is three inches measuring downward, about an inch measuring anteroposteriorly, and an inch in depth at its thickest part. It extends from above the tragus well below the angle of the lower jaw and behind the lobule of the ear. It is soft and pliable, painless, movable, and its consistency is not altered by movements of mastication. The overlying skin is unattached. The tongue is coated and tooth-marked, moist and tremulous. The palate is high and narrow.

**Neck.**—The neck is thick and short. No glandular enlargements are present.

**Chest.**—The apex beat is displaced downward and outward and is forcible. No murmurs audible. The second aortic is accentuated.

**Abdomen.**—The belly walls are greatly distended, tense and but slightly yielding. Percussion gives a tympanitic note distributed over practically the entire abdominal surface, the pitch changing at places, but the note retaining withal its tympanitic quality. This condition has been present for years, and has never seemed to cause the patient any particular inconvenience. His bowels move with a fair degree of regularity, and not much flatus is passed in the interim. Liver dullness is replaced by tympany. The spleen is not palpable. There is no apparent impediment to the action of the heart or lungs. The most active medicinal treatment does not seem to have the slightest influence in relieving the distention. The underlying source of this marked and persistent distention is probably the so-called "idiopathic dilation of the colon," of which some remarkable examples have been recorded.

**Extremities.**—The lower limbs are thickly scarred, probably the remains of a specific eruption. There are other scars scattered over the body which are doubtless of like origin. There is fairly extensive edematous infiltration of the pretibial structures and of the tissues of the penis. No scars appear on the latter organ.

**Urine.**—First examination: Amber, 1,015, acid, no sediment, no sugar, no albumin, no casts, numerous leukocytes, epithelial cells and one so-called "kidney cell," cylindroids. Second examination: Amber, acid, 1,012, no sediment, no sugar, no albumin by heat, nitric acid and nitromagnesium solution; pus cells, epithelia and cylindroids. Note: The hospital records for 1888 refer to a trace of albumin in the urine, without casts.

**CASE V.**—J. F., aged 45, white, grocer, German.

**Past History.**—Unobtainable.

**General Appearance.**—The patient is of excellent stature. The facial expression is that of stupidity and listlessness, the eyes dull and sleepy, the mouth broad and heavy. The face as a whole is square.

**Head.**—The head is only fairly formed. The forehead is retreating, the occiput flattened and the malar bones protruding. The ears are prominent and, with the exception of a large antitragus, are normally shaped. The arteries of the temporal region are tortuous. Below and in front of the right ear, and to a lesser extent behind the lobule, is a large egg-shaped swelling which arises just opposite the tragus, at which point the skin is deeply creased and wrinkled and attached to the lobule. This tumor attains its point of greatest thickness just above the angle of the jaw, whence it slopes gently downward and is lost below the ramus. The skin over the mass is unattached, deeply pigmented a brownish-red and hairless. The tumor itself is movable, painless, and elastic to the touch. Precisely the same condition obtains on the opposite side save that here the mass is not so large. The lips are negroid, especially the lower, which is bulky. The palate is broad and flat, anemic and more deeply corrugated in the region of the anterior fossa than normally.

**Neck.**—No glandular enlargements visible.

**Chest.**—The superficial veins of the upper chest are dilated, as indeed are those of the abdominal walls and extremities. The lungs are apparently healthy. The heart sounds are distant and muffled, but no murmurs can be heard. The pulse is hard and incompressible, the vessel atheromatous.

**Abdomen.**—No further abnormality detected. The spleen is not palpable and the hernial orifices are not occupied.

**Extremities.**—There is no edema.

**Note:** The hospital records under date of January 1, 1900, 2½ years before the above history was taken, read: "J. F. is just recovering from a severe laryngitis, which appeared to follow a pleurisy of about 2 weeks' duration. This began with a friction rub anteriorly. A small effusion formed, then disappeared, and a 'brassy' cough with pain in the throat began. A gray ulcer was seen on the left wall of the larynx."

**Urine.**—Amber, S. G. 1,020, acid, no sugar, no albumin, no casts.

In Case I of my series I am led to believe that the condition is one which may be regarded as a stigma of degeneration. In support of this view the following facts may be offered: The patient is an imbecile who, in addition to defective mentality, presents a number of physical infirmities commonly referred to as stigmata of degeneration, namely, malformation of the skull, large and illformed ears, broad and dome-shaped palate, pointed chin, negroid lower lip, pronounced deviation of the nasal septum, irregular, uneven and misshapen pupils, imperfect teeth, rotary lateral curvature of the spine and thoracic deformities. There is no obtainable history of syphilis and no signs of its existence. The analysis of the urine and the condition of the circulatory apparatus negative nephritis as a possible cause. Again, the delicately symmetric distribution of the parotid lesions, the fact that they are known to have existed for 10 years without altering in size, the peculiar pigment formation and the total absence of hair from the skin which covers them, confirm rather than refute this view.

In Case II syphilis first demands consideration as the most probable etiologic factor. In addition the accentuated aortic second sound, the atheroma of the peripheral arteries, the age of the patient, the history of alcoholism and of syphilis are more than vaguely suggestive of the existence of some kidney lesion unrevealed by the analysis of the urine.

In Case III there is a history of influenza, quinsy, alcoholism, salivation (most likely from mercury), and a suspicious history of syphilis with almost positive signs of a former specific eruption. Moreover, there are distinct signs of an apical tuberculosis and of a severe nephritis.

In Case IV, despite the absence of albumin, even in delicate trace, and of casts, it would seem superfluous to seek further for an explanation of the edematous condition of the lower extremities and of the penis. The

age of the patient, the probable existence of syphilis, the low specific gravity of the urine, the signs of cardiac hypertrophy without ruptured compensation as exemplified in the downward and outward displacement of the apex beat and its forcible impulse, the accentuated aortic second sound and the atheromatous condition of the peripheral arteries, appear to be sufficient to warrant at least a tentative diagnosis of interstitial nephritis and thus to explain the presence of the edema.

In Case V there is a history of an ulcerative laryngitis which may have been responsible for the parotid lesion.

Each of these cases has several points in common with the others. All the patients are above 30 years and present mental cases; all exhibit more or less acceptable stigmata of degeneration; three are almost unquestionably syphilitic; and, with the exception of Case I, nephritis has either been proved to exist or there are strong reasons for suspecting its existence. Few patients in the Philadelphia Hospital above 40 years of age go to autopsy and present normal kidneys.

Kyle<sup>6</sup> refers to a number of cases<sup>7</sup> reported by himself, of enlargement of the thyroid gland due, he believes, to the precipitation of certain substances which irritate this gland and stimulate its blood supply. He states, further, that he is convinced that a study of the saliva would reveal any alteration in the chemistry of the body, since "the secreting glands receive from the blood the supply from which they elaborate certain chemic compounds" so that "if an analysis be made of the composition of such secretion it would give a good index to the general condition of the individual. . . ." Such an explanation seems most fitting in the cases here reported. It is quite probable that certain cases of syphilis, nephritis and other morbid conditions are attended by the elaboration of irritant substances which bear a selective affinity for the structures of the parotid glands and that these substances exist in the saliva, in which one skilled in the details of organic analysis might be able to detect them. For a similar reason it seems probable that the prolonged use of such drugs as potassium bromid, iodine and iodoform, arsenic, antipyrin, mercury and salicylic acid might affect the parotids in the same way, since these drugs are eliminated in the secretions from these glands.

There is but one condition of which I have knowledge with which chronic bilateral parotitis could be confused, and that is symmetric hypertrophy of the masseter muscles, of which I have seen two cases. In the relaxed state the sensation imparted to the palpating finger is very similar, but immediately the patient exercises these muscles in the act of mastication the difference is apparent.

In conclusion, I wish to express my thanks to Dr. G. E. Pfahler, formerly assistant chief resident physician in the Philadelphia Hospital, for furnishing the photograph which accompanies this article.

**Typhoid Traced to Milk Supply.**—It is asserted that a contaminated milk supply is responsible for the numerous cases of typhoid which have lately appeared in Paterson, N. J. It was found that in 80% of the cases milk was supplied by one dealer. Investigation showed the presence of germs in this milk and from this finding the source of the contagion was traced to a family in the vicinity, several members of which were afflicted with typhoid fever and which supplied milk to the dealer in question. In order that no delay shall occur in locating the source of contagion should a future outbreak occur the Board of Health has adopted an ordinance requiring each dealer to notify the board from whom he receives his milk.

## TEA AND COFFEE INTOXICATION.<sup>1</sup>

BY

EMIL KING, M.D.,

of Fulda, Minn.

My reason for calling your attention to this subject is its importance to our patients and its apparent neglect by the medical profession. Few persons are found who do not use one or the other of these beverages every day, and the quantities consumed by this nation alone in one year in the aggregate are enormous. Both tea and coffee contain relatively large proportions of active ingredients, and we may be surprised that we do not meet even more cases of poisoning. Textbooks on the practice of medicine and on nervous diseases are silent on this question and its literature in our medical journals is scanty. The subject has not been as exhaustively studied as its importance demands and our attention is called to it so seldom that we are not impressed with its seriousness. Knowing so little about it we do not weigh its gravity, and in my opinion we are not properly on our guard to recognize the symptoms and to guard our patients against them. I feel certain that cases of poisonous action by tea and coffee are relatively frequent and that they are often overlooked. That the moderate use of these substances is probably highly beneficial is not to be denied, but we must also realize that excessive use leads to harm.

The active principles in tea and coffee are thein, caffeine and tannin. Tea contains from 3% to 5% of the former and from 5% to 10% of the latter, according to kind and quality.

In roasted coffee we find caffeine, from 1% to 2%, caffeine-tannic acid and several empyreumatic and volatile substances developed during the roasting process, some of which are collectively known as caffeine. The peculiar flavor in both tea and coffee depends on volatile oils which are present in minute quantities. The caffeine, thein and the tannic acid are the substances which do good or harm as the case may be. Chemically, caffeine and thein are said to be identical, it being stated that most of the caffeine in the market is manufactured from cheap tea, yet physiologists are not in entire accord, some claiming them to be identical in physiologic action, others denying this statement.

The physiologic action of caffeine and thein, stated briefly, is as follows:

1. They cause wakefulness, greater capacity for mental labor, and increased activity of thought by stimulation of the brain cells. Increase of the reflexes through stimulation of the spinal cord.

2. The heart's action is strengthened, being first slowed and then becoming more rapid and irregular. This effect is likened to that of digitalis but is more evanescent and also more rapid. It is generally conceded that this effect is due to stimulation of the medulla and not to direct action on the heart.

3. Diuresis occurs by direct stimulation of the secretory epithelium of the kidney, the solid as well as the liquid constituents of the urine being increased.

4. Thein is said, by some authorities, to have the following action in addition to the above: It causes a fall in body temperature while caffeine causes a rise; its action is more marked on the sensory system and caffeine on the motor system; it is a powerful local anesthetic and analgesic, while caffeine has no such effect.

5. The tannic acid exerts its wellknown astringent properties on the alimentary canal and undoubtedly has an injurious effect on gastric and intestinal digestion through the formation of insoluble compounds.

From this briefly outlined physiologic action of the principal active constituents of tea and coffee we can expect the following reactions when used to excess:

1. Constant overstimulation of the brain leads to exhaustion, the attendant train of evils being insomnia,

<sup>1</sup>Read before the Southwestern Minnesota Medical Society at a meeting held at Fulda, Minn., July 24, 1902.

vertigo, headache, neuralgia, flashes of light, mental dulness with exhaustion of mind, disinclination to work, and melancholia with apprehension of evil.

2. Increased and irregular heart action, ringing in the ears, muscular tremors, hyperesthesia and paresthesia, general weakness and disinclination to physical exertion.

3. Various forms of gastric and intestinal indigestion, with loss of appetite, formation of gas, tenderness of the stomach, with neuralgic pains in the abdomen.

4. Diarrhea when using coffee, and constipation with alternating attacks of diarrhea when using tea.

5. Loss of bodily weight.

Patients showing a mild degree of intoxication frequently present themselves for treatment, and the following symptoms are noted: Lassitude, mental and physical, sleepless or restless nights, headache or neuralgia, loss of appetite with fermentative dyspepsia, constipation in tea drinkers and some disturbance of the heart. Indeed, irregular heart beat is so nearly constant and peculiar in these cases that I regard it as almost pathognomonic of this condition and call your attention especially to it. When found, and alcohol and tobacco as a cause have been eliminated, you should suspect excessive use of either tea or coffee.

Two cases of such inebriation have been under my care within a year, the histories of which are interesting:

Last September I was called to see Mrs. G., an American, aged about 50. She gave the following history: She has been an invalid for many years, having been troubled with chronic constipation and biliousness, for which she has been under medical care a number of times. For several years the constipation has alternated with diarrhea, which latter condition has been constant for about eight months and on account of which I was called to see her. For several months she has been confined to her bed the greater part of the time on account of general debility. She is subject to insomnia, severe headaches and abdominal pains, is inclined to be melancholic and is resigned to her invalidism with the exception of the loose bowels. She is markedly emaciated, the skin is moist and has a peculiar yellowish and muddy appearance, a color I had once before seen in a case of chronic tea poisoning with obstinate constipation. Her temperature was slightly below normal, the heart's action weak and irregular. The abdomen was tender in the epigastrium and right costal margin, and tympanitic. Her lips were tremulous. I learned that she drank tea before breakfast, several cups with the meal, several more before dinner and so on through the day; like all toppers she drank it strong, early, late, and often. The treatment in this case consisted in forbidding her indulgence, in thoroughly flushing out the bowels, and the administration of Dover's powder, belladonna, and washed sulfur. She will not give tea up entirely and consequently she still remains an invalid, although she is now much more comfortable, in fact is as well as she cares to be.

The second case is that of W. H. K., Irish by birth and a farmer by occupation. He is 52 years of age, is a man of good habits, using alcohol and tobacco in moderation. He had pneumonia and pleurisy 14 years ago and has had attacks of bronchitis in the winter several times since. For the last four or five years he has had good health. His health began to fail early last January, when he lost all desire for food and became emaciated and too weak to leave the house. He had moderate diarrhea with undefinable pains in the stomach and bowels. There was great restlessness, inability to sleep and marked mental depression, and expecting to die he arranged his affairs accordingly. I saw him for the first time on February 19, when he presented the following picture: The face was pale and melancholic, tongue thickly furred. The lungs showed some bronchitis. The heart was normal in size but the beat was very uneven in time and tension. There was no evidence of arteriosclerosis. The reflexes are normal. Gait is steady but the hands and lips twitch. The urine was normal. The stomach was dilated, and the entire abdomen was dilated and tender on pressure. The pain was subjective, since palpation gave no pain when his attention was drawn to something else. I was unable to find organic disease and put him on general treatment. During the following two weeks he called on me several times, once with his minister, because the attacks of extreme restlessness with heart palpitation made him fear impending death. Early in March I again carefully examined him after one of his bad spells and told him I could find no organic disease and saw no reason why he should die. I explained to him that his peculiar symptoms were a puzzle to me and that I could account for them only on the theory of excessive use of either alcohol or tobacco. He then stated that he perhaps used coffee to excess. He drank about a quart after dressing in the morning, three or four cups with each meal and another generous draught before retiring at night. During his three months' illness he had been living on the drug and this explained the etiology of the case and the reason why he steadily grew worse

in spite of good nursing and otherwise careful treatment. The coffee was stopped at once and a roasted cereal preparation was substituted. I gave him bromids in moderate doses with nuxvomica, and for the diarrhea a powder containing Dover's 0.13 gram (2 grs.), pulv. kino 0.06 gram (1 gr.), washed sulfur 0.45 gram (7 grs.), four of these powders being taken during 24 hours. I also insisted on a generous mixed diet, assuring him it would cause no additional abdominal distress. In a few days he was able to sleep, the diarrhea lessened and the nervousness gradually passed away. The melancholia also left him and he made a good, although slow, recovery and by June he was in his usual condition of health.

This case taught me a useful lesson. I thought I knew my patient so well that it was unnecessary to question him closely as to diet during my first examination, and only my remark of the similarity of his symptoms to those caused by the use of alcohol and tobacco to excess led to the discovery of the cause of his illness.

These two cases present the symptoms most often noted, but many other manifestations have been described, such as epilepsy, intense vertigo simulating Ménière's disease and being mistaken for it, muscular pains and cramps, and even blindness has been caused by coffee. It is stated that total blindness is common among the Moors, especially in those over 50 years of age. In that country coffee is used to excess to a much greater extent than with us, for it takes the place of alcohol. Tea toppers as a rule belong to the fair sex, and the nervous manifestations seen as a result of its use are as protean as seen in hysteria.

Dr James Wood made an exhaustive study of the symptoms in 25 cases of tea intoxication, with the following result:

Simple headache.....	80%
Facial or capital neuralgia.....	92%
Vertigo.....	86%
Mental confusion.....	48%
Restlessness.....	48%
Hallucinations.....	16%
Nightmare and dreams.....	20%
Dependancy.....	44%
Anxiety.....	52%
Excitement.....	28%
Insomnia.....	56%
Palpitation of the heart.....	76%
Nausea.....	60%
Gastric and intestinal indigestion.....	56%
Bowels, constipation.....	48%
" alternating with diarrhea.....	28%
" diarrhea.....	8%
Sinking sensations in the pit of the stomach.....	52%
Anorexia.....	52%
Muscular tremors.....	61%
Pains other than in head.....	44%
Dyspnea.....	24%

These cases were observed during the summer time the percentage of serious symptoms being greater than usual as people drink more in hot weather.

In the treatment of these patients the essential point is to stop the habit; without this, relief is not to be expected. This is often difficult to accomplish, especially with women, as they are notoriously harder to control than men. Medicinal treatment is symptomatic and good recoveries may be expected if the habit is given up. I find no evidence that this form of inebriation leads to organic disease like alcohol, although the insane asylum reports of Ireland give excessive tea drinking a prominent place in the causation of lunacy in that country.

The susceptibility to this form of inebriation varies according to age, sex, occupation, susceptibility, temperament and climate. When used to excess the detrimental action is quite constant and some of the well defined symptoms outlined may confidently be expected.

From this brief study we should bear this condition in mind that we may give our patients the best advice and properly safeguard the public health.

## THE NATURAL STRUGGLE OF MANKIND AGAINST CONTAGIOUS DISEASE.

BY

CLAUDE DU BOIS-REYMOND,

of Berlin, Germany.

According to modern theories, tuberculosis is commonly said to be simply a contagious disease. This applies to a majority of the cases; the exact proportion, however, is not stated. If we compare what I propose to call the "*contagious energy*" of contagious diseases, most of the other typical forms—for instance measles—certainly far surpass tuberculosis, but this difference only relates to time—duration. Measles will certainly infect earlier and, in a given period oftener, than tuberculosis, but essentially the manner of propagation is the same—germs passing immediately from the diseased to the healthy individual, from man to man. This view has raised the hope that the ravages of tuberculosis may be gradually abated if as many patients as possible are detained in special infirmaries and at the same time all ejected germs destroyed, whenever that can be done; in short, if the chances of infection are lessened.

Bacteriology, in originating this theory, has certainly placed the clinical aspect of tuberculosis in an entirely new light. We are all familiar with the bacteriologic description of the tuberculous patient, scattering about him myriads of deadly germs, and daily and hourly threatening all around him with the terrible virus. If such visions are met in scientific papers, confirmed to all appearance by irrefutable experiments, small wonder that the fear of bacilli suggests to popular imagination even more exaggerated terrors. The very idea of contagion seems to partake of a contagious nature. It creeps into medical theory, favored perhaps by tempting hopes of a future easy and certain prevention of the disease and slowly, but surely, leads to overestimating the risk of infection. It seems surprising nowadays how little notice was taken of this risk before bacilli had been discovered. Surely the disease was well enough known to clinicians. They also seemed at the time to have judged pretty correctly the contagious energy of most other diseases, when they did not, indeed, err on the other side, by mistaking for contagious forms those which we now know to be not such. A certain degree of contagiousity was suspected at all times. Popular opinion in particular seems to have entertained some such ideas, but certainly nobody would have admitted that such stringent preventive measures as those mentioned could possibly be useful, far less necessary. The old and the new opinions on the subject seem, in fact, irreconcilable. Perhaps so sudden a change in the views of many medical men may be explained by the circumstance that the quality which I have termed "*contagious energy*" has hitherto, to my knowledge, never been precisely defined. We read and are taught that, according to common experience, clinicians consider a certain disease more contagious and another less so, but such judgments are based only on personal impression, instead of calculation, to which the question would seem perfectly well adapted.

The spreading of an epidemic is, indeed, not unlike the propagation of organic species, at least in numerical respect. Like the latter, the former may be reduced to certain rules, and therefore calculated. If a species consists of an equal number of individuals at the beginning and end of a given period, we must conclude that within that period increase and loss have been equal. Take, for instance, the census of a population. If it is the same on the first and last day of a year, it follows that within that year equal numbers of births and deaths have taken place. We can apply the same principle to any disease. Whenever a disease has not changed in frequency, the number of fresh cases must equal the loss of old ones—recovery and death, of course, both counting as loss. With the help of a little statistic research this self-evident proposition enables us to measure with sufficient accuracy the relative contagious energy which any genuine contagious disease may display.

Now, where true values of frequency are needed statistic evidence certainly is often misleading. But we only require a statement of unchanged frequency within a limited period, and for that we safely rely on statistics. Any omission may be supposed to affect all numbers equally; we are therefore justified in comparing them, as the error is practically eliminated. Statistics, however, show that some contagious diseases locally and periodically change in frequency. At intervals they rise to enormous epidemics, and again dwindle away to the lowest rates. From this we infer only that the measure of contagious energy which we are seeking may vary within certain limits. We must, in some cases, be content with an average figure that may be applicable only to a certain time and place. But most of our clinical knowledge is subject to similar restrictions. Speaking of variable contagious energy we do not wish to be understood in a literal sense. What really changes is probably, in most instances, not the nature of the virus, but of the medium acted upon. The term, of course, is a mere abstraction, intended to denote the absolute change in the frequency of infection, however caused.

Now we propose to measure contagious energy by the average number of healthy individuals infected by one single case and within one daily period, and this number we will call the "*daily rate.*" To simplify calculation let us first consider a fictitious disease of a perfectly regular character. We give it one day's duration, letting it begin one day after infection, and assume that under these conditions the frequency does not change. Let us suppose further that all men have equal predisposition for infection, which occurs from man to man only and once only in every individual. Evidently the daily rate is in this case unity. One average sick infects but one healthy individual. After one day all the sick of the preceding day are gone and an equal number of healthy appear on the sick list. The total figure of sick is every day the same. This daily rate, equal to one, we consider as a unity of contagious energy which we can apply as a measure to real diseases. This example is also well suited to show how swiftly frequency must rise or fall whenever the supposed balance is disturbed. Leave the duration of one day unchanged, but double the contagious energy (making the daily rate equal to 2) and the frequency will daily double, rising by powers of 2, as in the wellknown oriental tale of the chessboard: 1.2.4.8.16.32... Starting from one single case such a disease would have infected the whole population of the earth (estimated at about two thousand millions) after 30 periods, or within a month. If we now leave the daily rate unchanged but increase the duration to two days, the number of cases will rise almost as quickly as before. Within two days each sick will now infect two healthy. The daily infections then follow another kind of progression, complicated by the circumstance that part of the sick of each day will remain sick and consequently count a second time on the following day. The series has the peculiarity that every member is the sum of the two last preceding members. Starting from one case it runs: 1.2.3.5.8.13..... By means of the theory of catenary fractions any required member can be approximately calculated. I find that after the forty-fourth day this contagion would again have traveled over all human kind. On reversing the propositions the infections must fall at the same rate. Starting from one thousand millions of sick (the number of fresh infections on the thirtieth and last day) but reducing the "*daily rate*" to  $\frac{1}{2}$ , the number of cases falls, as it has risen, and after the thirtieth day it would arrive at 0, the disease would end. To reverse the conditions of the second series is not quite so simple. On account of the aforesaid complication the fall cannot be identical with the rise. But doubtless, on establishing suitable propositions, it may be caused to fall from its highest value to less than unity within the same lapse of time. Let us now suppose that neither increase nor decrease takes place, the number of sick remains constant. A very simple reflection will show what condition must be fulfilled in this case. Every sick within the space of his own contagious period must on an average infect but one healthy individual. It is because this new infected case takes the place of the departed one that the total number remains stationary. This state of things, generally speaking, is always arrived at if we divide the "*daily rate*" by the same figure by which the contagious period is

multiplied, or inversely. Or, stated otherwise: daily rate and period are, under this condition, reciprocal values. A somewhat important conclusion therefore follows from these apparently self-evident propositions. Of all contagious diseases maintaining an equal frequency during the period of observation we may state that their contagious period and their daily rate, *i. e.*, their contagious energy, are inversely proportional. That epidemics can spread and decline very rapidly is of course a well-known fact. If we have explained it theoretically at some length it was only to show that the equilibrium is in a state of great lability. The two factors are, as it were, balanced on very sensitive scales and the proportion is therefore highly exact whenever frequency really is approximately constant.

Consequently it is no mere casual coincidence that among known contagions the more active ones are throughout of shorter duration, and we may safely infer that the more chronic diseases possess in proportion less contagious energy the longer their contagious period extends. We must except, however, all epidemics rapidly changing in frequency, and, therefore, in contagious energy. They will, during such changes, recede further from this rule.

As a practical test let us take measles. I fear it is not accurately known what average number of days a case of measles must be called contagious. But the number might be approximately ascertained without much difficulty by close study of a smaller epidemic in a medium-sized town. Such research not coming within my reach, I will suppose at random that a period of 10 days would be found, which is about equal to the time of incubation. We would then affix to measles the daily rate: 0,1, that is to say: One case produces a second case within 10 days or 10 existing cases will cause one fresh infection per diem. At first, while the epidemic is spreading rapidly, the daily rate will of course be somewhat higher and toward the end a little lower, only in the middle period of the epidemic, when its frequency is approximately constant, the normal value of 0,1 is correct. The daily rates corresponding to the rise and fall, however, need not diverge very markedly from the normal value. The smallest numbers of cases that open and close the epidemic are of course almost accidental. They cannot give correct daily rates. The true rates probably vary within very narrow limits. That is best seen by comparison with our calculation if we substitute a period of 10 days for the one-day period. For, if the daily rate were doubled, we thus find that one single case must have produced two thousand millions after 300 days or in about 10 months. If it were lowered by one-half an equally rapid fall must take place. Evidently such variations are not borne out by ordinary experience. We know that the highest daily rate of measles, as of other contagions, occurs whenever they happen to travel into uninfected regions, as was observed by Panum in the well-known epidemic on the Faroe. These islands had been spared by the disease for 65 years when one case landed. Within about 7 months 6,000 persons or somewhat more than  $\frac{1}{2}$  of the whole population sickened, although the distribution of a scanty population over several islands was unfavorable to a quick spread of the disease. This growth from 1 case to 6,000 within 21 periods corresponds to a daily rate of not quite 0,15, or almost  $1\frac{1}{2}$  of the usual value (if it is permitted to apply our hypothetical period of 10 days). As, however, this figure is only an average for the whole extent of the epidemic, we should estimate the beginning a little higher, probably about twice as much. One average sick at the outset of this epidemic might therefore be supposed to have infected from two to almost three healthy persons within 10 days. Daily rates of similar height are certainly uncommon. But epidemic influenza or medieval plague may sometimes have attained or even surpassed these rates, both diseases that also revisit the same regions at long intervals and then spread very rapidly.

We will now try to apply the theory to tuberculosis. I am not sure whether tuberculosis is just now increasing or declining. But certainly the change, if any, is progressing so slowly that for the space of a year or even 10 years the daily rate may be considered fairly constant. Next we ought to ascertain the length of the contagious period. In the opinion of contagionists a tuberculous person is infectious from his first discharge of virulent bacilli to his last, whether the disease ends in recovery or in

death. Specialists on tuberculosis doubtless could state accurately the true average length of this period. Having no such exact data at my disposal I shall again be content with a free estimate. The period certainly is many times longer than in measles. I would suppose it to be more than one year and less than two; let us call it 500 days. For on one hand, we must consider the acute cases that sweep away the patient in a few months, on the other the probably larger number of chronic sufferers that linger for several years. I lay no stress upon the exact figure, but only on the fact that the length of time is approximately of this order. Supposing it to be 500 days, the daily rate must be 0,002. An average case will last 500 days until it ends by recovery or death and leaves one fresh case behind. Or, if one healthy person is to sicken every day, 500 cases must be present. Measles would be 50 times more contagious than pulmonary tuberculosis. Such a risk of infection appears insignificant if one recalls the vision of the tuberculous patient as described above. For the greater portion of humanity in ordinary traffic it may be called practically non-existent. Even if one inclined to shorten the contagious period to 400 or 300 days the contrast would still be striking. To be seriously endangered by the virus a healthy man would have to live at least several months in close proximity to a patient and concentrate, as it were, all the contagious energy upon himself. Infection would seem more probable only for husband and wife, children and other housemates, and especially for nurses of invalids. The old popular belief that only those living in close contact with, and principally in the married state with a patient, need fear contagion would seem a very near guess at the truth. All things considered, tuberculosis certainly would appear far less contagious than it is now generally believed to be. Moreover, it must be kept in mind that this theory, being purely deductive, does not by any means demonstrate tuberculosis to be at all contagious, but only affirms that if it be so the daily rate cannot exceed the stated figure, assuming all cases to arise from contagion. If therefore anybody believes that a larger fraction of tuberculous cases is not caused by inhaling or swallowing scattered germs he ought logically to lower the daily rate by the same fraction. And the noncontagionist, if disposed to deny contagion altogether, may do so, so far as our demonstration is concerned.

Judging from the foregoing description of the tuberculous patient and the relentless laws of geometric progression, untold numbers of tuberculous persons ought to be found everywhere, or rather they must many decades or even centuries ago have overrun all human kind. Where are all these sick? Here we must own that a very obvious objection arises. In evaluating the energy of contagion we have considered as infected only those that in turn become contagious themselves. The supposed high energy of contagion may therefore be true, all mankind may be really infected, if the majority of infected cases never appear in statistics and do not influence the daily rate because they remain in good health. They may at least be thought healthy and counted as such, though perhaps their lungs contain a few calcified tubercles. This argument I believe to be unanswerable. Infected in this sense, a very large proportion of the people in civilized countries may possibly be. Postmortem examinations in hospitals, though the apex of every lung is not investigated by microtomic methods, certainly bear record, as everybody knows, to an enormous percentage of these cases.

But this objection, whether right or wrong, cannot refute our conclusion that tuberculosis in its clinical aspect possesses very little or no energy of contagion. If the real malady is not dependent on contagion but on other circumstances, if the virus is present in the bodies of most men, while the remainder are not liable to take it, such contagion practically has ceased to be real contagion, and evidently nothing is gained by exterminating it by all possible means in the outer world. Let us now put to the test the common idea of destroying a contagious disease by isolation and disinfection. It will be seen why the prognosis must be unfavorable, and more especially so in chronic forms with low energy of contagion. For measles, the virus of which we cannot get hold of, complete isolation would be necessary. But to effect this we need only shut up each patient for ten days in order to prevent on an average one

fresh infection. Evidently this measure strictly applied in a large region would seem to lead quickly to a considerable fall in the frequency of measles. Still, calling to mind the Faroe islands, we doubt if it would succeed in really destroying the disease. As to tuberculosis, it is hoped that a combined process of isolation and disinfection will lower the chances of infection. Granting this work to be done so thoroughly that perfect protection were attained, these prophylactic measures would have to proceed for every single case throughout a period of 500 days, with the result of preventing only one infection. If we picture the amount of work required to exclude measles from a large country, and then allowing, of course, for differences, multiply this work by 50, it will be seen that this method of conquering tuberculosis may be called a slow one. But be it ever so slow, can this method be considered effective? Let us assume the modern protective measures to have already attained the final result. All germs in all homes and places of public resort are thoroughly destroyed by disinfection. At the same time all patients suffering from virulent discharge have been imprisoned in perfect sanatoriums where they cannot infect any healthy person, and where they are kept until recovery or death ensues. Would tuberculosis now be annihilated? The strictest contagionist, I believe, would doubt it. Innumerable bearers of latent tubercles would still remain to sicken from fresh attacks after pneumonia and other diseases or in consequence of privation and overexertion. The prophylactic work mentioned above must therefore be prolonged, repeated again and again for about a lifetime, unless these fresh cases are quickly to reestablish the old generally infected state. But what if even this had at length been attained, the entire country, all Europe perhaps, had been thus artificially cleared of the virus? Then indeed a generation wholly free of tuberculosis must be reared. And then maybe after the lapse of two lifetimes—say after 65 years—Europe might offer a condition with regard to tuberculosis analogous to the Faroe islands when the first case of measles landed. All predisposed children, however frail and delicate, must have grown up without risk of germs, then an unequalled field for a gigantic growth of an epidemic, or rather pandemic of tuberculosis would be prepared. How is infection to be warded off? Or is the contest by the same artificial means to be prolonged forever?

Now I wish to state clearly that I do not by any means intend to represent this fight as hopeless. I do not believe that tuberculosis will exterminate mankind, or that any other known disease will. In its time tuberculosis will pass away and man will suffer and die by new diseases. What I affirm is that we must fight the battle with other weapons and other allies if we are to defeat the enemy. Nature herself, our most powerful ally, has long ago entered the lists in our behalf. If it is true that latent tuberculosis is widely spread in our population and that stronger constitutions are insensible to, or in a certain degree seasoned against, a small number of tubercles, then nature has already, unaided by science, partly overcome the foe.

We have hitherto tried to show that daily rate and length of contagious period actually do influence each other. But if this be a fact, one may also inquire the cause of this relation. Why do contagious diseases follow this rule? Why are the more active ones of shorter duration and the longer diseases less infectious? We now ought to find that this disposition represents a useful or even necessary attribute of diseases, enabling them to live and thrive. But a similar rule of far wider reach exists which regulates the conditions of life over the whole organic world. Shortlived species must breed rapidly so as not to die out. Longlived species may multiply more slowly and will in the end thrive better thereby, because otherwise their means of existence would soon run short. The want of food, reacting either upon longevity or upon fertility, is probably the cause which tends universally to establish the most favorable relation between the two factors. Following up the analogy, it is evident that a contagious disease of short duration could not hold its own if the daily rate were too low, and on the other hand, mankind could not possibly long resist a chronic disease with high contagious energy. All genuine contagions that spread by direct infection may only therefore be ranged under the same law, if it be permitted to consider the species which bears

the disease as their means of existence or their "culture medium."

We must throw aside for a moment all our traditional dualistic and "anthropocentric" prejudices, and view the natural problem of "abnormity" and sickness clearly and critically from a higher vantage ground. Disease is then not a thing opposed to the laws of nature, nor is it merely a deadly conflict between parasite and host, it is in truth a kind of imperfect symbiosis. The microbes harmful to man are not intent upon his destruction, but on their own life and growth. The parasites of true contagion are even wholly dependent on their host. They destroy their own race if they exterminate the species with whose existence they have linked their own. Exceptionally and locally this does occur. In antiquity and in the middle ages whole villages and districts have sometimes been almost depopulated. We find the same even today in animals, for instance the disease of crayfish, which a few years ago all but destroyed our continental *astacus fluviatilis* in rivers and lakes. But these cases are exceptional and may be considered as miscarried attempts at symbiosis. Generally a more lasting relation is formed which tends toward a kind of equilibrium. When a disease enters a fresh territory for the first time with abnormally high daily rate, it gains an immense expansion and sweeps away all the more highly disposed (susceptible) individuals. On returning next time, if the interval was not too long, it will meet a somewhat deteriorated medium. Those naturally quite indisposed (nonsusceptible), whom the disease spares altogether, form the main stock, and next in order follow those that have recovered from the first attack. They also must have been originally less disposed. In the third place, there will be a certain number of individuals born after the first attack. These, of course, will suffer in the same proportion as the first time. Now two different suppositions arise which we will grant originally to be equally probable: the survivors of the first epidemic may have been rendered more predisposed to the disease, or less so.

In the first case, however, the returning epidemic will certainly reap a greater harvest than in the second. It will return earlier and therefore oftener within a given time and at each attack find a sufficiently disposed medium, so that the daily rate will remain high. Even the naturally nonsusceptible undisposed will at length suffer by the constantly repeated attacks and the species may die out altogether. Or by the sharp and rapid selection a perfectly immune residue may at last be left to represent the species. The epidemic then finding nothing more to attack must die out. It has destroyed itself. But whether parasite or host be victorious, at any rate in this case the battle will be decided quickly and must end with an early disappearance of the parasite.

The other case is more favorable to the disease. If the survivors of the first epidemic are less disposed on the return of the disease its harvest will certainly be smaller and the disease will also return later. Having deteriorated the medium it will be unable to hold its own until a new and disposed generation in sufficient number has sprung up. That means a respite for the host and thus a more lasting symbiosis of the two species can be evolved. There will be room in the world for both—for a certain time at least. The disease will lose in frequency, it will lower its own daily rate, until both species have adapted themselves to each other and the daily rate has fallen to that constant or moderately variable limit which secures the relatively best standard of existence to both species. This daily rate evidently is represented by the rule formulated above, which only meant the mathematic expression of a balanced or uniformly prolongable state. As an example let us imagine the Faroe islands larger and more thickly populated. Then the great epidemic of measles would not have ended. It would have found sufficient ground in the rising generation and would have smoldered on, as it were, creeping from place to place. A small epidemic would have remained behind with a normally low daily rate attacking mostly young children; in short, an epidemic such as is known in all large cities.

We have shown an apparent advantage to favor those contagions that happen to possess the faculty of leaving each time a protection against fresh infection behind them. They only can prolong existence and remain attached to the host-species

which suits them. It may be noted that this may serve as a kind of explanation how what is called "acquired immunity" must be developed by natural selection. The quality of forming protective substances, antitoxins, is useful to the parasites. They must be provided with it so as not to perish speedily by their own conquests. However to contagions of long duration and low energy this quality is useless. It may even be harmful in certain cases because the culture-medium of a thin population might easily be too far rarefied by immunization. It is again therefore no casual coincidence that the short and highly infectious contagions most markedly possess the immunifying quality. Also, it appears that tuberculosis in this respect does not answer to the description of a highly infectious disease. For it seems rather to cause a slight predisposition and the tuberculus that ought to produce immunity have been unsuccessful.

If a certain stability was said to take place in those cases which we described as lasting symbiosis, we did not mean to affirm that in truth the battle between host and parasite had come to an end. The fight only assumes a far slower pace, but it will go on, as in the other cases, by the means of selection and consecutive adaptation. So long as the bearer of parasites is sick, so long as he suffers the least disadvantage in the struggle of existence or forms a *locus minoris resistentie*, so long the war will be waged, at last I suppose in a quite latent manner, until finally the host-species has completely shaken off the parasite or until the latter, finding none but unattackable individuals, has been modified to indifference and perfect harmlessness. Thus clinical pictures may run through the stages of rise, of normal existence, and of decline.

We may then surely hope to shake off tuberculosis in the future, because an automatic process in nature aims at this end. We now ask what we ourselves can do to advance this process practically and hasten the result so far as possible. Disinfection and isolation seem only to lengthen the fight, as we have seen above. When they are successful they probably only prepare new vantage ground for the enemy. Of course I do not intend to protest against this medical work which is dictated by humanity. Tuberculosis sanatoriums minister to the welfare of sick individuals, and that gives them the right to exist, even if it should be proved that in so doing they depress the standard of public health. But on the other hand it should not be thought that whatever benefits the individual must also serve the ends of the species. On the contrary, these two purposes may be placed, and are probably most frequently placed, in opposite directions. But even if both were situated in the same quarter, it would be wrong to lose sight of the further end completely while striving to attain the nearer. Let us not be deceived: Tuberculosis sanatoriums with regard to the hygiene of healthy humanity are no better than a remedy given *ut aliquid factum esse videatur* (for the sake of appearances). Public health could doubtless be most quickly and thoroughly improved if we could discard all thoughts of humanity and work on the plan of the ancient Spartans or certain modern savages, who simply put to death all invalids. Such forcible methods are forbidden to civilized man, but their effect is sure enough, as we may observe in domestic animals and cultivated plants, any propensity to disease in these we are able to eliminate quickly—evident proof how mistaken it is to identify the welfare of the species with that of the individual. From a high point of view in social science we ought rather to be thankful that nature so often frustrates our medical efforts. For if in future we succeeded in really prolonging the life of a great percentage of tuberculous patients for many years more than today, the public standard of health would be depressed in the same proportion, and even in a growing proportion if we take into account the strong tendency of these patients to premature puberty and fertility. The struggle against the disease would undoubtedly be lengthened. We do no harm to the epidemic itself by curing as many patients as possible, though just now that may seem an expedient enforced by necessity for want of something better. What we need is a more general measure, one that will not increase but lower the number of predisposed individuals.

The true struggle against tuberculosis must take in hand the healthy, and in the first line the children. They should

be strengthened from birth and educated toward natural immunity. The history of medicine records one glorious example of an epidemic that has been warded off from entire nations only by prophylactic measures used by the healthy. We mean, of course, vaccination against variola. The vaccinated European living amid smallpox epidemics in foreign lands needs no isolation, no disinfection. No fewer germs enter his body than before Jenner's day, but the intruding germs are unable to develop. Will the study of bacteria in the future provide us with a remedy that will artificially prevent the outbreak of tuberculosis? That this is possible, must without doubt be conceded, notwithstanding all our deductions and rules. But if these are valid, they certainly justify us in declaring it to be highly improbable, and we must guard against counting too much upon it. Nevertheless in science often enough the unexpected has come true.

But even if this hope should be realized tardily, or not at all, if we enter the lists only with the weapons hitherto known, even if we had simply to leave the issue to nature, we need not despair of ultimate victory. Observing how the broad masses of our countrymen sin against every rule of health, in what a wretched state most children are brought up, it must be confessed that with the simplest measures of hygiene infinitely more might be achieved to strengthen our position of defense and to snatch countless victims from the disease. This is not the place to enlarge on the details of the problem. But if we build houses where tuberculosis may perhaps be cured, we should not shrink from pulling down houses where tuberculosis most certainly is bred. The entire rising generation ought to be trained from birth upward to the use of fresh air, bathing, sunshine, and breathing-gymnastics. These things could, with a minimum of expense, be utilized everywhere and for everybody. For the prophylactic treatment of the species they might still work wonders. The public opinion and, we grieve to say, even the medical opinion, is still greatly wanting in the proper comprehension for this subject, which has little relation to the true medical art. Widespread time-honored prejudices, deeprooted sins and abuses will have to be removed. Such progress can only be achieved slowly and by severe struggles.

But there lies the road along which never-failing nature herself leads us. Every individual dwelling must be converted into a sanatorium; that is the problem. Then tuberculosis will retreat faster and vanish sooner than if we placed a hospital at it beside every house.

NOTE.—After this essay was completed I found that part of the views it contains, but not the leading idea, had been anticipated. Adolf Gottstein, in several papers and in a little monograph, entitled "Allgemeine Epidemiologie," arrives at very similar conclusions. His work, which bears on the whole subject of epidemics, is based on ample statistic evidence. By a curious coincidence I have in some places chosen almost identical expressions, though I had never read his publications. To any reader of German interested in the subject I would particularly recommend the book. I may add, that if I had known it before, a considerable part of the essay might have been left unwritten.—C. du B-R.

**Additions to Rutland Sanatorium Recommended.**—The Massachusetts State Board of Charity in its report submitted consequent to an investigation concerning the need of an additional sanatorium for the treatment of tuberculosis in that State, recommends that before any definite action is taken toward establishing a new sanatorium the Rutland institution be completed and perfected by the addition of a probationary department, to consist of four simple brick cottages two stories in height accommodating not more than 35 patients each, these to be erected either on the grounds of the institution or within the town limits of Rutland. A moderate charge may be made for the board and treatment of such patients. The existing law, however, makes adequate provision for those who are unable to pay for their support. It is also recommended that in addition to the two examining physicians of the institution other physicians be appointed by the governor and council in all cities and towns of 15,000 inhabitants or over. These physicians shall be authorized to make preliminary examinations of all applicants and to furnish a report thereon to the chief examiners for their consideration and action. The several counties of the State, or two or more counties in combination, should be required by law to provide for the institutional care of all advanced cases of tuberculosis occurring in patients residing within their respective limits. However, any city or town establishing a sanatorium for the treatment of tuberculosis among its own citizens shall be exempted from the operation of such a law and from contributing to the establishment and maintenance of such a county institution.

## THE WORLD'S LATEST LITERATURE

## Boston Medical and Surgical Journal.

January 22, 1903. [Vol. CXLVIII, No. 4.]

1. Vaginal Celiotomy: Its Scope and Limitations. J. RIDDLE GOFFE.
2. A Case of Acute Pancreatitis, and Necrosis of Fat Tissue; Laparotomy; Drainage; Death Nine Days After Operation; Autopsy. GEORGE H. MONKS and DAVID D. SCANNELL.
3. Cerebral Syphilis. ALBERT E. BROWNRIGG.

**1.—Vaginal Celiotomy.**—There are two vaginal incisions through which we may reach the pelvic cavity, one posterior to the Douglas pouch and the other anterior to the cervix, separating the bladder from the uterus. The anterior incision possesses all the requisites of an exploratory incision, being free from danger, giving facilities for gaining the desired information, and opportunity for completing such surgical procedure as may be indicated. For incision and drainage of pelvic abscesses, the anterior method is rarely used, the opening being made posterior to the cervix or in the lateral sulci of the vagina. The indication for this is large pelvic abscesses in patients acutely ill, and in those prostrated by long-continued suppuration. Goffe emphasizes the necessity of having an incision sufficiently large to afford ample drainage, and the importance of avoiding any cutting of the uterosacral ligaments so essential in retaining the uterus in position. He believes that any cancer of the uterus that cannot give a fair prospect of cure by vaginal hysterectomy would better be left alone. He also believes in the principle that the uterus is supported exclusively by its ligaments, and that the ligaments alone are the proper tissues to utilize in restoring and maintaining a displaced uterus in its normal position; that these ligaments, either round or uterosacral, should be operated upon by vaginal incision, and that at the same time all ordinary complications, such as diseased appendages, etc., can be satisfactorily treated through the same incision. This is his experience. He has had 150 cases of displacement of the uterus, and no operation has given such universal satisfaction as shortening the round ligaments through vaginal incision. Goffe also advocates vaginal incision for removal of tumors and, wherever possible, prefers myomectomy to hysterectomy. The latest application of anterior vaginal incision is the relief of cystocele. The reason that operation for cystocele has so often been a failure, is the fact that the principle invoked is that of support from below rather than suspension from above. Goffe describes a procedure in which the bladder is attached high up on the broad ligament and anterior surface of the uterus with very satisfactory results. He asserts that the vaginal method lends itself to every form of conservative work; it requires patience, experience, and skill, and while the general surgeon will scarcely be expected to perfect himself in the technic of this line of work, there is every reason why the gynecologist should. [w.k.]

**2.—Acute Pancreatitis with Fat Necrosis.**—Monks and Scannell report the case. A woman of 40 had suffered two attacks similar to the present one, three and five years ago. The most marked symptoms were nausea, vomiting, constipation, epigastric and right hypochondriac pain, distended abdomen, temperature slightly elevated, pulse rapid and weak, and threatened collapse. These symptoms persisted for about four weeks, with varying intensity, but on the whole there was an improvement. A sudden exacerbation, together with the presence of a tender mass in the region of the left kidney, induced lumbar laparotomy. From the wound a dark-green necrotic fluid mass escaped; there was no perirenal fat. Examination of the fluid showed it to be necrotic fat. Death resulted and a necropsy showed the pancreas and left suprarenal disintegrated by a process of fatty necrosis. Attention is called to the following: The previous existence of two attacks, presumably due to gallstones, the connection of which with a subsequent pancreatitis is rendered probable by constantly accumulating evidence. The extension of the fat necrosis toward the left adrenal and kidney, emphasizing the value of posterior drainage in such cases. The possible importance of the destruction of the adrenal in producing the fatal issue. The negative results of bacteriologic examination in extensive necrosis of the pancreas and fat tissue. [A.B.C.]

**3.—Cerebral Syphilis.**—Brownrigg suggests that syphilitic lesions are determined to the brain by worry, shock or irritation from intoxicants in the same way as to other tissues by external injuries and accidents. He classifies these lesions as gummatous periarteritis, gummatous meningitis, obliterative endoarteritis, and the postsyphilitic degenerations, locomotor ataxia and paresis. The diagnosis often is very difficult from the innumerable series of combinations of functional impairment. The chief points that help to suspicion of the disease are headache, vertigo, nausea, vomiting, optic neuritis, cranial nerve palsies or paralysis, apoplecticform attacks or more gradual attacks of somnolence or coma with partial hemiplegia, irritability and general mental failure, polyuria and polydipsia, marked remittent character to all symptoms and their changeability. The usual time of onset is about the third year after primary infection. It has occurred as early as the first month. In such cases antisyphilitic treatment is apt to be more successful. If there has been hemiplegia, with much cerebral degeneration, some of the results will ever after remain. If the symptoms are arrested when simply caused by pressure from exudation about a nerve or center nearly complete recovery may be looked for. Mixed treatment should begin in the secondary stages and be continued to the end of the third year. When cerebral symptoms occur very large doses of iodids must be given. [H.M.]

## Medical Record.

January 24, 1903. Vol. 63, No. 4.]

1. A Contribution to the Pathogenesis of the Uremic State; the Probability of Its Physico-electric Substratum. HEINRICH STERN.
2. Reasons for Believing that the Only Way in Nature for Yellow Fever to Be Contracted by Man is from the Mosquito. JOHN W. ROSS.
3. Ankylosis of the Crico-arytenoid Articulation, Due to Acute Inflammatory Causes. D. BRYSON DELAVAN.
4. The Relations and Treatment of Follicular Conjunctivitis and Trachoma. ELLICE M. ALGER.

**1.—Pathogenesis of the Uremic State.**—Stern reviews various theories. Recapitulating the various points dwelt upon, makes it evident that uremia is founded on diminished electrical conductivity of the serum, or at least that this is a potent factor. None of the retained products of metabolism is toxic to any degree. The higher molecular concentration of the serum is due to these. The convulsions originate in the psychomotor centers. The hyperosmotic condition of the blood and liquids in the brain may occasionally stimulate the attack, but there is no analogy between the degree of concentration and the intensity of the process, nor between the degree of freezing point depression and the amount of retained nitrogen. In uremia large amounts of retained albuminous derivatives exhibit potent nonelectrolytic qualities. These interfere with ionization and retard ionic movement, lessening electric conductivity of the watery liquid in which the electrolytes are contained. The ions participate in augmenting osmotic tension and in depressing the freezing point; the excessive osmotic pressure of uremic serum is due to its neutral molecules. Determination of the freezing point discloses high molecular concentration, but not the degree of electric conductivity. Dissociation of electrolyte molecules occurs in the ratio of the dilution of the watery solution. Intravenous injection of water dilutes the serum so that it exhibits greater conductive properties. Conductivity is more readily established in uremia from parenchymatous than from interstitial nephritis, on account of smaller amounts of retained nitrogen. The reduction of the temperature in uremia contributes toward the reduction of conductivity. [H.M.]

**2.**—See *American Medicine*, Vol. IV, No. 25, p. 961.

**3.—Ankylosis of the Crico-arytenoid Articulation, Due to Acute Inflammatory Causes.**—Delavan says nothing is more common than to find a case of laryngeal ankylosis mistaken for one of paralysis. This is not strange since in many cases there is little or nothing to enable one to differentiate between fixation of one crico-arytenoid joint and a true paralysis of the muscles controlling its movements. Diagnosis must often rest upon a process of exclusion. The author reports several cases under the following captions: Acute laryngitis, temporary fixation; phlegmonous pharyngitis causing unilateral crico-arytenoid ankylosis; unilateral ankylosis follow-

ing diphtheria; complete ankylosis of right crico-arytenoid articulation following typhoid ulceration of the larynx; bilateral fixation following typhoid fever. An acute inflammatory process of short duration may result in only temporary fixation, but if the process is of longer duration fixation is apt to be permanent. In five of the six reported cases the fixation was unilateral; in the sixth it was bilateral and the continuous wearing of a tracheal cannula was necessary. No known treatment is absolutely curative; respiratory gymnastics and a climate which is unirritating to the upper respiratory tract is advised, together with the quick abortion or control of colds, nasal disturbances, etc. Prophylaxis of course consists in quickly controlling any causative inflammatory process. [A.B.C.]

**4.—Follicular Conjunctivitis and Trachoma.**—The regulations excluding immigrants and refusing school privileges to children make it very important to distinguish carefully between these two diseases. Most differential descriptions are useless for clinical purposes. The essential feature of trachoma is the hypertrophy of the conjunctiva. Without this there can be no development of scar tissue, and the disease is a trivial one. The occurrence of lymphoid masses, indistinguishable from those of folliculitis, should be considered as an epiphenomenon and not an essential part of the disease. The subjective symptoms of real trachoma are noticeable. Folliculitis gives no subjective symptoms, is in many cases noncommunicable, disappears eventually, with or without treatment, and leaves no trace behind unless mistakenly treated with caustics for trachoma. In both diseases Alger uses ichthyol 1 cc. (mxv), tincture of iodine 4 cc. (f3j), glycerin 30 cc. (f3j) three times weekly, with zinc sulfate solution on alternate days at home. [H.M.]

**New York Medical Journal.**

January 17, 1903. [Vol. LXXVII, No. 3.]

1. An Address on Chemical Pathology; the Field of Greatest Promise in Pathological Research. G. W. McCASKEY.
2. Anterior Transplantation of the Round Ligaments for Displacements of the Uterus. ALEXANDER HUGH FERGUSON.
3. Intestinal Indigestion and Its Relation to Arterial Sclerosis and Renal Disease. LEONARD WEBER.
4. "The Mechanics of Flat-foot," Causative, Preventive, Curative. EDWARD M. THOMPSON.
5. Topical Bloodletting as a Derivative and Repulsive Remedy in Congested and Inflamed Hemorrhoidal Bloodvessels and Tumors and in Other Affections. WILLIAM BODENHAMER.

**1.—Chemical Pathology.**—McCaskey outlines the evolution of chemical pathology and calls it the third great era—the chemical era—in the development of the science of pathology. He says that chemical pathology rests upon the foundations of cellular pathology and bacteriology; cell structure and function are none the less important—the pathogenic relations of certain microorganisms none the less certain—because the ultimate problems of disease have been transferred, as he believes they have, to the realm of physiologic chemistry. He starts with the fact that the various morbid processes produced by pathogenic organisms are the result of chemical products formed by them in their life history. He refers to the phenomena of suppuration—that the real pathogenic factor is chemical in its nature; and to the proteid substance, leukocidin, produced from *Staphylococcus pyogenes*, which if heated to 58° C. (136.4° F.) loses its leukocidal power. He then takes up the chemical attributes of the blood serum and states the fundamental principles of Ehrlich's theory, which he believes explains the phenomena of infection and immunity better than any theory which has thus far been presented. [C.A.O.]

**2.—Transplantation of the Round Ligaments.**—Ferguson describes and gives cuts illustrating his operation of anterior transplantation of the round ligaments for displacements of the uterus. After making a median incision through the abdominal wall, the lower angle of which reaches the suprapubic fold, he dissects the fat and skin from the anterior sheath of the rectus muscle on either side of the abdominal incision, corresponding to its lower third. He then makes a stab wound through the rectus muscle an inch from the median incision and 1½ inches from the pubic bone. Through this wound he grasps the round ligament and a portion of the broad ligament beneath it, near the uterus, with artery forceps. To prevent bowel complications he passes a continuous suture along the

parietal peritoneum from the puncture downward to the side of the bladder, and back posteriorly to the round ligament near the uterus. When the suture is tied, an anteroposterior partition of folded peritoneum is thrown between the iliac and bladder regions on each side. In some cases he sutures the round ligament to the parietal peritoneum for the same purpose. He then drags the proximal end of the round ligament through the rectus muscle and sews it and the subjacent portion of broad ligament to the anterior sheath of the rectus muscle, leaving a stump about half an inch long between the parietal peritoneum and uterus. The other side is dealt with in the same manner. The author claims a wide range of application for this operation, and says there is no interference of physiologic function. [C.A.O.]

**3.—Intestinal Indigestion.**—Weber reports three cases of chronic intestinal dyspepsia to show their possible relation as an exciting feature to subsequent arterial and renal sclerosis. He also believes that cholera infantum and similar acute and subacute gastrointestinal dyspepsias of children are frequently complicated and even terminated by acute nephritis, and says that if ptomaines and other toxins can do this in acute cases, why should not similar poisons chronically supplied insidiously produce renal changes of a chronic nature and more of the intestinal form of inflammation? From observations he concludes that iodids given in relatively small doses three or four times daily, and continued for many months and even years, have the power to retard, modify, and improve subacute and chronic inflammatory processes concerning the connective tissue of parenchymatous organs like the kidneys, the liver, the lungs, and particularly so the sclerotic disease of the arterial vessels. [C.A.O.]

**4.—The Mechanics of Flat-foot.**—As causative factors in the production of flat-foot Thompson mentions rheumatism, rachitis, paralysis, general muscular weakness, traumatism, direct or indirect, all of these causes being aggravated by body weight, prolonged standing or walking, and improper positions of the feet while on them. He believes that standing and walking with the feet at an angle of 90°, as is usually taught, increases the tendency to flat feet by throwing the center of gravity inside the apex of the plantar arch, causing mechanically a valgus or abduction and eversion of the foot. Many times a weakened arch may be rescued by directing a proper use of the feet—first by educating our patients to use the heel-and-toe method of walking, with the feet parallel rather than on diverging lines, and when running or jumping to catch the weight on the front of the foot and not on the heels. In very mild cases the deformity can be readily overcome and the pain relieved by means of adhesive plaster straps of sufficient length to reach in a spiral course to the knee. To reduce the deformity grasp the foot firmly and extend it sharply on the tarsus (this increases the space between the internal cuneiform and the astragalus). Then forcibly invert and adduct the foot and flex it again to 90°, maintaining the adducted and inverted position. In aggravated cases we may use a gradual correction by means of properly-applied braces; or a rapid correction under anesthesia with plaster-of-paris. The author believes the latter to be the more satisfactory. He describes an ankle brace which he has used with great success which is constructed with the object of throwing the center of pressure on the foot in such a way as will permit the parts to return to their normal relations in a natural manner. [C.A.O.]

**Medical News.**

January 24, 1903. [Vol. 82, No. 4.]

1. Cases Illustrating the Therapeutic Uses of the Röntgen Rays. SAMUEL BERESFORD CHILDS.
2. Subphrenic Abscess as a Complication of Appendicitis. HENRY A. CHRISTIAN and LOUIS C. LEHR.
3. A Consideration of the Scientific Application of Mechanical Vibratory Stimulation in the Treatment of Disease. MAURICE F. PILGRIM.
4. Tonsillitis Classified as an Infectious Disease. WALTER SANDS MILLS.

**1.—Cases Treated by Röntgen Rays.**—Childs, of Denver, reports a series of 14 cases treated by Röntgen rays. Six were of epithelioma; all were cured or still under treatment with such improvement as to warrant the expectation of complete cure. Three were of lupus erythematosus; all were cured. One

was of tuberculous glands of the neck; improved, but still under treatment. One was for secondary carcinoma of the spine and recurring nodules after complete excision of the breast; much relief from pain by the treatment, but the disease resulted fatally. One was of tuberculosis of the apex of each lung; the patient is improved and is still under treatment. One case of chronic eczema completely recovered. One case of Hodgkin's disease appears to be improved, and is still under treatment. [A.B.C.]

**2.—Subphrenic Abscess as a Complication of Appendicitis.**—Christian and Lehr state that in a collection of autopsies numbering 4,028 the cause of death in 86 was acute appendicitis, and in these 86 cases 7, or 8.13%, showed a purulent process in the subphrenic region. The authors cite the findings of many others who have contributed to this subject. They report 7 cases of subphrenic abscess following or complicating appendicitis. The histories are at some length. Of the 7, 5 were males and 2 females; the youngest was 11 and the oldest 50. The affection was unilateral in six instances, four times on the right and twice on the left, and bilateral in one instance. In four of the cases the process had extended from the subphrenic region into the pleural cavity, though in no case was the diaphragm perforated. Subphrenic abscess secondary to appendicitis may occur in one of four ways: A localized abscess in a general purulent peritonitis; by extension from the appendix to the subphrenic region by an intraperitoneal route, or by the extraperitoneal route; by way of the blood current as part of a general embolic septic process, or as a sequence of liver abscesses which are of embolic origin by way of the portal vein. Originating in either the first or last ways the abscess might equally well appear on either side. [A.B.C.]

**3.—Mechanical Vibratory Stimulation.**—This is applied for stimulation of the nerve or nerve centers concerned in and controlling the diseased organ, which are found principally in the spinal and sympathetic systems, in order thereby to stimulate and equalize blood currents and to stimulate secretion, excretion and the lymphatics. The tendency of the automatic functions of the body is to maintain equilibrium. Pilgrim has found that mechanical vibratory stimulation powerfully assists in accomplishing this. Results are more prompt and satisfactory than after other methods of treatment in neurasthenia and other nervous disorders, in ocular affections dependent on anemia or hyperemia, in goiter, in scoliosis, pelvic diseases (exclusive of pus sacs), in functional disorders of the digestive organs, pruritus, varicose conditions, indolent ulcers, incipient tuberculosis, subacute rheumatism and neuralgia. [H.M.]

**4.—Tonsillitis as an Infectious Disease.**—Mills believes this is more detrimental in the school-room than parasitic skin diseases, although not excluded by the departments of health. One attack predisposes to another. There is a definite period of incubation. Instead of being a local disease with severe constitutional symptoms, it seems rather an acute infectious disease with local manifestations. The onset is similar to that of other infections. The patient is prostrated out of all proportion to the local manifestations. Simple catarrhal tonsillitis, follicular tonsillitis, and quinsy are successive stages of the same disease. The patient should be isolated at once. At the onset aconite is indicated. With high fever, bounding pulse and intense congestion, a 1% solution of belladonna is the best remedy. In follicular tonsillitis phytolacca is almost specific in drop doses of a 1% solution every 1 or 2 hours, according to the severity of the case. [H.M.]

### Philadelphia Medical Journal.

January 24, 1903. [Vol. XI, No. 4.]

1. Tropical Diseases: Introductory Lecture in a Course on Tropical Diseases, etc. CHARLES F. KIEFFER.
2. An Early Case of Osteitis Deformans. J. C. WILSON.
3. Six Years of Medical Journalism: A Retrospect. JAMES C. JOHNSTON.
4. Spontaneous Rupture of the Heart, with a Report of Seven Cases. ARTHUR S. HAMILTON.
5. Atmospheric Pressure and Epidemic Influenza in Philadelphia. HOWARD S. ANDERS.
6. Legal Tests of Responsibility. RICHARD WEBB, Esq.

**1.—Tropical Diseases.**—This is an introductory lecture in a course on tropical diseases which is being delivered by Kieffer,

at Jefferson Hospital. Tropical medicine and practice is divided into diseases of the native and of the Anglo-Saxon settler. The native, as a rule, is underbred and underfed, hence when affected by disease the mortality is higher. The etiologic factors that especially obtain in diseases peculiar to the tropics are heat, infections and diseases conveyed by parasitic hosts, of which there is a large representation in medicine. The tropical phases of infection, immunity and acclimatization are discussed. [F.C.H.]

**2.—Osteitis Deformans.**—Wilson reports an early case of osteitis deformans (first seen by him three months ago), which increases the list of reported cases in this country to 17. The patient was a female of 50, who complained of persistent pain and tenderness in the right thigh. The bone involved was the lower end of the right femur. The case is of interest because it was of rapid development and involved at the time of observation a single bone and was attended with great and persistent pain. The patient now complains of pain at the lower end of the left femur, and is obliged to use a rolling chair. The case is made a matter of record in order that, if the opportunity should occur, its future course may be noted as a contribution to the clinical history of this strange malady. [F.C.H.]

**4.—Spontaneous Rupture of the Heart.**—Hamilton details the etiology, pathologic anatomy, symptoms, diagnosis, prognosis, and treatment of spontaneous rupture of the heart. He reports seven cases in detail, representing all those known to have died of spontaneous rupture of the heart out of a total of 1,693 deaths occurring among the patients at the hospital for the insane at Independence, Iowa. The diagnoses were all verified by an autopsy. An eighth case is added. [F.C.H.]

**5.—Atmospheric Pressure and Epidemic Influenza in Philadelphia.**—Anders concludes as follows: As in the case of the investigation of sunshine percentage the behavior of atmospheric pressure in relation to epidemic influenza is characteristic in the marked lack of equability; in the absolute daily (sometimes almost hourly) extremes and not in the monthly or yearly averages or means. [F.C.H.]

## CLINICAL MEDICINE

DAVID RIESMAN

A. O. J. KELLY

### EDITORIAL COMMENT

The association of chronic obliterative pericarditis with ascites has recently attracted some attention. Distinguished from the more usual cases of chronic obliterative pericarditis, which either run their course entirely devoid of symptoms, or sooner or later manifest themselves by the ordinary symptoms of disturbed or impeded circulation, there occurs a class of cases characterized clinically by marked ascites with little or no edema of the legs. In these cases the diagnosis of cirrhosis of the liver is usually made, but the necropsy discloses chronic obliterative pericarditis and certain morbid changes in other tissues and organs—notably, pleuritis, peritonitis, perihepatitis, red atrophy of the liver, cirrhosis of the liver, etc.—whence the designation "pericarditic pseudocirrhosis of the liver" suggested by Pick,<sup>1</sup> who first directed marked attention to the subject. Although the subject had attracted some attention in Germany, the only cases reported in this country, until within a year, are those reported by Osler<sup>2</sup> and by Cabot.<sup>3</sup> During the past year cases have been reported by Herrick and by Becker, and a detailed study of the subject has been undertaken by Nicholls<sup>4</sup> and by Kelly.<sup>5</sup> The number of cases reported is less than 45, including several doubtful cases, but that the condition is probably much more common than might appear at first sight, is suggested by the fact (among others) that two of the cases—those reported by Ewart<sup>6</sup>

<sup>1</sup> Zeitschrift für klinische Medizin, 1896, xxix, p. 385.

<sup>2</sup> Archives of Pediatrics, 1896, xlii, p. 3.

<sup>3</sup> Boston Medical and Surgical Journal, 1898, cxxxviii, p. 463.

<sup>4</sup> Studies from the Royal Victoria Hospital, Montreal, 1902, I, No. 3.

<sup>5</sup> American Journal of the Medical Sciences, Jan., 1903, cxxv, p. 116.

<sup>6</sup> British Medical Journal, 1899, I, p. 908.

and by Kelly—were operated upon for the cure of a supposed cirrhosis of the liver. The causation of the disproportionate ascites has occasioned much discussion, being attributed on the one hand to changes in the liver, the result of long standing congestion, and on the other, to a chronic peritonitis or perihepatitis. With adducing the reasons for the one or the other opinion, it is at least suggestive that most of those who recently have studied the question attribute the ascites to the alterations in the peritoneum; thus, inasmuch as there is associated disease of the precordium and peritoneum, frequently also the pleura, the symptom-complex is a manifestation of multiple inflammation of the serous membranes, a multiple serositis.

The clinical recognition of the condition commands especial interest from a practical point of view. As pointed out by Kelly this may be possible in certain cases by directing special attention to the history of a previous attack of acute pericarditis; to the early occurrence and subsequent disappearance of edema of the legs; to the marked ascites with little or no edema of the legs; to the enlarged liver early in the course of the disease (in some cases the liver appears not to have been enlarged), and to the small and distorted but otherwise normal liver in the later stages of the disease; to the absence or very late occurrence of marked enlargement of the spleen; to the tendency to the occurrence of repeated attacks of pain, tenderness, rigidity and, possibly, palpable and audible frictions in the right hypochondriac region—attributable to attacks of perihepatitis; to the rapid occurrence of the ascites after tapping (Rumpf's<sup>1</sup> patient was tapped 301 times); and to the physical signs of adherent pericardium—without which, it may be said, the disease is incapable of diagnosis. From cirrhosis of the liver, which it most resembles, this obliterative pericarditis with ascites may be distinguished by the symptoms and physical signs of adherent pericardium; by the absence of the etiologic factors of cirrhosis of the liver; by the slow, insidious, protracted and intermittent course of the disease; by the long periods of standstill during which the ascites may remain stationary and the patient in good condition; by the entire absence or transient presence of slight jaundice; by the absence in most cases of portal congestion and gastrointestinal disturbances—hemorrhages, diarrhea, hemorrhoids, enlargement of the spleen, marked dilation of the superficial veins of the abdominal wall, etc.; in some cases, by the association of an enlarged, smooth and firm liver, with marked ascites; and by the fact that in many cases the patient survives a large number of tappings. The symptom-complex is of extreme interest and will well repay careful study, which doubtless will lead to the correct clinical interpretation of symptoms now perhaps too hastily put down to cirrhosis of the liver.

#### REVIEW OF LITERATURE

**The Importance of Hyalin Casts in the Diagnosis of Renal Diseases.**—Defendorf<sup>2</sup> reviews the literature on this subject and gives statistics to show how frequently casts are found in apparently healthy persons. He concludes that hyalin casts, particularly in individuals past middle life, are of no clinical significance. However, it was found that nephritis is much more prevalent at this stage of life than is commonly supposed. This is especially true of the insane; in one institution as many as 57% of the inmates suffered from chronic interstitial nephritis. The origin of casts is still in doubt. Hyalin casts may occur as the result of chronic passive congestion of the kidney. If this condition can be eliminated one must seek the cause of hyalin casts in one of the four forms of chronic nephritis, which are chronic parenchymatous nephritis, chronic interstitial nephritis, chronic diffuse nephritis, and senile interstitial nephritis. In the first form of this disease hyalin

casts are rarely found alone but are accompanied by finely granular, waxy, and sometimes fatty casts; albumin is usually present, while the total quantity of urine and of solids is reduced. Hyalin casts, when alone, are most characteristic of the first stage of chronic interstitial nephritis; with them is seen an increase in the quantity of urine and a decrease of the specific gravity and the amount of solids. In the diffuse form of chronic interstitial nephritis hyalin casts are rarely seen alone, but are associated with considerable amounts of albumin. Finally, hyalin casts with or without the faintest trace of albumin may be the only distinctive symptom of senile interstitial nephritis. [W.E.R.]

**Notes on Aneurysms.**—Satterthwaite<sup>1</sup> reports 11 cases of aneurysm, seen postmortem, giving clinical data and conclusions. He believes that syphilis is the most frequent cause of aneurysm, though it is difficult to prove this from statistics. His experience shows that in thoracic and abdominal aneurysms the diagnosis is made in only one-fourth of the cases. One conclusion is that the larger aneurysms of these types have thus far baffled the best efforts of modern surgeons and that medical treatment has at least insured a longer lease of life and offers greater chance of cure if treatment be undertaken early. In the treatment the first consideration is rest, the second restriction in food and drink, the third cardiac sedatives. [A.G.E.]

**Adiposis Dolorosa.**—Dercum and McCarthy<sup>2</sup> report a case of adiposis dolorosa with necropsy and the results of a chemic study of the fat by Edsall. Among the interesting findings were an adenocarcinoma of the pituitary body and the presence of new-formed hemolymph glands in the subcutaneous fat. The thyroid presented few or no changes (in contradistinction to four cases previously reported by Dercum and by Burr). It is said that just what the role of the thyroid gland in this disease is is problematic, though the changes so far detected being atrophic, suggest that they may be related to the excessive production of fat. On the other hand, the marked changes in the pituitary body are suggestive, especially in view of the interrelationship that exists between the thyroid and the pituitary bodies. The pituitary body is thus brought into relation, though perhaps indirectly, with a fat-producing or fat-destroying function—a relation which, up to this time, has not been considered. The fact that the thyroid gland has been found diseased in every one of the five cases coming to necropsy cannot but be of significance. Thus far 28 cases have been reported. [A.O.J.K.]

**Mouth as an Index of Health.**—A suggestive article on this subject is contributed by Magee,<sup>3</sup> a dentist, who believes that physicians might profit materially by more often consulting the dental specialist. Fifty years ago the dentist was little better than a tooth carpenter. Today his education, in our best schools, fits him to give advice. There are still a few physicians who believe that the dentist's sole mission is to extract teeth and make artificial substitutes. Primarily these are his duties, but he has been obliged to meet the demands of necessity and urgency by giving attention to various lesions in the oral cavity. These lesions are often discovered by the dentist when overlooked by the physician. The significance of caries and changed oral secretions is detailed. [A.G.E.]

**Difficulties and Errors in the Diagnosis of Appendicitis.**—Cumston<sup>4</sup> discusses the different abnormal situations of the appendix, the classical symptoms of appendicitis, and reports a number of cases in which the diagnosis was difficult. Reference is made to the suggestiveness of left-sided pain which is believed to be due to a transposition of the cecum and appendix or to a long appendix reaching to the left iliac fossa. There are a few words relative to operative technic. [A.O.J.K.]

**The Results of Dr. Garnault's Experiments.**—Garnault<sup>5</sup> gives the report of the Pasteur Institute on the nodule removed from his arm November 12, by Tuffier, this nodule having developed at the place where a fragment of the tuberculosis liver of a cow was inserted under the skin July 13. Three guineapigs were inoculated with a part of the nodule, and by

<sup>1</sup> Deutsches Archiv für klinische Medizin, 1895, xv, 272.

<sup>2</sup> Yale Med. Journ., December, 1902.

<sup>1</sup> The Postgraduate, December, 1902.

<sup>2</sup> American Journal of the Medical Sciences, cxxiv, 994, 1902.

<sup>3</sup> Maritime Medical News, December, 1902.

<sup>4</sup> American Journal of the Medical Sciences, cxxiv, 243, 1902.

<sup>5</sup> Gazette Medicale de Paris, December 20, 1902.

the day of the report (December 15) had developed marked lesions of tuberculosis. Microscopic examination of the remainder of the nodule showed it to contain typical tubercles. The report concludes by stating the following facts: A fragment of a tuberculous nodule from a cow, inoculated into a human being, has produced a tuberculous lesion limited to the point of inoculation. In this lesion the tubercle bacilli have remained living and virulent for guineapigs for a period of four months after their transplantation. Garnault believes these results are sufficient to contraindicate Koch's statement, and will make no more inoculations. The epitrochlear and axillary lymph nodes were not involved, but as the wound is not yet healed, general infection is still considered to be a possibility. Garnault believes that his athletic constitution and the fact that he ate 400 gm. of raw meat daily, may have been factors in preventing general infection. Legislative measures to protect persons against bovine tubercle bacilli in meat, milk and milk products are considered justifiable. [A.G.E.]

**Bothriocephalus latus and the Causation of Primary and Secondary Pernicious Anemia.**—Willson,<sup>1</sup> referring to the rarity of infection with *Bothriocephalus latus* in this country, reviews the literature and reports a personal observation occurring in a Russian Jewess, aged 46 years. The case was of interest on account of the presence of two bothriocephali and the enormous lengths of the worms (a total of 82 feet, 3 inches) and over 12,000 segments. The characteristics of the worm are described in detail. There follows a valuable discussion of the nature of primary and secondary pernicious anemia and of the relationship of *Bothriocephalus* to the anemia. [A.O.J.K.]

**Elimination in Chronic Nephritis.**—Claude<sup>2</sup> claims that elimination in chronic interstitial nephritis is increased and only diminished in the last stages of the disease, or in consequence of an accidental complication. This is explained by the fact that development of the interstitial tissue determines an increase in the blood-pressure and cardiac hypertrophy, whereby an increased flow of blood to the glomerules is occasioned and also increased functional activity. When later the kidney structure is destroyed by the contracting tissue then the elimination is lowered and uremic symptoms appear. [J.H.W.R.]

**A Point in the Prophylaxis of Malaria.**—It is claimed by Le Roy des Barres<sup>3</sup> that malarial fever should be considered a contagious disease, especially in its acute form, and that malarial patients should, to a certain extent, be isolated. His reason is that mosquitos may carry the plasmodia directly from the patient to others who may be in the same room with him; for example, to an attendant who may sleep in the same room. Isolation should be practised, especially when there is an aggregation of persons, as occurs in the wards of a hospital. [B.K.]

**An Unusual Case of Fecal Accumulation.**—Salin<sup>4</sup> reports an interesting case occurring in a female, nullipara, 41 years old. As a child she suffered often colicky pains and from the age of 23 she had been constantly troubled with constipation, which only could be relieved by enemas, often six or seven of those in succession being necessary to obtain result. If she tried to take a laxative she would be violently sick with pains along the left side and vomiting, which would last for several days, her bowels, however, not moving. Curiously enough she suffered in this way only in the winter, in the summer the evacuations being most often voluntary. December, 1901, she noticed in the lower abdomen immediately above and behind the symphysis a tumor the size of a hen's egg, hard, immovable, and not tender, which soon disappeared. A few months later she felt another tumor of about double the size of the first one in the median line about midway between the umbilicus and the symphysis; it was hard, somewhat movable from side to side and growing quite rapidly in size. On examination at the hospital the lower part of the abdomen was found to be entirely filled by a tumor reaching from the symphysis up to three fingers' breadth above the navel, hard, slightly elastic, and somewhat movable, apparently adherent

to the abdominal wall. Uterus and ovaries palpable and plainly not connected with the tumor. The diagnosis of malignant growth of the abdominal wall was made and operation advised. The constipation and intestinal symptoms were ascribed to some adhesion between the tumor and the intestines. Upon opening the abdomen the true and surprising condition of affairs became apparent, the tumor not being situated in the abdominal wall but found perfectly free in the peritoneal cavity, and on closer examination located in the sigmoid flexure. The hardness was less marked, the tumor now distinctly pitting on pressure. It was plainly a case of fecal accumulation of an unusual degree. But no cause of the obstruction could be found. The intestinal walls, especially below the tumor, were thickened and numerous glands, ranging in size from a pea to a hazelnut, were seen in the mesentery. Fearing the presence of a malignant growth in the intestine the gut was resected and end-to-end anastomosis accomplished by means of the Murphy button. The mucous membrane was perfectly normal. No sign of malignant neoplasm. The entire gut was only hypertrophied and considerably distended. The tumor was free in the gut and consisted of a compact, homogeneous fecal mass weighing 2½ kilograms (5½ pounds). Patient made a rapid recovery. Button passed on the fourteenth day. Movements of the bowels have since been spontaneous. [A.E.E.]

**Recovery from Suppurative Meningitis Due to the Colon Bacillus.**—The case reported by Nobécourt and Du Pasquier<sup>1</sup> was that of an infant of seven months which, following acute gastrointestinal infection with diarrhea and slight fever, exhibited signs of meningitis. Lumbar puncture revealed an increase in the cerebrospinal fluid. All the symptoms then abated, but in a day or two both gastrointestinal and meningeal manifestations became more pronounced. Lumbar puncture then confirmed the diagnosis of suppurative meningitis due to the colon bacillus. Though the symptoms were severe the infant recovered. Lumbar puncture is thought to have possibly been of value. [A.G.E.]

**Acute Lymphatic Leukemia Without Enlargement of the Lymph Glands.**—Dorothy Reed<sup>2</sup> gives the results of a careful study of a case of acute lymphatic leukemia without enlargement of the lymph glands, and discusses the nature of the disease. She believes that while we cannot state positively that the lymphocyte of the blood comes from the bone-marrow we have no proof that the lymphocyte comes from the lymph gland alone, and that her case as well as others in the literature go to prove that acute lymphatic leukemia, whether lymphoid or myelocytic, is due to changes in the bone-marrow, the other hematopoietic organs being involved, if at all, secondarily. Thus we have no right to apply the term myelogenous to one form of leukemia alone; on the contrary, she suggests that there are three forms of leukemia, all due to myelogenous changes. These should be known as the myelocytic, lymphoid, and mixed-cell, if we wish to make the blood picture the basis for clinical divisions. Any of these three forms may be acute or chronic; the myelocytic is usually chronic, the lymphoid usually acute. The nature of the disease, the etiology, and the primary focus in the body are believed to be still undiscovered. Leukemia as we know it is simply the manifestation of some poison which affects especially the bone-marrow, the blood-forming organ in the adult, and ultimately proves fatal. [A.O.J.K.]

**Transmissibility of Bovine Tuberculosis to Man.**—After reviewing briefly the recent discussions and papers concerning the intercommunicability of bovine and human tuberculosis, Köhler<sup>3</sup> concludes that neither their similarity, dissimilarity, nor transmissibility from one to the other has either been proved or disproved; more time must elapse and more work must be done before definite statements regarding any of these points can be made. It is much more important to guard against infection from man to man than from cattle to man, however, and it must be our endeavor to prevent such infection in the future as in the past. This is best done by improving the hygiene of the dwellings, factories, and other places where tuberculous people are likely to be. If possible they should be isolated in sanatoria. It is of especial importance

<sup>1</sup> American Journal of the Medical Sciences, cxxiv, 262, 1902.

<sup>2</sup> La Semaine Médicale, December 3, 1902, p. 400.

<sup>3</sup> Gazette Hebdomadaire de Médecine et de Chirurgie, December 25, 1902.

<sup>4</sup> Hygela, Stockholm, October, 1902.

<sup>1</sup> Gazette hebdomadaire de Médecine et de Chirurgie, December 7, 1902.

<sup>2</sup> American Journal of the Medical Sciences, 1902, cxxiv, 653.

<sup>3</sup> Deutsche medizinische Wochenschrift, November 6, 1902.

that the populace be educated regarding the infectious character of the sputum, as through its means the largest number of cases are probably produced. If milk is sufficiently boiled, and meat of animals presenting extensive tuberculous lesions not offered for sale, there will be but little danger from infection by cattle. [E.L.]

**Treatment of Chronic Nephritis.**—Porter<sup>1</sup> discusses at some length the surgical and rational or dietetic treatment of Bright's disease. He goes into the histology and physiology of the kidneys, and accepting Metschnikoff's classification, calls the connective-tissue cells "macrophagi"; the epithelia and leukocytes "microphagi." When the work of the kidneys is excessive, the microphagi perform their function properly and without pathologic change, but if the nutritive supply is poor and the work is too great, then the macrophagi gain the ascendancy and there follows structural and functional change. The epithelial structure, or the intertubular tissue may suffer. When the retrograde change is confined to the former, a parenchymatous lesion results, the latter an interstitial lesion. The factors increasing the work of the kidneys and lowering nutrition are (1) the ingestion of more proteids than the system needs; (2) the presence of putrefactive fermentation in the alimentary canal, resulting in the production of toxic proteid elements; (3) the direct or indirect influence of microorganisms causing toxic products. The treatment of Bright's disease must be considered under two headings, that of prevention and that which deals with the disease after it has developed. Porter does not see how surgical interference can in any way remove any of the factors entering into the etiology of this condition. He recommends a well regulated, mixed diet, composed largely of the animal class; hygienic and therapeutic measures designed more to maintaining a perfect digestion and metabolism, and to lowering the work of the kidneys, rather than treatment direct at the pathologic lesion itself. In other words, the treatment should consist of measures to remove the etiologic factors operating to produce Bright's disease, rather than those directed to the treatment of the kidney itself. In this way often a complete physiologic cure can be established though histologically Bright's disease is incurable. [J.H.W.R.]

**Osteitis Deformans and Hyperostosis Cranii.**—Prince<sup>2</sup> reports three cases, with especial reference to the clinical features and pathology of the condition. Having reviewed previous communications, he states that we have no sure ground for differentiating hyperostosis cranii from osteitis deformans, and that both are probably trophic disorders. Various clinical and pathologic facts seem to indicate that they are at least allied disorders, and perhaps only different manifestations of one and the same disease. The osteoarthritic changes so commonly found in osteitis deformans are probably manifestations of the disease, and not complications. The results of autopsies thus far made do not at all exclude the nervous system as the seat of the trophic derangement, but the changes that have been found in the spinal cord and peripheral nerves and analogy with other known lesions like those of tabes and syringomyelia suggest a neuropathic origin similar to that of the myopathies. In future cases the nervous system should be exhaustively examined. [A.O.J.K.]

**Dysentery Due to Double Infection with Uncinaria Duodenalis and the Ameba Coli.**—This interesting case is reported by Ward.<sup>3</sup> The patient was an American physician, aged 32, who contracted the disease in the Philippines. Both infections are believed to have been present from the first. Improvement followed treatment, and by March, 1901, when he arrived in the United States, patient considered himself well, the attack having begun in May, 1900. In December, 1901, the disease recurred, and the patient entered the Albany hospital. Ameba coli and uncinaria ova were found in the stools. Oleoresin of male fern and quinin enemata effected an apparent cure. [A.G.E.]

**The Diagnosis of Tetany in Early Childhood.**—Thiemich's claim that galvanic overexcitability is the most constant symptom present in tetany and in itself is sufficient to diagnose cases of latent tetany during early childhood is

opposed by Ganghofner.<sup>1</sup> Thiemich, basing his statements upon the examination of 28 cases of tetany and of 43 normal children, says that if KOC is present, the current being below 5 milliamperes, a diagnosis of tetany may be made; if a current greater than this is needed the child may be said to be normal. The current need only be applied to one nerve. Ganghofner insists that mechanical irritability is also of great value, and to prove this reports the examinations made upon 50 children afflicted with tetany, employing Thiemich's method in all points; the right median nerve was the nerve examined; 49 of these showed an increase in mechanical irritability, and but 41 obeyed the mandate of Thiemich; but even in these cases the diagnosis was easily made. Therefore as valuable as Thiemich's findings are it must not be said that they only are of value. It is especially at the onset and toward the end of the disease that the symptoms of mechanical and electrical irritability do not always run parallel; sometimes one, and sometimes the other, will be the more prominent; the latter is also present in other nerve diseases, as in hysteria. Some of the nerves are more irritable than others, and it is wrong to depend upon examination of one nerve only. Many of these cases presented laryngospasms and eclamptic convulsions. [E.L.]

**The Aims of Postgraduate Instruction in Medicine.**—In his address Collins<sup>2</sup> deals mainly with the problem regarding physicians who come for postgraduate instruction after being in practice for some years. For those who desire a general "brushing up," he would suggest the acquiring of methods of examination, laboratory and clinical, the latter including familiarization with instruments of precision used in diagnosis. Time spent in seeing operations, in hearing teachers talk of disease, and in copying prescriptions, while not entirely wasted, may be spent much more profitably. Laboratory methods of the greatest importance to this class are: examination of the urine; staining of tubercle bacillus; examining cultures of diphtheria bacillus; and examination of the blood. An hour a day for three months will accomplish this. Finally, one of the most important things one learns from a postgraduate medical course is the necessity of going back. The physician who attempts to go on in the routine duties of his work for a longer period than five years is unjust to himself and unfair to his patient. [A.G.E.]

## GENERAL SURGERY

MARTIN B. TINKER

A. B. CRAIG

C. A. ORR

### EDITORIAL COMMENT

The subcutaneous injection of paraffin first introduced into surgery by Gersuny, of Vienna, seems to have found many useful applications, judging from the numerous recent publications on the subject. Gersuny originally suggested the use of the injections in filling out facial defects, such as saddle-nose, sunken cheeks left after operation, depressed scars, etc. In a recent paper<sup>3</sup> he also suggests the use of injections beneath Thiersch skin grafts in which the color is different from that of the surrounding skin, also in the pits left after bad attacks of smallpox. He has also used the injections in the region of an artificial anus to prevent incontinence of feces, and has injected it about the neck of hernia sacs to produce cure without operation. The desirability of adopting this method as a routine treatment in cases of hernia is very questionable; in large hernias the treatment would certainly not be successful, and it seems unlikely that it would be permanently so in many smaller hernias. On the other hand, it has proved of decided value in filling up defects, as suggested above. In situations in which it is disadvantageous to use hard paraffin, Gersuny has found a mixture of one part vaselin with four parts of olive oil very satisfactory. This mixture can be sterilized by boiling and is half fluid at ordinary room temperature, so that the injection is

<sup>3</sup> Zentralblatt für Chirurgie, 1903, Vol. xxx, p. 1.

somewhat more readily carried out than when hard paraffin is used. In injecting into tissues rich in bloodvessels a number of small injections is advised in place of one large injection. It has been found that after injection the vaselin is not only encapsulated with connective tissue, but bands of tissue ramify through it after a short time and hold the mass permanently in place. The danger of embolus from injecting into bloodvessels has been suggested. This can be avoided by introducing a needle and aspirating to determine that it is not in a vein before the barrel of the syringe is drawn full of the fluid for injection. Some who have used the method have reported suppuration with partial discharge of masses of paraffin injected, but it seems probable that if proper antiseptic precautions be taken this will be avoidable. If surgeons would keep the paraffin injection method in mind no doubt many useful applications would be found for this very simple procedure, and in many cases it would be easy to adopt this treatment instead of plastic operations, such as excision of scars, operation for saddle-nose, etc.

#### REVIEW OF LITERATURE

**Infective Arthritis.**—Marsh<sup>1</sup> pays tribute to Lister and says idiopathic arthritis, like idiopathic peritonitis, never occurs. Analogy between the synovial membrane of joints and the peritoneum is drawn and the tendency of each, particularly the former, to become involved in the various acute infectious diseases is noted. Thus we have pneumococcal arthritis, gonorrhoeal arthritis, arthritis following typhoid fever, scarlet fever, influenza, erysipelas, glanders, etc. The first group of cases embrace those with transient synovitis with limited effusion. Here treatment by rest, splint, and fomentations gives a good prognosis. A second group comprise those with marked swelling, effusion of fluid into the joint, which may later become turbid and even purulent. Here evacuation of the fluid with free irrigation is demanded. A third group have involvement of the periarticular structures, brawny swelling, skin reddened and shiny, suggesting a near approach to suppuration. This is typified in gonococcal infection. Here the disease runs a long and tedious course as a rule and prognosis should be guarded. A fourth group includes those in which the arthritis from the first is acute and destructive. Suppuration is early, destructive, and violent. This is typified in pneumococcal arthritis. Even under radical treatment the prognosis is unfavorable, for the suppurative arthritis is but one of the manifestations of a general septicemia. [A.B.C.]

**Gonorrhoeal Arthritis.**—Baquez<sup>2</sup> reports two cases of gonorrhoeal arthritis affecting sisters at the same time. Aspiration of the joint failed to demonstrate the presence of bacteria, but the condition went on to a suppurative arthritis, for which arthrotomy was performed, and cultures taken from fungoid outgrowths on the synovial membranes gave abundant colonies of the gonococcus. The infection was localized to a single joint in both cases. What joint was affected is not stated, but ankylosis resulted. [M.B.T.]

**Influence of Lister Upon Military Surgery.**—Ogston<sup>3</sup> says von Langenbeck was one of the first to take advantage of the teachings of Lister and to advise the discontinuance of amputation of the leg for gunshot wound through the knee or any similar wound. At first this was opposed, but it soon prevailed. Esmarch, carrying out the septic principle, introduced the first dressing packet for soldiers in the field. The abolition of probing in abdominal wounds was due to Lister. This practice ceased long before the advent of the small caliber and relatively aseptic projectiles. Most of the advances and improvements upon the methods of Lister have been made in military practice by surgeons on the Continent. [A.B.C.]

**Statistics of Operations for Appendicitis.**—Richardson<sup>4</sup> states that out of 1,002 abdominal operations at the Massachusetts General Hospital during 1901, those upon the appendix comprised 337. Second in frequency was hernia, 214 cases. Of

the operations for appendicitis 144 were for the acute variety without general peritonitis with 5 deaths, a mortality of 4.18%. Acute appendicitis with general peritonitis numbered 41 operations with 25 deaths, 60.9%. In 152 chronic cases there were no deaths. Richardson's private cases give practically the same results. He believes that operation is indicated in most if not all severe cases when first seen, unless the symptoms are unquestionably improving or the patient is hopelessly moribund. He also believes that increased experience is improving the results of intervention, even in bad cases. [A.G.E.]

**Lister and Pasteur.**—Hart<sup>1</sup> says Pasteur's work did not merely save life; in manufactures it was of great value; in average years in France the value of the cocoons produced reached 100,000,000 francs, while in 1863 and 1864 it fell to 24,000,000 francs, a yearly loss of 76,000,000 francs, or, roughly, \$15,000,000. Pasteur was unable to apply his researches to surgical treatment. Here Lister came in and by his knowledge in bacteriology, physiology and surgery, crowned Pasteur's work with a success which the world of science does not yet appreciate. [A.B.C.]

**The Treatment of Esophageal Carcinoma with Carcinoin Adamkiewicz.**—Pulawski<sup>2</sup> has treated a patient having carcinoma of the esophagus during a period of almost a year with Adamkiewicz's carcinoin, and makes the statement that in this case no positive favorable action was seen; in fact, it did not even produce a temporary improvement in her condition. [E.L.]

**Operation for Obscure Abdominal Pain.**—Prichard<sup>3</sup> reports the case of a woman of 53 who for nearly four months suffered from symptoms of acute cholelithiasis and obstructive jaundice, together with certain nervous symptoms and a variable temperature, running at times to 104° F. A long course of internal treatment failing to relieve the symptoms, laparotomy was done with the expectation of finding biliary stones. None was found, but for eight days following the operation the temperature remained normal, when it again rose. Certain pigmented blotches on the body suggested disease of the suprarenals. Strychnia and arsenic gave quick relief. A second case is reported. A woman of 57 had lived an idle, luxurious life, and for a number of years had suffered from fugitive pains in the abdomen. Lately they were more localized in the pyloric region, and much aggravated by walking, riding or any jolting exercise. After many consultations with various physicians and surgeons, Sir William Bennett consented to perform a laparotomy, believing with the author that adhesions and a weighty dragging stomach caused the pain. Some adhesions were found, removed, and considerable relief followed. [A.B.C.]

**Treatment of Cancer of the Breast.**—Lucas-Championniere<sup>4</sup> reports a mortality of 4 in 166 cases of amputation of the breast, these deaths being attributable directly to the operation. He believes that recurrence follows in every case of mammary carcinoma, and finds that local recurrence is exceptional. Recurrence in the subclavian glands is more frequent than in the axillary. Three cases of recurrence in the breast of the opposite side have been noted, these occurring 8 months, 2½ years and 10 years after operation. The writer does not sanction the removal of the greater pectoral muscle in breast amputation. From an anatomical standpoint this is not necessary, as the mammary lymphatics do not involve the muscle, and its removal may interfere with movements of the arm. After amputation he treats the wound with hydrogen peroxid, this substance perhaps destroying cancerous elements that remain. As after-treatment, magnesia and arsenic are employed. [A.G.E.]

**Aseptic Treatment of Wounds.**—Bloch,<sup>1</sup> of Copenhagen, studied under Lister 25 years ago, and was active in introducing the aseptic surgery in Denmark. One lecture each year is devoted to Lister and the results of his great work. He states that not long after the introduction of Lister's method the assertion emanated from Germany that antiseptics was unnecessary, since a sepsis would meet all the requirements. Though Bloch was the first to treat a whole series of major operations

<sup>1</sup> British Medical Journal, December 13, 1902.

<sup>2</sup> La Semaine Médicale, 1902. Vol. xxii, p. 393.

<sup>3</sup> The Old Dominion Journal, January, 1903.

<sup>1</sup> British Medical Journal, December 13, 1902.

<sup>2</sup> Deutsche medicinische Wochenschrift, November 6, 1902.

<sup>4</sup> La Médecine Moderne, December 31, 1902.

by the aseptic method, securing splendid results, he warns his classes that while it is almost ideal, it is impracticable in hospital practice with many assistants. He therefore urges anti-septic combined with aseptic treatment of wounds. In dressing wounds he takes a piece of sterile (aseptic) gauze and has an assistant pour upon it a 3% solution of carbolic acid (antiseptic) solution. This is then placed upon the wound and covered by sterile cotton wool, which is "hydrophob," or nonabsorbent, the primary gauze pad being "hydrophil" or capable of absorbing the wound discharges. [A.B.C.]

**Removal of the Superior Row of Carpal Bones in Acute Septic Disease of the Wrist-joint.**—MacLennan<sup>1</sup> reports a case of severe spreading cellulitis of the hand for which the carpal bones were removed. This drains all the joint cavities, and as the cartilage is gone from the bones their drainage requires only free escape of the exudations. Pyemia is prone to follow septic bone lesions, hence treatment must be radical. The removal relieves the distressing pain following ulceration of the cartilage. It prevents bony ankylosis, the resulting union being fibrous, and when requisite attention is given, considerable movement may be looked for. In order to reduce deformity to a minimum, the hand is put up in an extended position, and later the splint is worn only at night, while passive and active movements are performed during the day. [H.M.]

**Treatment of the Fractured Patella.**—V. Mikulicz-Radecki<sup>2</sup> pays tribute to Lister, and asserts that the eminent surgeon was the first to suture the fractured patella. This was published in 1877, and six years later Lister reported seven additional cases; thus the operation was fully established in surgical procedure. Mikulicz questions when to operate and when not to operate for fracture of the patella. No hard and fast rule can be laid down. "Blow" fractures, *i. e.*, those from external violence, he usually treats by medicomechanical means; whereas "tear" fractures, caused by over-action of the quadriceps and a combination of blow and tear fractures, such as when a person falls, striking the knee, usually he treats by suturing. In blow fractures the parapatellar ligaments are unorn, while in tear and combination fractures they are torn. A series of cases operated upon is reported. In 14 cases which were investigated after treatment, 12 appeared to have bony union of the patella, but on examination by the Röntgen rays only 8 were bony while 4 had a ligamentous union. Of 15 cases treated by apparatus without suturing, 9 were afterward investigated, and in 8 the result was good. Five of these cases which appeared to have bony union were submitted to the Röntgen rays and 3 were found ligamentous, the other 2 being bony. [A.B.C.]

**The Microscope as an Aid at Operations.**—Edebohls<sup>3</sup> mentions the comparatively slight recognition by surgeons of the value of an intelligent use of the microscope during surgical operations, this being especially true of England and France. He states that there is no good reason why the microscope, in competent hands, should not be used during operations at private houses, and urges the further use of this method. Several examples are given to prove the value of the study of frozen sections during operations. This is true of material obtained of uterine cureting, of obscure abdominal growths, and breast tumors. In at least three operations upon the kidneys such examination was necessary to differentiate between chronic interstitial nephritis and acute miliary tuberculosis. In one instance it decided between tuberculosis and miliary abscesses of the kidney. [A.G.E.]

**Roux's Operation for the Radical Cure of Femoral Hernia.**—Renton<sup>4</sup> has employed this method in 10 cases, seven of which have been previously reported. He is pleased with the method, and describes it as follows: Make an incision over the crural canal, isolate the sac, put a catgut ligature round its neck. A metal staple is passed obliquely through Poupart's ligament over the crural canal, taking care to avoid the femoral vein, and then it is gently hammered into the pubis. Stitch the skin incision. Care must be taken not to put the staple in too

tightly, which would injure Poupart's ligament, still it must be sufficiently secured to prevent any recurrence of the hernia. The staple remains permanently *in situ*; it causes no irritation, and does not injure the bone. The operation can be easily and quickly performed by any one who follows the above steps. Roux has operated on over 60 cases, the retention of the staple giving rise to no trouble, and there has been no recurrence of hernia. [A.B.C.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### REVIEW OF LITERATURE

**Vaginal Cesarean Section.**—Kallmorgen<sup>1</sup> reports a case of an eight months' twin pregnancy complicated with carcinoma of the portio delivered by vaginal cesarean section. Both children were delivered alive, but one died in 9 hours and the other in 14 days. The mother left the hospital apparently well in 26 days. The size of the growth made impracticable any delivery through distension of the cervix, and vaginal cesarean section was chosen because the operation is brief and the loss of blood relatively small. In such an operation it is advisable not to ligate the uterine artery until after emptying the uterus so as not to endanger the life of the fetus. [w.k.]

**Origin of Teratoma of Germinal Gland.**—Pick<sup>2</sup> thinks that in the investigation of the question whether the teratoma of the germinal gland originates in accumulated blastomere or in the fertilized polar cells, Marchand, and more recently Bonnet, has brought out in favor of the former theory the fact that these dermoid tumors contain not a trace of amnion or chorion. Pick reports in detail the case of a teratoma which he removed and subjected to microscopic examination; he gives the results of this examination, reviews the arguments of a number of investigators, and reaches the conclusion that the origin of these neoplasms is still unsolved. He states that the chorioepitheliomatous or vesicular molar products can enter in as constituent parts of a teratoma without any connection with pregnancy, in all parts of the organism, either male or female; and that between these peculiar neoplasms and the ordinary chorioepithelioma and vesicular mole of women there exists this chief distinction; the latter stands to its carrier in the relation of descendant, the former in that of consanguinity. [w.k.]

**Vaginal Cesarean Section.**—Weber<sup>1</sup> describes fully a case of carcinoma of the portio complicating pregnancy in which delivery was by vaginal cesarean section, the mother recovering and the child living one month after delivery. This method was given the preference as opening only the lower segment of the pelvis, producing far less shock and less danger of peritonitis than the classic method. Weber concludes that in those cases in which portio carcinoma is diagnosed at the end of pregnancy, and it is in the early stages so that it can be radically removed, and the pelvis is not narrow and the soft parts are yielding and distensible, vaginal cesarean section, according to Dührssen, seems to be the normal and proper operation. [w.k.]

**Lateral Incision Through the Pubic Bone.**—Leonardo Gigli<sup>1</sup> asserts that symphysiotomy from the surgical standpoint is not a correct operation. The difficulty in securing perfect asepsis in the joint, the still greater difficulty of keeping the parts in perfect juxtaposition during the healing process, and the many unfavorable results following the operation led the writer to seek some better way; and he considers that the lateral incision through the pubic bone by means of a wire saw invented for the purpose as a decided advance. He describes the instrument and the technic of the operation and gives a list of operations by different surgeons all with favorable results. Comparing these with the uncertain and often unfavorable results of symphysiotomy as reported by many operators he does not hesitate to recommend the lateral cutting of the pubic bone as preferable. The technic is simple, the hemorrhage is easily controlled, and the adjacent organs practically avoided and untouched. [w.k.]

## TREATMENT

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPELMAN

## REVIEW OF LITERATURE

**The Nature of and Treatment of Heart Disease at the Menopause.**—Ch. Flossinger<sup>1</sup> distinguishes three types of cardiac disease at the menopause: 1. Cardiac diseases aggravated by the menopause; these may be treated so far successfully that the disorder which is the direct result of the menopause may be relieved, leaving the organ in the same damaged condition in which it was previously; they are sometimes fatal when the heart is already feeble and has not the force to resist the additional strain as the result of the menopause. 2. Cardiac diseases solely the result of the menopause, without previous disease of the heart, and without lesions of the other organs; in these the cure is complete; however, at the end of a number of years, symptoms of arteriosclerosis may be manifested. 3. Cardiac diseases of the menopause in which the heart is healthy, but which are accompanied by a lesion of another organ. The third form is rare, only one case being reported. The pathology of these conditions consists principally in an increase in arterial pressure, which may result from several causes. The prognosis is usually favorable. The treatment consists in confining the patient to a milk and vegetable diet and the administration of ovarine, theobromin, digitalis, and the iodids in small doses, with resort to caffeine and to venesection in urgent cases. [L.F.A.]

**Clinical and Experimental Investigation on the Action of Thiocol and Sirolin.**—Drago and Coco<sup>2</sup> obtained excellent results in simple and tuberculous bronchitis by the use of thiocol and sirolin. The tubercle bacilli decreased in number and their affinity to staining became less and less. After cessation of treatment guineapigs were inoculated with the sputum. The animals gave no tuberculin reaction and developed none of the other symptoms of tuberculosis. The dose of thiocol was 1-5 grains and of sirolin 2 to 6 teaspoonfuls a day. [W.E.R.]

**Treatment of Syphilis by Intramuscular Injections of Hermophenyl.**—Nicolle<sup>3</sup> reports excellent results from the intramuscular injection of hermophenyl—sodium mercurio-phenol-disulfonate—in the treatment of syphilis. He injects 2 cc. (30 minims) of the following solution into the upper part of the thigh twice a week:

Hermophenyl . . . . . 0.1 gram (1½ grains)  
Distilled water . . . . . .9 cc. (2½ drams)

This should be sterilized in an autoclave.

Nicolle employed hermophenyl in this manner in 94 cases, and had only very slight accidents from its use; these he attributes to faulty technic. It does not cause persistent induration of the parts, abscesses, cicatrices, nor symptoms of mercurial poisoning. [L.F.A.]

**The Action of the X-ray.**—According to Snow<sup>4</sup> the x-ray produces the following effects upon living tissue: Impairment of nutrition, marked by alopecia and atrophy of the skin; irritation; inflammatory action, shown by a tanning dermatitis or deep necrosis, with sluggish reaction; a germicidal effect, at least as regards certain organisms. He believes the earliest effect of the x-ray is to stimulate the normal action of the tissue cells, which in some cases will supplant abnormal elements without evidences of disintegration; and that longer exposures destroy the vitality of abnormal tissue without affecting the normal structures. It is to this destruction of tissue of low vitality that the x-ray owes its efficiency in various malignant growths. He believes also that it causes contraction of the arterioles, in this way controlling pain and hemorrhage. Lupus and epithelioma and similar superficial neoplasms are invariably cured by the use of the x-ray. More deeply situated growths may also be favorably influenced, but it frequently taxes the skill and patience of the operator to produce complete cure; and when tumors underneath the skin or enclosed cavities of the body break down, as they often do under the use of the x-ray, they may produce an autoinfection which, in debilitated

patients, may prove fatal. Snow further recommends very urgently the use of the x-ray not only in inoperable cases, but also in conjunction with operation in every case in which the latter is suitable. In many cases which might be inoperable without the x-ray, permanent cure may take place by means of the conjunction of operation and radiation. Patients do not become more tolerant of the rays after prolonged treatment, and after a tumor has been removed from one part, a similar growth may occur at a distant point. [H.C.W.]

**Local Application for Corns.**—Brocq<sup>1</sup> recommends:

Salicylic acid . . . . . 1 gram (15 grains)  
Extract of cannabis indica . . . . . 0.5 gram (7½ grains)  
Alcohol, 90% . . . . . 1 cc. (16 minims)  
Ether, 62% . . . . . 2.3 cc. (37 minims)  
Flexible collodion . . . . . 5 cc. (80 minims)

To be applied every evening for eight days. On the eighth day a prolonged foot-bath should be taken, then with a scraper the mass of collodion, with the greater part if not all of the corn, may be removed. This treatment may be repeated if necessary. (This is but a slight modification of the wellknown process of Traill Green, which has become the basis of so many proprietary corn cures.) [L.F.A.]

**Parenchymatous Nephritis Due to Syphilis.**—The article by Wagner<sup>2</sup> is an analytic review of 12 cases, gathered from the literature, of acute parenchymatous nephritis following syphilitic infection, in which all possible etiologic factors other than the specific infection could be satisfactorily excluded, to which are added three cases from the Leipzig clinic. The diagnosis is difficult because of the many other possible etiologic factors; in 12 of these cases the symptoms appeared at the same time as the secondary syphilitic symptoms. Symptoms and course are those of ordinary nephritis. As regards prognosis, these cases are usually remarkable for their severity. The main interest of this article centers in Wagner's discussion of the therapy. Of 14 cases, 4 received no mercurial treatment, 3 died, 1 recovered. In 10 cases mercury was used, in some cases repeatedly, and in but one did any toxic effect of the mercury upon the kidneys appear; of these 10 cases, 2 died, the others recovered. Wagner concludes that specific treatment is therefore justifiable. [J.E.S.]

**Incompatibility of Calomel with Cocain Hydrochlorate.**—Marcel Jean<sup>1</sup> states that the addition of a solution of cocain hydrochlorate to calomel gives rise to a grayish, slate-colored discoloration, due to the liberation of metallic mercury. In those instances in which it is desired to form an ointment of cocain hydrochlorate, calomel or white precipitate, he advises first mixing the calomel with the fatty substance and then adding the cocain; by this means the calomel is coated with the fatty substance, and is protected from the action of the cocain. [L.F.A.]

## FORMULAS, ORIGINAL AND SELECTED.

## For Hemoptysis.—

Hydrastinin hydrochlorate } of each . . . 1 gm. (2 grs.)  
Cotarnin hydrochlorate }

Mix. Make 12 pills.

Dose: One pill every second to fourth hour. [S.S.C.]

## In Neurasthenia and General Debility.—

Sodium glycerophosphate } of each 4 gms. (1 dr.)  
Calcium glycerophosphate }  
Strychnin phosphate . . . . . .02 gm. (¼ gr.)  
Fluid extract of guarana, or }  
Fluid extract of coca, or } . . . 15 cc. (½ fl. oz.)  
Fluid extract of kola }

Citric acid, a sufficient quantity.

Aromatic elixir . . . . . 90 cc. (3 fl. oz.)  
Water sufficient to make . . . . . 120 cc. (4 fl. oz.)

Dose: 4 to 12 cc. (1 to 3 fluidrams) in water, three or four times daily after food. [S.S.C.]

**For weak heart, intermittent or irregular, with precordial pain, irrespective of presence or absence of valvular lesion:**

Adonidin . . . . . .005 gram (1/20 gr.)  
Extract of cactus . . . . . .008 gram (1/8 gr.)

Mix. Dose: One such pill thrice daily. If the condition is due to abuse of tobacco, add to each pill:

Picrotoxin . . . . . .002 to .003 gram (1/20 to 1/20 gr.)

[S.S.C.]

## ORTHOPEDIC SURGERY

H. AUGUSTUS WILSON

## EDITORIAL COMMENT

"A New Principle of Curing Club-foot in Severe Cases in Children a Few Years Old" is offered by Ogston.<sup>1</sup> He refers to those cases which have either not been treated in the first two years of life or in whom the treatment has not been satisfactory. Exception may well be taken to one or two of Ogston's statements. "Those who have had much experience of cases of this kind will admit that, though a great deal can be done by selecting the proper operations, yet none of our plans of treatment are thoroughly satisfactory; all require great and prolonged care and observation of the patient, and after operations are frequent." The unfortunate reliance upon operations and so-called plans of treatment is the undoubted cause for the expressed dissatisfaction. Operations for club-foot are never curative but are, when required, simply an aid to the cure, by removing the obstacles to normal muscular coordination. A club-foot cannot be said to be cured in which the voluntary control is impaired, even though the foot may be placed in a correct or over corrected position; and herein lies the serious error of considering an operation for correction as curative. "Plans of treatment" are not applicable to ever varying conditions and no two cases of club-foot ever present exactly the same phenomena of position, resistant tissues, malplaced tarsal bones, stage of ossification, constitutional health or ability for recuperation. To accomplish a complete recovery in cases of club-foot there must be an understanding of the mechanical functions to be recovered; this is apparently wanting in those who postpone the application of rational treatment, or who simply cut tendons and allow the case to relapse by neglect, or who consider braces to be curative. The diversity of views as to the existence of bone malformation at birth will in part account for the existing differences of opinions as to the propriety of resorting to operative procedures in early life. Druitt, Erichsen, and Ashhurst are among those who oppose the existence of original bone deformity, while Adams, Morton, and others incline to the view that the astragalus is malformed at birth, and Phelps says that the deformity of the soft parts is out of all proportion to the deformity of a bone. The changes in the bones often described are in a large measure due to postponement of appropriate treatment. This may be accounted for in either of two ways: First, that observed in uncorrected cases in which the process of ossification progresses and the partially dislocated tarsal bones become permanently deformed to suit the abnormal position of the foot; and, secondly, in those cases of more or less marked severity where, to stretch shortened tendons, there has been recourse to great mechanical force. In these cases the bones, whether deformed or not, yield to the pressure exerted and thereby become deformed, and ossify in their altered shape. In most instances both of these occurrences could and should have been avoided by the early recourse to operative procedures. It is not a question of saving time but of perfect correction. Ogston's statement that "If the whole or a considerable part of a tarsal bone be resected for club-foot, that bone, or portion of bone is lost; it is not restored," is not in accord with the experience of the writer and others who have seen cases many years after complete excision of the astragalus. If a new and modified form of astragalus does not develop in the place formerly occupied by the excised malformed astragalus, it is certain that something closely resembling it is produced which often facilitates establishment of function of the ankle-joint which is comparable with normal action. It may well be accepted that there are and always will be cases for one reason or another that have reached the usual period of school life, to which Ogston refers, with deformed feet, in whom he

considers his method is applicable. That this should be so is condemnation of the previous methods or want of attention. Ogston's new principle consists in removing by a Volkman sharp spoon the bony kernel or unossified cartilage so that the bone will be restored in correct contour from the ossification from the shell of cartilage which remains. Several bones can thus be dealt with through one external wound. While the operation which is described at length is a decidedly new principle of procedure for club-foot, similar to the Sedillot operation for caries, sufficient time has not yet elapsed to show its permanent results in function, which after all is the essential feature. It is to be regretted that Ogston's paper should leave the impression that the operation he advocated should be considered curative in that no indications are given for after-treatment to establish function or prevent relapses. The great hopefulness that caused the Phelps' operation upon the soft parts to be extensively adopted indicated the desire for improved methods. The relapses caused by the contracture or failure to grow proportionally; of the large cicatrix of the Phelps' incision caused a revulsion until one after another abandoned the procedure in the light of subsequent events. Both the Phelps' and the newer Ogston's operations are in marked contrast to the non-cutting methods advocated by Lorenz and must direct attention to the necessity for early correction with the least possible cicatrix, to the avoidance of undue restraint and to the early development of muscles which alone can induce normal functions.

**Tendon Transplantation.**—This subject has been enriched by two contributions of decided merit and of great historic value. Elting<sup>1</sup> says the credit for this brilliant idea has usually been accorded to Nicoladoni but in reality belongs to Duplay, who in 1876 employed the procedure in a case of traumatic loss of function of the arm. Waterman<sup>2</sup> says that "probably the first man who ever grafted a tendon for any cause was Missa. The case was reported in the *Gazette Salulaire*, 1770, No. 21. Velpeau in his encyclopedic work preserved Missa's case from oblivion, and while he does not appear to have done the operation quotes Champion as having done so." In the discussion before the Paris Surgical Society in 1874 Polaillon, apparently unaware of the cases of Missa and Champion, awarded the credit of priority to Denonvilliers and announced that he had grafted a tendon in 1873. The work on surgery written by Denonvilliers, Bernard and others does not mention tendon grafting. In 1874 Tillaux reported a case before the Paris Surgical Society. In 1875 both Duplay and Tillaux reported cases before the Paris Surgical Society. Waterman observes: "It appears reasonable to suppose that tendon transplantation has been done in the past more generally than is believed to have been the case." In April, 1881, Nicoladoni appears to have first transplanted healthy tendons to correct paralytic talipes calcaneus in the methods previously used by others for other purposes. It is interesting to note that some five cases were operated upon by the so-called Nicoladoni method by Von Hacker, Maydl and others attached to Albert's clinic invariably for pes calcaneus, but the ultimate results appear to have been disappointing, and Waterman says that as early as 1886 the operation was definitely abandoned by the German and Austrian surgeons. Milliken and Parrish, of New York, announced as did Nicoladoni that they had introduced a new and original principle into surgery; Parrish first performed the operation in May, 1892. Since 1892 many operators have had recourse to the transplantation method; among the most conspicuous are Drobnik, Winkelman, and Goldthwait. The last named started in 1894 with the impression that the method was original;

<sup>1</sup> Tendon Transplantation in the Treatment of Paralytic Deformities, *Albany Medical Annals*, April, 1902, p. 187.

<sup>2</sup> Tendon Transplantation; its History, Indications and Technic. *Med. News*, July 12, 1902.

<sup>1</sup> British Medical Journal, June 21, 1902. (See abstract).

but careful research, for which he is noted, revealed the case of Nicoladoni but not those of Missa and Denonvilliers. It is interesting to observe the conclusions reached by Elting and Waterman, after their laborious study of the literature. Elting advocates tendon transplantation as the most satisfactory method of treatment yet suggested in the treatment of many deformities due to muscular paralysis or weakness. Waterman expresses the opinion "that we must seldom expect to secure by transfer of function alone complete equilibrium between antagonistic muscles. We must content ourselves with a gradual strengthening of those portions of muscles which are compelled to perform new duties." When it is considered that the class of cases usually considered suitable for this procedure are more or less hopelessly paralytic, it will be understood that entire restoration of function is out of the question and that apparently insignificant improvement is often a gain of paramount importance to the patient. Both papers point out the impropriety of continuing to designate the procedure Nicoladoni's operation even when it is applied to one of its uses, *i. e.*, pes calcaneus.

#### REVIEW OF LITERATURE

**Internal Derangement of the Knee-joint.**—Frank E. Peckham<sup>1</sup> says that internal derangement of the knee-joint is caused by a displacement of the semilunar cartilages, which may be very slight, with an immediate return to its normal position, or it may have all grades of severity up to complete dislocation, with a firm locking of the joint in consequence. Symptoms: Effusion may or may not be present. The joint is weak, giving way at intervals, possibly causing the patient to fall, followed a little later by actual locking of the joint. The knee is slightly flexed, painful, tender to pressure on inner side of patella, and it is often impossible to completely extend the leg. Increased lateral mobility of joint and ligamentum patella often elongated. With the knee slightly flexed, there is possible a slight twisting motion, and it is thus that the accident happens, consequently any apparatus which would prevent complete extension would surely prevent a recurrence. One other important thing the apparatus does is to prevent any separation of the inner condyles. These three things are actually accomplished by a Shaffer apparatus which the writer uses in such cases with uniformly successful results. Ten illustrative cases are cited. [It is with pleasure that an abstract furnished by the author is here given in the manner originally suggested by Dr. George M. Gould. It cannot be questioned that the author is the one best able to provide an abstract of his paper that will give the essential features as he wishes them to appear. Attention is again called to this subject with the hope that authors will furnish abstracts of their papers, not to exceed 150 to 200 words, and thereby secure accuracy that will be appreciated by the readers.]

**Congenital scoliosis** is the subject of a valuable paper by A. Broca and Albert Mouchet,<sup>2</sup> giving a condensed review of 35 cases. Of these, 29 were reported by Hirschberger,<sup>3</sup> 1 by Codivilla,<sup>4</sup> 1 by A. C. Fleury,<sup>5</sup> 1 by Bonnaire, and 3 by Broca and Mouchet. Radiographs of the last three are in the Musée Dupuytren. In each of these three cases there was a supernumerary half vertebra situated between the first and second lumbar vertebra. Codivilla's case had a supplementary half vertebra between the second and third lumbar vertebrae. This instructive contribution adds to the pathologic knowledge of scoliosis, and will be read with interest by those who may be inclined to rely upon any of the so-called plans of treatment, and will indicate the necessity for the individual study of each case in order to appropriately meet its requirements.

**Results After Treatment of Pott's Disease.**—Taylor<sup>6</sup> reports 39 cases treated in private practice by the use of Taylor's

apparatus, where the cases were observed and the deformity recorded for 10 or more years. Tracings of the spinal contour at the time of treatment and at the last examination are appended in each. The findings show that (1) the application of spinal support was nearly always promptly followed by the relief of pain and other acute symptoms, and by improvement in general health; (2) the patient was cured in 33 cases, the cure in a considerable number being practically perfect as regards health, figure and function; (3) 13 cases showed arrest or decrease in deformity; (4) regarding the final amount of deformity, the location of the disease was more important than any other factor, the cervical region being most favorable, lumbar next, and dorsal the least; (5) it was necessary in most cases to continue spinal support long after pathologic cure, owing to the tendency to increase of deformity from static conditions; (6) ankylosis is therefore later, rarer, and less extensive than usually assumed. [A.G.E.]

**Postmortem Findings After the Lorenz Method.**—Bradford and Soutter<sup>1</sup> quote Chatala and Veau in their report of the postmortem findings in the hip-joint of a child of 4 years, treated by the Lorenz method and dead of diphtheria one month after reduction. The pectineus was torn almost completely asunder; the capsule, which was unusually thick in front and thin behind, did not present an hour-glass contraction. The cotyloid cavity was well shaped, with well marked borders; the round ligament was present, and the femoral head small. The neck was marked by a cartilaginous prolongation on the posterior surface, not on the anterior. Manipulation with the specimen showed the upper part of the acetabular border which separated the two cavities, the true and the false, to be the chief obstacle, by its prominence, to reduction by direct traction. To effect reduction it is necessary to flex the femur on the pelvis and make slight external rotation, thus the head is brought down in the posterior part of the acetabulum where the border is less prominent; the thigh should be then abducted and the head will slip into the acetabulum. Fixed in external rotation with extension the head is held closer to the acetabulum by the tension of the capsule than in internal rotation, which relaxes the anterior part of the capsule. [A.B.C.]

**Operative Substitution for the Paralyzed Quadriceps Femoris.**—Magmes<sup>2</sup> reports the very favorable results of transplanting the sartorius and biceps femoris in three cases of quadriceps paralysis in consequence of acute anterior poliomyelitis. In no case was the sartorius paralyzed, and in each case the leg was capable of flexion and extension after the operation. The procedure followed by Schanz is the following: He exposes the quadriceps tendon immediately above the patella by an incision 15 cm. (5 inches) long, and cuts a slit through its center. A second incision is made posteriorly and through it the sartorius and biceps are separated from their insertion, and loosened for about one-third of their length. They are brought forward through openings made between muscles and fascia, and passed through the slit made in the quadriceps tendon, pulled tight, and so tucked up as to form a sling. He uses silver to fasten the tendons, and closes the wound without drainage. The limb and pelvis are put into a plaster dressing in the line of extension. After 10 days the skin sutures are removed; after three weeks a short plaster cast is applied, and this is taken off after six weeks, when active and passive movements are employed to produce usefulness of the limb. [E.L.]

**After-treatment of Erosion of the Knee-joint.**—Collier<sup>3</sup> states that much of the disfavor for the operation of erosion for tuberculous knee-joint is due to bad results from want of care in the after-treatment, the joint becoming fixed in flexion. The patella should be kept freely mobile from the first. The inclination to flexion, always present, is much greater so soon as the patient begins to walk. To prevent this, place the limb in full extension so soon as the skin sutures are removed and fix in plaster, leaving a window through which the patella may be moved from side to side several times a day to prevent it becoming adherent to the femur. At the end of four to six months the cast should be removed, and if there is voluntary

power of extension the patient may be allowed to walk without support. If power of extension is not present, apparatus should be worn for at least two years. [A.G.E.]

**Acquired High Position of the Scapula.**—This deformity, first described and attributed to rickets by Kölliker<sup>1</sup> in 1898, differs from that known as Sprengel's deformity, which is congenital and apparently more frequent. A case of the acquired variety is described by Bender (*Münchener med. Woch.*, March 4, 1902) in a girl of 12 years. There were evident signs of rickets, and the radiographic picture showed a rickitic deformity of the scapula, characterized by increased curvature of the bone and a hook-like formation of the inner upper angle, enlargement of the coracoid process, and anterior displacement of the articular surface. The treatment consists in securing mobilization of the scapula by passive and active orthopedic exercises; and, later, in the use of an apparatus that draws the scapula downward and inward, in order to maintain the improvement. It may be necessary to add resection of the coracoid process and upper angle, with division of the shortened muscles. [D.R.]

**School Children Examined for Spinal Curvatures.**—Bradford and Soutter<sup>2</sup> report the findings of physicians who examined the school children of Lausanne, France, where 2,314 children were examined, and anteroposterior curvatures were found in 5.8%, boys being slightly more frequently affected. Curvature affected 2.7% in the lower class, and 4% in the upper class. Of these, 9% only showed evidence of rickets. In half the cases the curvature was combined with scoliosis. In scoliosis, a difference in the length of the limbs was not an important predisposing cause; of 571 scoliotics, only 6.8% had shortened limbs. The influence of flat-foot is slight in the development of scoliosis, for this defect existed on one side in 23.9% of the boys (1,290 cases), but in only 8.4% of the scoliotics. Of the 2,314 children, 24.6% were scoliotic. Boys were affected nearly as frequently as girls; boys 23%, girls 26.7%. Left scoliosis increased with less frequency than right as the children grew. Lumbar scoliosis was much more common in girls, while dorsal scoliosis is nearly as common among boys. Scoliosis, according to Eulenburg's figures, increases in frequency rapidly in the age of school life, 8.9% being between the age of 2 and 6; 88.6% from 6 to 14, the age of entrance into scoliosis being 6. [A.B.C.]

**Painful Foot.**—Schanz<sup>3</sup> discusses the symptoms and treatment of flat-foot, giving numerous valuable points toward its diagnosis and treatment. It is rarely congenital, but usually arises when there is a disproportion between the weight resting on and the supporting ability of the arch of the foot. Rickets, fractures, sprains, obesity, occupations necessitating standing, etc., are the causes. Its symptoms are pain existing at any and all parts of the foot, associated with or without change in its structural build. No one painful point is typical for the condition, but pain may appear anywhere. Weariness on the slightest exertion, peculiar stiffness of foot while walking, waddling gait, are the other prominent symptoms. Such patients often wear old and warm shoes, their feet perspire, are swollen and edematous, there is much tenderness especially on passive supination. The treatment for flat-footedness consists in the wearing of soles, which increase the arching of the foot, and have to be made for each individual case. Firm bandages, rubber stockings, adhesive plaster, well-fitting shoes, are also of service. [E.L.]

**Treatment of Congenital Torticollis.**—E. Noble Smith<sup>4</sup> gives practical points in the treatment of uncomplicated congenital torticollis which may be summarized as follows: (1) Division of the contracted sternomastoid muscle is usually required; (2) a retention apparatus is not usually necessary in uncomplicated cases, either before or after operation; (3) in operating, the open wound is desirable in the majority of cases, certainly when the clavicular attachment of the muscle has to be divided; (4) a vertical incision between the two attachments is useful because (a) it is less likely to leave a noticeable scar than is a transverse cut, and (b) through this one opening both

the sternal and clavicular portions of the muscle can be divided; (5) the incision should be about 1½ inches in length from the level of the clavicle upward. The patient should be kept in bed in one position for from 7 to 10 days after the operation; (6) subsequent treatment depends on the condition of the patient previous to operation. In children of 6, structural changes will not be severe and little difficulty will be experienced in keeping the head straight. If there is a tendency to resume the former position massage and special exercises will correct it. In older patients, especially adults, the tendency will be stronger but the same treatment generally suffices. Cases with severe lateral curvature will need special treatment, but these are not considered within the scope of the paper. Notes on four cases with illustrations are appended. [A.G.E.]

**The Treatment of Club-foot in Children.**—Ogston<sup>1</sup> asserts that ossification of the tarsal bones does not occur until comparatively late. He has therefore devised a plan of operation as follows: After the usual disinfection an Esmarch's tourniquet is applied to the leg and tenotomy of the tendo-Achilles is performed. An incision through the skin is made in a gentle curve beginning in front of the external malleolus and extending forward with its convexity toward the sole, until it terminates over the calcaneo-cuboid joint on its dorsal aspect. When its edges are retracted the outline of the astragalus is visible. The soft parts covering it and the cartilaginous shell surrounding its osseous center are then divided by a shorter incision in the same line as the cutaneous one, the knife being made to sever everything down to the bony kernel. A Volkmann's spoon, slightly curved forward at its neck, is passed into the wound of the cartilages and the whole bony center, save the upper part constituting the pulley between the two malleoli, is cautiously scraped out. The feeling conveyed through the spoon at once tells when the cartilage is reached. The foot is now placed in the attitude of rectification, and usually the improvement is very great. If the correction be not sufficient, as will be the case in very severe deformity, it is necessary to apply the same treatment to the cuboid and calcis, which stand in the way. The skin incision is glided over the cuboid till its outline can be seen and felt, and it also is incised and its bony center completely scraped out, sparing all its cartilaginous shell. The anterior end of the calcis is similarly treated and then the rectification is satisfactory. [A.B.C.]

**Hallux Valgus.**—The curative treatment of hallux valgus lies in orthopedic and operative measures. The first consists in the application of a tampon of felt between the first two toes; a diachylon bandage is bound from the base forward on the toe, at its anterior extremity it is turned and carried along the internal border of the foot and fastened at the back; a cord from the anterior extremity of the binder is fastened on the inner side of the shoe. A plaster apparatus is applied after straightening. If surgical intervention is necessary, the best method is resection of the neck of the metatarsal bone, cuneiform osteotomy. An incision is made on the dorsal surface of the first metatarsal bone about half an inch inside of the corresponding tendon; the periosteum is loosened so as to expose a bony angle at the external summit, which may then be removed by a chisel. [L.F.A.]

**Surgical Treatment of Spastic Infantile Paralysis.**—Jones<sup>2</sup> states that nothing can be expected from medicine in the treatment of this condition. He has operated upon more than 100 patients, and says that a large proportion of children suffering from severe spastic paralysis may be transformed into useful members of the community and enabled to walk with comparatively little deformity. The cases not amenable to surgical treatment are the idiot, the microcephalic, and the violently irritable type of diplegia. Technic is discussed by Jones, who has operated on patients aged from 12 months to 20 years. Treatment of these patients should resolve itself into a system, such system including operative, mechanical, and educational stages. The surgeon must have the case under control for at least 12 months. The new Liverpool Country Hospital for Chronic Diseases of Children is to have a ward where paralytic patients can be kept as long as it is necessary. [A.G.E.]

**Changes in the Medical Corps of the U. S. Army for the week ended January 24, 1903:**

KELLOGG, PRESTON S., contract surgeon, leave granted is extended twelve days.

HULL, A. R., contract surgeon, is granted leave for twenty-one days, from about February 4.

MERRICK, JOHN N., contract surgeon, is granted leave for one month to enable him to appear before the Army Medical Examining Board at the Presidio, February 9, for examination for commission as first lieutenant and assistant surgeon.

SEEVERS, ROBERT E., contract surgeon, Fort Harrison, will proceed to Fort Missoula for duty during the temporary absence of Contract Surgeon John N. Merrick. On completion of this duty, Contract Surgeon SeEVERS will rejoin his proper station.

O'NEILL, JOSEPH A., contract surgeon, leave granted December 15 is extended one month, and upon expiration of his leave he will proceed to San Francisco, Cal., and report for transportation to Manila, P. I., for assignment to duty.

TURNBULL, First Lieutenant WILFRED, assistant surgeon, having reported his arrival at San Francisco, Cal., will report to Fort Myer for duty.

HARTUNG, HENRY, hospital steward, is relieved from further duty with company of instruction No. 2, hospital corps, Fort McDowell, and will proceed to Fort Columbus to relieve Hospital Steward Herbert Curtis. Steward Curtis will proceed to Fort McDowell and report to the commanding officer, company of instruction No. 2, hospital corps, who will send him to Manila, P. I., for assignment to duty.

SHEPHERD, JOHN M., contract surgeon, is granted leave for one month, on account of sickness.

**Changes in the Medical Corps of the U. S. Navy for the week ended January 24, 1903:**

HART, G. H., KAINES, A. W., FOSTER, T. C., BLOCK, W. H., and DYKES, J. R., appointed acting assistant surgeons—January 20.

ARNOLD, W. F., surgeon, detached from Cavite Naval Station and ordered to Port Isabela, P. I.—January 21.

OMAN, C. M., assistant surgeon, detached from Port Isabela and ordered to the Frolic—January 21.

GRUNWELL, A. G., passed assistant surgeon, detached from the Naval Hospital, Norfolk, Va., and ordered to the Naval Hospital, Washington, D. C.—January 21.

HUNTINGTON, E. O., passed assistant surgeon, detached from the Navy Yard, New York, and ordered to the Maine—January 21.

KERR, D. B., passed assistant surgeon, detached from recruiting duty and ordered to the Wabash—January 21.

HOLCOMB, R. C., passed assistant surgeon, commissioned passed assistant surgeon—January 21.

DELANCY, C. H., assistant surgeon, detached from recruiting duty and ordered to Naval Hospital, Norfolk, Va.—January 21.

BOGAN, F. M., assistant surgeon, detached from Naval Hospital, Washington, D. C., and ordered to the Navy Yard, Washington—January 21.

DEBRULER, J. P., appointed assistant surgeon, January 3, 1903—January 21.

CAMPBELL, R. A., acting assistant surgeon, ordered to duty with recruiting party—January 21.

KEENE, W. P., acting assistant surgeon, ordered to duty with recruiting party—January 21.

CHAPMAN, R. B., acting assistant surgeon, ordered to duty with recruiting party—January 21.

PLUMMER, R. W., passed assistant surgeon, detached from recruiting duty and ordered to the Prairie—January 22.

FURLONG, F. M., passed assistant surgeon, detached from recruiting duty and ordered to the Navy Yard, New York—January 22.

MILLER, J. T., acting assistant surgeon, ordered to recruiting duty—January 22.

JANNEY, W. H., acting assistant surgeon, ordered to the Naval Hospital, Port Royal, S. C.—January 22.

MOORE, A. M., surgeon, retired, appointed member Board of Examiners, Civil Engineers, Chicago, Ill.—January 24.

BYRNES, J. C., surgeon, additional duty as member of Board, Examination of Civil Engineers, New York—January 24.

BLACKWELL, E. M., assistant surgeon, additional duty as a member of Board, Examination for Civil Engineers, New York—January 24.

**Changes in the Public Health and Marine-Hospital Service for the week ended January 22, 1903:**

BAILHACHE, PRESTON H., surgeon, leave of absence for thirty days from January 6, 1902, amended so that it shall be for twelve days—January 22, 1903.

AUSTIN, H. W., surgeon, leave of absence for three days, under paragraph 179 of the regulations.

GUITERAS, G. M., passed assistant surgeon, granted leave of absence for seven days from January 19, 1903, under paragraph 181 of the regulations.

OAKLEY, J. H., passed assistant surgeon, leave of absence for two days granted by Bureau letter of January 13 revoked—January 20, 1903.

KORN, W. A., assistant surgeon, to proceed to Delaware Breakwater and assume temporary charge of the station during the absence, on leave, of Passed Assistant Surgeon C. H. Lavinder—January 17, 1903.

BOGESS, J. S., assistant surgeon, granted leave of absence for four days from January 21—January 16, 1903.

SAMS, F. F., acting assistant surgeon, leave of absence for thirty days from January 1, 1903, granted by department letter of January 5, amended to read thirty days from January 5—January 14, 1903.

PUBLISHED WEEKLY AT 1321 WALNUT STREET, PHILADELPHIA, BY THE AMERICAN-MEDICINE PUBLISHING COMPANY

VOL. V, No. 6.

FEBRUARY 7, 1903.

\$5.00 YEARLY.

**Statistics of Railway Accidents.**—During the year ending June 30, 1901, there were 282 passengers killed and 4,988 passengers injured in United States railway accidents. During the same time there was not a passenger killed by train accidents in all England, Scotland, Wales, or Ireland. Including employes, trespassers, and grade-crossing victims, the total figures of accidents in the United States from railway accidents are for the year ending June 30, 1901, 61,794—killed, 8,455; injured, 53,339. Of employes one out of every 400 was killed, and one out of 26 injured. Of passengers one was killed for every 2,153,469 carried, and one injured for every 121,748 carried. About  $2\frac{1}{2}$  collisions, and  $1\frac{1}{2}$  derailments occurred per 100 miles of road per year, and the losses, not including damages to freight or on account of personal injuries or deaths, average about 3,800 per 100 miles. How long will the American people endure this reckless and brutal sacrifice of life on the part of railway companies? England shows us that it is unnecessary. Undoubtedly, also, the mere financial expense of it to the railroads is much greater than would be its prevention.

**The Causes of Railway Accidents.**—The recent appalling collisions and accidents to trains seem at first to point to a rapid increase of carelessness, but it is noteworthy that the terrible figures remain about in proportion to the population each year. From the reports submitted to the Interstate Commerce Commission in 27 of the more serious collisions the principal causes were: Forgetfulness by conductors and enginemen, who run their trains past stations at which, according to written orders in their pockets, they should stop; overlooking one of a number of orders; mistakes in reading hours or names in written orders; misreading watches or miscalculating time; misreading time tables and train registers; carelessness in identifying trains at meeting stations. Besides these errors of the men on the trains there are mistakes by train dispatchers in issuing telegraphic meeting orders and by telegraph operators at stations in receiving, copying, sending, and delivering telegraphic orders which are sent by the dispatcher to the men in charge of trains and are repeated back to the dispatcher. Collisions occur also by reason of complications following deliberate neglect to carry out certain safeguards. In other words, a single mind is likely to

become careless or make any one of the many errors of sense or judgment which result in accidents. In many instances railway employes are required to be on duty, or voluntarily remain for so unusual a number of hours as to suggest that accidents more or less frequently result from that cause. The work of operating trains in which these men are engaged requires a high degree of mental and physical vigor. If their powers are impaired by service exceeding the limits of ordinary endurance there is liable to be a loss of that alertness on which the safety of the traveling public so constantly depends. From the data compiled it appears that in seven serious cases occurring in six months the men at fault had fallen asleep on duty or had been constantly on duty from 15 to 25 hours before the accident.

**The Remedy for Railway Accidents.**—We have before stated our belief that not only are accidents at sea and on railways caused by temporary working overtime, by overfatigue, illness, carelessness, etc., but that these things are also due to old age. "He was our oldest and most experienced man," is often given as an excuse, when in fact it is precisely the fault. Age and long bearing of responsibility blunts the senses and the mental alertness which really prevents accidents. All pilots, captains, engineers, etc., should be pensioned or transferred to other positions at a certain age, beyond which it is unsafe to trust them with the hazardous responsibilities. It has long been recognized that two pilots must be on duty in the wheelhouses of ferry-boats, etc., and why should not two engineers be on duty on every passenger locomotive? The old style of engine permitted the fireman to act as a second to the engineer. The new machines forbid this. Let a third man be added. Two train dispatchers should be in charge of each principal office, and overtime work should be prohibited by law in trainmen. Automatic couplers and power brakes have been made compulsory by law and have served to lessen somewhat the number of casualties, but there are many other ways that a nation careful instead of reckless of the lives of its people should demand which would stop the hideous maimings and deaths at present unnecessarily permitted.

**Dr. Razlag's Method of Treating Leprous Patients.**—In Public Health Reports there have

appeared reports of a method of treating leprosy patients advocated by Dr. Adolph Razlag, of Vienna, Austria, but spoken of as an American citizen, whereby the cure and final extinction of leprosy is assured. According to the reports of Surgeon John M. Swan to the U. S. Consul at Canton, China, of January 10 and April 25, 1902, no new or secret drug is used, the reliance being upon rational therapeutics combined with thoroughgoing personal hygiene, and great care as to reinfection. Each case should be studied separately; the treatment is symptomatic, and is required for five or six months. A recent and more extended report prepared by Dr. Razlag and forwarded by U. S. Consul McWade to the Assistant Secretary of State, says that of the four cases treated three have returned to their work apparently cured, the fourth, a desperate case when undertaken, being still under treatment. Dr. Razlag now gives the details concerning 14 new patients under treatment, and who show cures or partial cures most encouraging, although the treatment has lasted only at most less than four months, when a year is usually required to effect cure. In a vivid way Dr. Razlag describes the filthy conditions whereby infection and reinfection are brought about in China. All villages have a percentage of 3, 1, or 0.5 of cases, Canton itself having a total of 20,000 lepers. Heredity accounts for only about one-eighth of the cases. In order to carry out effective treatment, Dr. Razlag (who has borne the expenses of experimentation himself) advises the setting apart of an island whereto all lepers may be removed and thorough control established. The island of Molokai is suggested. Detailed description of the sanitary and hygienic conditions necessary are given in the report. Chief among these are kindness to and freedom of the patients so far as is not inconsistent with isolation; thoroughgoing medical authority and care; and absolute separation of the sexes to stop the inheritance of the disease. The mortality among lepers is not higher than among patients with other tropical diseases, and typhoid, pneumonia, smallpox, cholera, plague, dysentery, pernicious fevers, and anemia are almost unknown among the leprosy. The appointing of a leper commission of 10 is recommended, to have charge of the plans and arrangements. The treatment advised by Dr. Razlag is given in the columns of our therapeutic department.

**Child Labor Reform.**—There are nine States in which children of 14 are not allowed by law to be employed in factories and mercantile establishments. In New York a lax administration of the law is being proceeded against by a number of associations and many public-spirited citizens. The work of organization is largely in the hands of a devoted social worker, Miss Helen Marot, who has gathered over 1,000 cases of evasion of the law. Governor Odell's sound position taken in his message has had the effect of focusing public attention upon the evil of child labor in the entire State. In New Jersey Governor Murphy also spoke clearly of the same abuse, and advised that the power of removal of factory inspectors should be lodged in the Governor. In Illinois Governor Yates asks for more inspectors, placing the desired number at fifty. Illit-

eracy is increasing in Illinois; in 1890 this State was fifth in the table showing percent able to read and write in children from 10 to 14 years of age, while in 1900 it was the fifteenth. There are about 20,000 children at work in the State, one-third of whom are believed to be under 14, and no educational test is required of children before securing work. There is no law preventing night work. In Pennsylvania the child labor evil is almost unrestricted. There are at least 36,000 children at work in its stores and factories, besides the breaker-boys in the coal regions. Its illiteracy rate is high. The United Mine Workers have formulated a bill for the Pennsylvania Legislature which includes the following provisions:

"Abolition of night labor for all females, and for boys under 16 years of age.

"The raising of the age under which no child can be employed in Pennsylvania factories from 13 to 14 years.

"The reduction of the number of hours in a working day from 12 to 10.

"The raising of the age limit of breaker-boys from 12 years to 14 years, and of boys who work inside the mines from 14 to 16 years."

In North Carolina there are three bills before the Legislature, and in Virginia and South Carolina there are two. In Alabama, where the child labor bill was defeated in the last session, active preparations are being made to force the fight for the children at the next session of the Legislature in June.

**American Street Gamins.**—Without special attention one would not rightly estimate the numbers of uncared-for street urchins in our cities, nor their moral and sanitary condition. *Charities* devotes an interesting chapter to these youngsters—the thousands of newsboys, bootblacks, peddlers, office boys, messenger boys, telegraph boys, etc. Here are some excerpts about them:

"The House of Refuge holds 800 boys of 16 and under. Most of them have always lived in the streets, and are classed as 'workers,' 'loafers,' or 'thieves,' though many of them belong by turn to all three classes. As the superintendent told me, all the work of the House of Refuge is planned to undo the bad teaching of the street, its false morality, its failure to train for any permanent trade, its irregular periods for work and meals and sleep, its tense, nervous life, sustained and poisoned by double a man's portion of coffee, cigars, and cigarettes. I know a large number who average four bowls of coffee each meal. In the streets near Newspaper Row I found over 100 sleeping. Other hundreds sleep in stables, condemned buildings, back rooms of low saloons, etc."

"He made his money and spent it—like a man. He contracted venereal disease before he was 15. In one boy's lodging-house I learned that the majority of the inmates have had a disease of this nature."

"Many messenger boys do all-night work between all-night houses and all-night people."

"His spare time he began spending against the law in certain all-night billiard-rooms, centers for the younger crooks of the Bowery. He became a famous winner with the dice. At 14 he began spending two nights of every week in a hideous place which is rightly called 'the sink' for all the city's prostitution. In one year he contracted the most loathsome of all its diseases. By 16 his face was as terrible as the face of a leper. A few months later he died."

"Some there are who rise to higher places, but those who succeed are the first to leave the street. Their influence is lost upon it. Not so with the failures. The toughs, beggars, and criminals remain to teach those who follow."

Unprotected by law, untaught except by vice, unknown of religion, these orphans of civilization have evil, disease, and death as almost the sole wages for their service.

**What constitutes the practice of medicine?** is a question of the greatest importance, because all the quacks and antis are seeking to break down any rational or legal definition of the term. In the noble efforts to place the practice of medicine upon a more honorable and scientific basis in Colorado by the Colorado State Board of Medical Examiners, in a draft of a new registration law the board thus clearly and wisely states its answer to the query, "What Constitutes the Practice of Medicine?"

Any person shall be regarded as practising medicine within the meaning of this act who shall attach to his or her name the title "M.D.," or "Surgeon," or "Doctor," in a medical sense, or advertise in any manner or hold himself or herself out to the public in this State as a physician, surgeon, doctor, or as a person who shall diagnosticate or offer to diagnosticate any physical or mental disease of any person, or suggest, recommend, or prescribe any form of treatment for the intended palliation, relief, or cure of the same, with the intention of receiving therefor, either directly or indirectly, any fee, gift, or compensation whatsoever. It is hereby further provided that the doing of any of the things hereinbefore set forth, or the maintenance of an office for the reception, examination or treatment of any one in manner as hereinbefore set forth, or the exposure of signs, circulars, or advertisements, or any other device or information indicating thereby the occupation of the person or persons as that of being engaged in the practice of medicine as hereinbefore defined, shall be considered as *prima facie* evidence in any prosecution brought under this act. Nothing in this act, however, shall be construed to prohibit gratuitous services in case of emergency, nor shall it apply to commissioned surgeons of the United States Army, Navy, or Marine-Hospital Service, while so engaged, nor to regularly licensed physicians in actual consultation from another State or Territory, nor to regulate regularly licensed physicians actually called from other States or Territories to attend specified cases in this State.

**The Passing of Hypnotism.**—We recently spoke of the evils of popular hypnotism and of the dangers arising from its use by the ignorant. Since then the warning has been emphasized by others, and now German scientists are extending it to the heretofore seriously entertained therapeutic applications. From Berlin comes the report that the commission of experts in mental diseases appointed by the Ministry of Education to investigate the healing value of hypnotism reports that it is essentially worthless. The commission was composed of Professor Mendel and Drs. Gock, Munter, and Aschenborn, who were appointed during the faith healing excitement there a year ago. The report declares hypnotism cannot produce organic changes, nor cure epilepsy nor hysteria, but it can be used helpfully in some instances by removing symptoms through suggestion. In Cleveland, Ohio, a plea was recently made in the defense of a criminal, later convicted of murder in the first degree, that he had been hypnotized and thus incited to the crime. The Court told the jury that this testimony could be "accepted for what it was worth," and a recommendation for mercy by the jury followed, resulting in a sentence of life imprisonment. The folly of this recommendation is evident. If hypnotic influence is

powerful enough to compel the commission of a crime, it is plain that it destroys the accountability of the hypnotized tool. If so there would be no justice in the plea for mercy and lessening the severity of the sentence. But in that case the punishment should be inflicted upon the hypnotizer, who in the Cleveland trial seems to have escaped free.

**"Health Day."**—We are not of those who cynically laugh at all the experiments in sociology and legislation made by our "American Republics." Some of them may appear absurd to pessimistic old age, but future philosophers will perhaps find the way of life and thinking of the self-satisfied as ridiculous, or even more so, as that of the unsatisfied occidental experimenter. From Salt Lake City (*absit omen!*) comes the report of a bill introduced into the Utah Legislature creating a new legal holiday to be called "Health Day." By its provisions the first Monday in October is created a holiday throughout the State. On this day it is made compulsory for every person in the State to clean and disinfect thoroughly dwelling houses, stores, theaters, public halls of all kinds, and in fact every building of the kind used by the people. The City Councils, Town Boards, and Commissioners are instructed to enforce the law, and there is a penalty of \$50 for failure on the part of any person to clean up and disinfect as provided. Of course the scornful will at once ask, what new kind of cleaning and disinfection is that which occurs but once a year? But, also of course, there is a mouth-closing answer to that in the counter that it is far better to wash up once a year than not even once in any year. It would certainly be of advantage to health and longevity if a rigidly enforced health day were forced upon the slums of New York and Philadelphia as often as once a year.

**The College of Physicians of Philadelphia** is the oldest medical society in America that is not a State organization. Its long history, extending over a period of 116 years, is intimately connected with the development of the science and art of medicine on the American continent. It has been one of the main factors, if not the main factor, in making Philadelphia the medical center of the United States. Through its Fellows, directly and indirectly, have been fostered the renowned schools of learning, the great publishing houses, and the medical journals that have constituted such a powerful force in perpetuating this preeminence. The wonderful library of the college, exceeded in this country only by the library of the Surgeon-General at Washington, has been the mainspring of the scientific work done in the city. Through its noble traditions the college has given to the profession of this city a dignity and an ethical spirit that could hardly have been evolved through any other force. The chief pride of the institution has always been its magnificent library. The growth of this has been so phenomenal that the building which, when finished in 1863, was expected to be large enough to serve its purpose for many generations, has become entirely too small; and the great problem has been how, with the limited funds at its disposal, the college could make suitable provision for its expanding library.

The gift of \$50,000 which Mr. Carnegie, at the suggestion of Dr. S. Weir Mitchell, has promised the college, on condition that the same amount shall be raised by the college itself, is likely soon to become available; for, through the efforts of a committee, a good proportion of the sum needed has been collected, largely from the laity. It is needless to emphasize the debt that the public owes to the College of Physicians. The position of Philadelphia as a medical center, the high standard of practice existing here, the flourishing condition of the medical schools—all are intimately interwoven with the history of the College of Physicians, and all of these redound to the advantage of Philadelphia's citizens. Two plans are under consideration for dealing with the needs of the institution; one is to enlarge the present structure by adding a story, and the other is to build an ample edifice on a new site. If the college should grow in the next fifty years in the same ratio as it has in the last half century the old building, even if enlarged, will be sure to be too small. In 1886, at the close of the first century of its existence, the College of Physicians of Philadelphia possessed 34,234 volumes, exclusive of duplicates. On November 1, 1902, the library contained, as Mr. C. P. Fisher, the librarian, kindly informs us, 60,860 bound volumes, 12,761 unbound volumes, and 64,227 theses and dissertations and pamphlets. We sincerely trust that the \$50,000 upon which the materialization of Mr. Carnegie's gift depends will soon be wholly raised.

**The fight against smallpox by a small city,** as illustrated by Altoona, Pa., will prove encouraging to all health officers. And not at all encouraging to anti-vaccinationists, if there are any such who care for facts. In 1902, according to Health Officer Miller, there were in Altoona 79 cases of smallpox, occurring in 30 households and in which 229 persons were exposed. Six patients died, not one of whom had been vaccinated. A capital report published in an Altoona paper describes the facts of each case. These are illustrative:

CASE II.—One case smallpox. Eight members in family. None ever vaccinated. Seven vaccinated after case was diagnosed. Four developed varioloid and three escaped by being vaccinated. CASE XIX.—One case smallpox. Never vaccinated. Four other members in family. One had been vaccinated and three had not been vaccinated. Three vaccinated after three weeks' time and all developed smallpox. The one previously vaccinated escaped. CASE XXIII.—One case smallpox. Not vaccinated. Thirteen other members in family never vaccinated. Some vaccinated after disease developed. Five had varioloid and eight smallpox. An infant born to one of the patients during time of disease and vaccinated at the age of one week escaped. CASE XXVIII.—Two cases smallpox. Neither ever vaccinated. Five other members in family never vaccinated. Immediately vaccinated and one developed varioloid and four escaped.

**What is unprofessional or dishonorable conduct?** is thus answered by the Colorado State Board of Medical Examiners in its draft of a proposed law to regulate the practice of medicine in the State:

The revocation and refusal of certificates shall be for any of the following causes, to wit: The employment of fraud or deception in applying for license on diploma or in passing the examination provided for in this act; conviction of crime involving moral turpitude; habitual intemperance in the use of

ardent spirits, narcotics or stimulants; unprofessional or dishonorable conduct. The words "unprofessional or dishonorable conduct," as used herein, are hereby declared to mean: First, the procuring or aiding or abetting in procuring a criminal abortion; second, the obtaining of a fee on the assurance that a manifestly incurable disease can be permanently cured; third, betrayal of a professional secret to the detriment of a patient; fourth, causing the publication and circulation of advertisements of any medicine or means whereby the monthly periods of women can be regulated or the menses can be reestablished, if suppressed; fifth, causing the publication and circulation of advertisements of any kind relative to diseases of the sexual organs tending to injure the morals of the public.

**Autres Temps, Autres Mœurs.**—In old countries the names of institutions are carried on unchanged, and to later generations they are often strange echoes of ages whose thoughts and feelings were as different as if from another world. In our country we do not willingly submit to such persistence of old names, and the tendency is emphasized by a growth of democracy and socialism which claims as a right what was once accorded as a favor. Illustrations of this have lately occurred in New York, where the names of some of the institutions in the Department of Charities have been changed. The *Almshouse* on Blackwell's Island will henceforth be known as the *New York City Home for the Aged and Infirm*, or more concisely, the *City Home for the Aged and Infirm*. The *King's County Almshouse* will have the same name with the addition of the term, *Brooklyn Division*. The *Randall's Island Asylums and Schools and Infants' Hospital* will be called the *New York City Children's Hospitals and Schools*. The *Richmond Poorhouse and Poor Farm* will be called the *New York City Farm Colony*. The *Outdoor Poor Department* is renamed the *Bureau of Dependent Adults*. We suspect that it will not be many years before another change will be made in the last title, and the term *Dependent* omitted.

## EDITORIAL ECHOES

**Cruelty to Animals.**—We stand aghast at the tales of Indian cruelty to animals, but if a bill which has passed the House of Representatives and is now before the Senate should become a law, it would lead to an amount of cruelty to animals that would put us on the same level. Twenty-five years ago the American Humane Association succeeded in securing a law which forbade the keeping of livestock in cars more than twenty-eight consecutive hours without food or drink. No farmer who cared for the health of his animals would allow them to go unfed for so long a period. But even that ordinance has been frequently disregarded, and now the Livestock Association asks that it be made lawful to keep animals in cars without food or water, at all seasons of the year, for forty consecutive hours. The tortures of thirst to which the poor beasts would thereby be subjected in midsummer would be simply fiendish. But that is only one side of the question. All meat eaters would be injured by such a law. Even now meat in our markets is too often unpalatable. It is well known to hunters that venison is hardly fit to eat if the deer has been kept in prolonged agony by the chase, and physiologists explain the chemical changes in the meat brought about under such circumstances. The agony of thirst would, in the same way, affect all the meat of animals transported great distances. And all this to increase the profits of an organization which boasts that it represents a capital of \$600,000,000!—[*N. Y. Evening Post.*]

## BOOK REVIEWS

**International Clinics.**—Volume III. Twelfth Series, 1902. Philadelphia: J. B. Lippincott Company.

Dr. Cattell's farewell volume well maintains the standard that he has set during his useful service as editor of the "International Clinics." We would call special attention to the article on The Urticarias by Professor H. Hallopeau; to Dr. Thayer's discussion of the availability of The Newer Diagnostic Methods for the general practitioner; and Walsh's excellent article on Insect Pests. Borrissof's article on The Function of the Digestive Glands should be carefully studied. It deals with the pancreas, which is assuming new importance in clinical medicine. Other articles are equally interesting, but these have appealed most strongly to the present reviewer.

**Nothnagel's Encyclopedia of Practical Medicine: Diseases of the Bronchi, Lungs, and Pleura.**—Philadelphia and London: W. B. Saunders & Co., 1902.

Of this book—the fourth volume of Saunders' American edition of "Nothnagel's Encyclopedia of Practical Medicine"—one may truthfully say that excellent as it is in the original it appears distinctly improved in its English dress. Representing as it did at the time of its issuance in the German the sum total of our knowledge of the subjects of which it treats, the distinguished American editor has found little to add, still less to modify, and scarcely anything to controvert. The additions, however, are noteworthy, and materially enhance the value of the book; taking cognizance of the results of recent researches, they include, as stated in the editor's preface: Some new matter on the anatomy and physiology of, and on foreign bodies in, the bronchi; the pathology, bacteriology and treatment of bronchitis; fibrinous bronchitis or bronchiectasis; eosinophilia and the results of Fränkel's researches in asthma; the blood and the urine in pneumonia; the bacteriology of catarrhal pneumonia; the surgical treatment of abscess, gangrene, and other pulmonary affections; the employment of modern methods of research, especially the Röntgen rays for purposes of diagnosis; the bacteriology of pleuritis; recent studies of Morse on the leukocytes in pleuritis; the Litten diaphragm phenomenon, etc. As a whole, the volume is extremely satisfying. In addition to the matter usually found in books of its class it contains much that will be sought in vain elsewhere. Thus Hoffmann gives an excellent discussion of bronchial stone and stone asthma, as well as of other foreign bodies in the bronchi—a subject that the American editor has somewhat embellished. As a matter of fact, the treatment of the entire subject of diseases of the bronchi is much the best of those known to the reviewer. It would have been wise, however, to have incorporated in the index a reference to pulmonary aspergillosis, streptothrix infections, etc. The discussion on pneumonia merits a careful perusal and a wide dissemination. It is especially valuable, *inter alia*, in that it exhibits the somewhat diverging views of two men of wide experience. Dr. Anfrecht, whose statements are based upon a large necropsy experience, distinguishes sharply between croupous and catarrhal pneumonia, between what is commonly termed lobar and lobular pneumonia, believing croupous pneumonia to be a clearly defined disease strictly different from other varieties of lobar pneumonia, and characterized anatomically by an evenly distributed granular appearance of the cut surface of the lung—an appearance absent in other pneumonias in which an entire lobe is involved. He states also that the term lobular pneumonia should be discarded, believing that the disease, to which this term commonly is applied, is a progressive disorder originating in the finer bronchi and bronchioles. Dr. Musser, on the contrary, states that a clearer conception of pneumonia would be had if the lung process were considered to be one of the many manifestations of a pneumococcus infection, and that thus the clinical course, the complications, and the sequels would be clearly understood. It is needless to add that the reasonableness of this view is emphasized by the detection of the pneumococcus in the blood of many patients suffering from pneumonia. Without pointing out many other excellent features of a

notable book, one may say that its plan is encyclopedic, its arrangement practical and scientific, its tone conservative and judicious, and that it exhibits a commendable dearth of ponderous Germanisms that inevitably creep into even the most painstaking rendering into English of German scientific thought.

**The Pathology and Differential Diagnosis of Infectious Diseases of Animals.**—By VERANUS A. MOORE, B.S., M.D. With an introduction by DANIEL ELMER SALMON, D.V.M. Taylor & Carpenter, Ithaca, N. Y., 1902.

For many years students of medicine have felt the need of a connected work dealing with the important points concerning the etiology and pathology of the infectious diseases of animals. The important contributions to this subject are found usually in the reports and bulletins of the Department of Agriculture, treatises on comparative pathology, and in journals devoted to veterinary medicine (mainly German); sources not readily available. Except as these lesions illustrate or have some important relation to similar conditions in man the student of human pathology never hears of them; and the student of veterinary pathology is dependent on the lectures of his instructor. Dr. Moore has rendered an invaluable service in bringing together in convenient book form a lucid, interesting, and accurate account of the infectious diseases of animals, which will be of assistance to both the student and the teacher of medicine, be he interested in man or the lower forms. After an opening chapter dealing with the general consideration of etiology, infection, etc., the various diseases are taken up under the general headings of (a) diseases caused by vegetable microorganisms (streptococci, bacteria, higher fungi); (b) those due to animal forms (protozoa, higher parasites), and (c) those diseases, presumably infectious, of which the cause is not known. An attempt is made to avoid controversial points. The descriptions, therefore, represent our present accurate knowledge. To each description are appended references to the important literature. The illustrations, in colors and in black and white, are very satisfactory. The book is in convenient form, the paper and type good. It deserves an extensive sale.

**The New International Encyclopedia, Vol. V.**—New York: Dodd, Mead & Co.

The principal medical articles in Volume V are as follows:

Colic in Animals	Coughing
Collodion	Counterirritants
Colloids	Cramp
Colocynth	Cremation of Dead
Color Blindness	Creosote
Colored Hearing	Cretinism
Colostrum	Criminology
Coma	Crisis
Compressed Air Treatment	Croup
Concussion of Brain	Crystalline Lens
Conjunctivitis	Cutaneous Sensations
Constipation	Deaf Mutes
Contagious Diseases	Deformities
Contract Surgeon	Degeneration
Convulsions	Dilirium
Corn	Dentistry
Cornea	Dependent Children
Copaiba	

The following subjects may be treated under other heads, but cross-references should have been inserted:

Collapse	Collyrium
Comedo	Confinement
Depressants	Copper (medical aspect)

*Creosote* should have a cross-reference to *creosote*. *Signs of death*, we fear, may not be treated under *Life*, to which there is a cross-reference. We also do not see why *colic in the human being*, which is not mentioned, is not as important as "colic in animals." There is no allusion under *Crystalline Lens* to cataract. The article on *Coma* seems altogether too short for the importance of the subject. Of exceptional value are the articles on *Colored Hearing*, *Compressed Air Treatment*, *Contract Surgeon*, *Cremation of the Dead*, *Criminology*, *Deaf Mutes*. Some of these we feared would be omitted, and their inclusion shows that the authors are not to be caught napping.

**Pharmacology and Therapeutics.**—By ARTHUR R. CUSHNY, A.M., M.D., Professor of Materia Medica and Therapeutics in the University of Michigan. Lea Brothers & Co., Philadelphia and New York.

From its first appearance Cushny's textbook has been recognized as a valuable addition to pharmacologic literature; and the present edition is an improvement upon its predecessors. The arrangement is logical; the language is clear and precise; the statements are accurate and trustworthy; the whole spirit of the book is sane and scientific. It fills a distinct place in the literature of its subject—fills this place well, and were it blotted out there would be a vacuum easily discernible; nevertheless, it is of much less merit from the viewpoint of clinical therapeutics. It is distinctly a laboratory book, written from the experimentalist's viewpoint, and seeing all things through the experimentalist's spectacles. The problems of disease as the practising physician meets them are, however, very different from the questions capable of laboratory decision by experimentation upon animals of various species, and especially upon healthy animals. Toward the solution of the practical questions of what to do at the bedside this book helps little; this is but to say that it has the defects of its qualities. On the other hand, it gives to the clinical therapist a full and accurate account of matters concerning which he has not had the time or opportunity to obtain original information. He can depend upon the faithfulness and the accuracy with which experiments are recorded, and the sanity of the judgment with which their results are collated and analyzed; yet he cannot practise medicine successfully with no further information than these pages afford him as to the powers of the agents of the *materia medica* in relieving human beings whose physiologic processes have been perturbed. A few examples may be given of the omission of recommendations that from a clinical standpoint are of everyday necessity. The stimulating action of camphor upon the heart in cases of threatening collapse is recognized, but the expedients of dissolving it in oil, or, preferably, in ether, in order to assure absorption when administered subcutaneously, are not mentioned. Doubt is thrown upon the action of musk as a cardiac stimulant—and it is true that the dirt dispensed for musk by many druggists cannot have a beneficial action, and may do harm; but the pure tincture of a good quality of Siberian musk, obtained from a trustworthy source, has so often in the hands of the reviewer produced decided therapeutic effects at the bedside that he would be sorry to be deprived of this valuable cardiac and cerebrospinal stimulant. The use of adrenal preparations in the treatment of exophthalmic goiter is not mentioned; and the value of picrotoxin in the treatment of vasomotor disorders—especially those of the menopause—does not seem even to be suspected. From the article upon oxygen it would be difficult to get any definite direction as to the manner in which this lifesaving agent ought to be used, the circumstances under which it is helpful, or the conditions in which it is useless; and we have failed to find the needful warning against its use in febrile cases of pulmonary tuberculosis, when it can only accelerate death. The use of thiosinamin locally or by injection, is referred to, but concerning its administration by the stomach we find no comment. The article upon the therapeutic uses of iodoform is quite incomplete, and the reference to its internal administration in pulmonary tuberculosis especially unsatisfactory. The clinical results reported by many observers of large experience and good repute—men capable of scientific discrimination in their estimate of results—have established for this drug a value altogether independent of its action or want of action upon the tubercle bacillus. And so we might continue—and the author might reply that these omissions are intentional, and that he has purposely excluded from his book all recommendations for which experimental verification and explanation are wanting. But therapeutics is an art and not a science. Much is necessarily empiric; much that is true in practice is falsely explained, and much that is good in practice lacks explanation. Yet even before Laveran quinin cured malaria, and neither the old Jesuit nor so modern a therapist as Bartholow could tell why. Before Newton bodies tended to approach one another with a force directly proportional to mass and inversely proportional to the square of distance, and as a

consequence thereof apples fell to the earth. Would not he who should have denied the descent of the apple and refused to hold his basket under the tree because the word gravitation had not yet been coined, have been a very incomplete pomiculturist and a one-sided philosopher, even from a laboratory standpoint?

**Human Anatomy.**—A Complete Systematic Treatise by Various Authors, Including a Special Section on Surgical and Topographical Anatomy. Edited by HENRY MORRIS. Published by P. Blakiston's Son & Co. Price, \$6 net.

Standard and complete works on anatomy cannot differ as to facts, but a wide difference often appears in the presentation of these facts. Description, the number, kind and quality of illustrations, and the arrangement of the subject matter, are subjects demanding special care in compiling a work on anatomy. In all of these the third edition of Morris meets the requirements in the present advanced method of instruction in anatomy. The work has been carefully revised, and with the exception of the chapters on the anatomy of the eye and circulatory system, changes of more or less importance have been made in all the sections. Some illustrations have been changed, others displaced by new ones, and the total number has been increased by more than 50. This work is particularly adapted to the needs of the student and the busy practitioner. The surface markings on the illustrations are particularly good, different colors being used to differentiate different systems of organs. The surface marking on bones, delineating by markings of different colors, the origin and insertion of muscles is of much value to the student. The portion of the work devoted to topographic and surgical anatomy will be of interest to the surgeon. We know of no standard work better suited for teaching the intricate subject of anatomy than Morris.

**The Practice of Surgery.**—A Treatise on Surgery for the Use of Practitioners and Students. By HENRY R. WHARTON, M.D., and B. FARQUHAR CURTIS, M.D. J. B. Lippincott Company, Philadelphia and London.

The third edition of this work has appeared, comprising a volume of some 1,200 pages, profusely illustrated. It is of course admitted that a single volume cannot discuss all the points in a subject like surgery which within a comparatively few years has grown to phenomenal proportions. Recognizing this the authors have wisely limited their discussion to the essentially practical subjects in the science, suiting the volume alike to the busy practitioner and the student. While all the subjects included in the usual treatises on surgery are ably discussed, we would direct favorable attention to that part devoted to fractures and dislocations. Certain illustrations depicting the position of the bones involved in luxation, particularly at the hip joint, are the best which have come to our notice. It has evidently been the aim of the authors to describe conditions and diseases with sufficient thoroughness to enable the practitioner to recognize the condition and to describe fully such appropriate treatment as the situation demands. In this they have fully succeeded, and we bespeak for this work the popularity which it merits.

**Materia Medica and Pharmacology.**—By DAVID M. R. CULBRETH, Ph.G., M.D., Professor of Botany, *Materia Medica*, and Pharmacognosy in the Maryland College of Pharmacy, etc. Lea Brothers & Co., Philadelphia and New York, 1903.

The author states that the outlined list of proposed official drugs and preparations already determined by the Committee on Revision of the Pharmacopeia has been used as a guide in preparing this edition. In consequence, a number of articles that are to be accepted have been treated prominently, while those that are to be discarded have been treated briefly. The recapitulation tables contain only those drugs which will be recognized officially. In many other respects likewise the volume will be found to reflect the spirit of the new Pharmacopeia. The arrangement of the drugs conforms strictly to that followed in the previous editions; thus substances organic and inorganic, which have a common origin, are associated together as nearly as possible; those next related follow in regular order, the basal or parental source being thus paramount. The pharmaceutic rather than the pharmacologic element predomi-

nates in the discussion of topics. The pharmacodynamics and therapeutics of the various drugs are given very briefly, and in general rather than specific terms. The work is thus adapted chiefly to the use of druggists and students of pharmacy, and as such serves an admirable purpose.

**Therapeutics of Dry Hot Air.**—By CHARLES EDWARD SKINNER, M.D., LL.D., Professor of Thermo-therapy in the New York School of Physical Therapeutics, etc. A. L. Chatterton & Co., New York.

This book is written by an enthusiast. It is full in its description of apparatus and methods, and in this respect is valuable. Its therapeutic recommendations must be taken with several grains of salt of good quality. There is no question, however, that within bounds, and with due individualization, the methods here advocated are useful in many chronic conditions that resist all treatment by drugs, and that such methods deserve wider recognition and employment than they have yet received.

**A Manual of Medical Treatment, or Clinical Therapeutics.**—By I. BURNEY YEO, M.D., F.R.C.P., Emeritus Professor of Medicine in King's College, London. W. T. Keener & Co., Chicago, 1902.

The revised edition of Yeo's work consists of two volumes containing upward of 1,500 pages. The original plan of approaching therapeutics from the viewpoint of the disease instead of the drug has been adhered to and deserves unqualified praise. Notwithstanding this, treatment has been made the important part as shown by the four pages devoted to the etiology and pathology of dysentery and eleven pages to its treatment, one of the latter being made up of selected formulas. The pathology of the various diseases has been brought well abreast of the times. Additional subjects, such as the treatment of hay-fever, paralysis agitans, cerebral tumors, erysipelas, cerebrospinal fever, rickets, scurvy, and purpura have received consideration in this edition. American writers are freely quoted. Illustrations are few, perhaps too few for a work of this magnitude. The book as a whole is so thoroughly satisfactory that minor points of possible criticism may be overlooked. We believe, however, that a separate index for each volume would have added greatly to the convenience of the reader.

#### BOOKS RECEIVED.

[Prompt acknowledgment of books received will be made in this column, and from time to time critical reviews will be made of those of interest to our readers.]

**A Clinical Study of an Epidemic of Cerebrospinal Meningitis:** With special reference to symptomatology and treatment.—By J. RUTTER WILLIAMSON, M. D. Thacker, Spink & Co., Calcutta, 1902.

**Pharmacology and Therapeutics:** A Text-book of Pharmacology and Therapeutics; or, the Action of Drugs in Health and Disease.—By ARTHUR R. CUSHNY, A.M., M.D., Professor of Materia Medica and Therapeutics, University of Michigan, Department of Medicine and Surgery, Ann Arbor, Mich. Third edition, revised and enlarged. In one handsome octavo volume of 750 pages, with 52 engravings. Cloth, \$3.75 net; leather, \$4.75 net. Lea Brothers & Co., Publishers, Philadelphia and New York, 1903.

**Transactions of the American Surgical Association:** Vol. xx.—Edited by RICHARD H. HARTE, M.D., Recorder of the Association. Printer, William J. Dornan, Philadelphia, 1902.

**The Malarial Fevers of British Malaya.**—By HAMILTON WRIGHT, M.D., Director of the Institute for Medical Research, Federated Malay States. P. Blakiston's Son & Co., Philadelphia, 1902. Price, \$1.20 net.

**International Clinics:** A Quarterly of Illustrated Clinical Lectures and especially prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose, and Throat, and other Topics of Interest to Students and Practitioners by leading Members of the Medical Profession throughout the World.—Edited by HENRY W. CATTELL, A.M., M.D., Philadelphia, U. S. A., with the collaboration of JOHN B. MURPHY, M.D., Chicago; ALEXANDER D. BLACKADER, M.D., Montreal; H. C. WOOD, M.D., Philadelphia; T. M. ROTCH, M.D., Boston; E. LANDOLT, M.D., Paris; THOMAS G. MORTON, M.D., Philadelphia; JAMES J. WALSH, M.D., New York; J. W. BALLANTYNE, M.D., Edinburgh, and JOHN HAROLD, M.D., London, with Regular Correspondents in Montreal, London, Paris, Leipzig, and Vienna. J. B. Lippincott Company, Philadelphia and London. Cloth, \$2.00. Volume 4, series 12.

**Quiz Compend:** Diseases of Children: Especially adapted for the use of medical students.—By MARCUS P. HATFIELD, A.M., M.D., Emeritus Professor of Diseases of Children, N. W. U. Medical School, Physician to Wesley Hospital, Home for Crippled Children, Chicago Orphan Asylum, etc. Third edition, thoroughly revised. Price, 80 cents net. P. Blakiston's Son & Co., Philadelphia, 1903.

**An Epitome of Physiology:** For Students and Practitioners of Medicine.—By THEODORE C. GUENTHER, M.D., of the Norwegian Hospital, Brooklyn, and AUGUSTUS E. GUENTHER, B.S., formerly Assistant in Physiology in the University of Michigan, Ann Arbor. In one 12mo volume of 250 pages, with 57 engravings. Cloth, \$1.00 net. Lea Brothers & Co., Publishers, Philadelphia and New York, 1903.

## AMERICAN NEWS AND NOTES.

### GENERAL.

**Source of Plague at Mazatlan.**—It is asserted that the Department of State has received advices from Mazatlan, Mex., stating that searching investigations by the authorities show that the plague was brought to that city by rats among vegetables shipped direct from Chinatown, San Francisco. The Charity Commission of the city has received \$130,000 to be used in combating the plague, and money is still pouring in from all parts of the country.

**New Disease in Furs.**—An exchange states that a new disease has arisen from the prevalent use of furs. The malady is supposed to be a germ disease and is not contracted from the expensive furs, but rather from those of the cheap quality, which have been dyed and otherwise treated to imitate the more expensive. Those in the fur shops who are continuously trying on furs are particularly prone to this disease from abrasions which may be upon the face, neck, or arms.

**Sanitary Telephone Apparatus.**—A citizen of Buffalo, N. Y., has invented the apparatus. It consists of a package of tissue paper suspended on a wire over the transmitter, with a hook to spread a single sheet in front of the opening. Before using the instrument the uppermost sheet is brought forward on the wire and turned downward over the bell until it is suspended on the wire. This prevents the speaker's mouth from coming in contact with the mouthpiece and inhaling disease germs that may have found lodgment on the apparatus. After using the instrument the sanitary sheet is stripped from the hook and replaced by a fresh one for the next speaker.

**Mortality and Injuries Due to Train Accidents.**—According to a statement recently published by the Interstate Commerce Commission, during the three months ended September 30, 1902, there were 263 persons killed and 2,613 injured in train accidents in the United States. Other kinds of accidents, including those sustained by employes while at work and by passengers in getting on or off the cars, etc., bring the total number of casualties up to 12,007, the killed numbering 845 and the injured 11,162. The total number of collisions and derailments was 2,448, of which 1,444 were collisions and 1,014 derailments. Of these 51 collisions and 92 derailments affected passenger trains.

**Carnegie Institution.**—In a summary of the Year Book Professor Gilman, ex-president of Johns Hopkins University, states that the methods of administration of the Carnegie Institution thus far developed are general rather than specific. Efforts have been and will be made to secure cooperation with other agencies established for the advancement of knowledge, while care will be exercised to refrain from interference or rivalry with them. For example, if medical research is provided for by other agencies, as it appears to be, the Carnegie Institution will not enter that field. Systematic education will not be undertaken, and sites or buildings for other institutions will not be provided.

**Hospital Benefactions.**—PHILADELPHIA: The late Jacob M. Engel bequeathed \$1,000 each to the Jewish Hospital Association, the Jewish Foster Home, and the Jewish Maternity Home. TAUNTON, MASS.: The late Mrs. Rebecca C. Ames bequeathed \$5,000 each to the Massachusetts General Hospital and Boston Home for Incurables for the establishment of a free bed in each institution in memory of her husband. She also bequeathed \$50,000 to Harvard College, the income of which is to be expended for the maintenance and support of any of the poor and meritorious students of the college. BALTIMORE, MD.: Under the will of the late Mrs. Margaret M. Smith, of this city, the Church Home and Infirmary will receive \$4,000 for the purpose of endowing a bed for an adult person, to be called the "Charles Fisher Smith bed," and the Home for Incurables will receive \$1,000.

**Condition of the Leper Colony in the Hawaiian Islands.**—The committee of senators appointed to investigate the condition of lepers in the Hawaiian Islands have completed their labors and submitted their recommendations to Congress. A visit was made to the islands and 176 witnesses were examined. The leper colony was visited and the condition found unsatisfactory. The committee advises that the management of the colony be transferred from territorial control to the Marine-Hospital Service with headquarters at Washington, and that a general leprosario for all lepers of the United States be established in the Hawaiian Islands. There are 538 leprosy patients in the settlement, and the opinion is expressed that there are many hundreds of other cases in the territory. One feature of the committee's report relative to the moral condition in the colony is the following: Under the existing management of the leper settlement indiscriminate, legitimate, and illegitimate cohabitation is permitted. Marriages are suffered to be celebrated between leprosy men and women regardless of their physical condition. Children are born in the settlement of leprosy unions and as a result of concubinage; and, strange as it may appear, the leading officials seem to regard all this not only as permissible, but protest vigorously against a system of segregation that would prevent it.

## NEW YORK.

**Opposition to Tenement House Law Amendment.**—At the recent meeting of the New York State Medical Society a resolution was adopted deploring any weakening of the present tenement house laws, and urgently requesting the Legislature to permit no changes to be made that will in any way decrease the amount of light and air available for people living in such houses, or in any way taking a backward step in regard to their sanitary conditions.

**New York Medical College and Hospital for Women.**—The new wing which has been added to the hospital is now open for the reception of patients. The building includes an operating-room, 2 laboratories, 14 private rooms, and 3 wards. Further additions will be made as soon as more money can be raised. Through the efforts of the Hospital Guild, the hospital's floating debt of \$21,000 has been paid.

**Appropriations for Insane Asylums in New York.**—Those interested in the subject are making complaints that the Governor of New York has refused to keep his promise with reference to appropriations for the State insane asylums. It is stated that previous to his election a promise was practically made that the total appropriation should not fall short of \$4,779,000. In fact, this was carried so far that detailed figures for each of the separate institutions were submitted and approved. It now appears that the Legislature, it is said, under the direction of the Governor, will make appropriations upon the same basis as those of last year, which will fall \$279,000 short of the amount promised.

**Asylum Superintendents Not Consulted in New York.**—Among various bills introduced in the New York Legislature relative to the care of the insane is one which provides that when, in the opinion of the fiscal supervisor of State charities and the State architect the inmates of the institutions for the insane are able to assist in repairing old buildings or in the erection of new ones, they may be set at such work. It is ironically asserted that if the State architect and the State fiscal agent can determine when a lunatic is able to work, it might be well for the Governor to have a law passed under which these officers shall determine when a person is insane. Are the superintendents of institutions for the insane in New York merely figureheads?

**Crusade Against Tuberculosis.**—According to the statistics of the New York Health Department there is a large increase in the number of cases of tuberculosis in the Borough of Manhattan. This condition of affairs has led to the formation of plans for the amelioration of the condition of the sufferers. One plan under consideration by the Tuberculosis Committee of the Charity Organization Society provided for the erection of such institution as is needed by private subscription. Another plan is to have a municipal sanatorium under the supervision of the Health Department. The New York Medical Society advises that in the effort to check the ravages of the disease every senior student in every grammar and high school should be required to pass an examination in the method of preventing the spread of tuberculosis. Societies for the prevention of tuberculosis should be organized in every community. Public lectures should be given frequently by one who understands the facts and has the ability to impart them. By such educative efforts much might be done to teach the young the sanitary science of everyday living. Compulsory registration by physicians of every case of tuberculosis should be required. Opening of dispensaries for the treatment of the disease and the establishment in every city of a receiving hospital for patients suffering from tuberculosis were also recommended. The State has been urged to hasten the building of the hospital, for which an appropriation of \$100,000 was made two years ago.

**Investigations of Bellevue Hospital.**—A male probationary nurse, recently discharged from Bellevue Hospital, has made the following sensational charges against the management and other nurses in the institution: "That nurses administer strychnin, digitalis and other powerful drugs to patients supposed to be at the point of death, so as to 'tide them over' until other nurses come on watch, thus avoiding having to 'lay them out;' that morphin is given without authority to patients, so as to keep the ward quiet; that records of pulse temperature and respiration are taken by guesswork instead of by observations; that sleeping on duty is common, and that one patient died of hemorrhage while the nurse slept; that nurses take whiskey and wine from the drug closets to drink themselves and to give to employes, and that they skim milk intended for patients on milk diet." At a meeting of the Board of Trustees of the Bellevue Hospital, held after an investigation had been made, it was declared that the most searching investigation had failed to disclose any evidence as to the truth of the charges made. The new superintendent has announced that hereafter any bruises or injuries a patient may have received before coming to the hospital will be described on the "history slip," so that the responsibility for subsequent injuries may be exactly located. It will be remembered that this is the very system which was promised by the authorities more than two years ago, after an investigation which followed the death of a patient in the insane pavilion.

## PHILADELPHIA, PENNSYLVANIA, ETC.

**An original method** has been devised by a masseur of Philadelphia for acquiring the title "Doctor." Claiming to have graduated from a foreign university he assumed the title Ph.D., apparently hoping and believing that the title "Doctor" thus derived would be construed by physicians perhaps and patients particularly to mean "Doctor of Medicine." When confronted by statements from his assumed "alma mater" that he possessed no such title he abandoned the scheme.

**Rigid Sanitary Rules in Chester.**—A new Board of Health has been appointed in the city of Chester, Pa., and the mayor has instructed them to use the most vigorous measures to combat disease in the city. It has been alleged that proper care is not taken by physicians and others who visit the Municipal Hospital, hence more stringent measures will be instituted to prevent the spread of infection from this source. Vaccination and quarantine rules are to be rigidly enforced.

**Miscellaneous.**—DR. HARVEY CUSHING, of Baltimore, will deliver a lecture on "The Blood Pressure Reaction of Acute Cerebral Compression," a sequel to the Mütter lecture, before the W. W. Keen Surgical Society, Thursday, February 12, at 8 o'clock. The profession is cordially invited to attend.—DR. W. W. KEEN, professor of surgery at the Jefferson Medical College, recently received the degree of Doctor of Science from the Northwestern University of Chicago.

**Philadelphia Society for Organizing Charity.**—From the Twenty-fourth Annual Report (1902) of the Board of Directors of the Eighth and Ninth Wards Association of this Society we take the following excerpt:

There are many causes for the poverty existing in the Eighth and Ninth Wards. Intemperance takes the lead and is followed in its destructive course by desertions, lawsuits, imprisonment, the neglect of children, and in some instances by insanity and suicide. Sickness is a common cause, and brings many a thrifty family to destitution. Still another cause is the helplessness of the defective class. A few of this class are properly cared for in institutions, but many of them are considered ineligible for any of the institutions, and remain in their homes, contributing little or nothing to the support of the family. Idleness, another cause of poverty, when added to laziness, produces a class of people who live upon their wits, upon chance, upon friends—upon anything from which human parasites may extract a living. These people become public nuisances, and will continue to thrive as long as misguided benevolence allows them to live without work. The cooperation of the poor in caring for their poorer neighbors has been a great help to the society. They give of their limited means what they are often not able to give; they care for the sick neighbor as conscientiously as for their own sick, teaching a lesson of true charity.

## SOUTHERN STATES.

**School Medical Inspectors.**—An amendment to the bill providing for 11 medical inspectors of the public schools of the District of Columbia to be appointed by the Board of Education at \$500 a year has been introduced into the Senate. It provides that these inspectors must have had at least five years' practice in medicine in the District of Columbia and must be appointed after competitive examination.

## WESTERN STATES.

**For Original Research.**—It is reported that John D. Rockefeller will provide for the establishment of a large hospital in connection with the University of Chicago. It is rumored that he will give whatever amount will be necessary to carry out the idea of a comprehensive institution for original research into the causes and cures of disease. It is proposed to have an institution on the cottage order, one building being devoted to contagious diseases, a second to surgery, and the third to another medical field. Work in the projected hospital will be entirely apart from that at Rush Medical College. Research will be carried on by postgraduate experts. It is said the University officials refuse to confirm this report.

**Michigan State Board of Health.**—At a recent meeting it was decided that a committee of the State Board should confer with a similar committee of the State Medical Society, for the purpose of perfecting a bill to be introduced into Legislature, providing for the establishment of a State Sanatorium for the treatment of tuberculosis. In view of the fact that hydrophobia is widely disseminated throughout the State, it was recommended that municipal and township authorities be requested to order the muzzling of all dogs at large, and make and publish regulations to that effect. A short bill defining diseases dangerous to public health, and providing that the State Board of Health or some other competent body be authorized to declare publicly such disease dangerous to the public health under the law, was approved.

**Increased Appropriation for Insane Asylums.**—The State Board of Charities has prepared a bill which the Legislature of Illinois will be asked to pass, asking for an appropriation of \$5,005,890 for the 15 charitable institutions in the State. Of this amount \$3,647,000 is for "ordinary expenses," and \$1,358,890 is for special purposes. Two years ago the total amount appropriated for the same institutions was \$4,438,024.92. The increased appropriation asked for is based on the fact that

the previous appropriation was insufficient to meet the ordinary expenses of the institutions. The Legislature will be asked to appropriate \$75,000 for the Eye and Ear Infirmary of Chicago. This is for the purchase of additional ground and the construction of additional buildings for inmates suffering with contagious and infectious diseases.

**Medical Legislation.**—The following excerpt is taken from the message of the Governor of Michigan: The State Board of Registration in Medicine favors amendment to the medical law having in view both the elevation of the standard and the uniformity of the act in connection with medical laws of States which have taken an advanced position, in order that worthy and well qualified physicians and surgeons who have been legally authorized to practise under the laws of other States may be given the right to practise in this State without being forced to submit to a repetition of the examination which they have previously undergone. In order that Michigan may be able to take advantage of the proposed reciprocal relations, it will be necessary to raise the standard of medical requirements of this State to that of the States willing to enter into reciprocity.

**Coal Famine and the Public Health.**—The following, taken from the bulletin of the Chicago Health Department, is of interest as showing the pernicious influence exerted on the general health of large cities by the scarcity of coal:

Unrevised returns of mortality for the month of January, 1903, show an increase of 10.4% (or 344) in the actual number of deaths from all causes and at all ages, and of 11.4% in proportion to population, as compared with January, 1902, when coal was abundant at one-half the price or even less than that it now commands—when it can be obtained at all. These two facts are cited together because, in the judgment of the health department, the latter is the principal if not the sole cause of the former. A large proportion of the excess deaths is, as was stated in the bulletin of January 10, due to cold and exposure caused by the coal famine and which at that date had affected the health of fully 10%, or nearly 200,000 of the population of the city. The facts are so portentous and the situation so grave, that the commissioner makes them the feature of the present health bulletin. On January 19 the city council passed an ordinance declaring that "an emergency now exists in the city of Chicago which threatens the health and lives of citizens, owing to the scarcity of coal," and appropriated \$25,000 "to be expended by the department of health in meeting such emergency." At the same meeting an order was passed, authorizing and empowering the mayor "to appoint a committee of citizens to cooperate with the department of health in the purchase and distribution of coal," as authorized by said ordinance.

**Plague in San Francisco.**—According to the Public Health Reports, 93 cases of plague with 89 deaths have occurred in San Francisco between March 6, 1900, and December 11, 1902. In eight cases it was claimed that the patients had come from other parts of the State. The longest lapse that has occurred between cases is 92 days, during which time Chinatown was being cleansed by the State Board of Health; the next longest 72 days, which ended February 22, 1902. So far as is known, there have not been over five cases that are even probably contacts, and as to one or two of these the connection is doubtful as to whether it was contagion from one to the other or from a common source. An autopsy is performed in all cases suspicious of plague, such as acute buboes, pneumonia and acute febrile diseases, and also when the cause of death is not evident, as fracture of the skull, chronic tuberculosis, ascites, etc. In all cases of plague the usual and ordinary bacteriologic tests were made before diagnosis was established. When death occurs the body is buried in lime and the City Health Board has the room in which the person was found sick or dead closed, disinfected with sulfur, and a quarantine placed over it for 5 to 15 days. The Chinese have been urged to report even trivial cases, but thus far it has been impossible to secure their full confidence and cooperation. If they believe the case to be one of plague they rarely report it, because they fear the quarantine and the necropsy.

**Colorado Medical Statute.**—A joint committee composed of the chairmen of the Legislative Committees from the Colorado State Medical Society, Colorado Homeopathic Society, and the Colorado State Eclectic Medical Association have concluded that amending the defective parts of the present law is the most expedient, the most practical and probably the most attainable legislation. Therefore this joint medical legislative committee has harmoniously agreed upon the necessary amendments, an epitome of which is as follows:

FIRST—The repeal of the "ten year" clause.

SECOND—The adoption of an amendment increasing the fee for registration on diploma to \$10.00, and by examination to \$25.00, and further, providing for the maintenance of the State Board of Medical Examiners from fees received, instead of by appropriation.

THIRD—The adoption of a clear, broad, legal definition of what constitutes the practice of medicine.

FOURTH—The adoption of an amendment empowering the State Board of Medical Examiners to refuse and revoke licenses for immoral, dishonorable or unprofessional conduct.

To enable the committee to carry out such a plan it has been decided to request every member of the medical profession in the State to immediately remit to the secretary-treasurer of this committee, Dr. S. D. Van Meter, of Denver, the sum of \$2.00. It must be expressly understood that none of this money will be used in "lobbying." Absolute failure is preferred rather than recourse to such means to secure legislation which

is principally for the protection of the public, and for the benefit of our profession only in the satisfaction of raising the moral and educational standard of its Colorado members.

## FOREIGN NEWS AND NOTES

### GENERAL.

**Rats and Plague.**—After the discovery of the plague bacillus by Kitasato and Yersin, the remarkable susceptibility of rats to the disease became apparent from inoculation experiments. It was also found that the rats ate the bodies of patients dead from plague, thus inoculating themselves. Therefore cases of plague may appear suddenly in human beings, when it is afterward found that rats spread the contagion. Where many dead rats are found, an outbreak of the plague is to be expected. In an article in *La Médecine Moderne* for August 13, 1902, Olschanetsky, of Constantinople, has reviewed this subject with historic details. But epidemics of plague have been observed in which rats played no role. He advises preventing the introduction of rats from ships, especially those with disease aboard. For though an epidemic among rats cannot always be shown to have been the cause of an epidemic among human beings, it probably plays an important etiologic role in the propagation of the plague.—[*Baltimore Sun*.]

### GREAT BRITAIN.

**King's Tuberculosis Sanatorium.**—The names of the successful competitors for the three prizes offered for the best essays on the construction of King Edward's Hospital for Tuberculosis have been announced. The first prize, \$2,500, was awarded to Arthur Latham, of London, with whom was associated as architect Mr. William West, of London; the second, \$1,000, was awarded to F. J. Wethered, of London, with whom were associated as architects Messrs. Law and Allen, of London; and the third, \$500, was awarded to E. C. Moreland, of Croydon, with whom was associated as architect Mr. G. Moreland, of Croydon. An advisory committee, the members of which were all prominent English physicians, was chosen to pass upon the merits of the essays, and specialists from all countries were invited to compete. In all 180 essays were sent in by foreign physicians. The essays which received the prizes are published in the *Lancet*, January 3, 1903.

### CONTINENTAL EUROPE.

**French and English Mortality.**—Prof. Brouardel, of the French Bureau de l'Hygiène, states that the vital statistics of France that are available represent only about 13,000,000 out of a total of 39,000,000 of population and that the deathrate in 1900 was 21.9 per 1,000 and the birthrate 21.4. In England the deathrate for the same period was 18.2 and the birthrate 28.7, that is, France had 144,000 more deaths and 284,000 fewer births than would occur in the same number of English people. With regard to the causes of mortality it was found impossible to obtain particulars for comparison, except from towns comprising only about one-third of the total population, but these supply noteworthy figures. London, with its population of 4,500,000, has nearly twice as many inhabitants as Paris, with its 2,500,000. The general deathrate of Paris in 1900 was 20.6, that of London was 18.8. London had 86,007 deaths, Paris had 51,725 or about 4,500 more than London in proportion to its population. The most conspicuous excess was in pulmonary tuberculosis, from which there were 10,072 deaths in Paris as against 7,748 in London, or 4.01 compared with 1.75 per 1,000. From fever there were 912 deaths in Paris against 765 in London, or proportionately rather more than twice as many, while from diarrhea there was 3,178 deaths in Paris and 3,564 in London, or 1.27 compared with 0.78.

### OBITUARIES.

**John Morris**, of Baltimore, Md., January 29, aged 79. He was a graduate of the Bellevue Medical College, New York City, and was also a licentiate of the Rotunda Hospital, Dublin, Ire., where he served as an interne. He was ex-president of various local associations, among which were the Medical and Chirurgical Faculty of Maryland; Maryland Inebriate Asylum; the State Lunacy Commission; the Maryland State Board of Health, and the Pennsylvania and Maryland Medical Society. In 1875 he was a delegate to the British Medical Association, which met in Edinburgh; to the Industrial Medical Congress, which met in Brussels, and to the French Scientific Congress, which convened at Nantes. He was for 30 years president of the city school board and served as postmaster of Baltimore during President Buchanan's administration. In 1855 he was presented with a gold medal by the citizens of Norfolk, Va., for his volunteer services in combating the yellow fever.

**Morill Wyman**, said to be the oldest physician in Massachusetts, died in Cambridge, Mass., January 30, aged 90. He was graduated from the Harvard Medical School in 1837. In 1833 he became adjunct professor of the theory and practice of medicine at Harvard College, but relinquished the chair after three years' occupation. He was a

member of the American Academy of Arts and Sciences and of many professional bodies. His writings on medical subjects were of wide range. He was elected an overseer of Harvard in 1875, and was given a degree of Doctor of Laws in 1885.

**Henry Addison Mandville**, of South Orange, N. J., January 31, aged 44. He was graduated from the College of Physicians and Surgeons, New York City, in 1891. He was a member of the New York Pathological Society, the New York Academy of Medicine, Hospital Graduate Society, Manhattan Surgical Society, and various other organizations. He was attending surgeon to the colored hospital in New York City until recently.

**James M. Ridge**, of Camden, N. J., January 30, aged 76. He was graduated from the University of Pennsylvania in 1852. He was a member of the Bucks County Medical Society, and of other medical societies and organizations. For a number of years he was connected with the New Jersey State Board of Health.

**James H. O'Toole**, of Charlestown, Boston, Mass., January 27. He was graduated from the Medical School of Maine, at Bowdoin College, Brunswick, Me., in 1880. He was a member of the Massachusetts Medical Society and of the Boston Medical Society.

**Margaret T. Shutt**, in Springfield, Ill., January 24. She was graduated from the Cornell University Medical College, New York City, in 1899. She had served on the medical staffs of Bellevue and Kings County Presbyterian hospitals, New York.

**Alexander T. Gordon**, near Sigmund, Culpeper county, Va., January 14, aged 70. He was graduated from the Medical College of Virginia, Richmond, in 1858. He served as surgeon in the Confederate army during the Civil war.

**Irvin L. Benner**, of Sellersville, Pa., January 25, aged 32. He was graduated from the University of Pennsylvania in 1893, and was a member of the Pennsylvania State Medical Association.

**Samuel A. Work**, in Vandalia, Mich., January 6, aged 60. He was graduated from the University of Michigan, Ann Arbor, in 1883, and was a member of the American Medical Association.

**Thomas J. Grove**, of Petersburg, West Virginia, February 1, aged 74. He was graduated from the University College of Medicine, Richmond, Va., in 1849. He was an army surgeon.

**Isaac H. Shields**, in Philadelphia, January 13, aged 64. He was graduated from the University of Pennsylvania in 1860. He served as surgeon during the Civil war.

**John H. Xelowski**, of Oklahoma City, Okla., in Decatur, Ill., January 16. He was graduated from the College of Physicians and Surgeons, Chicago, in 1900.

**David C. Bryan**, in Hot Springs, Ark., January 14, aged 42. He was graduated from the Central College of Physicians and Surgeons, Indianapolis, in 1887.

**Marbury Brewer**, of Baltimore, Md., January 24, aged 72. He was graduated from the University of Maryland School of Medicine, Baltimore, in 1850.

**Charles B. Adams**, of Vanceburg, Ky., died in Portsmouth, Ohio, January 14. He was graduated from the University of Louisville (Ky.) in 1893.

**William W. Misner**, at Tacoma, Wash., January 3, aged 48. He was graduated from the Hahnemann Medical College, Chicago, in 1883.

**James M. Alexander**, in Anabel, Mo., January 13, aged 40. He was graduated from the University of the State of Missouri, Columbia, in 1886.

**George N. Gage**, in East Washington, N. H., January 10, aged 51. He was graduated from the Boston University School of Medicine in 1877.

**William Gibson**, of Alexandria, Va., January 28, aged 73. He was graduated from the Pennsylvania Medical College, Philadelphia, in 1853.

**Peter R. Everett**, in Cleveland, Ohio, January 13, aged 68. He was graduated from the Jefferson Medical College, Philadelphia, in 1856.

**Walter F. Randolph**, of Bedford, Iowa, died in Chicago, January 4. He was graduated from the Rush Medical College, Chicago, in 1870.

**William Mote**, at Hog Point, Ind., January 9, aged 70. He was graduated from the Medical College of Ohio, Cincinnati, in 1856.

**B. E. Jeter**, probably the oldest practising physician in Southwest Virginia, died near Coyner's Springs, Va., January 30, aged 84.

**Thomas B. Bush**, of Lawrenceville, Ga., January 11, aged 33. He was graduated from the Atlanta (Ga.) Medical College in 1894.

**W. C. Cundiff**, in Somerset, Ky., January 6. He was graduated from the Vanderbilt University, Nashville, Tenn., in 1900.

**P. M. Womble**, of Baltimore, Md., January 30. He was graduated from the Jefferson Medical College, Philadelphia, in 1848.

**Richard S. Markell**, in Cloverdale, Cal., January 10. He was graduated from the McGill University, Montreal, in 1867.

**S. B. Johnson**, of Luzerne, Warren county, N. Y., January 29. He was graduated from the Albany Medical College in 1845.

**Henry Helfrich**, of Allentown, Pa., February 1, aged 99. He was the oldest resident of Lehigh county.

**Fairfax Schley**, of Frederick, Md., February 1, aged 79.

## CLINICAL NOTES AND CORRESPONDENCE

[Communications are invited for this Department. The Editor is not responsible for the views advanced by any contributor.]

### A FURTHER NOTE ON THE PERINEPHRIC FAT.

BY

W. W. KEEN, M.D.,  
of Philadelphia.

Since writing the note which was published in *American Medicine*, January 31 last, my attention has been called by Dr. Wyllis Andrews, of Chicago, to a monograph on Wanderniere, by Walkow and Deletzin, Privatdocenten in the Military Medical Academy in St. Petersburg, and published in Berlin in 1899 by Hirschwald.

In this elaborate monograph of 350 pages I find the two layers of the perinephric fat distinctly alluded to and described on pages 26, 27 and 32.

From it also I obtained two references of importance showing earlier descriptions of the same fatty layers. The first is a paper by Zuckerkandl in the *Medizinische Jahrbücher*, Vienna, 1883, p. 59. Zuckerkandl particularly describes the layer of connective tissue between the two layers of fat and calls it the "fascia retrorenalisis."

The second reference is to a paper by Gerota in the *Arch. f. Anatomie*, Leipzig, 1895, with two plates which illustrate distinctly the two layers of fat and the fascia between them. Both Gerota and Zuckerkandl give the name of "pararenal fat" to the outer layer.

In spite of these two papers, one even dating 20 years back, these two layers of fat seem to have escaped the observation of both anatomists and surgeons, hence I thought it well to call attention to the matter. Until my attention was called to Walkow and Deletzin's monograph, I was not aware that any such description had been published.

### TREATMENT OF FRACTURES OF THE PATELLA.<sup>1</sup>

BY

DAVID C. PEYTON, M.D.,  
of Jeffersonville, Ind.

Fracture of the patella, while constituting only about 1% to 2% of all fractures, demands the most careful consideration on account of its close proximity to the knee-joint, and also in consequence of the very imperfect and unsatisfactory union of the fragments by the ordinary mode of treatment. The relative infrequency of the fracture of this bone is probably in part due to its small size and compact formation, as well as its convex anterior surface and the readiness with which it may be moved about in its position. It occurs more frequently in the male than in the female; the ratio being about five or six to one, and more frequently between the ages of 25 and 55. The very old and the very young are almost exempt from this fracture, but when occurring in extreme old age statistics show it almost always to be in the female, the youngest patient probably on record being five years old, reported by Hamilton in his 127 cases. Dittmer reports one case in a boy of 9.

The two potent factors in the etiology are muscular action and direct violence. I am convinced that the sudden and violent contraction of the quadriceps extensor is the cause of a large majority of these fractures and that only a relatively small percent are the result of direct violence. It is true that more than 60% of these fractures are of the transverse variety and it is equally true that the transverse are always the result of violent and sudden contraction of the quadriceps, while the vertical, stellate, comminuted, and compound are probably due to direct violence of one kind or another. The fracture by muscular action probably occurs when the knee is in a position of semi-flexion, for in this position the middle portion only of the under surface of the patella is resting on the anterior surface of the condyle. The action of the quadriceps at this time being almost

<sup>1</sup> Read before the twenty-eighth annual meeting of the Mississippi Valley Medical Association, Kansas City, Mo., October 15, 1902.

at a right angle to the surface of the patella, in case of a sudden and severe contraction serves as a most efficient agent in causation. It is probable that a small percent are due to combined effect of the muscular action and direct violence. It is difficult to estimate correctly the relative importance of the various known causes, for the reason that the statements made by the patient at the time of or after the injury are untrustworthy and misleading. The patient stumbles and falls after an effort to catch himself and an examination discloses a fracture of the patella. The patient, as a rule, is unable to give an intelligent account of the fall and especially of the point of contact, and he concludes he must have fallen upon the knee-cap, and no doubt this conclusion was reached by his knowledge of the fact that the patella was fractured. However, if we but bear in mind the very important part played by this muscle—that it is the great extensor of the leg, being united below in a single tendon attached to the patella, and that the entire anterior aspect of the femur is covered by it from the trochanters to the condyles—we can readily understand the important part played by it in the cause.

The displacement of the fragments depends largely upon the character of fracture, for those resulting from direct violence, such as the vertical, comminuted, and some oblique rarely show much displacement, for in this class of fractures we have rather extensive contusion of the soft parts, while only the minimum laceration obtains. It is in the transverse fracture that we have the most pronounced separation and general displacement of the fragments. It is in this class that we have the extensive laceration of the aponeurotic and fibrous coverings of the bone, as well as laceration of the synovial membrane of the joint and rupture of the prepatellar bursa. The joint soon fills with blood and exudate, which serves to further separate the fragments, and may cause a tilting forward of the distal fragment, and a little later, the gradual retraction of the ligamentum patellæ increases the separation. The fractured surface of the proximal fragment is often drawn in toward the cavity of the knee-joint, due to the action of the vasti fibers inserted into its sides. Other displacements, as the lateral and angular, are recognized later on. As a result of the increased stretching of the fibrous union we may have a lateral angular displacement. Anterior angular displacement sometimes occurs as a result of cicatricial retraction of the lateral soft parts. The associated injuries to the soft parts almost invariably result in opening the knee-joint, the lateral expansions and capsule being usually involved.

The diagnosis of fracture of the patella is comparatively easy, and only in rare instances do we meet conditions rendering a diagnosis uncertain and difficult. Sometimes we do not reach the patient until a considerable length of time after the injury, when we may find the joint greatly distended, and at the same time so little displacement of the fragments that a positive diagnosis is not to be thought of. The absence of crepitus also adds to the uncertainty, and notwithstanding the statements by some of our most eminent writers to the contrary, in my own experience and in the experience of others with whom I have discussed the question, crepitus is seldom a symptom, for the very good reason that in almost every instance the aponeurotic covering, if not actually torn, is stretched so as to admit of separation of the fragments, the covering dropping between the fragments, and this, together with the hemorrhage which always occurs, is quite sufficient to prevent crepitus. Usually, however, the fracture is readily recognized by sight and touch; the division of the bone, with more or less separation of the fragments with individual mobility, renders the nature of the injury unmistakable. The degree of loss of motion is dependent largely upon the extent of laceration of the lateral expansions. The distention of the joint comes on rapidly, the result of blood and serum effused into the cavity, and extensive ecchymosis of the surrounding tissues follows quickly.

The question of the expediency of treatment by open arthrotomy or the nonoperative procedure is as yet, in the minds of some, not settled, and as one of the enthusiastic advocates of the treatment by open arthrotomy, I am ready to admit that in some cases this plan is not advisable, and the non-

operative treatment should be employed. Of course in patients over 50 and in those in whom the physical condition is below the standard, I would not resort to the open method. Neither would I recommend the open arthrotomy when it is not possible to get the patient into a well-equipped hospital, or when the operation is to be done by other than a surgeon whose technic is absolutely perfect; for with the foregoing counter-indications, the dangers of sepsis, ankylosis, loss of limb, or possibly loss of life, are greatly to be feared. But with a healthy patient under 50, and a surgeon who will conscientiously carry out the slightest detail needed to secure perfect asepticity, and who is imbued with the true spirit of aseptic surgery, the patient will have a good joint by reason of perfect bony union, and in a much shorter space of time. The first essentials in the treatment of every case are to immobilize the joint by suitable posterior splint, elevate the foot and apply the ice-bag for three or four days to check effusion and limit inflammation, when a close-fitting roller bandage will be found of service. There have been a great many kinds of dressings suggested and tried, many of them having only historic interest, all having some points of virtue, but in most instances falling short of the prime object of treatment—perfect apposition of the fragments. This I do not consider possible in the nonoperative method, and the dressing that offers the nearest approach is the one to be employed. Personally I prefer securing the fragments in the best possible apposition and applying a shield of adhesive plaster above and below the knee in such a way as to maintain apposition of the fragments. Hamilton's method of a wooden incline plane is also good as a nonoperative procedure. In treatment by the nonoperative method the union is always necessarily fibrous on account of the interposing of fibrous tissue between the fragments, and no prolongation of the period of immobilization will secure bony union unless this is removed. Later we have stretching of the fibrous union, greatly reducing the usefulness of the joint. Open arthrotomy should not be done for eight or ten days following receipt of injury, as inflammatory action usually follows, so that the danger of infection is greatly increased by immediate operation. After application of the icebag and compress for some days, the plan I follow is to open the joint by transverse incision from condyle to condyle, exposing the fragments and removing all clots, freely irrigating the cavity with normal saline solution and suturing the edges of the torn aponeurotic covering with chromicized catgut. This brings the fragments into perfect apposition. The superficial incision is then closed with silkwormgut, without drainage, and the joint immobilized by a posterior splint, with either the plaster-of-paris or crinolin dressing (I prefer the latter on account of its lightness). This dressing is left on for about four weeks, when it is removed and passive motion begun. At the end of six weeks all restraint is withdrawn and the patient advised to walk and actively move the joint. It is not good policy, however, for the surgeon to resort to severe efforts to flex the joint beyond certain limits too early, for in so doing he is liable to destroy the union and reseparate the fragments.

It was my privilege a few months since to witness a case with Dr. Bullitt, of Louisville, in a woman with transverse fracture of both patellas. The patient had been standing on the pavement during icy weather of last winter, when, without warning, first one and then the other patella snapped, due, undoubtedly, to the action of the quadriceps in the effort to maintain an erect posture. Dr. Bullitt operated in about ten days after the accident, employing the open method, and closing the torn fibrous coverings with chromicized catgut, using no wire to hold the fragments, doing as pretty an operation as it has been my pleasure to see with the most satisfactory results.

In my own cases in which I have resorted to the open method the results have been most satisfactory. Only a few months ago a man of 48 had a transverse fracture of the patella and I employed the open method, getting a perfect joint.

My friend, Dr. Rodman, of Philadelphia, is a strong advocate of the treatment by open arthrotomy, and has operated on some three or four patients in the past year by wiring, and with good results. I do not think, however, the insertion of wire through the bony substance is necessary to hold the frag-

ments in apposition, but on the contrary, the amount of handling and bruising of the parts which this method entails makes it inadvisable. Of course, in old cases of fracture with much disability from nonunion, wiring is probably best. After all, the prime indications in the operation are to remove fibrous material interposed between the fragments and to clear the joint of blood clots and to perfectly appose the fragments. In all cases of compound fracture the operation should be done immediately.

To summarize: By the nonoperative procedure we always obtain a fibrous union. This union, which at first may leave the fragments only half an inch apart, in a few months may not only stretch so as to allow a separation of three or four inches, but may also stretch unevenly, rendering the joint almost useless. The patient is confined in dressing for months, with a much longer period of disability, and in the end has a very imperfect joint. This, in case he is a laboring man with a family to support, is a very serious matter. The treatment by open arthrotomy always gives a bony union, and at the end of four weeks the patient is out of dressing, and in six weeks should be walking; and in a short time is able to resume his work, and this, too, with a good joint.

### THE METRIC SYSTEM IN USE.

BY

CHARLES PLATT, M.D.,  
of Philadelphia.

Those of us who know the metric system to be the only scientific system of weights and measures, often experience a mild wonder that the old absurdities should still be adhered to by the majority. The fact can be explained only by the wrong methods used for the popularizing of the system, by the improper use of the system in the journals, and, to go further back, by the false method of instruction in the schools. The error, it seems to me, lies in the idea that we must forever compare the new with the old. We are taught that 1 foot = 0.30479 meter, that 1 inch = 2.53995 centimeters, that 1 meter = 3.28089 feet, that 1 grain = 0.06479 gram, etc.—no wonder the method fails to appeal to the beginner when the beginning is made from so false a start. This method of comparison is not natural. Instead of expressing to us, as it should, a definite conception of space, of weight, or of length, the statement of the metric unit only calls to mind a more or less hazy memory of an equivalent imperfectly learned and uncertainly remembered.

I would protest, then, against the use of the comparison in writing, but if this is to be retained I would appeal for care in the manner of expression. Medical dosage is by no means so exactly determined as to call for the elaborate fractions so frequently found in our journals, and, it should be remembered, it is not sufficient that we declare the decimal system a simple one, we must demonstrate that fact by stating our metric units in simple terms.

When a man writes "chloral hydrate, 0.65 gram to 0.97 gram (10 to 15 grains)," it is evident that the medicine was administered in the grain dosage, despite the parenthesis, and that the statement of the corresponding metric dose is the result of calculation or of reference to a table of equivalents. Certain it is that the statement as made advances the use of the metric system not at all, and, indeed, the contrary effect is produced, for, "10 to 15 grains" requires a less effort of the memory than does "0.65 gram to 0.97 gram." Is the proper dosage of chloral hydrate so exactly limited, however, as to call for this exact equivalent? Would it not be as useful to state the dose as from 0.5 to 1.0 gram? Exact equivalents profit nothing and will forever prevent the attainment of the desired end. Approximate equivalents are easily remembered, exact equivalents are not, and every time one meets with the latter in reading there is an involuntary pause and the continuity of the sentence is lost in an effort to compare the doses critically.

There is another feature of the case that requires notice and that is where equivalents are stated the writer should observe the utmost care that the statement in the less familiar system should be correct. In a single recent article, for instance, one

finds the following: "0.03 gram ( $\frac{3}{20}$  gr.)," "0.02 gram ( $\frac{1}{2}$  gr.)," "0.03 gram ( $\frac{1}{2}$  grain)," "1.2 grams to 2.6 grams (30 grs. to 40 grs.)," "2 grams (30 grains)." It is evident that all of these figures can not be correct, and a pause is required to enable the reader to discover the errors. In this particular example the variations are, it is true, small, but a similar degree of carelessness might easily attain to a mortal dignity.

In a recent abstract the following prescription was given:

Tinct. aconite rad. . . . . cc. 0.32 mv  
Spir. aetheris nitrosi . . . . . cc. 11.25  $\bar{3}$ ijj  
Liq. ammonii acetatis, q.s. ad. . . . . cc. .90  $\bar{3}$ ijj  
M. Sig.—cc. 7.5 ( $\bar{3}$ ij) in water every hour or two.

Suppose, with a praiseworthy desire to be up to date, some innocent reader should copy here the metric prescription; one of two things might happen, the druggist might return the prescription for correction, or he might ignore the "q.s. ad." and make up the prescription as it otherwise stands, in which case the patient would receive something over 3 minims of the aconite tincture instead of the  $\frac{1}{2}$  minim intended.

Another recent abstract gives

Thiocol . . . . .	9	7 grams (2½ drams)
Syrup of bitter-orange peel . . . . .	.93	3 grams (3½ ounces)
Boiled water . . . . .	.85	5 grams (5 ounces)

And these are fair examples of what one constantly reads!

Would it not be well to revise the school instruction in weights and measures? Would it not be well to use greater simplicity in the comparison of the metric system with the old? Would it not be well always to use the simplest metric expression possible? Would it not be well to use greater care in the statement of metric formulas?

To those who have found that "the art which is long" leaves no time for unnecessary labor, and who believe that simplicity can be attained only by the exclusive use of the decimal system, these suggestions, commonplace though they be, are offered with the hope that the desired goal may be brought thereby somewhat the nearer.

### REMOVAL OF FOREIGN BODY FROM THE ESOPHAGUS.

BY

R. J. WARD, M.D.,  
of East Barrington, N. H.

A patient recently came to my office complaining of having swallowed a fish bone between three and four hours previously. It had lodged in the esophagus just below the larynx, and caused considerable mental and physical distress. A probang not being at hand I was at a loss what to do until I recalled a statement once made by Dr. Gile, Professor of the Practice of Medicine in the Dartmouth Medical College, when lecturing on diseases of the intestinal tract. He said that a snarl of thread swallowed and then withdrawn was very effectual in removing foreign bodies from the esophagus. I acted upon this suggestion, using ordinary grocer's twine for the snarl, and a fish bone an inch in length was successfully removed.

I recently treated a powder wound of the hand as suggested in *American Medicine* for July 6, 1901, with absolutely negative results, the H<sub>2</sub>O<sub>2</sub> having no effect whatever on the powder stains.

**Inspection of Barber Shops.**—A bill which is to be introduced into the Massachusetts Legislature makes it unlawful for any person to follow the occupation of barber in that State unless he shall have first obtained a certificate of registration. Such certificate will be granted after the candidate has successfully passed an examination given by a Board of Examiners appointed for this purpose. This board, consisting of three persons who have had at least five years' experience as barbers, will be appointed by the Governor. The eligibility of its members as to the knowledge of their profession is to be decided by the State Board of Health. Their term of service will be three years. This board is to prescribe such sanitary rules as it may deem necessary, with the approval of the State Board of Health, and it is authorized to annul the certificate or permit of any barber neglecting to practise his occupation in a manner conducive to the sanitary interest of the public.

THE SURGICAL TREATMENT OF PUERPERAL INFECTION.<sup>1</sup>

BY

MATTHEW D. MANN, A.M., M.D.,

of Buffalo, N. Y.

Professor of Obstetrics and Gynecology in the University of Buffalo.

It is not at all surprising that the wonderful results which have been obtained in the treatment of pelvic inflammatory diseases by surgical means should have led gynecologists to think that much might be done by operation for the relief of similar conditions following confinement or abortion. Much interest has been aroused in this subject of late. At the Congress of Gynecology and Obstetrics, held in Rome this last summer, the question of hysterectomy for puerperal infection was very carefully discussed, and, incidentally, other operations under similar circumstances received some attention. That certain operations can be done with benefit seems to be admitted, but others are still *sub judice*, while some are condemned entirely. It is my purpose to go over the whole ground and to discuss briefly each of the operations which have been suggested.

That there are different infections during the puerperium is now well proved. The various germs act in different ways, and, therefore, produce conditions calling for different surgical procedure. The saprophytes confine themselves to dead material and do not penetrate deeply into living tissue. The commonest and one of the most deadly germs, the streptococcus, not only penetrates tissue deeply, but does it so rapidly as almost to defy arrest. Sometimes it goes by the lymphatics; sometimes by the veins; and often gets into the peritoneal cavity and into the blood. If it is circumscribed, either in the peritoneum or the connective tissue, it produces abscess; in the veins it causes suppuration, thrombosis, and metastatic abscesses; while in the peritoneal cavity it may set up an adhesive or a suppurative inflammation of greater or less extent. The gonococcus travels mostly by surfaces. The tubes are, therefore, often affected, that not being the case in streptococcus infection. The gonococcus infection generally, though not always, appears late—10 to 12 days or more after labor—and is usually circumscribed and not very virulent; though this is not always the case, for I recently saw, in consultation, a pure gonococcus infection fatal and with a temperature of 111°. Gonorrhoeal peritonitis also occurs. Time forbids my saying more on pathology, interesting as it may be. The colon bacillus, Löffler's bacillus, the typhoid bacillus, the staphylococcus, and others, sometimes play an active part in the production of these important conditions.

The operations which have been generally recommended or suggested are:

**Curetage.**

The removal of ruptured or inflamed tubes.

The removal of infected fibroid or ovarian tumors.

The opening or removal of ovarian abscesses.

The opening of parametric abscesses.

The opening of the peritoneum for exploration; for septic peritonitis; for vaginal drainage in early peritoneal infection.

Hysterectomy, vaginal or abdominal.

Removal of thrombosed and infected veins.

**Curetage.**—Most infections begin in the uterus, and produce at once an inflammation of the lining membrane. This endometritis, depending on the character of the infection, may be either putrid or septic. If portions of the placenta or membranes be retained they are almost certain, sooner or later, to become the nidus for a saprophytic infection with a resulting stinking dis-

charge and marked constitutional symptoms. In a true septic endometritis the bad-smelling discharge is wanting, though the systemic poisoning may be more marked. In either case the exact nature of the infection should at once be determined by Döderlein's or Williams' method. After this the interior of the uterus should be explored, and if the examining finger finds anything within the uterus, or any roughness, then the offending body must at once be removed. For this, most surgeons use a curet, but I very much prefer the curet-forceps or a forceps of my own devising, modeled on Luer's polypus forceps. With this, pieces of placental tissue can be readily removed, after which the surface may be gently cureted, disinfected, and packed with gauze.

In septic endometritis, when there are no foreign bodies and a perfectly smooth lining membrane, I can not see how any good can come from the curet. The septic germs travel so rapidly that it will be impossible to get out all the infected tissue unless the operation is done within a few hours or minutes of the onset. That the curet has done much harm in these cases I truly believe, and, therefore, would not ordinarily advise its use, except in putrid endometritis.

It is in the cases of mixed infection that the curet must be handled with discretion. One thorough scraping which leaves a smooth surface, followed by a long douche of 1 dram of Churchill's tincture of iodine to the pint, or the careful washing out of the uterus with hydrogen dioxide or some other good antiseptic, succeeded by a full packing of the uterus with iodoform gauze, should suffice. This should be followed by a culdesac operation, and the curetage not repeated, as there will be no necessity if it is well done at first, and no benefit in a repetition if the germs have penetrated deeply into the uterine tissues. Very deep curetage may do more harm than good by breaking into or removing the reaction layer, which is nature's way of offering protection against the entrance of germs into the tissues or system. The rule regarding curetage, then, should be, do it only when clearly indicated; do it thoroughly, but not roughly or too forcibly, and then do not repeat.

**Removal of Ruptured or Inflamed Tube.**—One fallopian tube may be perfectly healthy and allow of the passage of an ovum, while the other is the seat of a purulent inflammation. During labor the pus tube may be so injured as to start up an acute inflammation, or may be even ruptured, allowing the pus to escape into the peritoneal cavity. The history of the case must be our chief reliance in making a diagnosis. Should we be able to recognize such a condition I think all will agree that the abdomen should at once be opened, cleaned and the diseased tube removed.

**Infected Fibroid or Ovarian Cyst.**—One of the most dangerous conditions which we can meet is the infection of a fibroid tumor as the result of an intrauterine infection. This is more apt to come after abortion than after labor at term. As a result of the presence of the tumor retention of the secundines is quite apt to occur. Septic endometritis is then pretty certain to follow, with a resulting infection of the tumor. Septic infection in the presence of a uterine fibroid, following labor, and especially an abortion, should be an almost certain indication for prompt hysterectomy. It has been my fortune to see two such cases, both of which proved fatal from delay, while I am sure both patients would have been saved had operation (*i. e.*, a hysterectomy) been allowed early.

A few cases of the infection of an ovarian cyst have been reported. Such a condition should mean prompt removal, not only of the cyst, but also probably of the uterus, though the latter step should be governed by the condition of the case.

The presence of any kind of a newgrowth in a puerperal woman should lead the attendant to the greatest watchfulness and care.

<sup>1</sup> Read before the Cincinnati Obstetrical Society, January 9, 1903.

*The Opening of Ovarian Abscesses.*—Dr. Henrotin, of Chicago, read a paper in 1895 before the American Gynecological Society in which he advocated early operation by the vagina in acute pelvic inflammation, postpartum or otherwise, for the emptying of parametric and ovarian abscesses. While I have operated in this way in the acute stage of such inflammation I have never met the kind of cases which he described. The large number which he reports would seem to indicate that they are very common, but my experience does not agree with his. I have seen acute inflammation of the tubes (gonorrhoeal) greatly benefited by early vaginal operation and drainage. The patients, however, were not cured. This is another thing and does not belong in this paper. Henrotin's operation is quite different, both in technic and in indications from Pryor's, to be referred to later. Henrotin's paper should be carefully studied, for its suggestions seem to be most excellent and should be followed by those seeing this class of cases.

*Parametric Abscesses.*—How best to treat these patients, except in the early stage, as suggested by Henrotin, I have not determined to my entire satisfaction. Bitter experience has taught me not to open the abdomen when there is evidence of acute suppuration postpartum. Such an infection is almost certain to be streptococcal in its origin, and to let free acutely infectious streptococcal pus into the abdomen is almost sure death. The mass may be one-sided and feel like a pus-tube, but don't be deceived. If necessary for a diagnosis, open through the vagina; explore and drain, opening the abscess if possible through the vagina without opening into the healthy peritoneum, as Henrotin suggests, or wait until the abscess gets large enough to show a fluctuating spot in the vagina and then open and drain.

Sometimes these abscesses are far out in the broad ligament near the pelvic wall. In that case they can best be reached by an incision inside of Poupart's ligament outside of the peritoneum. It may be necessary to open the abdomen in order to make an accurate diagnosis.

Should an abscess in the broad ligament be found on opening the abdomen, it is best to try and open it, with one hand in the abdomen as a guide, either into the vagina or at the groin, and not to open it into the abdomen. The reason has already been given. This I have succeeded in doing with good results. These are often difficult cases to manage, and cannot be treated like ordinary pus-tubes or ovarian abscesses.

*Exploratory Laparotomy.*—In many cases of puerperal infection, we may be in doubt as to the exact nature of the lesions present. The question will then come up as to an exploratory laparotomy for diagnostic purposes. On general principles, I should be entirely opposed to such a procedure. I object in these cases to operating unless there is some recognizable lesion revealed by an examination, under an anesthetic if necessary. To open the abdomen in the hopes of finding something which can be treated in this way seems to me wrong, and I have never done it. As Hirst says, "The surgeon should demand some tangible evidence of those forms of sepsis which are amenable to surgical treatment" before operating. Hirst also says that "an exploratory abdominal incision should be made, as a rule, only when it is desired to determine if a pelvic mass presumably containing pus is situated within or without the peritoneal cavity, and if the abscess had better be evacuated through the abdominal cavity or extraperitoneally." This agrees with my own views already expressed in another part of this paper.

*Septic Peritonitis.*—When purulent accumulations within the abdomen, either encysted or free, can be made out, or are strongly suspected, then the abdomen may be opened (perhaps under cocaine) and the abdomen washed out and drained. A free incision must be made, and large quantities of hot saline solution used. Possibly packing the pelvis with sterile gauze according to

the method employed by Joseph Price may do good. Dr. Price assures me, in a very recent letter, that he has saved many such cases, making a four-inch incision and putting in a "cofferdam" of sterile gauze after thoroughly washing out. He adds: "The puerperal cases are the most dangerous and most difficult to save. The peritoneum may be greatly soiled, but a wash and drainage will save them after many of the common practices have failed."

By the old methods only a very few (Zweifel, in Rome, mentioned two) of the cases of diffuse peritonitis have been saved; but, nevertheless, if seen within the first 24 hours every case should have the chance to be derived from an operation. Most of the cases which have been saved have probably been those in which the pus was encapsulated (Zweifel). The results obtained by the open method make it imperative on every one to try it. The diagnosis is often very difficult.

*Vaginal Drainage Early in Septic Infection.*—We owe this method of operating to Dr. Wm. R. Pryor. The originator of the method applies it to all cases in which he cures for puerperal endometritis. The reason for it is that although the endometritis may begin as a simple putrid or saprophytic inflammation, it is apt very soon to be converted into a true septic disease by the advent of some of the septic germs, which find a good culture medium in the discharges already present.

Fearing that a mixed infection may be present, or may be soon introduced, and that the septic infection may run away from the reach of the operator, he seeks to head it off by draining and disinfecting the pelvic peritoneum. After thoroughly curetting and packing the uterus with iodoform gauze, he opens into the culdesac of Douglas. He then gently palpates the adnexa, liberating all adhesions and freeing the individual organs. The next step is to pack the pelvis as far as the fallopian tubes with iodoform gauze. In this way an immense quantity of serum is drained away. He combines the use of large quantities of salt solution with the operation, for the purpose of stimulating the kidneys and supplying fluid to replace that drained away.

While it is perhaps going too far to say that this operation is indicated in all cases when it is necessary to curet, it is not too much to say that in every case of septic endometritis, either pure or mixed, if seen before the broad ligaments are involved or a general peritonitis set up, the operation should be done. If the case is seen too late for this kind of drainage, then the culdesac may still be opened, as suggested by Henrotin, for the purpose of letting out accumulations of pus, either in the connective tissues, ovary, or peritoneal cavity, as the case may be.

This operation seems to be a real advance, and has given such good results in the hands of its author as to warrant its further trial. I have tried it a few times, with good results when it was done early enough. This is the all-important point. Promptitude in operating is an essential to success; delay may be fatal.

*Hysterectomy.*—We now approach the most important question connected with the whole matter. Is it ever justifiable to remove the uterus when it is seriously infected postpartum? This was one of the questions discussed at Rome, and the almost unanimous opinion was that, as yet, the indications are too undetermined, too vague, to allow of this operation being done very often. Fehling, by letter, learned that out of 94 prominent gynecologists 41 had never done this operation, while 53 had done 61 operations, with a mortality of 55.7%.

There were 19 abdominal hysterectomies with 31.5% mortality.			
" " 33 vaginal	"	"	69.6% "
" " 4 supravaginal	"	"	50% "
" " 4 following abortion	"	"	75% "

The most striking fact in this table is the great mortality in the cases of vaginal extirpation over the abdominal.

Fehling raises the question, since according to different statistics from 18% to 5% only of patients with puerperal infection die as the result of these operations, were not more lost than would have perished if left alone. He says that hysterectomy in general septicemia is useless; that the only rational indication is when the source of the infection or intoxication is limited to the uterus. This can only come from the retention of the placenta or secundines, which cannot be otherwise removed, or from sloughing fibroids. Such indications, he thinks, are very rare. Leypold believes that hysterectomy should be done only when all the symptoms show that the uterus alone is the seat of the active source of the infection, and when all other means have failed.

H. Treub collected 724 cases of severe puerperal infection in his clinic, of which 34 terminated fatally, and he concludes that only two of these could have been helped by hysterectomy.

Tuffier says that the great difficulty is to determine when to operate—to act too early is a mistake; to delay until too late makes it useless. Pinard dwelt on the difficulty of deciding on the proper indications. He admitted only three indications: the retention of putrid secundines, a sloughing fibroid, and perforation of the uterus. The retention of a decomposing placenta could only occur in cases of an excessively adherent placenta, such as is very rarely seen, or in cases of abortion when the uterine canal is blocked by some kind of a growth so that the interior of the uterus cannot be reached. If the secundines, under these circumstances, are not expelled and later become infected, a hysterectomy seems to be the only way out of the dilemma. The question of sloughing fibroids has already been considered. In cases of dissecting metritis, or of abscess-formation in the uterine walls, hysterectomy might be indicated; but there are two difficulties which stand in the way—one is the difficulty of diagnosis, and the other is the fact that under these conditions the surrounding peritoneum and connective tissue are quickly infected through the lymphatics, and the veins are also often involved.

When we consider all the difficulties surrounding these cases: the difficulties of diagnosis; of determining the time when the operation should be done; the weakened condition of the patient, with high temperature and feeble and rapid pulse—we must conclude that "he who operates often operates too much."

As yet science has not given us any sure means of determining either the time or the indications, and we must wait patiently for further investigations to settle some of the mooted points. Fortunately, the acknowledged methods are very often sufficient. Douches, curetage, drainage, packing with iodoform gauze, and a certain medication, in the majority of cases serve to bring the patient safely through. It is a disgrace that these cases still occur as often as they do. The profession is somewhat at fault for not using careful prophylaxis, but so long as women are delivered by ignorant and dirty midwives, and in unclean, often filthy, surroundings, cases of infection will occur. It must be our object to see that these conditions are ameliorated as much as possible by the enforcement of proper tenement-house laws and by laws for the proper supervision and education of midwives. Midwives there will be so long as we have a large poor foreign population. While we may wish to do away with them is it not better to acknowledge the necessity and to seek to rectify the trouble as much as possible rather than to let it go on without any supervision or control?

*The Removal of Infected and Thrombosed Veins.*—One other surgical procedure has been suggested and carried out in bad cases of puerperal pyemia. These cases are essentially chronic and therefore give time for careful study. A. Sippel<sup>1</sup> described these cases and advised the removal of the uterus and with it the ovarian and the uterine veins.

He claims that it is not the infection of the uterus or the metastatic foci which gives the repeated chills, but the accumulation of pus and toxins in the veins, which from time to time make their way into the general circulation and cause the chills. If this source of poisoning could be removed then the other results of the infection might get well and the patient be saved. Freund, Brunn, Trendelenburg, and Zweifel have all operated to remove the veins, both the ovarian and the hypogastric, under like circumstances. They do not consider hysterectomy necessary, but remove the veins even without opening the abdomen, by an incision in the groin. To get at the ovarian veins, however, the abdominal cavity must be opened and the veins sought under the posterior peritoneum. The veins must be opened, the clots removed, and then the veins tied as near the large vessels as possible.

Trendelenburg<sup>1</sup> reports the following case:

Patient aborted September 6, 1901. Chills and fever followed. September 19 parametric abscess opened per vaginam. October 12 excision and ligature, extraperitoneally, of the right hypogastric vein. No chills for ten days. Chills recurred. November 12 ligature and resection of 5 cm. of the ovarian vein. Clot contained streptococci. No more chills. November 28 opening of a metastatic abscess in the right shoulder. Recovery.

I relate the case, as it well illustrates the character of the affection and the method of treatment. So far as I have read very few cases have been done in this country, and it is time that we paid more attention to so important a subject. These cases generally prove fatal. Moreover, they give one plenty of time for a careful diagnosis and for securing the best advice and operative skill. They differ materially from the more acute cases and seem to offer a proper field for surgical intervention. Sippel advises that the abdomen should be opened in every case, because in this way the entire field can be carefully gone over and all the affected veins removed. This method must certainly be followed if the operator considers it necessary to remove the uterus at the same time. Zweifel admits that we will meet cases in which the disease has advanced too far for a cure, as when, for example, the thrombus has reached the common iliac vein. He insists, also, on the extirpation of the veins, and not simply on their ligature. He also insists on abdominal section, and says that from the celiotomy alone none of the patients will die.

I have said nothing about the removal of suppurating tubes and ovarian abscesses of gonorrhoeal origin occurring late in the puerperium. Pus-tubes usually tend to become chronic and make up a considerable share of the operative work of the gynecologic surgeon. It is seldom necessary to operate on them within the month following labor. The only important point in this connection is that, as I have already said, these cases must be carefully diagnosed from parametric abscesses, so as to avoid letting acutely infectious streptococcal pus escape into the peritoneal cavity.

Ovarian abscesses are more common and may demand operation earlier in the puerperium. It is my belief that these cases should, if they fluctuate, be opened through the vagina rather than through the abdomen, as the pus is very apt to be acutely infectious and to lead to general diffuse peritonitis.

I have now gone over all the operations which have been proposed for the relief of the conditions resulting from infection during the puerperium. While the more radical operations, except under very special conditions, do not seem to hold out much encouragement, the milder operations, if properly employed, are full of promise and hope. There is no disease which so appeals to our sympathies as this. It seems so unnecessary, coming as it does after physiologic process. We know so well that with proper care it is generally avoidable, and that its presence is due either to ignorance, neglect, or the accident of a pernicious environment.

<sup>1</sup> Zentrbl. f. Gyn., 1894, No. 28.

<sup>1</sup> Sippel, loc. cit.

We must meet, then, every suggestion for its cure with a cordial interest, examine carefully into its merits, and finally reject or adopt it as reason and experience may dictate. We cannot afford to neglect any suggestion, no matter how startling it may be, without careful consideration, with the hope that, at last, we may be able either to banish the disease entirely, or else to meet it satisfactorily at its inception.

## RELATION OF THE INNERVATION OF AN ORGAN TO THE INFLUENCE OF SUPRARENAL EXTRACT UPON IT.<sup>1</sup>

BY

S. J. MELTZER, M.D.,

AND

CLARA MELTZER, B.A., M.D.,

of New York City.

Research Scholar of the Rockefeller Institute for Medical Research.

(A preliminary communication from the Rockefeller Institute for Medical Research.)

Ever since Oliver and Schaeffer discovered that the intravenous injection of suprarenal extract causes a considerable rise of blood-pressure, it was stated by many investigators that subcutaneous injection of the extract exerts no influence upon the blood-pressure. The rise in the pressure lasts only a few minutes, and it is generally stated that it is neither preceded nor followed by any lowering of the normal blood-pressure. As a reason for the failure to effect an influence by the subcutaneous injection, it is assumed by many writers that the tissues oxidize the suprarenal extract. We have, however, to record the fact that the prolonged contact of the blood with the extract does not deprive it of its effect upon the blood-pressure. Furthermore, a subcutaneous injection of the suprarenal extract is effective in other respects, for instance, it causes muscular paresis or paralysis or even death, and from recent investigations of F. Blum and others, we know that subcutaneous injection causes temporary glycosuria. We would then have to assume that the oxidizing effect of the tissues is restricted to the blood-pressure raising constituent of the extract.

In a series of experiments with intravenous injections of adrenalin in rabbits in which the bloodvessels of one ear were deprived of the vasomotors, we observed that the blanching of the ear of the operated side lasted a good deal longer than on the normal side. Furthermore, after a few minutes of blanching, the ear on the normal side became perceptibly more congested than before the injection of the adrenalin.

For an explanation of these phenomena we have formed a working hypothesis which we shall not discuss here extensively, but of which we shall mention that it contained the assumption that small doses of the extract favor vasodilation when the central nervous influence is intact; when the bloodvessels are deprived of central nervous control, however, they affect chiefly constriction.

From this new point of view we began to study anew the effects of subcutaneous injections, expecting that the slow absorption will permit the entrance of the extract into the blood only in small doses at a time. From our long series of experiments we shall mention to you only the chief results which we hope to be able to demonstrate.

Briefly stated they are as follows: In all cases in which either the sympathetic was resected, the ganglion removed, the third cervical cut, or when all vasomotors together were eliminated, the subcutaneous injection of a sufficient dose of adrenalin causes invariably a distinct constriction of the bloodvessels of the ear. The constriction sets in a few minutes after injection, progresses slowly, and lasts for many hours, sometimes not returning to normal till the following day. The degree of the

constriction rarely reaches that which is observed for a few minutes after intravenous injection. When the operation is performed only on one side, the normal ear does not take part in the constriction unless the injected dose is very large and the animal very young.

As a rule we see, on the contrary, a more or less distinct widening of the bloodvessels of the normal ear; they remain either constantly dilated for some time or the rhythmic changes occur more frequently, the dilation being the predominant feature. The dose which favors dilation in the normal ear has to be smaller than that which causes constriction in the operated side.

Another point of great interest is the behavior of the pupil. Lewandowsky, Borouttsau, and Langley have reported that intravenous injection of the suprarenal capsule causes dilation of the pupil which lasts less than a minute. We have observed that when the sympathetic is cut a subcutaneous injection of adrenalin causes a dilation of the pupil on the operated side which can last an hour and longer. It is a remarkable fact that such an effect does not take place if an injection is tried on the day of operation.

Of great interest and possibly of great practical importance is our experience with instillation into the conjunctival sac. Many observers have stated that instillation has no effect upon the condition of the pupil. We have established the fact that when the sympathetic is cut instillation will cause a dilation of the pupil lasting for some time.

Our results demonstrate in the first place that the suprarenal extract which in the normal animal causes by subcutaneous injection no effect upon the pupil and nearly no constricting effect upon the bloodvessels, causes a distinct and lasting effect when the sympathetic nerve is cut. In other words, a substance which exerts no effect upon a normal organ can exert a considerable effect of long duration if this organ be deprived in some way of a nervous control. This appears to us to be a principle of fundamental importance. For instance, any pharmacologic product, the effects of which are usually studied on normal animals, can exert an entirely different effect on diseased conditions which involve a diminution of nerve influence. The same applies to toxins; the primary effect might be different from what we know, if the innervation of one or the other organ be impaired. In fact, all the normal metabolic products, just like suprarenal extract, might cause pathologic phenomena when there is a primary derangement of the innervations of some organ.

That the easy method of instillation of adrenalin into the conjunctival sac might be of diagnostic value regarding the efficiency of the sympathetic innervation is quite obvious. It has already been of some help to us and we hope to be able at some future time to report positive results.

## METHODS OF CLOSING THE ABDOMINAL INCISION.<sup>1</sup>

BY

W. D. HAGGARD, M.D.,

of Nashville, Tenn.

Professor of Gynecology, Medical Department, University of Tennessee; Formerly Professor of Gynecology and Abdominal Surgery, University of the South; Gynecologist to the Nashville Hospital; Fellow of the Southern Surgical and Gynecological Association; Member of the Woman's Hospital Society of New York, etc.

Some of the great problems of surgery have been solved, and we are now mostly concerned in the perfection of operative technic. Success is only achieved through patient attention to every detail. The frequency and benefaction of surgery of the abdomen renders a study of any of its various phases of great practical value.

The one step common to all abdominal sections, and

<sup>1</sup> Presented, with demonstrations, before the New York Pathological Society, January 14, 1903.

<sup>1</sup> Read before the Middle Tennessee Medical Society, at Lewisburg, May 15, 1902.

which I esteem to be of very great importance, is the closure of the abdominal incision. The frequency of hernia following section is more than it should be, and I believe it can be very much reduced.

The fact that over 400 cases of ventral hernia were admitted to the Hospital for the Ruptured and Crippled in New York in six years gives an idea of the unpleasant frequency of this sequel. It is difficult to collect accurate statistics as to this accident. It does not result until months or years have elapsed; the patient often applies to another surgeon; it is almost impossible to get the data of all cases. Abel,<sup>1</sup> of Leipsic, who has given in a monograph of 98 pages the most thorough and exhaustive study of this question extant, offers the following: In 665 cases followed up, in which celiotomy was performed in Zweifel's clinic 1887-1894, among those in which hernia occurred, 38% appeared in the first six months; in 26% in the second six months; in 13% in the second year; and in 23% still later.

A number of eminent surgeons have admitted 10% of hernias following the through-and-through suture, which is employed in a large proportion of celiotomies today. The 665 cases of primarily healed wounds previously mentioned as collected by Abel<sup>1</sup> gave the following analysis:

Button suture, 61 cases; 18 hernia.....	29%
Muscle suture, 25 cases; 6 hernia.....	24%
Fascial suture, 254 cases; 20 hernia.....	8.0%

The lowest percentage of hernia was in the group of 50 cases in which the fascia was united by cumol catgut; only 3 hernias occurring, or 6%, prior to 1894.

To minimize the possibility of this occurrence should be the earnest endeavor of every man who has occasion to open the abdomen, and it is the purpose of this paper to analyze the methods by which this may be accomplished.

It may be admitted at the outset that no plan of closure can absolutely restore the structures to their original condition, because the strong fibrous interlacement of the aponeurosis of the sheaths of the recti muscles cannot be restored; but by a careful imitation of nature's arrangement as nearly an ideal result as possible can be obtained.

The first and greatest aim in the closure of the incision, and at the same time the greatest prophylactic against hernia, is the aseptic healing of the wound in its entirety. I. S. Stone estimates that from 8% to 10% suppurate. Abel<sup>1</sup> observed the following results in suppurative cases:

Of 50 cases with simple button suture 34 hernias resulted, or 68%
Of 27 " " " muscle " 18 " " " or 64%
Of 52 " " " fascial " 16 " " " or 31%

Roughly, therefore, hernia follows in from  $\frac{1}{3}$  to over  $\frac{2}{3}$  of all infected wounds. Of 49 cases in which the degree of suppuration was known, in 33 in which it was superficial only, 15 hernias followed; whereas in 16 cases of extensive suppuration hernia resulted in every instance.

Aside from obtaining and maintaining a rigid aseptic technic throughout, there are several precautions to be taken with the wound. All oozing should be absolutely controlled. Forciclosure usually suffices, but if not, each bleeding point should be carefully tied with small silk or catgut. Any frayed or ragged bits of tissue should be trimmed off. Care should be taken not to detach the parietal peritoneum. Some operators obviate this by sewing the peritoneum to the skin on either side by a provisional stitch before the intraabdominal exploration is begun. Bruising by instruments and manipulation should be avoided. Turk ingeniously overcomes this by putting a layer of sterile rubber dam over the abdomen, cutting through it and after the incision proper is completed tucking it in the wound, and holding it by a wire clothes-pin arrangement. This is especially useful in suppurative cases, as it protects the wound perfectly.

In suturing, no dead space should be left. This is especially important in the method of closure by layers. Fluid accumulating makes an admirable culture medium, and if it does not become infected may cause a hematoma that will interfere with healing.

McBurney drains all incisions by a little wick of rubber tissue, one-half as large as a cigaret paper, folded upon itself and introduced at either angle and removed at the first dressing. It forms a little gutter and fluids find their exit over its smooth surface along the line of least resistance. It is well to roll a gauze pad along the incision and express any fluids before applying the dressing.

Lastly the employment of rubber gloves will aid materially in lessening the liability of infecting the wound.

The choice and sterility of suture materials is the most essential point. Unfortunately the sterility of absorbable sutures—catgut and kangaroo tendon—in all instances is not absolute; and nonabsorbable sutures—silver wire and wormgut, and silk—while they can be rendered absolutely sterile by boiling, if buried act as a foreign body and sometimes occasion trouble. If they perforate the skin they require removal. Moreover, stitchhole abscess not infrequently results from *Staphylococcus epidermidis albus*.

The oldest and simplest method of closure is the through-and-through, or mass suture. It takes in all structures, skin, fat, fascia, muscle and peritoneum, and is tied over the line of incision. Silkwormgut, since its introduction into surgery and endorsement by Bantock and others, has been most employed. Silver wire and silk are rarely used.

Instead of tying the ends the Germans shotted them over a lead plate or button. Gerster and his confreres in this country occasionally use them, but mostly as so-called tension sutures. Statistics show that this method gives more hernias than any other (29% to 68%).

The homologous approximation of the several planes of the parietes by continuous suture of layers has largely supplanted this method in the hands of abdominal surgeons; but the mass suture remains the quickest method and must sometimes be used for that virtue. When glass or gauze drainage is used through the incision, interrupted sutures are the best. In thin subjects with short incisions, and when carefully applied, the results are very satisfactory.

A cutting or trocar-pointed, straight or half curved needle should be threaded on both ends of a faultless strand and introduced from within out. It is supposed that this is better than piercing the skin from without in, as this carries the skin coccus in and invites stitch abscess. The peritoneum and fascia are caught with forceps and drawn out to insure the latter against retraction. The fascia is the bulwark against hernia. The circle of the suture should include a little of the peritoneal margin, a deep sweep in the fascia and only about  $\frac{1}{8}$  inch of the skin. The sutures should be about  $\frac{3}{8}$  inch apart. They should not be drawn tightly enough to blanch the skin, but only tight enough to hold all the structures in accurate juxtaposition. Instead of the second tie over the surgeon's knot, if a third whirl be given to the surgeon's knot the suture will not slip. This will allow any suture which may be too tight to be subsequently loosened. Intermediate approximation sutures may be inserted if there is any gaping.

Should peritoneal drainage be necessary it should be at the lower angle and the provisional sutures at that portion of the wound tied when tube or gauze is removed. The sutures should remain ten days or two weeks. There is no objection to leaving an aseptic suture longer, say three weeks, as an additional safeguard.

There have been a number of modifications of this classic manner of closure:

1. Separate union of the peritoneum by continuous

<sup>1</sup> Progressive Medicine, June, 1899.

suture of catgut or silk with the other structures included in interrupted wormgut sutures. This avoids possible contamination extending along the suture-tract into the peritoneum. I have seen a patient of a colleague die from peritonitis from a stitch infection extending in this manner.

2. Separate closure of fascia by a running suture of catgut combined with the through-and-through suture of wormgut. This gives greater certainty of uniting this important structure.

The late, distinguished Dr. Horace Tracy Hanks, of New York, introduced a continuous suture of wormgut after the through-and-through or mass sutures were in place, simply to hold the fascia in apposition while tying the external sutures. He would withdraw the one in the fascia after tying. I suggested that he leave it. It was about the time Kelly introduced the buried mattress suture of silver wire. In two incisions which I closed for Dr. Hanks at the Woman's Hospital in 1896, I employed a continuous silver stitch in the fascia and allowed it to remain, the ends protruding at the angles. Through-and-through sutures of wormgut were used also. In attempting to pull the wire out in the first case two weeks after, it broke just where it entered the skin and retracted; the other end had been put upon tension and cut short flush with the skin. There was nothing to do but allow it to remain buried in the fascia. It gave no trouble. I have kept up with the patient and the wire has remained quiescent these six years. It is needless to say that she has a very firm scar and a most excellent guarantee against hernia. The suture in the second case was withdrawn at the end of two weeks. So far as I know, that was the first case in which a longitudinal nonabsorbable suture was introduced into the fascia, allowed to remain until union was complete and then withdrawn. I have used this method in a number of instances since, withdrawing the suture. I have also allowed it to remain if the patient was very fleshy.

The frequency of hernia is undoubtedly increased with the thickness of the abdominal wall. In another of Abel's tables he found among primary-healed wounds:

1.5%	"	"	"	"	"	little	deposition	of	fat.		
3.7%	"	"	"	"	"	"	moderate	"	"		
4.3%	"	"	"	"	"	"	marked	"	"		
6.9%	"	"	"	"	"	"	very	marked	deposition	of	fat.

The through-and-through suture is contraindicated in very fat abdominal walls. If tied tightly enough to bring the other structures together, the suture is too tight for the fat. Its nutrition is constricted. It finally yields and then liquefies, and the wound is likely to suppurate. Krug and others deliberately leave the fat and skin open after entering the peritoneum and fascia in preference to suturing it. If, however, the skin only is brought together the fat falls together by atmospheric pressure, or a loose catgut suture can bring the walls into apposition.

W. E. B. Davis, of Birmingham, has ingeniously solved the problem of holding the deeper structures together by through-and-through sutures in obese subjects by a little silver tube through which the free ends of the wormgut suture, as they emerge from the fascia, are thrust. The requisite amount of traction to bring the structures snugly together is made by pulling the free ends of the suture through the tube and pushing it down. Perforated shot are then crushed on the ends of the suture above the tube, which protrudes above the skin. The fat can then be left open to granulate, or it can be held by adhesive straps, or the skin can be sewn together. I was not aware of this device until it was brought out in the discussion at the Southern Surgical and Gynecological Association in November, 1901, although it had been published previously.

In May, 1901, I operated on a boy of 12, about five hours after the beginning of a recurrent attack of appendicitis. I presumed the infection was confined to the appendix thus early and made the short McBurney criss-cross incision, cutting

through skin and fascia of external oblique, but separating the fibers of the internal oblique at right angles to the incision instead of cutting across its fibers. The appendix was, to my surprise, perforated, and I felt it necessary to drain. I could not, of course, close the internal oblique on account of the drainage. I put two sutures of wormgut in the internal oblique and peritoneum, but did not tie them, as the gauze drainage came up between them. I left them long and protruding through the incision in the fascia and skin which was closed by interrupted wormgut at all points, save the drainage opening, where a provisional suture was left untied.

When the gauze was removed on the second day, I slipped little silver tubes, which had been made for me meantime, over the two sutures in the peritoneum and internal oblique, pulled them taut and shot them; then tied the skin suture at the drainage point. The wound healed and all the sutures were removed on the eighth day. The patient remains free of hernia after a year. Had I anticipated drainage, I would have made the usual oblique incision.

3. Another modification of the through-and-through suture is that of Montgomery, who in addition to sewing the peritoneum with continuous catgut, introduces the interrupted mass sutures through skin and fascia, and to make sure of the fascia, unites it separately with catgut.

4. Another disposition of the mass suture is in the form of the figure 8. The suture is inserted through skin, fat, and fascia of one side (right), crosses over and goes through fascia, muscle, and peritoneum of the opposite side (left), is brought back through the same structures of the other side (right), again crosses and goes through fascia, fat, and skin of the opposite, or left, side. The free ends are then tied over the line of incision.

In 1896 Edebohls described the method of closing the peritoneum, fascia and skin separately by continuous catgut suture. That was the beginning of the popularization of the laminated or layer method of closure, which has steadily gained in favor and is the method of choice. Kelly says: "The best method of closure is that which brings the tissues into exact approximation, layer by layer, in the order they occupied before division, and holds them there until firmly united, with the least risk of infection."

Different operators have employed varying methods to obtain this object. The trouble has been to decide definitely which is better—the absorbable (animal) suture or the nonabsorbable (buried) suture. The difficulty is that the absorbable sutures cannot be rendered universally sterile and the sterile sutures are not absorbable.

Edebohls was disappointed with buried wormgut, and was led to employ chromicized catgut that remained 30 days. On the other hand, Kelly introduced the buried mattress suture of silver wire, and Clark claimed for it that the healing of the wound is almost invariably quite ideal. The wires sometimes work out, or have to be removed, but only in the rarest instances has ventral hernia occurred as a postoperative sequel.

In some quarters there is a prejudice against catgut, but when it is boiled in alcohol in a hermetically sealed tube, or sterilized by boiling cumol, it has been free from criticism in my hands.

It was my practice until recently in closing the abdominal incision, when I was not obliged to close in a hurry on account of the condition of the patient, to unite the peritoneum with a continuous whipstitch of fine silk. Before tying, pressure was made upon the parietes to expel the air. The fascia was pulled out by small vulsella, or mosquito forceps, and sewn with a Hagedorn needle. For the skin the Halstead subcuticular suture of silver wire was used. The results from this method were very pleasing. I have employed catgut in the skin, which has the advantage of not requiring removal. Wormgut is very good, but the silver wire has many advocates, especially at Johns Hopkins, on account of its so-called antiseptic effect in the tissues, its rigidity, and the beautiful line of closure it gives. The ends are simply tied loosely together over a small pad of gauze and it can be removed by a smart pull at the end of a week. It is done so quickly that the patient is hardly aware of it.

The scar is evanescent and sometimes only visible as a hair line. In the negroes I have had to look carefully to detect it after a few months.

The ideal method is one that accurately closes each layer separately by a reliably aseptic suture that can easily be drawn when it has accomplished its purpose. These requirements are met by the use of silkwormgut in that manner. Montgomery ascribes the suggestion of that method to Haughey, of Battle Creek. The longitudinal suture, however, has perhaps been used by many surgeons. In 1896 I first employed a continuous removable suture of wire in the fascia. Halstead has for several years closed the skin of all wounds by a longitudinal subcuticular suture that was withdrawn.

It remained for Davison<sup>1</sup> to perfect the method of Haughey by the simple, original modification of putting a small reverse bowknot at the ends of the sutures, which acts like a shot on either end and is easily untied when the suture is to be removed by simultaneous traction on both ends. His description of the method of the introduction and removal in the fascial layer will illustrate:

A small reverse bowknot is tied four or five inches from the end of the strand. The edges of the fascia are caught by forceps and held by an assistant. The suture is introduced into a firm place in the fascia back from the end of the wound and drawn tightly up to the knot, and the wound is closed by the continuous herring-bone suture. At the last stitch the suture is shirred up tightly, grasped by a smooth-pointed dissecting forceps at its exit from the fascia, and another reverse bowknot tied below the point of the forceps. . . . The ends are allowed to hang out at the angles of the wounds. This suture is removed in two or more weeks. Simultaneous traction on the two ends unties the knots, then the suture is clipped close to the skin at one end and withdrawn by an artery forceps.

The skin is closed by the Halstead subcuticular stitch of silkwormgut. The ends of the peritoneal and skin suture are not knotted, but simply protrude at either angle. They may be stained different colors, or otherwise marked for identification. In general the advantages of this method are:

1. Certainty that all suture or ligature material placed in the wound has been made sterile by boiling in water.
2. Accurate layer approximation of tissue.
3. Removal of the buried sutures when healing is complete.
4. Capillary drainage for each layer.
5. Safety of intestines from injury during application of the sutures.
6. Rigidity of application.
7. Minimum line of irritation on the peritoneal surface and consequent adhesions to the viscera.
8. Slight scar in the skin, there being no perforation of the skin by sutures.
9. All of the advantages of a permanent buried suture without the danger of future irritation and extrusion of the knot.
10. The advantages of an absorbable suture without the danger of loss from the suture, and without producing a nidus for septic germs from the blood current during absorption.

NOTE.—I have used this method of closure in 11 cases in the last two months with perfect results as to clean wound healing and minimum scar.

#### CONCLUSIONS.

1. The most reliable statistics prior to 1894 show that hernia occurs in from 6% to 29% of abdominal sections.
2. Suppurating abdominal wounds result in from 31% to 68% of hernia (according to the method of suturing).
3. The frequency of hernia is increased with the thickness of the parietal wall.
4. The longer the incision, the greater is the likelihood of hernia.
5. Drainage openings predispose to its production.
6. The site of the incision does not materially add to the occurrence, if suturing is uniform.
7. Abdominal supporters have absolutely nothing to do with the prophylaxis of this condition.

<sup>1</sup> Annals of Surgery, March, 1892.

8. Subsequent pregnancy does not influence its occurrence.

9. The best preventive of postoperative hernia is the aseptic healing of the wound.

10. Through-and-through suture is satisfactory in thin subjects with short incisions, and is recommended when rapid closure is imperative.

11. The best method of suture is one which insures accurate coaptation of the fascia.

12. The method of closure in three layers by continuous silkwormgut in peritoneum fascia and subcutaneously seems to be freer from objections than any other. Its extended trial is desirable.

13. The patient should be confined to bed from 2½ to 3 weeks to insure thorough organization and consolidation.

14. After a wound is completely healed no other influence acts deleteriously upon the permanence and resistance of the cicatrix.

15. It is believed that less than 2% of abdominal incisions should become infected, and not over 3% of hernias should result.

## FEEDING OF INFANTS AND CHILDREN.<sup>1</sup>

BY

FREDERICK J. MANN, Ph.B., M.D.,

of Poughkeepsie, N. Y.

The mortality among children under five years of age in large cities is about 40% of all deaths. Dr. Shakespeare figures from the mortality tables of Philadelphia for a period of years that between one-fourth and one-fifth of all children die before ending the first year of life, from diseases of the digestive system. One-tenth of all children do not live a month and one-third die before the age of three months. These facts I bring forward to show the importance of my subject. We all know that infantile diseases are more serious as well as more fatal in those fed by the bottle.

In the summer of 1894 I had charge of the Infants' Summer Hospital at Charlotte, a Rochester, N. Y., charity, and I here observed the good effects of breast feeding. This was shown by the fact that only 13% of the babies treated that year were wholly or in part breast fed, and that none of these cases was fatal, showing a less severe sickness, a constitution more able to resist disease, or both. A fact accepted largely by the laity, and also, I am sorry to say, by some members of the medical profession, that an increasing number of women cannot nurse their infants has been too prevalent. The result is that artificial substitutes are advised and used when frequently efforts made by the mother under medical advice would result in a supply of breast milk proper in both quality and quantity. If each mother could be made to believe that her infant would die if not breast fed, there would be a large increase in the number of successful lactations. The proper time to begin to consider the feeding of an infant is ten months or more before its birth. The mother must be taught how much healthier breast babies are, and her health should be built up so that it will be possible for her to nurse her baby. A rational life, proper clothing, substantial, nourishing diet; the bowels, kidneys and skin kept active, and what medication may be indicated, may be mentioned as a means to attain this end.

When breast milk disagrees or is insufficient in quantity, it will generally be found that the mother is anemic, constipated, or otherwise in poor health; that she is not receiving a plentiful, plain diet with abundance of fluids, or that she is not getting enough fresh air and exercise. The drugs usually indicated are iron and laxatives; of these Bland's pills and ca-cara may be mentioned. Beer once daily will often correct the tendency

<sup>1</sup>Read before the Dutchess County (N. Y.) Medical Society, July 9, 1902.

to constipation due to the extra amount of milk which is taken. Vomiting and disturbed stools in the infant are often caused by a too high percentage of proteids in the mother's milk and this is best overcome by exercise, always short of fatigue. Smallness in quantity of breast milk by no means shows poor quality. Weight first and then the age and general development and condition of the child are the best guides; if needed, breast feeding can be eked out by an addition of modified cow's milk. If three or more bottles a day are needed, it is best to give both breasts at each nursing, to prevent the supply of breast milk rapidly diminishing.

We are living in an age of infant foods and of milk modifications, but it is only right to protest against their use when not necessary and against the prevalent idea that they are as safe as mother's milk. The wretched pseudo scientific statements issued with the proprietary baby foods try to show that bottle feeding is better than breast feeding and I am sorry to say people do not realize that the deathrate among such artificially fed infants is considerably greater than among those who are fed at the breast.

Cautley, of London, in his new work on the "Feeding of Infants," states that more harm than good has been done by the various substitutes for mother's milk, not but what they do good in properly selected cases but because they are often used when not needed and the infant is thus deprived of breast milk, which is far more beneficial. Too many babies are put on bottles for lack of rational treatment of the mother. Some children thrive on almost anything, others require more careful care and many, many others, if they do not succumb to intercurrent diseases, often suffer from various acute and chronic digestive troubles—marasmus, rachitic, scorbutic, etc. The pudgy fat bottle baby of the patent food type is in no way on a par with the firm vigorous breast infant, and as the bottle baby grows older it is more liable to disease. Many children who break down in school life or who later suffer from chronic digestive, nervous and other complaints, can attribute a large part of their troubles to the fact that they were deprived of human milk and so did not secure the right foundation. Most bottle-fed babies are rachitic although often so mildly as not to be noticeable.

When we cannot secure breast milk for an infant it is easy to order some prepared commercial food with printed directions how to use it and which is claimed to be the one baby food sure to agree in all cases, food and directions being made by some one who has never seen or heard of the infant in question. This is not right, even if it does save the doctor some trouble. Each case should be studied by itself and the right and best food for that child be advised.

The modification of milk by the percentage method is considered today by practically all of the best known authorities in pediatrics of the country to be without doubt the best method of artificial feeding.

Percentage feeding is not the easiest method for the doctor, as it requires each case to be studied by itself; but the gain is that each child receives food so prepared as to suit its wants, and not something prepared by wholesale in a factory. I was told recently, by a gentleman well qualified to speak, that a certain food, which he mentioned by name, was prepared from skimmed and practically dirty refuse milk. What surety have we that commercial foods are pure and clean. Of course some infants will grow fat on almost anything, but the best teaching is against the use of such foods, for they often do harm and are rarely needed. They are not founded on correct ideas. They often contain considerable starch, which is foreign to milk, or said starch has been converted into sugar, which is not the natural milk sugar. When prepared as directed they frequently do not contain sufficient proteids or fats. When not prepared with fresh milk they do not have the proper composition, and if fresh milk is to be used, why not use the

percentage method? When the doctor has figured it out, it is very easy for the mother to follow it. This method uses such proportions of cream, milk, sugar, and water as will make the percentage of fats 3 to 4, sugar 6 to 7, and proteids from 1.5 to 1, or to so modify the proportion of 4.7.1 (or 3.6.1) as is indicated by the condition of the child. When first changing from the breast, as with a very young infant, it is desirable to use a weak mixture, and then to increase it by steps. Curdy stools indicate too much proteids. Rancid, sour vomit, as a rule, points to an excess of fat. Watery diarrhea often means too much sugar. A child growing well, but suffering from diarrhea, indicates too much or too strong food, and vomiting may mean the same, or that the child eats too quickly. It is needless to state that the number of feedings and the intervals between must be properly regulated. Dr. Freedman, of New York, read an interesting paper at the last New York State Society meeting on a "Simple Method of Milk Modification." This was published in *American Medicine*, May 3, 1902.

A child at birth has considerable iron stored up in its system, especially in the liver, which it draws upon, as milk contains comparatively little iron. A child is apt to become anemic if weaning is too long delayed or if it is kept exclusively on milk for too long a time. From the seventh to the tenth month the ferments which digest farinaceous foods are present in sufficient quantities to call for that class of foods. The glands which secrete the diastatic ferments have developed so far by this time as to indicate that the first natural supplement to make is farinaceous food. As soon as the teeth are well enough developed to chew it, a dry crust of stale bread, at first once and later twice a day is advised. This exercise develops the jaws and helps to prevent crowding of the teeth, which leads to dental caries and digestive disturbances. The custom of the present day to direct all food to be either chopped or in some way made fine seems a mistake. Meat juice is injurious owing to the large amount of extractive substances it contains, which do little except excite the nervous system and tax the excretory organs. They render the urine hyperacid, and the child suffers from those diseases which are known as the uric acid group. Among these are urinary incontinence, rheumatism, chorea, nervousness, anemia, etc. Hence it follows that meat and its preparations should be allowed but little in infancy and early childhood. They also create a dislike for the farinaceous foods, fats and fresh vegetables, which are the best foods. Sufficient fats and carbohydrates are needed by the child to supply the demand for heat, energy, nervous and muscular work. Fats and carbohydrates decrease proteid metabolism and allow a normal growth and development of the child.

#### SUBSEQUENT REPORT OF A CASE OF EXCISION OF THE SYMPATHETIC FOR CHRONIC GLAUCOMA.<sup>1</sup>

BY

HOWARD F. HANSELL, M.D.,  
of Philadelphia.

The history of the patient that makes the text for this short communication has been given in detail before this Section by Dr. de Schweinitz at one of the meetings earlier in the year. It is, in brief, as follows:

A poorly-nourished man of 23 had noticed failing vision in June, 1901, and by September of the same year his sight had become so bad that he had been obliged to give up his occupation. His condition, as recorded by Dr. William Zentmayer, who examined him in November at Wills Hospital, was horizontal nystagmus, V, counting fingers at one foot, pupils dilated, T +2; field, as measured by candles, contracted to 10° around the fixation point. In December he came under the care of Dr. de Schweinitz, at the Philadelphia Hospital. His

<sup>1</sup> Read before the Section on Ophthalmology, College of Physicians, Philadelphia, December, 1902.

examination, the notes of which he has kindly furnished me, shows V, shadows in the temporal field, pupils dilated, deep cupping of the optic nerve heads, T +2; under eserin the pupils contracted, tension was lowered and vision was slightly improved. On December 18 the right superior cervical ganglion of the sympathetic was excised by Drs. Hearn and DaCosta. Result, myosis and slightly lowered tension, continuing three days. Patient had dysphagia lasting 24 hours, and moderate ptosis, but no enophthalmos. No permanent change for the better or worse. January 31, 1902, the same surgeons removed the left superior cervical sympathetic. This operation had no effect upon the condition of the left eye. The pupil was not contracted and tension was not lowered. Recovery from both operations was prompt and without complication.

During the past eight months the man has had at least two attacks of acute glaucoma, during one of which he was under my care at the Jefferson Hospital. Blindness in the left, the acutely inflamed eye, was complete, pupils widely dilated, T +3. The ciliary and ocular pain on the left side was intense. A few hours after admission I performed paracentesis of the cornea, draining the anterior chamber of the greater part of the aqueous humor, and during the remainder of his stay instilled eserin. Tension was reduced, pain relieved, and in two days vision was restored to that obtaining before the attack. De Schweinitz has stated to me verbally that he had treated the patient in a similar attack and with equally good result.

In this case of chronic glaucoma, therefore, the value of double excision of the sympathetic, skilfully done, was negative. The operations had no permanent effect, favorable or unfavorable, upon vision, and moreover they were unavailing in preventing at least two onsets of acute glaucoma.

In order to form a correct estimate of the value of any procedure in therapeutics, operative or medicinal, the subsequent history of the patient and the final results are essential. This truth is trite and so universal in its application that illustrations are not needful. Excision of the sympathetic has been practised for the cure of the chronic forms of glaucoma with uncertain results. In some cases the tension has been lowered and the pain relieved, and even vision improved for some days or weeks after operation, but in most or all the cases the final outcome has not been published. After Jonnesco's report of immediate cessation of pain, fall of tension, reduction in the size of the pupil, and improvement in sight when the optic nerve has not been totally destroyed; Abadie's account of a man whose one eye had been enucleated for glaucoma and who suffered so intensely in the other from glaucoma that he begged for enucleation, but in whom excision of the superior cervical sympathetic ganglion was followed by cessation of all symptoms, even to clearing up of the media; Bull's successful case of typical unilateral glaucoma, T +3, V = light perception, and severe pain; we, who have had no experience, are led to believe that an effective remedy has been found. That this expectation has not been realized is apparent from the conclusions of more conservative surgeons who have carefully weighed the evidence for and against, and who believe that the operation is justifiable after other means have been tried without result. Others again, Panas, for example, are opposed to it. Coover<sup>1</sup> says the only deleterious effects upon the patient are numbness of the ear and of the inferior maxillary, and Mullen<sup>2</sup> that ptosis and enophthalmos may occur as remote effects.

The indications for the operation, as expressed by H. J. Williams,<sup>3</sup> and concurred in by most writers on the subject, are glaucoma simplex, inflammatory glaucoma when iridectomy has failed, hemorrhagic glaucoma early in the disease and absolute glaucoma with pain.

Marple's<sup>4</sup> conclusions, after analysis of the results of 86 excisions, are fair and unprejudiced, and give evidence of good judgment: 1. The operation is a safe one in the hands of a skilful surgeon. 2. While positive conclusions may not yet be reached, some of the glaucomatous eyes have been improved for some months. 3. The results are so various that we cannot say just to

what class of cases it is most applicable. 4. It does not replace iridectomy but may possibly supplement it in case the former operation is declined or has resulted disastrously to the other eye.

In considering the advisability of adopting this operation it is well to study results obtained from procedures that have stood the trial of time. One of the most recent publications is that of F. Meddel,<sup>1</sup> who gives the results of the treatment of 258 glaucomatous eyes in Hirschberg's clinic. Iridectomy furnished the best results, improvement in 77% of chronic and 82% of acute glaucoma. In the majority of cases of simple glaucoma it preserves vision and in some improves it. Iridectomy is the chief but not the exclusive treatment. Nine of the patients were successfully treated by eserin only.

Microscopic examination of the excised ganglion has shown in some cases that it is sclerosed, but no one has explained the connection between the sclerosis of the ganglion and the development of glaucoma. Rohmer<sup>2</sup> believes that the superior cervical ganglion controls the vascularization of the posterior segment of the globe and that the ciliary ganglion controls that of the anterior segment. He removed the ciliary ganglion in six glaucomatous sightless eyes that on account of pain would otherwise have gone on to enucleation, and has been highly gratified by the results.

The same writer gives a remarkable history of the results of 17 cases of excision of the sympathetic. In chronic simple glaucoma five-sixths of the cases were improved, in chronic inflammatory two-thirds. Five hemorrhagic cases were improved, while the acute and subacute were least responsive. With such brilliant results as these by the simpler operation, there seems to be no need to resort to the more complicated and severe operation of removal of the ciliary ganglion.

It is the fashion for all the writers on this subject to draw conclusions. I have but one to offer, deduced from a study of the papers here alluded to, some other articles not mentioned, and from the final result of the case recorded, and my conclusion is that the operation is justifiable in an exceedingly small number of cases, and those selected, of simple, noninflammatory and of hemorrhagic glaucoma, only after every other available remedy has been ineffectual and the patient, having been informed of the probable outcome, requests its performance. And one more thought. I believe that sympathectomy is inferior to enucleation in sightless, painful, glaucomatous eyes, for the danger in the former is greater and the result less sure.

NOTE.—Since reading this paper the patient has had a third attack of acute glaucoma relieved by paracentesis of the cornea, eserin and pilocarpin sweats.

## HYPODERMOCLYSIS IN PNEUMONIA, WITH REPORT OF A CASE.\*

BY

MAURICE KAHN, M.D.,

of Leadville, Colo.

Visiting Physician to the Children's Home; Division Surgeon, D. & R. G. R. R.

I feel that no apology is necessary for inviting your attention to a comparatively new treatment of pneumonia. The succeeding tables show conclusively that we have by no means approached even satisfaction, to say nothing of having realized the ideal in the treatment of this disease. Therefore any measure that may reduce the present appalling fatality is worthy of our profound consideration.

The following table is taken from Dr. Joseph Eich-

<sup>1</sup> Philadelphia Medical Journal, March 16, 1901.

\* Read before the Lake County (Colo.) Medical Association.

berg's able article on "The Serum Treatment of Pneumonia."<sup>1</sup>

	Mortality.
In New York Hospital for 6 years, 536 cases treated.....	32.16%
In Johns Hopkins Hospital for 7 years, 155 cases treated.....	28.4%
In Roosevelt Hospital for 6 years.....	35.6%
In Pennsylvania Hospital for 3 years, 216 cases treated.....	16.1%
In Boston City Hospital for 8 years, 3,088 cases treated.....	34.6%
In St. Bartholomew Hospital for 5 years, 691 cases treated.....	10%
In Cincinnati Hospital for 6 years, 337 cases treated.....	34.5%

Furthermore, the following table evidences that in New York and Chicago at least pneumonia has been more fatal than tuberculosis:

In New York, from 1840 to 1900, deaths from pneumonia, 56,092.	
In New York, from 1890 to 1900, deaths from pulmonary tuberculosis, 50,440.	
In Chicago, from 1890 to 1900, deaths from pneumonia, 25,228.	
In Chicago, from 1890 to 1900, deaths from pulmonary tuberculosis, 22,957.	

The foregoing is sufficiently eloquent without further comment.

The antitoxin treatment of pneumonia I believe is destined eventually to supplant all other forms of treatment of this disease, but so long as it remains in the experimental stage, and until it shall have been proved safe and trustworthy, we must support our reliance with other methods.

The credit for the first use of salt solution hypodermically for the cure of pneumonia doubtless belongs to Dr. F. P. Henry, of Philadelphia, who is said to have used it as early as 1890.<sup>2</sup> W. C. Johnson<sup>3</sup> gives the credit to C. A. Penrose, of Baltimore, who reported his case in July, 1899, but unquestionably Dr. Johnson was not familiar with Dr. Henry's earlier work.

With the modern theory concerning the pathology of pneumonia, viz., that it is a general toxemia with local manifestations, our one endeavor must be to occasion so far as possible a diminution in the amount of toxin already in the system and to inhibit to the greatest extent its reformation. At present I think this is best accomplished by hypodermoclysis. Penrose<sup>4</sup> found that the infusion of salt solution in several cases of pneumonia promoted the activity of the kidneys and sweat glands, relieved delirium, reduced temperature, and increased the force of the heart. Lenhartz records that the results of intravenous saline injections in acute diseases in children, were increased heart force and lowered blood-pressure. The consequent lavage of the entire system aided diuresis and diminished the toxins, caused rapid excretion of chlorids, and the high specific gravity of the urine showed that much waste was being eliminated.

It is no longer a theory but an established fact that subcutaneous infusion of salt solution is invaluable for renal elimination of poisonous accumulations. Moreover, I believe the best safeguard against heart failure in pneumonia is secured by diminishing the toxins, which, in the light of our present knowledge, is best effected by the exhibition of subcutaneous salt injections.

In one complication, says Broadbent, venesection may be of great service. This is early in the attack when the invasion of the lung is so rapid that the right ventricle is unable to cope with the sudden resistance in the pulmonary circulation. This condition is evidenced by marked cyanosis, orthopnea, a small, short pulse with a violently beating heart, staring eyes, and an agonized expression. Under such circumstances the relief by bleeding is striking, and when 16 oz. to 20 oz. has been withdrawn all the distressing symptoms will have disappeared. Like results are not to be expected later when asthenia has become a prominent feature.

This is seemingly logical and apparently harmonizes with modern pathology, but would it not be eminently more conservative and more beneficial to bleed one into his own bloodvessels? Say by administering full doses of "veratrum viride, which reduces the force of the heart, thus diminishing the *vis a tergo* which drives the blood to the lungs and at the same time dilates the abdominal bloodvessels and so invites the blood into

them."<sup>6</sup> This seems to me preferable to venesection, as it is not followed by the exhaustion which succeeds blood-letting, so that later with the advent of the second stage, after the effect of the veratrum viride has worn off, the blood, by this time diluted with salt solution, is permitted to return to the circulation. Thus the persistent depression of phlebotomy is avoided. In this connection it may not be amiss to mention that it is the theory of the conservation and the increase of the phagocytic power that has stimulated experimentation with antidiphtheric serum in pneumonia, aside from its specific antitoxic property.

It appears to me unreasonable to suppose that a weak solution of blood which must exist after venesection followed by salt infusion, as advised by Porter,<sup>7</sup> should be more efficacious in withstanding the onslaughts of disease than the stronger solution which obtains after the injection of salt solution without an antecedent phlebotomy. For will not the toxins continue to be manufactured? Will they not be thrown into the system more rapidly in the face of diminished resistance which must follow depletion? Will not depletion reduce in number the system's guards—the leukocytes—as well as toxins? Then why not leave our position as unassailable as may be, retain our army intact (by not practising phlebotomy) and endeavor to weaken the strength of the attacking forces (by diluting the toxins with injections of salt solution) and thus give the phagocytes a favorable opportunity to combat the enemy? Saline infusion weakens the invading army but not the defensive army, whereas bleeding weakens both. What we wish to accomplish is to bring the toxin-laden blood as near its norm as possible. And by gaining the norm (imagining this feasible) we eliminate the danger of this dreaded disease. Failing this, as of course we must, it follows that the nearer we approach the norm the further we recede from a perilous position.

CASE.—I was called to see the patient whose case has supplied the text for this paper the morning of December 25, 1899, and found a woman about 50, well developed and fairly well nourished. Previous history is negative. Present illness began December 24, with chilly sensations, hot flushes, a feeling of general discomfort and malaise. The morning of December 25 she had a chill. Temperature at the time of my visit was 102.5°, pulse 120 with the physical signs of a developing right basal pneumonia. On December 27 she was markedly worse. During the night the embarrassment of the heart and the respiration grew more and more serious, despite the hypodermic use of .01 gram ( $\frac{1}{100}$  grain) of strychnin, 0.002 gram ( $\frac{1}{50}$  grain) digitalin, 0.001 gram ( $\frac{1}{100}$  grain) atropia and 2 cc. (30 minims) whisky within two hours. By this time the patient had a pulse of 160, temperature of 105.5°, Cheyne-Stokes respiration, pronounced cyanosis, cold arms, legs and forehead, and was apparently moribund. Further medication seemed useless. I then tried hypodermoclysis—giving her in all four injections within six hours, aggregating about three pints. The immediate effect was astonishing. The pulse became slower and of better quality, the temperature dropped, cyanosis disappeared, respiration became regular, consciousness returned, a general mild perspiration superseded the dry skin, and diuresis was marked. I regret now that an examination of the urine was not made. For two days following, rectal injections of salt solution were given at intervals. The subsequent history of the case is of no great interest. On the ninth day of the disease, as there had been no voice sounds nor rales for three days, with absolute dullness of the involved area, acupuncture was performed. Result—"dry tap." From this time on recovery was slow, but on the whole satisfactory. Treatment was symptomatic till February 16, the day of her discharge.

**Plan to Stop Grave Robbing.**—A bill has been introduced into the Indiana Legislature creating a commission to distribute unclaimed bodies and bodies of paupers to the various medical colleges. The bill is the result of wholesale grave robberies in Indianapolis, for which more than 20 men are under indictment.

## ELECTROLYSIS IN EUSTACHIAN SALPINGITIS WITH STRICTURE: REPORT OF 75 CASES.

BY

ELLWOOD MATLACK, M.D.,

of Philadelphia.

Chief of the Nose, Throat, and Ear Dispensary of the German Hospital, Philadelphia.

The ability of the negative pole of a galvanic circuit to cause disintegration and absorption of certain forms of pathologic tissue has long been recognized. It has been proved in hundreds of applications in the cases forming the subject of this paper, and can readily be demonstrated by any one.

When an electrode is passed into the tube and meets with a mechanical obstruction so great that further advance is impossible, the passage of a current of a few milliamperes will, in a half minute or so, cause such a shrinkage of the tubal structures as will usually allow further progress with ease.

As a rule, a certain amount of inflammatory swelling occurs lasting several hours, after which more or less permanent absorption of the thickened tissues results. Repeated applications of the current cause a permanent enlargement of the caliber of the tube.

The procedure has been recommended as a remedial measure upon a number of occasions in the past, and is mentioned in several of the textbooks, while of recent years Dr. Duell and some other New York surgeons have reported an extensive series of cases.

I have very little to add to the conclusions already reached by Dr. Duell, but desire to present the following series of 75 cases treated during the past year, in the endeavor to find its proper place in the treatment of deafness.

These patients have not been selected. They include every deaf person applying for treatment and willing to submit to it. Some have been deaf for 20 or 25 years, others following various systemic diseases, and some presented cicatricial conditions following old otorrhea, which are included to show an apparent stimulation and increased functional activity of the auditory nerve. Finally, very few can be said to be typically favorable cases in which the pathologic changes were practically confined to the tube, not having yet involved the deeper structures nearer the stapes and labyrinth.

I have seen very few normally patulous eustachian tubes even in slight degree of deafness. On the other hand, many have been so tight as to require several applications of the current before the smallest electrode could be passed into the middle ear. In one instance I was unable to reach the tympanum, probably on account of a tight scar of syphilitic origin.

The symptoms usually associated with eustachian obstruction in addition to deafness include a sense of fullness in the head, sounds of the patient's voice returning with abnormal intensity, cracking sensations during swallowing, pain in the neck in the tubal region, and finally the vast array of subjective sounds varying in pitch and intensity known as tinnitus. The tests would be expected to show negative Rinné or diminished air conduction with relatively increased bone conduction, and diminished sound perception for the lower tones of the scale.

It has been my experience that all these symptoms are relieved or cured in all cases of more or less uncomplicated eustachian obstruction. I believe this cure will be permanent if the nasopharynx is kept in normal condition by appropriate treatment. The result is certainly much more lasting than that following the inflation with air or medicated vapors through the catheter.

There is a tendency at present to regard all cases of aural sclerosis with associated deafness as due, even in their incipiency, to fibrous thickenings and ankyloses in the region of the stapes and labyrinth. They tend to grow rapidly worse, and the patients often suffer con-

siderably from head-noises. I have been able in many such patients to restore the hearing to a greater extent by electrolysis than by any other method of treatment with which I am familiar. It is not possible to say just how permanent this result will be. They are almost without exception complicated with more or less stenosis of the tube.

I have relied for the most part upon the watch, the Rinné test, and the voice to determine the hearing power of these patients, and have not hesitated to accept the statements of the patients and their friends in reference to improvement or the reverse.

The current used varied in strength from one to five milliamperes, and was obtained from an ordinary galvanic battery, the positive (sponge) electrode being held in the hand of the patient and the negative (gold-tipped wire) passed through an insulated eustachian catheter for about 35 mm. into the middle-ear cavity. The duration of treatment was one minute or less as a rule. The bougie, after one or more applications, gradually overcomes the resistance of the stricture, and finally enters the tympanic cavity and there moves freely. Successive sizes are passed until the tube has resumed its normal caliber. This result can be secured in the vast majority of cases, but not in all.

Asepsis of all instruments and of the nasal cavity is essential to secure the best results and render the treatment harmless. With care, little inconvenience will be felt by the patient. After one application, a patient had a slight emphysema of the face lasting a few hours, apparently caused by displacement of the catheter by the pharyngeal muscles. I have also seen one case of acute otitis media develop during the course of the treatment, but this was probably due to another cause (influenza).

About the usual nasal conditions were present in this series. The septum rarely in the median line, most frequently to the left, hypertrophic rhinitis with tendency to dryness and crust formation in the region of the pharyngeal vault, and especially the later, sclerotic changes supervening after years of low inflammatory action. No case of atrophic catarrh is included here. A peculiar roughness of the tubal walls was observed in the more chronic sufferers, and notably in the syphilitic ones.

I have made an attempt at classification from the clinical features to throw more light upon the prognosis:

1. In three patients a syphilitic element was prominent. One showed cicatrices extending across the posterior pharyngeal wall from an old ulceration. I was never able to pass even the smallest electrode into the tube for a greater distance than a half inch. The deafness (unilateral) was not influenced by the treatment. In the second case, a colored man, with extreme deafness and diminished range of tone perception at both ends of the scale, and head-noises of peculiar intensity, great improvement followed the successful opening of the tube. This was accomplished with great difficulty and only after many unsuccessful efforts, inflammatory bands having apparently been thrown across the tube in various directions. After several months of treatment he was able to report a complete disappearance of the head-noises and very great improvement of hearing. At the last treatment a medium-sized electrode entered the middle ear without difficulty. In a third patient there was moderate narrowing of the tube, slight deafness, but very annoying tinnitus in both ears. These symptoms have at present all disappeared, but he reports every three or four weeks to see that there is no tendency to relapse.

2. I would like to include here three cases of the most promising type, which unfortunately are but rarely seen by the specialist. In 75 cases, only 3 of salpingitis in its incipient stage were encountered. Autophony, slight tinnitus, and impaired hearing at times were the only symptoms, and they were noted early by these patients

probably on account of their occupations, musicians (two cornetists, one violinist). The tubal swelling disappeared completely and the functions of the parts were restored after a few applications of the current, combined with treatment addressed to the nasal membrane. There is reason to believe that deafness in the vast majority of instances originates in this way and could be held in check indefinitely. Politzer inflation combined with the most skilful local treatment can show results comparatively transient without the aid of electrolysis.

3. Two cases of great deafness occurring in boiler-makers are recorded. One had lasted for over 15 years. In both very great stenosis of both tubes was noted, while a fair amount of functional activity of the auditory nerve remained as shown by cranial bone-conduction. Both passed from observation too soon for positive results to be obtained further than relief of the tinnitus.

4. Here are grouped together 21 cases on account of their chronicity. The patients have suffered from deafness for 15 or more years and marked improvement would hardly be expected from any form of treatment. The list, however, offers some notable exceptions. In one of these the nasal cavities were blocked by irregular projections from an old fracture of the septum. These were removed by electric trephine to allow passage of catheter. Nearly two months elapsed before the smallest electrode could be passed into the tympanic cavity, but from that time on his improvement has been rapid, so that while still under treatment, he attends without difficulty to an occupation requiring good hearing. The tinnitus has disappeared and conversation of ordinary loudness is heard with ease. I have no doubt that in time a limit will be reached beyond which improvement will not continue, and after which it may be necessary to repeat the treatment perhaps once a month to retain what has been gained, but this applies more or less to all other measures of relief.

Another exceptional patient of this class had been growing deaf since childhood. Several members of his family are afflicted in the same way, one brother at present using electrolysis. A watch could not be heard at the beginning of treatment and the voice only when much intensified. Negative Rinné test and diminished perception of low tones were elicited. He is 34 years of age, and at various times during his life has undergone approved treatment by specialists without marked improvement. I found the usual cicatrices in both tubes, but succeeded without great difficulty in restoring the normal caliber. He represents one of the most successful cases of the series; his hearing, while not normal, is sufficient for all ordinary occasions.

A third patient has discarded the use of a hearing-trumpet, which before treatment was necessary. My notes further record three patients in this class in whom the hearing was greatly improved.

In the remaining ones, although the tube in almost every instance was rendered of practically normal size, the hearing improved slightly or not at all, which was, of course, to be expected, in view of the advanced sclerotic and degenerative changes affecting the more deeply-seated structures.

The tinnitus, however, was almost always lessened, and in a few instances disappeared.

5. Seven cases of aural sclerosis without marked tubal obstruction, but with secondary involvement of the auditory nerve. Electrolysis, used after other means had failed, was also unsuccessful.

6. Finally, I include here 29 cases of chronic tubal disease. They represent what might be regarded as average cases of catarrhal deafness, the watch being heard in all before contact with the side of the head. The deafness in almost all is bilateral, but greater on one side than the other. The Rinné test negative; Galton's whistle heard normally; diminished perception of lowest tones of scale and autophonia were the symptoms.

Intranasal abnormalities were universally present. The septum was in the median line in two cases, but in the others often so extremely distorted as to suggest its etiologic relation to the tubal condition. In four operative measures were necessary to allow access to the tube for the catheter. The left nostril was the one more commonly occluded; in the majority the deafness was by far the greatest in the left ear. Chronic inflammatory changes in the nasal mucous membrane, and especially in the nasopharynx and extending into the eustachian tube, were always present. These were hypertrophic in nature—no case of atrophic rhinitis being under treatment.

Catarrh of the tube with swelling caused various degrees of stenosis and obstruction, most marked, of course, at the isthmus—scarcely noted beyond that point, as any bougie met no further obstruction before entering the tympanum (one exceptional case noted). As a rule, there was progressive narrowing of the tube until the isthmus was reached, after which further progress was easy. A temporary swelling of the tissues often followed the withdrawal of the bougie, sometimes lasting several hours and accompanied by an increase of the deafness and other symptoms. In two or three instances this occurred during the application of the current and caused some difficulty in extracting the bougie. Increasing experience confirms the impression that the best results are obtained by the use of the current only once a week—thus allowing time for any inflammatory reaction to subside.

All these patients had been treated by others, with more or less skill, before electrolysis was tried, and were not improved. About one-third of the number passed from observation or did not persist in the treatment for three months, and while some were improved, I think that conclusions should not be drawn from them. Of the remainder, the patency of the tube was always restored, the nasopharynx rendered normal so far as possible, the tympanum inflated through the catheter, often with medicated vapors, massage of the drum practised in some, and every other means used that experience would suggest as likely to benefit the hearing.

I can report cure of the autophonia and tinnitus in all these cases, increased limit of tone perception, and great improvement of the hearing. All these results may, I think with justice, be attributed to the more thorough treatment rendered possible by the permanent opening of the eustachian tube.

*General Conclusions.*—These 75 cases represent applications of electrolysis extending into the thousands, which should be sufficient to allow a fairly accurate estimate of its value.

Excluding purely labyrinthine conditions, it has been of service in almost all other forms of deafness, and especially in cases of moderate degree, in which the most pronounced changes were in the tube.

The best results cannot be obtained from its unaided use, so this should be supplemented by any other measures that have formerly been found of service. It is especially important to have free access to the tube, and to this end septum irregularities should always be corrected and hypertrophies of the turbinals cauterized. I use a routine way in all cases—solutions of iodine, menthol and camphor, conveyed to the parts by nebulizers—to improve the circulation in the nasopharyngeal mucous membrane. After electrolysis has restored the normal caliber of the tube, a further use of vapors to the middle ear after the method of Dench will be found of great value.

Patients who have been persuaded to continue in this line of treatment for a sufficient length of time are unanimous in their approval, and I am convinced that it marks a distinct advance in aural therapy.

I am indebted to Drs. S. H. Brown and J. L. Galbraith for aid in the treatment of many of these cases and for tabulating the results.

## VITAL STATISTICS: A PLEA FOR ACTUARIAL ADMINISTRATION AND CONTROL OF THE GREAT RESOURCES OF PREVENTIVE MEDICINE.

BY

JOHN S. FULTON, M.D.,  
of Baltimore, Md.

In the arts and sciences it is commonly observed that men's failures are oftenest traceable, not to want of knowledge or experience, or of ingenuity or logic, but to imperfect mastery of five-finger exercises. A sort of drunkenness which we call "enthusiasm" inflates us with a scorn of 'prentice tasks and with the conceit that we may go ahead *per saltum*. Consumed with haste to be master workmen, we acquire a wealth of implements and abandon the education of our thumbs. When the too obedient tools bring us to derision, we are driven back to the finger drill that will make one a craftsman probably, and at length a master, perhaps. This propensity to neglect the mechanical adjustment of one's self to one's materials, and to be supplied with every sort of unthinking machinery, particularly afflicts the modern practice of preventive medicine.

Preventive medicine has, within a generation, acquired territory from every adjacent science. Craftsmen possessing special and peculiar training have entered the service of hygiene, bringing the queer tools and unfamiliar methods of small provinces in science, speaking the provincial dialects, not understanding each other, not well enough understood to be assigned definite metes and bounds within a new environment. The offerings are valuable, but their profusion is bewildering. Another generation may pass before the serviceable energies of the chemists, physiologists, bacteriologists, geologists, meteorologists, engineers, economists, architects, sociologists, entomologists, and actuaries are safely geared to the machinery of public hygiene. Among these new forces some are strong enough to run the whole machine, and that possibly not to smash. The commissioned officers of hygiene are so much impressed with the performances of some of these specialists as to have forgotten, apparently, that the theory and practice of hygiene rest upon an older science, which in some form or other is fundamental to every other science, and that the several underpinnings must be compacted into a solid foundation upon which the complex and ponderous machine can be made to run steadily.

Public hygiene is built upon, is controlled and directed by, and is everlastingly in debt to vital statistics. The might and the right to direct the future of preventive medicine, to make and to terminate contracts, to approve and reject risks, to test materials and methods, to invest means and to distribute profits, these things belong inalienably to vital statistics. Every wheel that turns in the service of public health must be belted to this shaft, otherwise preventive medicine must remain invertebrate and unable to realize the profits available from the magnificent offerings of collateral sciences. If the unborn historian of hygiene in the twentieth century shall find one anomaly more curious than any other, it will be that the twentieth century, opening with prodigious resources, immediately available, ran a third or half its course before these resources became so standardized that each unit of power might be accounted for in a definite scheme of vital statistics.

It is for the immediate articulation of the statistics of public hygiene that this paper pleads, and against the misuse of such statistics as we have that protest is made. The situation is not absolutely bad. Indeed, we might congratulate ourselves upon progress, if the statistic spine of preventive medicine were not so far outgrown by other parts of the organism.

## THE FEDERAL CENSUS.

The foundation of vital statistics rests upon the federal census, which we seem to have agreed shall be taken once in 10 years. A decennial enumeration of the population, properly made, skilfully analyzed, and promptly published, will suffice for the primary needs of sanitarians. The establish-

ment of the United States Census Bureau on a permanent footing will enable the medical profession to impress with some effect the importance of certain reforms which have hitherto been asked in vain, and there is ground for hope that the particular information needed by hygienists will in future be better collected and better presented.

However satisfactory the census reports may have been to those who had most influence in formulating the details of the work, never a census has furnished the data most desired by sanitarians. Medical statistics were not attempted until 1850, and not once since that time has a crude deathrate for the country been determined. The Census Office determines the population of the country as nearly as possible on a given day, usually in June (*i. e.*, the number of the survivors of the census year); but does not determine the mean population for the year ending on the assumed date of the census, and this mean population is the true number of those who furnished the mortality up to the last day of June in that year. This gives too large a divisor. The dividend, on the other hand, has always been too small, representing in large part the results of the enumerators' efforts to collect the data concerning deaths for a year by inquiry among the living at the end of the year. We have, therefore, no statistics comparable with the statistics of other countries. But, what is worse, we are unable to make comparisons between separate areas in our own country at the same period, or even to compare the data of different periods for the same area.

The census officials have not been blind to the futility of the enumeration method of collecting death returns in non-registration areas. On the contrary, in the reports of the Tenth and Eleventh Census the results are repeatedly criticised by Dr. Billings, as indicating not the mortality rates, but the more or less defectiveness of enumerators' returns.

The blunder was nevertheless repeated in the Twelfth Census, and that against the protest of a great majority of the registration officers of the country. A committee of the American Public Health Association strongly urged upon Congress an amendment to the last Census bill, giving the Director of the Census discretionary power to make records of all deaths occurring within representative areas of nonregistration States for a period of one year, and to apply the derived ratios of these data to the entire population of the States so handled. In this way complete and satisfactory records of all deaths, within a measured period and in a space of representative constitution, might have been made by competent observers at the time and place of their occurrence. With fresh and exact data, all the rates computed for the registered portion of a State would have been trustworthy, and when applied to the whole State would have given approximately true figures. This amendment, if utilized as the language of the amendment permitted, merely in a tentative way, being operated in selected portions of but one or two nonregistration States, would have served as a check upon the work of the enumerators, and, coming into comparison with the older practice, would have allowed a reliable judgment of its own merits.

But when the amendment was under consideration no participant in the earlier errors was at hand to plead for better methods. The Census Office was for the twelfth time to be organized *de novo*, and although the humble confessions of previous failures were quoted in the memorial which accompanied the amendment, the National Legislature, taking no counsel of its own commercial wisdom, rejected the advice of the sanitary bookkeepers. The data of the Twelfth Census are therefore no more applicable to the work of public hygiene in the nonregistration States than those of the Eleventh Census.

For the "registration area" of the Twelfth Census the statistics may be accepted as fairly approximate, but the population is excessively urban, and includes so many new cities that the group as a whole cannot be taken as representative of the population of the country. The Census Office divides the registration States into two groups, those whose returns of deaths, being collected under stringent laws, may be accepted without further inquiry, and those whose returns, when compared with the enumerators' returns, show more or less incompleteness. Of this latter class those whose returns, when compared with the enumerators' returns, show a difference not exceeding 10%, are

taken into the statistic account, and with the first class constitute the "registration area," which the Census Office utilizes for the purposes of comparing the results of the Twelfth with those of the Eleventh Census.

The Eleventh Census determined its "registration area" upon a looser standard. Its list of States included Massachusetts, Connecticut, New Hampshire, Vermont, Rhode Island, New York, New Jersey, Delaware, and District of Columbia, and to these were added 83 cities outside those States, giving in all a registration population of 19,650,440. Delaware is very properly excluded from the "registration area" of the Twelfth Census, and Maine and Michigan are added to the list, together with 153 cities of 8,000 or more population in other States, giving in all a registered population of 28,807,269.

In but four of these States was registration found to be complete enough in 1900 to allow the enumerators' schedules to be withdrawn and local returns to be substituted therefor. These four States were Massachusetts, Connecticut, Rhode Island and New Hampshire.

In New York, New Jersey, Maine, Michigan and the District of Columbia it was found that 20% of the enumerators' returns were of deaths not registered in the locality. Admitting, for the moment only, that the local registration could be safely amplified by the enumerators' returns, it must be clear that the enumerators' returns are subject to two undetermined discounts, one for errors of total omission, and the other for errors as to the time of death. Enumeration experience in 1890 was carefully tested, and the deficiency on account of records wholly missed amounted to 30%. The Census Office in 1890 hinted at an even greater deficiency. Of the discount for error in time nothing is known except that it is greatest in the earlier months. The statements of those interrogated concerning the occurrences of exactly a year past are at best inaccurate, and when the inquiry extends from June to June, so including parts of two calendar years, considerable error must result. Perhaps the registration in these ten States was better than the Census Office was led to believe. Certainly the registration of the four New England States was reliable, and if these returns were applied to a correct population for the period of their occurrence the rates would be useful.

But in 1890 there were not four New England States whose returns were complete. Registration in Connecticut, New Hampshire and Rhode Island was in 1890 no better than in New York and New Jersey in 1900. The populations of these several States are, however, fairly homogeneous, do constitute the best registration area which the country affords, and deserve a separate statistic treatment which the federal census does not give.

By including in the registration population 183 "registration" cities in nonregistration States the statistic results are distinctly vitiated. Among these "registration" cities are many whose populations are of abnormal age, race, and sex constitutions, and some whose records are subject to a sort of vicious manipulation which will presently be considered.

The death returns made by the health departments of the cities in nonregistration States are said to be "corrected" by the enumerators' returns. This simply means that the local official returns are amplified by the number of those enumerators' records which are not found in the local official returns. Before the Twelfth Census no offer of copies of those excess returns was made to local officials, although such copies would have been of service to the local officers. If they were found correct, the sources of failure in the local registration might have been discovered, while, if found incorrect, the errors in enumerators' returns would have been exposed. The excess enumerators' records of the Twelfth Census were offered to the local registrars, but upon condition that no prosecutions at law should be based upon them, and that they should be paid for at the rate of two cents each. It would seem clear that a verification of these unregistered deaths was of no less interest to the Census Office than to the local registrars, and a free tender of the list would have been fairly compensated by a report upon the results of investigation by the local registrars. The local registrars to whom the census offered these bargain-counter remnants were of two classes: those who preferred that the matter should remain in doubt, and therefore did not want the

lists, and those who did not want the lists because they were quite sure that, except by the hazard of grave crime, no death within their districts could escape registration.

Eventually the Census Office concluded to offer the lists free of charge, and several hundred excess enumerators' returns were sent to my city in a nonregistration State. Their investigation is now in progress. Up to the present time it can only be said that the chief, if not exclusive, source of error is, as might have been expected, in the duplication of records. The enumerators' records have been easily identified as more or less erroneous returns of registered deaths, whose true data, copied from the official records made at the time and place of the events, had been sent to the Census Office. In this way one death entered twice into the census enumeration, figuring once perhaps in each of two disease columns, or of two age columns, or month columns, or once in a residence and once in a hospital.

There are "registration" cities where certain deaths are thrown out of the list because there are plausible reasons why they should not be counted (*e. g.*, deaths of nonresidents), and certain other deaths are excluded from the city registry for reasons just as plausible (*e. g.*, extrarban deaths of citizens); where the control of the deathrate lies partly in the count, but chiefly in the discount. The returns of these cities really needed the enumerators' correction.

In view of all the sources of error and of the nonrepresentative character of the several areas whose statistics are combined and compared, it savors somewhat of hardihood to offer the derived ratios as indices of profit in public health. We are told that in 1900, 341 "registration" cities of 8,000 and over gave a combined deathrate of 18.6 per 1,000, while in 1890, 271 "registration" cities gave a combined deathrate of 20 per 1,000, showing a gain of 2.4 per 1,000, or 11% in 10 years. The average age at death in 1890, we are informed, was 31.1 years, while in 1900 the deaths in the total population of 28,807,269 included in the 10 "registration" States and 153 "registration" cities in nonregistration States, occurred at the average age of 35.2 years. The alleged 12% increase in the duration of human life is offered for our admiration. To mistake the average age at death as indicating the mean duration of life is a common error of the uninitiated, but no self-respecting expert can afford to wink at such a blunder, for it rests upon the assumption that populations are, in a qualitative sense, fixed or stable, while it is an elementary principle of vital statistics that populations are unstable, and that all determinable variations must be taken into account. The qualitative variations of population, even in a country as old as Great Britain, are so wide that Chadwick was able to make the generalization that in healthy districts the mean age of the living is, as a rule, less than the average age at death, while in unhealthy districts the reverse is the case. As an extreme instance of the variations found in practical experience, one may cite the observation of Rumsey, who found in London in the fifties a deathrate of 24 per 1,000, an average age at death of 29 years, an average age of the living 26 years, and an average expectation of life reaching to 37 years, all in the same population at the same time. What, then, shall be said of the ratios derived from the incoherent heterogeneous data of the Twelfth Census? The crudest two-factor rates of an unschooled registrar are not so crude.

All this is not, however, to be imputed to the Census Office for sin. The failures were for the most part inevitable in the nature of the case, and they are exhibited here not so much for reproof as for exhortation. The difficulties of enumeration by the federal Census Office of deaths in nonregistration areas were and ever will be insuperable. Enumerators' data should be tabulated and displayed without any correction by local returns, and so brought into amazing contrast with that one nineteenth part of the Union whose death records are collected by local officials day by day, year in, year out.

The Census Office now maintains a continuous organization for purposes more numerous and complex than were formerly contemplated. The first census was a political necessity in order to apportion the congressional representation of the several States, and while the value of vital statistics has been somewhat neglected in the development of the incidental advantages of a federal census, there is now good reason to

believe that this subject will receive adequate treatment. The vital conditions of large areas will perhaps for some decades have to be investigated by the Census Office through its own agents and without the aid of local official registration. The discredited enumeration method was confessedly as disappointing to the statisticians of the Twelfth Census as it was to those of the Tenth and Eleventh, so that we may expect some plan to be devised, and perhaps perfected in the intercensal period, whereby the vital conditions of nonregistration areas may be approximately determined. It would seem that the registration data of some part or the whole of the District of Columbia could be utilized for comparison with the data obtained by census officers in some comparable area in one of the contiguous nonregistration States.

For quite reliable results we must wait upon the will of the people to record for themselves the vital statistics of their several sovereign States, and the Census Office has, as we shall see presently, joined heartily in a movement to extend the practice of local registration.

#### STATE REGISTRATION OF DEATHS.

To one who realizes how great a structure of practical hygiene is delayed for want of a suitable foundation in vital statistics, the growth of the practice of registration seems dismal. But the registration idea has in fact spread rather rapidly. In 1880 real registration under operative laws was practised in Massachusetts, New Jersey, the District of Columbia, and in 19 cities in nonregistration States. In 1890 the practice of registration had extended to five more States, and the number of registration cities in nonregistration States had risen to 83. In 1900 there was some sort of registration of deaths in 37 States, and in 16 of them the registration was as good as it was in the nine States accredited by the Eleventh Census as registration States.

But the registration idea has not produced similar or comparable results in all of the States where it has taken root. Indeed the spread of registration has brought into painful prominence the greatest diversity both of methods and results. The hopeless process of an annual census of deaths is yet in use in five States, and the results range from tolerably poor in Vermont to wholly worthless in Kansas. The great States of Pennsylvania and Ohio are in this class. In 28 States physicians, or other persons acquainted with the facts, are "required" to make returns of all deaths within periods of from 24 hours to a year after their occurrence, but these "requirements" are practically inoperative in about 20 of these States. Fifteen States have discovered that the burial permit will insure registration at the time and place of death, but of these 15 we must count off eight as having failed to insure the burial permit. Of the remaining seven, Indiana insures the application for a permit to bury by authorizing the State Board of Health to disinter and interrogate the corpse. This resurrection feature is entirely novel in the practice of registration, but it is said to have made Indiana a registration State, without having caused an uprising of the silent majority. The States whose burial permit laws are effective are no more than seven.

Diversity of practice appears also in placing the official responsibilities. Local (county or township) registration officers may be county clerks, health officers, auditors, assessors, recorders of deeds, or Orphans' Court officials. State registration is centralized sometimes in the State Board of Health, again in the Department of State. No sort of uniformity appears in the publication or tabulation of vital statistics, and the blanks and other printed forms employed are of almost infinite variety as to size, arrangement and contents.

The idea of permanent preservation of the records has not been strongly impressed upon the official mind except in one or two States where ancient records are now either wholly lost or under process of restoration at great expense.

A strong movement has been made against all this neglect and incongruity, and in respect at least of a definite scheme of classification of causes of death, notable advance has been made. A number of experienced registration officials with the aid of expert statisticians and hygienists undertook in 1897 to bring about a general agreement among American registration offices to employ the Bertillon classification of diseases and causes of

death for statistical purposes. The claim was never made that this classification meets exactly the requirements of modern pathology or that its intrinsic merits for any other than statistical uses are surpassing. The Bertillon scheme had, however, at the time a good prospect of receiving international recognition, having been planned with this in view, and its general adoption in this country offered the best prospect of securing a practical basis of comparable statistics. The subject was effectively presented at successive meetings of the Conference of State and Provincial Boards of Health, the American Public Health Association, and the American Medical Association, and its adoption by registration areas, new and old, followed. This movement received a further impetus at the International Medical Congress at Paris in 1900, when the Bertillon classification was revised by a committee including members from all parts of the world, and was approved by the congress as a practical international classification for statistical purposes. The United States Marine-Hospital Service published and distributed a good translation of the scheme. The Director of the Twelfth Census adopted the scheme, and with the establishment of a permanent Census Office the Bertillon classification became the authorized plan of accounting in American vital statistics.

As contributing toward the extension of the practice of registration to new areas, and toward needed reform in States where registration is more or less defective, the Census Office has printed and distributed a circular on the subject ("Vital Statistics, No. 71"). The opening words of this circular are significant: "The Census Office is primarily interested in the registration of deaths because the data required for the mortality statistics can only be obtained in complete and reliable shape where deaths are recorded *immediately after their occurrence*, under compulsory registration laws. It is impossible to secure a complete record of deaths *in any other manner*."

The important part of the circular is a paper prepared by the Committee on Demography and Statistics of the American Public Health Association, and the title of this paper is "The Essential Requirements of a Law for the Registration of Deaths and the Collection of Mortality Statistics." This brief and well considered document states in logical order the several features which are absolutely essential to a working law, eight in number, as follows:

1. Deaths must be registered immediately after their occurrence.
2. Certificates of death should be required.
3. Burial or removal permits are essential to the enforcement of the law.
4. Efficient local registrars are necessary.
5. The responsibility for reporting deaths to the local registrar must be fixed.
6. The central registration office should have full control of the local machinery, and its rules should have the effect of law.
7. The transmission and preservation of the records should be provided for.
8. Penalties should be provided.

Barely two pages are devoted to the statement and explanation of these eight points. Where experience has approved more than one method of accomplishing an essential result the alternative procedures are clearly described. This brief document is, as it professes to be, an authoritative guide, and any competent attorney should be able with its aid to formulate an effective law for the registration of deaths in a State where the subject is wholly new. The appendix to this interesting circular shows again good results of consultation and cooperation between federal and local statisticians. It describes a standard certificate of death, which provides for all the data essential to the work of the Census Office and to the private and local uses of such records.

Among the other evidences that the Census Office has now a definite grasp of this important subject, one should mention the "Manual of International Classification of Causes of Death," published in November, 1902. No such handbook has heretofore been available to American registrars, and it will at once take rank as indispensable. Its contents deserve extended notice, but we can only allude here to its double index to the classification of causes of death as returned in the census of 1900. Very many of the perplexities encountered by registrars in the assignment of a statistical value to medical certificates can be solved by refer-

ence to this book. To the perfection of this manual every registrar should contribute, for it is beyond the power of one man to make a complete concordance of the medical terms used in death certificates.

The question of State registration was brought up in the House of Representatives on April 23, 1902, by Mr. Russell, who introduced a joint resolution calling upon State authorities to cooperate with the Census Office in securing a uniform system of death registration. On the principle of one thing at a time and that done well, this resolution spoke of the registration of deaths only. The resolution was referred to the Select Committee on the Census, and was returned with a favorable report, but amended so as to include the registration of births. It therefore appears that the statistics of life and death have at last reached equal rank with the statistics of coal and cotton in the esteem of the National Legislature.

We have said so much about State registration because the subject is most inadequately treated in State laws, and because it is useless to hope that the practice of registration of deaths can be brought to anything like uniformity, or can fully serve the uses of preventive medicine, until all the people are brought within its scope. Some of our best registration States leave sparsely settled areas out of the account.

Naturally the value of registration is most appreciated in dense communities, and it is quite possible that the general practice of registration in cities has delayed the adoption of effective State laws applicable to rural populations. In such States as New York and Pennsylvania, where the great majority of the people live under local registration laws, the need of registration in rural and suburban districts seems perhaps not imperative, and besides there are practical difficulties in organizing a central registration office safely adjusted to a multitude of independent local offices. With the rapid growth of cities the relations of municipal sanitation to the hygiene of suburban and rural districts is coming more and more into view, and chiefly in respect to food and drink these relations are vital. Municipalities are everywhere clamoring against the villagers and rustics who abuse the watersheds, flavor the cabbage, lettuce, and celery with night-soil, ship infected milk to town, and sell the wornout cow to the city butcher. It is time that urban influences should combine to compel a strict and systematic accounting of deaths and the causes of death in the rural districts.

[To be continued.]

**Hospitals for Insane.**—The State Charities Aid Association, which is required by law in the State of New York to make an annual report to the State Commission in Lunacy relative to the condition of the State hospitals for the insane, have made their report, and advise that the present State Commission, which with the Governor has charge of the insane institutions of the State, be set aside, and that local boards be substituted, as was the condition formerly. They take up carefully the reasons given by the Governor for signing the bill which is now in legal operation. Most of them were for fraud, extravagance, etc., on the part of the old local boards. They charge as follows: Upon a careful study of these instances it was found that 18 of the 23 were based on a misunderstanding of the facts, such as attributing to boards of managers expenditures for which the Commission in Lunacy was responsible, and alleging extravagance in the case of expenditures which had been made in the interest of economy, and had resulted in a financial saving; and that 4 out of the 5 cases that could be substantiated had occurred previous to the establishment of the system which it was proposed to overthrow, and would have been impossible under that system. The only case which could be substantiated, occurring under the system which was to be supplanted, was one of alleged bribery, in which a manager and a treasurer of one of the State hospitals were implicated. Even in this instance, however, it would seem as if there must have been some error, for the Governor has since appointed one of the accused persons as a member of the new Board of Visitation for the hospital in question. Serious fault is found with the present condition, which permits the Commission of Lunacy to name the stewards for each of the State hospitals. The steward is a subordinate officer, and according to law performs his duties under the direction of the superintendent, by whom he was formerly appointed. The fact that he is now appointed by the Commission causes friction between him and his superintendent, to whom he feels no especial responsibility. A change to the former method of appointment is urgently recommended.

10. Preliminary Note on an Experimental Research into the Means of Controlling the Blood-pressure. GEORGE W. CRILE.

**1.—Surgery of the Stomach.**—Bevan holds that operations for carcinoma should be limited to such cases as permit of apparent entire removal of the disease, and also to a few well-selected cases in which gastroenterostomy promises relief. Radical removal produces in a small percent of cases entire cure. Complete gastrectomy is still in the experimental stage. Cases in which jejunostomy is preferable to morphin and rectal feeding are extremely rare. Gastrostomy is seldom worth while. For ulcer gastroenterostomy gives a small mortality and usually a permanent cure. Experience proves it superior to excision. It is the operation of choice in pyloric obstruction, hemorrhage and perforation. In hour-glass contraction, gastro-anastomosis is indicated. He describes the technic of operative procedure and after-treatment, and pleads for wider application of surgery in gastric lesions. In benign disease, results have been brilliant.

**4, 5.**—See *American Medicine*, Vol. III, No. 24, p. 990.

**6.**—See *American Medicine*, Vol. III, No. 25, p. 1048.

**7.**—See *American Medicine*, Vol. III, No. 25, p. 1039.

**8.—Venereal Prophylaxis.**—Weiss believes that prostitution, the main source of venereal disease, cannot be suppressed during the present moral evolution of the race. Reglementation is impracticable here on constitutional grounds, and because of its limited hygienic value. Moral efforts and sanitary measures are promising of results. The latter can step in only after infection has occurred, and require a liberal supply of hospitals and dispensaries for free treatment and sterilizing of sources of contagion. Individual prophylaxis by means of applications of silver and mercury is at present the only feasible means of preventing in part the spread of venereal disease. We should have a national meeting similar to the International Conference for the Prophylaxis of Venereal Disease. [H.M.]

**9.**—See *American Medicine*, Vol. III, No. 25, p. 1057.

**10.—Means of Controlling Blood-pressure.**—Crile points out the defects and limitations of strychnin, alcohol, nitro-glycerin, digitalis, and saline solution. Uniform pressure on limbs and trunk by means of a pneumatic rubber suit gives a definite control of blood-pressure of from 25 to 40 mm. Patients may be placed in any position during operations because the blood flows back to the heart regardless of posture. Adrenalin chlorid acts on heart and vessels but not on the vasomotor center. It must be used carefully in great dilution with saline solution, usually 1 to 50,000. In large doses it may overstimulate the inhibitory mechanism of the heart. This may be prevented by atropin. Its effects may be obtained after death. [H.M.]

**1.**—See *American Medicine*, Vol. III, No. 25, p. 1048.

2, 3.—See *American Medicine*, Vol. III, No. 25, p. 1049.

4.—**Conservatism in Acute Mastoiditis.**—Acute inflammation of the mastoid cells practically always comes from extension from the middle ear, and this extension does not follow if free drainage is obtained early, hence Snow believes the first indication is to incise the drum-head promptly and freely, and the second is to keep inflammatory action and pus development within bounds by cold or heat. The knife should enter near the lower margin in the posterior half, carrying it well through to the inner wall, up and out through the attic to bone tissue, cutting then deeply out along the posterior superior wall of the external canal. The latter portion of the incision not only drains the attic, but relieves the periosteal tension where most needed, the lower wall of the mastoid antrum. Unless unmistakable improvement is noted within 24 to 36 hours the securing of better drainage is imperative. Sufficient nurses, giving faithful care, are essential, as free drainage must be secured and the ice-bags changed in less than every five minutes. Intense heat may be as constantly applied, but Snow prefers cold. He believes that if the work and nursing are thoroughly carried out, over 50% of the external operations can be avoided, and there are too many cerebral complications following the latter to warrant taking unnecessary risks. In support of the conservative position he can report 45 cases so treated, each of which presented the indications usually laid down for external operation. [H.M.]

5.—See *American Medicine*, Vol. III, No. 24, p. 992.

6.—See *American Medicine*, Vol. III, No. 25, p. 1058.

7.—See *American Medicine*, Vol. III, No. 25, p. 1061.

8.—**Therapy of Orthopedic Surgery.**—Shaffer believes this branch of surgery will develop along conservative, not operative lines. In its present stage it represents, especially from a mechanical standpoint, inspiration rather than study and research. The scientific method, as it is used by ophthalmologists, for instance, must be adopted to describe certain deformities, not only for permanent record, but to meet the intelligent comprehension of the profession. There is a tendency to cultivate the surgical at the expense of the mechanical. Medical colleges should be equipped with a completely appointed mechanical laboratory. [H.M.]

9.—**Primary Carcinoma of the Nasal Chambers.**—Darnall reports a case, the seventy-ninth on record. The prognosis is decidedly unfavorable. The average duration is about a year and a half, his own case living only seven months. Unless reasonably sure of being able to remove all diseased tissue, it is better not to attempt operation, for interference only accelerates the disease. [H.M.]

### Boston Medical and Surgical Journal.

January 29, 1903. [Vol. CXLVIII, No. 5.]

1. Chylous Ascites: Report of Case Due to Total Occlusion of the Thoracic Duct. PERLEY P. COMEY and WM. W. MCKIBBEN.
2. Lesions of Tibial Tubercle Occurring During Adolescence. ROBERT B. OSGOOD.
3. The Side-chain Theory. ADDISON S. THAYER.
4. The Open-air Treatment of Syphilis. E. H. DOUTY.

1.—**Chylous Ascites from Occlusion of the Thoracic Duct.**—Comey and McKibben report the case. A man of 61 who had been unusually healthy, was taken with a chill, severe pain in the right leg and groin, high fever, diffused pain and disturbed digestion. In a day or two the right leg began to swell, became reddened and edematous. The swelling ascended to the abdomen, chest and right arm. It resembled a general infection with cellulitis. The diagnosis was phlebitis. In a few days the constitutional symptoms disappeared and the patient was out of bed, the swelling persisting. On three occasions, some weeks apart, sudden symptoms of heart failure and collapse appeared. In each instance, save the last, the patient soon rallied and was up again. Four weeks before his death the patient was tapped for ascitic accumulation, about seven quarts of apparently pure chyle escaping. This continued to discharge to some extent until death. Necropsy showed the chylous fluid abundant in the abdomen and in the right pleural cavity, crowding the lung up into small space. The thoracic duct was

hard, thickened and indurated. Microscopic examinations at numerous levels showed the duct occluded by inflammatory exudate. This had caused the chylous ascites and death. The origin of the accumulation was apparently not suspected until chylous fluid was obtained by tapping. [A.B.C.]

2.—**Lesions of the Tibial Tubercle Occurring During Adolescence.**—Osgood gives a general discussion on these lesions, symptoms, prognosis, and treatment, and concludes as follows: The adolescent tibial tubercle, from its situation and mode of development, is susceptible to injuries, especially in athletic subjects. These lesions are usually caused by a violent contraction of the quadriceps extensor. Fracture and complete avulsions of the tubercle are rare, cause loss of function, and are easily diagnosed, usually clinically and always by means of the Röntgen ray. Avulsions of a small portion and partial separation of the tubercle are more common. They do not cause complete loss of function, but without treatment long continued serious annoyance. The diagnosis should be made by a combination of the clinical and Röntgen ray pictures, and before the latter are accepted as evidence both knees should be skiagraphed and accurate technic observed. [A.B.C.]

3.—**The Side-chain Theory.**—Thayer endeavors to present the theory of Ehrlich, explaining the technical terms employed for the benefit of the nonspecialist. He briefly discusses bacteriolysins, hemolysins, and agglutinins, and minimizing methods for the production of spermatotoxins, neurotoxins, and nephrotoxins. [H.M.]

4.—**The Open-air Treatment of Syphilis.**—Douty, after five years' observation of patients in the high Alpine altitudes, concludes that 30% of the men patients there who have pulmonary tuberculosis are syphilitic. He says other observers place the estimate at 50%. His firm conviction is if these men had had a course of open-air treatment and thorough feeding directly the syphilitic infection was recognized they would never have contracted tuberculosis. He observed during many years' practice at Cambridge, England, that the athletic, well-fed student living much in the open air suffered far less during an attack of syphilis than did the bookworm who lived much indoors and, as a rule, was poorly fed. In view of these and other observations, the author believes open-air treatment, extending over a period of one or two years if possible, should be urgently insisted upon by those having to do with the early treatment of syphilis. It is just as applicable here as in the treatment of tuberculosis. In each it rehabilitates the blood and increases the resisting power of the individual, and thus enables him to combat the systemic poison. [A.B.C.]

6. A Treatment for Spina Bifida, with the History of a Case. FREDERIC GRIFFITH.

1.—See abstract No. 4 present issue under *Boston Medical and Surgical Journal*.

2.—**Profound Deafness; Recovery.**—Roosa reports a case following a large dose of quinin. The diagnosis at first was congestion of the acoustic nerve and the treatment calomel and blisters, followed by mercury, iodid of potassium, and pilocarpin. Since these failed to improve hearing the diagnosis was changed to anemia, and strychnin and alcohol administered with sufficient improvement in one ear to allow ordinary conversation to be heard. Ten years later after several recurrences of deafness in the better ear the patient was again placed on strychnin and Russell's emulsion with complete recovery of hearing in both ears, which has continued from 1898 until now. [H.M.]

**3.—Dermatitis from Röntgen Light.**—Beck is of opinion that Röntgen-light idiosyncrasy exists, analogous to iodoform idiosyncrasy. For diagnostic purposes the exposure should be as short as is consistent with securing a good skiagraph. Fortunately, the longest exposure for the pelvis does not now, with the aid of the Wehnelt interrupter, require more than 10 minutes' exposure, and this will be tolerated even by susceptible individuals. Protection for diagnostic purposes should not be resorted to since it defeats the purpose of the exposure. Only when the rays are used for therapeutic purposes does the possibility of susceptibility merit attention; and here the degree of penetration, the question of protection and the distance of the tube from the surface treated all demand careful consideration. For instance, in treating a hairy or other benign growth on the face very carefully regulated tentative exposures should be made before resort is had to longer exposures, and the unaffected surrounding surface should be protected by a shield. Since Volkmann and Heidenhain long ago demonstrated the presence of cancer cells in the fascia overlying the great pectoral muscle, even when only small movable nodules exist in the breast, it is evident that no shield is desired in exposures for mammary cancer, for the beneficial effect is desired over a large surface. And since the influence is usually desired immediately the tentative process to determine idiosyncrasy is disregarded and full and lengthy exposures are instituted from the first. The author has little faith in any permanent good resulting from the treatment of deep-seated growths by Röntgen light. [A.B.C.]

**4.—Maritime Quarantine.**—Souchon reviews the Louisiana regulations whereby vessels avoid detention by disinfection at the last port touched with five days interval between this and a second disinfection at the quarantine station, the latter being necessary to neutralize the effect of a possible case following the first disinfection so light as to be unrecognized. National floating disinfecting plants would make it possible for vessels on long trips to be disinfected five days before reaching port so as not to be detained after the second disinfection. He also gives the special regulations for fruit vessels. [H.M.]

**5.—Solarization of the Nude Body After Administration of Iron.**—Bleyer briefly discusses the effect of actinic rays on iron salts outside the body, the study of which led to experimentation on 100 tuberculous and anemic patients with various inorganic and organic preparations. These after the administration of the iron preparation were placed in the rays of the sun or electric light arc. After a week the blood count showed an enormous increase over older methods of administration. Very favorable results were obtained with tropon, which caused the least digestive disturbance. A simple way to give iron with rapid showings is by sprinkling the powder or Blaud's mass on hard-boiled egg. [H.M.]

**6.—The Treatment of Spina Bifida.**—Griffith reports the case. The child was a female, and with this exception was fairly strong, healthy and vigorous. Tumor formation appeared directly after birth, and was of rapid growth. Excoriation, ulceration, and threatened rupture yielded to boric-acid ointment and cotton dressing. At three months the tumor extended from the last lumbar to the tenth dorsal vertebra. Small drops of clear fluid appeared on the surface of the apparently unbroken sac and indicated the necessity for prompt interference. Operation was done with the child in the exaggerated Trendelenburg position, achieved by its being placed on the back of a chair placed with legs in the air upon a table. The child's legs were secured to the chair-legs. The tumor was first tapped with trocar and cannula, and some six ounces of clear fluid removed. The small opening in the membranes was found, likewise the bony aperture, but the child's condition precluded any attempt at osteoplastic work. The sac was trimmed away and its base closed by sutures. It was put to rest in the Trendelenburg position, and reacted promptly. Though weak, it apparently did well until the fifth day, when the mother accidentally let it fall to the floor. The shock was great, and it died a few hours later. The author is of opinion that the absorptive power of the gauze dressing was detrimental by removing large quantities of cerebrospinal fluid, which but for the inclined position had resulted fatally. In another case a different dressing would be used. [A.B.C.]

## New York Medical Journal.

January 24, 1903. [VOL. LXXVII, No. 4.]

1. A Study of the Deaths Occurring in New York City on the Opposite Sides of Twenty Streets During the Year 1895. ALFRED E. THAYER.
2. Cases Illustrating Some of the Newer Points in the Surgery of the Day. ROBERT T. MORRIS.
3. Chronic Gastritis and Gastric Motor Insufficiency in Children. F. L. WACHENHEIM.
4. The Treatment of Nonparalytic Strabismus, Including a New Operative Procedure. J. H. WOODWARD.

**1.—A study of the deaths occurring in New York City on the opposite sides of 20 streets during the year 1895** has been made by Thayer with a view to determine if there was a difference in mortality on the north side of the streets as compared with the south side. The results show the mortality greater on the north side of any street in the district studied. The higher north mortality is due chiefly to pneumonia, pulmonary tuberculosis, and nephritis. The first two are especially fatal during cold weather, when the proper ventilation of living and sleeping-rooms is most likely to be neglected. He believes that the greater freedom on the south side from these causes is due chiefly to the advantages of sunlight and ventilation. Zymotic diseases appear to be independent of these conditions. [C.A.O.]

**2.—Cases illustrating some of the newer points in the surgery of the day** are reported by Morris. The first case is that of chondroma occurring in a woman of 24. The mass was attached to the upper part of the left humerus, and was about the size of a hen's egg. In such cases when there is doubt as to whether the growth is benign or malignant, Morris advises the removal of a segment and its diagnosis by frozen section on the spot that we may proceed in accordance with our findings. After the removal of the growth he closes the wound with a subcuticular suture of very small catgut, which will be absorbed in two or three days. Over the suture line he places a collodion gauze dressing. Sometimes instead of this he places a strip of Cargile membrane next the suture line. The second case is that of a man of 20 who had a lacerated wound extending the entire length of the forehead and nose. The wound was cleansed from dirt and treated with balsam of Peru and gauze packing for four days, at the end of which time the local hyperleukocytosis being presumably adequate to protect against infection, he trimmed the margins of the wound and closed as before. The third case was one in which he removed a gangrenous perforated appendix through an incision 1½ inches long, making no effort at thorough cleansing of the peritoneum, and closed the wound without drainage. Septic peritonitis was well under way at the time of operation. Apparently there was primary union, but 10 days later there was rise of temperature and evacuation of a subcutaneous collection of pus, which did not involve deeper structures. In this case he depended upon the leukocytes and a proper management of the lymph channels of the peritoneum for the result. Another case was that of ununited fracture of the tibia and fibula. The field of operation was prepared with a sulfid depilatory, which removes the hair in about five minutes and leaves the skin thoroughly aseptic at the same time, thus avoiding the more elaborate preparation. Morris has experimented gradually with this method of preparation, and he believes it as thorough as if hours had been expended in the preliminary work. [C.A.O.]

**3.—Chronic Gastritis and Gastric Motor Insufficiency.**—The article is based on the observation of children between the ages of 2 and 12 years. Wachenheim states that chronic gastritis is one of the commonest affections of childhood, and that motor insufficiency of the stomach is quite often associated with it, concurrently or secondarily. Every thorough examination includes the use of the stomach tube, comparison of the removed stomach contents being made with the record of recent ingesta. The outlines of the stomach may be defined by percussion before and after inflation with Seidlitz powder. The value of succussion must not be ignored, and care should be taken to determine the upper border of the organ to guard against being deceived by any displacements. Motor activity is best determined by inspecting the stomach contents for food remnants from the previous day. Chemical tests of the stomach contents should be made regularly for general acidity, free

acid, and peptones; in special cases the fatty acids and ferments may be the subjects of investigation. The large quantities of mucus especially characteristic of chronic gastritis require for its thorough removal repeated washings with a weak alkaline solution. Diet and lavage are of special importance in the treatment. HCl and a bitter tonic are also useful. In motor insufficiency nux vomica takes the front rank, acting as a general stimulant to peristalsis; it is well combined with bismuth and sodium bicarbonate to check fermentation, and magnesia to counteract the constipating tendency of these two. Illustrative cases are reported. [C.A.O.]

**4.—Nonparalytic Strabismus.**—Woodward believes that the many failures in the operative treatment of strabismus are due especially to the free division of the overacting muscle so universally practised. He says that tenotomy of a muscle diminishes its functional power, and after it the eyeball is no longer sustained in its normal position in the orbit, but projects forward to a greater or lesser degree. He details his method of operating by advancement of the antagonist, but says that the pull of the overacting muscle upon the sutures was always too great for security against failure. Recently he has tried to obviate that difficulty by stretching the overacting muscle, hoping to paralyze or weaken it temporarily. He believes this will prove to be a useful preliminary to advancement of the antagonist. [C.A.O.]

### Medical News.

January 31, 1903. [Vol. 82, No. 5.]

1. The Limitations of the X-ray in the Treatment of Malignant Tumors. WILLIAM B. COLEY.
2. A Plea for a Neurological Hospital in New York. L. PIERCE CLARK.
3. The Negro as a Criminal and His Influence on the White Race. LOUIS EDELMAN.
4. Affections of the Labyrinth Resulting From General and Organic Disease. THOMAS R. POOLEY.
5. Is Any Diseased Condition Necessarily Self-limited? EDWIN R. MAXSON.

**1.—Limitations of the Röntgen Rays in the Treatment of Malignant Tumors.**—Coley has treated 75 patients with malignant tumors by this method. All were inoperable, and many were recurrent after operation. Twenty-seven were sarcoma, and in five of these the tumor entirely disappeared after from 4 to 10 months' treatment, but in some metastatic recurrence took place; 9 cases showed great improvement, while the remaining 13 showed little or no improvement. Twenty-one cases were cancer of the breast; in 3 of these small recurrent nodules disappeared after a few weeks' treatment, but in each case they recurred; in no instance has he observed a large recurrent cancer of the breast disappear under Röntgen ray treatment, but in most cases there has been temporary improvement; in some instances the pain was increased, though generally it was lessened. Ten were cases of deep-seated intraabdominal tumors—2 of the rectum and sigmoid, 4 of the uterus, 1 of the bladder, 3 of intraabdominal sarcoma; 1 case of cancer of the cervix is apparently cured; 1 of the cases of sarcoma is apparently much improved, the other 2 are unimproved; 1 case of cancer of the sigmoid is apparently improved; the remaining cases of deep-seated growths are unimproved. Fifteen were carcinoma of the head, face and neck; the superficial epitheliomas showed the best result, but even here 7 to 10 months elapsed before the ulcers were healed; the 3 tongue cases showed no improvement. A case of advanced Hodgkin's disease has shown remarkable improvement—glands in the neck, axillas, and groin have nearly disappeared, and the splenic tumor has decreased in size two-thirds under four months' treatment. Coley says the field for the Röntgen rays is in cases of inoperable and recurrent growths, and even here further time and study are necessary to determine its true value. [A.B.C.]

**3.—The Negro as a Criminal.**—Edelman gives the statistics as to the comparative number of criminals in the white and negro race in various localities and attributes the greater percentage among the blacks to the effects of slavery, to ignorance and to environment. The best means of diminishing crime is a strong vagrancy law and a reformatory school for children. He suggests the purchase of a State farm so that whenever a man becomes idle and a figure in police circles he can be given an opportunity to go to work or leave the State. [H.M.]

**4.—Affections of the Labyrinth from General and Organic Disease.**—Pooley considers these principally from a clinical standpoint, with some reference to pathology. The auditory is oftener affected than any other sensory nerve. Cerebral hyperemia and anemia and ordinary meningitis seldom cause serious change. In hemorrhagic pachymeningitis with deafness, extravasations have been found between the fibers of the auditory nerve. Cerebrospinal meningitis is the most common cause of acquired deaf mutism. The postmortem appearances are swelling and hyperemia of the nerve trunk, with purulent matter around it and in the labyrinth, and in the latter extravasations of blood. Lesions of the cerebral vessels have caused degenerative changes in the labyrinth. In brain tumor complete deafness is rare. Atrophy of the nerve has occurred in several cases of ataxia. In grip disturbances of equilibrium occur rarely, sometimes followed by total deafness, due either to the specific organism reaching the labyrinth or to inflammation of the nerve. The latter is probably more often the case. In mumps the manner in which the ear is attacked still remains doubtful. When the labyrinth only is affected the disease may be on one or both sides, and is generally complete and incurable. It is likely the poison sets up plastic inflammation, followed by atrophy. In typhus, typhoid and variola cases of inner ear affection are recorded in the literature. Pooley believes the lesions which have been attributed to malaria are due to quinin. Syphilitic affections are due far oftener to the inherited than to acquired form, and in the latter they may be secondary or late tertiary manifestation. The prognosis is better in very recent acquired syphilis than in hereditary cases. In Bright's disease cases occur in which loss of hearing and albumin are the only symptoms present. [H.M.]

**5.—Is Any Diseased Condition Necessarily Self-limited?**—Maxson claims to have arrested typhoid fever by doses of sodium sulfocarbolate; 2 to 4 grains given every six hours with tincture of nux vomica, 2 or 3 minims, and cinchonidin in the interval. Patients seen early in the disease are allowed to stay out of bed during the day and to get about light business in a week. When not seen until intestinal ulceration threatens he applies wet cups to the back of the neck and sometimes a blister to the epigastrium. These patients are generally out in two weeks. He continues tonics and antiseptics for two weeks longer. In diphtheria, scarlatina, and rubeola antiseptic treatment has given as favorable results, the average duration of all contagious diseases being less than one-half that under other treatment. [H.M.]

### Philadelphia Medical Journal.

January 31, 1903. [Vol. xi, No. 5.]

1. Tropical Diseases. CHARLES E. KIEFFER.
2. Insanity Among Soldiers of the American Army in the Philippine Service. A. B. RICHARDSON.
3. The Relation of the Prefrontal Lobes to Mental Function. CHARLES W. BURR.
4. Case-book Record of 183 Operations on the Mastoid Bone. LEVI JAY HAMMOND.

**1.—Tropical Diseases.**—Kieffer considers the subject of acute dysentery, which he divides etiologically into endemic (amebic) dysentery, epidemic (bacillary) dysentery, and sporadic dysentery, each of which is detailed. The amebic and bacillary dysentery include about 95% of all cases. He has found *Bacillus pyocyaneus* a very important etiologic factor, and when the disease is caused by this germ there is a tendency for the extension of the disease into the ischioanal fossa and perirectal tissues, with the formation of extensive abscesses in these locations. In the treatment of acute tropical dysentery, absolute rest in bed is of the utmost importance. Ipecacuanha is the drug par excellence. To be of value, the drug must be administered in one large decided dose, and if possible without producing nausea, which is accomplished in the following manner: Nourishment of every description is withheld for 3 to 4 hours, 15 to 25 drops of tincture of opium are given, and a small sinipism applied to the epigastrium. A half hour subsequently, when the effect of the opium begins, 30 to 60 grains of powdered ipecac, stirred up in 1 to 2 ounces of water are administered. If the ipecac is vomited within an hour, it must be repeated, preferably as soon as the nausea sub-

sides. The remedies next in order are the salines. Local treatment is of little value in acute dysentery, the best results being obtained in the chronic variety. A golden rule in tropical practice in any fever that is not profoundly modified by quinin, properly exhibited in a reliable preparation, is not malaria. [F.C.H.]

**2.—Insanity Among Soldiers of the American Army in the Philippine Service.**—Richardson believes that the popular impression of the prevalence and unfavorable character of insanity among the soldiers of the Philippine army has been greatly exaggerated. Considering the character of the service and the climatic conditions, the percentage is very low. He shows that the character of the disease in nearly all cases is quite favorable. A series of 319 mental cases are detailed, and only one was diagnosed as paresis. [F.C.H.]

**3.—The Relation of the Prefrontal Lobes to Mental Function.**—Burr reports a case which, when studied in association with the large number of similar cases in the literature, adds evidence in favor of the view that the prefrontal region is in closer relation with mental processes than some other parts of the brain. This is not the same thing as to say that the prefrontal region is the center of mind; whether the left or the right lobe is of predominant importance is not yet decided. Disease in either may cause mental symptoms. [F.C.H.]

## CLINICAL MEDICINE

DAVID RIESMAN

A. O. J. KELLY

### EDITORIAL COMMENT

**Intravenous Injections of Formaldehyd in the Treatment of Puerperal Septicemia.**—Through the newspapers the country was recently apprised of the successful treatment of a case of puerperal septicemia at the Bellevue Hospital, New York City, with intravenous injections of a formaldehyd solution. The announcement naturally aroused a decided interest, and has been widely discussed in professional and lay circles. A good deal might be said as to the propriety of allowing such matters to appear in the lay press previous to their publication in the professional journals, but Dr. Barrows, who has used the treatment with such apparent success, has, we are glad to say, not lost much time in publishing his report in the proper place.<sup>1</sup> The treatment is based upon theoretic considerations and upon experiments made by Dr. Maguire, of London, and Professor Ewing, of Cornell University. The latter injected into his own veins dilute solutions of formaldehyd and found that, unless too strong, they produced no deleterious effects. The patient treated by Dr. Barrows was a negress, aged 26, admitted to the Bellevue Hospital with a temperature of 104°, a pulse-rate of 124, and a respiration-rate of 30. She was in labor, and there was a fetid, bloody discharge from the vagina. On the following morning she was delivered of a macerated, decomposed fetus of about six months' growth. After delivery the patient had a severe chill. The temperature rose to 105°. Despite irrigation of the uterus and curetment, symptoms of general sepsis supervened. Blood cultures showed the presence of the streptococcus. When seen by Dr. Barrows, the woman had a temperature of 108°; the pulse was from 150 to 160, and the respirations were 38. She received an intravenous infusion of 500 cc. of 1:5,000 aqueous solution of formalin. Within three hours her temperature had fallen to 105°; within six, to 101°. It rose again to 103°, and then rapidly dropped to 95°, the pulse being 86 and the respirations 22. Rising again to 103°, a second infusion of the same formalin solution, this time of 750 cc., was then given. The patient had a slight chill, but without further rise of temperature, which in the course of 12 hours fell to normal. Several blood cultures were made, but none after the first showed any streptococci; nor did any changes take place in the red blood-corpuscles. The woman is

now to all intents entirely well. The albuminuria that was present has disappeared; at no time was there any blood in the urine. Dr. Barrows warns against the indiscriminate use of the method when blood cultures have not been made. The treatment also presupposes the adoption of proper surgical measures. It is likewise suggested that normal salt solution be used for making the formalin solution, instead of distilled water, as in the case reported. We are aware of one case in this vicinity in which intravenous infusion of formalin solution was employed. The case was that of a tuberculous patient, apparently in extremis. After the injection of 300 cc. of a 1:5,000 formalin solution, marked improvement occurred. It is entirely too soon, however, to draw conclusions from these meager data, and considerable work will be necessary before we can pass from *post hoc* to *propter hoc* explanations.

**A Serum for Scarlet Fever.**—The cable is being kept busy reporting discoveries of cures for infectious diseases. Since the beginning of the year the discovery of a cure for leprosy has been proclaimed; Tizzoni has found a serum for pneumonia, and now Baginsky announces that Aronson, of Berlin, has succeeded in producing an antiscarlet fever serum. How this is made is not stated. Quite recently, after very patient study, Baginsky succeeded in isolating from scarlet fever a streptococcus—an organism the etiologic relation of which to the disease is very doubtful. There would seem to be, *a priori*, but little prospect of finding a curative serum before the real cause of the disease has been discovered. However, a positive opinion must be suspended until detailed reports have been received.

### REVIEW OF LITERATURE

**Acute Inflammation of the Pharyngeal Tonsil.**—Acute pharyngeal tonsillitis occurs as an accompaniment to catarrh of the neighboring mucous membrane. Beckmann<sup>1</sup> gives the symptoms of this condition and states that it occurs frequently both in adults and children. If the inflammation remains confined to the tonsil it may heal spontaneously and remain unnoticed, but on the other hand, it may pass on to a general infection. The inflammation often extends to the nearby sinuses and the deeper air passages. From experiments on the lower animals Beckmann concluded that this condition may be transmitted from person to person by means of the discharges. Fully 95% of the acute and chronic inflammations of the middle ear are due to pharyngeal tonsillitis. Swelling of this tonsil may close its lymph channels and thus cause the retention of detritus, which suppurates and develops into an abscess. Pharyngeal tonsillitis often accompanies rheumatism and the acute infectious diseases. The pharyngeal tonsil should always be removed when diseased, as it interferes with the treatment of all nasopharyngeal conditions. [W.E.R.]

**Syphilis in Glassblowers.**—Gailleton<sup>2</sup> considers this question from the viewpoints of prophylaxis and legal responsibility. Under the first are recommended covering of the instrument and sanitary visitation. The employer is responsible if a journeyman blower contracts syphilis from instruments with which he is obliged to work. The amount of damage depends not alone on the effects of the disease itself, but also on the duration of professional incapacity while the person is under treatment. Gailleton suggests that each owner of a factory keep a register of health to be signed by the employes, and that each one on leaving be given a certificate. [A.G.E.]

**Inoculation Tuberculosis.**—Lassar<sup>3</sup> has made investigations regarding the frequency of cutaneous tuberculosis through accidental inoculation in men connected with slaughterhouses and its percentage frequency in the general run of a large skin service. Of 365 men connected with the Berlin abattoirs he found 7 afflicted with tuberculosis of the skin, while three others had

<sup>1</sup> Berliner klinische Wochenschrift, December 15, 1902.

<sup>2</sup> Lyon Medical, December 7, 1902.

<sup>3</sup> Deutsche medicinische Wochenschrift, October 2, 1902.

<sup>1</sup> New York Medical Journal, January 31, 1903.

suspicious lesions. Of 108,000 patients afflicted with cutaneous diseases 34 presented tuberculous nodules; 4 of these were butchers. He believes danger of direct inoculation is very insignificant except in the case of individuals who work with tuberculous cattle. He does not excise these lesions, but after making the part bloodless burns them away with the thermo-cautery under local anesthesia. [E.L.]

**Venesection in Acute Nephritis.**—Marsden<sup>1</sup> briefly reviews the history of venesection. The two vital indications affecting all age periods are danger of asphyxia with overfilled right heart and overloading of the blood with chemic waste products of the body. These conditions are most typically met with in some cases of acute nephritis. If one remembers that bleeding is to be continued only so long as increased pressure in the venous system exists the risk of air entering can be avoided. The value of venesection is chiefly from the mechanical relief obtained, not from the withdrawal of the blood itself, since the alkaloidal poisons of uremia are in close combination with the tissues. If the balance of the circulation be restored after being disorganized for variable periods of time, it is readily conceivable that a return of suitable pressure in the renal vessels may initiate the recovery of the organ. Venesection, however, should not be adopted as routine treatment, but only when dilation of the right heart follows overstrain and failure of the left ventricle. [H.M.]

**A case of fulminating purpura** following scarlet fever (with necropsy) is reported by Biss.<sup>2</sup> [A.O.J.K.]

## GENERAL SURGERY

MARTIN B. TINKER

A. B. CRAIG

C. A. ORR

### EDITORIAL COMMENT

**Decortication of the Kidney.**—The question of operative treatment of chronic nephritis continues to attract considerable attention. Since Edebohl's<sup>3</sup> reported his series of eight cases of various forms of nephritis in which complete recovery followed decortication of the kidney, a number of other surgeons have undertaken the operation with more or less success, and clinical and experimental work has been done to determine the rationalé of the procedure. The results of operations thus far reported have been highly encouraging, but it seems unfortunate that so little care has been taken to study cases before operation. Experimental studies of decapsulated kidneys in animals have failed to show the reason why the operation does good. Albarran and Bernard<sup>4</sup> report that after stripping the fibrous capsule of the kidney in rabbits a rapid regeneration occurs. The capsule is completely reformed within two weeks after the operation, and at the end of two months it is as dense as the normal capsule. The cortex of the kidney itself shows microscopically superficial lesions, which are of slight importance. It is difficult from these experimental studies to see what favorable influence stripping the capsule can have, for the newly formed fibrous capsule is as resistant as the original capsule and is not more vascular. So early as 1899 experiments similar to these were undertaken by Dudley Tait, of San Francisco, in a series of studies of eversion of various organs, including the testicle, bursae, etc., and it was noticed that in two months after eversion of the kidney capsule a dense, adherent, fibrous mass surrounded the organ. At the November meeting of the California Academy of Medicine, Johnson reported a series of experimental studies which confirm in every respect the results obtained by Albarran and Bernard. Rovsing<sup>5</sup> reports a series of 17 operations with very careful examinations of the urine from separate kidneys chem-

ically, microscopically and bacteriologically, in every case. He believes that while there may be little difference in the chemical constituents of the urine or the appearance of the kidney in various forms of nephritis, those cases in which infections of the urine are found are likely to be benefited by operation, while such favorable results are not to be expected in the aseptic cases of nephritis. While up to this time we lack conclusive information, it seems likely that there is danger of surgical treatment of nephritis being carried to an extreme and that without some definite indications for operation can be discovered routine operation in these cases can hardly be considered justifiable. The present enthusiasm for operation in these cases is not unlike that which has been seen for other procedures, such as operations for tuberculous peritonitis, cirrhosis of the liver, etc., in which the rationalé could not be definitely determined.

### REVIEW OF LITERATURE

**Parenchymatous Gastric Hemorrhage.**—Moser<sup>1</sup> reports the case of a man of 41, who complained of abdominal pain, localized to right side of umbilicus, nausea, with copious vomiting, and hyperacidity for some time. A previous similar attack yielded to lavage, alkalies, and careful dieting. Hemoptemesis and melena were prominent symptoms during the present attack; they recurred almost daily, and exploratory laparotomy became necessary. Nothing of importance was found, and the operator performed a gastroenterostomy. Death resulted a few days later, the result of progressive asthenia. Necropsy showed hypertrophied gastric walls, especially the muscular coat, pale, slightly swollen mucous membrane, with four bleeding points near the pylorus; only one of these showed deficiency of epithelium. He discusses the causes of parenchymatous gastric hemorrhage at some length, and concludes that they were due to spasmodic pyloric stenosis, existing during life, and to chronic gastritis. [E.L.]

**A Double Gunshot Wound of the Left Ventricle; Suture and Recovery.**—Peyrot<sup>2</sup> reports the case of a man of 26 who had shot himself in the left breast with a small revolver ball. When seen 3½ hours after the accident no pulse could be felt. Over the entire left side there was hyperresonance, the respiratory sounds could not be heard, the heart sounds were feeble, and occasionally a murmur was noted. The operation revealed a perforated pleura, a pneumothorax, a perforated left lung, a bleeding pericardial wound near the apex, and a hemopericardium. The left ventricle was perforated anteriorly near the left border; this wound was sutured with catgut. The wound of exit on the posterior surface of the left ventricle near the auriculoventricular groove was sutured with more difficulty, as the cardiac contractions were violent. The myocardium received a superficial tear during the operation. Both pericardial and pleural sacs were drained. The operation lasted 35 minutes. Both drains were removed after 48 hours. Recovery was uneventful. [E.L.]

**Tincture of Green Soap for Disinfecting Instruments.**—To render instruments aseptic, Gerson<sup>3</sup> wraps them in cotton which has been soaked in tincture of green soap; thus clothed they are laid away until needed, when they are unwrapped and are ready for use without any further disinfecting. He has proved their asepsis by means of bacteriologic examinations. Asepsis is due to their being surrounded by a bacteria-proof coat. The advantages of this method are rapidity, simplicity, and ease with which sterility is effected; absolute and constant sterility; and instant availability. [E.L.]

**Exstrophy of the Bladder Following an Operation.**—Some weeks after the removal of an epithelioma of the urethra and neck of the bladder in a woman of 64, a small tumor appeared in the vestibule. It enlarged rapidly; at first reducible with the patient lying on her back, it later became irreducible. A tumor the size of a fist was found to consist of the entire inverted bladder protruding between the labia. The red

<sup>3</sup> Deutsche medicinische Wochenschrift, October 23, 1902.

and swollen mucous membrane, its transverse folds, and the ureteral openings were plainly visible; there was complete incontinence of urine. Pique<sup>1</sup> reduced the bladder through a median abdominal incision and attached it with six sutures to the anterior surface of the retroverted uterus. The uterus and bladder were then fastened to the abdominal wall. The condition was cured at once. [E.L.]

**Gonorrheal Urethritis in Male Children.**—Fischer<sup>2</sup> has been able to collect from the literature 69 cases of gonorrheal urethritis in male children and reports two occurring in his own practice. He gleaned the following facts from the study of these cases: Balanitis, balanoposthitis, and posterior urethritis is frequent and occurs very early in the disease; painful erections were never observed; strictures and rheumatic affections are rare, incontinence of urine is common. The symptoms at the onset are much more violent than in adults and its spread along the urethra is very rapid. The greater number of cases are due to accidental contact (not sexual) with individuals afflicted with the disease, though a large number, especially in big boys, is the result of attempted cohabitation. [E.L.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### REVIEW OF LITERATURE

**Mitral Stenosis Complicating Pregnancy.**—Wilkes<sup>3</sup> reports two cases of mitral stenosis ending fatally after the first parturition, illustrating the danger which attends this form of heart disease during gestation and labor. Patients who present symptoms of serious circulatory disturbance in the early months of pregnancy, or those who have with difficulty escaped a fatal issue from cardiac failure in a previous labor, should be given the benefit of induction rather than premature labor, as the latter, whether spontaneously or artificially induced, appears to be attended with as heavy a mortality as labor at term. Wilkes thinks women with serious mitral stenosis should, if they seek opinion on the subject, be advised not to marry. [w.k.]

**Treatment of Enuresis.**—Walko<sup>4</sup> reports a number of cases of idiopathic and symptomatic enuresis which were cured by practising bimanual massage, one finger in the rectum, the other hand over the symphysis; from three to five treatments were necessary to achieve this result. He considers enuresis in cases where the bladder is normal to be due to central inhibition, produced by accidental causes, and not to developmental disturbance or muscular weakness, as proved by the fact that suggestive methods of treatment, such as massage, cure the disease. [E.L.]

**Extirpation of the Septic Puerperal Uterus.**—Gradenwitz<sup>5</sup> quotes statistics from many surgeons, showing the extirpation of the septic puerperal uterus results in a mortality of about 50%. In 4 years (1898-1902), 113 cases of puerperal fever were treated in the Breslau hospital. In 26 of these the fever, caused by some affection of internal or external genitalia, decreased after brief symptomatic treatment with 3 deaths. In a second group of 23, in which the fever was evoked by a fresh perimetritic or parametritic postpartum abscess, the temperature sunk to normal with conservative operative treatment, involving no deaths. The third group of 26 suffered from putrid placental debris, the removal of which resulted in recovery with one exception. The remaining 38 cases were in an apparently hopeless condition when received, and of these 21 died. In only 7 of these was it deemed worth while to undertake the extirpation of the uterus, and of these 5 made complete recovery. In 4 of these there was a pronounced local infection, and in 1 the lymphatic form of pyemia. The 2 cases resulting in death were instances of pure septicemia without the presence of any local lesion or suppuration or swelling of lymphatics. [w.k.]

**Volvulus of the Small Intestine.**—In a patient of 25 Kirchmayr<sup>1</sup> observed two weeks after an abortion abdominal distention, nausea and vomiting, occasionally fecal, colicky attacks, and during these visible coils of small intestine, absence of flatus, but occasional passage of small masses of feces; a diagnosis of incomplete occlusion of the intestines was made, and this was confirmed by operation. The right tube had attached itself to the upper part of the free left border of the root of the mesentery; from this, corresponding to the two limbs of a Y, two cords had passed upward to be inserted into the omentum. As the uterus underwent involution the mesentery was pulled over to the right side of the pelvis, and the volvulus was begun. Some sudden traumatism made it complete, twisting it in such a way that the anterior surface of the mesentery looked backward, producing the obstruction. He discusses other cases with similar symptoms but less characteristic causal factors. [E.L.]

**Abdominal Hysterectomy for Uterine Fibroids.**—Bond<sup>2</sup> draws these lessons from his study of 50 cases of fibroid tumors: A history of prevailing sterility or frequent and repeated miscarriages; the disabling effect on the working capacity or enjoyment is due to pelvic pain and distress from pressure rather than to increased menstruation; the association of oöphoritis and cystic changes in the ovaries with tumor formation in the uterus; the frequency of degenerative changes especially in large tumors; and the invasion of the uterine walls by numerous small fibroids. In regard to treatment his conclusions are that the decision to operate must depend on danger to life and the amount of disablement, ill health, and suffering which are caused by the disease. The uterus can be safely amputated at any level, and the absence of recurrence of fibroid disease in the stump or cervical portion of the uterus is an argument in favor of cervical amputation as against panhysterectomy. In the former case, also, the pelvic floor is left intact. Myomectomy may be practised in cases of single and accessible tumors. In all cases where possible, one or both ovaries should be left in the operation of panhysterectomy for fibroid disease. The beneficial effect of the procedure is shown in the more complete convalescence and in the modified character of the artificial menopause. [w.k.]

**Küstner's Suprasympyseal Crucial Incision.**—Heil<sup>3</sup> warmly recommends Küstner's suprasympyseal crucial incision (transverse skin incision, vertical muscle, and peritoneal incision) in cases of ventrofixation. He says it offers the best cosmetic effect; it makes the wearing of an abdominal bandage unnecessary; it diminishes the danger of hernia. It can also be used with good results in cases of removal of tubes and ovaries. He avoids the formation of hematomas after the operation by the use of sandbags for from 24 to 36 hours after the operation. He reports his results in 12 cases of ventrofixation, which were perfectly satisfactory. In none of them had he to contend with the complication of hematoma formation. [E.L.]

**Tuboabdominal Pregnancy Unruptured at the End of Six Months.**—This case is reported by Gyselynek.<sup>4</sup> The patient was a woman of 36, who, after missing two menstrual periods, was seized with abdominal pain, metrorrhagia, vomiting and recurring syncope. After eight days these symptoms ceased, but recurred in three weeks. They then ceased for two months when they again recurred. Examination revealed a tumor in the right side of the pelvis and the diagnosis of extrauterine pregnancy was made. Section revealed a tumor the size of an adult head with adhesions to the intestines and meso-appendix. Total hysterectomy and appendicectomy were performed. Incision of the tumor showed it to contain a macerated fetus 31 cm. (8 inches) long, enclosed in amnion and chorion, and a placenta 14 cm. (5½ inches) in diameter. It sprang from the outer end of the right tube, both tubes and ovaries being normal. This case is classed as a tuboovarian pregnancy, the nutrition being supplied by excessively developed uteroovarian vessels and by vascular adhesions. [A.G.E.]

**TREATMENT**

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPELMAN

**REVIEW OF LITERATURE**

**Leprosy: the Treatment Recommended by Dr. Razlag.<sup>1</sup>**

—First of all, the baths are of great importance; I use cold or warm baths of fresh water; also seawater baths, and medicated baths, with iodine, tannic acid, permanganate potassium, liq. calcis sulf., just as the condition of the patient requires. As sudorific, generally jaborandi, or simply strong coffee or tea. Wounds: Chlorid or sulfate of zinc, hydrogen dioxide, ichthyol, chrysoarobin, arsenic, tannic acid, tr. ferri chlorid, iodine, ol. gynocardia odor., zinci oxid., creosote, croton oil, salicyl. acid, tr. iodine sozoidol, sodii, zinci and hydrargyri, permanganate potassium, strychnin, tar, etc. Dressing with plain absorbent cotton, sometimes with xeroform powder, but never iodoform. It is necessary in the treatment of wounds to make some combination of the above-mentioned drugs, especially in the use of ointments, for which purpose I generally prefer lanolin tar or glycerin. For the massage and friction of anesthetic skin, croton oil, strychnin sulf., chaulmoogra oil, in combination with ol. olive, and sometimes pure mucuna pruriens. The edema can be well reduced by leeches, and I strongly recommend the use of these to a large extent; but great care must be taken how and where to apply them. Internally, liq. pot. arsenitis, or arsenic pills in combination with strychnin and ichthyol; sodii salicyl., ol. jecoris aselli, guaiacol, creosote and sometimes airoil seem to produce more good effects than any other drug. I am well acquainted with the use of all the other drugs, as oils, ointments, and liquids used externally or internally, but finally came to the conclusion to keep on the above-mentioned treatment. Care must be taken that the wounds heal slowly, as a quick closing of ulcers, etc., produces generally again the appearance of nodula as well as edemas. The patients must expose themselves as much as possible to the air and be dressed only as much as will cover the body. It will be necessary to adopt in the beginning of the treatment exclusively my method, and nobody should be allowed to try any other treatment on the patients. It is necessary that every doctor shall get acquainted with this method of treatment if he attempts to treat lepers. It is also of great advantage to teach the improved lepers the treatment of wounds and bandaging, as they will thus, by helping the doctor, save a good deal of work. We must remember that no nation or race can be regarded as immune, and, apart from all theories, it is a fact that for everybody infection is dangerous. Hereditary leprosy counts no more than about one-eighth of the lepers; all the rest is a subjectively contracted disease. In the leper village, Fat Fung Yun, are 982 lepers, and of these there are only 106 cases of hereditary origin. A hereditary predisposition does not exist, as it is a clear fact that to such an infection a hereditary disposition is an empty theory and nonsense. In spite of what so many authors are writing about it, it is true that predisposition has a good deal to do with every kind of contagion or infection, but in this disease a hereditary predisposition is excluded.

**Thyroid Extract in the Treatment of Lipomas.**—Garand and Galland<sup>2</sup> report the case of a woman, aged 48, who for about 18 years had presented on the forearms a series of lipomas varying in size from that of a small pea to that of a peach. Under prolonged administration of thyroid extract these tumors disappeared almost entirely. During treatment it was necessary to combat symptoms of excessive dosage, such as tachycardia and diarrhea. Garand and Galland believe that this substance should be tried, not only in the treatment of multiple lipomas but also in large lipomas; since the local accumulation of fat is often associated with functional disturbances of the thyroid body. [L.F.A.]

**Ammonium and Rubidium Bromid in the Treatment of Epilepsy.**—Laufenauer<sup>3</sup> considers the double ammonium and rubidium bromid more sedative than the other bromids in the treatment of epilepsy. He has employed it in nearly all

forms of epilepsy. The average dose of 4 to 5 grains (60 to 80 grains) produces marked hypnotic and sedative effects when administered in the evening. The following formula may be used:

Ammonium and rubidium bromid . . . . .	6 grams (90 grains)
Syrup of lemon . . . . .	18 cc. (5 drams)
Distilled water . . . . .	100 cc. (3½ ounces)

Each tablespoonful contains 75 centigrams (11 grains) of the drug. [L.F.A.]

**Treatment of Syphilis by Hypodermic Injections of Mercury.**—Graves<sup>1</sup> reports four selected cases to illustrate the value of the hypodermic use of mercury, which has given him most satisfactory results. He uses a mixture made of equal parts of a 2% mercuric chlorid solution and a 2% sodium chlorid solution. Daily injections of 6 drops, or ½ grain, are given at first, the dose being increased and the intervening period lengthened according to the individual case. A larger dose than ¾ of a grain has never been used. [A.G.E.]

**Treatment of Convulsions of Unknown Origin.**—Périer<sup>2</sup> gives these directions: 1. Loosen the clothing around the neck, thorax, and abdomen, and place the patient on the back with the head slightly elevated. If constipation is present, an enema of oil, glycerin, and soap should be given. 2. If the patient has suffered from indigestion, vomiting may be provoked by tickling the uvula. This should be followed by a purgative enema. 3. At the same time a few drops of ether or chloroform may be inhaled, and the windows opened. 4. If the convulsion continues, a hot bath or a mustard bath should be given; the patient is then dried quickly and placed in bed. To prevent the return of the crises, the following solution may be used:

Ammonium bromid } Potassium bromid } Sodium bromid } Syrup of codein . . . . .	} of each 0.5 gram (7½ grains) 5.0 cc. (75 minims) 30 cc. (1 ounce) 100 cc. (3½ ounces)
Syrup of orange flowers . . . . .	
Lime juice . . . . .	
One teaspoonful every hour.	

5. The patient should not be left until the convulsion is entirely overcome, which is definitely determined only when the patient passes urine. [L.F.A.]

**Treatment of Lupus of the Face by Phototherapy.**—Lepeut<sup>3</sup> regards phototherapy as the treatment of choice for lupus of the face and exposed portions of the body, the beneficial effects being due to the inflammation and proliferation resulting from its application. The chemical rays also have a distinct bactericidal action. The treatment is painless, and results in the formation of smooth cicatrices. The proportion of cures produced by this means is greater than by any other method now employed. [L.F.A.]

**Gonorrhoeal Nonsuppurative Arthritis.**—Clere-Dandoy<sup>4</sup> emphasizes the value of urethrovessical irrigation with potassium permanganate solution in the diagnosis of obscure joint affections. In a great majority of cases of arthritis due to the gonococcus the above procedure will arrest the articular lesion. Patients deny having had syphilis, and will also deny the presence of gonorrhoea, acute or chronic. Hence the value of the treatment named. The writer uses very weak solutions of permanganate. [A.G.E.]

**Ointment for Fissured Nipples.**<sup>5</sup>—

Menthol . . . . .	1.5 grams (22 grains)
Salol . . . . .	2 grams (30 grains)
Olive oil . . . . .	2 grams (30 minims)
Wool fat . . . . .	.50 grams (12½ drams)

This may be applied twice daily. [L.F.A.]

**FORMULAS, ORIGINAL AND SELECTED.**

**For Pulmonary or Intestinal Hemorrhage.**—

Crystallized calcium chlorid, c. p. . . . .	15.5 gms. (4 dr.)
Codein sulfate or } Morphin sulfate } . . . . .	.06 gm. (1 gr.)
Essence of pepsin . . . . .	30 cc. (1 fl. oz.)
Distilled water, sufficient to make . . . . .	60 cc. (2 fl. oz.)

Mix. Dose: One teaspoonful in a little water every second or third hour. [S.S.C.]

## PATHOLOGY.

J. EDWIN SWEET

## EDITORIAL COMMENT

**The Etiology of Syphilis.**—The numerous descriptions of parasites, bacteria, etc., which are the cause of syphilis are the source of much interest and amusement to the profession, but their very number and various character have given rise to a spirit of extreme skepticism toward any new discovery whatsoever in the field of the etiology of syphilis. Among the latest discoveries is the bacillus of Joseph and Piorkowski,<sup>1</sup> who have been able, by a somewhat unusual procedure, to isolate an organism from the sperma of syphilitics. The culture medium is a fresh, sterile placenta. The bacillus can be transplanted from the placenta to agar, serum, and even gelatin. It is described as of the form of the diphtheria bacillus, and of the size of the subtilis; the placenta colonies are described as "dewdrop-like," on agar and gelatin the growth is like wax. The Gram test is positive. Joseph and Piorkowski report thirty-nine cases in which the infection had occurred from two months to five years previously, in which their bacillus was found. Fifteen cases in which the disease had been treated gave negative results. The bacillus was also found in syphilitic lesions of various nature and location. Control experiments with normal sperma on placentas gave, of course, negative results. Attempts to inoculate pigs were not successful. We are not in a position to speak with authority upon this "syphilis bacillus," but we trust that control researches will be immediately made by various able bacteriologists. We must confess, however, to a great degree of skepticism, for the results are too good to be true. It seems strange, too, that a bacillus of such size and present in such numbers in syphilitic lesions should have escaped the notice of the many able bacteriologists who have worked in this field. The proofs advanced by Joseph and Piorkowski would have been considered very satisfactory at one time in the history of medicine, but we have been led into false paths too often, and will await the further development of the new bacillus with great interest.

**Etiology and Pathology of Prostatic Enlargement.**—The monumental work of Ciechanowski, whose publication a few years ago produced a great change in our ideas concerning the etiology and pathology of enlarged prostate, is receiving the most general support. Greene and Brooke<sup>2</sup> have confirmed his result, and now Crandon,<sup>3</sup> in a very extensive and thorough study of the prostate, brings further support and adds observations of much value. He considers the senile vesical insufficiency, commonly referred to as "prostatism," to be not a single entity, but a complex condition. In this condition the chief exciting conditions are (1) atrophy of the bladder muscle and new growth of connective tissue infiltrating the muscles; (2) mechanical obstruction at the beginning of the urethra, which may be due to a posterior lip in front or a retroprostatic pouch, a true middle lobe, or an enlargement of one or both lateral lobes protruding into the urethra. Chronic cystitis intensifies these two causes. Stone in the bladder intensifies the condition, but is rarely a primary cause of insufficiency. Obstruction is more important than the atrophy of bladder muscle. The most marked causes are those with combined atrophy, connective tissue infiltration, enlarged prostate, and chronic cystitis. Fatty changes in the bladder muscle and arteriosclerosis of the vessels play no part in the condition. True prostatic enlargement is due to a chronic inflammatory condition occurring in the deepest portions of the prostate, midway between the periphery and the urethra. Here is found new connective tissue and con-

tracted scar tissue about the principal excretory canals of the gland. This contracting tissue compresses and occludes the lumina; the contained secretion cannot escape, and by its accumulation causes peripheral dilation of gland tubules. The peripheral dilation is more rapid and more marked the nearer to the exits the obstruction occurs. This dilation is the essential factor in producing the increase in the size of the gland; the newly formed connective tissue is unimportant, and the participation of muscle tissue (myoma) doubtful. In the same way atrophy of the prostate results when the new formation of connective tissue occurs at the periphery of the gland and compresses the blind ends of the tubules, the atrophy of which, combined with shrinking of the stroma, leads to the small prostate. As a result of his own observations and those of Itinger and Ciechanowski, Crandon concludes that the underlying cause of the usual form of prostatic enlargement (and of certain forms of atrophy) is the slow formation of a new connective tissue due to infection or to infection aggravating a senile degenerative process. The gonococcus is probably the most common specific infection because of (a) its frequency, (b) other inflammatory conditions are not common in this region, and (c) a great similarity exists between the histology of the gonorrheal process and that of the senile prostate. This explanation of prostatic enlargement seems most rational. We know that in a very large proportion of cases, according to some writers 90%, the posterior urethra is involved secondarily, sometimes with a definite prostatitis, frequently latent and unsuspected. The absence of history of gonorrhea is unimportant; patients with stricture frequently forget they ever had gonorrhea. The gradual acute involvement of the prostatic tissue is natural, the resulting connective tissue increase, and scar tissue formation produces obstruction of the prostatic ducts, dilation and proliferation of the glands results, certain subsidiary connective tissue changes occur, and the picture is complete. The course of the process as worked out by Crandon is most convincing and complete.

## REVIEW OF LITERATURE

**Cancerin "Adamkiewicz."**—Decker<sup>1</sup> contributes a short article upon the therapeutic value of the so-called specific for cancer, "cancerin," the preparation of Adamkiewicz. Decker has tested the "specific" in four cases, two esophagus carcinomas, one carcinoma of the stomach, and one of the descending colon. Decker reaches the same conclusion as that reported by Billroth, Kaposi, and Albert, namely, that "cancerin" has no appreciable effect whatever upon carcinoma. [J.E.S.]

**The Obtaining of those Products of Bacterial Metabolism Contained in the Cell-substance of the Bacteria.**—The article of Levy and Pfersdorff<sup>2</sup> is a description of a method for obtaining those bacterial toxins which are supposed to be contained within the bodies of the bacteria, and are very difficult to obtain in solution. The method is based upon the process of autolysis which occurs normally in old cultures of certain species of bacteria. The authors have obtained the toxin of anthrax in solution, but the paper is too much in the nature of a preliminary report to be of value. [J.E.S.]

**Retardation Phenomena in Fresh Immune Sera.**—Volk and Waelle<sup>3</sup> demonstrate that an immune serum can possess the peculiarity of causing agglutination in high dilutions, while less highly diluted tests cause incomplete agglutination, or even show no agglutination at all. This fact is of interest to all those who use Widal's test. [J.E.S.]

**On the Relation of the Animal Cell to Staining Mixtures.**—Mosse<sup>4</sup> gives simply the results of his work on the value of different staining mixtures for the determination of the reactions of the cell toward the staining reagents commonly employed in differentiating between basophilic and neutro-

<sup>1</sup> Deutsche med. Wochenschrift, Nos. 50, 51, and 52, 1902.<sup>2</sup> Jour. Am. Med. Association, xxxviii, 1051, 1902.<sup>3</sup> Annals of Surgery, December, 1902.<sup>1</sup> Münchener medicinische Wochenschrift, No. 51, 1902, p. 2146.<sup>2</sup> Deutsche med. Wochenschrift, No. 49, 1902, p. 879.<sup>3</sup> Wiener klin. Wochenschrift, No. 49, 1902, p. 1305.<sup>4</sup> Berliner klin. Wochenschrift, No. 49, 1902, p. 1148.

philic cell-components. Mosse's statement that the elements of the yolk change their character as the egg approaches maturity is suggestive of the possibility of more extensive changes in certain granules of the blood-cells than are at present recognized by pathology. [J.E.S.]

**On the Value of Cryoscopy in the Diagnosis of Death by Drowning.**—Revenstorff's<sup>1</sup> paper is a contribution to our knowledge of the methods applicable in forensic medicine. The method of determining the freezing point of the blood from both sides of the heart is based upon the fact long established experimentally that more or less of the fluid in which an animal is drowned passes through the capillaries of the lungs and dilutes the venous blood. Revenstorff reaches the conclusion that the method, when positive, *i. e.*, when it can be shown that the freezing point of the blood from the right side of the heart is higher than that of the blood from the left side, is valuable as additional evidence, and is very easily carried out; but decomposition rapidly removes any difference which may have existed, and the blood is not necessarily diluted during death by drowning. It must be concluded from this paper that the determination of the freezing point should be included among the regular forensic tests in every questionable case, but that the evidence thus obtained can at best be considered only as corroborative. [J.E.S.]

**Streptococcus Serum.**—Piorkowski<sup>2</sup> contributes an addition to our knowledge of the disputed question of the specificity of the streptococci. He has succeeded in obtaining a specific serum against the streptococcus which causes the disease called "Pferdedruse," a contagious, catarrhal affection of the nasal and pharyngeal membranes of horses, followed generally by suppuration of the neighboring lymph glands. The serum has protective and curative properties. It agglutinates the specific streptococcus in dilutions of 1-100, the streptococcus of angina but slightly or not at all, and other pathogenic species in dilutions of less than 1-25. Piorkowski concludes that there are specific races, and that success in the use of an antistreptococcus serum will be obtained only where an antiserum for the specific organism found in the particular group of cases is used. [J.E.S.]

**Researches on Epithelioma Contagiosum of Fowls.**—Marx and Sticker<sup>3</sup> have undertaken a study of this disease because of its relation to other diseases in which the epithelium is particularly affected, carcinoma, molluscum contagiosum, smallpox, etc. Their conclusions are that since the etiologic factor will pass the pores of a Berkefeld filter, it cannot be any of the various parasites which have been described as the cause; that it possesses a marked resistance to heat, etc.; that its virulence for the pigeon is lost by passing through the organism of the hen; and that the disease confers an immunity. [J.E.S.]

**The Pathology of the Large Bloodvessels of the Brain.**—Marburg<sup>4</sup> has made the interesting observation of calcification of the internal elastic membrane of the bloodvessels of the brain in comparatively young persons, even in a child of 6½ years. Marburg explains these cases in the same way that Virchow explained calcareous metastases—by the coincidence in the body of a degenerative bone process and a faulty excretion of lime salts. This explanation meets the case of the young child which suffered from severe rachitis, and died of scarlatina. The accepted explanations of early apoplexies and cerebral affections following disease of the bloodvessels are two in number—syphilis and hereditary weakness of the vessels. The author would add as a third factor this early, isolated calcification of the internal elastic membrane. Marburg has further observed in the larger bloodvessels of the brain the formation of cartilage cells, and he designates the process endarteritis cartilaginosa. He considers this a pure metaplastic process. [J.E.S.]

**Nencki's Researches on Hemoglobin and Its Relation to Chlorophyll.**—Frau Dr. Sieber-Schunoff's<sup>5</sup> object in writing this paper is evidently to acquaint the medical world with some of the results obtained by the physiologic chemist, v. Nencki.

The writer gives an historical sketch of v. Nencki's work which led to the discovery that hemopyrrol can be obtained from both hemoglobin and from chlorophyll, and that hemopyrrol is excreted from the animal body as urobilin. [J.E.S.]

**Benign Adenoma of the Stomach, Arising from Peptic Ulcer.**—Albu<sup>1</sup> reports an interesting case of a palpable, benign, tumor of the stomach, successfully removed by operation; the histologic construction of the tumor was that of simple glandular hypertrophy, developing from an old ulcer scar. [J.E.S.]

**Croupous Pneumonia with Sepsis Caused by the Pneumobacillus of Friedländer.**—In this case Friedländer's bacillus was isolated from the circulating blood and was also obtained from the pneumonic infiltration of the lung. Philippi<sup>2</sup> concludes that the pneumococcus of Fränkel cannot be considered as the sole cause of pneumonia; in rare cases Friedländer's bacillus can produce typical symptoms, and may be the cause of sepsis. [J.E.S.]

**Fat Metabolism in the Organism.**—Leo<sup>3</sup> has turned his attention to the question of what becomes of the glycerin, formed when the fats are broken up into glycerin and fatty acids. He describes a method for demonstrating the presence of glycerin, by the use of which he has found glycerin in an artificial mixture of stomach secretion and milk. His efforts to discover glycerin in feces and urine have met with negative results, even in the feces of persons to whom had been given as high as 80 gms. of glycerin. The urine of a series of patients suffering from a variety of chronic diseases gave negative results. In the urine of a patient with diabetes insipidus, Leo was able to demonstrate the presence of glycerin, a fact which, if borne out by subsequent research, may prove of importance in the study of this obscure disease. [J.E.S.]

**The Significance of Blood-platelets in the Blood of Syphilitics.**—Vörner<sup>4</sup> has turned his attention to the corpuscular elements described by Losdorfer in an address before the Medical Society of Vienna, and claimed to be pathognomonic of syphilis. Vörner describes their formation as was first described by Losdorfer, but calls attention to the fact which escaped Losdorfer's observation, that the process is identical with that first described by Arnold in his account of the development of the platelets of normal blood. Thus Vörner effectually proves the nonspecificity of these elements, and gives further proof of the fact by the discovery of the same elements in the blood of anemic patients suffering from gonorrhoea. Further, this platelet formation can only be observed in the blood of anemic syphilitics, and is a phenomenon due to the anemia, and having no direct connection with lues. [J.E.S.]

**The Diagnostic Value of Leukocyte Counts in Typhoid and in Surgical Suppurations.**—Kühn<sup>5</sup> arrives at the conclusion that leukocyte counts, especially in all cases of appendicitis, are of as great diagnostic value as the consideration of pulse and temperature. The facts must constantly be borne in mind, as emphasized by other authors, that severe septic processes, or general sepsis, can be accompanied by normal or subnormal counts, and that an hyperleukocytosis may be little marked in chronic processes, or may have already disappeared in cases of fully developed or encapsulated abscesses. [J.E.S.]

**The Influence of Albumins on the Coagulation of the Blood.**—Since it has been shown that gelatin regularly contains tetanus germs Brat<sup>6</sup> has investigated the value of a derivative of gelatin, gluten, which contains no tetanus germs with a view of determining its action on blood coagulation. The paper is of practical and theoretic interest. Brat shows that gluten has the same action as pepton, it prevents the coagulation of the blood; this is also true of gelatine. The value of gelatin injections cannot therefore be based upon any hemostyptic action, for its action is decidedly nonstyptic. Such injections do, however, aid in the formation of a thrombus, which fact Brat explains by assuming that substances are added to the blood which in some way cause an excessive deposit of plastic

material at the site of thrombus formation. This plastic material, he thinks, is derived from the blood-corpuscles. The therapeutic value of the injection of gelatin and its derivatives is therefore upheld, even though it is not to be explained as an hemostyptic phenomenon. [J.E.S.]

**The Carbohydrates of the Albumins of the Blood Serum.**—Langstein,<sup>1</sup> in a preliminary communication, claims to have made the important discovery that glucose is a constituent of serum globulin. The paper, while of immediate interest to the physiologic chemist alone, is of interest for its bearing upon the normal metabolism of the body, and especially for its bearing upon abnormal metabolism, particularly as seen in diabetes mellitus. [J.E.S.]

**The Hemolysins of Human Serum.**—Halpern<sup>2</sup> finds a decided increase of hemolytic action of the blood serum from patients suffering from typhoid, while in the serum from a variety of other diseases no change could be found, except in the case of one patient suffering from septicemia, where a decided decrease was demonstrated. [J.E.S.]

**The Behavior of the Blood in Measles and Scarlet Fever During Childhood.**—There is but little agreement concerning the state of the blood in measles and scarlet fever, in spite of the large volume of literature on the subject. Reckzeh<sup>3</sup> therefore has undertaken to make methodical examinations in 10 cases each of measles and scarlet fever. It is true that in but few cases will the differential diagnosis make any difficulty, but the behavior and state of the blood is such a constant one that in some instances it will clear up the diagnosis of a doubtful case. Probably the reason why there is so much disagreement in the results of the different authors is that each of them has examined only a very limited number of cases. Reckzeh's results may be summed up as follows: The number of the red corpuscles in general is but slightly altered, more, however, in scarlet fever than in measles. The same may be said concerning the character of the red cells and the amount of hemoglobin; in scarlet fever poikilocytes and normoblasts are occasionally found. The state of the leukocytes is much more characteristic. In measles there is either a normal number or a diminution of leukocytes; in scarlet fever there is hyperleukocytosis. In the former as the temperature falls the leukocytes gradually increase; in the latter the temperature and leukocyte curve run parallel. In both diseases, but especially in measles, is the number of polynuclear neutrophilic cells diminished, while lymphocytes, both large and small, are relatively increased. The eosinophilic cells are diminished in number in measles, reaching their normal state long after recovery; in scarlet fever they are constantly increased. [E.L.]

**Primary Obliterative Inflammation of the Main Trunks of the Hepatic Veins.**—This lesion is uncommon and rarely recognized, but its interest is more than that of a pathologic curiosity. Moore<sup>4</sup> gives the history of a previously unrecorded case and reviews 12 others collected from literature. The clinical manifestations are those of portal obstruction, ascites and dilation of the superficial abdominal veins. After five or six weeks death generally occurs from cardiac failure and general exhaustion. In most of the cases the condition appeared suddenly in the midst of apparent health. In the specimens examined by the writer the lesion was a primary proliferative inflammation independent of any prior thrombosis. The absence of any local change which could be regarded as the primary focus from which irritation might have extended to the vein compels the assumption of some hematogenous factor and the limitation of its action must be sought in local susceptibility. The lesion occurs nears the seat of important postfetal changes. The processes leading to obliteration of the ductus venosa close by may be called into renewed activity by some irritant such as syphilis. [H.M.]

**A Rapid Reaction for Bence-Jones Albumose.**—Boston<sup>5</sup> suggests the following method—depending upon the presence in the albumose of loosely combined sulfur: (1) 15 cc. to 20 cc. of

filtered urine are placed in a test-tube and to it an equal quantity of saturated solution of sodium chlorid is added, and the whole shaken; (2) 2 cc. to 3 cc. of a 30% solution of caustic soda are now added and shaken vigorously; (3) the upper one-fourth of the column of liquid is gradually heated over the flame of a Bunsen burner to the boiling point, whereupon a solution of lead acetate (10%) is added, drop by drop, boiling the upper previously heated stratum of liquid after each additional drop; (4) when the drop of lead acetate comes in contact with the liquid a copious pearly or cream-colored cloud appears at the surface, which becomes less dense as the boiling point is reached; and when boiling is prolonged for one-half to one minute the upper stratum shows a slight browning, which deepens to a dull black. This lessens in intensity toward the bottom of the tube. After standing the reaction becomes intensified, and a black precipitate falls through the clear liquid and collects at the bottom of the tube. [A.O.J.K.]
